Accreditation Statement: The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians.

Designation Statement: The ACR designates this live educational activity for a maximum of *54.25 AMA PRA Category 1 Credits*™. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

International Physicians: International physicians who register as part of a group and require *AMA PRA Category 1 Credit(s)*™ must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers and e-mail address. The information will be used to verify your meeting attendance.

The American Medical Association has an agreement of mutual recognition of continuing medical education credit with the European Union of Medical Specialties. International physicians interested in converting *AMA PRA Category 1 Credit*™ to EACCME credit should contact the UEMS.

Health Professionals: Participants may claim hours to receive a Certificate of Participation for an activity designated for *AMA PRA Category 1 Credit(s)*™. For non-CME sessions, attendees may also request a certificate of participation.

Disclosure Policy
It is the policy of the American College of Rheumatology to ensure that its CME activities are independent and free of commercial bias. To ensure content objectivity and balance, and guarantee that the content presented is in the best interest of its learners and the public, the ACR requires that all individuals in a position to control content disclose all relevant financial relationships with any commercial interest if the relationship is financial and occurred within the past 12 months. This includes the relationships of spouse/partners. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's CME Resolution of Conflict policy prior to the participation of the individual in the development or presentation of CME content.

As an educational provider accredited by the Accreditation Council for Continuing Medical Education, the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all those in a position to control content (e.g., speakers and moderators) participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships including, but not limited to:

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

None: Nothing to disclose

Abstract author disclosures are published online. Any individual who refuses to disclose relevant financial relationships is ineligible to serve as a planning committee member, presenter or author of an ACR CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

Abstract Embargo Policy
Accepted abstracts are made available to the public online in advance of the meeting and are published in a special online abstract supplement of the *Arthritis & Rheumatology* journal. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR website. However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting) **is under embargo until 4:30 PM Eastern Time on Saturday, November 12, 2016.**

Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying financial and other sponsors about this policy. If you have questions about the abstract embargo policy, please contact the public relations department at pr@rheumatology.org.

Copyright Policy
The annual meeting is a private event. Programs presented at the meeting are for the education of attendees and purchasers of recorded presentations as authorized by the American College of Rheumatology. The information and materials displayed and presented during this meeting are the property of the ACR and the presenter and cannot be photographed, copied, photocopied, transformed to electronic format, reproduced, or distributed without written permission of the American College of Rheumatology and the presenter. Any use of the program content for commercial purposes, which includes, but is not limited to oral presentations, audiovisual materials used by

speakers, and program handouts without the written consent of the ACR is prohibited. This policy applies before, during and after the meeting. The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

The names, insignias, logos and acronyms of the ACR, the ARHP and the Rheumatology Research Foundation are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology. Attendees who have questions about the ACR's copyright policy should contact the public relations department at pr@rheumatology.org.

Media
Credentialed media attend the annual meeting to cover stories for consumer, trade and other media outlets, and are easily identified by their black press ribbons. Media has access to all general sessions and limited access (at the discretion of speakers) to Meet the Professor and Workshop sessions. Media may use hand-held audio recorders and still cameras; moving video recording is also permitted with the permission of the presenter(s). The exception to this policy is that no photos or video are allowed in the Exhibit Hall and no photos or video are allowed in the Poster Hall without permission from the poster presenter. Press who would like general photos of the Exhibit Hall can obtain these after the meeting from the ACR. Attendees who have questions about the ACR's media policies should contact the public relations department at pr@rheumatology.org.

Photographs and Video Recording Policy
As a courtesy to our presenters, ACR policy does not permit photographs or recordings during educational sessions, including poster sessions. The only exception to this is for registered media, who should review their registration materials for more information.

Abstract Reprint (Reproduction) Policy
Copyright law covers all annual meeting abstracts published by the American College of Rheumatology. All rights reserved. No abstracts may be reproduced in any form or by any means, except as permitted under section 107 and 108 of the 1976 United States Copyright Act, without the prior permission of the publisher.

For the purposes of this statement, the term **"ACR Abstracts"** refers to all annual meeting abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARHP sessions and the late-breaking category.

For the purposes of this statement, the term **"ACR Posters"** refers to the accepted abstract **POSTER PRESENTATIONS** as presented in the poster hall during the annual meeting. **This does not include abstract text published in the online supplement of *Arthritis & Rheumatology.*** All ACR Posters are the property of the ACR or the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.
For the purposes of this statement, the term "reproduce" includes all forms of reproduction including, but not limited to, print, electronic and photographed formats.

For the purposes of this statement, the term "presenting author" refers to the author who is designated as the individual who will present the work during the ACR annual meeting, as identified through the abstract submission process.

Abstract Reprint Approval Process
- Excerpts of **ACR Abstracts** or **ACR Poster Presentations** in their entirety may not be reproduced without the prior written permission of the publisher.
- Permission requests for abstract content and other permission inquiries should be addressed to:
  Permissions Department
  c/o John Wiley & Sons, Inc.
  111 River Street
  Hoboken, NJ 07030
  Fax: (201) 748-6008
  wiley.com/go/permissions
- Commercial entities seeking permission to reprint must obtain all materials from the author and/or publisher John Wiley & Sons, Inc.
- ACR cannot provide any materials.

Reproducing ACR Abstracts and ACR Posters for Dissemination Prior to the Annual Meeting
- Requests to reproduce abstracts for dissemination prior to the annual meeting **will not be approved.**
- Per the **ACR Embargo Policy**, academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an abstract online.
- Permission to issue a press release does not require ACR approval. However, it must comply with the **ACR Embargo Policy**; violation of this policy may result in the abstract being withdrawn from the meeting or other measures deemed appropriate.
- For more information regarding press releases, please contact the ACR Public Relations Department at pr@rheumatology.org.

Reproducing ACR Abstracts and ACR Posters for Dissemination During the Annual Meeting
Following approval (see approval process above), an exhibiting organization may:
- Disseminate copies of individual ACR Abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may **not** be produced.
- Disseminate information summaries (title/date/time/poster number) of ACR Abstracts from its exhibit space.

- Summaries may not reference company or product names. Requests for approval must be submitted in writing to abstractreprints@rheumatology.org.
- Presenting authors may disseminate individual copies of their ACR Poster during their assigned poster presentation time.
- Dissemination must be limited to the area directly in front of their assigned poster space and may not interfere with other poster presentations.
- An electronic copy of the poster may be provided via a QR code generated by the presenter and included on the poster

Reproducing ACR Abstracts and ACR Posters for Dissemination After the Annual Meeting

ACR Abstracts

Following approval (see approval process above), the ACR permits ACR Abstracts (i.e., all abstract content published in the online supplement) to be reprinted and disseminated following the annual meeting.

- Booklets of abstracts (e.g., two or more) must include the following statement on the front of the booklet:
  Abstract(s) reprinted from the ACR/ARHP Annual Meeting held November 11-16, 2016. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).
- Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

ACR Poster Presentations

Following approval from the presenting author and ACR, copies of actual ACR poster presentations (i.e. images of the poster presentation hung in the poster hall) may be reproduced.

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must submitted to Wiley (see approval process above).
- Requests to reproduce individual **ACR poster or booklets of poster presentations** (e.g., two or more) must be submitted via e-mail to abstractprints@rheumatology.org.
- Poster reproduction requests must include the following:
  - Abstract ID Number
  - Abstract Title
  - Presenting Author's Name
  - A copy of Presenting Author's written approval (Please Note: An e-mail approval from Presenting Author is acceptable)
- **IMPORTANT: The ACR does not retain and cannot provide poster presentation images.**
- The following statement must be listed under each Poster reprint:
  Poster reprinted from the ACR/ARHP Annual Meeting held November 11-16, 2016. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).

Use of the ACR Disclosure Key

It is suggested when referencing disclosures in the reprints, that the ACR's disclosure key be added to provide adequate context for abstracts:
None: Nothing to disclose

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part-time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

Use of the ACR Name

- The names, insignias, logos and acronyms of the ACR, the ARHP and the Rheumatology Research Foundation are proprietary marks.
- Use of the names in any fashion, by any entity, for any purpose, is prohibited without the written permission of the ACR.

Use of the ACR Scientific Program Content

- Information displayed or presented at all sessions during the annual meeting is the property of the ACR or the presenter. Information may not be recorded, photographed, copied, photocopied, transferred to electronic format, reproduced or distributed without the written permission of the ACR and the presenter.
- Any use of the program content, which includes but is not limited to oral presentations, audiovisual materials used by speakers and program handouts, without the written consent of the ACR is prohibited.
- This policy applies before, during and after the meeting.
- The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RA-related autoantibodies are typically elevated prior to the onset of RA. Screening for autoantibody (aAb) positive individuals is a means to assemble a cohort at very high risk for future RA for epidemiologic and intervention studies. However, little is known about the stability of RA-related aAbs over time in individuals without RA who screen positive in a non-clinical setting.

Methods: Studies of the Etiology of RA (SERA) prospectively follows subjects who are RA-free but are at increased risk for future RA because they are a first-degree relative (FDR) of an RA proband (n=1774), or are from a cohort enriched for HLA-DR4 alleles (n=631). We tested serum aAbs to CCP (CCP2 and/or CCP3.1), RF, and RF IgG, IgA and IgM isotypes. Positivity was based on cut-offs as defined by manufacturer's recommendations (CCP and RF isotypes) or ACR recommendations (RF). Overall, 23% (551/2405) tested positive for at least one aAb during screening. To evaluate outcomes of aAb+ subjects identified via screening, the cohort was limited to those who had at least one follow-up visit after their 1staAb+ visit (n= 315). For prediction analyses, we explored high titer aAb, as defined by 2-times (2x) and 3-times (3x) the cutoff.

Results: Over a mean follow-up of 5.1 years, 146 (46.3%) remained aAb+ at all visits (Persistent), 61 (19.4%) were aAb+ again on at least one follow-up visit, but fluctuated between aAb negative and aAb+ during follow-up (Intermittently Positive), and 108 (34.3%) were seronegative on all follow-up visits (Reverter) (Table 1). To address the question as to what predicts a person will test aAb+ again in those who were screened-positive, we combined the Persistent and Intermittently Positive groups to form a group that was aAb+ on two or more occasions (n=207). To examine the likelihood of testing aAb+ again after a screened-positive test, we conducted bivariate logistic regression models with every variable listed in Table 1 as a potential predictor. Table 2 lists the variables significantly associated with testing positive again. Age, sex, race/ethnicity, FDR status, shared epitope status, ever smoking, high CRP, and joint signs were not associated with testing aAb+ after the initial screened aAb+ test.

Conclusion: In this cohort of at-risk individuals who screen aAb+, the presence of any aAb at > 2x cutoff at screening predicts who will test positive again, while a 3x cutoff does not improve prediction. Demographic and environmental exposures were not associated aAb+ persistence, perhaps due to their primary influence at other stages of disease, including the initial development of RA-related aAbs.

Table 1. Characteristics of Individuals in SERA who Tested Positive for an RA-related Autoantibody During Screening stratified by Autoantibody Status on Follow-up

	Persistent N = 146	Intermittently Positive N = 61	Reverter N = 108
Age at first positive visit (Mean±SD)	47.6±16.5	46.4±17.0	45.2±14.6
Number of visits (including screening) (Mean±SD)	3.4±1.7	4.7±1.5	2.9±1.3
Length of Follow-up in years (Mean±SD)	3.9 ±2.6	5.8±2.5	4.0±2.7
Sex (%female)	111 (76.0)	50 (82.0)	78 (72.2)
Race/Ethnicity (%Non-Hispanic White)	116 (79.5)	53 (86.9)	78 (72.2)
First Degree Relative of an RA Proband (%)	119 (81.5)	55 (90.2)	87 (80.6)
Shared Epitope positive (%)	70 (48.0)	39 (63.9)	64 (59.3)
Ever smoker (%)	51 (34.9)	23 (37.7)	42 (38.9)
CRP+ at first positive visit (%)	47 (32.2)	19 (31.2)	30 (27.8)
CCP+ at first positive visit† (%)	54 (37.0)	12 (19.7)	17 (15.7)
CCP+ > 2x cutoff at first positive visit† (%)	40 (27.4)	4 (6.6)	6 (5.6)
CCP+ >3x cutoff at first positive visit† (%)	32 (21.9)	2 (3.3)	6 (5.6)
RF+ at first positive visit (%)	53 (36.3)	18 (29.5)	27 (25.0)
RF+ > 2x cutoff at first positive visit (%)	25 (17.1)	4 (6.6)	4 (3.7)
RF+ > 3x cutoff at first positive visit (%)	14 (9.6)	2 (3.3)	3 (2.8)
RF isotype+ at first positive visit‡ (%)	98 (67.1)	43 (70.5)	73 (67.6)
RF isotype+ > 2x cutoff at first positive visit‡ (%)	51 (34.9)	13 (21.3)	11 (10.2)
RF isoty pe+ > 3x cutoff at first positive visit‡ (%)	41 (28.1)	6 (9.8)	5 (4.6)
≥1 Swollen joint at first positive visit* (%)	13/121 (10.7)	8/51 (15.7)	10/90 (11.1)
≥1 Tender or swollen joint at first positive visit* (%)	34/121 (28.1)	11/51 (21.6)	26/90 (28.9)

†Either CCP2 or CCP3.1 ‡ IgM, IgG, or IgA *joints included are: wrist, MCP, PIP, MTP and elbow; 57 individuals excluded due to missing exam data.

Table 2. Factors associated with the likelihood of testing autoantibody positive after the first positive (screening) test

aAb status at first positive (screening) visit	OR (95% CI)*	p-value	Percentage who test aAb positive again
Any aAb+ (definition of cohort)	-	-	65.7%
Any aAb+ > 2x cutoff	**5.50 (3.15-9.61)**	**<0.01**	85.2%
Any aAb+ > 3x cutoff	**4.49 (2.40-8.41)**	**<0.01**	85.6%
CCP+ †	**2.51 (1.38-4.54)**	**<0.01**	79.5%
CCP+ > 2x cutoff †	**4.59 (1.89-11.15)**	**<0.01**	88.0%
CCP+ > 3x cutoff †	**3.34 (1.36-8.23)**	**<0.01**	85.0%
RF+	1.57 (0.93-2.64)	0.09	72.4%
RF+ > 2x cutoff	**4.23 (1.45-12.38)**	**<0.01**	87.9%
RF+ > 3x cutoff	4.23 (1.45-12.38)	0.08	84.2%
RF+ isotype ‡	1.02 (0.62-1.69)	0.92	65.9%
RF+ isotype >2x cutoff ‡	**3.95 (1.98-7.87)**	**<0.01**	85.3%
RF+ isotype >3x cutoff ‡	**6.05 (2.33-15.72)**	**<0.01**	90.4%

*OR represents the increased odds of testing positive again given their particular aAB+ status (and titer) at the first positive visit. †Either CCP2 or CCP3.1 ‡IgM, IgG, or IgA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies suggest that antibodies to citrullinated protein antigens (ACPA) contribute to decreased hand bone mineral density (BMD) in RA-free individuals. No evidence exists with regard to associations of ACPA or rheumatoid factor (RF) with general osteoporosis or more clinically relevant lumbar spine BMD; a common site for compression fractures, immobility, and pain. Therefore, we sought to determine whether RA-related autoantibodies were associated with lumbar BMD in a community based population sample in order to help delineate whether previous findings of decreased hand BMD in those with RA-related autoantibodies may also indicate systemic bone changes.

Methods: In the Multi-Ethnic Study of Atherosclerosis (MESA), a multi-ethnic, multi-center, prospective study of community-dwelling individuals designed to study characteristics of subclinical and clinical cardiovascular disease, we evaluated 1924 participants with measures of RA-related autoantibodies: RF IgA and IgM isotypes and anti-cyclic citrullinated peptide (anti-CCP) antibodies, as well as volumetric BMD (vBMD) from the third lumbar vertebra (L3) by computed tomography. RA-related autoantibodies were analyzed as dichotomous variables (positive vs negative) based on pre-specified cut-offs, and vBMD was analyzed as a continuous variable. We investigated associations between RA-related autoantibody positivity and vBMD using ANCOVA, stratified by sex *a priori*, and adjusting for age, race, weight, diabetes, self-reported arthritis, current smoking, c-reactive protein, education, estimated glomerular filtration rate, albumin/creatinine ratio, physical activity (mets/week), hypertension, alcohol use, thiazide and loop diuretics (and hormone replacement therapy in women).

Results: Among 1924 MESA participants (956 women), the mean age was 62 years, and 40% were Caucasian, 13% were Chinese, 20% were African American, and 26% were Hispanic. Mean L3 vBMD was 111 mg/cc in women and 121 mg/cc in men. Twenty percent were positive for RF, and 1% of men and 2% of women were positive for anti-CCP (Table 1). In women, there was no association of vBMD with RF positivity or anti-CCP positivity in either minimally or fully adjusted models. Results were similar in men. Sensitivity analysis stratified by self-reported arthritis showed similar results.

Conclusion: In a multi-ethnic community-based population sample, RA-related autoantibody positivity was not significantly associated with lumbar BMD. As this finding was in contrast to previous findings in hand BMD, further research is needed to determine whether bone changes are local (e.g., RA-specific joints) or systemic.

Table 1. Proportion of MESA participants positive for RA-related autoantibodies and their association with bone mineral density

	Women (n=956)			Men (n=968)		
	n (%) positive	BMD B(SD)	p-value	n (%) positive	BMD B(SD)	p-value
Rheumatoid Factor (IgA or IgM)	189 (20)			193 (20)		
Adjusted for age and race		1.82 (2.6)	0.4881		4.52 (2.6)	0.086
Fully adjusted*		0.09 (3.1)	0.9774		3.97 (2.8)	0.1532
Anti-CCP	15 (2)			13 (1)		
Adjusted for age and race		13.84 (8.3)	0.0953		-2.33 (9.1)	0.798
Fully adjusted*		12.46 (9.8)	0.2035		-6.81 (9.4)	0.4673
Either RF or Anti-CCP	195 (20)			199 (21)		
Adjusted for age and race		2.83 (2.6)	0.2774		3.98 (2.6)	0.1261
Fully adjusted*		1.19 (3.1)	0.7028		3.20 (2.7)	0.2444

*Fully adjusted for age, race, weight, diabetes, self-reported arthritis, current smoking, CRP, education, eGFR, ACR, physical activity mets/week, HTN, current alcohol use, and use of thiazide and loop diuretics (and hormone replacement therapy in women) [Results are interpreted as the difference in BMD mg/cc in the RA-related autoantibody positive participants compared to the RA-related autoantibody negative participants.]

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Close relationship between the immune and skeletal systems has been recognized through the bone loss in rheumatoid arthritis (RA). Rheumatoid factor (RF) is present in approximately 70-80% of RA patients, which is an autoantibody directed against the Fc component of IgG and associated with osteoporosis and reduced bone mineral density (BMD) in RA. RF is also found nonspecifically in chronic inflammatory condition such as sarcoidosis, hepatitis B or C, and tuberculosis. However, the influence of RF to bone loss is scarcely known in subjects without any specific medical problem. This cross-sectional study aimed to investigate the association between the presence of RF and BMD in Korean healthy male subjects without any history of joint disease.

Methods: Of the 84,344 males who had undergone a comprehensive health checkup program in 2012, 1,390 healthy subjects were recruited, whose BMD and RF results were available. Subjects with history of diabetes, kidney disease, thyroid disease, and malignancy, and taking medicine regarding these diseases, osteoporosis, and arthritis were excluded based on self-reported questionnaire. The RF titer $\geq$ 20 IU/ml was considered positive. BMD was categorized into 3 groups based on T-score; normal (T-score $\geq$ -1.0), osteopenia (-1.0 > T-score > -2.5) and osteoporosis (T-score $\leq$ -2.5). The association between the presence of RF and BMD was assessed by multiple linear regression analysis.

Results: Of 1,390 males, the mean age was 52.8 ± 10.9 years (range, 22 – 83) and RF was positive in 64 subjects (4.6%). Demographics including smoking history, alcohol consumption, the frequency of vigorous exercise and body mass index (BMI), and laboratory data were not different between RF-positive and –negative subjects except hepatitis B surface antigen, which was more frequently seen in RF-positive subjects (15.6% vs. 4.3%, p = 0.001). Low bone mass (osteopenia and osteoporosis) of lumbar spine was more prevalent in subjects aged 50 or more compared with those younger than 50 years (28.0% vs. 10.7%, p < 0.001) while no differences of femur neck and total hip. RF-positive subjects had significantly lower BMD compared to RF-negative subjects in lumbar spine (1.10 ± 0.18 g/cm2vs. 1.17 ± 0.16 g/cm2, p = 0.002) but neither in femur neck nor total hip. In subjects with higher titer RF ($\geq$ 40 IU/ml), the mean BMD of lumbar spine was significantly decreased than those with lower titer RF (one-way ANOVA, F(3, 1190) = 3.527, p = 0.015). After adjusting for multiple confounders such as age, BMI, glomerular filtration rate, serum concentration of calcium, phosphorus, and uric acid, and lifestyle factors (drinking, smoking, and physical exercise), RF positivity was negatively associated with BMD at lumbar spine (B = -0.055 and SE = 0.027, p = 0.039).

Conclusion: Our results provide epidemiological evidence that the presence of RF could have an unfavorable impact on bone density in apparently healthy male subjects. Additional studies to elucidate the osteoimmunological mechanism of RF are warranted.

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis, defined by Tscore < -2.5, is one of the main consequences of RA and it appears early in the disease. It is twice as prevalent in RA as it is in the general population; and low bone mineral density (BMD) in RA is associated with increased risk of hip and vertebral fractures. It is not known exactly whether this degeneration begins in pre-clinical RA and whether joint symptoms provide clinicians insight into these degenerative changes, especially in the spine. Therefore, we investigated associations between RA-specific joint symptoms and thoracic BMD in a community-based cohort free of RA.

Methods: We evaluated associations between presence of RA-specific joint symptoms and thoracic BMD (tBMD) using computed tomography (CT) in 31 individuals from the Studies of the Etiology of RA who were RA-free based on the 1987 ACR and 2010 ACR/EULAR criteria for RA. A physician confirmed joint swelling; participants self-reported stiffness and pain in the wrist, elbow, or any metacarpophalangeal, proximal interphalangeal, or metatarsophalangeal joints. Thoracic BMD on CT was measured using OsiriX 7.5 (Pixmeo, Geneva, Switzerland), and calculated using average BMD of T7-T9 vertebrae. Sex-specific Tscores were calculated as follows: $T_{(female)} = (BMD_{(individual\ mean)} - 222)/36$; $T_{(male)} = (BMD_{(individual\ mean)} - 215)/33$; where < -2.5 is considered osteoporosis and < -1.0 is considered osteopenia. Associations between joint symptoms and tBMD were evaluated using ANCOVA and adjusted for age, race, body mass index (BMI), pack-years smoking, high sensitivity c-reactive protein (CRP), number of autoantibodies (Anti-CCP, RF-IgG, RF-IgM, RF-IgA), and the source of their recruitment into SERA (as a first degree relative or health fair participant).

Results: Among 31 SERA participants, average(SD) age was 54(13), BMI was 27(5), CRP was 3(4), Tscore was -1(2), 45% were women, 94% were non-Hispanic White, and everyone had an average of 1(1) autoantibody. Joint swelling was associated with lower Tscores, although the association was marginally significant (p=0.08). Neither joint stiffness nor pain was associated with Tscores (Table).

Conclusion: In a cohort of RA-free individuals, neither joint swelling, stiffness, nor pain was significantly associated with tBMD Tscores. These preliminary data were limited by small sample size. Joint swelling was marginally associated with tBMD, thus future research with larger sample size is required to determine whether joint swelling may be linked to bone density.

Table. Associations between joint symptoms and thoracic BMD presented as a Tscore

		Tscore

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent clinical-epidemiological data suggest that periodontitis (P) shows higher prevalence in rheumatoid arthritis (RA) patients. However, due to the scarcity of epidemiological studies, the strength of association is limited, with odds ratios (OR) ranging from 1.82-8.05. The prevalence of P in the adult Spanish population[1] varies from 16 -30%,with a lower prevalence of severe P (5-11%). Nevertheless, the prevalence of P in Spanish RA patients is unknown. Our purpose is: 1.To determine the prevalence of P and its association in RA patients in our reference area.2.To describe the characteristics of P in RA patients.

Methods: Observational, descriptive, cross-sectional, case-control study of RA patients > 18 years old (ACR/EULAR 2010) in a hospital Rheumatology Department, and a control group with non-inflammatory joint disease, who had at least 4 teeth, had not received dental prophylaxis or antibiotics 6 months before the study. Socio-demographic and anthropometric variables included were body mass index, smoking status, Graffar scale, stress level, annual dental prophylaxis, and co-morbidities such as osteoporosis (OP), diabetes mellitus (DM), dyslipidemia (DS), arterial hypertension, ischemic cardiovascular disease (ICD). Periodontal Variables: plaque index (PI), bleeding on probing (BoP), probing pocket depth (PPD), recession (REC), clinical attachment level (CAL). The dental team: 2 periodontists, 2 general dentists and 1 dental hygienist with inter-observer variability<30%. Full mouth CAL, PPD and periapical x-rays were taken. CAL was classified according to the European Workshop in 2005 (Tonetti),into level 0 (absence), TL1 (mild), TL2 (severe).Statistical analysis with Stata 13.1 using Student´s t test , Kruskal Wallis and Chi-square test.

Results: 344 patients were included: 187 RA (147 F/40 M) and 157 controls (101F/56M). The two groups were similar in age 54.9 (17.9), BMI 27.8 (4.6), stress level, DM and ICD and different in gender (>nº of males in controls), socioeconomic status (lower level in RA patients), > nº of current and former smokers in the RA group (19.25%vs 8.92%/ 24.6%vs 11.46%),OP (23.45% RA vs 7.8%), DS (hypertriglyceridemia) 11.23% RA vs 4.46% in controls. 182/187 RA patients had P (97. 33%) vs 104/157 (66.24%) with P in controls. Regarding severity P: TL1 in 52.41% RA vs 54.14%;TL2 in 44.92% RA patients vs 12.1% in controls (p<0.001), OR 18.55 (CI 95% 7.18-47.87),which was maintained after adjusting for confounders: OR 16.25 + 9.29 (95% CI 5.23 – 49.86). Moreover, RA patients had poor periodontal status with a dramatic increase in all periodontal parameters: PI, PPD, nº and percentage of PPD ≥5mm and BoP (p<0.001) compared with the control group.

Conclusion: 1.Our study showed a strong association between RA and periodontitis with an adjusted OR 16.25. 2. The prevalence of severe periodontitis was significantly greater in RA patients than controls or the general population. 3. There were no differences in the prevalence of mild periodontitis between groups. 4. With respect to severity, RA patients showed more severe periodontitis than controls. **References:** 1Bravo-Pérez M C-PE. Encuesta de salud oral en España

Lower Omega-3 Fatty Acid Biomarkers Are Associated with Inflammatory Arthritis in a Population Positive for Anti-Citrullinated Protein Antibodies

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibodies to citrullinated protein antigens (ACPA) can be elevated prior to onset of inflammatory arthritis (IA) and RA. However, understanding of factors related to development of ACPA, or transition from ACPA+ to clinically-apparent IA is limited. Omega-3 fatty acids (n-3 FA) have immunomodulating properties. In subjects at-risk for developing RA, we found higher levels of n-3 FA percentage in red blood cells (n-3 FA % in RBCs) were associated with a lower prevalence of positivity for ACPAs and rheumatoid factor (RF), suggesting n-3 FAs may be protective against development of autoantibodies. However, the relationship between n-3 FAs and IA in ACPA+ subjects remains unknown.

Methods: At Colorado-based health fairs from 2008-2014, subjects without a previous diagnosis of RA were tested for serum ACPA using the commercial assay anti-cyclic citrullinated peptide 3 (Inova), and were recruited for follow-up research study visits. At their baseline study visit, they underwent symptom assessment and joint examination; the presence of IA and RA by 2010 criteria was established. Blood was also drawn to measure n-3 FA % in RBCs, a biomarker that reflects the average n-3 FA levels over the preceding ~2 months. The relationship between IA and RBC n-3 FA% was assessed using logistic regression.

Results: Fifty-two ACPA+ individuals without a prior diagnosis of RA were identified at health-fairs and agreed to participate in a follow-up baseline study visit; 41 were without IA, and 11 had IA that was previously undiagnosed (none were on disease modifying therapy). Subjects with IA at baseline were more likely to be smokers and report taking n-3 FA supplements, and test positive for RF and C-reactive protein (Table 1). Increasing total n-3 FA and DPA levels in RBCs (an n-3 FA generally synthesized through physiologic processes and not dietary) were associated with significantly lower odds of IA at baseline, adjusting for > 10 pack years and n-3 FA supplement use (both of which met confounding criteria) (Table 2).

Table 1: Demographic and descriptive characteristics of participants positive for inflammatory arthritis compared to those who were not positive for inflammatory arthritis at the baseline study visit.

Variable	IA at Baseline: Yes (n = 11)	IA at Baseline: No (n = 41)	p-value
Age (mean ± SD)	56.5 ± 10.0	55.6 ± 10.3	0.80
Female n (%)	9 (81.8)	22 (53.7)	0.17
Non-Hispanic White n (%)	8 (72.7)	33 (80.5)	0.65
Education > High School n (%)	9 (81.8)	36 (87.8)	0.63
BMI (mean ± SD)	28.3 ± 6.4	26.9 ± 4.8	0.43
Ever Smoke Yes n (%)	9 (81.8)	18 (45.0)	0.04
Current Smoker Yes n (%)	3 (27.3)	2 (5.0)	0.06
Pack Years > 10 n (%)	5 (45.5)	8 (19.5)	0.12
Omega-3 Fatty Acid Supplement Use n (%)	9 (81.8)	19 (46.3)	0.04
Shared Epitope Positive n (%)	7 (63.6)	18 (43.9)	0.24
RF Nephelometry Positive n (%)	6 (54.5)	5 (12.2)	<0.01
C-Reactive Protein Positive n (%)	6 (54.5)	9 (22.0)	0.06

Table 2: Inverse association between omega-3 fatty % in red blood cells and baseline **presence of inflammatory arthritis**.

n-3 FA % in RBC	Odd Ratio	95% CI	p-value
Alpha-linolenic acid (ALA;18:3n-3)	2.35	0.85 – 6.51	0.10
Eicosapentaenoic acid (EPA; 20:5 n-3)	0.28	0.06 – 1.24	0.09
Docosapentaenoic acid (DPA; 22:5n-3)	0.14	0.04 – 0.54	<0.01
Docosahexaenoic acid (DHA; 22:6n-3)	0.51	0.22 – 1.22	0.13
EPA+DHA	0.45	0.15 – 1.02	0.09
Total n-3 FA (summed ALA, EPA, DPA, DHA)	0.30	0.10 – 0.92	0.04

Models adjusted for sex, pack years ≥ 10, and n-3 fatty acid supplement use. IA at baseline IA n = 11; No IA at baseline n = 41. Odds ratio is for a one standard deviation increase in n-3 FA% in RBC.

Conclusion: We found that lower levels of n-3 FAs in individuals were associated with IA in this unique population of ACPA+ individuals. These extend our prior work by suggesting that in addition to having a potentially protective effect against autoimmunity, n-3 FAs may also be important in the transition to IA once an individual is ACPA+. Our findings support the potential beneficial role of n-3 FAs in the preclinical state in RA, not only in decreasing the risk of developing ACPA and RF but also potentially decreasing the transition from an ACPA+ state to IA, findings which warrant further investigation.

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

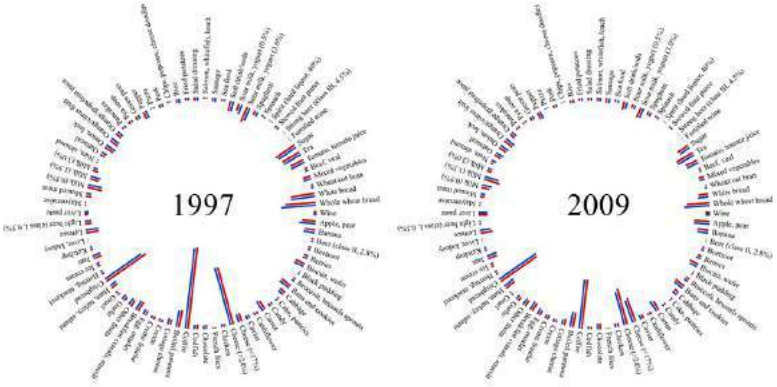
The interest of dietary factors in rheumatoid arthritis (RA) has increased among researchers and RA patients over the last decade. Although several interventions as well as epidemiological studies of dietary aspects have shown benefits for RA disease course, there is still a lack of specific dietary recommendations for RA. We hypothesized that women who have been diagnosed with RA change their diet in order to improve their disease status. The aim of this study was to investigate the long-term changes in diet after RA diagnosis in Swedish women.

Methods:

This study included primarily 22,007 women from the Swedish Mammography Cohort (SMC). These women were asked to complete two food frequency questionnaires (FFQ), in 1997 and 2009. In 2003, the SMC was linked to the Swedish Rheumatology Quality register (SRQ) and the Outpatient Register in order to track incident RA cases and provide clinical data. During the period from 1997 to 2009, 380 women were diagnosed with RA. Women who did not complete the FFQ in 1997 and/or 2009 were excluded (n=249). Dietary changes after RA diagnosis were analyzed based on the frequency intake of 82 food items in 1997 and 2009, with two approaches; linear mixed models (191 RA cases versus 21,567 non-RA cases) and hierarchical cluster analysis (191 RA cases versus 573 matched controls (non-RA cases)).

Results:

The majority of the 82 food items did not significantly differ in intake between RA and non-RA cases in 1997 and 2009. RA cases had significantly decreased intake of three and four food items in 1997 and 2009, respectively. (Figure)



Intake (times/week) in 1997	Non-RA	RA	p value
Wheat/oat bran	0.70	0.49	0.008
Blackpudding	0.35	0.28	0.027
Apple, pear	4.41	3.64	0.003

Intake (times/week) in 2009	Non-RA	RA	p value
Low-fat milk	2.52	1.96	0.045
Oatmeal	2.17	1.82	0.049
Fried potatoes	0.70	0.56	0.002
Beer, up to 3.5% alcohol	0.21	0.14	0.049

Results from mixed models showed that the dietary intake changed significantly from 1997 to 2009 for 44 (53.7%) food items in RA cases and 82 (100%) food items in non-RA cases. Both RA and non-RA cases increased/decreased their intake of all the food items in the same manner. Dietary changes between RA and non-RA cases were not significant for 79 (96.3%) food items, the very few significant differences were intake of whole wheat bread, rice and wheat/oat bran. Non-RA cases increased their intake of these three food items more than the RA cases. (Table)

Food item	Times per week 1997→2009 (mean ± SD) RA (n=191)	Non-RA (21,567)	p value
Whole wheat bread	6.80 ± 0.45	7.75 ± 0.04	0.037
Rice	0.81 ± 0.06	0.94 ± 0.01	0.034
Wheat/Oat bran	0.38 ± 0.11	0.62 ± 0.01	0.028

The hierarchical cluster analysis did not identify any meaningful clusters based on the total intake of all food items which did not allow comparison of dietary pattern changes over time between RA cases and controls.

Conclusion:

This study showed that women who had been diagnosed with RA had similar changes in dietary patterns over time as the general population, and did not change their diet due to their disease. Based on earlier evidence on the advantages of improved nutritious diet in RA, specific dietary recommendations for patients with RA are needed.

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Data capture of patient reported outcomes (PROs) is gradually shifting from data collection on paper in medical office to use of computer or mobile based technologies between doctor visits. Concerns have been raised that patients may have limited interest in contributing data over time, or that they may only record new data when there has been a change in their clinical status. We evaluated the patterns and factors associated with longitudinal PRO data capture among participants in the PCORI-funded Patient Powered Research Network for adult rheumatologic conditions, ArthritisPower.

Methods: Patients in the registry were asked to voluntarily complete PROs including the RAPID3 and 4 PROMIS instruments (pain interference, physical function, fatigue, and sleep disturbance) plus disease-specific information via a mobile application (App) on their smartphone or computer. We evaluated the average time assessment it took patients to

record each of the instruments and the total number of unique days that patients recorded PROs. Given the newness of the registry (launched late 2015), longitudinal data was defined as contributing at least 2 sets of PROs on unique calendar days. We tested the hypothesis that patients would contribute longitudinal data only when at least one of their scores exceeded a minimally important difference (MID) of any of the 5 PROs examined (generally 2-3 units for PROMIS instruments; 3.6 units for RAPID3). Demographic factors associated with multiple PRO reports were identified using logistic regression among patients who had been enrolled in the registry for at least 3 months.

Results: At the time of analysis, ArthritisPower had recruited 2,103 patients, most (approximately 68%) had RA, and 20% provided their Twitter handle. Average (SD) age was 50 (12); 87% were women. The mean assessment time for each of the PROMIS instruments ranged from a low of 16 seconds (sleep disturbance) to a high of 105 seconds (RAPID3). The average score for pain interference was 64.3 (SD: 6.3), physical function 37.5 (6.5), sleep disturbance 59.3 (8.4), fatigue 64.2 (8.4), and RAPID3 15.7 (5.3). Of 1,946 patients who registered the Smartphone App more than 3 months prior to analysis, 20.6% never contributed any PRO information, 53.3% answered once, and 26.1% answered at least twice. Among patients with longitudinal data (>=2 assessments), the mean change score of PROs between pairwise PRO assessments was <1 point for all instruments (Table). Only 23.1% of patients contributing longitudinal data had a change greater than the MID in any of the 5 PRO measures. Patients with RA (OR: 1.54, 95% CI: 1.14-2.06), biologic use (2.12, 1.43-3.15), and those with Twitter accounts (1.40, 1.08-1.82) were more likely to contribute longitudinal PRO data in the absence of regular reminders.

Conclusion: Multiple factors were associated with patient willingness to contribute longitudinal PRO data. Importantly, some patients were willing to contribute longitudinal PRO data even without a change in their health state exceeding any MID and without physicians' requests. Additional efforts are needed to engage patients to contribute PRO data over time, and to maximize patient engagement.

Tables: Mean change between 1st and 2nd visit among patients with longitudinal data

	Mean Change from 1st to 2nd Visit	**Absolute mean change from 1st to 2nd Visit**	**% of patients exceeding change > MID**
PROMIS Physical function	-0.4 (3.8)	2.7 (2.7)	34.2%
PROMIS Pain Interference	-0.4 (5.4)	3.9 (3.6)	52.3%
PROMIS Sleep Disturbance	0.2 (6.1)	4.6 (4.0)	56.0%
PROMIS fatigue	-0.03 (6.6)	4.8 (4.4)	55.6%
RAPID3	0.2 (3.8)	2.8 (2.6)	29.8%
MID: Minimally important difference (3 points for PROMIS instruments and 3.6 for RAPID3)

Effects of Alcohol Consumption on the Severity of Inflammation in Hand and Foot Joints Detected with MR Imaging

L. Mangnus[1], M. Reijnierse[2] and A.H.M. van der Helm- van Mil[3], [1]Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]Radiology, Leiden University Medical Center, Leiden, Netherlands, [3]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Moderate alcohol consumption is associated with a lower risk on RA development. (1,2) It is also associated with less severe systemic inflammation. Based on these data, we hypothesized that alcohol consumption is also associated with the severity of local inflammation in hand and foot joints at presentation of RA. Second, as symptom-free individuals also have a low degree of MRI-detected inflammation in MCP, wrist, and MTP joints (3), and because alcohol consumption is shown associated with C-reactive protein (CRP) levels in a J-shaped curve in the general population (4), we also supposed that alcohol consumption is associated with the severity of inflammation in small joints in symptom-free volunteers. The present large-scale MRI study was undertaken to evaluate these hypotheses.

Methods: MRI was performed at disease presentation in 171 RA-patients, included in the Leiden Early Arthritis Clinic (EAC) cohort and in 193 asymptomatic volunteers from the general population. Alcohol consumption was analysed as continuous measure and also categorized in four groups; non-drinkers, participants that consume 1-7 drinks/week, 8-14 drinks/week and >14 drinks/week and analysing a dose effect. A unilateral contrast-enhanced 1.5T MRI of MCP, wrist and MTP-joints was performed. Each MRI was scored by two readers on synovitis, bone marrow edema and tenosynovitis; the sum of these yielded the MRI inflammation score. Association of alcohol consumption with CRP was also evaluated. Kruskal Wallis test was used.

Results: Although a J-shaped curve was seen in the association between alcohol consumption and CRP level in RA-patients, with the lowest levels in patients consuming 1-7 drinks a week (p=0.037), alcohol consumption was not associated with the severity of MRI-detected inflammation of hand and foot joints at presentation with RA (p=0.55). Also within asymptomatic volunteers alcohol consumption was not associated with the severity of local inflammation in hand and foot joints (p=0.33).

Conclusion: Despite the facts that other have shown that moderate alcohol consumption is protective to RA development and associated with less systemic inflammation in the general population, and that our data confirms a J-shaped association of alcohol consumption with CRP-levels in RA, there is no association between alcohol consumption and the severity of inflammation in hand and foot joints. The pathophysiological mechanism of the protective effect of alcohol is not well understood but the present data suggest that local inflammation is not involved. References: 1. The Utility of Screening for Infectious Diseases in Recipients of Anti-TNF-α Therapy _ Choi, Kristal, Mertz, Lester, Heigh, Russell, Yiannias, James, Blair, Janis

Background/Purpose: Tumor necrosis factor-α inhibitors (TNF-I) are commonly used today to treat a wide variety of immune-mediated disorders. These medications are linked with an increased risk of mycobacterial, viral, and fungal infections, and some society guidelines recommend screening for tuberculosis (TB), hepatitis B (HBV) and C (HCV), human immunodeficiency virus (HIV), and active life-threatening fungal infections. The aim of our study was to determine the number of patients with infectious diseases identified on screening; and to describe what evaluation, treatment, and follow-up transpired for these individuals.

Methods: We electronically searched for all patients receiving TNF-I from 9/4/2010 to 4/22/2015. The records for patients screening positive for HBV, HCV, TB, and HIV were then reviewed in detail.

Results: 2218 individuals received TNF-I during the study period. 656 patients had at least one of the following laboratory tests checked: hepatitis B surface antibody (HBsAb), hepatitis B surface antigen (HBsAg), and hepatitis B core antibodies (HBc total Ab). Of these, 37 (5.6%) were positive for HBsAb only, 1 (0.1%) was positive for HBsAg only, 3 (0.5%) were positive for HBc total Ab only, and 5 (0.8%) were positive for both HBsAb and HBc total Ab. One patient had a known history of chronic HBV prior to the initiation of a TNF-I, and one patient was tested due to the development of symptoms only. Thus, there were 7 (1.0%) new diagnoses of HBV diagnosed by screening. All 7 cases were maintained or eventually started on their TNF-I. One case received treatment with lamivudine when started on a TNF-I. 662 patients were tested for HCV via antibody test, and 2 (0.3%) were found to be positive on pre-screening. Follow-up RNA testing was negative in one case and positive in the other. The latter patient was referred to Hepatology, and the initiation of the TNF-I was delayed due to the new diagnosis. 557 were tested for TB via the QuantiFERON-TB Gold In-Tube assay, and 13 (2.3%) were positive. After excluding patients who had a known history of latent TB and those who were tested due to the development of symptoms only, there were a total of 7 (1.3%) new diagnoses of TB found on screening. Five (71.4%) cases were diagnosed with latent TB, and were appropriately treated. TNF-I was initiated in 4/5 cases after > 1 month of treatment with isoniazid. Two positive assays found on pre-screening were thought to be false positives, and TNF-I was initiated with no TB treatment. Two patients were screened for HIV with an antigen and antibody combination assay, and both were negative.

Conclusion: Few new cases, and no active cases, of HBV, HCV, TB, and HIV are identified in recipients of TNF-I therapy during routine screening.

	HBV	HCV	TB	HIV
Total number screened	656	662	557	2
Total new cases diagnosed on screening (%)	7 (1.0%)	2 (0.3%)	7 (1.3%)	0 (0%)
Pre-screening	4	2	5	0
Annual screening	3	0	2	0
TNF-I delayed or held	0	1	4	0
Treatment initiated for infection	1	0	5	0
Sub-specialty referral	6	1	7	0

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To examine drug prescribing trends for patients with rheumatoid arthritis (RA) over recent years and compare them to matched non-RA subjects.

Methods: Retrospective prescription data were examined from 2005-2014 in a population-based cohort of patients with RA and comparable non-RA subjects. Index date was 1/1/2005 for both cohorts. Drugs for or related to the treatment of RA were excluded. Comparisons between cohorts of percentages of patients with at least 1 prescription in a specific drug category/class were performed using Poisson regression models adjusted for age and sex.

Results: A total of 497 patients with RA (71% female) and 527 non-RA comparator subjects (70% female) were included in the study. Median age at index for RA and non-RA subjects was 61 years (range 25-95) and 63 years (range 26-95), respectively. Among the patients with RA, the median duration of RA at index was 7.5 years (range 0 to 24.8). Median time from index to last follow-up for both cohorts was 9.9 years. Comorbidities prior to index were similar among both cohorts with notable exceptions of peptic ulcer disease (13% non-RA vs 19% RA; p=0.006) and peripheral vascular disease (12% non-RA vs 19% RA; p=0.006). Former and/or current smoking was more common among patients with RA (55%) compared to non-RA (46%; p=0.018). The overall observed percentage of subjects who were prescribed at least 1 drug over the ten-year period was somewhat higher among the RA compared to non-RA subjects (relative risk [RR]: 1.04; 95% confidence interval [CI]: 0.99, 1.08). Over the study period, both cohorts demonstrated significant increases in the percentages of patients with at least 1 prescription (7% increase over 10 years in RA, p<0.001; 11% increase in non-RA, p<0.001). Drugs that were more common among RA than non-RA subjects included antimicrobials (50% RA vs 41% non-RA in 2014; RR: 1.24), calcium metabolism modifiers (10% RA vs 6% non-RA in 2014; RR: 1.78), thyroid hormone replacement therapy (23% RA vs 19% non-RA in 2014; RR:1.21), antidepressants (34% RA vs 27% non-RA in 2014; RR: 1.12), antiasthma/inhaled glucocorticoids (RR: 1.21), proton pump inhibitors (28% RA vs 18% non-RA in 2014; RR: 1.45), anti-ulcer (RR: 1.58), contraceptives (5% RA vs 2% non-RA in 2014; RR: 1.69), anti-hypertensives (55% RA vs 49% non-RA in 2014; RR: 1.11) and some others. Prescription drugs that were less common in RA than non-RA were statins (29% RA vs 35% non-RA in 2014; RR: 0.83) and other antilipemic drugs (RR: 0.56). Use of pregabalin/gabapentin (RR: 1:18; 95%CI: 0.98-1.44) and ophthalmic (RR: 1.10; 95%CI: 0.97-1.24) drugs was not statistically different between those with RA and non-RA subjects.

Conclusion: There was a marked overall increase in prescriptions drugs for both RA and non-RA cohorts over the study period with some prescribing patterns differing between the cohorts. RA patients, at higher risk for cardiovascular events, were consistently prescribed less statins and non-statin antilipemic and were regularly prescribed more proton pump inhibitors than non-RA comparators. The clinical implications of these differences in prescribing patterns require further evaluation.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze clinical remission in patients with early RA and undifferentiated arthritis (UA) during the first 2 years of treatment using methotrexate (MTX) and prednisone.

Methods: Database included patients diagnosed with early RA, less than 2 years of evolution. Patients were divided into 3 groups according to when the treatment was started 0-3 months, >3-6 months or >6 months of onset of symptoms. Descriptive statistics were applied to each of the variables Student’s t-test and the chi-squared test were applied and Fisher’s exact test was used where necessary. Univariate analysis was performed using Mann Whitney test and Multivariate logistic regression models were used to measure the association with remission defined by DAS 28, SAI, CDAI, and ACR/EULAR scores. A value of $p \leq 0.05$ was considered significant.

Results: Of 2078 included patients, 442 were available for the intent-to-treat analysis (ITT). 83% were women with mean age 52.74 years (SD 14.05) and a median duration of symptoms of 6.5 months (IQR 3.0–12.0) by the time they entered into the study. Of the total, 303 (68.6%) had RA (ACR 1987) and 139 (31.4%) UA. ESR 35.15 mm/h (IQR15-48.75), CRP 16.77 mg/dl,(IQR 0.5 to 11.51), positive RF in 275 (62.2%) patients. The clinical characteristics at baseline were: HAQ 1.17 (IQR 0.5-1.75), DAS 28 5.14 (SD 1.32), CDAI 25.98 (IQR 15-35), IAS 28.68 (IQR 18.42-38.57), hands SENS 8.34 (IQR 2-13), feet SENS 2.64 (IQR 0-4). During the study, 415 (93.9%) received MTX (average dose 15mg/week) and prednisone (average dose 7.97 mg/day) in 410 (99.8%) patients. MTX and prednisone were initiated with a mean at 8.83 (IQR 3-13) months and 7.55 (IQR 2-12) months, respectively, from the onset of symptoms. The patients who reached remission at some point in 2 years follow-up measured by DAS 28 were in 305 (69%), by IAS in 288 (65.2%), by CDAI in 255 (57.7%) and by ACR/EULAR score in 224 (50.7%) patients. Table 1 and 2 show higher remission percentages in a group of patients were treated with combination therapy with MTX and prednisone, especially in those who the onset of symptoms was before 6 months of evolution of the disease. In multivariate analysis, patients treated with MTX achieved remission at some point the follow up with DAS28 (OR 3.88, 95%CI 1.66-9.06, p=0.002), IAS (OR 2.98, 95%CI 1.50-5.88, p=0.002), CDAI (OR 3.00, 95%CI 1.57-5.72, p=0.001), ACR/EULAR score (OR 2.80, 95%CI 1.49-5.25, p=0.001) and lower HAQ at baseline in those who had less 3 months from the onset of symptoms. Table 1: Remission percentages in patients who received combined treatment with MTX and prednisone. Univariate analysis.

Remission	MTX/Prednisone (NO) n (%)	MTX/Prednisone (YES) n (%)	P
DAS 28 < 2.6	93 (60.0%)	212 (73.9%)	**0.004**
SAI < 5.5	87 (56.1%)	201 /70.0%)	**0.005**
CDAI < 2.8	81 (52.3%)	174 (60.6%)	0.11
ACR/EULAR	65 (41.9%)	159 (55.4%)	**0.007**

Table 2. Remission by the different scores depending on the time of treatment start from the onset of symptoms. Univariate analysis.

Remission	MTX/Prednisone 0-3 months n (%)	MTX/Prednisone >3-6 months n (%)	MTX/Prednisone > 6 months n (%)	P
DAS 28 < 2.6	87 (73.7%)	70 (76.8%)	128 (63.7%)	**0.04**
SAI < 5.5	87 (73.7)	67 (70.5%)	121 (60.2%)	**0.03**
CDAI < 2.8	82 (68.9%)	60 (63.2%)	100 (49.8)	**0.02**
ACR/EULAR	74 (62.2%)	56 (58.9%)	85 (42.3%)	**0.01**

Conclusion: Early treatment with MTX and prednisone is associated with greater opportunities to reach remission.

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biomarkers to recognize patients with a more intensive therapy necessity in rheumatoid arthritis are essential and scarce. VIP has shown immunoregulatory properties both *in vivo* and *ex vivo* in human and murine cells. We recently reported that low VIP serum levels are associated to a worse clinical course in patients with early arthritis. We aim to validate the association of genetic variants of VIP to its serum levels in a new cohort of early arthritis patients and to associate those variants with treatment requirements.

Methods: Princesa Early Arthritis Register Longitudinal (PEARL) study includes patients with early arthritis (EA). Demographic, clinical, laboratory, therapeutic, radiological data and biological samples are systematically collected

along follow-up (baseline, 6, 12, 24 and 60 months). We carried out the study in two phases with two different sets of patients from the PEARL register after a preliminary screening, as follows: *Screening* VIP serum levels were measured by Enzyme-Immunolinked-Assay (EIA, Martinez et al. 2014) in a set of EA patients. From that set, 11 patients with high and 9 patients with low VIP serum levels were selected for sequencing of VIP gen. Amplification and sequencing was performed using BigDyeDirect sequencing kit (Applied Biosystems) and were analyzed by capillary electrophoresis on a 3500xL genetic Analyzer (Applied Biosystems). 16 single nucleotide polymorphisms (SNPs) were selected due to its differential distribution in patients with extreme VIP levels. *Discovery and Validation Phases* Genetic variants selected by sequencing were genotyped in 93 EA patients for the discovery phase of the study and 131 EA patients for the validation phase, using pre-designed SNP Genotyping Assays (Applied Biosystems). In both sets of patients VIP serum levels were measured by EIA. We used the backward-stepwise selection to fit several multivariate models by generalized estimating equations for repeated measures after previous bivariate analysis to determine the adjusting variables. Statistical analysis was performed using Stata 12 for Windows (StataCorp PL, College Station, TX, USA).

Results: We found that patients with CC genotype of the SNP rs688136 had higher serum VIP levels either in the discovery and validation populations, as well as in the meta-analysis of both sets (p=0.033, p=0.007 and p=0.004, respectively). This effect was impaired by the presence of minor alleles of rs35643203 and/or rs12201140, which had a clear trend towards the association with low serum VIP levels (p=0.118 and p=0.049 respectively). We also observed a significant correlation between the combination of the different alleles of those SNPs and the treatment intensity. Patients with CC genotype of rs688136 and no minor alleles of the two other polymorphisms required less treatment than those who had the CC genotype but at least one of the minor alleles (p=0.022).

Conclusion: In two populations of patients of the PEARL study a combination of genetic variants of VIP associated with VIP serum levels are also associated with the requirements of treatment of those patients.

Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: to analyze failure predictors to anti-tumor necrosis (TNF) therapy in patients who have switched these drugs during chronic arthritis treatment.

Methods: BIOBADASAR is a national registry from Argentina. Patients with Autoimmune Rheumatic Diseases are included with appropriate diagnostic criteria and different forms of chronic arthritis who are treatment with biological drugs (bDMARDs). A control population matched for diagnosis and demographic features, free of bDMARDs therapy is included. Using this registry, we have analyzed patient switching of TNF antagonists. The log-rank test was used to compare survival curves, and Cox regression models were used to assess independent factors associated with discontinuing medication.

Results: From August 2010 to January 2016, 3397 patients were registered with: RA 2745 (78.6%), PsA 395 (11.3%), JIA 150 (4.3%), AS 107 (3.07%); mean age: 57.1±14.8 yrs; 78.4% female. 1853/3397(54,5%) patients received a total of 2079 treatment cycles: Etanercept (ETA) was used in 1155 (55.6%), adalimumab (ADA) in 601 (28.9%), infliximab (INF) in 156 (7.5%), certolizumab in 118 (5.7%) and golimumab in 49 (2.4%). More than one anti TNF was used in 1520/1853 (82%) patients. The median survival time of TNF antagonists was 36 (range, 1-243) months. TNF antagonists were discontinued in 890 (42.8%) cycles. The reasons for discontinuation were inefficacy in 350 (39.3%), adverse events in 274 (30.8%), lack of drug provision by medical insurance in 173 (19.4%), lost to follow-up in 57 (6.4%), pregnancy in 15 (1.7%), unknown reasons in 13 (1.59%) and disease remission in 8 (0.9%) patients. ETA was discontinued in 502/1155 (45.4%), mostly 117 (23%) due to lack of insurance payment ((p=0.001), INF was discontinued in 54 (51.9%) due to persistently active disease (p=0.005). Survival of the first TNF antagonist after one year of treatment was slightly higher for certolizumab (0.85 (95% CI 0.77-0.91) and ETA (0.82, 95%CI 0.80-0.84)) compared to golimumab (95%CI 0.80, 0.65-0.89), ADA (0.79, 95%CI 0.76- 0.82) and INF (0.77, 95% CI 0.69-0.84). Among patients with concomitant use of MTX, 65.7% (585) were discontinued vs not in 830 (69.8%) (p=0.045); corticosteroids were discontinued in 50.8% vs not in 34.9% ($p \leq 0.00001$). In a logistic regression model, predictors of discontinuation were: female (OR 1.59, 95% CI 1.26–2.00), ≥60 years old (OR 1.28, 95% CI 1.06–1.53), smoker (OR 1.51, 95% CI 1.11–2.05), use of corticosteroids (OR 1.97, 95% CI 1.62–2.38), INF (OR 8.73, 95% CI 5.17–14.7), ETA (OR 3.48, 95% CI 2.30–5.27) and ADA (OR 3.38, 95% CI 2.20–5.19). Concomitant use of MTX had a protective effect (OR 0.67, 95% CI 0.55–0.82).

Conclusion: We found higher rates of discontinuation of TNF antagonists in patients who used INF and ETA, including a higher frequency of discontinuation due to inefficacy in INF and lack of coverage by insurance in ETA. Specific analysis of failure predictors identified being a female, ≥60 years old, a smoker, and use of corticosteroids, INF, ETA and ADA as the main failure predictors of discontinuation of TNF antagonists in patients with chronic arthritis. On the other hand, the concomitant use of MTX had a protective effect.

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is one of the most important extra-articular manifestations of rheumatoid arthritis (RA). The prevalence of RA associated ILD (RA-ILD) is reported as 1-58% depending on the study population and the definition of ILD, and RA-ILD is known to be associated with increased respiratory infection and higher mortality in RA patients. Recently, use of biologics is increasing; however, the safety and persistency of biologics in RA-ILD patients are not established. We aimed to compare the incidence of adverse events (AEs) and persistency of biologics in RA patients with or without ILD.

Methods: A total of 981 RA patients with chest radiograph or chest computed tomography (CT) data at enrollment were extracted from BIOlogics Pharmacoepidemiologic StudY (BIOPSY) cohort, a nationwide multicenter prospective inception cohort for biologic users of RA patients in Korea. We classified them into two groups: 1) RA-ILD group as patients with ILD, and 2) RA-non ILD group as patients without ILD detected by chest radiograph or CT. We compared the incidence of AEs including respiratory infection and mortality during use of biologics between two groups, and then tested the differences of drug discontinuation rates due to AEs, infection, and respiratory infection between RA-ILD and RA-non ILD groups using Kaplan-Meier survival analysis and log-rank test. In addition, crude and multivariable Cox proportional hazard model were used to identify the impact of ILD on AEs in RA patients with biologics.

Results: The 42 patients (4.3%) revealed to have RA-ILD by chest radiograph or chest CT, and the rest of 939 patients were included in RA-non ILD group. Patients in RA-ILD group were older (62.6 ± 9.6 vs. 51.8 ± 13.2 years, $p<0.01$), and male patients were more in RA-ILD group (31.0% vs. 13.3%, $p<0.01$). During mean follow-up of 20 months with 1,611 person years (PY), the incidence of AEs was higher in RA-ILD group compared with RA-non ILD group (IRR 1.55, CI 1.11-2.17). In addition, the incidence of infection and respiratory infection were higher in RA-ILD group (IRR 2.38, CI 1.32-4.30 for infection, IRR 3.00, CI 1.50-5.99 for respiratory infection, respectively). The biologics discontinuation rate due to AEs was comparable in two groups ($p=0.13$), whereas the biologics discontinuation rate due to infection ($p=0.03$) and respiratory infection ($p<0.01$) were significantly higher in RA-ILD group. After adjusting for variables, age (HR 1.27, CI 1.15-1.41) and having ILD (HR 10.77, CI 2.26-51.41) were risk factors for mortality in RA patients with biologics.

Conclusion: The incidence of adverse events, especially respiratory infections were higher in RA-ILD patients with biologics compared with RA-non ILD patients. In addition, the biologics discontinuation rate due to infection, especially respiratory infection was significantly higher in RA-ILD patients. Concerning the mortality, ILD increased the mortality in RA patients with biologics.

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients score their global disease activity (ptGD) on average higher than physicians (phGD). This difference can vary between countries with high and lower gross national income (GNI). Also, patients with RA in lower GNI countries have less access to biologic disease modifying anti rheumatic drugs (bDMARDs) and synthetic (cs)DMARDs. With targeted treatment aiming at low disease activity (LDA) or remission, this could influence treatment. The aim was to compare differences between ptGD and phGD in high and lower GNI countries and to assess if potential differences are associated with disease activity measures.

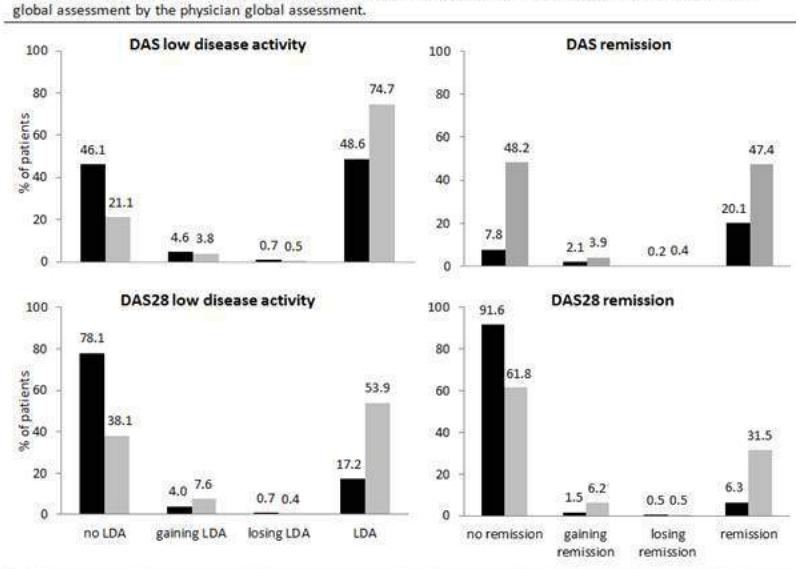
Methods: RA patients included in the METEOR database were selected from countries ≥30 patients with >1 visit, available phGD and disease activity score (DAS) or DAS28. Countries were divided in high and lower GNI (World Bank definition, high income GNI per capita ≥$12746). ptGD and phGD were measured on a 100 mm visual analogue scale (100 worst score). A difference ≥20 mm between ptGD and phGD (GDdif=ptGD–phGD) was considered clinically relevant. Susequently, ptGD was artificially substituted by phGD in the DAS and DAS28, in order to assess the potential influence of the discrepancies in globals on the number of patients in LDA or remission.

Results: From high GNI countries 6928 patients were included, from lower GNI countries 5136 patients. DAS was available in 10420 patients (6179 from high GNI countries), DAS28 in 11173 patients (6839 from high GNI countries). Patients from lower GNI countries had higher disease activity [mean (SD) DAS28 4.6 (1.8) vs 3.4 (1.8); DAS 2.5 (0.9) vs 1.8 (0.9)], longer disease duration at diagnosis [55 (69) vs 27 (59) weeks] and less often reached LDA [DAS28 49% vs 75%; DAS 20% vs 48%] or remission [DAS28 7% vs 32%; DAS 20% vs 48%] than patients from high GNI countries. Compared to high GNI countries, in lower GNI countries, more patients had a GDdif ≥20mm with ptGD>phGD (44% vs 30%) and fewer patients had a GDdif <20mm (47% vs 67%). Also, more patients had a GDdif ≥20mm with ptGD<phGD (9% vs 3% in lower vs high GNI countries). Replacing ptGD by phGD resulted in a mean (SD) change in DAS and DAS28 of 0.09 (0.1) and 0.4 (0.6) in high GNI countries and 0.9 (0.1) and 0.4 (0.7) in lower GNI countries. For both DAS and DAS28, the percentage of patients changing disease activity status is low in all countries, with most patients gaining LDA or remission (fig 1).

Conclusion: Compared to high GNI countries, patients from lower GNI countries had higher disease activity and less often reached LDA or remission. Clinically relevant differences between ptGD and phGD were found in more than 1/2 of the patients in lower GNI countries and in 1/3 of the patients in high GNI countries, with potentially more impact on disease

activity assessments in lower GNI countries than in high GNI countries. These results give further support to observations that access to 'good RA care' is worse in lower than higher GNI countries (inequity).

Figure 1: Percentage of patients changing DAS and DAS28 disease activity status after replacement of the patient global assessment by the physician global assessment.



Black bars represent lower gross national income countries: Brazil, India, Mexico and South-Africa. Grey bars represent high gross national income countries: Czech Republic, Spain, France, United Kingdom, Greece, Ireland, Italy, Netherlands, Portugal, Qatar and United States. Outer bars describe patients not changing disease activity status. The inner two bars describe patients changing disease activity status. LDA = low disease activity.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is well known that patients with RA experience health-related job loss, more days absent from work (i.e., absenteeism), and to a greater extent, a decrease of at-work productivity (i.e., presenteeism). However, little is known about the effect of biologic treatments on absenteeism and presenteeism. The aim of this study was to investigate whether achieving clinical response to treatment, and changes in physical ability and quality of life (QoL) during the first six months predict absenteeism and presenteeism at one year in patients commencing treatment with biologic therapy for RA.

Methods: Patients recruited to the British Society for Rheumatology Biologics Register for RA (BSRBR-RA) commencing biologics for RA and in full or part-time paid employment at inclusion were included in this study. DAS28, HAQ, and QoL (EQ-5D) were measured at baseline, six months, and 1 year. Patients were categorised into good/moderate vs. poor responders according to the EULAR response criteria at 6 months. Changes from baseline in physical ability and QoL at 6 months were calculated. Absenteeism in the last month, and presenteeism (*0=no interference – 10=complete interference)*, were measured at all three time points using the RA specific Work Productivity Survey (WPS-RA). Due to excessive zero values in the WPS-RA, zero inflated negative binomial regression (ZINB) was used to assess whether treatment response, HAQ and EQ-5D changes at six months predicted absenteeism and presenteeism at one year.

Results: Since most patients were still in employment at 1 year (work disabled n=4), data on 263 patients with baseline and 1 year WPS-RA were used. The mean age was 51 years (SD 8.6), median disease duration was 6 years (IQR 3-13); 78% were female. At baseline, median [IQR] scores were: DAS28 5.8 (5.3-6.4), HAQ 1.3 (0.6-1.6) and EQ-5D 0.6 (0.5-0.7). At baseline, 21% reported ≥1 days absent from work, and the median presenteeism score was 3.0 (IQR 0-5). Presenteeism scores significantly improved over 1 year (median 1.0 [IQR 0-4], Kruskal-Wallis Test: $H(2) = 18.70$, $p<0.001$), as did absenteeism (17% reported ≥1 days absent) although a Chi-square test demonstrated this to be non-significant. Compared to non-responders, EULAR good/moderate responders were 2.8x more likely to be classified in the zero group for presenteeism at 1 year, (OR 2.89, [95% CI 0.99, 8.50], *p=.0.05*), and although non-significant there was a trend towards increases in HAQ at 6 months resulting in lower probability of being in the zero group presenteeism at 1 year ($p<0.07$) (table 1). Changes in EQ-5D scores at 6 months did not appear to predict presenteeism or absenteeism at one year.

Conclusion: The results suggest that if a moderate/good response to biologic therapy is observed at six months, a reduction in presenteeism over the following six months can be expected. The results of this analysis are promising, particularly with regard to presenteeism which remains to be a major economic issue. Table 1. Six month predictors of presenteeism and absenteeism at one year follow up.

The Impact of Disease-Related and Contextual Factors on Work Outcomes in Chronic Inflammatory Arthritis Patients Treated with Biologics: A Systematic Review

Jenny Shu[1], Panos Lambiris[2] and Claire Bombardier[3], [1]Department of Rheumatology, University of Toronto, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Toronto General Hospital Research Institute, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biological therapy has been shown to have a positive effect on work outcomes, such as work participation and/or work disability in patients with chronic inflammatory rheumatic diseases. However, work outcomes are often dependent on contextual factors. Our objective is to specifically identify both the disease-related and contextual factors that impact work outcomes in patients with chronic inflammatory arthritis treated with biologics.

Methods: A systematic literature search was conducted using the Medline, Embase, two Cochrane, and CINAHL databases as well as hand searches from conference archives and clinicaltrials.gov to identify publications relating to chronic inflammatory rheumatic diseases (specifically rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA), systemic erythematous lupus (SLE), Sjogren's syndrome, or systemic sclerosis (Ssc)) in double-blind, randomized-controlled biological therapy trials with work outcomes as a primary or secondary outcome. Only studies that describe a relationship between either a disease-related or contextual (CoFas) factor and work outcome were included. A critical appraisal of the included studies was performed to determine methodological flaws in the study design and to assess for possible bias.

Results: Of the 1649 abstracts retrieved, 13 studies met inclusion criteria. The RCT's included 3 chronic inflammatory diseases (AS= 3, PsA =2, RA = 8). The follow-up period was between 12 weeks to 2 years. Biologics used include etanercept (4 studies), infliximab (3 studies), adalimumab (3 studies), and single studies with golimumab, abatacept, and certolizumab pegol. Despite study heterogeneity, there was an overall positive effect of biological therapy on work outcomes. Disease-related factors which correlated with work outcomes included patient-reported outcomes such as the health assessment questionnaire (HAQ) in 7 studies, fatigue in 3 studies, and pain in 2 studies, as well as specific disease activity and remission markers. Only 6 studies examined contextual factors. Specifically, personal factors such as female gender (4 studies) and older age (4 studies) had a negative impact on work outcomes. Environmental factors that correlated with better work outcomes include non-manual type of jobs, higher baseline number of hours worked, and lower baseline number of sick days.

Conclusion: Our results show that the positive effect of biological therapy on work outcomes is likely a result of interplay between better disease control as well as favorable patient and work environment contextual factors. Further trials identifying these variables will be important for the evaluation and prediction of work outcomes in RCT's with biological therapy for patients with chronic inflammatory diseases.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Targeted blockade of tumour necrosis factor (TNF) has been a major therapeutic advance in the treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS). TNF (or "cachectin", as it was initially called) may be responsible for the weight loss observed in patients with active RA via its inhibitory effect on the enzyme lipoprotein lipase which regulates fat metabolism. "Rheumatoid cachexia" may be an important contributor to morbidity and mortality in RA. Low body weight in RA patients was associated with increased disability and radiological progression of joint damage. Other factors are also important in RA-related weight loss, for example lack of physical activity due to joint pain and restriction of movement, or anorexia from a combination of ill-health and medications. The effect of corticosteroids (CS) on body weight is an important confounder. TNF inhibition has been associated with variable effects on body weight in patients with inflammatory arthritis. We sought to determine if TNF inhibition (TNFi) resulted in weight gain in patients with inflammatory arthritis.

Methods: In this retrospective cohort study, the following data were obtained for all patients initiated on a biologic disease modifying anti-rheumatic drug (bDMARD) through the Mid-North Coast Arthritis Clinic (MNCAC) for inflammatory arthritis up to Jan 25, 2012: age, sex, type of inflammatory arthritis, initial bDMARD, body weight at 3 initial consecutive time-points, CRP, ESR, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) or Disease Activity Score-28 joints (DAS28) as appropriate, and oral corticosteroid dose (mg/d). Change in body weight over 3 time-points following commencement of the initial bDMARD was calculated. Regression modeling (mixed linear models) was undertaken to ascertain the effect of parameters (age, sex, disease activity, bDMARD, daily dose of oral corticosteroid) on body weight.

Results: N=301 patients were initiated on a bDMARD. N=98 were excluded for the following reasons (insufficient time on treatment for 3 weighs, n=55; incomplete data, n=32; intentional weight loss, n=9; refused weighing, n=1; failure to commence therapy, n=1). The remaining 203 patients were included and had commenced the following bDMARDS: 184 TNFi, 8 tocilizumab, 8 abatacept, 3 rituximab. Patients initiated on a TNFi gained weight at the rate of 0.03 (95 CI: 0.013-0.035, $p<0.001$) kg per week, independent of corticosteroid dose and disease activity. There was no change in weight in those initiated on a non-TNFi bDMARD (n=19).

Conclusion: TNF inhibition resulted in minor weight gain. This side effect is often forgotten. It is possible that weight loss may be predictive of clinical response to TNFi. This needs to be investigated in a larger prospective study

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are known to have an increased comorbidity burden. Presence of diabetes or other comorbidities such as cardiovascular disease (CVD) may affect the treatment decisions for RA. Limited information is available regarding biologic initiation patterns in RA patients with various comorbid conditions. We aimed to compare the frequency of diabetes and other comorbidities in RA patients starting different classes of biologic DMARDs.

Methods: Using longitudinal claims data from Medicaid (2000-2010), Medicare (2008-2013) and a commercial health plan (MarketScan 2006-2015), we conducted a cohort study that included RA patients who initiated a biologic DMARD. We included 3 categories of biologic DMARDs: 1) TNF inhibitors (TNFi), 2) abatacept and 3) other biologics including rituximab, tocilizumab and tofacitinib. Patients were required to be naive to all biologic DMARDs for at least 365 days prior to the date of the 1st biologic drug dispensing (i.e., index date). We assessed the prevalence of diabetes and other comorbidities in the 365-day period prior to the index date in each data source.

Results: There were a total of 148,584 biologic DMARD initiators: 25,878 in Medicaid, 40,663 in Medicare and 81,831 in MarketScan. Mean age (SD) in years was 46.8 (12.0) in Medicaid, 73.1 (6.3) in Medicare and 53.7 (13.0) in MarketScan. Over 75% were female. Across all three databases, 115,903 (78%) started a TNFi, 13,547 (9%) abatacept and 18,922 (13%) other biologics. Diabetes was common, affecting 22.8% in Medicaid, 35.3% in Medicare and 17.7% in MarketScan. Hypertension (36.1-78.6%), hyperlipidemia (21.3-67.7%), coronary heart disease (8.3-30.0%), heart failure (2.7-14.7%) and other cardiovascular comorbidities were common in all three databases. Compared to abatacept or other biologic initiators, TNFi initiators were younger and had a lower proportion of CV comorbidities including coronary heart disease, heart failure, stroke, and atrial fibrillation and malignancy at baseline. Differences in diabetes prevalence across treatment groups were less pronounced (**Table**).

Conclusion: Diabetes and CV comorbidities were common in RA patients starting a biologic DMARD across all three databases. Cardiovascular comorbidity profile was different in TNFi initiators compared to initiators of abatacept or other biologics. Our findings highlight the need for future research accounting for these differences appropriately in comparative effectiveness and safety studies of biologic DMARDs in multimorbid RA patients to inform treatment decisions.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a well-known risk factor for osteoporosis and hip fracture. Recent studies suggest RA patients fracture at a younger age and suffer higher rates of morbidity and mortality[1]. The purpose of this study is to characterize RA patients with hip fracture in an integrated healthcare system in the US.

---

[1] Lin YC et al. Rheumatoid arthritis patients with hip fracture: a nationwide study. *Osteoporos Int*. 2015; 26:811-817

Methods: This retrospective cohort study, conducted in Kaiser Permanente Northern California, examined data from 13,550 women ≥ age 65 years with an incident hip fracture during 2000-2010. Demographic characteristics, comorbidity index (Charlson, CCI), prior fracture history and recent bisphosphonate (BP) therapy (2 prescriptions £1 year prior to hip fracture) were determined using health plan databases. RA was defined by a problem-list diagnosis and ≥3 visit diagnoses of RA. Rehospitalization (£30 days of discharge) and mortality outcome (£1 year) were assessed post-fracture. Standard descriptive statistics were used to examine differences in age, race/ethnicity, CCI, recent BP use, and prior fractures among women with and without RA experiencing hip fracture. Multivariable logistic regression analyses were used to examine the association of RA and mortality, rehospitalization, and recent BP use.

Results: Among 13,550 women who had a hip fracture, 339 (2.5%) had RA. Women with RA were slightly younger compared to women without RA (mean age 79.4±6.9 vs 82.5±7.4), and were twice as likely to be under age 75 (29.5 vs 15.1%, p<0.01). A larger proportion of RA patients were of non-white race/ethnicity (23.3 vs 16.3%), had greater comorbidity (CCI≥3, 37.5 vs 21.5 %), and were more likely to have had a prior fracture (44.8 vs 37.3%; all p<0.01). Fracture type (femoral neck vs trochanteric fracture) was similar between the two groups. Overall mortality rates at 1, 3, 6, and 12 months did not differ significantly for women with vs without RA (5.0 vs 6.4%, 10.6 vs 12.8%, 14.8 vs 17.0%, and 19.8 vs 22.9%, respectively), and RA status was not associated with greater mortality outcome even after adjusting for differences in age, race/ethnicity, prior fracture, recent BP use and CCI (adjusted odds ratio, OR 0.9, 95% CI 0.7-1.2). Readmission rate within 30 days was also similar for women with and without RA (12.7 vs 12.0%, p=0.69), with no increased risk for women with RA (adjusted OR 1.0, CI 0.7-1.4). However, women with RA had 3-fold greater odds of having received bisphosphonate therapy within the year prior to hip fracture (adjusted OR 3.0, CI 2.3-3.8).

Conclusion: Women with RA were younger and had greater comorbidity at the time of hip fracture. However, RA status did not appear to be independently associated with increased morbidity and mortality post hip fracture. The higher proportion of RA women with a prior fracture and evidence of recent BP therapy is consistent with their higher underlying fracture risk. Future studies should focus on prevention strategies to decrease risk of hip fracture in RA patients.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: NAFLD is a leading cause of chronic liver disorders, unrelated to significant alcohol use. RA and NAFLD have shared risk factors such as age, gender, race/ethnicity, metabolic syndrome, obesity, diabetes, and dyslipidemia[1]. Little is known about the incidence of NAFLD in patients with RA. This study determined the incidence rate, time to event, and factors associated with the development of NAFLD in this population.

Methods: Longitudinal data from the Corrona RA registry (2001-2014) of adults without NAFLD (n=17,481) were used in this retrospective analysis. The Fibrosis-4 index[2], a validated noninvasive tool, was used to determine the presence of NAFLD (score ³1.3) at baseline**.** Kaplan Meier and adjusted Cox proportional hazard analysis were used to determine the incidence rate, time to event, and the predictors associated with NAFLD. Factors identified *apriori* and significant variables from the unadjusted analysis were included in the multivariate analysis (see Table 2).

Results: At baseline, the mean age of the cohort was 54 years (SD 12.4); 88 % were Caucasian; 79% female; with an average RA disease duration of 8 years. The most prevalent comorbidities were hypertension (37%), dyslipidemia (22%), and metabolic syndrome (19%). About 72% had a BMI ≥25, 70% were currently using MTX, and 40% reported using alcohol. The cumulative overall incidence was 31%; mean time to NAFLD was 7 years, 1.4% with advanced disease (see Table 1). In the multivariate analysis (see Table 2), independent predictors for increased risk for NAFLD were age (middle and elderly), hypertension, CVD, dyslipidemia, metabolic syndrome, exercise, use of MTX, and non-MTX antirheumatic drugs. Factors associated with reduced risk of NAFLD were gender (female), BMI ≥25, all RA disease duration categories, having insurance and being divorced/separated.

Conclusion: During the study period of 13 years, a third of patients with RA in this study developed mild/moderate NAFLD in a fairly short period of time. RA patients with dyslipidemia, metabolic syndrome, hypertension and cardiovascular disease were at higher risk for developing NAFLD. The ubiquitous prevalence of NAFLD is an emerging public health challenge, highlights the need for early diagnosis and management of NAFLD.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence and characteristics of patients with nonalcoholic fatty liver disease **(**NAFLD) have not been well characterized in the RA population. The purpose of this analysis was to report the incidence rates and time to event by key risk factors among patients with RA.

Methods: Longitudinal data (2001- 2014) on a cohort of adult RA patients without NAFLD at the index baseline visit from the Corrona Registry were used in this retrospective analysis. Fibrosis-4 index[1] was used to determine the presence of NAFLD. Kaplan-Meier survival analysis was conducted to determine rate and time to event (NAFLD). Breslow (Generalized Wilcoxon) test was used to determine if there were significant differences in the survival distribution for the categorical variables.

Results: This incident NAFLD cohort consisted of 17,481 RA patients. As shown in table 1, higher NAFLD incidence rates were seen among the elderly (53.2), women (70.9), and Caucasians (85) per 1,000 patient years. At baseline, those in Clinical Disease Activity Index remission had the lowest incidence rate whereas the highest rates were seen among those in low disease activity (15.4 vs. 29.3 cases per 1,000 person-years). Those with metabolic syndrome (vs. without) and MTX users (vs. nonusers) had higher incidence rates of 115.3 vs. 45.4 and 69.1 vs. 25.9 cases per 1,000 person-years, respectively. Nonusers (vs. users) of steroids and biologics also had higher incidence rates (62.7 vs.30.2 and 55.5 vs. 39.4 cases per 1,000 person-years respectively) as was for nonsmokers and nonusers of alcohol. There was significant difference in the time to event (NAFLD) for the elderly (4.5 years vs. younger 11.6 years), men (6.4 years vs. 7.3 years for women), and African Americans (6.7 years vs. 8.1 years for Caucasians). Similar differences were also seen for patients with (vs. without) metabolic syndrome, diabetes, dyslipidemia, cardiovascular disease, and hypertension, as well as users of methotrexate, steroids, non users of biologics, smokers, and nonusers of alcohol.

Conclusion: In this cohort of RA patients**,** incidence of NAFLD varied by demographic factors (higher for Caucasians and women) as well as clinical factors with the highest among those with metabolic syndrome followed by nonusers of alcohol. However, among RA medications, only current use of methotrexate was associated with higher NAFLD rates. Onset of NAFLD appears to be sooner for those with the presence of chronic risk factors such as metabolic syndrome, diabetes, dyslipidemia, CVD, and hypertension. Further understanding for the appropriate management of RA patients at risk for NAFLD is warranted.

Table 1: NAFLD Incidence Rate by Key Risk Factors and Time to Event among RA Patients (N= 40,300, n=17481)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is a major source of morbidity and mortality in RA, but current management goals follow general population recommendations without tailoring based on RA characteristics. The published and internally validated Expanded Risk Score for CVD in RA (ERS-RA) may provide useful information for CVD management. The ERS-RA identified 3 modifiable RA factors at baseline which were predictive of future CV risk: prednisone use, functional status as defined by the health assessment questionnaire disability index (HAQ-DI), and the clinical disease activity index (CDAI). We examined whether changes after baseline in these modifiable RA factors correlate with changes in CVD risk.

Methods: Using data from a large RA registry of 15,711 subjects recruited from rheumatology practices in North America, we categorized 10-year risk of CVD using the ERS-RA. We then used Cox proportional hazards regression to determine if adding information on RA factors during follow-up, had effects on relative risk of CV events (MI, stroke, CV death). Changes in the three modifiable factors were categorized as follows: prednisone use was noted as unchanged, increased if daily dose was increased by at least 25%, or decreased if lowered by at least 25%; HAQ-DI score were categorized as unchanged, increased if higher by at least 0.5 units, or reduced if lowered by at least 0.5; and CDAI was categorized as unchanged, increased if higher by at least 25%, or decreased if lower by 25%. Cox proportional hazards models were fit using updated information on the three RA factors using information updated every six months. Hazard ratios were estimated worsened or improved values, compared with no change from baseline.

Results: Median follow-up in this cohort was 34 months with 53,861 person-years of follow-up. During this period, 342 CV events were confirmed for an overall incidence rate of 6.35 per 1,000 person-years (95% CI 5.71 -7.06). The **Table** illustrates the considerable changes in RA factors after baseline, with more than half of subjects demonstrating changes in CDAI, 30% in prednisone use, and 26% in HAQ-DI. Multivariable hazard ratios demonstrate a 30% reduction in CV risk for subjects with reduction in HAQ-DI (95% CI 0.46 – 1.06) and a 56% increase in risk for subjects with increased prednisone dosage (95% CI 1.12 – 2.16).

Conclusion: Cardiovascular risk appears to be modifiable for patients with RA. These preliminary analyses suggest that improvements in HAQ-DI score and reduced prednisone dose may be associated with reduced CV risk overtime. If confirmed, this information may provide useful evidence for constructing CV risk management recommendations specific to RA.

Table. Change in RA modifiable CV risk factors from baseline.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: New treatments have improved the short term outlook for patients with inflammatory polyarthritis (IP) over the past 20 years. However there is limited evidence on whether long term outcomes have changed. This study compared the 10 year outcomes (mortality, disease activity, disability) in 2 cohorts of patients recruited in 1990-4 and 2000-4.

Methods: Adults, aged ≥16 with ≥2 swollen joints for ≥4 weeks, were recruited to the Norfolk Arthritis Register (NOAR). Patients recruited from 1990-94 and 2000-04 made up cohorts 1 (C1) and 2 (C2) respectively. Patients were excluded if baseline assessment was ≥2 years after symptom onset. Baseline assessments included demographics, smoking status, 51 swollen / tender joint counts (SJC51 / TJC51), HAQ and self-report comorbidities. RF, ACPA and CRP were measured from stored blood samples. Patients were reassessed at 1-3, 5, 7 and 10 years. CRP was only measured at 5 and 10 years when blood samples were taken. Mortality data were provided by the Office for National Statistics. Censoring occurred after 10 years of follow up. The association between cohort and mortality was assessed using a Cox proportional hazard model. The associations between cohort and longitudinal disease activity (SJC51 / TJC51) / disability were assessed using random effects models. First age at symptom onset and gender were included as covariates. Then additional variables (baseline RF, ACPA, smoking status; time varying DMARD use, HAQ, SJC51, TJC51, CRP, comorbidities) were included.

Results: Of 1653 included patients (C1 = 1022, C2 = 631), 962 (58.2%) patients met the 2010 RA criteria (C1 = 614 (60.1%), C2 = 348 (55.1%)). At baseline, patients in C2 were older, had lower SJC51 / TJC51 but had worse HAQ (see table). 948 patients (57.3%) completed 10 years of follow up (C1 = 607 (59.4%), C2 = 341 (54.0%)) whilst 306 (18.5%) patients died (C1 = 187 (18.3%), C2 = 119 (18.8%)). In an age and gender adjusted model, C2 was associated with a reduced risk of death compared to C1 (HR 0.77, 95% CI 0.61, 0.97). Adjusting further for possible confounders did not explain the reduced risk (HR 0.69, 95% CI 0.51, 0.94). C2 had lower longitudinal SJC51 compared to C1 in age and gender adjusted (SJC51: β -1.79, 95% CI -2.22, -1.36) and further adjusted models (SJC51: β -1.56 95% CI -1.94, -1.19). TJC51 was also lower in C2 and approached significance (age and gender adjusted: β -0.18, 95% CI -1.01, 0.65; further adjusted: β -0.65, 95% CI -1.31, 0.01). Physical disability was higher in C2 compared to C1 (β 0.09, 95% CI 0.03, 0.16), adjusting for age and gender. In the further adjusted model disability did not differ between cohorts (β -0.03, 95% CI -0.09, 0.03).

Conclusion: Over 10 years mortality risk and disease activity were improved in C2, although disability was not. C2 patients may have increased expectations of the efficacy of therapy or increased availability of devices may explain the similar HAQ scores.

Table – Baseline characteristics of all patients and stratified by cohort

	Total cohort		1990-94		2000-04

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have reported increased overall mortality in association with rheumatoid factor (RF) in RA. However, the clinical significance including health outcomes of RF in general populations are incompletely known. Thus, the aim of this study was to determine the association of RF with mortality due to all-causes, cardiovascular disease (CVD), and cancer-cause in Koreans without RA participating in a health-screening program. Furthermore, we analyzed whether the titers of RF had implication for the mortality outcome in healthy screening subjects.

Methods: A cohort study was performed in 295,837 participants free of osteoarthritis or rheumatoid arthritis (RA), and who had undergone health screening between 2002 and 2012 and been followed-up to determine the risk of all-cause, CVD, and cancer-specific mortality with respect to the presence or titer of RF. To determine whether the participants were deceased, we used National Death Index death certificates.

Results: The prevalence of RF positivity (≥ 20 IU/mL) was 4.4%. During 1,447,403 person-years of follow-up, 1,402 participants died. Comparing subjects with RF-negativity with those positive for RF in a sex-adjusted model, the HRs for

all-cause and cancer mortality were 1.66 (95% CI = 1.39–1.98) and 1.84 (95% CI = 1.44–2.35), respectively. After adjusting for confounding factors, RF positivity was still significantly associated with the risk for all-cause or cancer mortality (HR=1.50, 95% CI = 1.19–1.90; HR=1.56, 95% CI = 1.12–2.16, respectively). However, the HR for cardiovascular mortality was not higher in subjects with RF-positivity than in those with RF-negativity (HR=0.98, 95% CI=0.45–2.11). The HRs for all-cause, CVD, and cancer mortality were estimated in terms of RF levels. After adjusting for confounding factors, all-cause and cancer mortality risk was significantly greater in subjects with an RF titer greater than 100 IU/mL than in those with RF-negativity (HR=2.68, 95% CI=1.72–4.19; HR=2.89, 95% CI=1.58–5.28, respectively). On the other hand, RF titer did not show significant association with an increased risk of CVD mortality.

Conclusion: In healthy South Korean examinees without RA, RF was associated with a greater risk of all-cause and cancer mortality, suggesting that it predicts greater mortality, even among the apparently healthy population. This result would shed new light on the clinical significance of RF on mortality in the general populations.

A Rheumatologist's Assessment of Therapy Responses (Rxresp) and Rheumatoid Factor Status (neg/pos) in 1995 Predicted Mortality through 2015 in a Community-Based Cohort of Incident Rheumatoid Arthritis Cases and Matched Control Subjects

Alfonse T. Masi[1], Azeem A. Rehman[2], Laura Jorgenson[3] and Jean C. Aldag[3], [1]University of Illinois, College of Medicine at Peoria, Peoria, IL, [2]Neurosurgery, University of West Virginia Medical School, Morgantown, WV, [3]Medicine, University of Illinois College of Medicine at Peoria, Peoria, IL

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Greater disease severity, older age, positive serum rheumatoid factor (RF), and long-standing glucocorticoid usage contribute to increased mortality of rheumatoid arthritis (RA) patients. This study aimed to analyze all-cause mortality through 2015 as related to 1974 baseline cohort entry demographic factors, 1995 clinical assessment of therapy response (Rxresp) of incident RA, and RF status pre- and post-onset of RA vs non-RA matched cohort control (CN) subjects.

Methods: All incident RA cases identified in 1995 from the 1974 community-based cohort (n=21,061 adults) satisfied 1987 revised ACR criteria. Cases (n=54) were matched (1 RA: 4CN) with 216 cohort CN subjects on age, gender, and race (Caucasian). All subjects (N=270) were regularly followed for survival. Two investigators independently determined causes of death (CODs) from the completed death certificate codes without knowledge of RA vs CN status. Baseline (1974) serum isotype-specific IgM and IgA RF assays were performed (TheraTest Laboratories, Chicago, IL) with coefficients of variation (CVs ±SE) of 16.0 (±2.1) and 20.2 (± 1.6), respectively. In 1995, RF status was also extracted from RA patients' clinical records. Therapy response (Rxresp) categories (1= good, 2=fair, 3=limited) were assessed by the sole community rheumatologist. Cox regression models estimated hazard ratios (HRs) for all-cause mortality through 2015, including covariates of 1974 demographic and baseline serological variables, 1995 Rxresp, and RF categories by 1974 and 1995 results (0=both negative, 1=only 1995 positive, 2=both 1974 and 1995 positive).

Results: The 38 (70.4%) deaths in 54 RA exceeded (p=0.003) the 102 (47.2%) in 216 matched CN (Table). The difference (p=0.012) persisted in Cox models (Exp β 1.66, 95% CIs 1.12-2.47), including covariates of cohort entry age deciles (p<0.001, Exp β 2.70, 95% CIs 2.19-3.33), years of completed education (p=0.010, Exp β 0.91, 95% CIs 0.85-

0.98), and degree of cigarette smoking (p=0.048, Exp β 1.13, 95% CIs 1.00-1.28). In Cox models, 19 good Rxresp RA had similar (p=0.978) mortality to their 76 matched CN (Table). Mortality was strongly (p=0.001) increased in 35 fair/limited Rxresp RA vs 140 CN (Exp β 2.11, 95% CIs 1.33-3.33) (Table). The 35 fair/limited Rxresp RA had significantly (p=0.012) greater mortality (29, 82.9%) than the 19 good Rxresp RA (9, 47.4%) (Table). In 15 RF-negative RA cases in 1974 and 1995, the 8 good Rxresp had similar mortality (63%) to the 7 fair/limited Rxresp cases (57%) (p=1.00). In the 39 RF-positive cases, fair/limited Rxresp was a strong (p=0.002) predictor of mortality (Table, footnote). Mortality of RA cases was also predicted (p=0.015) by a scale of 1974 and 1995 RF status, particularly for 1974 and 1995 RF-positive cases (p=0.004, Exp β 6.25, 95% CI 1.80-21.7) (Figure). Fair/limited vs good Rxresp independently predicted (p=0.013) RA mortality in Cox model, including the RF scale (0,1,2) and demographic covariates (Fig).

Conclusion: Assessment in 1995 of fair/limited vs good Rxresp in RA patients predicted (p=0.012) greater mortality through 2015, particularly in RF-positive cases (p=0.002). Mortality was significantly (p=0.004) greater in 9 consistently RF-positive RA vs 15 consistently RF-negative cases. Interaction of Rxresp categories and RF status on RA mortality outcome deserves further research.

Mortality Outcome of Rheumatoid Arthritis (RA) Patients through 2015 by their Rheumatologist's assessment of having Good vs Fair or Limited Responses to Therapy in 1995 and by Negative vs Positive Serum Rheumatoid Factor in 1974 and 1995

Baseline Serum Inflammatory Biomarkers at Cohort Entry in 1974 Predicted Cardiovascular Disease (CVD) Mortality from 1995 through 2015 in a Prospective, Community-Based Study of Incident Rheumatoid Arthritis (RA) Patients and Matched non-RA (CN) Subjects Author Block: Alfonse T. Masi[1], Azeem A. Rehman[2], Laura C. Jorgenson[1], Jean C. Aldag[1], [1]University of Illinois College of Medicine at Peoria, Peoria, IL. [2]University of West Virginia, Morgantown, WV.

Background/Purpose: Inflammatory pathways have been incriminated in total and cardiovascular disease (CVD) mortality of rheumatoid arthritis (RA) patients (Arthritis Rheum. 2005 Mar;52(3):722-32). Current studies have analyzed serum inflammatory biomarkers in RA patients as related to total and CVD mortality outcomes. No reports are available on serum inflammatory biomarkers before clinical onset of RA as related to total or CVD mortality outcomes. The aim of this study is to investigate baseline pre-clinical inflammatory biomarkers as related to all-cause and CVD mortality of incident RA cases and matched non-RA comparison (CN) subjects in a long-term prospective cohort.

Methods: All incident RA cases were identified who had onsets between 1977 and 1995 from a 1974 community cohort (n=21,061 adults) and satisfied 1987 revised ACR criteria. Cases (n=54) were matched (1 RA: 4CN) with 216 cohort CN subjects on age, gender, and race (Caucasian). All subjects (N=270) were regularly followed for survival through 2015. Two investigators independently determined causes of death (CODs) from the completed death certificate codes without knowledge of RA vs CN status. Baseline (1974) serum immunologic factors were anonymously assayed at national referral laboratories. Assay values were log-transformed and standardized by z-scores in females and males. Multiple imputation (MI) was utilized to enter a minority of randomly missing biomarker z-scores. Individual biomarker z-scores were also analyzed as ranks (1= lowest, 5= highest) within the 54 separate matched sets of 1 RA and 4 CN. Logistic regression was used to identify ranked variables which predicted mortality outcome through 2015, in total deaths and by CVD, respiratory, malignancy, and all other CODs. The dichotomized (neg=0, pos=1) z-scores of predictive ranked factors were entered as covariates in Cox regression models in addition to 1974 baseline demographic and CN_RA status. Pairs of independent dichotomous (neg/pos) selected z-scores were combined (0=both negative, 1=either positive, 2=both positive) to enhance mortality prediction.

Results: In all subjects, total mortality was predicted by ranks of C-reactive protein (CRP) ($p=0.033$, Exp β 1.17, 95% CIs 1.03-1.33). The CVD deaths were predicted by ranks of soluble tumor necrosis factor receptor 1 (sTNF-R1) ($p=0.001$ Exp β 1.41, 95% CIs 1.14-1.75) in Cox regression models, including baseline demographic covariates. The dichotomous (neg/pos) z-scores of the preceding predictive biomarkers were paired (CRP_sTNF-R1) into a 3-scale score, which significantly predicted total mortality ($p=0.002$, Exp β 1.42, 95% CIs 1.13-1.78). That paired predictive biomarker (CRP_sTNF-R1) was an even stronger predictor of CVD mortality ($p<0.001$, Exp β 2.06, 95% CIs 1.39-3.07) (Figure 1). Its Exp β was slightly greater for RA [2.97 (0.97-9.09)] than CN [1.98 (1.27-3.10)], but was significant ($p=0.003$) only in the larger sample of CN subjects. Excluding the preceding 50 CVD deaths, the paired biomarker did not predict ($p=0.130$) total mortality in 220 remaining subjects (Figure 2). In the 220 non-CVD subjects, mortality differed slightly ($p=0.045$) between those who had neither vs both dichotomous z-scores positive. As found in our previous analyses, RA vs CN status did not predict ($p=0.357$) 50 CVD deaths [Expβ=1.37 (0.70-2.70)] (Figure 1), but did significantly ($p=0.003$) predict all other-cause mortality combined in the remaining 220 subjects [Expβ=2.10 (1.29-3.41)] (Figure 2). The paired biomarker was not a significant predictor of the separate non-CVD CODs.

Conclusion: Ranks (1-5) of serum CRP and sTNF-R1 z-scores significantly predicted either total or CVD mortality in 270 subjects. A 3-scale pairing of the preceding dichotomous z-scores (CRP_sTNF-R1) significantly ($p<0.001$) predicted CVD mortality, but not ($p=0.130$) non-CVD mortality in the remaining 220 subjects. The relation of pre- and post-clinical onset serum inflammatory biomarkers to total, CVD, and other cause-specific mortality deserves further study in RA and CN subjects.

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RA patients are known to be at increased risk of vascular morbidity and mortality, although conflicting reports exist for incident RA patients. Our aim was to evaluate the risk of cardiovascular and cerebrovascular disease (CVD) mortality in seniors with incident RA in Ontario, Canada.

Methods: We undertook a population-based cohort study of incident RA patients aged 66 years or older (ensuring comprehensive drug coverage) from 2000 to 2013. We identified four non-RA general population comparators for each RA patient, matched on age, sex and region of residence. All patients were followed until death (primary cause due to CVD ascertained from vital statistics, with censorship for deaths due to competing cause), out-migration, or end of study period (Dec 2013). Crude and adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using multivariable Cox models, controlling for time-varying drugs (statins, antihypertensives, NSAIDs, COX-II inhibitors), baseline comorbidities, healthcare use, and socioeconomic status.

Results: 28,322 RA patients and 113,288 comparators were followed for 142,534 and 502,823 person years, respectively. During a median follow-up of 4 years, 1,947 (6.9%) RA patients and 6,340 (5.6%) comparators died due to CVD, corresponding to CVD mortality rates of 13.7 (95% CI 13.1-14.3) and 12.6 (95% CI 12.3-12.9) per 1000 patient-years, respectively. Risk of vascular mortality was not greatly increased in incident RA relative to age/sex/area-matched comparators (unadjusted HR, 1.02; 95% CI 0.96-1.09; adjusted HR, 0.98; 95% CI 0.91-1.05). Risk for CVD mortality was lower in patients using statins (HR, 0.60; 95% CI 0.56-0.64), COX-II inhibitors (HR, 0.68; 95% CI 0.59-0.78) and NSAIDs (HR, 0.74; 95% CI 0.62-0.90), and in those with a prior joint replacement (HR, 0.80; 95% CI 0.72-0.90); and greater with pre-existing comorbidities (coronary artery disease, hypertension, COPD/asthma, renal failure, cerebrovascular disease, acute myocardial infarction, diabetes), use of antihypertensive agents (HR, 1.17; 95% CI 1.09-1.25), and being in a lower socioeconomic status (HR, 1.32; 95% CI 1.20-1.46)

Conclusion: In these analyses, seniors with incident RA were not shown to have an increased risk of vascular mortality, although longer follow-up is warranted. Use of statins, COX-II inhibitors, and NSAIDs was associated with a decreased risk for vascular mortality, although residual confounding cannot be ruled out.

Session Title: Epidemiology and Public Health - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is one of the most important extra-articular manifestations in patients with rheumatoid arthritis (RA). The prevalence of ILD in patients with RA has been shown to vary widely between 1% and 58% depending on the study population and the definition of ILD. Some studies have supported ethnicity-related differences in the prevalence of ILD and ILD in RA; however, these results have not yet been conclusive. In addition, ILD is known to be associated with higher mortality; however, the effect of ILD on mortality among Asian RA patients is not enough. In this study, we aimed to determine the prevalence of ILD in Korean patients with RA and assess the effect of ILD on their mortality.

Methods: A total of 3,555 patients with RA with chest X-ray or chest computed tomography (CT) data at enrollment were extracted from the KORean Observational study Network for Arthritis (KORONA) cohort, a nationwide prospective cohort for patients with RA in Korea. Patients were classified into two groups: 1) ILD group as patients with ILD by chest X-rays or chest CT scans, and 2) non-ILD group as patients without ILD by these modalities. After comparing demographic and clinical characteristics at enrollment between the groups, log rank test was used to test the differences in survival between the ILD group and the non-ILD groups. With adjusting age, sex, smoking history, medications, RA severity, and comorbidities, cox proportional hazard model was made to identify the impact of ILD on RA mortality.

Results: Sixty-four patients (1.8%) were identified with ILD. The ILD group patients were older at diagnosis (54.9 ± 11.6 years in ILD group vs. 45.5 ± 12.9 years in non-ILD group, $p<0.01$) and at enrollment (63.2 ± 9.2 years vs. 53.6 ± 12.1 years, $p<0.01$) than non-ILD group patients, and male (29.7% vs. 15.5%, $p<0.01$) patients were more common in the ILD group. In regard to medication, methotrexate was used less (57.8% vs. 82.1%, $p<0.01$), and oral glucocorticoid was used more (89.1% vs. 76.3%, $p=0.03$) in the ILD group compared with the non-ILD group. During mean follow-up of 24 months, 6 patients (9.4%) in the ILD group and 25 patients (0.7%) in the non-ILD group died; survival rates were significantly worse in the ILD group ($p<0.01$) by log-rank test. On adjusted analysis, ILD was significantly associated with an increased mortality risk (HR 9.41, CI 3.63-24.39, $p<0.01$); the risk of mortality in patients with ILD was even higher than in patients with cardiovascular disease (HR 4.85, CI 2.03-11.64, $p<0.01$) or malignancy (HR 3.40, CI 1.19-9.68, $p=0.02$).

Conclusion: The prevalence of ILD was 1.8% in Korean patients with RA. ILD was a major risk factor for increased mortality in p atients with RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Epidemiology and Public Health - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The evolution of RA and axSpA is characterized by alternated periods of flares and remission. This fluctuating disease activity can be self-assessed by a single question [1]. The objective was to assess the frequency of flares when assessed weekly and the link between flares and well-validated patient reported outcomes (PROs).

Methods: In this prospective longitudinal multicenter observational study aiming to explore physical activity and its relation with disease activity. Patients had definite axSpA (ASAS criteria) or RA (ACR/EULAR criteria). Patients were asked to complete every week during 3 months different PROs including pain and patient global assessment (PGA) and flare status. Flares were recorded using the question (« has your disease flared up during the last 7 days ? ») [1], with a categorical response: no flare, flare lasting 1 to 3 days or flare lasting more than 3 days. Flare frequency was calculated by the number of reported flares divided by the number of completed questionnaires over the 3 months. The frequency of flares in RA and axSpA patients was compared by Mann-Whitney test. Pain and PGA were compared across assessments according to flare status using ANOVA on repeated measures (linear mixed-effects model).

Results: 86 patients (45 RA and 41 axSpA patients) were included in this analysis: 37 (43.0%) were males, with a mean age of 46.3 (±11.7) and a mean disease duration of 10.8 (±7.9) years, 48 (55.8%) were receiving a biologic. RA and axSpA patients had respectively a mean DAS 28 of 2.2 (±1.0) and a mean BASDAI of 3.5 (±2.1). Patients reported flares on average in 23.9% (±23.1) of the weekly questionnaires, with a mean frequency of '1 to 3 days flares' and '>3 days flares' respectively of 17.2% (±17.0) and 6.7% (±14.1). Flare frequency and duration of flares were higher in RA than axSpA, in particular for short flares, though this difference did not reach statistical significance (Table 1). Pain and PGA were higher when patients self-reported flares and in particular longer flares rather than "bad days" (Table 2). Table 1: Mean frequency of flares per patient according to their duration in RA and axSpA patients

	All patients (n=83)	RA (n=45)	axSpA (n=41)	p
Frequency of all flares, mean (SD)	23.9 (±23.1)	27.0 (±24.5)	20.5 (±21.3)	0.20
Frequency of 1-3 days flares, mean (SD)	17.2 (±17.0)	20.4 (±19.5)	13.8 (±13.1)	0.16
Frequency of >3 days flares, mean (SD)	6.7 (±14.1)	6.6 (±10.9)	6.8 (±17.1)	0.31

Table 2: PROs according to flare status

	No flare (n=836 questionnaires)	1-3 days flares (n=191 questionnaires)	>3 days flares (n=73 questionnaires)	P
Pain 0-10, mean (SD)	2.2 (±1.8)	4.4 (±1.7)	6.5 (±2.0)	<0.0001
PGA 0-10, mean (SD)	2.3 (±1.9)	4.4 (±1.8)	6.4 (±2.3)	<0.0001

Conclusion: self-reported flares were frequent in RA and axSpA, in this population of long-standing disease with good inflammation control. Long flares (>3 days) were less frequent. Self-reported flares were substantiated by higher PROs. More work is needed on long-term effects of flares. 1. VP Byberk et al, RMD Open, 2016; 2(1):e000225.

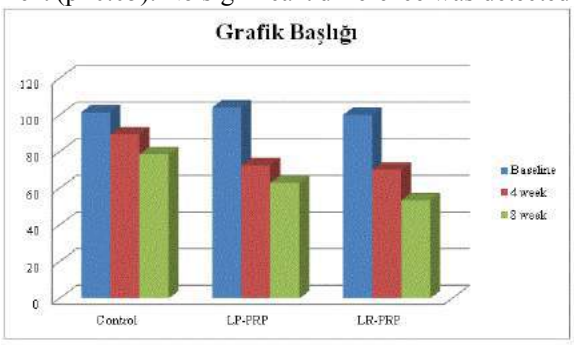
Comparison of effects of leukocyte-rich and leukocyte-poor platelet-rich plasma on pain and functionality in patients with lateral epicondylitis Melek Yerlikaya[1], Havva Talay Çalýþ[1], Serap Tomruk Sütbeyaz [1], Hatice Sayan[1], Nurdan Ýbiþ[1], Ali Koç[2], Çiðdem Karakükçü[3] [1]Kayseri Training and Research Hospital, Department of Physical Medicine and Rehabilitation, Turkey, [2]Department of Radiology, Kayseri Training and Research Hospital, Kayseri, Turkey, [3]Department of Biochemistry, Kayseri Training and Research Hospital, Kayseri, Turkey

Background/Purpose : We think that leukocyte concentration in PRP can affect local inflammatory response. In this study, we aimed to compare effects of leukocyte-rich and leukocyte-poor PRP on pain, functionality and post-injection local inflammatory reactions and adverse effects in patients with lateral epicondylitis.

Methods : Overall, 90 patients with lateral epicondylitis-related pain (VAS score≥5) over >3 months were included to the study and randomly assigned into 3 groups. Normal saline (1.5 cc) was injected to the group 1 while a single dose of LP-PRP (1.5 cc) and LR-PRP (1.5 cc) were injected to groups 2 and 3, respectively. Same exercise program was prescribed to all three groups. The patients were assessed with VAS, Patient-Rated Tennis Elbow Evaluation (PRTEE), grip and pinch strength, extensor tendon thickness and cortical derangement at baseline and on weeks 4 and 8 after therapy. All patients were questioned regarding paracetamol use and adverse effects after therapy.

Results: The mean age was 47.63±9.05 years in the control group while 45.03±8.57 years in LP-PRP and 46.49±8.73 years in LR-PRP group. The groups were comparable regarding age. No significant differences were detected between groups regarding, VAS, PRTEE, , grip and pinch strength measurements, extensor tendon thickness and cortical derangement (p>0.05). No significant difference was detected in paracetamol use and post-injection reactions among groups.



\s **Figure 1:** Patient-based PRTTE scores in groups

Conclusion: In our study, PRP was found to have no superiority to control groups in patients with lateral epicondylitis. Leukocyte concentration in PRP was also found to have no association to improvement in pain and function or adverse effects.

Prevalence of Growth Hormone Deficiency in Fibromyalgia Patients

Thomas Romano, Private Practice, Martins Ferry, OH

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Low levels of Insulin-dependent growth factor 1 (IGF-1) have been described in Fibromyalgia (FM) patients, suggesting that they have adult growth hormone (GH) deficiency. The prevalence of low IGF-1 and low GH has not yet been described. This study describes these prevalences.

Methods: Seventy-eight female FM patients were studied over a four year period in a solo private rheumatology practice. All fulfill 1990 and 2010 ACR FM criteria. Mean age was 45 years (range 20-68). Serum IGF-1 levels were measured and IV GH stimulation testing performed using either arginine or glucagon as the secretagogue.

Results: Mean IGF-1 was 133 ng/ml as compared to the expected level of 235 ng/ml. Of the 78 patients, 70 had low-for-age IGF-1. Of the 48 that took the IV GH stimulation test, 44 failed necessitating the use of subcutaneous GH preparations . The prevalence of GH deficiency in FM was at least 56%.

Conclusion: GH deficiency is more common than believed in FM. More FM patients should be so tested.

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Brain imaging techniques including functional magnetic resonance imaging (fMRI) may be useful in probing the mechanisms of action of centrally acting analgesics. Previously we have used brain resting state functional connectivity (fcMRI) outcomes to predict clinical pain response in fibromyalgia (FM) for the two efficacious compounds pregabalin (PG), preclinically shown to reduce presynaptic cell calcium thereby reducing the concentration of glutmate, an excitatory neurotransmitter, into the synapse, and milnacipran (MLN), preclinically shown to inhibit the reuptake of serotonin and norepinephrine, improving descending modulation. Here we extend our analyses to determine if these compounds have a differential effect on brain connectivity patterns in human patients with fibromyalgia.

Methods: 28 female FM patients were included in this study. 13 completed a double-blind placebo-controlled crossover study with PG, and 15 completed a similar study with MLN. All patients underwent a 6 minute fcMRI scan pre- and post-treatment for both the drug and placebo (PBO). Patients reported clinical pain pre- and post-treatment using a 0-10 rating scale. fcMRI data were analyzed with *a priori* regions of interest approach using the Conn toolbox running in SPM8 and Matlab. Regions previously identified as independently predictive for PG and MLN were cross-utilized in both data sets. Changes in fcMRI were analyzed in SPM8 with paired t-tests (within treatment) and a flexible factorial interaction (PG vs MLN) that included seed-to-whole brain correlation maps. Finally, PG and MLN were directly contrasted with a two-sample t-test.

Results were significant on the cluster level with a false discovery rate p value < 0.05 derived from an uncorrected voxel level p value < 0.001. Significant results were correlated with changes in clinical pain in SPSS v22 Results: PG significantly decreased fcMRI between the anterior and posterior insula seeds to the dorsolateral prefrontal cortex (DLPFC, $p = 0.003$ and $p = 0.05$). Decreases in PG anterior insula – DLPFC fcMRI were associated with reduced clinical pain ($rho = 0.830$, $p < 0.001$). MLN significantly increased fcMRI between the subgenual anterior cingulate (sgACC) seed and the inferior parietal lobule (IPL, $p = 0.040$). Increased sgACC – IPL fcMRI was associated with reduced clinical pain ($rho = -0.515$, $p = 0.049$). When directly compared MLN significantly increased and PG significantly decreased fcMRI between the right DLPFC seed and the precuneus ($p = 0.007$). PG DLPFC – precuneus fcMRI, decreases were associated with reductions in clinical pain ($rho = 0.808$, $p = 0.001$). No PG seeds produced significant fcMRI relationships in the MLN data and no MLN seeds displayed significant fcMRI relationships in PG data.

Conclusion: These data demonstrate differential effects of PG and MLN on resting brain activity, thus providing further evidence that these compounds may have different mechanisms of action. PG was found to act more so on pro-nociceptive brain regions, whereas MLN acted more so on an anti-nociceptive brain region. These results suggest that a combination of

both PG and MLN in the same patient may be more effective due to the medications working on separate yet complementary brain processes.

Dysautonomia and Osteoporosis in 2300 Ehlers-Danlos Hypermobile Patients, As Defined By the Brighton Criteria

Jaime F. Bravo, Medical School, Universidad de Chile, santiago, Chile

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Dysautonomia and Osteoporosis in 2300 EDS type III patients, as defined by the Brighton criteria

Background/Purpose: To highlight the high frequency of Dysautonomia (Dys) and Osteoporosis in Ehlers-Danlos type III (EDS-III), complications that are very frequent and usually undiagnosed. Identify the percentage of EDS-III that are not hypermobile (negative Beighton Score (BSc) with positive Brighton Criteria (BC)). Stress the need to make the diagnosis using the Brighton Criteria and not relaying only on the Beighton Score .

Methods: We have studied 2300 EDS-III patients. The BSc and the BC were applied to all patients. Age: range 16 - 87, average 44.43. Females 78.7%. Patients were grouped in < 30 y/o (A), and over 30 y/o (B). Dysautonomia was clinically evaluated in 2283 patients. Densitometries were done in 1060 patients (OMS criteria). Patients younger than age 16 were excluded since the BC has been validated only for ages 16 and over.

Results: 2300/2868 patients had EDS-III (80.2%). BSc negative: 51.0%. Dys total group: positive: M 30.14%, F 56.16%; Group A: M 60.8%, F 84.04%; Group B: M 21.6%, F 60.1%. BMD total group: normal 31.6%, Osteopenia 47.9%, Osteoporosis 20.5%; **Osteopenia**: Group A: M 45.7%, F 50.4%, Group B: M 53.5%, F 48.0%; **Osteoporosis**: Group A: M 8.6%, F 9.8%, Group B: M 20.0%, F 22.9%.

Positive Dysautonomia (1164) in 2283 EDS-III patients evaluated

Positive	**Total Positive Group n = 1164**		**Group A (< 30 y/o) n = 382**		**Group B (≥ 30 y/o) n = 782**	
Males	148	30.4 %	65	**60.8 %**	83	21.6 %
Females	1016	56.2 %	317	**84.0 %**	699	60.1 %
	1164		382		782	

Bone Mineral Density studied in 1060 EDS-III patients

	Total Group	Group A (< 30 y/o) n = 89		Group B (≥ 30 y/o) n = 741	
	%	Males	Females	Males	Females
Normal BMD	31.6	45.7	50.1	26.5	29.1
Osteopenia	47.9	45.7	40.1	53.5	48.0
Osteoporosis	20.5	**8.6**	**9.8**	20.0	22.9

Conclusion: • EDS-III is extremely frequent in our Clinic (80.2%), referral Center. • Significant percentage of EDS-III patients are not hypermobile (BSc negative in 51.0%). In some studies, many EDS-III patients are excluded when only applying the BSc rather than the BC, this is our reason for preferring to use the term Ehlers-Danlos type III, instead of Ehlers-Danlos Hypermobile. • Dysautonomia is very prevalent in young EDS-III females (84%). Low BMD is frequent, even at young ages, including Osteoporosis, 8.6% in males and 9.8% in females.

Association Between Fibromyalgia and Bone Mineral Density: A Systematic Review and Meta-Analysis

Sikarin Upala[1] and Anawin Sanguankeo[2], [1]Internal Medicine, Bassett Medical Center, Cooperstown, NY, [2]Bassett Medical Center, Cooperstown, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Previous studies have shown that fibromyalgia syndrome (FMS) is associated with low level of physical activity and exercise, which may lead to an increased risk of osteoporosis. However, studies of bone mineral density (BMD) in fibromyalgia have shown conflicting results. Thus, we conducted a systematic review and meta-analysis to better characterize the association between FMS and BMD.

Methods:

A comprehensive search of the databases of the MEDLINE and EMBASE was performed from inception through May 2016. The inclusion criterion was the observational studies' assessment of the association between fibromyalgia and bone mineral density in adult subjects. Fibromyalgia was diagnosed in accordance with the American College of Rheumatology (ACR) criteria for the diagnosis of fibromyalgia syndrome. BMD was measured at the lumbar spine and femoral neck by dual-energy X-ray absorptiometry (DEXA). Pooled mean difference (MD) of BMD at each site and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method. The between-study heterogeneity of effect-size was quantified using the Q statistic and I^2.

Results:

Data were extracted from 4 observational studies involving 680 subjects. At lumbar spine (L2-L4), BMD is significantly decreased in patients with FMS compared with controls with pooled MD of -0.02 (95% CI -0.03 to -0.01, P-value=0.003, I^2=0%) (Figure 1). At femoral neck, BMD is not significantly decreased in patients with FMS compared

with controls with pooled MD of -0.01 (95% CI -0.02 to 0.01, P-value=0.23, I^2=0%) (Figure 2).

Conclusion:

In this meta-analysis, we observe that bone mineral density at lumbar spine is decreased in FMS compared with normal individuals. Patients with FMS should be assessed for risk of osteoporosis. Figure 1: BMD at Lumbar spine

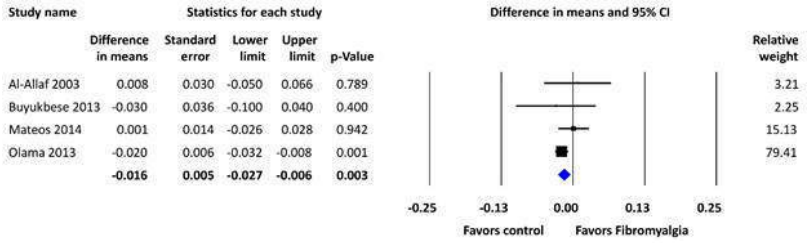

Figure 2: BMD at Femoral Neck

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Our aim was to investigate the thiol/disulphide homeostasis, which has an important role in many cellular activities such as antioxidant protection, detoxification, cell growth and apoptosis in fibromyalgia patients.

Methods: The study population was formed of a total of 93 participants; 46 females of which were diagnosed with fibromyalgia and 47 (1 male, 46 females) healthy volunteers. Fibromyalgia patients were diagnosed using criteria American College of Rheumatology (ACR). In both groups, native thiol-disulphide exchanges were examined using the

automated measurement method newly developed by Erel and Neselioglu.

Results: When we determine at the thiol/disulphide homeostasis parameters in both groups, we can see the mean native thiol (p=0.000), total thiol (p=0.004), native thiol/total thiol (p=0.000) levels and white blood cell (p=0.040) were lower in the fibromyalgia group than the control group. The mean disulphide level (p=0.008), the disulphide/native thiol ratio (p=0.000), the disulphide/ total thiol (p=0.000) levels and glucose (p=0.041) were higher in the fibromyalgia group when compared to the control group. A negative correlation was determined between age, marital status, waist circumference, fibromyalgia impact questionnaire (FIQ) and native thiol, total thiol levels. Low thiol levels and high disulphide levels in the fibromyalgia patients were found to be independent of gender, age and body mass index.

Conclusion: In this study we have shown that thiol/disulphide homeostasis may be used as a novel oxidative stress marker in fibromyalgia patients. Further studies are needed to confirm the pathophysiologic role of thiol/ disulphide homeostasis in fibromyalgia.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia Syndrome [FMS] is a common chronic pain disorder. Pregabalin (PGB) is one of three medications approved by the FDA for treatment of FMS. Substance P (SP), a neuropeptide known to facilitate pain transmission, is elevated in the cerebrospinal fluid (CSF) of FMS. The mechanism of PGB benefit in FMS is uncertain, but it is known to inhibit SP production by neurons *in vitro*. Our objective was to measure PGB's effect, if any, on CSF SP in FMS.

Methods: This study was investigator-initiated, -designed, -conducted, and –analyzed. It was randomized (2:1, PGB:PBO), double-blinded, placebo (PBO)-controlled, and involved only FMS females, 18-65 years of age. Funding was provided by a research grant from Pfizer Inc., which also provided the study medications (150mg PGB capsules, identical-appearing PBO). It was not an efficacy or safety clinical trial, since the primary outcome variable was biological (mean change in CSF SP level with PGB therapy). The 1990 ACR Research Classification Criteria were required for entry. At Screening (Visit #1), informed consent was obtained, patients were examined for diagnosis, validated self-report measures were completed, a blood sample was obtained, participants began to taper-off potentially-interfering medications, and were off for 5+ half-lives. At Baseline (Visit #2), the self-report measures were repeated, CSF was collected for storage at -70°C, and patients were randomized to PGB or PBO, at bedtime. The dosage was increased over a period of 2 weeks to therapeutic (300-450 mg/24 hrs). After 6 full weeks of therapeutic dosage (Visit #4), the Patient Global Impression of Change (PGIC) was assessed, and a second CSF was stored. Numbered CSF samples were analyzed in-blind for SP and biogenic amines. Treatment groups were contrasted on the mean, using analysis of variance, and on categorical outcomes with Fisher’s Exact Test. All statistical testing was two-sided with a significance at 5%.

Results: The study was originally powered for 90 randomized subjects, but, a budget cut limited the sample size, leaving the study inadequately powered. Eighty four patients signed informed consent; 38 screen failed; 46 were randomized (PGB n=31, PBO n=15), five randomized patients later withdrew consent (PGB n=3, PBO n=2). A total of 41 completed the study (PGB n=28, PBO 13), each with 2 stored CSF samples. At Baseline, treatment groups did not differ in any respect (demographic, clinical, laboratory). At Visit #4, the PGIC distribution varied significantly (p=0.02) with treatment [PGB 60.7% (17/28) cf. PBO 30.7% (4/13) reporting being Much- to Very Much-Improved] while CSF SP had increased numerically in both groups (CSF SP, fmol/ml, PGB +15.8±56.7, PBO +10.8±60.2, p=0.94). Correlations between clinical outcomes and spinal fluid measures were noted. A statistical model was developed. The observed adverse events had been anticipated, and were generally mild. One post-spinal headache was considered serious, as it required blood patch treatment.

Conclusion: The study design produced comparable treatment groups. PGB affected clinically relevant improvement in more than half of the PGB-treated patients but the CSF SP concentration trended to rise.

Lateral Epicondylitis Treatment: Comparison of Bandage, Laser Therapy and Extra-Corporeal Shock Wave Therapy

Fatma Icyer[1], **Hulya Uzkeser**[2] and Saliha Karatay[3], [1]Physical Medicine and Rehabilitation,, Ataturk University,Faculty of Medicine, Erzurum, Turkey, [2]Physical Medicine and Rehabilitation, Ataturk University Medical Faculty, erzuru, Turkey, [3]Physiotherapy and Rehabilitation,, Faculty of Health Sciences, Gazi University, Ankara, Turkey
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lateral epicondylitis is one of the most common conditions affecting elbow and characterized by a lesion of the common extensor tendon with or without inflammation. Main aim of treatments is pain relief and restoration of muscle condition. There is a wide spectrum of treatments used for management of lateral epicondylitis such as analgesic medications, exercise, orthoses and physical therapy. Extra-corporeal shock wave therapy is recommended as an alternative treatment for lateral epicondylitis. Although there are wide varieties of treatment choice, there is no consensus on its management. The aim of this study was to compare the efficacy of bandage, laser and extra-corporeal shock wave therapy in the treatments of lateral epicondylitis.

Methods: In this prospective, randomized controlled trial; 60 patients (44 women, 16 men, and mean age 46, 1±10 years) with lateral epicondylitis were enrolled. Patients were allocated into 3 treatment groups. Group 1 received only bandage, group 2 received bandage and laser, group 3 received bandage and extra-corporeal shock wave therapy. Outcome measures were visual analogue scale, disabilities of the arm, shoulder, and hand questionnaire, Nottingham health profile, pain-free grip strength, Duruoz hand index and Patient rated tennis elbow evaluation. All patients evaluated initially, at fourth week and after twelve week.

Results: All groups including splinting had statistically significant improvements compared to pre-treatment, posttreatment. The improvements were observed in more parameters in laser group than the other groups.

Conclusion: To our knowledge, this is the first study that comparing extra-corporeal shock wave therapy and laser therapy in laterals epicondylitis. In this study we found that splinting, combination of splinting and laser or extra-corporeal shock wave therapy has positive effects on pain, function and quality of life in the management of lateral epicondylitis. However, the laser therapy seems to more effective than the others.

Human Papilloma Virus Vaccination, Fibromyalgia and Dysautonomia

Manuel Martínez-Lavín[1], Paola-Kinara Reyes-Loyola[2] and Laura-Aline Martinez-Martinez[3], [1]Rheumatology, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico, [2]Rheumatology, National Institute of Cardiology, Mexico, Mexico, [3]Rheumatology, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, TX, Mexico

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In a questionnaire-based case series, we described the clinical features of 45 patients who had the onset of a chronic illness soon after HPV vaccination. Fifty three percent of them fulfilled the 2010 ACR fibromyalgia diagnostic criteria (Clin Rheumatol 2015;34:1981). The objective of the present report is to correlate fibromyalgia severity with dysautonomia severity in an enlarged cohort of patients who developed a chronic ailment soon after HPV vaccination.

Methods: We e-mailed the 2010 ACR fibromyalgia diagnostic criteria questionnaire and a validated dysautonomia questionnaire (COMPASS-31) to individuals who had the onset of a chronic illness after HPV vaccination. Those subjects who had a disease onset within the following three months after HPV immunization are included in this report. We correlate the total COMPASS-31 score with the following 2010 ACR fibromyalgia diagnostic criteria domains: Polysymptomatic Distress Scale, Widespread Pain Index values, and Symptoms Severity Scale.

Results: Fifty five eligible patients filled out both questionnaires. Thirty five (63 %) of them fulfilled the 2010 ACR fibromyalgia diagnostic criteria. At vaccination time, those patients who fulfilled the 2010 ACR fibromyalgia diagnostic criteria were older than those who did not (17 +/- 8 year old vs. 14 +/- 5 year old. $P = 0$ 0.038). Twenty three percent of all post HPV vaccine fibromyalgia girls had their disease onset within 24 hours after vaccination. In the fibromyalgia group COMPASS-31 score was 52-4 +/- 17-8, reflecting widespread dysautonomia symptoms. Likewise fibromyalgia domain scores were high, implying the presence of severe fibromyalgia (table). COMPASS-31 score correlated with the three 2010 fibromyalgia diagnostic criteria domains: With Polysymptomatic Distress Scale ($rho=0.642$, $p<0.0001$), with Widespread Pain Index ($rho=0.550$, $p=0.001$) and with Symptoms Severity Scale ($rho=0.633$, $p<0.0001$). After a mean period of 4.5 years after vaccination, none of the immunized girls with fibromyalgia was able to work or attend school on a regular basis.

Conclusion: This questionnaire-based case series sub-analysis suggests that in young girls, disabling fibromyalgia may follow HPV vaccination. Correlations between Compass-31 scores and the 2010 fibromyalgia diagnostic criteria questionnaire suggest that in this group of HPV vaccinated girls, fibromyalgia and dysautonomia may share clinical and pathogenetic features. Table

Post HPV vaccination fibromyalgia patients (n = 35)	
Age (years)	20 ± 8
Female	100 %
Age at first HPV dose	17 ± 8
Illness onset within 24 hr. after vaccination, n (%)	8 (22.9%)
Illness onset between 24 hours to 3 months, n (%)	27 (77.1%)
ACR 2010 FM Polysymptomatic Distress Scale	36 ± 13
ACR 2010 FM Widespread Pain Index	10 ± 5
ACR 2010 FM Symptoms Severity Scale	26 ± 9
COMPASS-31 scale value	52.4 ± 17.8

Small Fibre Neuropathy Biopsies (SFN) in Primary Fibromyalgia Revealed Predominant Association with Metabolic Syndrome (in addition to other known treatable causes of SFN) but No Clear Distinction Related to Biopsy Results

Euthalia Roussou[1], Johnathan Chan[2], Istvan Bodi[3] and Aleksandar Radunivics[2], [1]Rheumatology, Dr, London, United Kingdom, [2]Neurologist, London, United Kingdom, [3]Department of Clinical Neuropathology, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess patients with primary fibromyalgia (pFM) for small fibre neuropathy (SFN) and to correlate biopsy results between groups and with known causes of SFN

Methods: A total of 21 patients with pFM (M:F=19:2) had 3mm skin punch biopsies from 2 leg sites-proximal and distal (20cm below right iliac crest and 10cm above right lateral malleolus) following appropriate consent. PGP-5 has been used as a pan axonal marker. Clinical assessments obtained on pain, sleep disturbance, effect of the disease on well being past week and past month , FM pain and FM fatigue (all on a VAS 0-10; 10=worse positive). Fabro fatigue scale (0-90), Rotterdam emotional scale (30-120) ability to perform activities (8-32; 8 best ability). Each patient from the pFM group was examined for conditions known to be associated with SFN [1]: namely: Thyroid disease (hypo and hyper), metabolic syndrome, insulin resistance, diabetes, Family history (Fx) of diabetes, impaired Glucose tolerance, sarcoid, coeliac disease, B12 deficiency, chemotherapy drugs, para-neoplastic syndrome, antiviral drugs, Human Immunodeficiency Virus (HIV), Neurotoxins, palindromic rheumatism, Fx of psoriasis, hepatitis, Systemic Lupus Erythematosus, Sjogren's, amyloidosis, restless syndrome, Guillain Barre, demyelinating polyneuropathy, complex regional pain syndrome and alcoholism. Demographic, ethnic, clinical, laboratory and disease associated comparisons between SFN(+) and SFN(-) biopsy groups took place.

Results: Age (mean) of the group was of 44.48 years (y) sd (+10.9) range (20-73). Age of symptoms onset was of 32.7 y (+ 10.9)(range 12-50) while mean age of diagnosis was 40.5 y (+ 8.9)(range 21-55). Data on tender point evaluation showed that all 21 patients were fulfilling 2011 criteria for FM while 18 of 21 patients were fulfilling the 1999 criteria having >11 tender points. Biopsy results showed 14 patients of 21 (66.6%) of pFM patients to be positive for SFN while 7 patients (33.3%) were negative. Looking at SFN associations, a total of 19 of 21 patients with pFM(90.4%) had an

associated cause from those listed related to SFN. More specifically 7 patients had metabolic syndrome (including diabetes and Fx of diabetes), 5 patients had hypothyroidism, 4 had B12 deficiency and 3 patients had family history of psoriasis. No predominant distribution according to biopsy results was found. Similarly no difference between the demographic, ethnic, clinical or laboratory characteristics between SFN (+) and SFN(-) found.

Conclusion: Metabolic syndrome along with other known causes of SFN is related to pFM. Reference: [1]. Hovaguimian A, Gibbons C. Diagnosis and treatment of pain in small fibre neuropathy. Curr Pain Headache Rep. 2011;15(3)193-200.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Traumatic experiences are postulated mediators of the development of Fibromyalgia Syndrome (FMS). The STRONG STAR Consortium study of PTSD provides a unique opportunity to study FMS in a large population of service members (SM) exposed to combat stress. We have previously reported a baseline 3% prevalence of fibromyalgia among active duty service members prior to deployment (Hildebrand et al, 2014). This cohort has now been re-assessed following deployment to a combat environment.

Methods: Active duty US SM were recruited as part of a STRONG STAR Consortium study to evaluate genetic and environmental predictors of combat-related PTSD. Participants completed surveys immediately prior to overseas deployment to a combat environment and again upon return. The research classification of fibromyalgia was ascertained using the modified 2010 ACR survey criteria. Demographics, military service, and PTSD were assessed using standardized and psychometrically validated assessments.

Results: Questionnaires were completed both prior to and following deployment by 1761 SM from the original cohort of 4119. The pre-deployment (pre-D) prevalence of FMS was 2% vs post-deployment (post-D) 8% ($p<.00001$, odds ratio 8.2, 95% CL=4.8-14.0). The prevalence of PTSD was 20% pre-D and 23% post-D ($p<.0415$, OR=1.2, 95% CL=1.0-1.45). Stratification of groups by their fibromyalgia and PTSD classification revealed several trends: Among those without FMS pre-D, 13% of SM with pre-D PTSD developed FMS post-D (i.e., developed FMS during deployment) while only 6% without PTSD pre-D developed FMS post-D ($p<.0001$, OR=2.4, 95% CL=1.64-3.59). Among those without FMS pre-D, 23% with post-D PTSD developed FM, while only 3% of those without post-D PTSD met criteria for FMS ($p<0001$, OR=11.0, 95% CL=7.3-16.6). Conversely, 71% who met criteria for FMS pre-D also met criteria for pre-D PTSD while only 19% without FMS met criteria for PTSD ($p<.00001$, OR=10.2, 95% CL=5.0-20.9). Post-D, this ratio was similar in that 68% who met criteria for FMS also met criteria for PTSD while only 19% who did not meet criteria for FMS met criteria for PTSD ($p<.00001$, OR=9.4, 95% CL=6.5-13.6). For those SM gaining a new PTSD diagnosis post-D, the rate

of new FMS was also significantly higher (22%) than for those who did not acquire new PTSD post-D (2.3%, p<.00001, OR=11.8, 95% CL=7.2-19.3).

Conclusion: This is the first longitudinal study to assess the prevalence of FMS before and after a military deployment to a combat environment. Exposure to an environment in support of combat operations is strongly associated with an increased prevalence of FMS. Additionally, FMS and PTSD appear to be highly comorbid. Future research should consider the influence of other mental health diagnoses, repeated deployments, head injuries, genetic variations, and particular job exposures on the risk for FMS.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A consistent line of investigation proposes that fibromyalgia is a sympathetically maintained neuropathic pain syndrome. Moreover it has been suggested that dorsal root ganglia and peripheral sensory neuron sodium channels may play a major role in fibromyalgia pain transmission (BMC Musculoskelet Disord. 2012;13:23). Ambroxol (2-amino-3,5-dibromo-N-[trans-4-hydroxycyclohexyl]benzylamine) is a secretolytic agent used in the treatment of various airway disorders since the late 1970s. More recently it was determined that this compound also has potent anti-neuropathic pain properties. In vitro studies have shown that ambroxol is stronger than lidocaine in sensory neuron sodium channel blockade (Neurosci Lett, 2006;395:179). Furthermore; this medication is effective in the neuropathic pain animal model (Pharmacol Biochem Behav. 2010;97:249). Ambroxol has good safety profile. In many countries this compound is freely dispensed as over-the-counter medication. Our objective was to evaluate the add-on effect of ambroxol in the treatment of fibromyalgia.

Methods: In this one-group pretest-posttest open label pilot clinical observation we recruited 26 patients with fibromyalgia that fulfilled the 2010 ACR diagnostic criteria. The institutional ethics and research committees approved the protocol. Ambroxol was added to the stable pharmacological therapy. Ambroxol was prescribed at the usual clinical dosage of 30 mg PO 3 times a day x 1 month. At the beginning and at the end of the study all participants filled out the following questionnaires: the Revised Fibromyalgia Impact Questionnaire (FIQ-R), the Hospital Anxiety and Depression Scale (HADS), the 2010 ACR diagnostic criteria including the following domains: Widespread Pain Index (WPI), Symptoms Severity Scale (SSS) and Polysymptomatic Distress Scale (PDS).

Results: Patients mean age was 45±10 years. All of them female. At the end of the study; FIQ-R decreased from a baseline

value of 62±15.6 to 51.1±18.9 (p = 0.023). VAS for pain decreased from 76.4±14.4 to 56.2±30.4 (p = 0.010). WPI diminished from 14.6±3.0 to 10.4±5.2 (p = 0.001), SSS from 9±4 to 7±2 (p=0.014), PDS from 24±5 to 17±7 (p<0.001). HADS anxiety and depression scores had not significant changes. Side effects were minor and did not required drug withdrawal.

Conclusion: In this pilot study the use of ambroxol was associated to decreased fibromyalgia pain and improved fibromyalgia symptoms. The open nature of our study does not allow extracting the placebo effect from the positive results. The drug was well tolerated. Ambroxol newly recognized pharmacological properties could theoretically interfere with fibromyalgia pain pathways. Dose finding controlled studies are warranted.

Small Fiber Neuropathy in Rheumatology Clinics

Samy Metyas[1], Ramy Messiah[2], Tina Gettas[2], Christina Chen[3] and Daniel Arkfeld[4], [1]University of Southern California, Keck School of Medicine, Covina, CA, [2]Research Associate, Covina Arthritis Clinic, covina, CA, [3]Department of medicine, University of Southern California , Keck School of Medicine, Los Angeles, CA, [4]Div of Rheumatology, Keck School of Medicine, University of Southern California-Los Angeles County Medical Center, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: , Small Fiber Neuropathy (SFN) is a condition prevalent in patients with rheumatic diseases, particularly Fibromyalgia. The presence of neuropathic pain with normal nerve conduction studies raises the possibility of a neuropathy confined purely to the small unmyelinated nerve fibers: a small fiber neuropathy. Our clinical observations suggest small fiber neuropathy is an under-recognized but common manifestation of fibromyalgia that has important diagnostic significance. Testing for SFN assists providers in formulating specific diagnosis of symptoms in patients evaluated by rheumatologists. These small fiber neuropathies can be diagnosed through a 3-mm punch biopsy and may offer insight into the pathogenesis of some cases of fibromyalgia. Objective:, The purpose of this study is to discuss SFN, the importance of its association with rheumatologic conditions, diagnosis and treatment.

Methods: ,This was retrospective open label study carried out at two centers. 19 patients diagnosed with fibromyalgia according to American College of Rheumatology criteria underwent epidermal nerve fiber density to determine if the patient has SFN. A 3-mm punch biopsy samples were obtained from the right leg; 10 cm proximal to the lateral malleolus and 10 cm distal to the greater trochanter of the lateral upper thigh. Both specimens are placed in anatomically designated sample tubes. Biopsy samples were shipped to the Corinthian Reference Lab in Benbrook, Texas (with the exception of one sample sent to Therapath Neuropathology Laboratory in New York) where nerve fibers are manually counted and patient's biopsy specimen are interpreted. Nerve fiber density is determined through pathological review.

Results: 19 patients were in the study, 16 females (84.2%) and 3 males (15.8%) underwent skin biopsies, every patient had been diagnosed with and being treated for fibromyalgia and complaining of neuropathy with normal nerve conduction test , 6 patients have Sjogren's Syndrome (31.6%), 2 patients have Hashimoto's thyroiditis (10.5%), 1 patient has sarcoidosis (5.3%), 6 patients have low vitamin D (31.6 %), 5 patients have low vitamin B12 (26.3%), 3 patients have Rheumatoid Arthritis (15.8%) and 3 have lupus (15.8%). Upper and lower normal values were provided specifically for each patient to which each patients nerve fiber density was compared to. 11 patients (57.9%) presented with significantly decreased upper and lower nerve fiber density. Only 1 patient (5.3%) had normal lower nerve fiber density values and 5

patients (26.3%) had a normal upper nerve fiber density value. Two patients (10.5%) had both normal upper and lower nerve fiber density.

Conclusion: Results obtained coincide with our clinical observations that SFN serves as a component in patients with rheumatologic conditions, specifically fibromyalgia. 17 out of 19 patients with fibromyalgia and neuropathic pain were found to have a small fiber neuropathy based on reduced epidermal nerve fiber density on a standard 3-mm punch biopsy. Impaired small fiber function in patients with fibromyalgia, pointing towards a neuropathic nature of pain in fibromyalgia. These results suggest testing of possible underlying conditions including connective tissue disease, glucose metabolism, vitamin D deficiency, B12 deficiency, sarcoidosis, and others is warranted. Further large prospective study is needed including treating underlying conditions and or other modalities including use of immune globulin.

Novel Composite Responder Endpoints for Fibromyalgia Therapy Assessment

R Michael Gendreau[1], Lesley Arnold[2], Daniel J. Clauw[3], Judith Gendreau[4], Bruce Daugherty[4] and Seth Lederman[4], [1]Gendreau Consulting LLC, Poway, CA, [2]University of Cincinnati, Cincinnati, OH, [3]Chronic Pain & Fatigue Research Center, University of Michigan, Ann Arbor, MI, [4]Tonix Pharmaceuticals, New York, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Novel composite responder definitions for fibromyalgia (FM) clinical trials have been proposed by the Outcome Measures in Rheumatology (OMERACT) FM subcommittee. These definitions which include key symptom and functional domains relevant to FM patients, were validated using outcome data from 12 previous registration trials of 4 other medications (Arnold L et al, Arth Rheum 64:885, 2012.) TNX-102 SL* is a proprietary sublingual formulation of cyclobenzaprine hydrochloride (2.8 mg) being studied for conditions with sleep disruption, including fibromyalgia and post-traumatic stress disorder (PTSD). "BESTFIT" was a 12-week Phase 2, randomized, double-blind, placebo-controlled trial conducted at 17 US sites, designed to evaluate this medication as a potential treatment for FM. A total of 205 participants were randomized (TNX=103; placebo=102).

Methods: The two recommended OMERACT responder definitions were evaluated: the FM30 Short, which defines a responder as ≥30% reduction in pain, ≥10% improvement in physical function plus a ≥30% improvement in either sleep or fatigue, and the FM30 Long, which defines a responder as ≥30% reduction in pain, ≥10% improvement in physical function plus ≥30% improvement in any two of the following measures: sleep, fatigue, depression, anxiety or cognition. Individual patient level analyses determine if each participant in the study met the response criteria.

Results: The table below compares a standard pain responder analysis (≥30% improvement in pain based on daily diary data), which was the secondary efficacy endpoint in the "BESTFIT" study, to the alternative composite responder

Responder Definition/ Result (pain based on diary)	Physical Function Measure	Additional Symptom Measures	Result (TNX-102 SL vs. placebo; p-value)
30% Pain Responder	None	None	34.0% vs. 20.6%; p=0.033
FM30 Short Ver 1	SF-36 physical function	1[a]	23.3% vs. 11.8%; p=0.038
FM30 Short Ver 2	SF-36 PCS score	1[a]	25.2% vs. 11.8%; p=0.015
FM30 Long Ver 1	SF-36 physical function	2[b]	21.4% vs. 9.8%; p=0.031
FM30 Long Ver 2	SF-36 PCS score	2[b]	23.3% vs. 9.8%; p=0.011

PCS: Physical Component Summary

[a]1: either FIQR sleep or FIQR energy;
[b]2: any 2 out of FIQR sleep, FIQR energy, FIQR depression or FIQR anxiety.

definitions proposed by OMERACT.

Additional improvements in other domains were noted as well. Systemic adverse events reported were similar to placebo. The most common local adverse event was transient tongue or mouth numbness occurring in 44% of the TNX-102 SL patients and in 2% of placebo patients.

Conclusion: Routine bedtime usage of TNX-102 SL improved multiple symptoms of FM. Comparison of response rates determined by either 30% reductions in pain alone, or by the proposed composite definitions, were all statistically significant. Although the apparent response rate for the composite definitions is necessarily less than that seen with the pain response only analysis, the actual statistical separation between treatment groups is enhanced. This analysis using the composite responder criteria developed by OMERACT suggests that the improvements in FM symptoms in this study of TNX-102 SL may not be limited to an analgesic response, since these composite criteria also require improvements in other somatic and functional symptoms.

* TNX-102 SL is an Investigational New Drug and has not been approved for any indication.

Fibromyalgia Impact Is a Potential Mediator for the Associations of Self-Efficacy and Pain Catastrophizing with Physical Functioning in Persons with Fibromyalgia

Sun Yu[1], Lori Lyn Price[2], Jeffrey B. Driban[1], William F. Harvey[1] and Chenchen Wang[1], [1]Rheumatology, Tufts Medical Center, Boston, MA, [2]Biostatistics Research Center, Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

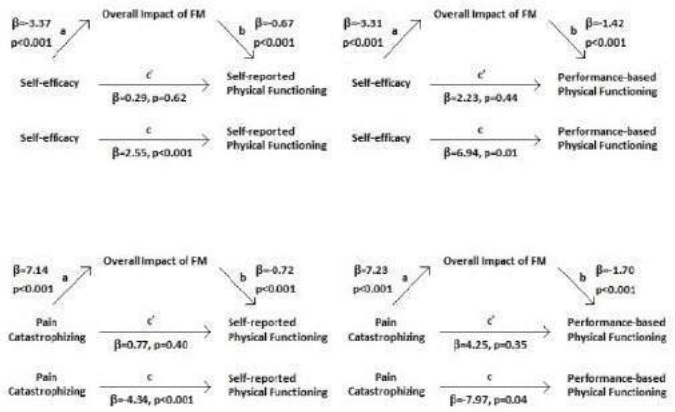
Background/Purpose: Fibromyalgia (FM) is a chronic multidimensional disorder that causes physical and psychological impairment, incurring significant healthcare costs. Self-efficacy and pain catastrophizing have been shown consistently to predict disability in chronic pain populations. However, the extent and the mechanism of their impact on physical functioning in people with FM are yet unclear. The purpose of this study is to examine if self-efficacy and pain catastrophizing are associated with both self-reported and performance-based physical functioning in individuals with FM. We also explore the potential of the overall impact of FM as a mediator.

Methods: We analyzed the baseline data from a randomized controlled trial comparing the effects of Tai Chi and aerobic exercise in individuals meeting both the 1990 and 2010 ACR Criteria for FM. Participants completed the 8-Item Arthritis Self-Efficacy Scale modified for FM (ASES-8, range 0-10), Catastrophizing subscale of the Coping Strategies Questionnaire (CSQ-CAT, range 0-42), 36-Item Short-Form Health Survey Physical Functioning scale (PF-10, range 0-100), and the Revised Fibromyalgia Impact Questionnaire (FIQR, range 0-100), with higher scores indicating higher levels of the respective constructs measured, as well as the 6-Minute Walk Test (6MWT, measured in meters). Pearson correlation and multivariate linear regression analyses were used to test for associations. We also performed mediation analyses (Baron and Kenney with Sobel test and bootstrapping) using the FIQR as a mediator.

Results: We included 224 participants (mean age: 51.8 years [SD=12.0]; mean BMI: 30.7 kg/m^2 [SD=6.7]; 92.9% women; 61.2% white; 22.3% black). ASES-8 and CSQ-CAT were significantly associated with PF-10 (r= 0.25 and -0.30 respectively, both p<0.001) and with 6MWT (r=0.17 and -0.14 respectively, p=0.01 and 0.04 respectively). When adjusted for age, gender, obesity, and education, only the association between CSQ-CAT and 6MWT became insignificant (p=0.06). In addition, mediation analyses revealed that the FIQR attenuated the associations of ASES-8 and CSQ-CAT with PF-10 and 6MWT (see Figure).

Conclusion: Our study shows that, while FM patients' belief in the ability to manage FM-related symptoms and the tendency to catastrophize pain may shape the perception of his or her physical capacity and also influence the level of physical performance, they may not independently predict physical functioning in individuals with FM. The results of the mediation study show that the overall impact of FM, often viewed as a dependent variable, attenuates the associations between the cognitive constructs and physical functioning, suggesting its potential as a mediator. Future longitudinal studies designed to verify the directionality of the relationships are warranted.

Figure. Mediation Analyses*



*Results of the mediation study using the method suggested by Baron and Kenney with Sobel testing and bootstrapping. Path a: independent variable to mediator; Path b: mediator to dependent variable after controlling for independent variable; Path c': indirect path through mediator; and Path c: direct path; Total: c + c'. *Data used were cross-sectional and the directionality is not yet verified.*

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Mirogabalin is a novel, preferentially selective a2d-1 ligand intended for treatment of pain associated with fibromyalgia and neuropathic pain. Mirogabalin efficacy and safety was evaluated in a randomized, double-blind, placebo-controlled and active comparator (pregabalin)-controlled, adaptive proof-of-concept phase 2 study in patients with diabetic peripheral neuropathic pain (DPNP) (*Diabetes Care* 2014;37:3253–61). Mirogabalin administered once or twice daily (5-30 mg/d) showed early and sustained reductions in average daily pain score (ADPS) relative to placebo ($P<0.05$ for 15, 20, and 30 mg/d) after 5 wk of treatment. Pain reduction with pregabalin 300 mg/d was not significantly different from placebo at end of 5 wks' treatment. The most common adverse events (AEs) with mirogabalin were dizziness (9.4%), somnolence (6.1%), and headache (6.1%). Here we report key secondary outcomes of mirogabalin on patient-reported pain and sleep interference.

Methods: Adults (≥18 years) with type 1 or 2 diabetes, HbA_{1c} ≤10% at screening, and DPNP for ≥6 months were eligible. Subjects (N=452) were randomly assigned (2:1:1:1:1:1:1 ratio) to receive placebo, dose-ranging mirogabalin (5, 10, 15, 20, or 30 mg/d), or pregabalin (300 mg/d) for 5 wk. Secondary efficacy end points included modified brief pain inventory (BPI) score, and average daily sleep interference score (ADSIS).

Results: At wk 5, statistically significant reduction in ADSIS was observed in the mirogabalin 15, 20, and 30 mg/d groups, compared with the placebo group (**Fig 1**). Baseline and mean changes from baseline in ADSIS and ADPS values at wk 5 (**Fig 2**) were strongly correlated. Four of the 6 BPI subscales showed significant differences in change from baseline to end point in at least 2 of the mirogabalin groups (15 and 30 mg/d), compared with placebo ($P<0.05$). Overall, a low incidence of treatment-related AEs was reported for mirogabalin.

Conclusion: These results support the efficacy of mirogabalin for improving patient-reported pain and sleep interference in patients with DPNP. Results support a direct impact on pain at the 3 highest tested doses of mirogabalin in this DPNP population. Current data did not support an indirect effect of mirogabalin on pain via an improvement of sleep, in contrast to what has been reported for pregabalin. This may be owing to duration of the current study and variability of results observed at tested doses of pregabalin across the larger and longer duration DPNP pregabalin studies. Investigation is underway in large phase 3 studies to clarify the relationship in pain reduction and sleep improvement. **Figure 1. Mean change in ADSIS from baseline to end of treatment.**

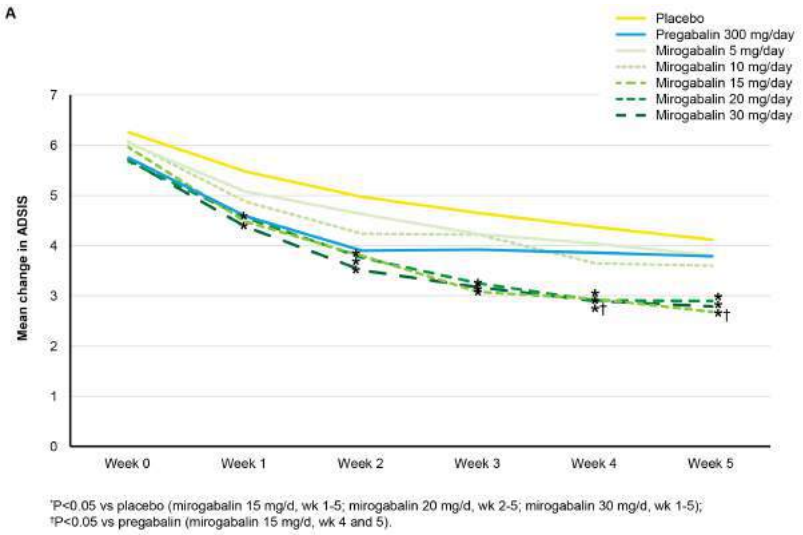

Figure 2. Correlation plot of weekly ADPS change from baseline and ADSIS change from baseline at wk 5 (LOCF).

Tai Chi Significantly Modulates Resting State Functional Connectivity of the Cognitive Control Network in Fibromyalgia

Jian Kong[1], Kristen Jorgenson[2], zengjian wang[2], Emily Wolcott[3], William F. Harvey[4] and **Chenchen Wang**[4], [1]Massachusetts General Hospital, Boston, MA, [2]MGH, Boston, MA, [3]Tufts Medical Center, Boston, MA, [4]Rheumatology, Tufts Medical Center, Boston, MA

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is a common and complex musculoskeletal pain syndrome with unsatisfactory treatment options. Studies suggest that Tai Chi mind-body exercise may be a promising treatment for Fibromyalgia. However, the underlying mechanism of Tai Chi remains unclear. Previous studies suggest that Tai Chi may modulate individuals' cognitive function which interacts reciprocally with pain. Thus, in this pilot brain imaging study, we first compared the resting-state functional connectivity (rsFC) of the cognitive control network (CCN) of FM patients to that of the matched healthy controls, and further examined how Tai Chi practice can modulate the CCN rsFC in relation to clinical outcomes.

Methods: We conducted a 3-month, non-randomized comparison trial of Tai Chi for participants with FM (ACR 1990 and 2010 criteria) vs. healthy controls. The 60-minute group sessions occurred twice-weekly. Each subject participated in two identical fMRI scanning sessions at baseline (Scan 1) and 3 months (Scan 2) after the end of Tai Chi intervention. Using a 3T Siemens MRI system, 8-minute resting state fMRI data were collected. Healthy matched controls were scanned only once. We also administered the Revised Fibromyalgia Impact Questionnaire (FIQR) before and after each fMRI scan. Seed-based rsFC was analyzed with CONN (https://www.nitrc.org/projects/conn/). Bilateral dorsolateral prefrontal cortex (DLPFC) was applied as the seed to explore the rsFC of cognitive control network. A threshold of voxelwise $p< 0.005$ and $p< 0.05$ Family-Wise Error (FEW) correction was applied for rsFC analysis.

Results: Twenty-one participants with FM and 20 age, gender, and BMI-matched healthy controls completed the study. One individual with FM and 1 healthy control were excluded from the rsFC analysis due to excessive head movement during scan. After Tai Chi interventions, there was a significant decrease in the total FIQR score (mean ± SD, pre: 45.7 ± 18.3, post: 36.4 ± 21, $p < 0.001$) and the three FIQR domains: Function (pre: 12.2 ± 6.1, post: 8.5 ± 6.4, $p< 0.001$), Overall Impact (pre: 8.9 ± 6.2, post: 7.0±5.7 $p<0.05$), and Symptom (pre: 25.4 ± 8.3, post: 20.9 ± 11.7, $p< 0.02$). Analysis of CCN rsFC showed that compared to matched healthy controls, FM patients were found to have significantly greater rsFC between DLPFC and bilateral rostral anterior cingulate cortex (rACC) / medial prefrontal cortex (MPFC), and the left precentral gyrus. In addition, we found 1) significant increase in the DLPFC rsFC at left rACC / MPFC after Tai Chi practice, and 2) a significant positive association ($p = 0.026$) between the baseline cluster Fisher z values at rACC/MPFC and corresponding cognitive performance, measured by the FIQR Overall Impact subscores after controlling for age at baseline.

Conclusion: Our results suggest that Tai Chi practice can significantly increase rsFC between the CCN and rACC / MPFC over 12 weeks in patients with FM. Our study further implies that Tai Chi may achieve clinical improvement by strengthening the cognitive control / adaption / coping process in individuals with FM. Elucidation of the mechanism will open a new window for FM management.

Pregabalin Dose-Response for Sleep Quality and Pain Response in Fibromyalgia: A Post-Hoc Analysis of Three Randomized Trials

Andrew Clair[1], Ed Whalen[1], Neal Thomas[1] and **Lynne Pauer**[2], [1]Pfizer, New York, NY, [2]Pfizer, Groton, CT

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

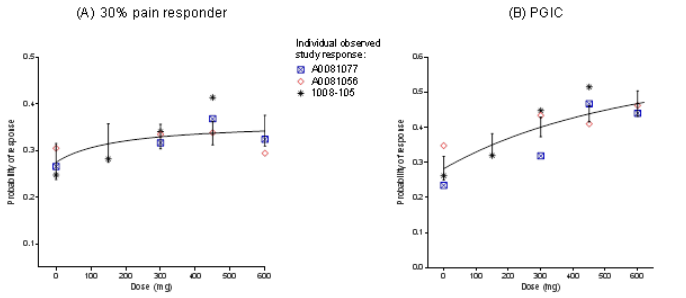
Background/Purpose: Pregabalin is often administered for treatment of fibromyalgia (FM) at daily doses lower than approved by the US Food and Drug Administration (starting dose 150 mg; recommended dose 300–450 mg). The objective of this post-hoc analysis was to characterize pregabalin efficacy across a range of doses and set expectations regarding the incidence of adverse events (AEs) through the course of FM treatment.

Methods: A hyperbolic E_{max} dose-response model using patient data pooled from 3 FM placebo-controlled trials examined the dose-response of pregabalin for pain (≥30% pain response), patient global impression of change (PGIC) and sleep quality. All patients had a diagnosis of FM based on the 1990 ACR criteria. After starting treatment, new incidences of AEs by study week were used to assess safety. Trials are identified by Pfizer study number (ClinicalTrials.gov identifier): 1008-105, A0081056 (NCT00645398), A0081077 (NCT00230776).

Results: The likelihood of FM patients achieving ≥30% pain response incrementally increased from 27.5% (90% CI, 23.8–31.5%) with placebo to 31.5% (27.5–35.8%) at 150 mg/d, 33.0% (30.4–35.7%) at 300 mg/d, 33.7% (31.3–36.3%) at 450 mg/d and 34.2% (31.0–37.6%) at 600 mg/d. The likelihood of improvements in PGIC increased in a dose-dependent manner with higher pregabalin doses (Fig. 1). Incremental improvements in sleep quality also occurred with increasing doses (Fig. 2). It was not possible to estimate the value of E_{max} and ED_{50} parameters for sleep quality over the current dose range and therefore the upper plateau of the dose-response curve was not attained for this endpoint. The resulting curve appears linear, a finding not expected over a broader dose range or using data from different trials. Dizziness and somnolence were commonly reported AEs. New incidences of dizziness and somnolence were highest after 1 week of treatment and were considerably fewer subsequently, decreasing week by week for the same dose (Fig. 3).

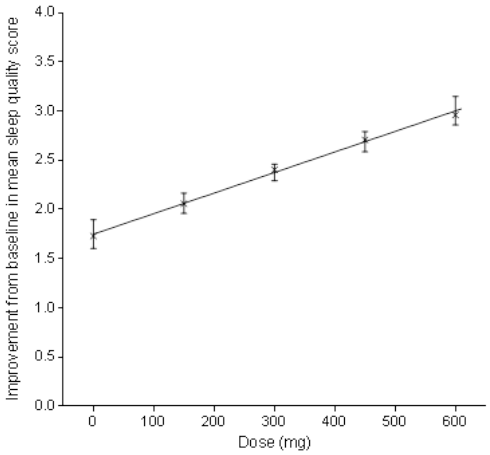
Conclusion: These data demonstrate the dose-response of pregabalin for pain, PGIC, and sleep, and highlight the incremental benefit of achieving the maximum recommended doses of 300–450 mg/d for treatment of FM. Common AEs are generally seen within 1 week of starting treatment, with few subsequent new reports for the same dose. This study was sponsored by Pfizer.

Fig. 1 Dose response analysis of effects of pregabalin on (A) pain relief and (B) PGIC at study endpoint



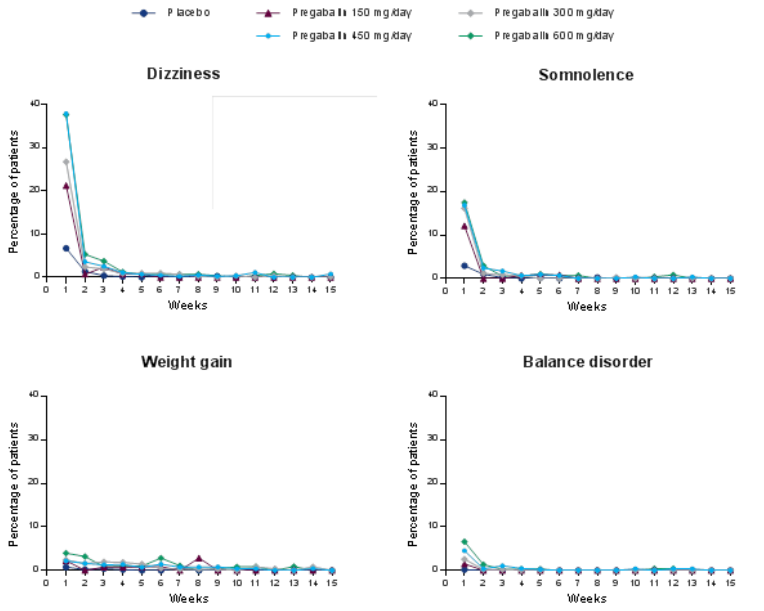
The data points are the individual observed study response, the curve is the hyperbolic E_{max} model and the bars are ± 90% confidence intervals for the true response proportion.

Fig. 2 Dose response analysis of effects of pregabalin on sleep quality at Week 8



Data shown are the combined mean observed study response ± 90% confidence intervals for studies A0081077, A0081056 and 1008-105 at Week 8.
Sleep quality scores range from 0 = 'best possible sleep' to 10 = 'worst possible sleep'.

Fig. 3 Incidence of most common adverse events in FM patients, by study week



Treatment-emergent adverse events (all-causality) reported in ≥5% of pregabalin-treated patients and, twice the rate of the placebo group, and with adverse event related discontinuation ≥1%.

Session Time: 9:00AM-11:00AM

Efficacy of Cannabis flos in patients with fibromyalgia: a monocentric observational study

Background/Purpose: Fibromyalgia (FM) is a syndrome characterized by chronic widespread pain, fatigue, sleep and affective disturbances. Treatment is based on the symptomatic relief of symptoms but only modest results are achieved. There are few evidences on the effectiveness of cannabinoids in the improvement of FM symptoms. A cannabinoid (Cannabis flos 19%), containing tetrahydrocannabinolic acid 19% and cannabidiolic acid <1% used as orally decoction, is available in Italy for treating chronic pain. The aim of the this study was to evaluate the efficacy of Cannabis flos 19% on pain, fatigue, sleep disturbances, anxiety and depression in FM patients.

Methods: Fifteen patients affected by FM according to the ACR 2010 criteria and treated with Cannabis flos 19% (30 mg twice a day for the first month, 60 mg twice a day for the second month), have been evaluated at baseline and after 2 months of treatment with the following questionnaires: the Fibromyalgia Impact Questionnaire revised (FIQR), the Fibromyalgia Activity Score (FAS), the Functional Assessment of Chronic Illness Therapy (FACIT), the Pittsburgh Sleep Quality Index (PSQI), the Zung Self-Rating Anxiety Scale (ZS-RA) and the Zung Self-Rating Depression Scale (ZS-RD).

Results: Table 1 shows the demographic and clinical characteristics of the patients involved in study. 11/15 patients completed the 2-months follow up. After 2 months of treatment a statistical significant improvement in the terms of medians values of VAS pain (8.2±1 *vs* 6.2±2.4, p= 0,0273), FAS (7.8±1.7 *vs* 6.2±2.1, p= 0,0494), FACIT (13.5±7.4 *vs* 22.9±10.5, p= 0,0042), ZR-SA (66.2±14 *vs* 57.6±13.3, p= 0,0172) and ZS-RD (58±10.3 *vs* 48.7±11.5, p= 0,0491) has been found; while the median FIQ-R scores (74.4±17.2 *vs* 60.3±24.3, p= 0,0615) and sleep disturbances scores (PSQI, 11±2.8 *vs* 10.5±3.8, p= 0,5435) didn't change. Two patients (13%) stopped the treatment for inefficacy. Furthermore, although adverse events range from mild to moderate two patient stopped the treatment: one for the apparence of confusion and sweating and one for the mood deflection.

Conclusion: This study showed that Cannabis flos 19% is effective in improving pain, fatigue, anxiety and depression in FM patients. Further studies are suggested in order to confirm this preliminary data on efficacy and safety of this therapy for treating FM patients. **Table 1. Patients with Fibromyalgia in General Have Higher Self-Report Questionnaire Scores Than Patients with Rheumatoid Arthritis: Implications for Clinical Trials and Clinical Research

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster I: Basic Science Focus

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) who are included in clinical trials generally are selected for measures indicating high disease activity, such as more than 6 swollen and/or tender joints and/or erythrocyte sedimentation rate (ESR) greater than 28. These inclusion criteria enhance the possibility of documenting responses to therapy. Patient questionnaire scores are correlated significantly with joint counts and to a lesser (but nonetheless significant) extent with ESR and other laboratory acute phase reactants. However, observations in clinical care suggest that scores on a multidimensional health assessment questionnaire (MDHAQ) generally are higher in patients who have distress, such as fibromyalgia or depression etc., than in patients with RA, unless the RA patients also have secondary distress. We therefore analyzed formally scores on an MDHAQ in patients with FM vs RA seen in routine care.

Methods: All patients with all diagnoses seen at one academic rheumatology center complete a multidimensional health assessment questionnaire (MDHAQ) at all visits in the waiting area, before seeing the rheumatologist in routine care. The MDHAQ includes 0-10 scores for physical function (FN), 0-10 pain (PN) visual analog scale (VAS), 0-10 patient global estimate (PATGL) VAS, compiled into a 0-30 RAPID3, as well as a 0-10 fatigue VAS, 0-48 RADAI self-report joint count, 0-60 symptom checklist, and demographic data. Mean levels of measures were compared in patients with RA or FM, analyzed using t tests.

Results: Patients with FM had higher scores for all MDHAQ scales studied, including FN, pain, PATGL, fatigue, RADAI, and symptom checklist (Table) ($p<0.001$). For example, RAPID3 scores were 11.4 for RA vs 17.8 for FM ($p<0.001$) (Table).

Conclusion: Evidence that patients who have FM have higher MDHAQ scores may initially appear to compromise the possible value of self-report questionnaire data in RA. However, the data may be informative in clinical research and clincial care in at least 2 ways: 1. It may be desirable to exclude patients from clinical trials who might have self-report scores that are extremely high, e.g., pain VAS >8/10, symptom checklist >24/60 of 60, as these patients are unlikely to respond to therapy, whether they have primary or secondary FM while meeting criteria for another rheumatic disease. 2. In routine care, high MDHAQ self-report scores may provide clues to identify patients who have primary or secondary FM, which is seen in 15-30% of patients with RA, SLE, or other rheumatic diagnoses. High self-report scores in FM may prove informative in rheumatology toward better interpretation of clinical researchand improved patient care.

Mean levels of MDHAQ measures in RA and FM

	RA	FM
Function (0-10)	2.6	3.6
Pain (0-10)	4.8	7.4
Patient Global Estimate (0-10)	4.3	6.9
RAPID3 (0-30)	11.4	17.8
RADAI self-report joint count (0-48)	10.6	
Fatigue (0-10)	3.9	6.9
Symptom Checklist (0-60)	7.6	17.5
$p < 0.001$ for all

Identification of Endogenous Autoantigens Bound to Anti-Citrullinated Peptide Antibodies in Rheumatoid Arthritis: A Key Role for Citrulline

Residues in Histone 4

Xiaobo Meng[1], Peyman Ezzati[1], Irene Smolik[2], Carol Hitchon[3] and Hani El-Gabalawy[4], [1]UNIVERSITY OF MANITOBA, WINNIPEG, MB, Canada, [2]Arthritis Center, University of Manitoba, Winnipeg, MB, Canada, [3]University of Manitoba, Winnipeg, MB, Canada, [4]University of Manitoba Arthritis Center, Winnipeg, MB, Canada

Session Title: Genetics, Genomics and Proteomics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-Citrullinated Peptides Antibodies (ACPA) aid in rheumatoid arthritis (RA) diagnosis. The nature of autoantigens specifically bound to ACPA immune complex *in vivo*remains unclear. We therefore sought to identify citrullinated proteins bound to ACPA immune complexes in RA synovial fluids (SFs) and to delineate their immunodominant epitopes.

Methods: ACPA were isolated from RA and non-RA SFs by immunoaffinity using immobilized cyclic citrullinated peptides-3 (CCP3). The composition of the antigen-antibody immune complexes was determined using mass spectrometry. Synthetic peptides containing citrulline residues derived from the target protein were used in ELISA assays to determine the immune reactions of sera from RA patients, controls, and a cohort of first degree relatives of RA patients.

Results: Histone family members were the most frequent autoantigens bound to anti-CCP3 antibodies in RA SFs. H4, H3, H2B, and H2A were identified in 90%, 68%, 53%, and 42% tested samples respectively. A histone 4 peptide containing citrulline at position R39 (Cit39) was a specific ACPA autoantigen to all anti-CCP3+ RA SFs (n=34). Another citrulline at R40 (Cit40) proved to be minor antigenic. Anti-H4 Cit39-40 antibodies were found in sera from 93% (158/170) of anti-CCP3+ RA patients, 77% (20/26) anti-CCP3+ individuals without arthritis, and 2.5% (2/80) controls.

Conclusion: Histones are prominent endogenous autoantigens binding to anti-CCP3 antibodies from RA patients. Anti-citrullinated histone 4 accounts an important part of all ACPA detected by anti-CCP3 standard.

Session Title: Genetics, Genomics and Proteomics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are skeletal muscle disorders characterized by proximal muscle weakness and inflammation. Recent studies have suggested that endurance exercise improves disease activity in PM and DM by suppressing inflammation and promoting muscle growth through activation of an aerobic muscle phenotype. The molecular mechanisms underlying disease improvement are not fully understood. We hypothesized that endurance exercise induces alterations in skeletal muscle microRNAs that control genes and proteins relevant to disease pathogenesis.

Methods: Patients, diagnosed as PM or DM according to the Bohan and Peter classification, were randomized into a 12-week endurance exercise group that consisted of cycling for 1 hour/3 times a week or a non-exercised control group. Muscle biopsies from the vastus lateralis were collected before and after the 12-week training program. MicroRNA expression profiling was determined using the Affymetrix platform, mRNA using the Illumina platform and proteomics using SuperSILAC mass spectrometry. Post intervention values were normalized to pre-intervention values and a t-test for unequal variance comparing exercised vs. control patients was used to determine significant changes ($p<0.05$). Ingenuity Pathway Analysis (IPA) MicroRNA Target Filter was used to identify gene targets. Gene expression profiling and proteomics were used to verify microRNA targets that were altered by exercise in the patients' skeletal muscle. IPA Core Analysis was used to determine the function of significantly changed transcripts and proteins.

Results: Endurance exercise differentially altered 188 microRNAs. Approximately one fourth of these microRNAs are predicted to target over 12,000 genes. We have found that endurance exercise alters microRNAs that affect various processes involved in the pathogenesis of myositis. MicroRNA-target transcripts altered after endurance exercise control genes that affect vasculature, inflammatory cells and skeletal muscle cells. We also found that anti-inflammatory, anti-fibrotic, and muscle regenerative and metabolic processes are affected favorably. MicroRNA-targeted proteomic analysis of these samples further confirmed that these pathways are altered at the protein level.

Conclusion: To our knowledge, this is the first systems biology study investigating microRNA, and its regulation on mRNA and protein, before and after exercise in myositis patients. Identified microRNAs can serve as biomarkers to assess disease progression, as well as monitor responses to therapy.

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Growing numbers of studies show increased expression in Osteoarthritis (OA) of inflammatory cytokines, such as IL-1β and TNFα, in joint tissues and peripheral blood mononuclear (PBM) cells. The IL1 receptor antagonist (IL1RN) gene cluster region has been associated with susceptibility to knee OA, thereby further implicating inflammation in OA pathogenesis. In these studies, we examined the association of IL-1RN haplotype with the radiographic severity of symptomatic knee OA (SKOA).

Methods: Genomic DNA from SKOA patients from three cohorts (NYU I, NYU-II and OAI – clinical characteristics are described in Table 1) in this prospective analysis were used to genotype three single nucleotide polymorphisms (SNPs) [rs419598, rs315952 & rs9005) based on our prior publications. Genotyping was accomplished by PCR using validated SNP primers and probes (Applied Biosystems) along with detection using allelic discrimination computation. Genotypes were scored blinded to all patients' data. Statistical analyses for associations of genotype with OA radiographic severity used Chi square and Fisher's exact test, with linear regression, adjusting for age, gender and BMI. Non-fasting Heparin plasma IL-1Ra levels were determined using R&D system ELISA kit.

Results: Carriage of two copies of a haplotype consisting of IL1RN rs419598, IL1RN rs315952 and IL1RN rs9005 (TTG-2), had a population frequency of 18%, and was associated with a significantly increased risk of more severe radiographic SKOA (KL1-2 vs. KL3/4; OR > 3.07; 95% CI 1.67 -5.68; p=0.000), compared to SKOA patients with zero copies of TTG (TTG-0) in all three cohorts (Table 1). Furthermore, narrower baseline radiographic medial joint space width (mJSW) was similarly associated with TTG-2 haplotype (Table 2). TTG-2 patients exhibited decreased JSW compared to TTG-0 patients of comparable age (50-80 years), consistent with earlier onset of disease. Biologically, TTG-2 patients in two of the cohorts had reduced plasma concentrations of the "protective" IL1RN gene product, IL-1Ra, (297 to 338 pg/ml; p=0.14) relative to TTG-0 OA patients.

Conclusion: IL-1RN haplotype TTG (rs9005, rs419598 and rs315952) predicted high risk for greater severity of radiographic knee OA. Carriers of two copies of the TTG SNP also exhibited lower plasma IL-1Ra concentrations. These data are consistent with the hypothesis that a relative deficiency of IL-Ra typified by TTG-2 patients results in enhanced IL-1β action in joint tissues and more severe OA. These genetic markers may also be useful as tools for enriching OA clinical trials for disease progressors.

Table 1: Baseline Clinical Characteristics and Association of IL-1RN Haplotype (TTG) With Radiographic Severity In Symptomatic Knee OA Patients

Detecting Novel Candidate Risk Genes in Rheumatoid Arthritis with Gene-Based Association Testing

Aleksander Lenert[1] and David Fardo[2], [1]Internal Medicine, Div. of Rheumatology, University of Kentucky, Lexington, KY, [2]Biostatistics, College of Public Health, University of Kentucky, Lexington, KY
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Genetics, Genomics and Proteomics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is driven by immune-system dysfunction with contribution from genetic risk factors. Emerging data from genomewide association studies (GWAS) of single nucleotide polymorphisms (SNPs) has revealed 100 risk SNPs in RA outside the HLA region. Beyond GWAS, novel approaches for interpretation of big data are needed to unravel the complex genetics of RA. Our aim is to identify novel risk genes to improve the power of GWAS. We performed a gene-based association analysis using extended Simes procedure (GATES) in RA.

Methods: Our dataset consisted of 14,361 RA cases and 43,923 controls from GWAS meta-analysis in Europeans, from publicly available summary statistics[1]. All RA cases fulfilled the 1987 ACR criteria or were diagnosed by a rheumatologist. A powerful Knowledge-based mining system for Genome-wide Genetic studies (KGG) was used to run GATES for gene-based association testing with 8,694,488 SNPs (excluding extended MHC, chromosome 6, 25-33 Mb)[2]. Genes were defined as ± 5kb. Genomic control was calculated by median of Chi-square statistic. We accounted for linkage disequilibrium (LD) between SNPs from 1000 Genomes Project for Europeans. Bonferroni correction was used for multiple testing. LocusZoom was used for visual interpretation of risk loci and genes.

Results: Our genome analysis build used ~8.7 million SNPs assigned to 25,539 genes; 51% of SNPs were located inside genes. GATES revealed a total of 115 genes significantly associated with RA compared with controls ($p<1.96E-6$, Bonferroni corrected). The majority of GATES top gene hits were located on chromosomes 6, 1, 2 and 19 (22.6%, 20%,

7.8% and 7.8% respectively). From these 115 genes, we identified 43 RA risk loci: 23 risk loci contained a single top risk gene, while 20 risk loci contained two or more risk genes by GATES. Compared to the meta-GWAS results by Okada et al.[1], our GATES top genes were replicated for 26 loci; however 17 risk loci had a different top gene by GATES. Our analysis revealed 1 potentially new RA risk locus, located on chromosome 11 (start position 118528941 bp) containing TREH-PHLDB1-MIR6716. Additionally, GATES identified 6 new top gene hits for each of the following 6 risk loci: RPP14 (for DNASE1L3-ABHD6-PXK), PXT1 (for ETV1), MIR5708 (for TPD52), DDX6 (for CXCR5), SUOX (for CDK2), and PCAT29 (for LOC145837). 3 of these loci (ETV1, TPD52 & CDK2) are novel RA risk loci identified by Okada et al.[1] and require further analysis to determine top risk genes in the region given our GATES results.

Conclusion: Gene-based association analysis with GATES of big data from meta-analysis of GWAS confirmed prior risk loci and identified potential novel candidate gene hits in RA. Our results will be used subsequently to identify gene-gene interactions and perform genomewide pathway analysis to improve our understanding of the complex genetics in RA.

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Protein-protein interactions are essential for the control of cellular functions and critical for regulation of the immune system. One example is the binding of Fc regions of Immunoglobulin G to their receptors (Fcγ Receptors). High structural homology between FcγRIIIa and FcγRIIIb has led to the lack of specific agents against this important therapeutic target. We aimed to develop a novel drug development pipeline using artificial binding proteins called Adhirons both for the identification of novel therapeutics and to guide drug discovery through the identification of novel hot spots/ druggable surfaces on the receptor.

Methods: We transiently transfected vectors encoding FcγRIIIa and FcγRIIa ectodomains into HEK293T cells and the resulting secreted proteins were purified. We additionally cloned sequences encoding full-length FcγRIIIa, FcγRIIIb and FcγRIIa into expression vectors and created stably transfected HEK293 cells expressing each receptor. The FcγRIIIa ectodomain was used as a target for screening an Adhiron library using ‘phage display. High affinity binders were used in Surface Plasmon Resonance (SPR), cellular assays (IgG binding assays and immune complex-induced TNF release and phagocytosis in THP-1-derived macrophage cells) and X-ray crystallography.

Results: Here we report the identification of FcγRIIIa-specific Adhirons. SPR experiments confirmed a pool of Adhirons that bound FcγRIIIa, but not FcγRIIa. Selective blockade of IgG binding to FcγRIIIa, but not FcγRIIa or FcγRIIIb, was detected for 3 Adhirons using flow cytometry assays in HEK293 cells that ectopically expressed individual FcγRs. We also demonstrated blockade of immune-complex induced effector functions downstream of FcγRIIIa signalling in THP-1-derived macrophage cells. Co-crystal structures revealed one Adhiron bound directly to the Fc binding site whereas two others acted as allosteric inhibitors. The structural basis for the specificity of the competitive inhibitor has been defined.

Conclusion: The results suggest that Adhirons can be developed to inhibit protein-protein interactions that were previously considered to be "undruggable". Adhirons that inhibit the activatory FcγRIIIa (expressed on macrophages) but not the highly homologous FcγRIIIb (expressed on neutrophils), have been identified. This level of specificity has not been achieved using more conventional monoclonal antibody-based technology. Furthermore, the allosteric binders highlight a novel FcγRIIIa 'hot spot', which could be used in *in silico*-based Medicinal Chemistry design tools.

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biological agents (boDMARDs) have modified the therapeutic management of patients with rheumatoid arthritis (RA). However, boDMARDs can induce sustained remission in only 30% of RA patients. Identify predictive markers of response to boDMARDs would be a real progress in clinical practice. Wang et al. previously explored response to tocilizumab (TCZ) by genome-wide association in 1,683 RA patients. They found out eight loci not recognized to be linked with the interleukin (IL)-6 pathway. More recently, Enevold et al. have shown a haplotype of 3 single-nucleotide polymorphisms (SNPs) on *IL6R*gene associated with clinical response to TCZ (AAC haplotype for rs12083537, rs2228145, and rs4329505, respectively) in a retrospective cohort of 79 RA Caucasian patients. Our study aimed to test the association of these 3 SNPs with TCZ response in two populations of French RA patients.

Methods: *Patients:* Two independent RA cohort were used for this study: 1) TOCI, a multicentric retrospective French

study including 160 RA patients treated with TCZ, 2) ROC, a multicentric prospective French randomized controlled trial comparing the efficacy of a second TNF blocker to another boDMARD (abatacept, TCZ or rituximab) in RA patients who failed to a first TNF blocker. Among the 292 patients included in ROC, 62 patients received TCZ after randomization in the non-TNF blocker arm. Patients were evaluated at 0 and 3 months after initiation of TCZ. Efficacy of TCZ was assessed using the European League Against Rheumatism (EULAR) response criteria. *Genotyping:*3 SNPs on IL6R were genotyped using KasPar method on both samples (LGC-genomics, UK). *Statistics:*the proportion of patients with EULAR response (moderate or good) was compared across the genotypes of the 3 SNPs on TOCI and ROC studies. A meta-analysis was performed, by allele analysis, to confirm the association on the 2 samples with Mantel-Haenszel method.

Results: Fourty height patients in the TOCI group (78.7 %) and 125 patients in the ROC group (79.6 %) reached good or moderate EULAR responses. The SNP rs2228145 did not respect the Hardy Weinberg equilibrium. The GG genotype of rs12083537 was significantly associated with a lower response rate in both cohort [TOCI: 89.2% of responders for AA genotype vs 65.2 % for AG or GG genotype (p=0.044), ROC patients: 87.2% of responders for AA genotype vs 72.2 % for AG or GG genotype, p=0.018]. Combining these two studies, we confirmed the lower response rate with G allele carriage (OR (95% CI) = 0.35 (0.16-0.61), p=0.001). No association was found with the SNP rs4329505 (alone or in a haplotype with rs12083537).

Conclusion: In this study, the rs12083537 of IL6R was associated with response to TCZ in two different independent RA cohorts. Although insufficient to be used in the daily practice, these results strengthen literature data in the search of predictive markers to the response to TCZ.

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Killer immunoglobulin-like receptors (KIRs) are expressed predominantly on the surface of natural killer (NK) cells and some T-cells and are important in regulating the inflammatory phenotype of these cell types. The 17 known KIR genes are arranged in variable content haplotypes that differ substantially in composition across the human population. Specific HLA subtypes act as KIR ligands, and the repertoire of HLA and KIR alleles carried has been shown to alter risk for autoimmune or infectious diseases by shifting activation thresholds of cytotoxic NK cells. We aimed to interrogate patterns in, and statistical interactions between, *KIR* genes and *HLA* alleles in a large population of individuals with ankylosing spondylitis (AS), in which *HLA-B*27* in particular exerts a substantial genetic contribution to disease.

Methods: Gene dosages across *KIR* loci were imputed from Immunochip genotype data for 10464 AS cases and 15239

control *HLA*-typed individuals using the statistical package KIR*IMP. Differences in *KIR* gene content and haplotype composition were assessed, with additional consideration of *HLA* type used to investigate gene-gene interactions and co-occurrence patterns in cases and controls.

Results: We identified a statistical interaction between the HLA-Bw4 recognising *KIR* genes *KIR3DL1* and *KIR3DS1* and *HLA-B*27* (a Bw4 type allele). Presence of the NK cell activating receptor *KIR3DS1* increased risk of AS in *HLA-B*27* positive individuals, but was protective in *HLA-B*27* negative individuals *(P interaction = 0.007)*. In contrast, inhibitory receptor *KIR3DL1* exhibited the opposite pattern of association, with presence of the gene being protective in *HLA-B27* positive individuals but risk predisposing in *HLA-B*27* negative individuals *(P interaction = 0.002)*. We observed a suggestive disease association with KIR locus variant rs775859 *($P=2x10^{-5}$)* and a significant interaction between the variant used to tag the presence of the *KIR2DL5* gene and *HLA-B*27 ($P=3x10^{-4}$)*, with carriage of both *KIR2DL5* and *HLA-B27* increasing disease risk. Intriguingly, a significantly lower frequency of *KIR2DL5* was also seen in *HLA-B*27* positive controls relative to *HLA-B27-ve* controls *(P=0.001, OR=0.81)*, indicative of evolutionary pressure against this co-occurrence. In *HLA-B*27* negative individuals there was a strong interaction between the *KIR2DL3* gene and *HLA-C*12* (*P interaction* = $7.1x10^{-5}$).

Conclusion: Interactions between HLA-B*27 and specific KIR receptors may contribute to AS by altering the inflammatory activity of NK cells.

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: One of the causes of insufficient response to biological drugs is the production of anti-drug antibodies (ADA) (1). These antibodies can decrease the effectiveness of treatment by altering bioavailability or by neutralizing the drug. In addition, they may contribute to hypersensitivity reactions. Some ADA are directed against IgG allotypes, which are protein polymorphisms able to induce an immune response in incompatible subjects. Infliximab (INX) and adalimumab (ADM) have the G1m17,1 allotypes, while about 50% of the Europeans are homozygous for the incompatible G1m3,n allotypes. Therefore, the allotypes could contribute to ADA and, in this way, explain the recently described loss of efficiency of INX in allotype-incompatible RA patients (2). This motivated our analysis of the usefulness of IgG1 allotypes as biomarker of the development of ADA against INX and ADM.

Methods: The presence of ADA was determined in 252 consecutive patients with inflammatory arthritis in the Hospital La Paz (116 with rheumatoid arthritis (RA), 74 with ankylosing spondylitis (AS), 26 with psoriatic arthritis, 17 with non-radiographic spondylitis, 11 with spondylitis and inflammatory bowel disease, 3 with uveitis and 5 with other arthropathies). Patients were assessed during INX treatment (151), or with ADM (82), or sequentially during treatment with INX and ADM (19). ADA were determined by two-site bridging ELISA as described (1). Allotypes of IgG1 were determined by genotyping 2 SNPs, rs1071803 (for allotype G1m17 / G1m3) and rs11621259 (for allotype G1m1 / null)

with the SNaPshot Multiplex kit (Applied Biosystems) as reported (2).

Results: Patients with compatible allotypes (carriers of G1m17,1) showed a larger frequency of ADA (33% *vs.* 20%, p = 0.02) and a trend toward higher titers of these antibodies (18.0 x10^3 *vs.* 8.3 x10^3 AU, ns) than patients with incompatible allotypes (homozygous for G1m3,n). This association was clearer in patients treated with INX (41% *vs.* 25%, p = 0.03) than in those treated with ADM (18% *vs.* 12%, ns). ADA were more frequent in patients treated with INX than in those treated with ADM, as already known. Multivariate analysis showed that the frequency of ADA was increased in patients with RA compared to other diseases (OR = 7.6, p <0.0001), and decreased in older patients (OR = 0.65 per 10 years, p < 0.001). Other factors, such as sex, having AS against other diseases, and treatment with methotrexate or corticosteroids, were not associated with ADA.

Conclusion: Patients with compatible allotypes showed more frequently ADA than patients with incompatible allotypes, showing for the first time this association in patients treated with INX and reinforcing the previously reported association for ADM (3). These results suggest a genetic factor in linkage with the allotype, but different from it, that will predispose to ADA. References: 1. Pascual-Salcedo D, et al. Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite the revolutionary impact of TNF inhibitor (TNFi) therapy in rheumatoid arthritis (RA), up to 40% of patients fail to respond adequately. Whilst non-responder (NR) patients can be switched to alternative therapies at 3 months, many experience a delay in switching as some will subsequently respond to treatment by 6 months, which may be detrimental to patient outcomes. Ideally, blood-based biomarkers would be available to objectively predict and monitor response to TNFi but current measures, such as CRP levels, do not correlate very well with objective measures of synovitis. The aim of my work therefore, was to identify an expression signature to predict or monitor treatment response to adalimumab in a large sample cohort of patients about to start treatment.

Methods: 50 extreme EULAR good-responders (GR) and 20 extreme NR to adalimumab were selected from the Biologics in RA Genetics and Genomics Study Syndicate (BRAGGSS) cohort. Total RNA was extracted from whole blood using the MagMAX™ RNA isolation kit before (baseline) and following 3 months of therapy. RNA was amplified and converted into biotinylated sense-strand DNA using the Affymetrix WT PLUS kit and hybridized onto Affymetrix GeneChip® human transcriptome arrays. Quality control and differential expression analysis (both individual transcripts and splice variants) were assessed using the Affymetrix expression and transcriptome analysis console™ and appropriate Bioconductor packages. Weighted gene co-expression network analysis (WGCNA) was performed to identify co-regulated genes correlated with response. WGCNA alleviates the multiple testing issue inherent in microarray data analysis and could hold greater power for detecting clinically applicable biomarkers.

Results: In GR, there were 11 gene co-expression modules, which significantly changed over 3 months of treatment. The most significant module (p= 1e-05) was highly enriched for genes involved in macrophage function, specifically osteoclast differentiation, chemokine signaling and leukocyte transendothelial migration. Transcript significance for treatment time-point and module membership were highly correlated, suggesting genes which change over time are the most important genes within the module. The module was also highly correlated with individual DAS components: tender joint count, swollen joint count, patient global health and CRP. This immune based signature of response is consistent with findings at the individual transcript and splice-level, which showed significant changes in HLA, T-cell signalling and MMP genes implicated in RA pathogenesis. Specifically, upregulation of immune genes at 3 months could reflect migration of immune cells from the inflamed joint into the peripheral blood in a positive response to therapy. No significant changes were observed over time in NR.

Conclusion: Identification of an immune blood-based signature of response early in the treatment time-course could aid timely therapeutic switching in NR. It could also offer a superior measure of ultrasound-determined synovitis than CRP alone. Subsequent work will include replication in an independent cohort and integration of genotype and serum microRNA data.

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The reasons for the ethnic disparities in rheumatologic and autoimmune diseases (ADs) are largely unknown. We posit that population-specific selection influencing the allele frequencies at some loci contribute to ethnic

disparities. Relative to other African-Americans (AA), the Gullah population of coastal South Carolina and Georgia has lower European admixture and higher ancestral homogeneity from the Sierra Leone (SL) area in West Africa. The shorter genetic distance between the Gullah and SL suggests that population genetic signals, such as regions under recent selection, may be more easily detected in the Gullah than in other AA populations. We sought to leverage the relative closeness between the Gullah and SL to identify autoimmune risk alleles with evidence of population differentiation that may result from geographically restricted, subtle selective pressure.

Methods: We computed the fixation index (F_{ST}) between populations, a measure of population differentiation that measures the degree of genetic differentiation at a locus. Using genome-wide genotype data on 277 healthy Gullah, 400 SL, and 203 YRI from the HapMap3 Project, we computed the Weir and Cockerham's (1984) F_{ST} (in VCFTOOLS) and the Hudson estimator for F_{ST} (in EIGENSOFT) between Gullah and SL, and Gullah and YRI. A total of 582,100 autosomal SNPs met standard GWAS quality control. We prioritized variants in the top 0.01% of highest F_{ST} between populations, then selected gene regions where at least another variant was in the top 0.1% of highest F_{ST}. For these genes, trait associations were compiled from the *NHGRI-EBI GWAS Catalog*, and *Ingenuity Pathway Analysis*was used to identify significant pathways and biological functions among the top genes.

Results: Although the low F_{ST} estimates between the Gullah and their ancestors supports their genetic proximity (F_{ST}=0.003), the loci in the top 0.01% of highest F_{ST} were different between Gullah and SL, and between Gullah and YRI. While the loci with highest F_{ST} between Gullah and SL were enriched for genes involved in *Cellular Function and Maintenance* (P=6.1E-04), the top genes between Gullah and YRI were enriched for *Cancer*functions (P=4.1E-04). Although only a small fraction of the genes have been reported as associated with an AD, the most significant pathways were immune-related, for both the genes showing population differentiation between Gullah and SL (antigen presentation, P=4.9E-04; allograft rejection signaling, P=8.3E-04), and between Gullah and YRI (CCR3 signaling in eosinophils, P=4.8E-04; role of NFAT in regulation of the immune response, P=1.5E-03).

Conclusion: We identified several regions that show evidence of selection in the Gullah, including the *HLA* and *CD36*, which are known to be under selection that happened pre-admixture. The paucity of genes associated with ADs might be due to the lack of genetic association studies in AA. The enrichment of immune pathways suggests that autoimmune risk alleles might be present in the Gullah, as well as other AA. Given the increased prevalence of several ADs in AA, identification of regions under selection in the Gullah can further the understanding of the natural history and disease risks in AA and help explain the ethnic disparity.

Genetic heterogeneity in the risk of lupus nephritis according to ancestry

Background/Purpose: Lupus nephritis (LN) is a severe consequence of systemic lupus erythematosus (SLE) that affects minority populations in higher proportions. The causes behind these ethnic differences are not fully elucidated. We aimed to identify genetic variants that contribute differentially to the risk of LN across different ancestral groups.

Methods: 1244 SLE patients from five different racial/ethnic groups were studied. Genome-wide single nucleotide polymorphism (SNP) genotyping was performed with the Axiom LAT1 array (World Array 4, Affymetrix), which is composed of 817,810 SNP markers across the genome and was specifically designed to provide maximal coverage for diverse ethnic populations, including West Africans, Europeans and Native Americans. Genetic ancestry was determined by principal component analysis (PCA). The first 3 PCs (pc1, pc2, pc3) separated Europeans (n=535), Hispanics (n=252), African Americans (n=232) and Asians (n=223). A further PCA was performed to separate northern (n=295) vs southern Europeans (n=242). We utilized a candidate gene approach for genetic variants that have been identified in previous genetic studies of SLE risk, chronic kidney disease and/or LN. Allele frequencies for risk alleles were calculated for each ancestry group. Case-control associations between candidate SNPs and LN were performed within each ancestry group, adjusting for disease duration and principal components. We also utilized meta-analysis to test for heterogeneity and examine associations across the 5 ethnic groups.

Results: Overall, 606 participants (48.7%) had LN as defined by the ACR renal criterion. The prevalence of LN varied across the ethnic groups, ranging from 38% to 60.7%. Sixty out of 67 candidate gene SNPs varied significantly in frequency across the 5 ancestry groups ($p < 7$ E-4) in patients without LN. Association tests for risk of LN within each ancestry group revealed differences in the magnitude and significance (Table 1). Moreover, most SNPs were associated with LN for only 1 or 2 ancestry groups. The most significantly associated SNPs included recently identified risk variants for chronic kidney disease GWAS such as *NFATC1*, suggesting pleiotropy/poligenicity. Tests of heterogeneity (Breslow-day test, I2 square statistic) revealed significant heterogeneity according to ancestry for 6 candidate SNPs, indicating differential contribution of genetic risk variants to risk of LN according to ancestry.

Conclusion: These results demonstrate significant variation in the frequency of risk alleles as well as differential association with the risk of LN according to ancestry. These findings further support the hypothesis that genetic factors contribute importantly to observed ancestry differences in severe outcomes of SLE.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Genetics, Genomics and Proteomics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome and systemic lupus erythematosus (SLE) are chronic, autoimmune diseases that are related by clinical and serological manifestations as well as genetic risks. Both diseases are much more commonly found in women compared to men at a ratio of about 10 to 1. We have previously shown that relatively common X chromosome aneuploidies, 47XXY (Klinefelter's syndrome, 1 in 500 live male births) and 47XXX (1 in 1000 live female births), are enriched among men and women, respectively, with Sjögren's or SLE. We undertook this study to describe rare X chromosome aneuploidies among large cohorts of patients with these diseases.

Methods: We examined large cohorts of Sjögren's syndrome or SLE patients with intensity plots of X chromosome single nucleotide polymorphism (SNP) alleles. In addition, we also carried out karyotype of peripheral blood mononuclear cells from Sjögren's syndrome and SLE subjects.

Results: Among 2,426 women with SLE we found three patients with a triple mosaic consisting of 45X/46XX/47XXX, a statistically significant increase compared to controls and the known birth rate by binomial confidence intervals. Among 2138 women with Sjögren's syndrome, one patient had 45X/46XX/47XXX with a triplication of the distal p arm of the X chromosome in the 47XXX cells. Neither the triple mosaic nor a partial triplication were found among controls. In fact, the triple mosaic occurs in approximately 1 in 25,000 to 50,000 live female births, while a partial triplication such as the one found is even rarer. In another cohort of Sjögren's patients, we found a mother-daughter pair in which the mother had an inversion of the proximal region of Xq and the daughter had a Xp isochrome with partial triplication of distal Xp.

Conclusion: Very rare X chromosome abnormalities are present among patients with either Sjögren's or SLE. These rare variants may be informative as to location of a gene or genes on the X chromosome that mediate a gene dose effect as well as critical cell types in which a gene dose effect is operative.

Polymorphisms of *ERAP1, IL23R* and *TRAILR1* are associated With MRI-Sacroiliitis in Early Axial Spondyloarthritis: Data from the French DESIR Cohort

Background/Purpose: Spondyloarthritis (SpA) is a highly heritable disease, often affecting the sacroiliac joints. Single nucleotide polymorphisms on *ERAP1*, *IL23R* and *TRAIL-R1*(or Tumor Necrosis Factor-related Apoptosis-inducing Ligand Receptor 1) are associated with SpA susceptibility and structural changes on sacroiliac joints on radiographs. The aim of this study was to test the association between these polymorphisms and the presence of sacroiliitis on magnetic resonance imagery (MRI), in a French early SpA cohort (DESIR: Devenir des Spondyloarthrites Récentes).

Methods: All patients included in the DESIR cohort fulfilling the Assessment of SpondyloArthritis international Society (ASAS) diagnosis criteria for axial SpA, AMOR or European Spondyloarthropathy Study Group (ESSG) criteria, were included in this study. All MRI were scored by two experienced readers, according to Spondyloarthritis Research Consortium of Canada (SPARCC) score and ASAS definition. *Genotyping:* Three SNPs on *IL23R (rs1004819, rs10889677, rs2201841)*, 4 SNPs on *ERAP1 (*rs17482078, rs10050860, rs27434, rs2287987*)*, 1 SNP on *TRAILR1* (rs20575) were genotyped using KasPar method (LGC-genomics, UK). The haplotype of the 3 SNPs on *IL23R* and the 4 SNPs on *ERAP1*were built with Plink software. *Statistics:* Univariate analyses using a Chi square test and a Wilcoxon tests were performed to assess whether a haplotype of *ERAP1, IL23R* and a genotype of the SNP on *TRAILR1*were associated with MRI sacroiliitis or SPARCC score respectively.

Results: Among the 708 patients included in the DESIR cohort, 645 fulfilled at least one of the criteria set for SpA. Among them, 403 (62,6%) patients were *HLA-B27* positive. 214 patients (34.2%) had a MRI sacroiliitis and 161 (25%) patients had SPARCC MRI sacroiliitis score higher than 4. The haplotype TAG of *IL23R* was associated with MRI sacroiliitis with SPARCC criteria (SPARCC median=0.75 [0-8] in TAG patients versus 0[0-2] in non-TAG patients, p=0.0021), while rs20575 on *TRAILR1* was associated with MRI sacroiliitis using SPARCC criteria (SPARCC median=1[0-6.5] in G allele carriers versus 0[0-2] in G allele non-carriers, p=0.0046). These associations were stronger in *HLA-B27* positive patients (SPARCC median in TAG carriers of *IL23R* = 1[0-10.5] versus 0[0-4] in TAG non-carriers, p=0.0058; in G allele of *TRAILR1* carriers: 1.5[0-10.5], versus 0[0-4] in G allele non-carriers, p=0.0044). The haplotype CCAT of ERAP1 was associated with MRI sacroiliitis with ASAS criteria (47.1% of patients with sacroiliitis in CCAT carriers, versus 30.4% in non-carriers, p=0.046). Stratification on the presence of *HLA-B27* enhanced this association (60% of patients with sacroiliitis in CCAT carriers, versus 31.6% in non-carriers in *HLA-B27*positive patients, p = 0.0035).

Conclusion: In the DESIR cohort, *ERAP1, TRAILR1* and *IL23R* polymorphisms were associated with the presence of MRI sacroiliitis in SpA, particularly in *HLA-B27*patients. *This work received an institutional support by the French Society of rheumatology.*

Session Date: Sunday, November 13, 2016

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Susceptibility to ankylosing spondylitis (AS) is primarily genetic; thus far 113 susceptibility variants for AS have been identified. However, most of the AS associated SNPs do not directly affect protein-coding genes. Studies of disease- and trait-associated SNPs suggest they may act by affecting gene regulatory regions in specific cell types or tissues. Therefore, identifying the AS relevant cell types is crucial for further mechanistic studies.

Methods: We applied several bioinformatics methods to utilize epigenetic, gene and protein expression information to identify the primary relevant cell types through which genetic variants associated with AS operate. In total, there are 113

AS associated loci; 39 of them show genome-wide significance in AS-only analyses, whereas the remainder are genome-wide significant in analyses leveraging pleiotrophy with other related diseases (Crohn's disease (CD), psoriasis, primary sclerosing cholangitis (PSC) and ulcerative colitis (UC))[1].

Results: AS-associated SNPs are disproportionately found in regions bearing epigenetic marks indicating transcriptional activity found in immune cell types including monocytes, CD4+ and CD8+ T cells, NK cells, regulatory T cells, and B cells. Gene expression studies showed enrichment of AS associated loci in genes specifically expressed in monocytes and NK cells while protein expression study shows protein products of AS associated loci were significantly enriched in CD8+ T cells. Epigenetic analyses also showed evidence that AS-associated signals operate in gut cell types including in mucosa from the small intestine, sigmoid colon and rectum. These findings particularly relate to pleiotropic loci also associated with IBD, psoriasis, and PSC.

Conclusion: These findings highlight the role of key immune cell types in the mechanism by which genetic associations with AS drive the disease, as well as providing further evidence for the involvement of the gut in the pathogenesis of AS.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with a chronic inflammatory disease such as rheumatoid arthritis (RA) are at higher risk of developing cardiovascular diseases (CVD). Interleukin (IL)-32 has previously been shown to be involved in the pathogenesis of RA and might also be linked to the development of atherosclerosis. However the exact mechanism linking IL-32 to CVD still needs to be elucidated.

Methods: Whole blood was obtained from individuals from the NBS cohort and RA patients from 2 independent cohorts to study the influence of a functional genetic variant IL-32 on lipid profiles and CVD risk. DNA was isolated and genotyped for the single nucleotide polymorphism (SNP) rs4786370 in *IL-32* using a taqman genotyping assay. Lipid profiles were measured and matched to the specific IL-32 genotypes.

Results: The allelic distribution of the IL-32 promoter SNP was similar in all three groups. Interestingly, significantly

higher levels of high density lipoprotein cholesterol (HDLc) were observed in individuals from the NBS cohort and RA patients from the Nijmegen cohort homozygous for the C allele (p=0.0141 and p=0.0314 respectively). This finding was independent of the presence of plaques or previous CVD events in these groups. In contrast, the CC-genotype was associated with elevated low density lipoprotein cholesterol (LDLc) and total cholesterol (TC) in individuals at higher risk for CVD (plaque positive) (p=0.0396; p=0.0363 respectively). Within RA patients with a previous CVD event, the LDLc and TC levels were lower compared to RA patients without a previous CVD event, independent of the genotype (p<0.0001).

Conclusion: The rs4786370 promoter polymorphism of IL-32 is equally expressed in all three cohorts. However, this genetic variant has a specific functional effect on the lipid profile of individuals from the NBS cohort and RA patients, resulting in increased HDLc levels. Future studies should focus on the mechanism behind the increase in HDLc in individuals with the IL-32 promoter SNP and its possible protective role against CVD.

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: 17 genetic loci have now been identified to confer susceptibility to JIA; several of these loci harbour genes involved in the *IL2* pathway suggesting that this may be an important signalling cascade involved in JIA. It is hypothesised that the regions containing variants increasing the risk of disease may act as regulatory elements that modulate gene expression. Indeed capture Hi-C data, which identifies physical DNA interactions, has shown that a JIA susceptibility single nucleotide polymorphism (SNP), rs9979383, located in a gene enhancer region, makes strong contact with the promoter of RUNX1, a crucial transcription factor involved in the regulation of IL-2. Characterising the extent of these interaction and understanding the underlying mechanism is likely to provide important information as to how this variant increases risk of JIA. The aim of this study was to design a bioinformatics pipeline to prioritise the most likely functional candidate SNPs and to design and perform functional experiments to define the mechanisms by which these JIA associated variants contribute to disease pathogenesis.

Methods: In order to prioritise the most likely functional candidate SNPs for follow up a bioinformatics pipeline was designed, curating bioinformatics tools and data to create a step-wise assessment of each SNP. In-house generated Capture

Hi-C data for the *IL2* pathway regions were assessed for interactions between associated SNPs and nearby genes. Fragments near JIA associated SNPs showed looping at several points around the haematopoiesis master regulator gene; *RUNX1*, a key gene in the *IL2*pathway. Chromosome Conformation Capture (3C) experiments were implemented to validate interactions in the selected regions. To test for a genotype specific effect nine B-lymphocyte cell lines, three of each genotype, were selected for this experiment.

Results: The highest prioritised SNP in the *RUNX1*gene region was identified as rs9799383 based on transcription factors, Hi-C data and histone marks. Interactions in TT genotype cell lines occurs significantly more frequently in one tested interaction. Interestingly, a 1.7 fold increase in frequency is observed in the same interaction when data from all cell lines are grouped together, as well as a separate interaction showing a 2.7 fold increase in interaction frequency.

Conclusion: The bioinformatics approach to investigating potential functional variants proved to be highly informative and aided the design of 3C experiments. Cell lines grouped by genotype show mostly insignificant difference compared to controls, however one genotype specific interaction is observed in TT cell lines. This observed interaction appears to interact with the RUNX1 promoter region. The observed long range interactions are indicative of a distal regulatory effect that may influence gene expression of *RUNX1*. These findings inform further experiments and have suggested several potential transcription factors which may be driving JIA susceptibility in the *RUNX1* region.

Session Title: Genetics, Genomics and Proteomics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is an inflammatory arthritis associated with psoriasis estimated to present in approximately 14% of psoriasis patients in the UK. As a complex disease, PsA is influenced by both genetic and environmental factors. Genome-wide association studies (GWAS) have reported risk alleles for both PsA and psoriasis that are common, with a frequency > 5% in the population. However, association with rare coding alleles has not yet been reported for PsA alone.

Methods: In this study, we attempt to identify rare coding variants (MAF < 5%) associated with PsA. We genotyped 41,267 variants in 1,980 PsA cases and 5,913 controls of Caucasian decent using the Infinium HumanExome-12 BeadChip (v1-0) (Illumina) and the Infinium HumanCoreExome-24 BeadChip (v1-0) (Illumina). We applied single-point analysis

using the Fisher's exact test in PLINK with all variants passing QC. We performed multiple-variant analysis with rare variants alone using the SKAT package in R. We then applied conditional analysis using PLINK to investigate independent effects. We also analysed an independent cohort of 2,234 PsA cases and 5,708 healthy controls of European descent, where we performed single-point analysis using Firth logistic regression. A meta-analysis of the discovery and independent summary statistics was performed using PLINK.

Results: Upon performing single-point analysis, we found the strongest association at the rs35667974 SNP (P=2.39x10^{-6}, OR=0.47), mapping to the *IFIH1* gene and encoding an Ile923Val missense mutation. We replicated this association within an independent North American dataset (P=2.5x10^{-5}, OR=0.49), which was highly significant in meta-analysis with the discovery dataset (P=4.67x10^{-10}). *IFIH1* was also found to have a strong association when performing multiple-variant analysis (SKAT, P=6.77x10^{-6}). The association of the rare coding allele was independent of the common PsA variant at the same locus (rs984971) when performing conditional logistic regression (P_{cond}=4.0x10^{-6}) and conditional haplotype analysis (P=2.95x10^{-7}).

Conclusion: For the first time, we report a rare coding allele at *IFIH1* to be protective for PsA. This association has been previously reported for psoriasis and type 1 diabetes, highlighting the relevance of this allele in immune-related diseases. The association that we identified in PsA provides strong evidence to suggest that *IFIH1* is a causal gene. This finding could provide further insight into the mechanism of disease for PsA. The functional role of *IFIH1* might be investigated in PsA using this coding change.

Longitudinal Expression of CXCL10 in Psoriasis Patients that Develop Psoriatic Arthritis Patients Fatima Abji[1], Remy Pollock[1] Kun Liang[2], Vinod Chandran[1,3], Dafna D. Gladman[1,3] [1]University of Toronto, Toronto Western Hospital, [2]Department of Statistics and Actuarial Science, University of Waterloo, [3]Division of Rheumatology, Faculty of Medicine, University of Toronto

Background/Purpose: Psoriatic arthritis (PsA), an inflammatory musculoskeletal disease, develops in approximately 30% of patients with psoriasis. We previously found that C-X-C motif chemokine 10 (CXCL10) was elevated in psoriasis patients that developed PsA compared to those that did not develop PsA over the same psoriasis duration, thus suggesting CXCL10 is a predictive biomarker of PsA. In this study, we monitored the expression of CXCL10 over time in psoriasis patients that develop PsA.

Methods: Psoriasis patients were followed prospectively beginning in 2006, and were assessed yearly by a rheumatologist for the presence of PsA. Psoriasis patients who developed PsA were termed 'converters', and serum samples were taken at baseline and follow-up visits. The expression of CXCL10 and CRP were measured using Milliplex MAP human magnetic bead panels (EMD Millipore), according to the manufacturer's instructions. Data were acquired using the Luminex 200 system and analyzed with the Bio-Plex Manager software (Bio-Rad Laboratories). Statistical differences in protein levels prior to PsA conversion were compared by the Wilcoxon signed rank test and post-conversion by the Friedman test with a Dunn's Multiple Comparisons post-test ($p<0.05$ was accepted as significant).

Results: CXCL10 and CRP were measured in 19 psoriasis patients at baseline and at five follow-up time points. CXCL10 levels decreased over time (Figure 1), with a significant reduction at follow-up visit 3 (median 269.4 pg/ml, interquartile range [IQR] 198.6-399.6), visit 4 (median 225.3 pg/ml, IQR 155.1-387.9) and visit 5 (median 226.5 pg/ml, IQR 193.2-450.8) compared to post-conversion visit 2 levels (median 562.16 pg/ml, IQR 338.5-601.8, $p<0.001$). No significant differences in CRP levels were observed.

Conclusion: We observed a reduction in serum CXCL10 expression in psoriasis patients after they developed PsA which was maintained over time. These results support our previous findings of elevated CXCL10 in synovial fluid compared to serum from PsA patients, reflecting the localized production of CXCL10 over time. This study contributes to our understanding of the role of CXCL10 in the pathogenesis of PsA.

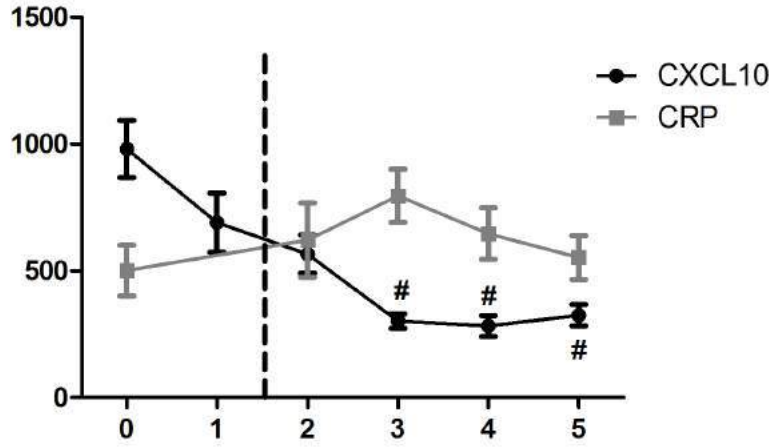

Figure 1: Line graph of CXCL10 and CRP expression in serum from 19 psoriasis converters measured at baseline (0) and follow-up visits (1-5). Dashed line indicates conversion to PsA. A significant difference compared to the post-conversion visit (2) is indicated by # ($p<0.001$). CRP concentration is expressed per 100 ng/ml.

Session Title: Genetics, Genomics and Proteomics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In the general population, an increase in chronological age is associated with differential DNA methylation of particular CpGs in a highly conserved fashion. Since age is a key risk factor for many rheumatic diseases, we tested whether DNA methylation (DNAm) patterns exhibited during normal aging occur prematurely in subjects with systemic autoimmune rheumatic diseases (SARD).

Methods: Peripheral blood $CD4^+$T-cells and $CD14^+$monocytes were sorted from incident treatment naïve rheumatoid arthritis (RA, n=13) and systemic sclerosis (SSc, n=17) subjects, as well as systemic lupus erythematosus subjects (SLE, n=12 - not all of whom were treatment naïve), and healthy controls (HC, n=8). Illumina HumanMethylation450 BeadChip and Illumina TruSeq stranded RNA-seq were used to perform genome-wide methylome and transcriptome analysis. First, we compared chronological and predicted age across SARDs using the Horvath calculator, a publicly available 'epigenetic-aging-signature' based on DNAm levels at 353 CpG sites (*Genome Biology* 2013). Second, using principal component of explained variance (PCEV), we examined whether the 353 CpGs were associated with chronological age in treatment-naïve RA and SSc, separately. Finally, we verified the findings from the PCEV analysis by examining the methylation levels in RA and SSc at sites that have been reported to correlate between chronological age and methylation levels (Lin and Wagner, *PLOS Genetics*2015).

Results: Across SARDs, the estimated age predicted using the Horvath calculator was younger than chronological age in both T-cells (average age acceleration -6.04 years, p=1.4E-12) and monocytes (average age acceleration -1.2 years, p=0.023). We found similar results in SSc [T-cells average age acceleration -7.91 years (p=7.36E-09), and monocytes average age acceleration -2.51 years (p=0.015)], and in RA T cells (average age acceleration -6.49 years, p=6.59E-0.4). We were unable to establish differences in predicted and chronological age in RA monocytes and SLE T cells and monocytes. PCEV analysis showed that the 353 CpGs in the Horvath model correlated with age in SSc (p value 0.002), but not in RA (p 0.268). We verified the findings of the PCEV analysis by examining methylation levels at CpGs reported to be correlated with aging (97 hyper- and 402 hypomethylated). Again, the CpG sites correlated with age as expected in SSc. However, while the correlations with hypermethylated CpGs were as expected in RA, this was not the case with hypomethylated CpGs, where evidence of more methylation than expected in both T cells and monocytes was found.

Conclusion: The models that predict aging-associated epigenetic drift in the general population did not predict premature aging in our SARDs patients. Moreover, age-associated DNAm patterns at hypomethylated CpG sites seem to be coherently modified in RA. This provides additional evidence supporting dysregulated aging in RA and novel mechanistic clues.

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although a number of epigenetic alterations have been revealed in rheumatoid arthritis (RA), it remained an open question whether these epimutations play role in RA etiology or are consequences of the pathogenesis. We investigated how arthritis-specific DNA methylation events could contribute to the dysregulation of a gene regulatory network leading to increased autoantibody production, and development of polyarthritis in a mouse model of RA.

Methods: In B cells isolated from arthritic mice, DNA methylation profile changes were explored by methylated CpG island recovery assay (MIRA-chip). Disease-associated gene expression patterns were also investigated using microarray platforms and quantitative *reverse transcription PCR (*RT-qPCR). DNA methyltransferase inhibitor, 5`-Azacitidine (Aza) was employed to reactivate hypermethylated genes in cell cultures and animal studies. Gene expression changes were monitored using RT–qPCR and Western blotting. Mice with proteoglycan-induced arthritis (PGIA) were treated with Aza and its effects were followed in B cells by flow cytometry, histochemistry, RT-qPCR and ELISA. ShRNA expressing plasmid constructs were constructed and introduced into cell cultures for targeted silencing of gene of interest.

Results: A group of promoters with arthritis-specific DNA methylation profile was identified by MIRA-chip. The promoter region of AhR transcription factor encoding gene was differentially methylated in B cells isolated from arthritic mice, which de novo hypermethylation resulted in downregulated expression of AhR. Selective inhibition of DNA methylation restored AhR expression, which was associated by reduced expression of post-recombinant IgG1 in B cells and low level of IgG1 in sera of Aza treated animals. AhR directly regulates genes are implicated in germinal center formation within secondary lymph nodes. Aza treatment provided significant protection against disease onset, and abolished inflammatory reactions in synovial joints of arthritic mice.

Conclusion: AhR is a master regulator of IgG maturation and its epigenetic inactivation by DNA methylation significantly contributes to RA pathogenesis. Targeted reactivation of AhR employing DNA methylation may have therapeutic potential for treatment of polyarthritis.

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The urate transporters are one of the genetic determinants of serum uric acid concentrations. In the present study, we describe the analysis of sequencing variants in the *ABCG2*, *SLC17A3*, *SLC22A11* and *SLC17A1* genes, physiologically important urate transporters whose dysfunction can play a role in pathogenesis of hyperuricemia, in a cohort with primary hyperuricemia and gout.

Methods: The cohort consisted of 150 individuals: 32/118 primary hyperuricemics/gout. The definition of hyperuricemia was as follows: >420/360 µmol/l at two repeated measurements at intervals of at least 4 weeks in men/women. Gouty arthritis was diagnosed according to the 1977 preliminary criteria of the American College of Rheumatology for acute arthritis of gout. Patients suffering from secondary gout were excluded. In total, 7050 PCR amplicons were sequenced directly: 10 for *SLC17A3*, 10 for *SLC17A1*, 10 for *SLC22A11*, 17 for *ABCG2*.

Results: In the *SLC17A3* gene were found 7 intronic/3 exon variants (2 non-synonymous *rs1165165*, rs*56027330*), in *SLC17A1* 7 intronic/1 non-synonymous exon variant (*rs1165196*) and in *SLC22A11* 3 intronic/4 exon variants (2 non-synonymous *rs201209258*, *rs75933978*). Allele frequencies for all exon and intron variants found in *SLC17A1, SLC17A3* and *SLC22A11* genes were not statistically significant compare to general Caucasian population. In the *ABCG2* gene, 16 intronic variants were detected. In the case of c.689+1G>A, related to an individual with severe gouty phenotype, two abnormal splicing variants were identified: a) r.[532_689del]; b) r.[532_689del], r.[944_949del]. Identified deletions lead to frameshift and premature stop codon introduction[1]. From the 9 exon variants detected, there were 7 non-synonymous: p.V12M (*rs2231137*), p.Q141K (*rs2231142*), p.R147W (*rs372192400*), p.T153M (*rs753759474*), p.F373C (*rs752626614*), p.T434M (*rs769734146*) and p.D620N (*rs34783571*). Heterozygous p.V12M variant was detected in 7 individuals. Heterozygous variant p.R147W, p.T153M, p.F373C, p.T434M and p.D620N was detected once, variant p.D620N was detected twice also in heterozygous state. All these five allelic variants were *in silico* predicted using Polyphen, Sift and Provean program as a probably damaging and were not detected in control cohort of 150 normouricemia subjects. The p.Q141K, previously functionally characterized variant with a strong effect on uric acid secretion impairment, was in cohort of hyperuricemic/gout patients presented with significantly higher minor allele frequency (MAF)=0.19 (42 heterozygotes/5 homozygotes), than in population of European origin (MAF=0.09) and world-wide population (MAF=0.12).

Conclusion: Our results show that genetic factor *ABCG2* should be considered as one of the common risks for hyperuricemia/gout. In clinical practice, *ABCG2* dysfunction can be estimated easily by genotyping and these findings will help to recognize a trait of hyperuricemia at a very early stage**.** References*:* 1. Session Date: Sunday, November 13, 2016

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The treatment of rheumatic diseases can be both expensive and ineffective with up to 1/3 of patient's failing to respond to current treatments. There is therefore a need to identify new effective treatments and to target the best treatment to individual patients. Although genetic studies have been successful in identifying common variation associated with disease susceptibility, a large proportion of these lie outside traditional protein-coding regions. Many show enhancer activity but it is often unclear which gene(s) they regulate and how they contribute to disease. Chromatin folding brings linearly distant areas of the genome, such as promoters and enhancers, into close proximity, driving gene expression. Capture Hi-C (CHi-C) is a new method which interrogates these interactions in a high-throughput, high-resolution manner, linking implicated enhancers to causal genes. Utilising our existing CHi-C data on 3 rheumatic diseases, RA, JIA and PsA, targeting all known genetic associations, we explored the potential of this interaction data to identify potentially causal genes that are targets for existing drugs, which could be repositioned for use in these diseases.

Methods: Chromatin interaction data for T- and B-cells in the 3 diseases was re-called using CHiCAGO v2 using a score cut-off of ≥ 5. Interactions between disease regions and gene promoters were identified using BEDTOOLS v2.21.0 and intersected with known drug targets from DrugBank v4.5.0. Existing treatments for each disease were identified by the presence of the relevant name in the 'indication' field.

Results: Overall 850 genes were identified as interacting with a rheumatic disease associated region. Of these, 61 are existing drug targets (303 drugs) (Table 1) and 9 are existing therapies used in the treatment of disease, primarily RA.

Table 1 Summary of drug targets identified by CHi-C

Disease	Number of genes identified by CHi-C	Number of genes which are existing drug targets	Number of drugs Identified	Number of drugs withdrawn	Number of drugs currently used	Number of drugs for potential repositioning
RA	510	41	106	4	9	93
JIA	324	16	74	0	1	73
PSA	196	13	147	0	0	147
All	850	61	303	4	9	290

Conclusion: Our study identifies genes which are implicated in disease, are the target of existing drugs and offer the potential for drug repositioning. Of the potential drugs identified for RA, 14 are used in the treatment of various cancers particularly leukemias and 11 are used in the treatment of diabetes and multiple sclerosis. Interestingly, 17 potential drugs identified for PsA are used in the treatment of schizophrenia and 11 in the treatment of hypertension. This data shows a novel insight into how functional annotation of genetic associations in rheumatic diseases can provide gene targets for re-positioned therapies.

Session Title: Genetics, Genomics and Proteomics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The interplay between miRNAs and their mRNA targets might constitute an important mechanism in the regulation of the proatherothrombotic status of SLE and APS patients. Aim: To investigate the contribution of deregulated miRNAs to the altered gene profile associated to cardiovascular disease (CVD) in SLE and APS.

Methods: Thirty-three SLE patients, 23 APS patients, and 27 healthy donors were included in the study. Gene Expression Microarray (44K, Agilent, one colour) and nCounter microRNA Expression Arrays (NanoString Technologies) were performed, respectively, to analyze mRNA and miRNA expression profiles on isolated monocytes. Target genes of the differentially expressed miRNAs and interaction networks were identified by using the Ingenuity Pathway Analysis Software (IPA). The resulting identified interactions were validated by RT-PCR on the whole cohorts of SLE and APS patients. The predicted miRNA-mRNA interactions were also tested by functional analyses using microRNA over expression experiments in monocytes purified from SLE and APS patients.

Results: Comparative analysis of the mRNA profiles showed significantly different expressions of 1222 genes in SLE and 519 genes in APS monocytes in relation to healthy monocytes. Functional analysis by using IPA showed that about 30% of altered genes were involved in inflammation and cardiovascular disease (CVD). Comparative analysis of the microRNA profiles showed significantly different expressions of 37 miRNAs in SLE and 22 miRNAs in APS monocytes. Functional IPA analysis showed that microRNAs altered were mainly related to connective tissue disorders, inflammatory response and reproductive system disease in both autoimmune conditions. In SLE, a total of 63 genes were inversely correlated, and predicted as CVD-related target genes of 23 differentially expressed microRNAs. In APS, a total of 56 genes were inversely correlated, and predicted as CVD-related target genes of 19 differentially expressed miRNAs. Interaction networks of those genes and some microRNAs differentially expressed in SLE and APS monocytes were also identified and showed to be specific of each autoimmune disease. Among them, the overexpression of STAT3, PPARg and CMKLR1 associated to inhibition of miR-130a and miR-149 were verified in SLE patients. In APS patients the overexpression of IL-1A, LDLR, TGF-b, VCAM, VEGF-A and STAT-1 were associated with inhibition of miR-199, miR-30 and miR-145. The expression of these genes and miRNAs correlated with specific parameters related to inflammation, oxidative stress and thrombosis in each autoimmune disease. Moreover, association of these genes and miRNAs with the occurrence and type of thrombotic events, obstetric complications and presence of pathologic CMIT were demonstrated. Transfection studies further confirmed the relationship between these identified target genes and specific miRNAs in both autoimmune disorders.

Conclusion: We have identified novel and specific microRNA-mRNA regulatory networks related to CVD in SLE and APS patients, thus delineating novel genetic controls of the diverse biological processes and factors related to the cardiovascular pathology present in these autoimmune conditions. Supported by FIS (PI01333/2015) and CTS-7940.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Genetics, Genomics and Proteomics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is a complex disease with heterogeneous manifestations. It seems unlikely that all patients labeled as SLE have homogenous molecular pathology. An approach to evaluating the complexity is gene expression, wherein all the transcribed genes are assessed at once. Here we looked at the use of the Chaussabel 2008 modules developed on Affymetrix arrays in a heterogeneous adult SLE patient. The goal was to evaluate performance in separating disease activity from quiescent disease within lupus.

Methods: This study was conducted with SLE patients from the Hopkins Lupus Cohort following informed consent. Adult patients were eligible if they were aged 18 to 75 years old and met the definition of SLE as defined by the revised American College of Rheumatology classification criteria. Clinical and laboratory values were recorded at every visit. High disease activity was defined as presence of nephritis and significant proteinuria. Low disease activity was defined as PGA = 0 and the absence of steroids or immunosuppression (other than hydroxychloroquine). Typical SLE was a random mix of SLE disease activity including nephritis. Healthy controls were recruited and had no evidence of autoimmune disease. RNA collected from whole blood and analyzed as previously described [1]. Comparison with the pediatric SLE cohort used publically available data on the NIH GEObus (GSE11909).

Results: Patient characteristics are shown in the below Table 1.

	High Activity N=13	Low Activity N=25	Healthy N= 51	Typical SLE N=95
Average Age (sd)	43.9(12)	44(14)	39(11)	46(12)
Ethnicity (%)				
African American	23	44	27	38
White	62	52	73	58
Average SLEDAI	7	0	NA	2.7
Mycophenolate (N)	6	0	NA	21
Azathioprine (N)	2	0	NA	12
Average Prednisone (mg)	8.5	0	NA	3

Table 1. The 13 patients universally have lupus nephritis at the clinical visit, eight of who were already on therapy. There are a higher proportion of African Americans in the Low Activity group. Table 2 shows the results of the modular analysis. We were not able to demonstrate the significant plasmablast signature seen in the pediatric population. We were able to show a higher neutrophil signature with the lupus nephritis group.

Module Name	Module Number	Pediatric SLE Untreated vs. HC		Adult SLE High vs No Activity		Adult SLE SLE vs HC	
		UP	DOWN	UP	DOWN	UP	DOWN

none	3.9	2	11	1	29	3	23

Table 2. Comparison of modules between patient groups.

Conclusion: The Chaussabel modules showed notable differences between active lupus nephritis and quiescent disease. The interferon module, as defined in the 2008 modules, did not markedly differ between the groups analyzed. The neutrophil module was notably increased in the lupus nephritis population. **References:** 1. Zollars, E. *et al*. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Genetics, Genomics and Proteomics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Monogenic autoinflammatory diseases are mainly disorders of innate immunity and characterized by unprovoked inflammatory attacks. We studied a consanguineous family with two affected children, with an initial diagnosis of Familial Mediterranean Fever (FMF). While recurrent febrile attacks with serositis, high acute response and parental origin were consistent with FMF, disease onset before age one year, delay in growth, no mutation in MEFV and poor response to colchicine were not typical features of this disease.

Methods: SNP genotype data for all family members were used for multipoint linkage analysis. Targeted sequencing was performed for *MVK* residing in one of the linked regions and seven other autoinflammation related genes, *IL1RN, LPIN2*, *MEFV, NLRP12, NLRP3, TNFRSF1A* and *PSTPIP1*. After the identification of the causative mutation, serum IgD and urinary mevalonic acid levels were measured.

Results: Linkage analysis detected seven candidate regions. The largest candidate region, at 12q24.11-q24.31 (LOD=1.92), contained 191 genes. Novel homozygous c.481T>C (p.Cys161Arg) mutation in *MVK*, the gene responsible for Hyper IgD Syndrome (HIDS) was identified. At the protein level, cysteine at position 161 is totally conserved in mammals. Urinary mevalonic acid was not detected for either patient, and serum IgD level was slightly elevated for only one patient.

Conclusion: We identified a novel homozygous *MVK* mutation in patients with a FMF-like disease but without a typical HIDS phenotype. We hypothesize that this novel mutation underlies the atypical clinical presentation. Phenotypic variability of HIDS is well known, and our findings further expand the *MVK* mutation phenotype.

Impact of a Patient Support Program on Abandonment of Adalimumab Treatment Initiation in Patients with Rheumatoid Arthritis, Ankylosing Spondylitis, and Psoriatic Arthritis

Philip Mease[1], Manish Mittal[2], Martha Skup[2], Matthew Davis[3], Arijit Ganguli[2], Scott Johnson[3] and Michael Schiff[4], [1]Swedish Medical Center and University of Washington, Seattle, WA, [2]AbbVie Inc., North Chicago, IL, [3]Medicus Economics, LLC, Milton, MA, [4]University of Colorado, Greenwood Village, CO
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment abandonment (failure to start therapy after prescription) is common among patients (pts) prescribed specialty pharmaceuticals. AbbVie offers a pt support program (PSP) for adalimumab (ADA)-treated pts, which includes assistance with medication costs, nurse support, injection training, pen disposal and medication reminders.[1] PSP may reduce abandonment in RA, ankylosing spondylitis (AS) and psoriatic arthritis (PsA). We investigated associations between PSP and rate of ADA treatment abandonment in US pts with RA, AS and PsA.

Methods: A longitudinal study was conducted using pt-level data from AbbVie's PSP database linked with Source Healthcare Analytics US claims data. Pts aged ≥18 years with a RA, AS or PsA diagnosis, ≥1 pharmacy claim (paid or reversed) for ADA and no ADA claim before 2012 were included; the index date was the first ADA claim from 1/2012–1/2015. Pts required medical coverage ≥3 months pre-index date and pharmacy coverage ≥3 months pre-/post-index date. Abandonment was defined as reversal of first ADA claim (eg, pt did not take possession of medication) with no paid claim during 3 months of follow-up. Abandonment rate was compared between pts who enrolled in any component of the PSP (PSP cohort) vs those who did not (non-PSP cohort) within 30 days of treatment initiation using 2-sample z-test of proportions. The likelihood of abandonment was assessed using logistic regression, controlling for baseline characteristics.

Results: A total of 16780 pts (RA: 6200 PSP, 6155 non-PSP; AS: 451 PSP, 525 non-PSP; PsA: 1785 PSP, 1664 non-PSP) were included. At baseline in RA and PsA, PSP pts were younger (50.5 vs 52.0 yr; $P<.0001$ and 48.5 vs 49.3 yr; $P=.042$, respectively) and less likely to be male (20.4% vs 22.5%; $P=.005$ and 41.2% vs 47.8%; $P=.0001$, respectively) than non-PSP pts. No significant difference was observed regarding age in AS, but PSP pts were less likely to be male vs

non-PSP pts (50.1% vs 57.7%; *P*=.018). The PSP cohort had lower expected per-patient out of pocket contribution for ADA across diseases (RA [$222 vs $312; *P*<.0001], AS [$136 vs $240; *P*<.0001] and PsA [$179 vs $261; *P*<.0001]) and greater frequency of specialty pharmacy use for first ADA fill (RA: 55.7% vs 47.3%; *P*<.0001, AS: 65.4% vs 49.5%; *P*<.0001, PsA: 58.8% vs 54.8%; *P*=.0173). After controlling for baseline characteristics among PSP vs non-PSP pts, abandonment risk was 78% lower in RA (6.0% vs 26.4%; odds ratio [OR]=0.22; *P*<.0001), 85% lower in AS (3.8% vs 20.2%; OR=0.15; *P*<.0001) and 77% lower in PsA (4.8% vs 21.9%; OR=0.23; *P*<.0001) (**Figure**).

Conclusion: Enrollment in AbbVie's free-to-patient PSP was associated with 77–85% reduced abandonment of ADA treatment among US pts with RA, AS and PsA. **References:** 1. https://www.humira.com/humira-complete

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RA is a chronic, debilitating condition for which there is no cure. To identify and better understand the perspectives of both healthcare providers (HCPs) and patients (pts) regarding RA treatment and management, the RA NarRAtive global advisory panel developed an HCP- and pt-based survey.

Methods: The RA NarRAtive initiative comprises a global advisory panel of 39 RA experts. An HCP-based and a pt-based survey, designed by the working group, were fielded online between Aug 2015 and Oct 2015, and between Sept 2014 and Jan 2016, respectively. Responses are presented from pts treated by a rheumatologist, and HCPs who were rheumatologists in all countries (orthopedists also included in Japan). All respondents are from the same 15 countries.

Results: 3,987 pts responded, of whom 1,667 were managed by a rheumatologist: mean age 51.5 years (yrs), 64% female, median time since diagnosis 7 yrs; respondents represented a wide spectrum of disease activity: moderate to severe (33%; 556) and severe (10%; 159). In total, 1,666 HCPs responded to the survey, 51% were mostly in office- or clinic-based practice and 22% were in mostly hospital- or lab-based practice; mean number of pts with RA that HCPs saw per month was 92.0; HCPs reported that disease activity was moderate to severe in 32.5% of their pts and severe in 17.4%. In the HCP survey, 90% of respondents were satisfied with their communications with pts; however, 68% acknowledged, 'I wish my pts and I talked more about goals and treatment.' In the pt survey, 53% of pts acknowledged that dialogue with the HCP would optimize the management of their RA. However, 61% of respondents felt uncomfortable raising concerns or fears to their HCP. 93% of HCP respondents discussed quality of life (QoL) issues with their pts including impact of RA on ability to work, participation in activities, and lifestyle goals. 86% discussed treatment-related issues including adherence to therapy, medication preferences, and whether pts seek treatment from other HCPs. The most common topics that patients reported worrying about and that HCPs believed their patients worry about are similar; although a greater proportion of HCPs believed their pts worry about treatment side effects/failure. HCPs and pts had similar views on what they would most like to change about currently available RA medications, ie severity and number of side effects, cost, and efficacy. RA remission was ranked higher in the HCP survey than in the pt survey as a treatment goal; while pts frequently referred to symptom reduction. Overall, 88% of HCPs agreed that pts who are involved in making treatment decisions tend to be more satisfied with their treatment experience; 74% felt that pts who are not involved are less likely to adhere to treatment. Setting treatment goals with pts and agreement on the treatment plan are considered important by 78% and 79% of HCPs, respectively, as well as being able to have an open dialogue (86%).

Conclusion: Differences between treatment goals set by pts and HCPs were reported, thus highlighting the importance of an open pt-HCP dialogue in the successful management of RA. These findings could help improve adherence and pt satisfaction with their disease management.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Mobile medical Applications (mApps) with diary functions and integrated patient-reported outcome instruments allow patients (pts) with rheumatoid arthritis (RA) to self-monitor their disease apart from out-pts visits and thus might strengthen self-management. In a project evaluating the usability of a mApp with diary function we studied pts' given information technology (IT) prerequisites, especially their hitherto use of Internet and apps on mobile devices.

Methods: Inclusion criteria were RA diagnosis, age of consent and German speaking. 268 consecutive RA out-pts were screened, 157 (58.6%) owned an App-compatible device, and 60 pts (38.2%) agreed to complete paper-based questionnaires assessing experiences and knowledge regarding IT aspects, App/internet use, and sociodemographic and clinical trial data. Ethic approval and pts' signed informed consents were obtained. The identifier at clinicaltrials.gov is NCT02565225.

Results: Pts were predominantly female (78.3%), mean±SD age was 50.1±13.1 years (yrs), mean disease duration 10.5±9.1 yrs. 50% had a high education level. 93.3% reported substantial experience with a smartphone, 70.0% with a tablet. 80% wanted to use the project-App on their smartphone, 20% on their tablet. Pts were familiar with their devices for 3.0±2.4 yrs. Internet use via the device was reported for private (91.7%) and official business issues (30.0%). 43.3% confirmed Internet use via the device during business hours. It was accessed via the contract of their device by 66.7% (3G 37.5%; 4G 27.5%), via WIFI at home (81.7%) or in public areas (35.0%) for 2.3±2.9 hours/day. 90.0% already used Apps, these reported use of health (24.1%), diet (9.3%), games (37.0%), communication/social media networks (59.3%), news (59.3%), weather information (79.6%), music (33.3%), sport (20.4%) and productivity (24.1%) Apps. Most (94.4%) stated use of free-of-charge Apps, 44.4% of Apps with costs. Although being informed that the project mApp was not build to send data via the Internet 18.3% believed that data entered in the mApp will be stored in a cloud, 35.0% had no idea how the data is stored. 51.7% think they know the way an App works. Perceived data security on their App-compatible device was rated 3.0±1.4 (1(= high)–6(= low) Likert scale). 63.3% rated new media technology as predominantly beneficial for patient-physician interaction.

Conclusion: More than half of the pts owned App-compatible devices. Pts apply them for mobile Internet and App use even in business hours. Technical requirements for patient-physician communication via mobile devices are fulfilled in these pts, although IT literacy seems still to be narrowed in some pts. However, eHealth concepts via a mApp for monitoring disease apart from the physician visits seem feasible. Our project will deliver further important data of the mApp - a powerful tool at our fingertips.

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Health services addressing employment needs for people with arthritis are lacking. To address this need, we developed the Making it Work (MiW) program, an on-line self-management program aimed at helping people with inflammatory arthritis (IA) deal with employment issues. As part of a randomized controlled trial evaluating program effectiveness, this study aimed to explore participants' experience and obtain insight on the perceived benefits and drawbacks of participating in the MiW program.

Methods: All MiW participants who attended the final group meeting between January 2015 and April 2016 were included in this study. Semi-structured debrief group discussions were conducted by the group facilitator at the end of the last online group meeting, which was recorded and transcribed. Using content analysis, transcripts were coded and concepts grouped into meaningful clusters to identify emerging themes. All participants had IA; were currently employed; aged 18-59 years; concerned about their ability to work; and had access to a computer.

Results: The sample included 62 participants [87% female; mean (SD) age: 46(9.9) years; disease duration: 9(9.1) years; with RA (51%), AS (13%), PsA (18%), or SLE (18%); working full time (69%); 19% self-employed]. Several participants highlighted the problem solving and goal setting technique, as well as strategies to manage fatigue and stress, as "really helpful" tools for managing their arthritis both at and outside of work. People newly diagnosed with IA or interested in making changes to their work now or further "down the road" described the modules as most "informative". Some expressed interest in revisiting the material in the future. However, not all module content was relevant for everyone, as job situation (e.g. self-employed) or disease characteristics (e.g. those without fatigue) meant some content (e.g. disclosure or job accommodations, or dealing with fatigue) was not applicable to some workers. Perceived benefits/drawbacks of participation clustered around four themes: 1) Heightened awareness of how their arthritis affected their work; of their rights; and of resources available to them. 2) Empowerment vs. Frustration. Although most participants felt empowered by their increased awareness, a few became increasingly frustrated because they were unable to make changes to their work situation. 3) Improved self-efficacy. Many described feeling more confident about dealing with the challenges at work due to their arthritis, as a result of strategies and skills learnt. 4) Validation, resulting from groups meetings. Participants described that recognizing that their symptoms and struggles at work were shared by others with IA provided emotional relief from self-blame and self-doubt; being able to identify with and connect to other group members was comforting; receiving confirmation for strategies they had been using prior to MiW encouraged them to "keep at it".

Conclusion: This study provides insight into what participants found helpful about the MiW program. These findings are informative to health professionals assisting clients in dealing with employment issues and researchers designing arthritis programs dealing with employment.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient (pt) support programs (PSPs) are offered to Rheumatoid arthritis (RA) pts to help manage treatment of this chronic disease. Little information is available regarding the impact of these PSPs on disease management and factors affecting their use. The purpose of this study was to assess characteristics and predictors that influence pt participation in the PSP among adalimumab (ADA)-treated RA pts.

Methods: In this multinational, ex-US study, RA pts with an insufficient response to ≥1 disease-modifying antirheumatic drug (DMARD) newly initiating ADA (1 prior biologic DMARD was allowed) were enrolled. Pts were offered a panel of "Core elements" (starter pack, call center/hotline, nursing services, educational material, and injection guide; offered in all participating countries) and "Other elements" (e.g, refill reminders, email, newsletters, support groups, home delivery, and financial assistance; vary by country) of PSP. PSP participation was captured via a PSP utilization questionnaire at each study visit. Pts were classified based on PSP participation: ever (PSP users) vs never (PSP non-users) which served as a dependent variable in a multivariate logistic regression model examining the following parameters: baseline (BL) age, sex, race, RA disease duration, prior use of biologic DMARD, Health Assessment Questionnaire Disability Index (HAQ-DI), Patient Activation Measure-13 (PAM-13), BL Simplified Disease Activity Index (SDAI), and BL 28-joint DAS based on CRP (DAS28(CRP)).

Results: Of the 1,025 pts included in the Intent-to-treat population, 48.7% were PSP users. The BL demographics and clinical characteristics are enlisted (Table). After adjusting for BL demographics and clinical characteristics, the odds ratio of using a PSP was significantly lower in pts who previously used a biologic DMARD. Several factors, including female sex, and higher HAQ-DI, and DAS28(CRP) at BL, had statistically non-significant lower likelihood of PSP utilization (**Figure**). Study discontinuation rates were significantly (P<0.001) lower among PSP users vs PSP non-users (25.5% vs 41.6%).

Conclusion: In pts with moderate to severe RA newly initiating ADA, PSP users were found to have differences in baseline demographics and clinical characteristics. After accounting for these baseline differences, being naïve to prior biologic DMARD treatment was significantly associated with PSP participation. Pt participation in the PSP was associated with better retention in the study, underscoring a potential link between PSP participation and treatment adherence that should be further explored in prospective studies.

Figure: Predictors of PSP use among RA patients. Odds ratios are adjusted for each other

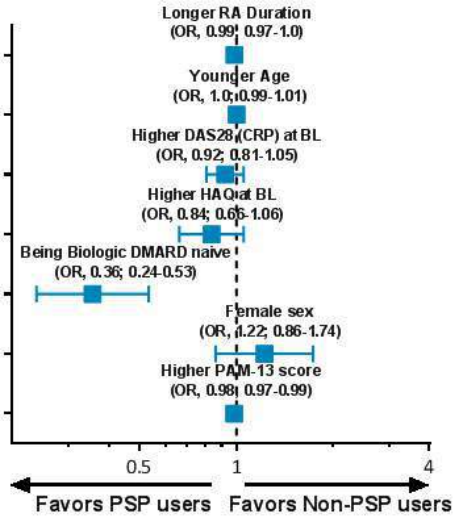

Table: Baseline Demographics and Clinical characteristics

	All Patients (N=1025)	PSP-users (N=499)	PSP-non-users (N=526)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The University of Alberta Division of Rheumatology has launched a new multidisciplinary clinic, the On-TRACC Program (**O**n **T**reating **R**heumatoid **A**rthritis – Providing **A**ccess to **C**are), which provides aggressive treat to target (T2T) disease modification and co-morbidity management in a shared-care model of rheumatologists and advanced care practitioners (ACP). Primary Objective: To evaluate patient satisfaction in patients enrolled in the On-TRACC program compared to those treated in general rheumatology clinics through a patient satisfaction survey.

Methods: We performed an observational cross-sectional survey study using a modified version of the Leeds Satisfaction Questionnaire (LSQ), a validated and reliable tool developed for inflammatory arthritis (IA) outpatient clinics, to compare satisfaction between the two patient groups: On-TRAAC and the traditional model of care (TMC). The six groups included in the questionnaire's subscales, and thus assessed with this survey included: (1) provision of information, (2) empathy with the patient, (3) attitude towards the patient, (4) access to and continuity with the caregiver, (5) technical competence and (6) overall satisfaction. A sub-group analysis of patient satisfaction between the first and second visit in the On-TRACC group was also performed. Markers of disease activity including DAS 28-CRP, HAQ (Health Assessment Questionnaire) and CRP were assessed over time in the On-TRACC group.

Results: A total of 75 patients completed the survey (27 patients in the On-TRAAC group and 48 in the TMC). The average age of the participants was 53 years and included 24 males and 51 females. The overall satisfaction score was 4.36 in the TMC group and 4.48 in the On-TRAAC group (higher values represents higher satisfaction). Ten patients in the On-TRAAC group performed the survey at least twice and showed an overall trend towards improved satisfaction on subsequent visits with an initial overall satisfaction score of 4.48 and follow up score of 4.55. No statistically significant differences were noted between groups, or within the On-TRACC group. Within the On-TRACC group, markers of disease activity including DAS 28 CRP, HAQ and CRP all showed improvement between baseline and follow-up visits.

Conclusion: While patients in both treatment groups were very satisfied with their care, patients in the On-TRACC group were at least as satisfied with their care as those in the TMC, and there was a trend towards improved satisfaction with the multi-disciplinary care model. This has important implications as it lends support to the use of this alternate model of care in the provision of services to those with IA, which has potential benefits from both a clinical and health economics perspective. Larger patient numbers with longer follow-up are needed to provide meaningful comparisons between these different models of care. Table 1. Baseline characteristics and overall satisfaction

Characteristic	On Tracc Group (n=27)	TMC (n=48)
Mean age (Range) ± SD	50.6 years (22-85) ± 16.63	54.4 years (18-87) ± 16.39
Gender	6 Male (22%) 21 Female (78%)	18 Male (37.5%) 30 Female (62.5)
Duration of Inflammatory Arthritis	< 1 year = 8 (30%) 1-5 years = 6 (22%) > 5 years = 13 (48%)	< 1 year = 6 (12.5%) 1-5 years = 22 (46%) > 5 years = 20 (41.5%)
Ethnic Origin	22 Caucasian (81%) 2 Asian (7.5%) 2 First nations (7.5%) 1 Mixed ethnicity (4%)	Unknown
Smoking Status	2 Current smokers (7%) 8 Ex-smokers (30%) 17 Never smokers (63%)	Unknown
Baseline CRP	5 patients < 1 (19%) 20 patients > 1 (74%)	Unknown
Baseline DAS 28 CRP	10 patients < 2.6 (37%) 15 patients > 2.6 (56%)	Unknown
Overall Satisfaction	4.48	4.36

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-reported outcomes (PROs) are key to enabling the comprehensive assessment of patient-centered benefits in comparative effectiveness research (CER). However, the relationships between different PROMIS instruments and condition-specific disease activity measures in diseases such as rheumatoid arthritis (RA) have not been well studied. The objectives of this analysis were to evaluate the longitudinal relationship between different PROMIS instruments and the RAPID3, a measure of self-reported patient disease activity.

Methods: Four PROMIS instruments: pain interference, physical function, sleep disturbance, and fatigue as well as the RAPID3 were administered to participants in the PCORI-funded ArthritisPower patient registry. After descriptive analytics, we estimated multiple correlations between PROMIS instruments and the RAPID3. For each PRO instrument and with each assessment used as the unit of measure, we used model of fit, also called R-squared (the proportion of variance of outcomes that can be explained by the predictors), calculated from mixed models to understand how longitudinal PROs were related to each other. Using pain as an example, we evaluated the R-squared for each model with additional PROs and demographic factors including enrollment age, sex, race, twitter account, region and visit times.

Results: A total of 1,546 unique participants who answered the survey one or more times was included in the analysis, with mean (SD) age of 49 (12) years. The mean score for pain interference was 63.7 (SD: 7.0), physical function 37.5 (7.1), sleep disturbance 58.4 (8.7), fatigue 63.8 (8.8), and RAPID3 15.5 (5.7). Most PROMIS instruments were low to moderately (around 0.2) correlated with each other and the RAPID3. Using pain interference as an example, R-squared measures revealed a high total variance explained (R^2=49%) between pain interference and physical function (Table); those involving pain, physical function, fatigue, sleep disturbance and RAPID3 also revealed a higher variance contribution with these additional PROs (66%). Additional adjustment for demographic factors added little variance explanation (1.4%).

Conclusion: PROMIS pain interference, physical function, sleep disturbance, fatigue instruments and RAPID3 are low to moderately correlated to each other. Age, gender, race and other demographic factors play little role in explaining variance in PROs. These results suggest potential efficiencies in using some measures to predict or impute the values for other measures and to optimize the frequency of patient data collection using at-home technologies including Smartphone Apps.

Table: Total variance explained by predictors (R-Squared) using PROMIS pain interference as the dependent variable		
Models with PROMIS pain interference as the dependent variable	**Pain variance that was not able to explained by predictors**	**Total pain variance that could be explained by predictors (R-Squared)**
Baseline model: no predictors	42.6	N/A
Model with predictors: PROMIS physical function	22.6	46.9%
Model with predictors: PROMIS physical function, sleep	20.7	51.6%
Model with predictors: PROMIS physical function, sleep, fatigue	18.7	56.1%
Model with predictors: PROMIS physical function, sleep, fatigue, RAPID3	15.3	64.1%
Model with predictors: PROMIS physical function, sleep, fatigue, RAPID3 and others (age, gender, race, region, etc.)	15.1	64.7%
Model with only demographic predictors: age, gender, race, region, etc.	42.3	0.7%

Familiarity Vital for Telemedicine Uptake Among Parents of Pediatric Rheumatology Patients

Danielle R. Bullock[1], Richard K. Vehe[2], Lei Zhang[3] and Colleen K. Correll[1], [1]Pediatrics, University of Minnesota, Minneapolis, MN, [2]Department of Pediatrics, University of Minnesota, Minneapolis, MN, [3]University of Minnesota, Minneapolis, MN

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The United States pediatric rheumatology (PR) workforce is committed to a mission of providing children access to PR care. With a limited number and distribution of pediatric rheumatologists, telemedicine has been proposed as one way to meet this mission. Because low familiarity with telemedicine is a known barrier to successful implementation, the purpose of this study was to assess familiarity with telemedicine and how this influenced opinions about this modality among parents/guardians of PR patients in the Upper Midwest.

Methods: For six weeks in 2015, English-speaking guardians of patients being evaluated at the University of Minnesota

Pediatric Rheumatology Clinic were eligible to participate in a needs-assessment survey. Responses were analyzed using descriptive statistics.

Results: Of 221 participants eligible for the survey, 159 (72%) responded. The majority were guardians of adolescent Caucasian patients and had private insurance. The most common diagnosis was juvenile idiopathic arthritis, and 28% (45/159) traveled more than three hours to the clinic. Only 8% (13/158) of respondents reported that they or a family member or friend had ever used telemedicine, and the majority of respondents (75%, 115/154) felt that they did not know enough about telemedicine to determine if such visits are better, equal, or worse to in-person visits. Fifteen percent (23/154) felt that telemedicine visits are worse than in-person visits, and 10% (16/154) felt that telemedicine visits are either equal or better. Those familiar with telemedicine were more likely to report a preference for telemedicine over in-person visits (27% vs 3%; p=0.0087). They were also more likely to report telemedicine visits as equal to or better than in-person visits (42% vs 8%; p=0.0033), and 60% (3/5) of these respondents preferred telemedicine visits themselves. Still, an overwhelming majority of respondents (95%, 144/152) reported a preference for in-person visits over the option of telemedicine, and this preference persisted even when travel to the clinic was reported as inconvenient (inconvenient 92%, convenient 97%; p=0.2881). Neither views on telemedicine visits compared to in-person visits nor preference for in-person visits significantly differed by patient demographics, insurance type, length of time the child was a patient in the clinic, travel time, or frequency of internet use.

Conclusion: Most respondents prefer in-person visits over the option of telemedicine; however, familiarity with this modality was low, and most did not feel that they knew enough to assess the quality of telemedicine visits. Familiarity with telemedicine positively influenced both a preference for telemedicine and the assessment of the quality of telemedicine. Sample bias existed because only those who came to the PR clinic were surveyed. Efforts to increase familiarity with telemedicine may foster increased acceptability and are therefore vitally important when implementing a telemedicine program.

Patient-Clinician Co-Participation in Design of an App for RA Management Via Telehealth Yields an App with High Usability and Acceptance

Rebecca Grainger[1,2], Tobias Langlotz[3], Hermaleigh Townsley[4] and William Taylor[1,5], [1]University of Otago Wellington, Wellington, New Zealand, [2]Wellington Regional Rheumatology Unit, Hutt Valley District Health Board, Lower Hutt, New Zealand, [3]Department of Information Science, University of Otago, Dunedin, New Zealand, [4]Department of Medicine, University of Otago Wellington, Wellington, New Zealand, [5]Wellington Regional Rheumatology Unit, Hutt Valley District Health Board, Wellington, New Zealand

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Traditional management of rheumatoid arthritis (RA) is by rheumatologist review 3 to 6 monthly. This is not sustainable in many healthcare systems as demand exceeds rheumatologist capacity, with these demands projected to increase. Mobile software (an application or app) could enable patients to provide remote monitoring of health status via patient reported outcomes (PROs), patient-performed joint counts and electronic messages to health care professionals (HCP). This worked aimed to 1. Assess opinions of people with RA and HCP regarding design and functionality of an app and acceptability and usefulness of an app assisted telehealth approach for RA 2. Develop an app and 3. Assess usability of the app.

Methods: Semi-structured interviews were undertaken with people with RA (ACR 2010 criteria) and HCP, recruited

from a hospital rheumatology service. Interviews explored technology use, app functionality, barriers and facilitators to app use and potential impacts of app implementation on service provision and experience. Thematic analysis was performed and recruitment concluded when saturation achieved. An app (RAConnect) was developed in iOS and android with design and function informed by interview data. People with RA used RAConnect on their mobile devices for one month then usability was assessed (System usability scale) and free text feedback collected.

Results: Nine people with RA (27-79yrs, 7 females, 1-26yrs of RA, low-moderate disease activity) and 11 HCP were interviewed. Four themes were identified 1. Variable app readiness. 2. Reduced barriers with high app usability and text message communication. 3. Pros and cons of PROs, with some ambivalence 4. Resource allocation and engagement - PRO reporting via an App is acceptable to guide HCP in allocation of limited resource while also increasing patient engagement. Usability testing with 16 people with RA confirmed RAConnect had high usability (SUS 80/100, 90th centile). Both the app and a telehealth approach had high acceptability. "*I think a wraparound thing like RAConnect would allow better spacing between appointments and for me it would make them less stressful*."48Male "*I think that it has the potential to be very useful in managing my RA. It is easy to use and may mean less visits to the rheumatologist*." 49Male. "*It'll be a great tool for both the Doctors, their clinical staff and their patients."* 70Female.

Conclusion: A patient-held app for RA monitoring and communication with rheumatology care provider will be acceptable and desirable for many patients. Further research is required to develop multi-media material to train people with RA to perform joint counts and to validate patient-performed joint counts. During implementation assessment of the patient experience of using this telehealth system, disease outcomes, costs and impact on workflow of HCP will be required.

2015 ACR/ARHP Workforce Study (WFS): Adult Rheumatology Specialists in the United States: Effect of Gender and Generation

Chad Deal[1], Marcy B. Bolster[2], Jonathan S. Hausmann[3], Daniel Battafarano[4], Seetha Monrad[5] and Marcia Ditmyer[6], [1]Orthopedic and Rheumatology Institute, Cleveland Clinic Foundation, Cleaveland, OH, [2]Massachusetts General Hospital, Boston, MA, [3]Rheumatology, Beth Israel Deaconess Medical Center, Boston, MA, [4]Medicine, San Antonio Military Medical Center, San Antonio, TX, [5]Internal Medicine/Rheumatology, University of Michigan, Ann Arbor, MI, [6]University of Nevada, Las Vegas, NV

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Workforce surveys are essential to plan for training, recruitment, practice management, funding, and access to care. Gender and generational differences may have significant effects on the future rheumatology workforce. The 2015 WFS provides a description of the current workforce and projected supply and demand models for 2015-2030.

Methods: Web-based surveys were distributed to U.S. rheumatology professionals and Fellow-in Training (FITs). Supply (current providers, new graduates, retirement/workload trends, practice settings) and demand (healthcare utilization, practice trends, disease prevalence, population demographics, per capita income) factors were calculated.

Results were compared with the 2005 rheumatology workforce study.

Results: The response rate was 38.5% from adults (1297/3366) and 93.4% from FITs (464/497). The supply/demand model predicts a 31% decline in clinical FTE supply from 4,997 to 3,455 by 2030, and a 138% increase in demand from

6,155 to 8,184 by 2030, generating an excess demand for 4,729 adult rheumatologists. Gender/generational effects were subsequently estimated. The current adult workforce is 59% men and 41% women. In 2015, annual patient visits were 3,133 for men and 2,249 for women rheumatologists, compared with 2005 a decline of 14% for men and 19% for women overall and 17% for men and 35% for women rheumatologists under age 40. By 2030, women are projected to comprise 59% of the workforce. Millennials (born 1982-2004) comprise 6% of the current workforce and 50-75% of the 2030 workforce. Since 2005, there has been a reported 5% decrease per week in patient load for millennials which had a synergist effect when added to gender-generational modeling. 18% of current fellows reported planning part-time employment, 90% of whom were women. The declining clinical FTE relates to rising women/male ratio, millennials, and part-time workers.

Conclusion: The rheumatology workforce will be primarily millennial women by 2030, with the shift from a majority of men to women projected to occur between 2018 and 2020. Since women comprise the majority of part-time workers, and conduct fewer patient annual visits, this has significant implications for rheumatology supply. The millennial generation brings a higher percentage of women into the rheumatology workforce and greater emphasis on work-life balance for both sexes resulting in a predicted reduction in patient visits, clinical FTEs per rheumatologist and overall working hours. Whether millennials will continue working fewer hours throughout their careers is unknown. Women, the majority of our future workforce, are more likely to work part-time. Millennials, both men and women, see a lower patient volume at a time when demand for rheumatology FTEs will increase. The next decades bring challenges for rheumatology requiring innovative approaches to provide access to care for patients.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a unique inflammatory arthritis that affects the skin, nails, and the joints. Most of the patients consider PsA to have a significant effect on their quality of life, which significantly impairs work productivity and daily activities. The aim of this study was to determine the long-term effects of anti-TNF agents on work productivity measures in patients with PsA.

Methods: Male or female patients with confirmed diagnosis of PsA and initiated an anti-TNF treatment were enrolled and followed-up for 9 months in this multi center, prospective, observational post marketing study. Patients evaluated workplace and household productivity by completing Work Productivity and Activity Impairment (WPAI) questionnaire and assessed global assessment of disease activity, pain, and fatigue using a visual analogue scale (VAS) at baseline and every 3 months until 9th month visit. Disease Activity Score 28 (DAS-28) was evaluated by the physicians at each visit according to the American College of Rheumatology Response Criteria for rheumatoid arthritis. Patients enrolled between January 2014 and April 2016 were included in this initial statistical analysis.

Results: A total of 120 patients were included in this study and 55.0% of the patients were female. Mean (±SD) age was 41.5 (±11.1) years and mean time since diagnosis of PsA was 6.7 (±6.5) years. Mean duration of anti-TNF treatment was 8.9 (±2.2) months. Significant improvements were observed in the number of swollen and tender joints, as well as score of enthesitis and dactylitis at the end of the study comparing to baseline ($p<0.001$). At each visit an improvement in DAS-28 scores was observed when compared to the previous visit ($p<0.001$). Throughout the study, all patient reported VAS scores (global assessment of disease activity, nocturnal back pain and fatigue, total back pain, global assessment of pain and fatigue) reduced significantly ($p<0.001$). Mean number of missing working days was significantly reduced (5.3 vs. 1.3 days; $p<0.001$), however the numerical increase in mean number of working hours was not statistically significant when compared to baseline (39.5 vs. 45.6 hours; $p=0.126$). Patients experienced an improvement in work productivity on the basis of missed hours during the last 7 days due to health problems ($p<0.001$). Patient reported WPAI scores revealed that during anti-TNF treatment, health related problems that effect productivity were significantly reduced ($p<0.001$).

Conclusion: Patients with PsA experienced a significant improvement in their clinical evaluations and work productivity during long-term anti-TNF treatment.

Table 1. Mean results at each visit and statistical significance

	N	Mean	p
Mean number of missing working days (per month)			
Baseline	106	5.3	
3rd month visit	87	2.9	**<0.001**
6th month visit	81	1.7	
9th month visit	73	1.3	
Mean number of working days (per week)			
Baseline	106	6.1	
3rd month visit	87	6.0	0.194
6th month visit	83	6.0	
9th month visit	75	5.5

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is recommended that management of rheumatoid arthritis (RA) requires regular quantitative assessment of RA activity. Treat to target management could be facilitated by use of smartphone applications ("apps") for input, storage, and transmission of validated RA disease activity measures. These data could be used by rheumatologists in clinical practice or by people with RA. However, potential users of apps must have confidence in app quality. This review assesses the functionality and quality of apps for RA disease activity monitoring by: 1) systematically identifying apps for monitoring of RA; 2) summarizing and comparing features to RA disease activity monitoring guidelines; and 3) rating app quality according to the recently developed Mobile App Rating Scale (MARS)[1].

Methods: A systematic search of the Google Play and iTunes stores was conducted to identify smartphone apps designed for measurement of RA disease activity by people with RA and rheumatologists. Apps were excluded if: 1) content was for information, education, or reference only; 2) for use by clinicians only: 3) only included treatment algorithms; or 4) were not in English. Android and iOS Apps were downloaded to smartphones and features/functionality described then apps rated by two independent reviewers using the MARS. App features were compared with EULAR and ACR recommendations for monitoring of RA disease activity.

Results: The search identified 721 apps in the Google Play store and 216 in iTunes store, of which 19 unique apps met criteria for inclusion (16 Google play, 11 iTunes store, 8 both). Fourteen apps included at least one validated instrument for measurement of RA disease activity. Eleven apps allowed users to enter a joint count (homunculus n=4, number of joints n=7). Eight of these apps used the standard 28 swollen and tender joint count and functioned as composite disease activity (CDA) calculators, with no capacity to store data. Eight apps included at least one ACR/EULAR recommended RA CDA measure but only one provided the formula for calculation. Ten apps included data recording, storage, and retrieval. Only one app, Arthritis Power, included both a RA CDA measure and tracked data but this app did not include the standard 28 joint count. The median MARS score for apps was 3.41 (maximum 5). Of the five apps which scored >4/5 on the MARS rating, only one included a CDA score endorsed by ACR/EULAR but this app did not have a data tracking function.

Conclusion: No current apps for RA have functionality for entry of validated disease activity instruments, composite disease activity measures including 28 joint counts, and allow tracking of these data. Current apps are configured as calculators for rheumatologists or tracking tools for people with RA. The latter do not uniformly collect data using validated instruments. Apps which were higher quality according to the MARS collected only patient reported outcomes. Collaboration between rheumatologists, people with RA, app developers and health systems is required to develop appropriate, high quality apps for use by rheumatologists and people with RA in co-management of RA. 1. Is Patient Support Program (PSP) Participation Associated with Longer Persistence and Greater Adherence Among New Users of Adalimumab?

Einav Srulovici[1,2], Vishvas Garg[3], Adi Ghilai[2], Becca Feldman[2], Moshe Hoshen[2], Ran Balicer[2], Martha Skup[4] and Maya Leventer-Roberts[2], [1]School of Nursing, University of Haifa, Haifa, Israel, [2]Clalit Research Institute, Clalit Health Services, Tel Aviv, Israel, [3]AbbVie Inc, North Chicago, IL, [4]AbbVie Inc., North Chicago, IL

First publication: September 28, 2016

SESSION INFORMATION

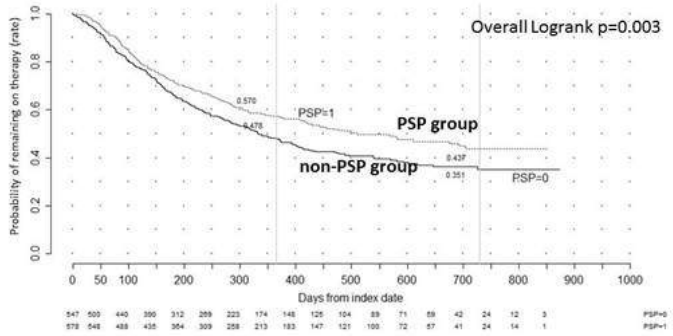
Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In Israel, patients treated with adalimumab (ADA) can enroll in a patient support program (PSP) provided by AbbVie, which includes a home visit by a registered nurse, telephone calls, and outreach by mail. Clalit Health Services (CHS), a payer/provider system with over four million members, maintains a complete electronic medical record database, which can be used to track the effect of PSP on outcomes. The objective of this study was to examine whether PSP participation is associated with a longer persistence and/or a greater adherence to ADA.

Methods: This is a retrospective cohort study of new ADA users, comparing PSP enrollees (PSP group) vs. those that did not enroll (non-PSP group) using patient-level data from the CHS database. The index date was defined as the date of the patients' first purchase of ADA occurring between 01/08/2012 and 31/12/2014. Demographic and clinical characteristics were compared between groups at baseline. Persistence was assessed using survival analyses of time until discontinuation, defined as the date of the last purchase or prescription preceding a 90-day gap without a purchase. Adherence (medication possession ratio) among patients persistent on ADA was compared between PSP and non-PSP groups using the *Mann-Whitney U test* during the 0-6 months, 0-12 months, and 12-24 months following the index. Subgroup analyses were conducted by clinical indications (rheumatoid disease (RD), inflammatory bowel disease (IBD), and dermatologic disease).

Results: There were 755 patients in the PSP group and 765 in the non-PSP group who met the inclusion criterion. Baseline characteristics were similar between cohorts. Among those with at least 6 months of follow-up post-index date, the PSP group had significantly longer mean persistence as compared to non-PSP group (319 vs. 298 days, respectively; p=0.003). Subgroup analyses yielded similar findings for the clinical indications of RD (p=0.015) and IBD (p=0.031). Further, at 12 and 24 months, the PSP group was more likely to be persistent on medication as compared to the non-PSP group: 57.0% vs. 47.8% (p=0.002) and 43.7% vs. 35.1% (p=0.003), respectively (**Figure**). The mean adherence rates among those with varying lengths of persistence were all greater than 80%. The 6-month adherence rate among those with at least 6 months persistence was significantly greater for the PSP group compared to the non-PSP group (p=0.024). Subgroup analyses yielded similar finding in the clinical indication of RD (p=0.046)**.**

Figure. Survival Analysis of Time to Discontinuation in the PSP vs. Non-PSP groups



Conclusion: A patient support program provided by Abbvie was associated with a longer persistence among new users of ADA. It was also associated with a higher adherence rate within the first 6 months.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The 2015 ACR Workforce study updated the current and projected adult rheumatology workforce for the next 15 years.

Methods: The 2015 ACR/ARHP Workforce Study was completed using several primary and secondary data sources, including, ACR member database, state licensure registries, 2005 ACR workforce study, professional organizations, and other medical literature. These data were supplemented with a web-based survey about work settings, practice patterns, retirement planning, and demographics. Utilizing an integrated workforce modeling methodology, supply and demand projections were computed for adult rheumatologists from 2015-2030. The factors affecting supply included the current adult rheumatology workforce, demographic changes, the number completing fellowships, retirement trends, patient workload and practice settings. Multivariate regression modeling was used to determine significant factors affecting demand. These included healthcare utilization, provider practice trends, disease prevalence, population demographics, per capita income and access to care trends. Clinical FTE was defined as 1.0 FTE for private practice and 0.5 FTE for academic practice. It was assumed that 80% of the adult rheumatology workforce was in private practice vs. 20% in academic practice.

Results: The 2015 ACR current adult workforce is estimated to be 5,595 providers (4,497 Clinical FTE). A comparison of the actual vs. clinical FTE projections from 2015 through 2030 are presented in Figure 1. The estimated excess demand for 2015 is 1,118 (6,115 demand-4,997 supply) which equates to an excess demand of approximately 36%. By 2030, the Clinical FTE is projected to be 3,455, a 31% decrease from 2015. A projected demand of 8,184 translates into an excess demand of 4,729 (138% increase) from 2015. Projected trends are similar to those from the 2005 workforce study (Figure 2). These trends are likely due to increase in aging population/retirements, coupled with the decrease in clinical FTE relative to increases in number of females, part-time workers, and millennials.

Conclusion: The rheumatology workforce projections reflect a significant shift in the mix of the future workforce by 2030. Over the next 15 years, baby boomer retirements, a millennial predominance, and a female gender shift, will parallel an increased demand in adult rheumatology care. Regional and innovative strategies will be necessary to manage access to care and reduce barriers to care for rheumatology patients.

Figure 1. Comparison Total Numbers vs. Clinical FTE for Adult Rheumatologists

Figure 2. Comparison of Projected Supply and Demand of Adult Rheumatology Workforce

Performance of the Patient Reported Outcomes Measurement Information System (PROMIS) Measure for Physical Function in Early RA

Till Uhlig, Inge C Olsen, Anna-Birgitte Aga, Siri Lillegraven, Tore K Kvien and Espen A. Haavardsholm, Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Patient Reported Outcomes Measurement Information System (PROMIS) initiative has developed and calibrated item banks for the assessment of physical function and other domains chronic diseases. Our objective was to assess the construct validity of PROMIS 20 items for physical function (PROMIS PF-20) in patients with early rheumatoid arthritis (RA).

Methods: RA patients who fulfilled the ACR/EULAR 2010 classification criteria, with <2 years from first patient reported swollen joint and who were DMARD naïve with indication for DMARD treatment were included in the tight control treat-to-target ARCTIC trial. The 230 patients were at baseline assessed with PROMIS PF-20 which had been translated to Norwegian according to recommended procedures. Other assessments were disease activity score based on 44 joints (DAS), patient global assessment of disease activity, investigator global assessment, pain and fatigue on 100 mm visual analogue scales, and health related quality of life (SF-36) with physical (SF-36 PCS) and mental (SF-36 MCS) component summaries. Patients were grouped according to DAS as low (<2.4), moderate (>2.4 and <3.7), and high (>3.7) disease activity. Pearson's correlation coefficient is used to assess correlations, and Analysis of Variance (ANOVA) to assess difference between DAS groups.

Results: The mean (SD) age for the 230 patients in ARCTIC was 51.4 (13.7) years, disease duration 7.1 (5.4) months, DAS 3.5 (2.0), 61.0% were females and 82.2% anti-CCP positive. Correlations between PROMIS PF-20 and many other outcomes were mainly moderate to high (patient global -0.68, pain -0.66, SF-physical functioning scale 0.83, and SF-36 PCS 0.82), but associations were lower for investigator global -0.44, fatigue -0.38, and SF-36 MCS 0.23 (all p<0.001). The table shows how higher DAS levels discriminate PROMIS PF-20 and other outcomes. **Table**: Scores according to disease activity groups (Means and SD)

	Low DAS N=43	Moderate DAS N=102	High DAS N=85	P-value (ANOVA)
PROMIS PF-20	46.0 (9.1)	40.4 (7.4)	34.0 (6.7)	<0.001
Patient global (VAS)	30.8 (21.1)	45.2 (21.2)	64.8 (20.4)	<0.001
Pain (VAS)	30.4 (21.9)	44.7 (21.2)	60.4 (21.6)	<0.001
Fatigue (VAS)	30.7 (28.1)	38.9 (26.4)	47.2 (30.2)	0.006
SF36 PCS (0-100)	43.5 (9.6)	37.7 (8.0)	31.0 (8.1)	<0.001
SF36 MCS (0-100)	49.7 (10.6)	49.9 (10.1)	47.9 (11.0)	0.39
Investigator global (VAS)	20.6 (11.7)	34.2 (14.2)	58.3 (16.5)	<0.001

Conclusion: Evaluation of physical function applying the PROMIS PF-20 was feasible, and our results support construct validity of the instrument.

An Analysis of Malpractice Litigation in Rheumatology

Arpan Prabhu[1], Raghav Gupta[2], Ranjit Thomas[3] and Chester V. Oddis[4], [1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]Rutgers New Jersey Medical School, Newark, NJ, [3]Tufts University, Medford, MA, [4]Rheumatology/Clinical Immunology, University of Pittsburgh, Pittsburgh, PA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Medicine is an increasingly more litigious environment, and the probability of a practitioner facing a medical malpractice claim is high. Given the tumultuous liability insurance climate, and a shift in the public attention towards curbing the practice of defensive medicine, an understanding of medical malpractice claims is prudent. To the authors' best knowledge, no studies have provided an analysis of malpractice litigation in the subspecialty of rheumatology. This study delineates the medico-legal factors that compel plaintiffs to file medical malpractice claims related to the management of rheumatic diseases.

Methods: The online legal database, WestLaw, was searched to delineate all medical malpractice cases related to rheumatology across a 31-year period from 1985-2015. All state and federal jury verdicts and settlements relevant to the search criteria were considered.

Results: A total of 30 rheumatic disease malpractice cases were evaluated in this 31-year period. Ten cases were excluded from the analysis due to duplicity or lack of relevance to rheumatology. The average age of the patient was 51.9 years, and 45 percent were female. The cases were distributed across 10 states. The jury found in favor of the plaintiff in 20 percent of cases with a mean payout of $2,776,364, and in favor of the defendant in 60 percent of the cases. A failure to diagnose and/or a failure to treat in a timely manner were the two most commonly alleged causes of malpractice. Settlements were reached in 15 percent of the cases with most payouts undisclosed. Rheumatologists accounted for 33.3 percent of all named defendants.

Conclusion: In the case of rheumatic disease, a majority of the verdicts were in favor of the defendant, and settlements were reached in the minority of cases. When the verdict favored the plaintiff, mean payouts were substantial at over $2 million. Rheumatologists accounted for a small percentage of all co-defendants.

Transforming Healthcare in Rheumatology: From Inpatient to Outpatient Care without Reductions in Healthcare Quality

Andreas P Diamantopoulos[1,2] and Timothy T Brown[1], [1]Public Health, University of California, Berkeley, Berkeley, CA, [2]Rheumatology, Haugesund Hospital for Rheumatic Diseases, Haugesund, Norway

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The implementation of a major program to improve the quality of care in inflammatory arthritides (rheumatoid arthritis-RA, spondyloarthritis- SpA and psoriatic arthritis- PsA) included the increased use of biologics and shifting clinically appropriate cases from inpatient to outpatient care, in response to patient preferences. These changes led to a significant improvement in patient outcomes, reductions in the number of inpatient days of care, and increases in the use of outpatient care. This is the first study to examine the reimbursement and patient outcome implications of this quality improvement program, which is similar to other programs being implemented across Norway and internationally. The aim of this study is to examine quantitatively the changes in reimbursements and patient outcomes associated with this programmatic change in inflammatory arthritides.

Methods: This prospective observational study was performed at the Department of Rheumatology, Hospital for Rheumatic Diseases in Haugesund, Norway. Before May 2016 the Department of Rheumatology required 22 inpatient beds. After 1 May 2015 the quality improvement program was implemented, including a major switch from inpatient to outpatient healthcare, and the number of beds required was reduced to 6. The Diagnosis related group (DRG) system was used to measure the clinical production of the department for the period from May 1 to December 31, 2015 and compare it

to the same period in 2014. One DRG point is reimbursed at 21 000 Norwegian Krones (US$2520). The mean Modified Health Assessment Questionnaire (MHAQ) for patients with RA and PsA and mean BASFI (Bath Ankylosing Spondylitis Functional Index) for SpA were used as outcome measures indicating the quality of care provided.

Results: From May 1 to December 31 2014, 981 admissions were recorded, while during the same period in 2015 the number was reduced to 534. The production of the inpatient unit from May 1 to December 31, 2014 was 871 DRG points while during the same period in 2015 production was reduced to 623 DRG points. The number of outpatient clinic consultations increased from 4 397 in during the same period of 2014 to 5 588 in during the comparable period in 2015 and the number of DRG points increased from 539 to 654, respectively. The mean MHAQ (RA and PsA) and mean BASFI (SpA) at the end of December 2015 were 0.47 and 3, respectively, while in December 2014 the comparable measures were 0.47 and 3, respectively (p=1 and p=0.9). In total 2 800 000 NOK (335 000 USD) was saved during the study period compared to 2014.

Conclusion: Switching from inpatient to outpatient care for patients with inflammatory arthritides leads to lower costs and reduced number of medical errors without any reductions in quality of health care provided. These encouraging results should be further confirmed in larger studies.

Effects of DMARD Tapering on Treatment Costs and Work Productivity in Rheumatoid Arthritis Patients- an Analysis from the Prospective Randomized Controlled RETRO- Study

Background/Purpose:

Achieving remission is the most important treatment goal in patients with rheumatoid arthritis (RA). With the development and wider use of highly effective disease modifying anti-rheumatic drugs (DMARD) about half of RA patients reach a state of disease remission, raising the question about tapering or stopping anti-rheumatic treatment. The aim of this study was to assess the effect of a controlled DMARD tapering regimen on treatment costs and work productivity in RA patients in remission.

Methods:

101 RA patients in sustained remission (DAS28 <2.6 for more than 6 months), enrolled in the multicenter randomized controlled RETRO Study, were analyzed (1). Patients either continued DMARDs (arm1), tapered dose by 50% (arm 2) or entire stopped DMARDs after tapering (arm 3) for one year. Assessment of DMARD costs and work productivity was done every three months in all 101 patients including those remaining in remission and those relapsing a re-starting their original DMARD regimen.

Results:

RA patients treated with conventional DMARDs, baseline quarterly treatment costs of 154€ remained stable in arm 1 (156€), while decreasing to 81€ in arm 2 and 75€ in arm 3. In patients treated with biologic DMARDs quarterly treatment costs were 5,708€ at baseline. They remained stable in arm1 (5,533€) and decreased to 3,036€ in arm 2 and 2,668€ in arm 3. Overall DMARD costs were reduced by 327,292€ within one year, while outcome was very good with patients either remaining in remission or immediately regaining remission when exposed to original DMARD regimen after relapse.

Conclusion:

Controlled tapering of DMARD treatment leads to effective reduction of treatment costs in RA patients in sustained remission.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The increasing uptake of smartphones and health apps provides opportunities for epidemiological studies to collect regular information from large numbers of people. This offers temporally-rich self-reported data as well as access to novel data such as geolocation. However, the extent to which participants will join and remain engaged with such studies over time is not clear. It is also unclear whether certain subgroups will remain more engaged than others, introducing possible selection bias. *Cloudy with a Chance of Pain* is a UK smartphone-based study investigating the link between the weather and pain in people with chronic pain. This study aimed to examine patterns of engagement and factors associated with it over the first six months.

Methods: Eligible participants in this study were recruited between 01/20/2016 and 02/29/2016. Follow-up data were available until 06/14/2016. After completing baseline characteristics, participants received daily prompts to complete a motif of 10 symptoms including pain, fatigue, and mood. Participants were categorised as 'active' if they reported data within the last 28 days of follow-up (05/17/2016-06/14/2016); we determined their rates of data completion prior to this period. Participants without data in the last 28 days were considered 'inactive'. The proportion of motifs completed was defined as the number of days with complete motifs divided by the number of possible complete motifs since recruitment. We examined differences between active and inactive participants, and between active users with high (≥80% motifs completed) and low (<80% motifs completed) engagement.

Results: We included 7124 participants reporting at least one symptom; 1459 (20%) were considered 'active'. Active participants were older (median (IQR): 54(45-62) vs 48 (40-58), p<0.001) and more likely to be female (83.4% vs 79.2%, p<0.001) compared to those inactive. Of the self-reported conditions, only headache and non-specific arthritis differed between active and inactive participants. Active participants completed 67% of possible motifs during the study period, compared to inactive participants who completed 8.7%. Of active users, 49% had high engagement throughout follow-up. Those with low engagement completed 43.2% of possible entries; only age was found to significantly differ between these groups (Table). Of the inactive participants, 1038 completed only one motif.

Conclusion: Following high initial recruitment, 20% of participants remained active after more than four months of data collection, half of whom provided data on more than 80% of eligible days. Engagement rates were higher in older participants. Although selection bias due to attrition needs to be considered when analysing results, these results suggest that our method is a viable and sustainable alternative to more traditional data collection.

	All participants (n=7124)		Of active users (n=1459):	
	Active (n=1459)	Inactive (n=5665)	High engagement (≥80% total motifs) (n=711)	Low engagement (<80% total motifs) (n=748)

Academic and Non-Academic Rheumatology: Practice Trends and Common Barriers to Practice from the 2015 ACR/ARHP Workforce Study Survey

Seetha Monrad[1], Daniel Battafarano[2] and Marcia Ditmyer[3], [1]Internal Medicine/Rheumatology, University of Michigan, Ann Arbor, MI, [2]Medicine, San Antonio Military Medical Center, San Antonio, TX, [3]Academy for Academic Research, Las Vegas, NV

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ten years have elapsed since the last ACR workforce study (WFS), and it is anticipated that rheumatologists will face many challenges to train and sustain a workforce of rheumatology specialists that will meet future needs. Analyzing the current workplace and identifying barriers to practice may help identify strategies and solutions.

Methods: As part of the WFS, a web-based survey was administered to the ACR membership, targeting clinically active practitioners. Survey responses were analyzed to compare demographics, practice patterns, retirement planning, and barriers to practice between rheumatologists working in academic work settings vs. those in non-academic work settings. Qualitative data was gathered regarding barriers to practice and assessed to identify common themes.

Results: There were a total of 1996 completed survey responses (31.5% response rate: 1996/6342) 1,578 of which provided information about practice setting and were included in the analysis; not every respondent answered every question. 54.5% (n=868) of respondents self-reported their primary work setting as non-academic (including solo practice, single- and multi-specialty, and government) vs. 45.5% (n=726) who reported working in academic settings. Demographics are listed in Table 1. Non-academics reported working slightly fewer hours per week than academics, but spent 50% more time seeing patients, and saw more than twice as many patients each week. Weak correlations were found in average reported work hours per week and patient workload ($r=0.227$; $p<0.01$) between academics and non-academics. 40% (n=348) of non-academic practitioners anticipate retiring in the next 10 years, compared with 29% (n=212) in academic settings. Almost 60% (n=391) of non-academic practitioners plan to reduce their patient load in the next ten years by up to 50%, compared to 40% (n=262) of academicians.

Table 2 lists the top 10 barriers to practice reported by respondents. Insurance issues and electronic health records (EHR) were the top two (2) barriers to practice reported by both those working in non-academic and academic settings. Two common areas of dissatisfaction were reimbursement rates (n=476; 29.8%) and requirements for EHR (n=457; 28.6%).

Conclusion: Despite a number of differences between current practitioners in academic vs non academics, rheumatologists identify common and pervasive barriers to practice regardless of practice setting. Advocacy efforts focusing on reimbursement levels and EHR implementation/use should be a high priority to help support the existing and future workforce.

Patient Support Program for Adalimumab-Treated Patients in Brazil: Impact on Patients' Adherence and Persistence

Roger A. Levy[1], Vanessa Teich[2], Roberta Fernandes[2], Anna Gulart[2], Leonardo Chaves[3], Vishvas Garg[4] and Martha Skup[5], [1]Rheumatology, Department of Rheumatology, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [2]Sense Company, São Paulo, Brazil, [3]AbbVie Inc., Chicago, IL, [4]AbbVie Inc, North Chicago, IL, [5]AbbVie Inc., North Chicago, IL

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Brazilian public healthcare system covers treatment with adalimumab for rheumatoid arthritis, Crohn's disease, ankylosing spondylitis and psoriatic arthritis, in line with local guidelines. Patients treated with adalimumab in Brazil can opt-in to a Patient Support Program (PSP) offered by AbbVie, which includes elements such as nurse and telephone support. The impact of this program on patient outcomes in the Brazilian setting has not been studied previously. The objective of the study is to evaluate the relationship of PSP enrollment and treatment utilization outcomes (adherence and persistence) among patients who initiate adalimumab.

Methods: Longitudinal data on the utilization of AbbVieÕs PSP were linked with the Brazilian Health System claims database called DATASUS, which includes data on patients that initiated treatment with adalimumab between 2013 and 2015. Patients using adalimumab in DATASUS not matched with AbbVie PSP database were categorized as non-users (non-PSP). Adherence was calculated using proportion of days covered (PDC), defined as the number of months of treatment with adalimumab divided by the number of months of patient follow-up. Patients were considered adherent if they had a PDC ³ 80%[1]. Persistence was calculated as the interval between treatment initiation and treatment discontinuation (defined as a gap of 90 days since the last obtainment of adalimumab). Adherence and persistence were compared between the PSP and non-PSP cohorts using *t* tests.

Results were segmented for patients with at least 6, 12 and 24 months follow-up. **Results:** 21,690 patients were included in the analysis: 3,313 in the PSP cohort and 18,377 in the non-PSP cohort. Patient characteristics were similar between groups: 63% were female, with an average age of 47 years (± 14.6). The percentages of patients with a PDC ³ 80% in the PSP vs non-PSP cohorts were: 89.4% vs 79.6% ($p<0.05$) in 6 months, 84.3% vs 68.6% ($p<0.05$) in 12 months and 77.6% vs 59.8% ($p<0.05$) in 24 months. The average treatment persistence in the PSP vs non-PSP groups were: 5.87 vs 5.73 months ($p<0.05$), 11.65 vs 11.05 months ($p<0.05$) and 22.37 vs 20.30 months ($p<0.05$) in the 6, 12 and 24 month time periods, respectively. Subgroup analyses by clinical indication showed consistent findings, in favor of the PSP, as displayed in Table 1.

Table 1: Differences in proportion of days covered (PDC) between patient support program (PSP) users and non-users segmented by disease, according to ICD-10 codes

Proportion of patients with PDC≥80%	PSP user	PSP non-user	Difference	p-value
Rheumatoid arthritis (M05.0, M05.1, M05.2, M05.3, M05.8, M06.8 and M08.0)				
6 months	88.5%	76.8%	11.7%	<0.05
12 months	81.2%	65.5%	15.7%	<0.05
24 months	77.5%	57.5%	20.0%	<0.05
Ankylosing spondylitis (M45 and M46.8)				
6 months	88.8%	82.0%	6.8%	<0.05
12 months	85.5%	71.0%	14.5%	<0.05
24 months	78.7%	62.5%	16.2%	<0.05
Crohn's disease (K50.0, K50.1 and K50.8)				
6 months	89.6%	82.6%	7.0%	<0.05
12 months	86.2%	71.9%	14.3%	<0.05
24 months	72.2%	60.6%	11.6%	<0.05
Psoriatic arthritis (M07.0 and M07.3)				
6 months	91.9%	81.9%	10.0%	<0.05
12 months	88.0%	72.1%	15.9%	<0.05
24 months	82.5%	63.6%	18.9%	<0.05

Conclusion: Across the indications studied, adalimumab users participating in the AbbVieÕs free-to-patient PSP demonstrated improved adherence and persistence to treatment compared to patients not participating in the PSP.

Rheumatology Care Utilization and Geographic Distance from Rheumatology Sites within the United States Veteran Affairs Health Care System

Jessica A. Walsh[1], Zachary Burningham[2], Chia-Chen Teng, MS[3], Daniel O. Clegg[4] and Brian C. Sauer, PhD[3], [1]University of Utah School of Medicine, Salt Lake City, UT, [2]SLC Veterans Affairs Medical Center, SLC IDEAS Center, Salt Lake City, UT, [3]Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [4]Division of Rheumatology, University of Utah Medical Center, Salt Lake City, UT

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Within the Veteran Affairs (VA) health care system, there are often large geographic distances between patients and rheumatology providers. The purpose of this study was to determine if Veterans with inflammatory arthritis (IA) living far from VA rheumatology sites utilize rheumatology providers and therapies less frequently than patients located close to rheumatology sites.

Methods: Veterans with IA were included if they had ≥2 international classification of diseases-9 (ICD9) codes for rheumatoid arthritis, psoriatic arthritis, or ankylosing spondylitis, prior to the beginning of the study period (January 1, 2014 to December 31, 2014). Geocoding was used to calculate the geographic distance between the coordinates of Veteran's home and the nearest VA site with rheumatology services. Exposure to medications was determined by medication dispensation. Primary and secondary stop codes were used to identify rheumatology encounters, defined as face-to-face visits with a rheumatology provider. Data sources included the national Corporate Data Warehouse and the Managerial Cost and Accounting Pharmacy dispensing data.

Results: The study included 75,804 Veterans, with 61.2%, 28.4%, and 10.4% living <40 miles, 40-99 miles and ≥100 miles from the nearest rheumatology site, respectively. The mean age ranged from 66.4 - 66.6, and 89 - 91% were male (Table 1). Rheumatology encounter(s) occurred for 43.7%, 33.7%, and 24.3% of Veteran living <40 miles, 40-99 miles and ≥100 miles from a rheumatology site, respectively (Figure 1). Higher percentages of Veterans living within 40 miles of a VA rheumatology site were exposed to non-biologic DMARD(s), biologic DMARD(s), and corticosteroid(s), compared to Veterans living 40-99 miles or >100 miles from a VA rheumatology site (Figure 2).

Conclusion: Rheumatology encounters occurred for fewer Veterans with IA living farther from VA rheumatology sites than Veterans living closer to VA rheumatology sites. Exposure to biologic DMARDs, non-biologic DMARDs, and corticosteroids was also associated with closer geographic proximity to VA rheumatology sites.

Table 1. Demographics, rheumatology encounters, and exposure to therapies

The 2015 American College of Rheumatology (ACR) Workforce Study: A Snapshot of Academic Division Directors

Marisa S. Klein-Gitelman[1], Daniel Battafarano[2], Seetha Monrad[3] and Marcia Ditmyer[4], [1]Div of Pediatric Rheumatology/PDD PTD, Lurie Children's Hospital of Chicago/NW University, Chicago, IL, [2]Medicine, San Antonio Military Medical Center, San Antonio, TX, [3]Internal Medicine/Rheumatology, University of Michigan, Ann Arbor, MI, [4]Academy for Academic Research, Las Vegas, NV

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The ACR has engaged in workforce studies as a mechanism to address ongoing and future needs of college members. In order to address needs over the next decade, the ACR developed and completed a workforce survey in 2015. The data included specific descriptive information about division directors (DD) who are critical to future training and research in rheumatology.

Methods: The ACR appointed a committee to develop a workforce survey in association with The Academy for Academic Leadership (AAL). The survey was completed on line by rheumatology professionals, fellows in training and patients with rheumatologic diseases. Secondary data included an environmental scan and comprehensive literature review. This abstract contains descriptive data obtained for rheumatology professionals who self-identified as division directors.

Results: There were 166 Division Directors who responded to the survey (61.5% (n=102) male, 37.3% (n=62) female and 1.2% (n=2) chose not to answer). The majority were adult rheumatologists (59.1%, n=94), 35.8% (n=57) were pediatric rheumatologists, 8 (5.1%) self-identified as Adult-Ped. A majority of respondents were between the ages of 46-65 (n=110; 69.1%), non-Hispanic (n=131; 82.9%), practicing over 20 years (n=84, 53.8%). The average number of years in their position was 10.3, with 27 (18%) reporting they have been in their position for more than 20 years with a preferred length as Director of 9 years. Over 40% (n=83) plan to retire in the next 10 years with 50% (n=78) planning on reducing their patient workload by up to 50% in the next ten years. Division Directors reported plans to recruit a total of 167 new faculty overall to 88 centers. Most clinical faculty recruits were for time in clinical practice and teaching with <25% effort in clinical research. Recruitment for translational or bench research and administrative positions were

unusual. Table 1 details retention and recruitment reported issues.

Conclusion: The DD survey reveals that the DD population is somewhat homogenous population who has served in their positions for lengthy periods. Most new recruitments are for clinical junior faculty. Recruitment and retention challenges involve inability to match salary, educational debt, no tenure, loss or lack of research funding and career advancement. There is a suggestion that improvement in divisional support and mentoring may promote retention in the academic workforce.

Table 1. Reported Retention and Recruitment Reasons

Most Common Reported Reasons	Retention - N(%)	Recruitment - N(%)
Educational debt	26 (10.0)	38 (14.0)
Inability to match salary	111 (42.5)	124 (45.8)
Tenure	9 (3.5)	7 (2.6)
Loss or lack of grant funding	48 (18.4)	80 (29.5)
Career Advancement	67 (25.7)	22 (8.1)

Table 2. **Most Common Reasons Reported for Leaving Academics**

- Lack of strong divisional and institutional support
- Difficulty obtaining funding for research and /or other activities
- Lack of autonomy of my practice schedule
- Desire for higher pay
- Desire for shorter work hours
- Inadequate mentoring
- Preference for community/clinical care
- Retired

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients are increasingly recruited from online communities to provide insight regarding their lived experiences and preferences for treatment and services. We compared physical, social, and emotional health patient reported outcomes in people with rheumatoid arthritis (RA) recruited from an online patient community with those seen in an arthritis clinic in one academic medical center.

Methods: Participants were recruited from 2 sources: a single academic rheumatology clinic, and www.creakyjoints.org, an online arthritis patient community. Clinic participants were selected through convenience sampling of patients. Online participants were invited via email and screened for probable RA using a modified version of the connective tissue screening questionnaire (CSQ) that added a DMARD checklist and questions concerning personal and family history of psoriasis to improve specificity for RA. Patients provided sociodemographic and disease information and completed PROMIS fixed item Short Forms (SF): Physical Function 4a/20a (PF), Pain Interference 4a/8a (PI), Fatigue 4a/7a/8a, Ability to Participate in Social Roles and Activities 4a/8a (PSRA), Depression 4a/8a, Anxiety 4a, and Sleep Disturbance 4a. PROMIS scores are reported as T-Scores with a population mean of 50 and SD of 10, with higher scores indicating more of the trait measured. Groups were compared using t-tests.

Results: Compared to clinic patients (n=52), online participants (n=200) had more education (69% vs 92% >High School), shorter disease duration (mean[SD]: 15[11] vs 10[10] yrs) and were more likely to be disabled due to RA (15% vs 32%) (all $p<0.05$), but did not differ by age, sex, or minority status. Most clinic participants were relatively well-controlled with 64.6% in LDA or remission; mean CDAI was 7 (SD 7). Scores comparing different length PROMIS SF for the same trait (e.g. fatigue) were similar. Compared with the US population, both groups had worse PF and greater PI and fatigue. Compared with clinic patients, online participants reported significantly greater impairments in PF (42[12]) vs 34[6]), PI (56[10] vs 65[7]), fatigue (55[14] vs 66[8]), PSRA (49[11] vs 39[7]), depression (50[11] vs 58[10]), anxiety (50[11] vs 58[9]) and sleep disturbance (51[10] vs 58[8])(all p's < .001).

Conclusion: These results suggest that patients recruited through online arthritis communities may differ in some demographic features from those seen in an academic clinic. On average, online participants reported significantly worse physical, social, and emotional health. A limitation of the study is the absence of information regarding disease activity, treatment, and comorbidities. Better understanding these differences will be important to improve generalizability of PRO results from online communities. Funding PCORI IP2-PI0000737 and SC14-1402-10818. **Table I. Comparison of selected RA symptoms and impacts between clinic and online patients.**

PROMIS short form	Clinic Mean (SD) N=52	Online Mean (SD) N=200	p value

Incremental Direct Expenditures Due to Osteoarthritis: A Nationally Representative Study Using Medical Expenditure Panel Survey Data

Jyothi Menon, Purdue University, West Lafayette, IN
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis is characterized by symptoms related to abnormalities in joints, subchondral bones and periarticular structures. In the United States, it was estimated that twenty-seven million adults suffered from osteoarthritis in 2005. The objectives of this study were to determine incremental health care resource utilization and incremental health care expenditures, associated with Osteoarthritis.

Methods: An observational database analysis was conducted using information from the Medical Expenditure Panel Survey (MEPS). Individuals 18 years of age or older and employed during 2011 were eligible for inclusion in the sample for analyses. Individuals were identified with Osteoarthritis diagnosis based on ICD-9-CM diagnosis codes. Out of a sample of 26,992 individuals, 1,354 were diagnosed with osteoarthritis. Using sampling weights provided, individuals with osteoarthritis were compared to individuals without osteoarthritis on health care resource utilization and expenditures.

Results: Compared to individuals with osteoarthritis, significantly lower mean unadjusted hospitalizations (0.24 v 0.09, $p<0.001$), mean unadjusted outpatient room visits (12.93 v 4.89, $p<0.001$) and mean unadjusted emergency room visits (0.33 v 0.22, $p<0.001$) were observed among those without osteoarthritis. Compared to individuals with osteoarthritis, significantly lower mean unadjusted inpatient expenditures ($3,563 v $1,1,91 $p<0.001$), mean unadjusted outpatient expenditures ($3,242 v $1,223, $p<0.001$), mean unadjusted emergency room expenditures ($295 v $ 187, $p<0.001$), and mean unadjusted medication expenditures ($2,336 v $962, $p<0.001$) and mean unadjusted total expenditure ($9651 v $3,415, $p<0.001$) were observed among those without osteoarthritis. Incremental health care resource utilization examined included annual hospitalization, annual hospital days, annual emergency room visits, annual outpatient visits. Incremental health expenditures examined included annual inpatient expenditures, annual outpatient expenditures, annual emergency room expenditures, annual miscellaneous expenditures, annual medication expenditures and annual total expenditures. Incremental resource utilization and incremental resource expenditures were estimated using regression models, adjusting for other covariates including age, gender, sex, region, marital status, insurance coverage, comorbidities, anxiety, asthma, hypertension and hyperlipidemia. Multivariate regression models revealed incremental mean annual resource use associated with osteoarthritis of 70 additional hospitalizations per 100 osteoarthritic patients annually, and 363 additional visits per 100 osteoarthritic patients annually. Mean annual incremental total expenditures associated with osteoarthritis were $2,046. Mean annual incremental expenditures were largest for inpatient expenditures at $826, followed by mean annual incremental outpatient expenditures of $659, and mean annual incremental medication expenditures of $325.

Conclusion: Osteoarthritis was associated with considerable incremental health care resource utilization and expenditures.

Regional Primary Care Rheumatology Networks for Patients with Rheumatic and Musculoskeletal Diseases: Need for a National Approach

Wilfred Peter[1], Florus van der Giesen[2], Cornelia H.M. van den Ende[3], Joost Dekker[4] and Thea P. M. Vliet Vlieland[5], [1]Orthopeadics, Rehabilitation and Physical Therapy, Leids University Medical Center, Leiden, Netherlands, [2]Orthopaedics, Rehabilitations and Physical Therapy, Leiden University Medical Centre, Leiden, Netherlands, [3]Department of Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [4]Rehabilitation Medicine, VU University Medical Center, Amsterdam, Netherlands, [5]Orthopaedics, Rehabilitation and Physical Therapy, Leiden University Medical Center, Leiden, Netherlands

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Regional primary care rheumatology networks of health professionals (HPs) are instituted to improve the quality of care for patients with rheumatic and musculoskeletal diseases (RMDs). The aim was to describe their characteristics, the success and failure factors, and the satisfaction of patients treated by network members in the Netherlands.

Methods: Data on the organizational structure and processes, education, patient load, perceived success / failure factors, and organizational / educational needs were collected by interviewing 19 existing network coordinators, and an online surveys among all members A maximum of 4 patients per member were asked to complete an online survey comprising the Consumer Quality Index (CQ) subscales Information, Attitude of HPs, and Cooperation and Self-management (range 1-4), and a Numeric Rating Scale on therapy satisfaction (range 1-10).

Results: 17 networks set membership criteria, 5 had a formal organizational structure, 7 imposed a membership fee, 17 collaborated with a hospital rheumatology department, 15 included only physical therapists, 18 organized network meetings for professionals and 11 for patients. There were 479 network members (median 18 per network, range 7-106). All coordinators expressed the need for central support regarding network organization and activities. Of 256 responders 54 (21%) did not completed the survey because they had not seen patients with RMDs in the past year. 214 network members (50%) completed the survey, 82 (38%) followed accredited postgraduate education on RMDs, whereas 159 (74%) expressed a need for standardization of postgraduate education and organizational support. The most frequently mentioned success factors were: patient satisfaction, presence of diagnostic and treatment protocols and the organization of meetings, whereas failure factors mentioned were: low patient load, poor visibility, suboptimal communication with rheumatologists and patients, and a lack of affordable and (continuing) postgraduate education. The 149 patients who returned the survey were highly satisfied: CQ Information 3.8 (SD 0.3); Attitude of health professionals 3.9 (SD 0.3); and Cooperation and Self-management 3.5 (SD 0.5), satisfaction mean score was 8.7 (SD 0.8).

Conclusion: Structure and process of regional primary care networks focusing on the management of patients with RMDs shows considerable variation. Although added value with respect to patient satisfaction is plausible, there is a need for support of regional networks on the national level, standardization of postgraduate education, improvement of communication with rheumatologists and patients and their visibility. **This study was financially supported by the Dutch Arthritis Association.**

Patient Satisfaction Survey of a Newly Set up Physiotherapist Lead Axial

Spondyloarthritis Clinic

Clare Longton[1], Marco Massarotti[2] and Marwan Bukhari[3], [1]Rheumatology, Royal Lancaster Infirmary, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, [2]Rheumatology, Royal Lancaster Infirmary, University Hospital of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, [3]Royal Lancaster Infirmary, Lancaster, United Kingdom

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Present guidelines (National Institute for Health and Care Excellence- NICE technology appraisal guidance TA143 2008 and TA233 2011; National Ankylosing Spondylitis Society 2010) on axial spondyloarthritis (AxSpA) support the management and monitoring of patients based on a pharmacological and physical measurement approach. In the UK, these patients often require multiple appointments with a variety of health professionals including Consultants, nurses and physiotherapists all reviewing different aspects of their condition.

Methods: To streamline these appointments, reduce the number of visits individuals need to make and release capacity in the consultant clinics, in 2014 we trialled a 'one-stop shop' approach with an experienced Advanced Rheumatology Physiotherapist leading the clinic with medical escalation and governance arrangements in place (see Figure 1). As this was a significant change in delivery of care we assessed the satisfaction of a sample of consecutive patients attending the clinic throughout a twelve month period. Patients were informed of the change in the service organisation prior to their attendance of the clinic. A validated Patient Reported Experience Measure questionnaire (PREM) (Bosworth A et al. 2015), as developed by Commissioning for Quality in Rheumatoid Arthritis (CQRA), a British multidisciplinary group of stakeholders, was used. The questionnaire comprises of 8 domains that have been evidenced as being most important to patients' experiences of National Health Service (NHS) services.

Results: 64 patients completed the questionnaire (mean age 51.6 ± SD11.7; M 58/64, 87.5%). Most of the patients (46/64, 71.9%) had a disease duration of more 10 years, with approximately 50% on biologics. Percentage of patients who answered 'strongly agreed' or 'agreed' for the overall satisfaction of the service was 100% (73.4% and 26.6% respectively). The specific domains results are shown in the table.

Domain	Number of Questions	Patient satisfaction (strongly agree or agree) (%)	Range (%)
Needs and preferences	5	99.1	95.3 - 100
Co-ordination of care	4	96.7	89.5 - 100
Information about care	4	93.3	85.1 - 96.9
Daily living	2	87.0	80.4 - 92.2
Emotional aspects	2	89.6	87.3 - 91.9
Family and friends	1	86.9	-
Access to care	1	100	-
Overall evaluation	-	100	-

Conclusion: Our study suggested that overall patients were satisfied that their care was delivered by an Advanced Physiotherapist. This could present significant improvements in cost and quality of care delivered to this patient group. Although all areas scored highly for satisfaction, some domains identified areas for potential improvement within the service. These will be reviewed after further evaluation with a wider sample population. .

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biological therapies have importantly contributed to controlling disease activity in patients with inflammatory rheumatic diseases. As the high costs of biologics are a threat to affordability and accessibility of these drugs for patients, attempts are made to decrease both the price and the quantity of the biological use. Examples of these attempts are start-/stopcriteria, dose reduction strategies and reduction of medication waste. Since recently, both intravenous- (infliximab) and subcutaneous (etanercept) biosimilars are available in Europe. Furthermore, pharmaceutical companies are altering their marketing strategies from a technology push/aggressive marketing targeted on individual doctors, to a new form of long term partnerships between hospitals as organizations and pharmaceutical companies. These partnerships should not only result in more attractive drug prices, but also to co-creation of innovations to improve decreased drug use, accessibility, affordability and the quality of healthcare. On top of that, long term partnerships prevent yearly time consuming price negotiations between hospitals and pharmaceutical companies. *Aim:* To create value-based long term partnerships between our hospital and pharmaceutical companies in order to improve both the quality and the cost-effectiveness of rheumatologic patient care.

Methods: First, an independent working group of rheumatologists and pharmacists employed at our hospital prepared a

list of interchangeable biologics for new patients with rheumatoid arthritis, psoriatic arthritis and spondyloarthritis. Then, nine pharmaceutical companies were invited to offer a proposition for partnership with our hospital. This proposition had to include a combination of a multi year attractive price proposition and a proposal for projects for optimization of biological drug use and/or improvement of rheumatology care. Separate meetings with the CEO, head of pharmacy and the medical managers of the rheumatology department of our hospital and representatives of the pharmaceutical companies were scheduled in order to discuss the propositions and find the common goals in the partnerships. All proposals were put in a model, in order to calculate long-term benefits/costs.

Results: 1936 patients in the Sint Maartenskliniek use biologics for their rheumatic disease. 21 rheumatologists of the Sint Maartenskliniek declared all tumor necrosis factor alpha inhibiting drugs (TNF-i), tocilizumab (RA only) and abatacept (RA only) interchangeable with respect to new patients with above mentioned diagnoses and declared the reference products of TNF-i infliximab (Remicade ®) and etanercept (Enbrel ®) interchangeable with their biosimilar counterparts for both new and current users. After separate sessions with individual pharmaceutical companies, three companies were selected and finally two were granted a first or second position of preference for a period of four years with a six month adjustment window of the price according to developments in the market. The model was used to calculate costs and benefits of each proposal. As a result of this process, a 25% reduction of the price of biologics was obtained (compared to last years price), as well as an increase in mutual investments in care projects such as e-health, medication adherence and care pathways.

Conclusion: Creating long-term alliances between hospitals and pharmaceutical companies is an effective strategy to achieve substantial reduction of medication costs (price and quantity) and improvement of quality of care.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The clinical effectiveness of supervised exercise therapy for individuals with knee osteoarthritis (KOA) is well known. However, it is unclear whether participation in a supervised therapy program impacts downstream utilization of health services. The purpose of this study is to determine the impact of four different supervised physical therapy (PT) programs on KOA-related health service utilization over a 2-year period.

Methods: This is a secondary analysis of data from a 2-year multisite randomized clinical trial of 300 individuals with KOA per ACR criteria. Participants were randomized to one of four PT strategies: (1) 12 visits of exercise therapy alone; (2) 9 visits of exercise therapy + 3 booster sessions spaced across 12 months; (3) 12 visits of exercise + manual therapy; (4) 9 visits of exercise + manual therapy + 3 booster sessions. Participants were queried at baseline, 1 year, and 2 years

regarding 12-month utilization of health services commonly accessed by those with KOA (**Table 1)**. Chi-square analyses compared health service utilization at baseline vs. 1 year and baseline vs. 2 years for the full cohort and for subgroups who did/did not receive manual therapy and booster sessions. Logistic regression was used to determine if treatment group allocation predicted health service utilization after adjusting for age, race, and baseline physical function.

Results: Across the full cohort, statistically significant reductions in utilization of many health services were observed following participation in the study (**Table 1**). Use of non-opioid and opioid pain medications for the knee reduced substantially over the two-year period. Reductions in knee joint injections and visits to physicians (especially primary care physicians) also significantly dropped over the study period. Logistic regression analyses revealed that treatment group allocation was generally not a significant predictor of health service utilization. Individuals who received booster sessions were less likely to have knee imaging at one year (adjusted OR 0.51; 95% CI 0.29-0.92). Those who received manual therapy were less likely to have had recent imaging at baseline (adjusted OR 0.59, 95% CI 0.37-0.94) and less likely to have visited a rheumatologist at 1 year (adjusted OR 0.50, 95% CI 0.26-0.95) and 2 years (adjusted OR 0.49, 95% CI 0.27-0.88). All other regression models comparing booster to non-booster groups and manual therapy to non-manual therapy groups did not achieve statistical significance.

Conclusion: Downstream utilization of many common health services reduced over two years for individuals with KOA participating in a randomized clinical trial of structured PT. The study did not include a control group so the reduction in utilization may not be a direct effect of participating in the PT intervention. Treatment group allocation was not a significant predictor of health service utilization.

Table 1. Utilization of Health Services Over Time: Overall Cohort

	Baseline (n = 300) **% (n)**	**1 year (n = 271)** **% (n)**	**2 years (n = 267)** **% (n)**
Knee Injection	33.0% (99)	24.0% (65)*	28.5% (76)*
Knee Arthroscopy	2.3% (7)	1.5% (4)	0.0% (0)
Knee Imaging	56.3% (169)	24.4% (66)	30.7% (82)
Non-Opioid Oral Pain Medication	82.3% (247)	69.0% (187)*	61.4% (164)*
Opioid Pain Medication	10.0% (30)	9.6% (26)*	5.6% (15)*
Primary Care Physician Visits	50.3% (151)	22.9% (62)*	27.3% (73)*
Orthopaedic Surgery Visits	35.0% (105)	24.0% (65)*	33.3% (89)
Rheumatology Visits	10.0% (30)	7.4% (20)*	11.2% (30)*
Rehabilitation Services	13.3% (40)	10.7% (29)	15.0% (40)
Massage Therapy	6.7% (20)	6.6% (18)*	5.6% (15)*
Durable Medical Equipment	17.3% (52)	12.9% (35)	17.6% (47)*

**indicates statistically significant difference from baseline utilization (p<.05)*

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Emerging models of care in rheumatology are integrating interdisciplinary approaches at different stages of the patient's care pathway. Such models of have recently been implemented in the early identification of axial spondyloarthritis (SpA). The Toronto Western Hospital SpA Screening Clinic links with community-based primary care physicians (PCPs), physiotherapists (PTs), chiropractors (DCs) and nurse practitioners (NPs) to facilitate the early detection of axial SpA and uses advanced practice physiotherapists and specialist rheumatologists located at an academic tertiary care hospital to confirm diagnosis and initiate early treatment for axial SpA. Collaborative inter-professional practice is an essential component for successful implementation of novel models of care for chronic diseases that require ongoing assessment and management from many health care professionals. The objective of this study was to examine the inter-professional satisfaction and perceptions of collaborative practice of an innovative model of care for the early detection of axial SpA in Toronto, Canada.

Methods: A cross-sectional survey was conducted of referring health care providers (HCPs) to the Toronto Western Hospital SpA Screening Clinic and included PCPs, PTs, DCs and NPs. HCPs were sent an electronic questionnaire with questions related to general satisfaction of the SpA Screening Clinic and HCP's perceptions and experience with the inter-professional collaborative process of the SpA Screening Clinic. An adapted version of the Modified Index of Interdisciplinary Collaboration was used to assess inter-professional collaboration. The survey was administered using Survey Monkey®. Data analyses consisted of descriptive statistics and were conducted using Microsoft Excel 2010.

Results: Thirty-two out of 59 (54%) referring HCPs participated in the survey. The majority of respondents were PCPs (65.6%), followed by PTs or DCs (21.9%). The majority of referring HCPs to the SpA Screening Clinic reported positive indicators of satisfaction and included: receiving communication about their referred patients in a timely manner (53.1%); being informed regarding their referred patients' management plan (51.6%) and future re-referral rate for another patient with suspected axial SpA (83.9%). Overall perceptions of inter-collaborative practice were high with respect to referring HCPs relationship with the SpA Screening Clinic: interdependence subscale mean score=2.04 (SD 0.41); newly created professional activities subscale mean score=2.19 (SD 0.2); flexibility subscale mean score=2.47 (SD 0.18) and collective ownership subscale mean score=2.25 (SD 0.21), with 1 representing the highest possible perception of collaboration and 5 being the lowest possible perception.

Conclusion: These results suggest overall inter-professional satisfaction and high levels of perceived inter-professional collaboration with an innovative model of care aimed at the early detection of axial SpA. The results of this study may inform future research on the impact of inter-professional collaboration on outcomes for patients attending the Toronto Western Hospital SpA Screening Clinic.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-engaged research can improve the safety and satisfaction outcomes of hip and knee arthroplasty (joint replacement surgery). Patients are able to identify the decisions that are most important to them when undergoing hip and knee arthroplasty and the factors they view as important in making those decisions.

Methods: Forty-nine participants were recruited from ArthritisPower Patient-Powered Research Network and CreakyJoints patient community to participate in structured one-hour discussions held via webinar during January to April 2016 to understand patient experience with joint replacement. Patients described decisions that were most important to them and the factors they used to make those decisions. Discussions were transcribed and coded to identify themes; patient decisions and factors were identified and categorized; and co-occurrence of decisions with factors was tabulated. Demographic and procedure-related characteristics were captured.

Results: Seven decisions emerged that were influenced by at least ten factors (Table). The most important decisions involved whether to have surgery, selection of surgery date, surgeon, facility, implant device, and ancillary health care professionals (HCPs) and services. Factors included current situation, expectations of having or not having surgery, professional and word-of-mouth familiarity with surgeon/HCP, procedure, services and device, and perceived value. Patients' current situation and health status and their expectations of surgery were most commonly used to make decisions about whether and when to have surgery. Patients' trust of and communication with doctors was the most commonly used factor when deciding on arthroplasty surgeon.

Conclusion: Arthroplasty patients are concerned about a variety of decisions. Patient-centered research should maximally address questions of importance to patients and this study is a first step in identifying and prioritizing topics that matter most to patients and the information that patients currently use to make joint replacement decisions. **Table: Arthroplasty Decisions Important to Patients and the Most Common Factors Influencing Them**

Decisions Important to Patients	Most Common Factors Influencing Decisions
Surgery: Whether to have partial or total hip/knee joint replacement surgery (arthroplasty)	Current life situation and health status (44%), Expectations of having surgery (11%), Expectations of NOT having surgery (11%), Information provided to patient by doctor or other HCP (11%), Alternatives to surgery that have been tried or are known about (11%)
Timing: When to have surgery	Current life situation and health status (38%), Expectations of having surgery (19%), Alternatives to surgery that have been tried or are known about (19%), Expectations of NOT having surgery (8%)
Surgeon: Which surgeon will perform surgery	Trust and communication with surgeon (45%), Perceived value of surgeon's expertise (19%), Expectations of having surgery (16%), Information accessed by patient autonomously (10%)
Facility: Where surgery will be performed (e.g., geographic location, specific hospital or medical center)	Information provided to patient by doctor or other HCP (28%), Trust and communication with HCP (18%), Firsthand familiarity with facility (18%), Expectations of having surgery (18%), Information accessed by patient autonomously (9%), Perceived value of facility expertise (9%)
Device: Which implant device will be installed during surgery	Expectations of having surgery (39%), Information provided to patient by doctor or other HCP (18%), Perceived value of device (16%), Trust and communication with HCP (11%)
Other HCPs: Who/which other health care professionals (HCPs) besides the surgeon will be involved in care during and after surgery (e.g., anesthesiologist, physical therapist)	Expectations of having surgery (30%), Trust and communication with HCP (20%), Current life situation and health status (20%), Perceived value of other HCPs (20%), Firsthand familiarity with other HCPs (10%)
Other Services: What other services will be necessary before, during or after surgery (e.g., mental health)	Expectations of having surgery (71%), Trust and communication with HCP (14%), Current life situation and health status (14%)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA), the most common type of arthritis, is prevalent and costly. Pain is the principal reason patients with OA seek treatment. Older adults with OA often report co-existing insomnia and depression. OA pain, insomnia, and depression greatly increase health care use (HCU) in this population. The purpose of this study is to examine the independent and combined effects of OA pain, insomnia and depression on HCU.

Methods: 8,057 participants aged 60+ with an electronic medical record OA diagnosis were mailed a screening survey which asked about their pain, sleep disturbance, and depressive symptoms. Pain was assessed by the Graded Chronic Pain Scale (GCPS); Grades 2-4 were positive for chronic pain. Insomnia severity was measured by the Insomnia Severity Index (ISI); a score of 7 or greater indicates at least mild insomnia. Depression was measured by the Patient Health Questionnaire depression scale (PHQ-8), with a score greater than 9 representing current depression. All participants were members of Group Health Cooperative (GHC), a Seattle-based health maintenance organization. HCU variables were extracted from participant medical records and included total number of office visits, length of stay (LOS) (days), and outpatient costs related to OA, insomnia and depression. Patient demographics (age, sex, race, ethnicity, education, employment and martial status), days of enrollment in GHC a year before screening date, and Charlson Comorbidity Index scores were also recorded. Negative binominal model and generalized linear model were used for the data analysis.

Results: 3,056 participants completed the survey and gave permission to access their medical records. Average age was 72 years; participants were largely Caucasian (87.4%), female (66.3%), married (59.3%) and highly educated (86.4% community college or higher). Participants had a positive level of pain (46.6%), at least mild insomnia (55.1%), and current depression (17.3%). For independent effects on HCU controlling for patient characteristics, OA pain, insomnia, and depression were associated with office visits ($p < 0.001$). In addition, OA pain ($p < 0.001$), insomnia ($p = 0.020$), and depression ($p < 0.001$) were associated with outpatient costs, but none were associated with LOS. For joint effects of those symptoms controlling for patient characteristics, pain was significantly related to office visits and outpatient costs ($p < 0.001$) but not LOS. Insomnia given pain level contributed to office visits ($p < 0.01$) but not for outpatient costs. Depression given pain level contributed to both office visits and outpatient costs ($p < 0.01$). No significant interactions were found between pain and insomnia, or pain and depression.

Conclusion: OA pain and depression were associated with office visits and outpatient costs in this population after adjusting for covariates. However, insomnia was only associated with office visits prior to adjustment. OA pain, insomnia, and depression were not associated with LOS in this population. Joint contributions of pain, insomnia and depression to HCU were additive.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Disease outcomes can depend, to a large extent, on one's ability to manage their condition effectively. For children with JIA this means managing oral, injectable, or intravenous medications, managing multiple appointments, regular blood work, imaging studies, and performing home exercise programs. These activities must be integrated into daily life with consideration for developmental, intellectual, and psychosocial well-being of the child and family. Provision of Self-Management Support (SMS) is one of 6 essential elements of care identified in The Chronic Care Model. Practice teams must develop systematic processes designed to address self-management and foster patient's confidence and self-management skills. However, providers are not routinely trained in providing SMS. The purpose of this study was to develop systematic processes by which practice teams within Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) develop skills, tools, and mechanisms to effectively implement SMS.

Methods: Three key components utilized to prepare for successful implementation of SMS by teams included: 1) provider and health care team training in Behavior Change Counseling (BCC), 2) tool development for self-management assessment, barrier assessment, and an action plan worksheet, 3) use of quality improvement (QI) methods to identify successful implementation processes, and to support their application within PR-COIN practice teams. A co-production model, including researchers, health providers and parents was used for tool development and process integration.

Results: Nine centers participated in two 4 hour training sessions on BCC and elements of SMS delivered via interactive webinar technology. A self-management assessment tool (assessing visit goals, self-efficacy, health distress, and adherence), barriers assessment, intervention tools, and action plan were tested across 9 centers and refined. Data tracking of performance for tool implementation and barriers to treatment were collected. 84% or participants completed BCC training. Aggregate data for tool integration into clinic flow was 85%. Of multiple barriers assessed, concern for long term side effects was highest for all medication modalities. Specific barriers to adherence of medications were forgetting to take medication and pain associated with injections. Monthly webinars were conducted to debrief on progress, learnings and share best-practices on SMS implementation. Feedback from teams and parents indicated SMS tools used in clinical encounters were helpful to address barriers/concerns of patients, to decrease provider assumptions and increase patient activation.

Conclusion: This project implemented a novel approach to SMS training with interactive webinar instruction showing feasibility of this technology to facilitate future spread of SMS skills training to other centers. The co-production model with caregivers collaborating with teams facilitated the tool development and relevance to target audience. Specific QI methods building on skills learned from participation in PR-COIN allowed more efficient uptake of SMS into clinic practice.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Health Services Research - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: China does not have primary medical care and referral system. Patients can choose any hospital or any doctor they like to seek medical care. As a result, most patients with rheumatic diseases rushed to a few large cities. Survey shows more than 40% of the rheumatic disease patients are unnecessary to go to hospital and they only need advices from specialist. Smart System of Disease Management (SSDM) is a series of applications for chronic diseases management, which develop the interaction between doctors and patients. The study shows that, after training, the RA patients can master the SSDM and perform self-management, including DAS28 and HAQ evaluations, as well as medication and lab test data entries. The purpose of this study is to evaluate the feasibility and benefit of the medical economics of online consultation based on SSDM by rheumatologist.

Methods: The rheumatologists and nurses implemented the education and training programs on using SSDM and assisted the patients in downloading SSDM APP. The SSDM includes doctors' application and patients' application. The patient application includes self-assessment (DAS28, HAQ), medication management, adverse events management and laboratory records. After data entry, patients can synchronize data to the authorized doctor. On the basis of understanding of the disease activities, medication and laboratory test results, the rheumatologists can accept consultation request from the patients and supply them with advices in forms of text and or telephone call.

Results: Between February 14, 2015 and June 12, 2016, 30 rheumatologists supplied 132 patients with 136 times free and 55 paid consultations. In which there were 176 times text Q&A and 15 telephone consultations. Paid consultation included 43 times text Q&A and 12 telephone consultations. The consulting fee ranged from RMB 50 to 500 yuan (USD:RMB =1:6.6) each in average of 275.45 ± 90.20 yuan, which rate match the registration fee in hospital. The total fee for consultations was 15,150 yuan. 75.8% patients receiving online consultation lived in different cities with the rheumatologists. If patients seek medical in hospital, in addition to the registration fees and medical expenses, the mean cost of transportation, accommodation, meals and lost wages was 1081.68 ± 523.28 (200 to 1,800) yuan. The total of cost for all patients would have been 248,250 yuan, which is 15.38 times higher than online consultation. SSDM can save up to 93.90% cost for patients. Survey shows all patients were satisfied and 64.86% of them were "very satisfied" with the consultation services.

Conclusion: Using SSDM system to obtain online consultation, Chinese patients with rheumatic disease can enjoy reduced cost with high satisfaction. In the era lack of primary care system in China, SSDM may serve a complimentary platform to control medical care cost, as well as relieve the tensions between health care professionals and patients.

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Excessive delays to rheumatologists have been documented and triage assessments of suspected IA referrals from primary care may be a key strategy to expedite access to rheumatologists. We evaluated the positive and negative predictive values (PPV and NPV) of triage assessments by extended role practitioners (ERP) for identifying patients with IA. We also estimated the time from primary care referral to rheumatology consultation, comparing those patients who were expedited by an ERP (suspected IA) versus those who were not.

Methods: Patients with possible IA were identified from rheumatologists' wait lists through a paper triage process. Patients were included if they were adults and newly referred by a general practitioner or nurse practitioner within the previous month. An ERP established a weekly triage clinic in each participating rheumatologist's office and assessed each patient using a standardized tool to identify patients for an expedited rheumatologist consult. Non-expedited patients went back on the waiting list to receive the next available routine appointment. Patients were then followed for three months post referral with dates of rheumatologist consultations and clinical diagnoses identified by chart review. We determined the proportion of patients correctly triaged by ERPs for expedited access. The median (interquartile range) time from primary care referral to the first rheumatologist consultation was determined, comparing patients who were prioritized for an expedited assessment versus those who were not, and compared to the provincial average (median: 66 days)*.

Results: Six rheumatologists agreed to participate in the study. Of 317 patients identified from the rheumatologists' wait lists as having possible IA, 177(56%) met inclusion criteria and received an ERP triage assessment (female: 67%; mean age (SD): 53 (14)). Of these, 75/177 patients (42%) were prioritized by the therapist for an expedited appointment with the rheumatologist. For expedited patients, 71/75(95%) were seen by the rheumatologist within 3 months of referral and the median (IQR) time from referral to rheumatologist consultation was 37 (24.3-54.8) days. Upon consultation, the rheumatologist suspected IA or connective tissue disease (CTD) in 58/71(PPV=0.817). Among those not prioritized**, 68/101 patients (67%) were seen by the rheumatologist within three months of referral and the median (IQR) time from referral to rheumatologist visit was 100 (68.3-131.5) days. Of those, 13/68 received a differential diagnosis of IA/CTD (NPV=0.809).

Conclusion: Triage by an ACPAC trained ERP resulted in a high number of patients with suspected IA/CTD being correctly prioritized for a rheumatology consultation. For prioritized patients, the wait time was less than the provincial

median. These results suggest that an ERP working in a triage role can improve access to rheumatology care for patients with suspected IA. *Widdifield et al. Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Differences in access to care that influence the timing and quality of treatment interventions may create outcome inequities for Aboriginal patients with inflammatory arthritis. Our study compares Aboriginal and Caucasian patients in disease presentation, treatment strategy, and outcomes over five years.

Methods: Participants were enrolled in a prospective multi-center early arthritis cohort, and treated with routine care. Inclusion criteria for the present study were < 1 year symptom duration, self-identified as Aboriginal or Caucasian, and completion of >1 follow-up visit. Baseline demographics, clinical characteristics, and therapy escalation for moderate (DAS28 >3.2) or high (DAS28 >5.1) disease activity states (defined as any of increased dose of methotrexate, addition of a DMARD, and/or addition or switching biologic) were compared using standard descriptive statistics. The frequency of remission and use of DMARD, biologic and steroid therapy were compared between groups. Mixed-model repeated measures and Poisson regression analysis were used to determine rates of change for disease activity measures over five years, with adjustment for baseline demographics and disease activity measures.

Results: The study sample included a total of 2173 patients (Aboriginal n=100; Caucasian n=2073), 70% female with mean(sd) age of 54(15) years, symptom duration of 179(91) days, and baseline DAS28 4.87(1.48). Differences in current smoking status, body mass index, education, and household income disfavoured Aboriginal patients (Table 1, all $p<0.01$). Aboriginal patients were more frequently seropositive and less likely to have erosions at baseline, but did not differ in symptom duration, number of comorbid conditions, nor baseline HAQ and DAS28 scores. Therapy was escalated at ~50% and 60% of visits where patients were in moderate and high disease activity states respectively, with no differences between groups in the frequency or type of strategy used (i.e. use of oral steroids, combination DMARD therapies or biologics). DAS28 remission was less frequent in Aboriginal patients at all visits up to 36 months (3 months 16% vs 30%; 12-months 16% vs 50%; 36-months 40% vs 59%, p values <0.01). This was driven by higher values for all DAS28

components. In particular, swollen joint counts in Aboriginal patients improved at a significantly slower rate (slope difference between groups p=0.029), and patient global scores did not improve significantly (p=0.115) in Aboriginal patients.

Conclusion: We observed differences in disease phenotype in Aboriginal patients, and worse disease outcomes despite having a treatment escalation strategy similar to the Caucasian population. This may reflect disparities in socioeconomic status and differences in environmental exposures associated with worse disease outcomes.

Racial Differences in Self-Reported Pain and Disability: A Longitudinal Study of Knee Osteoarthritis

Ernest Vina[1], Di Ran[2], Erin Ashbeck[2] and C. Kent Kwoh[3], [1]Rheumatology, University of Arizona, Tucson, AZ, [2]University of Arizona, Tucson, AZ, [3]Rheumatology, University of Arizona, College of Medicine, Tucson, AZ

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pain and disability from knee osteoarthritis (KOA) has been reported to be greater among African-Americans (AAs) than Whites (WHs), though progression in KOA-related symptoms by race has not been described. Our objective is to compare self-reported pain and disability between AAs and WHs, with or at high-risk of KOA, over 9 years of follow-up.

Methods: The Osteoarthritis Initiative is a longitudinal cohort study of participants with or at risk of KOA, with up to 9

years of annual self-reported pain and disability assessments including WOMAC pain, pain severity in the past 30 days using a numerical rating scale (NRS), and WOMAC disability. Mixed models for repeated measures were used to estimate race group means and change in group means during follow-up, adjusted for age, sex, education, marital status, body mass index, and depression. Generalized linear mixed models for multinomial logistic regression were used to estimate the relative odds of reporting clinical improvement and worsening, based on established clinically important differences [CID], for AAs compared to WHs. The referent outcome was no CID, and 2 knees per participant were accounted for with random intercepts.

Results: A total of 3790 WH and 874 AA subjects were included, with baseline mean WOMAC pain subscale scores of 1.9 (SD 2.8) and 4.4 (SD 4.4), respectively. During the first year follow-up, there was a significantly greater decline in mean WOMAC pain among AAs compared to WHs (-0.64 [95% CI: -0.78 to -0.50] vs. -0.15 [95% CI: -0.21 to -0.08]; $p<0.0001$), while mean pain levels remained stable between the 1 year and 9 year follow-up visits. Pain severity and WOMAC disability had similar patterns, with a significantly greater decline among AAs from baseline to first year follow-up, followed by relatively stable group means. However, AAs had significantly increased odds of reporting clinically important worsening and improvement in pain and disability among nearly all consecutive annual clinic visits, and across all three outcome measures, compared to WHs (Table 1).

Conclusion: Race-specific group means suggest that AAs report a precipitous drop in KOA-related symptoms between first administration at baseline and second administration 1 year later, followed by stable average pain and disability. Closer examination revealed that AAs were more likely than WHs to report CID, both worsening and improvement, in KOA pain and disability, revealing substantial within-person variance among AAs. Whether the increased variability in responses from AAs reflects fluctuations in actual pain and disability experienced or lack of cross-cultural instrument validity is unknown. Self-reported measures of symptoms are accepted as primary endpoints in randomized controlled trials (RCTs). RCTs that rely on changes in these measures to demonstrate drug efficacy may suffer from obscured treatment effects among AAs.

The Relationship Between Socioeconomic Factors and Dmards Use in Rheumatoid Arthritis

Adegbenga Bankole, Rheumatology, Carilion Clinic, Roanoke, VA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Healthcare Disparities in Rheumatology - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disorder affecting millions of Americans with societal costs estimated in the billions. With the expansion in the number of biologic drugs available, the cost of care has continued to increase. Socioeconomic factors have been shown to affect the likelihood of immunosuppressive therapy prescribed in RA. The purpose of this study was to examine the association between medication prescribed and socioeconomic factors including gender, race, and median household income.

Methods: This was a retrospective, single center, hospital-affiliated outpatient cohort study. A systematic review of the electronic medical record yielded over 4000 patient's records. These records were reviewed and of these, 116 patients who met the ACR/EULAR (2010) classification criteria for RA were randomly selected. General demographic information including age, gender and zip code, as well as serological testing was obtained through chart review. Supplemental socioeconomic information for each zip code in Southwest Virginia was obtained from the United States Government Census website. The data was analyzed by Kruskal-Wallis Test, Mann-Whitney U Test using SAS9.3.

Results: Table 1 outlines the frequency of medication prescribed in the cohort. Among the 116 patients, there was no relationship between socioeconomic factors and medication prescribed. There was no statistical relationship between gender and medication prescribed including NSAIDs (p=0.153), corticosteroids (p=0.172), DMARDs (p=0.26) and biological drugs (p=0.350).There was no statistical relationship between race and medications including NSAIDs (p=0.890), corticosteroids (p=0.221), DMARDs (p=0.475) and biological drugs (p=0.673). There was no statistical relationship between median household income and medication prescribed including NSAIDs (p=0.071), corticosteroids (p=0.296), DMARDs (p=0.228) and biological drugs (p=0.046)

Table 1
Medications Used in the Cohort

	Frequency	Percentage
None	31	27%
Biologics Monotherpay	2	2%
DMARDs	49	42%
Biologics+DMARDs	32	28%
DMARDs+Small Moleculars	2	2%
Total	116	100%

Table 2
Medications by Race

	Non-caucasian	Caucasian	p-value
Biologics	35.0%	30.2%	0.673
DMARDs	65.0%	72.9%	0.475
NSAIDs	60.0%	58.3%	0.890
corticosteroids	50.0%	64.6%	0.221

Conclusion: There was no relationship between socioeconomic factors and the medications prescribed in our RA cohort. This may be the result of standardization of RA treatment, and the adoption of "treat to target" ethos in RA. The limitations of this study include the small sample size and its restriction to a single center.

Rates and Determinants of Persistent Patient-Physician Discordance in Global Assessment of Disease Activity in Latinos with Rheumatoid Arthritis in the United States

George A. Karpouzas[1], Elizabeth Hernandez[2], Chelsie Cost[2] and Sarah Ormseth[2], [1]Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, [2]Rheumatology, Harbor-UCLA Medical Center, Torrance, CA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients and physicians often differ in their assessments of Rheumatoid arthritis (RA) activity [PGA and EGA respectively]. Such differences may jeopardize attainment of remission. We evaluated proportions of patients with persistently discordant and concordant evaluations (PGA-EGA) over time, and determinants thereof.

Methods: We evaluated 271 Latinos with established RA at baseline (T1) and 12 months later (T2). Tender (TJC) and swollen (SJC) joint counts, pain [visual analogue scale (VAS)], fatigue (VAS), disability [Health Assessment Questionnaire-HAQ-DI], and depression assessments [Patient Health Questionnaire-9 (PHQ9)] were collected. PGA and EGA were captured on 0-10cm VAS; persistent discordance was defined as (PGA-EGA)>=3cm at both time points. Persistently concordant (pC) subjects had -3<PGA-EGA<3, persistently positive discordant (pPD) had (PGA-EGA) >=3, while persistently negative discordant (pND) ones had (PGA-EGA) <=-3. Mutlinomial forward stepwise logistic regression analysis identified independent predictors of individual group membership compared to the pC group (referent).

Results: We observed pC in 94 (34.7%) subjects, pPD in 51 (18.8%), and pND in 4 (1.5%), [figure 1a]. Another 60 (22.2%) changed from baseline concordant to discordant [50 (18.5%) PD, and 10 (3.7%) ND], 43 (15.8%) from baseline PD to either C [41 (15.1%)] or ND [2 (0.7%)], and an additional 19 (7%) patients shifted from baseline ND to either C [15 (5.5%)], or PD [4 (1.5%)]. The magnitude of (PGA-EGA) difference in the four largest groups is shown in figure 1b. Patients in the pPD group were more likely to have higher T1 disability, pain, and depression scores, lower baseline TJC and SJC, and less likely to have improvement in pain compared to those in the pC (all p=<0.007, table 1).

Conclusion: Persistently positively discordant PGA-EGA assessments are common in Latinos with RA (18.8%), potentially jeopardizing remission attainment. Determinants of this state do not include markers of disease activity but rather, higher baseline functional disability, depression scores, pain, and lack of improvement in pain.

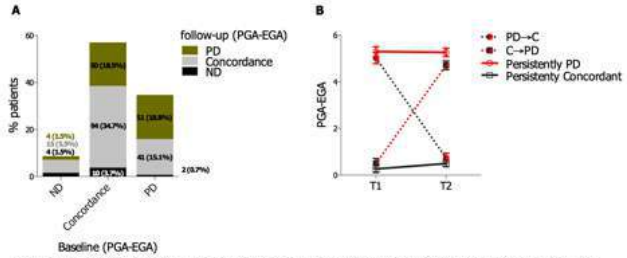

Figure 1: A. Persistence of PGA-EGA discordance over time. **B.** Magnitude of discordance between patients and physicians on respective evaluations of disease activity over time.

Table 1: Independent predictors of unique group membership compared to the persistently Concordant (pC) group as referent

Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies showed lower socioeconomic status (SES) was associated with higher disease activity and lower quality of life (QOL) in patients with rheumatoid arthritis (RA). However, health insurance system may influence the association between SES and disease outcomes. Because Japan has the unique national insurance system, all Japanese citizens are required to be enrolled in the national insurance system. In addition, most patients pay 30 % of medical cost whereas patients aged 70 and older, patients with low income and patients with disabilities pay 0 to 20 % of cost depending on age, income and severity of disabilities. The impact of SES on RA disease outcomes in the Japanese health system is still unknown because it has never been examined in a Japanese cohort. It is also important for policymakers in other countries to refer to Japanese findings when they make or improve their health insurance system. We evaluated the effect of SES among Japanese patients with RA on disease activity, activities of daily living (ADL) and QOL in the Japanese national health insurance system.

Methods: A questionnaire survey was conducted among 339 patients with RA in Kobe University Hospital. Clinical characteristics included age, sex, disease duration, Steinbrocker stage and class classification, rheumatoid factor, anti-citrullinated protein antibody, use of corticosteroid, methotrexate, and biologic. Disease activity was assessed according to the DAS28-CRP, ADL according to the Japanese version of the Health Assessment Questionnaire (HAQ), and QOL according to the Japanese version of the EQ-5D. SES included income, education level and occupation. Univariate and multivariate analyses were conducted to examine the association of SES with DAS28-CRP, HAQ and EQ-5D. Because proportion of biologic use and self-pay were assumed as the intermediate variables between SES and disease outcomes, we evaluated whether they were associated with SES to investigate the possible mechanism through which SES affected disease outcomes.

Results: Univariate analyses showed patients with lower income had significantly higher DAS28-CRP ($P = 0.03$) and HAQ score ($P = 0.001$). Although education level was not associated with DAS28-CRP, HAQ or EQ-5D, patients with occupation had lower HAQ score than patients without ($P < 0.001$). Multivariate analyses adjusted for the confounders revealed the similar results (Figure). Although patients with lower income had lower proportion of self-pay ($P < 0.001$), lower income was associated with lower proportion of biologic use.

Conclusion: SES may influence disease activity and ADL among patients with RA in Japan. Although Japanese health insurance system successfully decreased self-pay among patients with lower income, it did not have enough effectiveness to increase the proportion of biologic use among such patients. More efforts are needed to solve equity issue.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several factors including disease process and drug therapy allegedly predispose to infections in RA. Socioeconomic constraints on our setting impose unique impediments. RTI are rampant in younger women (WHO, 1999). Similar data in RA is woefully lacking.

Methods: A convenience sample of 400 consenting patients (ACR 1988 classified, age group 15-49 years, median disease duration 3 years, 80% RF/CCP seropositive) under supervised standard rheumatology care in a popular community center (CRD) were selected. On physician global assessment, patients were classified 10% asymptomatic, 56% mild, 34% moderate-severe [88% methotrexate, 33% chloroquin, 46% prednisolone (< 7.5 mg daily)]. 32 patients recalled past urinary tract infections and 6 had concurrent diabetes. Patients were interviewed comprehensively using a-priori validated relevant questionnaires. Gynecological examination was supervised by a senior gynecologist (RR).Vaginal smears (wet mount) were quickly examined (gold standard) by microbiologist (AV) to diagnose RTI as per WHO recommendations for community based management of RTI in developing countries; classified into bacterial vaginosis (includes gonococci/chlamydia),candida and trichomonas infections. No further culture/characterization studies were carried out. Standard methods used for statistical analysis (SPSS). Sample size of 384 subjects was calculated based on ~40% prevalence of RTI (Government of India Family Health Survey 1998-99).

Results: Prior to this study, none of the patients had ever volunteered or been questioned on RTI in our setting. Currently, relevant symptoms and clinical signs were recorded by 42% and 45% patients respectively. 39.3% cohort were diagnosed RTI; 32% bacterial vaginosis, 6.5% candidiasis, 0.8% trichomoniasis. 26% of RTI were asymptomatic; 9% lacked signs. A combination of vaginal itching and discharge and low back pain was 100% sensitive and 83.7% specific for diagnosis of RTI. None tested seropositive for syphilis. Some relevant features pertaining to QOL and functional ability were – HAQ (Indian version) disability classify- 84% mild, 16% moderate-severe; SF-36 data-61% moderate severe body pain and ~8% with major limitation on bathing/dressing. Several independent significant ($p<0.05$) risk factors for RTI(on univariate analysis/ logistic regression) were identified -notably * Age< 30 years, *small house, public toilet, *use of indigenous sanitary pads during menses,*difficulty/inability for certain physical activities (bathing, toilet use, lifting/carrying groceries, arising from floor), nervousness, * DMARD use (not an individual drug or steroid except chloroquine). Those marked with asterisk remained significant in a multivariable analysis; adjusted odds ratio for DMARD use 3.96 (95% confidence interval 1.9, 7.9).

Conclusion: This cross sectional community based clinical study unraveled a large burden of RTI in women suffering from RA. Surprisingly, the prevalence was similar to national statistics. However, regular screening algorithms for RTI are urgently required to prevent neglect and improve overall standard care in rheumatology practice.

Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The epidemiology of SLE has a complex gendered aspect, characterized by marked differences between the sexes in terms of the incidence, prevalence, and clinical manifestations. Males are reportedly less likely to be afflicted with SLE and women of childbearing age are disproportionately impacted. Females with SLE have more frequent exacerbations in general, but male patients appear to have significantly greater multi-systemic damage accrual and disease severity. Monitoring the fatal outcomes of SLE and frequency of common patterns of causes of death may offer insight into emerging health issues affecting contemporary SLE patients and can suggest the direction of future epidemiological investigations, particularly through a sex-based lens. This study provides a nuanced understanding of causes of deaths, related co-morbidities, and mortality differentials between males and females with SLE.

Methods: A cross-sectional study was performed on ~2.7 million death records from 2014 using the National Center for Health Statistics Multiple Cause of Death (MCOD) database, a population-based electronic medical recording of all death certificates issued in the United States. ICD-10 codes were isolated from the MCOD files and classified according to the Clinical Classifications Software (CCS), a well-developed categorization scheme that collapses ICD-10 codes into 260 clinically relevant categories. We compared sex-stratified demographic characteristics and the most frequently cited conditions in decedents with and without SLE. Relative risks quantified the risk of dying with the most frequently cited conditions among decedents aged ≤50 years comparing those with and without SLE to estimate the burden of premature deaths in this population.

Results: In 2014, there were 2,036 decedents with SLE in the United States. Females and Blacks comprised 86.2% and

30.7% of all SLE-related deaths, respectively. Female decedents with SLE died, on average, 22 years earlier (median age at death was 59 years) than those without SLE. Male decedents with SLE died 12 years earlier (median age at death was 61 years) than non-SLE males. Top causes of death in females and males with SLE were heart disease, diabetes, and hypertension. Among decedents aged ≤50 years, males with SLE had higher co-occurrence of coagulation and hemorrhagic disorders and chronic renal failure compared with those without SLE (RR: 16.69, 95% CI: 10.50-27.44; and RR: 5.76, 95% CI: 2.76-12.00, respectively). These co-morbid conditions were also important contributory causes of premature mortality among women, but to a lesser degree (RR: 4.98, 95% CI: 3.69-6.70; and RR: 8.55, 95% CI: 6.89-10.61, respectively).

Conclusion : Our findings identify important clinically relevant comorbidities that need to be considered more carefully in the course of patients' clinical management and the natural history of SLE disease.

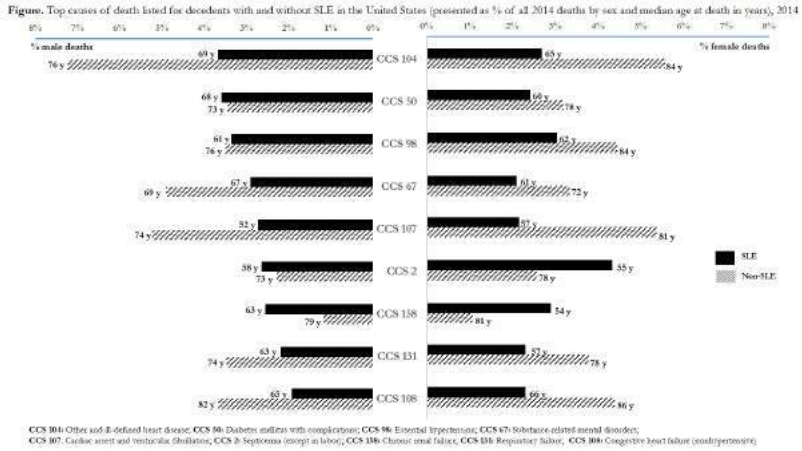

Figure. Top causes of death listed for decedents with and without SLE in the United States (presented as % of all 2014 deaths by sex and median age at death in years), 2014

CCS 104: Other and ill-defined heart disease; CCS 50: Diabetes mellitus with complications; CCS 98: Essential hypertension; CCS 67: Substance-related mental disorders; CCS 107: Cardiac arrest and ventricular fibrillation; CCS 2: Septicemia (except in labor); CCS 158: Chronic renal failure; CCS 131: Respiratory failure; CCS 108: Congestive heart failure (nonhypertensive)

Session Title: Healthcare Disparities in Rheumatology - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that can affect multiple organ systems and is associated with high morbidity. Studies have shown that there is a substantial health care costs associated with hospitalization of SLE patients. Among chronic, complex disease, often a small percentage of patients account for the majority of health care spending. **Objective:** To identify if there is a high risk, high cost group of SLE patients among all hospital admissions for SLE over a 2 year period.

Methods: We conducted a financial analysis of all admissions for systemic lupus erythematosus at the Strong Memorial Hospital between the July 1st of 2013 and June 30thof 2015. The total number of admissions for diagnosis code 710.0 was calculated based on primary or secondary diagnosis for the 2 fiscal years. The diagnosis of SLE was confirmed based on the presence of at least 4 criteria or had to be made by a rheumatologist. The age at time of admission and age when diagnosis of SLE was first made, gender, race, reason for admission and the zip code of the primary residence were recorded. Additionally, we noted the number of readmissions within a year and readmission within a 30-day period. We then determined the total cost of admissions, readmission and recorded the length of stay for all admissions and readmissions.

Results: The total number of confirmed cases of SLE admissions for the 2 years was 387 that comprised 202 patients. Of these 175 (45%) were due to readmissions (within a year) and 113 (29%) were readmissions within a 30 day period. The total cost of all admissions was $10,353,617 for the 2 years while the cost of readmissions was $1,772,675.00 per year. The cost of all readmissions within the 30-day period was $1,182,375 for the 2 year period. The length of stay for all SLE admissions was 1,564 days per year. Approximately, 44% of admitted patients were of American origin with 60% residing within the city of Rochester.Further analysis showed that 28 (16%) of the patients accounted for about 40% of the total cost of all admissions ($3,900,156), 45% of the length of stay, 49% of all admissions and 76% of all 30-day readmissions. These high risk patients were more likely to be younger, have earlier onset of SLE, more likely to be African American and more likely to be from within the city limits. The average cost of hospitalization for the high risk patients was $150,000 compared to $51,808 for other SLE patients. See Table

Conclusion: Hospitalizations of patients with SLE is a major cause for health care costs and readmission rates for SLE are high. A small group of high risk, high cost patient's account for majority of the hospitalization costs and length of stay among all SLE patient hospitalizations. A high-riskcare management plan could substantially reduce costs and improve quality of care for these patients.

	High risk SLE patient	**SLE patient**
Average cost/patient/YEAR	$ 150,000.06	$ 51,808.41
Average LOS/patient	48.3 days	15.6 days
Mean age (at admission)	38.2 years	45.5 years
Mean age (at initial diagnosis)	20 years	30.2 years
AA: C: A: H	61%: 29%: 7%: 3%	44%: 49%: 2%: 4%
Females: Males	82%:18%	91%:9%
Rochester zip code	75%	60%

Session Date: Sunday, November 13, 2016
Session Title: Healthcare Disparities in Rheumatology - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Some previous studies in Caucasian, Asian, and African-american patients have shown promising results for several urinary biomarkers in patients with lupus nephritis (LN). However, information regarding urinary biomarkers in Mestizo and Afro-Latin American patients is very limited. We investigated whether levels of urinary of monocyte chemoattractant protein 1 (MCP-1), neutrophil gelatinase-associated lipocalin (NGAL), ceruloplasmin (CP), transferrin (TP) and TWEAK are good biomarkers to differentiate patients with LN among Latin American SLE patients.

Methods: SLE patients meeting the revised ACR classification criteria for SLE were recruited from a referral University Hospital. Urinary levels of MCP-1, NGAL, CP, TF and TWEAK were measured using a commercial ELISA kits, R&D system, Minneapolis, USA for MCP-1, NGAL and TWEAK and Assaypro, Missouri, USA for CP and TF. Serum Anti C1q antibodies were measured by ELISA (Inova, San Diego, USA). SLE activity was measured with SLEDAI. Pearson or Spearman's rank correlations were used to examine associations between continuous variables. Additionally, ROC curves were done.

Results: 100 SLE patients were recruited (87% female) with median age of 33.4 ± 12.4 years and median disease duration of 7.6 ± 7.3 years. Mestizo (75%) and Afro-Latin American (22%) were majority. Mean SLEDAI score was 8.8 ± 9.0 and mean SLICC was 0.3 ± 0.6. Afro-Latin American had significantly higher prevalence of LN and serositis, and higher SLEDAI scores than Mestizo patients. All urinary biomarkers and anti C1q antibodies were significantly higher in patients with LN than in patients without LN. Additionally, NGAL, CP, TF and TWEAK were significantly higher in patients with active LN than in inactive LN (Table). NGAL levels were significantly higher in Afro-latin American patients (56 ± 56 vs 35 ± 46 pg/ml, $p=0.04$). No significant differences were found in urinary biomarkers levels among proliferative and non-proliferative forms of LN. We found significant positive correlation between all urinary markers and SLEDAI (r score ranging from 0.31-0.51, $p<0.05$ for all). A ROC curve for urinary biomarkers for LN in all SLE patients showed a good level of sensitivity and specificity for all, especially for CP (AUC 0.87), TF (AUC 0.84) and TWEAK (AUC 0.78).

Conclusion: In our cohort, Afro-Latin American were more severely affected with higher disease activity and more LN. We found several urinary biomarkers with good discriminative power to differentiate LN in Latin American SLE patients. Those markers were moderate correlated with disease activitiy. NGAL, CP, TF and TWEAK were significantly higher in patients with active LN.

Table. Urinary levels of several biomarkers and serum anti C1q antibodies according renal involvement and LN activity.

	Total SLE patients n=100	Group A LN n=66	Group B No LN n=44	p value A vs B	Group C Active LN* n=36	Group D Non-active LN N=21	p value C vs D

Session Date: Sunday, November 13, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: B cell subset proportions within the B cell pool, also known as B cell signatures (BCS), reflect not only systemic lupus erythematosus (SLE) disease activity status, but also therapy effects. In this study, we evaluated

whether socioeconomic-demographic, disease activity, immunologic, and treatment factors, may influence BCS in SLE patients.

Methods: Peripheral blood mononuclear cells were isolated from 37 patients who fulfilled the ACR Classification criteria for SLE, and from 14 healthy individuals. Socioeconomic-demographic (age, ethnicity, primary language, highest level of education, health insurance), disease activity (duration, SLEDAI score), and immunologic variables (parity, anti-dsDNA), as well as type of treatment received (standard of care therapy (SCT) vs Belimumab), were collected. B cell subsets (nonmemory =T1, T2, Follicular Mature (FM); memory =IgM, IgM/IgD, IgD, switched) were identified via flow cytometry. Student T-Test, one-way ANOVA, Dunnett's and Tukey's post-hoc tests were used for statistical analyses.

Results: Ethnicity, race, age, level of education, and primary language do not alter B cell subsets in SLE patients. SLE patients with either HMO-private or federal health insurance have less T1 subsets as compared to those with HMO-public insurance ($p = 0.0004$). SLE patients with either HMO-private or federal insurance have more FM subsets as compared to SLE patients with HMO-public insurance ($p = 0.0041$). Both T2 ($p = 0.0030$) and IgD ($p = 0.0389$) subsets from SLE patients with SLEDAI score 1-5 were lower as compared to healthy controls. Patients with SLE duration of disease from 0-5 or 6-10 years have lower T2 subsets as compared to healthy controls ($p = 0.0020$). Patients with SLE duration from 0-5 years have higher FM subsets as compared to healthy controls ($p = 0.036$). SLE patients have lower proportions of T2 subsets, irrespective of the presence or absence of anti-dsDNA, as compared to healthy controls ($p = 0.0052$). The presence of anti-dsDNA is associated with lower IgD subsets as compared to healthy controls ($p = 0.0204$). SLE patients with children have lower T1 ($p = 0.0326$) and higher FM ($p = 0.0448$) subsets as compared to those with none. SLE patients treated with SCT have lower T1 subsets as compared to those treated with both SCT and Belimumab ($p = 0.0303$). SLE patients treated with either SCT or Belimumab have lower T2 cells as compared to healthy controls ($p = 0.0102$). SLE patients treated with SCT have lower switched B cells as compared to those treated with both SCT and Belimumab ($p = 0.0064$). SLE patients treated with both SCT and Belimumab have higher switched B cells as compared to healthy controls ($p = 0.0064$).

Conclusion: To our knowledge, this is the first study showing that socioeconomic-demographic, disease activity, and immunologic variables are associated with unique B cell profiles in SLE patients.

Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: African Americans have higher rates of SLE and SLE nephritis compared to Caucasians. These epidemiologic associations come mainly from cohort studies that collect standardized information on SLE-related conditions but may not take advantage of the longitudinal data on comorbidities in the electronic health record (EHR). We assessed differences in comorbidities in African Americans vs. Caucasians with SLE using an EHR-based phenome-wide association study (PheWAS). Similar to genome-wide association studies, a PheWAS compares two groups using ICD-9 codes in place of single nucleotide polymorphisms.

Methods: We used our validated algorithm of ≥ 4 counts of the SLE ICD-9 code (710.0) and ANA positive ≥ 1:160 while excluding dermatomyositis and systemic sclerosis ICD-9 codes to identify SLE cases in a de-identified EHR called the Synthetic Derivative (SD). The SD contains over 2.5 million subjects with clinical data collected longitudinally over several decades. Our algorithm has an internally validated positive predictive value of 94% and a sensitivity of 86%. PheWAS was performed in African Americans vs. Caucasians adjusting for age and sex in logistic regression models and correcting for multiple testing using Bonferroni. PheWAS excludes subjects that have a one time count for an ICD-9 code to minimize the effect of coding errors.

Results: We identified 270 African Americans and 715 Caucasians with SLE. African Americans and Caucasians were predominantly female (89% vs. 90%, $p = 0.83$) with African Americans having a significantly younger current mean age (44 ± 17 vs. 53 ± 17, $p < 0.001$) and age at first SLE ICD-9 code (35 ± 16 vs. 43 ± 17, $p < 0.001$) with similar mean years of follow-up in the EHR (9 ± 5 vs. 10 ± 5, $p = 0.10$). Adjusting for sex and current age, compared to Caucasians, African Americans had 48 ICD-9 based phenotypes that met the Bonferroni threshold for significance ($p < 1.30 \times 10^{-4}$) including mostly renal and cardiac codes. The most significant codes were hypertension odds ratio (OR) = 4.25 (95% CI 3.05 – 5.92), $p = 1.43 \times 10^{-17}$, renal dialysis OR = 10.90 (95% CI 6.11 – 19.48), $p = 6.83 \times 10^{-16}$, and hypertensive heart and/or renal disease OR = 6.41 (95% CI 4.04 – 10.16), $p = 2.77 \times 10^{-15}$ (Table 1). Compared to Caucasians, African Americans were more likely to have codes related to SLE ACR criteria including pleurisy/pleural effusion, nephritis, pericarditis, pancytopenia, and joint effusions (all $p < 0.05$).

Conclusion: Using a large EHR, we found that African Americans had more codes related to ACR SLE criteria including renal disease as well as hypertension. While in the general population African Americans are twice as likely to have hypertension compared to Caucasians, our data show an even more pronounced effect in African Americans vs. Caucasians with SLE. Additional studies are needed to determine the mechanisms for this racial disparity.

Table 1.

ICD-9 Codes	Code Present	Code Absent	Adjusted Odds Ratio for current age and sex (95% CI)	p value
Hypertension (401)	423	494	**African American:** 4.25 (3.05 – 5.92) **Caucasian**: 1.00 (ref)	$p = 1.43 \times 10^{-17}$
Essential hypertension (401.1)	408	494	4.24 (3.03 – 5.94)	$p = 4.00 \times 10^{-17}$
Renal dialysis (585.31)	73	600	10.90 (6.11 -19.48)	$p = 6.83 \times 10^{-16}$
Hypertensive heart and/or renal disease (401.2)	119	494	6.41 (4.04 -10.16)	$p = 2.77 \times 10^{-15}$
Other anemias (285)	266	557	3.86 (2.75 – 5.41)	$p = 4.43 \times 10^{-15}$
End stage renal disease (585.32)	76	600	8.57 (4.97 – 14.79)	$p = 1.12 \times 10^{-14}$
Hypertensive chronic kidney disease (401.22)	103	494	6.63 (4.08 – 10.77)	$p = 2.27 \times 10^{-14}$
Acute renal failure (585.1)	149	600	4.43 (2.98 – 6.60)	$p = 2.19 \times 10^{-13}$
Pleurisy/pleural effusion (507)	127	700	4.39 (2.92 – 6.62)	$p = 1.30 \times 10^{-12}$

Anti-Neutrophil Cytoplasmic Antibodies (ANCA) in African-American Patients: Disease Associations and Clinical Outcomes in an Urban Cohort

Philip McCarthy[1], Jenna Hudy[2], Marie Melville[2], Danielle Robson[1], John McKinnon[2], Sandeep Soman[2] and Kathleen Maksimowicz-McKinnon[3], [1]Michigan State University College of Osteopathic Medicine, East Lansing, MI, [2]Henry Ford Hospital, Detroit, MI, [3]Rheumatology, Henry Ford Hospital, Detroit, MI

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antineutrophil cytoplasmic antibody-associated vasculitis (AAV) has been most extensively described and studied in non-African-American populations. The significance of and associations with ANCA in African-Americans, especially outside of AAV, has not been well characterized.

Methods: Retrospective chart review of patients self-identified as African-American with positive ANCA testing was performed. Records were reviewed in detail to classify patients as definite AAV using the revised Chapel Hill 2012 AAV criteria, probable AAV (in patients in whom biopsy evidence was absent but with a preponderance of clinical and serologic evidence to support the diagnosis), possible AAV (no biopsy evidence, compatible clinical/serologic picture, but less compelling evidence), and unlikely AAV. The presence of other autoimmune disorders, infectious disorders, and medications known to be associated with ANCA positivity were also documented.

Results: 77 African-American patients with ANCA were identified, of which 49 (63.6%) were female with a mean age of 57 at symptom onset. Of these patients, 21 had established AAV (27.3%), 3 had probable AAV (3.9%), 14 had possible AAV (18.2%) and 10 (13%) were deemed unlikely to have AAV. Eleven patients (14.3%) had drug-induced vasculitis, either from hydralazine or cocaine use. Sixteen patients (20.8%) had other autoimmune diseases, and of these, half were determined to have active vasculitis. Only 2 patients (2.6%) had vasculitis secondary to chronic viral infection (hepatitis). Patients most often were P-ANCA positive (51.9%), and often had other positive autoimmune serologies including antinuclear antibodies (42.9%) and rheumatoid factor (18.2%). Remarkably, 30 patients (38.9%) developed end-stage renal disease (ESRD). Considering other common comorbidities in this population potentially related to renal failure, diabetes mellitus (DM) was present in 20.7% of patients (mean duration=2 years, mean glycated hemoglobin=6.2) and hypertension (HTN) in 76.6% (mean duration 8 years, mean number of medications=1). Fourteen patients (18.1%) died, with a mean time to death of only 10 months from the time of their underlying diagnosis associated with ANCA.

Conclusion: ANCA are often detected in conditions other than AAV in African-American patients, and are frequently associated with other etiologies of vasculitis. Over one-third of African-American patients with ANCA developed ESRD, which given the data regarding HTN and DM in this population, seems unlikely to be wholly attributable to these comorbidities alone. Further study to explore the potential pathogenic role of ANCA in African-American patients, especially in regard to renal disease, is warranted.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Antineutrophil antibody-associated vasculitis (AAV) has been most extensively described and studied in non-African American populations. Little is known about the characteristics and outcomes of AAV in African American patients.

Methods: Retrospective chart review of patients self-identified as African-American with positive antineutrophil cytoplasmic antibody testing was performed. Records were reviewed in detail to establish disease classification of patients using the revised Chapel Hill 2012 AAV criteria.

Results: 21 patients with definite AAV were identified (10 GPA, 8 MPA, 3 with isolated renal AAV). Fourteen (66.7%) were female, with a mean age at symptom onset of 59 years. 4 patients (19%) were C-ANCA/PR-3 positive, all of whom had GPA. 100% of isolated renal AAV and 75% of MPA patients were P-ANCA/MPO positive. Nine patients (42.8%) were antinuclear antibody positive, and 5 patients (23.8%) had a positive rheumatoid factor. At the time of diagnosis for the 18 GPA and MPA patients, recurrent sinusitis was found in 12 patients (66.7%), but otalgia or otitis was less common, noted in only 4 patients (22.2%) Sixteen patients (88.9%) had pulmonary infiltrates, ten patients (55.6%) had diffuse alveolar hemorrhage, and 8 patients (44.4%) required mechanical ventilation at presentation. 11 patients (52.3%) of the entire cohort required hemodialysis at presentation, and 12 patients (57.1%) ultimately developed end stage renal disease (ESRD). Fourteen patients had concomitant hypertension, with a mean number of antihypertensive medications of 1.7. Seven patients had diabetes mellitus, with a mean glycated hemoglobin of 7.5 and mean duration of disease of 7.7 years. 9 patients (42.8%) developed at least one relapse, with a mean time to relapse of 20.5 months following diagnosis. Eight patients (38%) died, with a mean time to death from diagnosis of 32 months.

Conclusion: African-American patients with AAV frequently present with pulmonary and renal manifestations, which are often severe at onset, requiring supportive care. More than half of this cohort went on to develop ESRD, and over one-third died on average within 3 years following their diagnosis, demonstrating that AAV may have an aggressive course in these patients. There are many possible factors that could influence these outcomes, including other comorbid conditions, delay in diagnosis, genetics, environmental factors, and limited access to care. Further study is needed to better understand factors that influence AAV severity and course in this population in order to improve long-term outcomes and survival.

Call to Action: Cardiovascular Comorbidities in Medicare Rheumatology Beneficiaries

Gurjit S. Kaeley[1] and Sunita Dodani[2], [1]University of Florida, Ponte Vedra Beach, FL, [2]Cardiology and Epidemiology, University of Florida College of Medicine, Jacksonville, Jacksonville, FL
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Healthcare Disparities in Rheumatology - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular (CV) manifestations of Rheumatological inflammatory diseases have become increasingly recognized, and, in some patients, might even constitute the initial presentation of a Rheumatological disorder. The objective of this study was to examine the CV co-morbidities in Medicare beneficiaries using 2013 aggregated Part B Medicare data.

Methods: Aggregated tables by physician national identifier as well as State and HCPCS codes have been made available with beneficiary demographic and health characteristics. The 2013 data is based on all Medicare part B non-institutional claims. Since claims data is used for payment, it is felt that the documentation of disease processes is reliable. For each chronic condition outlined in table, the prevalence was averaged across all providers. Population numbers were calculated by multiplying unique beneficiary counts by percent prevalence. National disease prevalence percentages and numbers were obtained from the Medicare chronic conditions warehouse. Complete cases of data where then extracted to examine state trends. Beneficiary numbers with the respective disease were calculated, aggregated and plotted by state.

Results: Mean beneficiary age was 70 years with the majority of females, white, and aged between 65 to 74 (Table 1). The prevalence of hypertension (65%) and hyperlipidemias (53%) were highest CV comorbidities and were higher compared to the national figures. (Table 1). Moreover, all comorbidities were higher in the rheumatology beneficiary population compared to the national population. Ischemic heart disease prevalence was 32% compared to 19% in the national population. Of note, the prevalence of diabetes was slightly lower (29%) than the ischemic heart disease in both populations. State trends revealed that the highest prevalence of cardiovascular comorbidities was in Florida, even though California has the largest beneficiary population (Figure 1). The pattern of prevalence of hypertension and hyperlipidemia were closely related over all the states.

Conclusion: The past decade has brought many new insights regarding excessive burden of CV co-morbidities associated with Rheumatological inflammatory diseases. This study has highlighted strong evidence of high CV co-morbidities prevalence among Medicare beneficiaries placing this group under high CV risk category based on the recent national guidelines. Taken together, these findings underscore the complexity of the Rheumatological inflammatory diseases and highlight the key role of further epidemiological research in understanding these intriguing conditions. In addition, priority should be given to pay attention to control of factors affecting CV co-morbidities in this high-risk population.

Table 1: Key Demographic Factors

Demographic Factors	Number (Percentage)
Number of Female Beneficiaries	1,151,417 (75%)
Number of Male Beneficiaries	385,537 (25%)
Number of Non-Hispanic White Beneficiaries	1,184,949 (77%)
Number of Black or African American Beneficiaries	109,147 (7%)
Number of Hispanic Beneficiaries	75,352 (5%)
Number Other Race	26,352 (2%)
Average Age of Beneficiaries	70
Number of Beneficiaries Age 65 to 74	648,220 (42%)
Number of Beneficiaries Age 75 to 84	427,337 (28%)
Number of Beneficiaries Age Greater 84	150,172 (10%)
Number of Beneficiaries Age Less 65	287,963 (19%)

Table 2: Prevalence of Cardiovascular Co-morbidities

Chronic Condition	National Prevalence (n=55,277,442)	Rheumatology Beneficiary Prevalence (n=1,543,431)
Hypertension	20,426,302 (37.0%)	1,015,681 (65.3%)
Hyperlipidemia	16,347,454 (29.6%)	843,412 (53.0%)
Ischemic Heart Disease	10,547,270 (19.1%)	503,626 (32.4%)
Diabetes	10,441,385 (18.9%)	439,879 (29.2%)
Chronic Kidney Disease	6,050,057 (10.9%)	319,692 (22.2%)
Heart Failure	5,355,637 (9.7%)	249,987 (17.3%)
Atrial Fibrillation	2,863,545 (5.2%)	141,915 (9.7%)
Stroke / Transient Ischemic Attack	1,378,435 (2.5%)	57,944 (4.7%)

Rheumatology prevalence is calculated by averaging the percent prevalence of the chronic condition per provider.

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The goal of therapy of rheumatoid arthritis(RA) is to achieve a remission or at least low disease activity. Tocilizumab completely interrupt the effect of IL-6 and showed a full inhibition of CRP production[1]. So we are interested in whether it will influence the outcome measure to predict RAactivity in daily practice.This study aimed to investigate whether RA patients on tocilizumab therapy had the same efficacy on ultrasound and inflammatory parameters as compared with adalimumab treatment.

Methods: We compared RA patients on tocilizumab and adalimumab therapy and evaluated inflammatory parameters and ultrasound score. Gray scale synovial hypertrophy (SH) and power Doppler (PD) ultrasound were performed on bilateral dorsal radio-carpal joints of in patient. The sum of the score was calculated.Independent t test was used to compare inflammatory mediators and ultrasound scores between tocilizumab and adalimumab.

Results: A total of 48 patients with RA (24 tocilizumab and 24 adalimumab) were enrolled. The age, gender, rheumatoid factors and ACCP were no difference between these two groups. The mean ultrasound was 2.33±1.40 (Tocilizumab) and 2.08±1.53 (Adalimumab), p=0. 570. The ESR , CRP and DAS 28 were lower at Tocilizumab group. (Table 1)

Conclusion: From this study, in patients on tocilizumab therapy, the laboratory parameter and clinical evaluation was lower than adalimab depite the same ultrasound score beteen the two group. So we cannot measure disease activity based only on clinical evaluation. We suggest using PD ultrasound evaluation in all the patients on tocilizumab therapy to actually reflect the true nature of disease entity in these patients.

Table 1.Comparison between tocilizumab and adalimumab group based on laboratory and ultrasound score

	Tocilizumab(n=24)	Adalimumab(n=24)	P value
ESR (mm/hr)	20.75±25.19	47.38±26.22	0.001
CRP (mg/L)	0.97±0.89	11.71±12.43	0.001
DAS28	5.33±0.63	5.90±0.69	0.003
Ultrasound scores	2.33±1.40	2.08±1.53	0.558

Title: Anti-CCP Status Determines the Power Doppler Oscillation Pattern in Rheumatoid Arthritis – a Prospective Study Abstract:

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease leading to joint destruction. Serologically, it can be differentiated according to rheumatoid factor (RF), anti-cyclic-citrullinated-peptide antibodies (anti-CCP) or both. This differentiation is prognostically and therapeutically relevant. No method has been described to separate the two forms phenotypically. We hypothesize that a differentiation is possible by evaluating oscillation patterns in power Doppler sonography (PDS).

Methods: In a prospective study, 20 patients with anti-CCP-positive RA and 20 patients with anti-CCP-negative RA with active wrist synovitis were examined. A PDS scan was performed, and perfusion maxima (Pmax) and minima (Pmin) as well as the difference (ΔP) were determined by a blinded study member. The difference was standardized (sΔP) by dividing by Pmax, and the anti-CCP-positive and -negative patients as well as the RF-positive and -negative were compared to each other.

Results: In the ultrasonographic evaluation we found a highly significant difference in sΔP between anti-CCP positive and

anti-CCP negative patients (Median 19.01% vs. 42.92%, p<0.0001) (Fig.1). sΔP is independent of disease activity. ΔP did not differ between the groups. Also, in anti-CCP-positive patients there was a completely linear correlation between Pmax and Pmin, this was far less marked in anti-CCP-negative patients (Fig.2). The difference between RF positive and RF negative patients was significant, but less pronounced than for anti-CCP.

Conclusion: Anti-CCP-positive and anti-CCP-negative RA display different PDS oscillation patterns. This constitutes a non-serological parameter to differentiate between the two forms. The difference in PDS oscillation patterns suggests that the underlying pathological process differs between the forms.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Doppler ultrasound plays an increasing role for monitoring disease activity in rheumatoid arthritis (RA). This study aimed to evaluate the association between two semi-quantitative color Doppler ultrasound scoring systems (SQS) currently in use, and the novel quantitative scoring (QS) of color Doppler pixel count.

Methods: Adult patients with RA and inadequate clinical response to anti-rheumatic therapy were examined with musculoskeletal ultrasound (MSUS) upon entering a prospective study with add-on therapy. Dorsal MSUS of the wrists, metacarpophalangeal joint (MCP) 2-5 and metatarsophalangeal joint (MTP) 2-5 in both sides were performed. All MSUS images with sign of synovitis were collected and the QS was measured. Five assessors blinded to the QS evaluated all the images independently from each other, according to either SQS method. Association between QS and SQS was studied using correlations and multilevel models taking into account the clustering of ratings at the rater, patient and joint levels.

Results: Analysis of the 1190 ratings collected revealed a strong correlation (ρ=0.89, $p<0.0001$) and significant associations ($p<0.0001$, for all multilevel models) between QS and SQS. Correlations between QS and SQS according to Szkudlarek et al. (ρ=0.87, $p<0.0001$) or Hammer et al. (ρ=0.91, $p<0.0001$) were similar. A total of 239 (20.1%) images were given a SQS grade that did not match that expected based on initial QS, using predefined cutoffs. Main explanations for discrepancies were different perceived region of interest (ROI) (40.7%) and Doppler pixel count near cutoffs between SQS grades (32.3%).

Conclusion: We showed that both SQS methods correlated well with QS to assess synovial activity in RA. This suggests that any of these methods can be used to assess synovial activity in RA, but also that SQS methods are intrinsically limited when the Doppler pixel count is close to the cutoffs between the SQS grades. Another main reason for discrepancy was different perceived ROI that might underline the need for further consensus on how to define the ROI at the joint level. Analysis discrepancies between these methods may help guide further revision of criteria used to assess disease activity with MSUS in RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

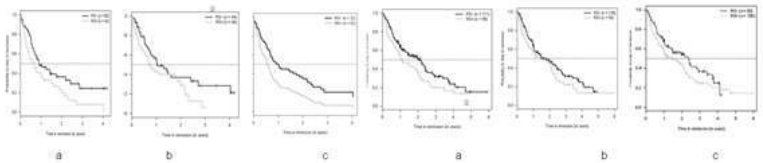
Background/Purpose: Previous publications have suggested that patients in clinical remission with residual ultrasound (US) synovitis flare more often and do not stay in remission as long as those without residual US synovitis. Those studies based essentially on Doppler mode have been performed in single centers by a few highly skilled operators. Recent studies performed among real life cohort have however shown that the predictive value of US could be not be as clear as previously suggested. The objective of this study was to investigate the predictive value of US residual synovitis on loss of remission in a real life settings and in particular how the time point when ultrasound was performed influence remission survival

Methods: This is retrospective longitudinal cohort study nested into the Swiss RA registry (SCQM) registry. It included all RA patients with at least one US score done in clinical remission (DAS<2.6) and at least two clinical evaluations implemented in the registry between 2009 and 2016. US significant residual synovitis was based on the Swiss SONAR score, which adopted the single joint definition of pathologies according to OMERACT for 22 joints using both a B mode and a Doppler mode. Flare was defined as DAS >2.6 or change in medication. Duration of remission was calculated either since the first visit before US with a DAS <2.6 or the last visit with a DAS>2.6. An early US subset group was defined when US performed within 6 months after start of remission. Left and right imputation analysis were applied to better estimated the real duration of remission before and after US was performed. Several cofactors for loss of remission were also analyzed.

Results: 264 RA patients were included. 328 eligible remission phases were available. 103/261 remissions were considered as early US (<6 months) according to the predefined mode of calculation. 198 loss of remission was objectivized in the overall cohort and 84 in early US subgroup. Time in remission before US whatever score used was the only independent covariate factor in both the overall cohort and the early US subgroup. The table summarized the hazard ratio for loss of remission adjusted for time in remission and other covariate using left (L) and right imputation (R) according to: B mode (>2 grade 2 synovitis), Doppler mode and combined score in the total cohort and in the early USsubset . Median times to loss of remission using B mode were 2.1 (95% CI: 1.4, 2.4) for US- and 1.1 year (95% CI: 0.9, 2) for US+ (log-rank p-value = 0.024) in the early subset group (right imputation).

	HR	Lower 95	Upper 95
Overall cohort: L/R	L/R	L/R	L/R
B mode n=328	1.2/1.3.	0.95/0.97	1.7/1.7
Doppler n=297	1.1/1.2	0.83/0.89	1.5/1.6
Combined score , n=281	1.3/1.4	0.95/*1.01*	1.9/2
Early US: L/R			
B mode, n=103/261	*2/1.5*	*1.2/1.08*	*3.2/2.1*
Doppler, n= 88/261	1.3/1.2	0.70/0.87	2.4/1.8
Combined score, n=84/221	1.7/1.4	0.88/0.96	3.3/2

Figure below summarize Kaplan -Meyer plot of time to loss of remission in the early US subset group according to a: B mode, b: Doppler mode, c: combined scores (left / right imputation).



Conclusion: Our study confirmed that ultrasound has a modest independent predictive value for loss of remission when applied in a real life cohort. In this condition, US done early in remission using B mode seems to have the best predictive

value.

Agreement Between DAS28-ESR, DAS28-CRP, SDAI, CDAI (Simplified/Clinical Disease Activity Index), ACR/EULAR Remission Criteria and Ultrasound Scoring (Naredo-12) in Patients with Rheumatoid Arthritis in Routine Care

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical remission is now a realistic goal in managing rheumatoid arthritis (RA) with treat to target strategy assessed according to different composite scores (DAS28, Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), ACR-EULAR 2011 for remission). There are, however, no validated ultrasound remission criteria because of continuing uncertainty on the signification of persistent synovial hypertrophy in B-mode or Power Doppler (PD) mode in RA patients in clinical remission. Objective: evaluate correlations between the validated 12 joints-Naredo ultrasound score (B-mode (0-3), PD (0-3), combined B+PD (0-6) or PDUS (0-3, max between B-mode or PD)) and the DAS28-ESR, DAS28-CRP, CDAI, SDAI and ACR-EULAR criteria for remission in routine care.

Methods: French multicenter cross-sectional study in 11 rheumatology departments. The inter and intra-observer reproducibility for the ultrasound scoring was good to excellent. Inclusion criteria were as follows: RA meeting ACR-EULAR criteria, <15 years of progression, DAS-28-ESR<2.6 for at least 3 months, with a stable treatment including corticoids if necessary (equivalent prednisone<0.1 mg/kg) for 6 months. A standardized US examination was performed by an experience ultrasonographist blinded to clinical data. Spearman's correlation coefficients were determined between the Naredo12 B-mode (min-max,0-36), PD mode (0-36), combined mode (0-72) and PDUS (0-36) scores and the different clinical remission scores. The impact of disease duration or duration of the clinical remission on ultrasound scores was also assessed (Kruskall-Wallis's test).

Results: 225 patients were included consecutively (58.6±12.4 years, 68.4% women, RA duration 6±3.7ans, 71.3% ACPA+, duration of remission 20.8±19.4 months, 92% on methotrexate, 52.4% on biotherapy, 9.8% on corticoids, DAS28-ESR=1.7, 75% in ACR-EULAR remission). 68.9% of patients had a PD Naredo score of 0, 82.7% ≤ 1, 90.7%≤2. Table 1 presents correlations between ultrasound scores and clinical scores. These correlations were weak to moderate, depending on the set of criteria. No association was found between ultrasounds scores and duration of the remission or of the disease.

Conclusion: The Naredo score in PD mode showed the best construct validity whatever the clinical score chosen, even though the correlations remained relatively weak, in part because of differences between the joints analyzed (12 US joints including ankles vs. 28 clinical joints without ankles). The CDAI and SDAI, which are more stringent for clinical remission appeared to correlate better than the DAS28-ESR score which is the most widely used in everyday practice. Other real–life studies are necessary to evaluate the potential added value of this combined US-clinical assessment of RA

remission in routine care.

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Restoring normal functioning is a major therapeutic aim. Differences in the sources of functional limitations should be considered in the interpretation of functional measures. We investigated the longitudinal relationship between HAQ and 7-joint ultrasound score (US7S[1]) in a prospective cohort of patients with RA.

Methods: A cohort of 185 RA pts (46 incident/139 prevalent, mean±SD age 55±14 years, 47% RF+, 63% ACPA+, baseline DAS28-CRP 3.7±1.5, HAQ 0.78±0.73, disease duration incident vs. prevalent pts. 0.9±0.7 vs. 8.1± 8.3 resp.) was followed up for 29±9 months. Assessments at baseline and then annually comprised DAS28-CRP, HAQ and US7S[1]. US7S includes 7 joints of the clinically dominant hand and foot and consists of 5 sub-scores for synovitis (syn) and tenosynovitis (ten) assessed by grey-scale (GS) and Power-Doppler (PD), and an erosions score (ES). A linear mixed model was used to assess the longitudinal relationship between US7 sub-scores and HAQ. We used current and time-lag models to explore the association between HAQ and predictors measured at the same time or at the previous visit 12 month ago, resp.

Results: Current model: In univariate analyses (table 1) HAQ was positively associated with GSsyn, PDsyn, PDten and GSten US7 sub-scores with resp. β coefficients significantly higher in incident than in prevalent patients. In a multivariate

analysis (table 2) the US7 sub-scores were individually no longer significant predictors of HAQ, although the R^2 of the model was improved by addition of US7 items from 37.4 to 48.7 ($p<0.001$ for improvement of R^2). Time-lag model: In multivariate analyses (table 3) after adjustment for previous DAS28 and/or previous HAQ, both previous PDsynUS and GSsynUS were significantly and inversely associated with the current HAQ (table 3).

Conclusion: US7S subscores for synovitis were associated with the reversible activity-related component of HAQ, and may help to identify patients with higher chance for functional improvement. **References:** [1]Backhaus M. et al. Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal ultrasonography (US) is one of the standard tools for the diagnosis and monitoring of rheumatoid arthritis (RA). Although we and other groups have proposed several sets of US assessment procedures in arbitrary combinations of selected joints, there is still no consensus in defining the joints to evaluate. Here, we investigated whether US assessment in the selected 8 joints which we have advocated as a routine assessment for detecting RA synovitis is also useful for monitoring response to treatment for RA.

Methods: Power Doppler (PD) US was performed in 24 joints, including all PIP, MCP, bilateral wrist and knee joints, as comprehensive evaluation in 15 RA patients treated with certolizumab pegol (CZP). Before and after treatment with CZP, PD signals and gray-scale (GS) images were scored semiquantitatively from 0 to 3 in each joint. Total PD score-24 and total PD score-8 were calculated by summing up PD scores of the 24 joints and the selected 8 joints (bilateral second and third MCP, wrist, and knee joints), respectively. Total GS score-24 and total GS score-8 were also calculated by summing up GS scores of the 24 joints and the selected 8 joints, respectively.

Results: Change amount of total PD score-8 by treatment with CZP exhibited strong correlations with the changes of disease activity indices, SDAI ($r_S = 0.92$, $p < 0.01$) and DAS28-CRP ($r_S = 0.89$, $p < 0.01$). Change amount of total PD score-24 also correlated strongly with the changes of SDAI ($r_S = 0.91$, $p < 0.01$) and DAS28-CRP ($r_S = 0.86$, $p < 0.01$), and the correlation coefficients were comparable with those for total PD score-8. Although the change of total PD score-8 correlated well with the changes of some components of disease activity indices, including swollen joint count ($r_S = 0.81$, $p < 0.01$), tender joint count ($r_S = 0.91$, $p < 0.01$), CRP ($r_S = 0.82$, $p < 0.01$) and ESR ($r_S = 0.63$, $p < 0.01$), there were no significant correlations between the changes of total PD score-8 and the changes of patient's global assessment ($r_S = 0.39$, $p > 0.05$) and evaluator's global assessment ($r_S = 0.22$, $p > 0.05$). The change of total PD score-24 correlated more weakly with the changes of swollen joint count ($r_S = 0.74$, $p < 0.01$) and tender joint count ($r_S = 0.86$, $p < 0.01$) as compared to total PD score-8. The correlation coefficients between the change of total PD score-24 and the changes of CRP ($r_S = 0.85$, $p < 0.01$) and ESR ($r_S = 0.62$, $p < 0.01$) were comparable with those for total PD score-8. There were no significant correlations between the changes of total PD score-24 and the changes of patient's global assessment ($r_S = 0.42$, $p > 0.05$) and evaluator's global assessment ($r_S = 0.27$, $p > 0.05$). The changes of total GS score-8 and total GS score-24 correlated to the changes of SDAI with the same level of correlation coefficients ($r_S = 0.69$, $p < 0.01$, and $r_S = 0.70$, $p < 0.01$).

Conclusion: This study indicates that the change of the 8-joint US scores by treatment correlated with the changes of disease activity indices as strongly as the change of the comprehensive 24-joint scores. Thus the 8-joint assessment can be a useful method for monitoring response to treatment in RA patients.

The 7-Joints Musculoskeletal Ultrasound Score (US7 score) Predicts Therapeutic Change in Patients with Early Rheumatoid Arthritis

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment decisions in patients with Rheumatoid Arthritis (RA) after the "Treat to Target (T2T)" -principle is widely recommended, as this management strategy leads to a better outcome (1). Recently, the additional use of musculoskeletal ultrasound (US) within the T2T-strategy was recommended (2). However, superior value in terms of outcome of US- compared to the use of (only) clinical scores-guided strategy has not been demonstrated (3). To assess potential clinical and imaging markers which may have the capacity to predict changes of therapy.

Methods: In this ongoing observational study ('Arthromark'), patients with early RA (disease duration $\leq$2 years) are included before therapy initiation/change and amongst others parameters are assessed by the clinical score DAS28(ESR) and by all items of the 7-joint US score (US7 score; (4)) at baseline (before therapy initiation/change), and after 1.5, 3, 6, and 12 months. At each visit, treatment decision of the antirheumatic therapy is performed according to the T2T-principle. Treatment change contains any modification of the antirheumatic therapies during the 12 months follow-up, i.e. doses escalation, combination of conventional DMARD therapies, and additional/change to biologic therapies. The following two patient groups were considered in the analysis: **1)** patients that underwent any change in the antirheumatic therapy, and **2)** patients that underwent none of the changes mentioned above. This analysis aimed to investigate the association between this change and the clinical (DAS28) and the ultrasound (US7) parameters at baseline. The differences between these two patient groups regarding baseline DAS28(ESR) as well as the ultrasound scores were examined applying statistical tests (Mann-Whitney-U test for continuous variables, χ^2test for categorical variables). The significance level was 0.05, which was not adjusted for multiple testing. Furthermore, ROC analysis was performed to investigate the ability of these baseline variables in discriminating the two patient groups.

Results: 74 patients were included in the analysis (average age 52.37 years; 75.68% female). On average, time since first diagnosis was about half a year (max. 2.03 years). At baseline, DAS28(ESR) was 5.14 (min. 3.37, max. 7.57) on average. No statistically significant difference was shown between the two groups regarding baseline DAS28(ESR), however in terms of the baseline US7 synovitis B-mode score, the US7 synovitis Power Doppler score, and the US7 erosion score (**Figure 1**). These results agree with the results of the ROC analyses (**Figure 2**), where the AUC of the baseline US7 synovitis B-mode score, the US7 synovitis Power Doppler score, and the US7 erosion score were significantly different from 0.5, indicating that these variables can discriminate patients with and without therapeutic change well enough. According to the ROC analyses, DAS28(ESR) and the US7 tenosynovitis scores (B-mode and Power Doppler) show relatively poorer discriminating performance.

Conclusion: These analyses give a quantitative insight into the association between DAS28(ESR) and US7 score measurements at baseline and any therapeutic change during the course of the study. The results suggest that the synovitis ultrasound scores (in B-mode and Power Doppler) and the erosion score, in contrast to DAS28(ESR), might be able to predict the therapeutic change during the treatment course of patients.

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Novel treat-to-target strategies present new challenges to treatment monitoring in rheumatoid arthritis (RA). To compare functional outcomes in early RA patients monitored by standard of care alone (clinical cohort) or with an additional musculoskeletal ultrasound examination (US cohort) following a treat-to-target strategy in a nationwide investigator-initiated study in Germany.

Methods: Functional, clinical and laboratory parameters monitored over 18 months in both cohorts were: Health Assessment Questionnaire (HAQ), Disease Activity Score 28 (DAS28), Visual Analogue Scale (VAS), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP). Ultrasound remission criteria used in the US cohort were: gray-scale ultrasound (GSUS) <2 at joint level and power Doppler ultrasound (PDUS) = 0. We additionally compared HAQ, DAS28, VAS, ESR and CRP in US cohort subgroups with and without ultrasound remission.

Results: In all 313 patients (US cohort: n=166, clinical cohort: n=147), laboratory activity, DAS28, VAS and HAQ decreased to low-disease activity levels within 18 months after the beginning or change of antirheumatic therapy, with no significant differences between groups. However, US cohort members with ultrasound remission (n=79) had significantly lower HAQ (0.401 vs. 0.741, p=0.002), DAS28 (2.2 vs. 3.4, p<0.001) and VAS disease activity scores (16.6 mm vs. 33.9 mm, p<0.001) than those without ultrasound remission (n=87).

Conclusion: Treat-to-target strategies reduced disease activity and improved functional outcomes (HAQ) in our early RA patients, irrespective of the monitoring regimen. However, patients with ultrasound remission had significantly better disease activity scores and functional outcomes. Accordingly, ultrasound should be strongly considered as an additional monitoring tool in clinical practice.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasonography (US) is an important tool in rheumatology practice. However, it highly depends on sonographer's experience. The **objective** of our study was to evaluate intra and inter-reader reliability of ultrasound assessment in rheumatoid arthritis (RA) using a Score named REUMA (Rapid Evaluation by US to Monitor Arthritis) among observers across Latin American using a web tool.

Methods: We conducted a cross-sectional study. Fifty-one Latin American ultrasonographers with different experience took part in a web- based US reading exercise evaluating static images from 20 RA patients. The 4 – joints US scores was calculated for each patient including bilateral radiocarpal, midcarpal and second metacarpophalangeal joints. Power Doppler (PD) and gray scale (GS) were graded from 0 to 3. US scores comes as the result of the addition of PD and GS score, with a total score ranged from 0 – 36, being 36 the highest disease activity. Five patients were evaluated twice in order to address intra – rater reliability. The inter and intra-rater reliability was assessed using a two-way random, absolute, individual and average-measures intra-class correlation coefficient (ICC), with reliability being poor for ICC <0.40, fair for 0.40 to 0.59, good for 0.60 to 0.74, and excellent for values between 0.75 and 1.0. Furthermore, we stratified sonographers according to US experience (defining High experience as: at least 5 years of experience and 80 US assessments/month), evaluating differences in intra – reader reliability, inter-reader reliability, and variation of observers means between patients. Statistical significance was assessed at a type I error rate of 0.05.

Results: A total of 1020 US image assessments were performed. Mean 4-joints US score was 17 ± 8 (Doppler subscale 10 ± 4; Synovitis subscale 7 ± 4). The ICC was in the excellent range for intra [(individual ICC = 0.945 (IC95% 0.905 – 0.965); average ICC = 0.972 (IC95% 0.950 – 0.982)] and inter- reader reliability [(individual ICC = 0.867 (IC95% 0.786 – 0.934); average ICC = 0.997 (IC95% 0.995 – 0.999)]. When comparing high with low experience sonographers, there

was no significant differences in intra-class correlation coefficient. However, there was a greater variation between the means among low experience readers, ranging from 13 to 22, in comparison with 14 to 18 in higher experience sonographers (**Figure 1**), which could introduce a bias to inter – reader reliability estimates.

Conclusion: Ultrasonography represents an excellent complementary tool to evaluate disease activity in patients with rheumatoid arthritis. However, its reliability is related to sonographer expertise and experience. Low – experience readers exhibit a higher variation on disease activity estimates. It is necessary to develope US training programs in order to improve reliability. **Figure 1.** Agreement with the mean between multiple observers in total score, gray and power doppler subscale.

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The assessment of cartilage and bone damage in rheumatoid arthritis (RA) has traditionally relied on radiographical analyses in which joint space loss served as a surrogate marker of cartilage loss. Discernment of the relative contributions of damage to cartilage and other soft tissue structures within the joint space narrowing score however is not possible. Recently musculoskeletal ultrasonography (MSUS) was shown to be a reliable and reproducible tool for the assessment of cartilage in RA in the small joints of the hand. We aimed to produce MSUS consensus-based definitions of cartilage change in RA and assess its intraobserver and interobserver reliability.

Methods: We conducted a Delphi study on US defined cartilage change and a proposed semiquantitative (SQ) US scoring system for cartilage change in RA. A written Delphi questionnaire was developed based on a systematic literature review and expert international consensus and was distributed via consecutive written questionnaires by email to a group 35 rheumatologists from 17 countries with experience in musculoskeletal US. Taskforce members performed US B mode examination of the metacarpal cartilage in metacarpophalangeal joints 2-5 in RA patients and the images were collected in an electronic database. A reference image atlas of cartilage changes was developed for scoring 123 anonymized images including 25 duplicate images. These were sent to the participants who independently scored the images. Intraobserver reliability was assessed by CohenÕs kappa and interobserver reliability by FleissÕ kappa.

Results: Group agreement (76-100%) was reached for 6 statements concerning: i) MSUS definition and assessment of normal hyaline cartilage, ii) elementary cartilage lesions in MSUS and iii) grading of elementary cartilage lesions inpatients with RA in a two-round Delphi consensus process. A three-grade SQ (0-2) scoring system (grade 0, normal cartilage; grade 1, minimal change: blurring of outer and/or subchondral margin, focal thinning or incomplete loss of homogeneity of echostructure; grade 2, severe: diffuse thinning or complete loss of homogeneity of echostructure) was agreed for scoring cartilage damage in RA (Figure 1). Both intra- and inter-observer reliability were good (κ value of 0.87 and 0.64 respectively).

Conclusion: This study demonstrates that US is a reliable tool for evaluating cartilage in RA and strongly supports the use of a new reliable semiquantitative MSUS scoring system for cartilage change.

Figure 1. Three-grade semiquantitative scoring system (0-2) for scoring cartilage damage in RA.

Session Time: 9:00AM-11:00AM

Background/Purpose: This study is a sub-analysis of the data from the patient cohort of STARTER (The Sonographic Tenosynovitis Assessment in RheumaToid arthritis patiEnts in Remission) study group conducted by the Musculoskeletal Ultrasound Study Group of the Italian Society for Rheumatology (SIR). In this study we have proved the association between prevalence of ultrasound tenosynovitis in patients with RA in remission and increased risk of flare in one year. The aim of this ancillary study was to evaluate if the patients in combo therapy with DMARDs and Biologic present lower ultrasound joint and/or tendon involvement in compare to patients treated with only DMARDs or Biologic in monotherapy.

Methods : STARTER is a multicentre cohort study promoted by the Musculoskeletal Ultrasound Study Group of SIR that includes 25 Italian rheumatology units. 427 consecutive patients with a diagnosis of RA according to the American College of Rheumatology (ACR) criteria 1987 or ACR/EULAR (European League Against Rheumatism) 2010 criteria and in clinical remission were recruited between October 2013 and June 2014; at baseline (T0), 6 (T1) and 12 (T2) months each patient was undergoing clinical evaluation (performed by rheumatologists blinded to the ultrasound data) and ultrasound by using a semi-quantitative score 0-3 gray scale (GS) and power doppler (PD) for the evaluation of the flexor and extensor tendons of the fingers and wrists. For each patient it was calculated a final score of GS-tenosynovitis, PD-tenosynovitis. The ultrasound remission was defined as a score = 0. Were included in the study 427 patients, divided into 3 subgroups according to background therapy at baseline: patients with biologic in monotherapy (BIO), patients with DMARD in monotherapy (DMARDs), patients in combo therapy (DMARDs + BIO).

Results : 257 patients completed the observation period. 49 pts in BIO group (19.7%, F34 / M15), 152 pts in the DMARDs group (59.14% -F105 / M47), 56 pts in BIO + DMARDs group (21.79% -F47 / M9). The demographic and clinical characteristics at baseline are presented in Table 1 and 2. At baseline, 56.03% (144/257) of patients showed tenosynovitis, the 48.98% (24/49) BIO, the 57.89% (88/152) DMARDs, the 57.14% (32/56) DMARDs + BIO. The tenosynovitis involvement at baseline, at 6 and 12 months showed into three different subgroups analyzed, has no

statistically significant changes (Fig. A). In the BIO group, there was a patient who had a flare few days prior to follow up visit at T12.

Conclusion : As shown in STARTER study, the prevalence of subclinical tenosynovitis is relevant in the subpopulation of patients with RA in clinical remission. The analysis into subgroups, based on the therapy performed, although it did not show any significant differences, demonstrated a trend to a lower prevalence of inflammatory manifestations of the tendons of the hands and wrists in favor of patients with combo therapy (DMARDs + BIO) than patients with only DMARDs o Biological in monotherapy. These results could indicate a higher probability to getting better outcomes in patients treated by combo therapy.

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Many imaging modalities, including ultrasound (US) have been used in evaluating rheumatoid arthritis (RA). Previous literatures revealed that US using power doppler imaging (PDI) may be correlated with the degree of synovitis and represent the disease activity in clinical course. The superb microvascular imaging (SMI) is a new software introduced by Toshiba, which can show a vascularity more sensitively excluding artifacts. Therefore, this prospective study was aimed to evaluate the clinical usefulness of the SMI technology for detection of active synovitis in patients with with RA, compared to power doppler imaging (PDI).

Methods: This prospective observational study includes 39 patients with RA (29 females; range of age, 18-83 years; mean age, 52.9 ± 18.1 years), from June, 2015 to May, 2016. All the included patients underwent ultrasound about both wrists and hands (radiocarpal or ulnaocarpal, metacarpophalangeal, and proximal interphalangeal joints; total 22 joints). All the

ultrasound examinations were performed at volar side of wrists and hands, using both PDI and SMI using Aplio TM 500 Ultrasound (Toshiba Medical Systems Corporation), and their results were scored for each joint from grade 0 to grade 3 according to the vascularity (grade 0, no vascularity; grade 1, single vessel; grade 2, vascular flow less than 50% in field of view; grade 3, equal to 50% or more). The sum of grades for 22 joints was compared between PDI (PDI-sum) and SMI (SMI-sum). We also evaluated the correlation between the sum of grades values and inflammatory laboratory parameters including the erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and disease activity score 28 (DAS28).

Results: The mean values of ESR, CRP and DAS28 were 31.0 ± 18.1 mm/hr, 8.17 ± 8.47 mg/L and 3.72 ± 1.08, respectively. The number of clinical remission (DAS28 score below 2.6) was 7 (17.9%). The positive rates of rheumatoid factor and anti-cyclic citrullinated antibody were 82.1% and 76.9%, respectively. The sum of grades 22 joints was significantly higher in SMI-sum compared to PDI-sum (14.33 ± 8.76 vs. 7.56 ± 5.71, $p < 0.001$). The SMI-sum score was highly correlated with the PDI-sum score ($\gamma = 0.789$, $p < 0.001$). The SMI-sum score and PDI-sum score were correlated with CRP value ($\gamma = 0.365$, $p = 0.026$; $\gamma = 0.473$, $p = 0.002$, respectively). All of the patients with clinical remission showed active synovitis at more than one joint in both SMI and PDI.

Conclusion: SMI can show more sensitive vascularity than PDI in RA patients. We can detect active synovitis in the RA patients with clinical remission through SMI. SMI could be a useful technology for evaluation of active synovitis in RA patients, especially for detection of clinically subtle, but active synovitis in the RA patients with remission.

Quality Assessment of Ultrasound Guided Synovial Biopsies Performed in Clinical Practice

Aurélie Najm[1], Marie-Françoise Heymann[2], Géraldine Bart[1], Yves Maugars[1] and Benoît Le Goff[1], [1]Rheumatology, Nantes University Hospital, Nantes, France, [2]Histopathology, Histopathology, Nantes University Hospital, Nantes, France

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial tissue is the principal target and end organ involved in the pathogenesis of multiple articular disease processes. Histological and bacteriological analyses of synovial tissue (ST) are useful in clinical practice for the diagnosis of undifferentiated arthritis. Ultrasound (US) allows an evaluation of the synovial thickness and inflammation. It also helps to perform real-time synovial biopsy and detect nearby structures such as tendons, nerves and vessels. The aim of this study was to assess quantity and quality of synovial tissue obtained by ultrasound guided synovial biopsies, in clinical practice.

Methods: We retrospectively analyzed all synovial biopsies performed between January 2007 and December 2014 in the Rheumatology Department of Nantes University Hospital. Synovial biopsies were performed under real-time US guidance (Philips HD11 XE) using a core biopsy needle with a 14 or 16G caliber semi-automatic Tru-cut needle. This technique allows to collect multiple synovial samples during a single procedure. Hematoxylin and eosin stained slides were analyzed by one operator (AN), blindly from clinical data. Size, area, presence/absence of synovial tissue, presence/absence of lining layer, other types of tissues were assessed and compared to pathologist's analysis (gold standard).

Results: 75 biopsy procedures were analyzed (73 patients). 125 samples were available for analysis corresponding to a median number of samples taken per patient of 1 (IQR 1-3). Mean length and width of the biopsy samples were 6.34 millimeters (mm) (+/- 3.60) and 1.70 mm (+/- 0.77) respectively. The mean total area of the samples was 8.77 mm^2. Biopsies showed synovial tissue at the histological examination in 102 samples (80.1%). The average area of synovial

tissue in these samples was 6.36 mm2 corresponding to 72.5% of the total area of biopsied tissue. The other types of tissue present on these biopsies were connective tissue in 101 cases (80.8%), adipose tissue in 42 cases (33.6%), tendon in 14 cases (11.2%) and fibrin in 24 cases (19.2%). The 23 sample retrieving no synovial tissue were composed of fibrin in 15 cases (12%), conjunctive and adipose tissue in 17 cases (13.6%), tendon in 3 cases (3.15%), cartilage in 3 cases (3.15%) and muscle in one case (0.8%). Synovial lining layer was found in 92.6% of the successful biopsies. Interobserver reliability for presence/absence of synovial tissue between AN and the pathologist was high with a kappa coefficient of 0.90 (95%CI = 0.763 to 1).

Conclusion: Our study is the first to assess quality and quantity of synovial tissue obtained by ultrasound guided biopsy, in the clinical setting. In 80% of the biopsy procedures, quantity and quality of the synovial tissue were high enough to allow a proper histological examination. Given the fact that conjunctive and adipose tissues as well as fibrin were frequently seen on histological examination, retrieving a minimal number of 3 samples per patient appears to be required for appropriate pathology assessment in the clinical setting.

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient satisfaction about health care experience has emerged, as a surrogate of quality of care. The Patient Protection and Affordable Care Act has allowed patient satisfaction data to help determine Medicare reimbursement. The use of US guidance for the injection and aspiration of joints has improved accuracy.[1] The aim of this study was to determine if differences exist in the level of patient satisfaction, functionality and quality of life in adult patients receiving US guided (USG) versus landmark guided (LMG) knee procedures.

Methods: This prospective, randomized study enrolled 40 patients undergoing knee procedures to USG or LMG groups. Visual analogue scale (VAS) for pain, Knee injury and Osteoarthritis Outcome Score (KOOS) and patient satisfaction score on 5 point Likert scale were measured pre-procedure, immediate (<30 mins) and late (2-4 weeks) post-procedure. Mann-Whitney U test and ANOVA were used to compare continuous variables and chi-square test was used for categorical variables.

Results: 37 patients were included in the final analysis after exclusion of 3 dropouts (18 in LMG arm, 19 in USG arm). There were no significant differences between patients getting LMG or USG procedures with respect to age, sex, race, ethnicity, pre-procedural VAS pain and pre-procedural KOOS scores (Table 1). Patients in both groups had significant decrease in pain immediately and later post-procedure. Those in the USG group had significantly better improvement in pain and satisfaction at both the end points. Patients getting USG procedures reported significantly better KOOS scores (Pain, Symptoms, Activities of daily living, Sports-recreation & Quality of life) at 2-4 weeks (Figure 1, 2).

Conclusion: USG knee procedures were associated with higher patient satisfaction, both immediately after the procedure and after 2-4 weeks. USG knee procedures resulted in greater improvement in symptoms, pain and quality of life scales after 2-4 weeks as compared to LMG knee procedures. In a time when patient satisfaction is increasingly important for

insurance reimbursement, our study supports not only better quantitative outcomes with pain and function, but also greater patient satisfaction with USG knee procedures. Reference: 1. Cunnington J et al. Arthritis and rheumatism. Jul 2010;62(7):1862-1869.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The development of ultrasound-guided synovial biopsy will enable synovial tissue collection from small joints and will facilitate molecular studies, thus improving the understanding of mechanisms of inflammatory arthropathies as small joints are frequently involved in these diseases. Objective: To assess the safety, tolerability and feasibility to perform synovial biopsies from wrist and metacarpophalangeal (MCP) joints, using a minimally invasive

ultrasound (US)-guided technique in patients suffering from rheumatoid arthritis (RA), spondylarthropathies (SA) or undifferentiated arthritis (UA).

Methods: Two target joints (TJ) were biopsied: wrist and MCP. Patients with at least one clinically swollen joint at these levels, suffering from RA, SA, or UA underwent a US examination. The TJ chosen for the biopsy was the joint with the most important inflammatory changes on gray-scale (GS) US. GS synovitis and power-Doppler (PD) activity were assessed by OMERACT scores, on the day of the biopsy, as well as 2 weeks (w), 6w and 6 months (m) after the biopsy. In addition, tendon tears, hematoma, paratenonitis and tenosynovitis were searched on US examinations. Patient-reported outcomes (PRO) were assessed as previously described[1]. A standard questionnaire (pain, swelling and stiffness of the TJ using a visual analogue scale from 0 to 10) was given to all patients on the day of the biopsy as well as 1w, 2w, and 6w after the biopsy. Tolerability and the patient-reported willingness to repeat the procedure was assessed using the five-point Likert scale

Results: 56 patients suffering from RA (36), SA (9) and UA (11) underwent US-guided biopsy of the wrists (28) and MCP (28) joints (Figure). A non-significant increase in pain 24 h after the procedure was reported by all except one patient. No difference in PRO of the biopsied joints was reported 2w and 6w after the biopsy, as compared to assessment before the biopsy. No infection or haemorrhage was observed after the biopsy. No differences in PRO after the biopsy were observed between patients suffering from RA, SA or UA. We registered three adverse events specifically linked to the procedure: persistent thumb hypoesthesia (1 patient), hypotension (vagal reaction) during the procedure (2 patients). At 6w and 6m follow-up, no other safety concerns were reported. At the TJ, US scores tended to decrease 2w after the procedure. Treatment response at the TJ was similar to the response of non-biopsied joints matched for the baseline US parameters.

Conclusion: With the exception of study of Kelly *et al,* data on safety, tolerability, feasibility and PRO using minimally invasive US-guided biopsy are lacking. In this work, we confirm that US-guided biopsy of wrist and MCP joints is feasible, safe and well tolerated by patients. Furthermore, no differences in PRO between RA, SA and UA were observed. As for any other innovative tool, this technique should be compared with other available techniques of synovial biopsy.

[1]Kelly S. et al. Ultrasound-guided synovial biopsy: a safe, well-tolerated and reliable technique for obtaining high-quality synovial tissue from both large and small joints in early arthritis patients. Ann Rheum Dis. 2015;74:611-6117. We acknowledge Pr C. Pitzalis and S. Kelly for giving us the opportunity to learn and further disseminate minimally invasive ultrasound-guided technique, and for fruitful discussions.

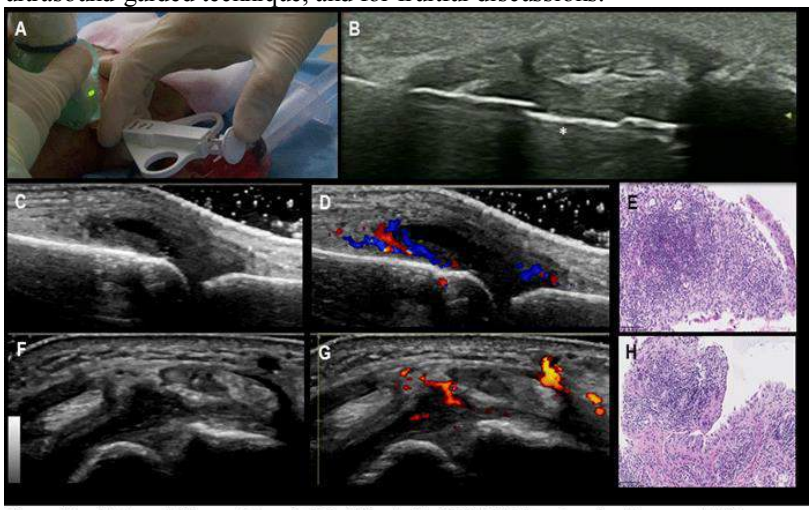

Figure. US-guided synovial biopsy of the wrist (A, B, F-H) and of the MCP (C-E) joints. Synovium biopsy needle (A) as seen with US (B) at the wrist level. A guillotine-type needle with an open throw (*) is used to cut the tissue. Prior to biopsy, MCP (C, D) synovitis is depicted by GS-US (C) and by color Doppler-US (D). Wrist synovitis (F, G) is depicted by GS-US and by PD-US (G). Histological images (E and H) of the corresponding GS-US (C and F) and Doppler US (D and G) images showing blood vessel proliferation and strong inflammatory infiltrates in the synovial sublining.

Reduction in Musculoskeletal Ultrasound (MSK-US) Payments in 2014: Effects & Consequences

Gurjit S. Kaeley[1] and Sunita Dodani[2], [1]Rheumatology, University of Florida College of Medicine, Jacksonville, Jacksonville, FL, [2]Epidemiology, University of Florida, College of Medicine & College of Public Health and Health Professions, Gainesville, Jacksonville, FL

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rapid rise in the use of diagnostic and interventional MSK-US within the Medicare population between 2011 and 2013 has been documented amongst non-radiology MSK providers.[1] Due to rapid escalation of cost and utilization, Medicare recently identified interventional MSK-US CPT 76942 as a potentially incorrectly estimated code leading to the reported payment reductions.[2] The key objective of this study was to determine the four-year trend of utilization of diagnostic and interventional MSK-US using the recently available 2014 Medicare Part B data. The secondary objective was to assess the impact of CPT 76942 code revaluation by Medicare.

Methods: A retrospective secondary analysis of Medicare Physician Supplier Payment Summary (PSPS) files from 2011 – 2014 was used to describe the services and total payments on utilization of MSK-US. PSPS data is aggregated on multiple factors with certain exclusions, including absence of technical costs such as those billed by Radiology. Therefore, service count data more accurately reflects utilization across specialties. CPT 76881, 76882 and 76942 were coded as diagnostic MSK-US and interventional MSK-US respectively. Non-duplicative billing claims of these codes were summed for each years and provider specialty. MSK provider specialties were also grouped into six groups. Descriptive analysis was conducted using R-Studio (Version 0.98.1102) and Tableau (Version 9.3).

Results: Interventional MSK-US services continued to grow in most specialties except for Radiology where they continued to decline every year (Table 1). Orthopedics continued to rank the highest for interventional MSK-US services, whereas Rheumatologists' services remained fairly stable with a minor reduction from 2013 to 2014. Strikingly, there was a 60-65% cut in payments in 2014 (Figure 1). There continued to be a greater utilization of interventional than diagnostic MSK-US among all MSK providers except Podiatry (Table 1 and 2).

Conclusion: A marked dissociation of interventional MSK-US services from diagnostic services continued to be seen in most MSK specialties. The radical cut in payments is notable not only due to its magnitude but also that it pre-dated bundled billing of common joint injections with MSK-US. The next logical step for future research will be to assess and correlate the reduction in the observed payment with the reduction of interventional MSK-US. 1. Kaeley GS, Kraemer D, Smotherman C, Dodani S. Musculoskeletal Ultrasound (MSK-US): Innovation or Overutilization? Arthritis Rheumatol. 2015;67.

2. 2014-Medicare-Physician-Fee-Schedule-Final-Rule. 2014

Table 1. Stratified Services and Payments for Interventional MSK-US:2011-2014

INTERVENTIONAL MSK-US		SERVICES			PAYMENTS

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasound imaging is highlighting the prominent role of tendinitis in systemic rheumatic disease. Because of challenging anatomy, limited literature exists on the sonographic appearance of the posterior tibialis (PTT) and the peroneus brevis (PBT) tendon entheses. Our objectives were to determine the anatomic features and best imaging techniques of normal PTT and PBT using musculoskeletal ultrasound and to compare these findings to subjects with inflammatory arthritis.

Methods: Per IRB approval, subjects over the age of 18 without previous foot/ankle fracture or surgery were enrolled as: healthy controls (HC), rheumatoid arthritis (RA), and spondyloarthropathy (SpA). Bilateral PTT and PBT entheses were imaged longitudinally to compare two angles of insonation: 1) perpendicular to the skin surface and 2) 45˚ cephalad. A MyLab 70 Biosound Esaote Ultrasound machine with 6-18 MHz linear transducer was used with standardized presets. Three sonographers, blinded to demographics, diagnosis and each other, scored the images on multiple semi-quantitative scales, including tendon visibility/irregularity, pre-insertional and insertional tendon diameter, Doppler signal, presence of erosions, and tenosynovial effusion. Statistical analysis was conducted by the chi squared test, Tukey multiple comparisons post hoc test, and a mixed-effects, ordered logistic regression analysis.

Results: Eighty-eight subjects were enrolled: HC (n=37), RA (n=21), and SpA (n=20). Complete enthesis visualization was achieved more frequently in the perpendicular than in the cephalad view for the PBT (76.3% versus 58.7%), but more frequently in the cephalad view for the PTT (58.0% versus 19.6%). The PTT partially inserted and traversed the navicular en route to the metatarsals in 87.3% of subjects. Table 1 demonstrates the findings at the PBT and PTT entheses. Insertional tendon diameters were not significantly different. RA and SpA subjects had higher rates of PTT fiber disruption, tenosynovial effusion, and Doppler signal than HC. No significant differences existed at the PBT enthesis. Controlling for patient demographics, intra-observer variability, and idiosyncrasy of the grading system, RA and SpA subjects were 5.1 times (log-odds ratio 1.63, $p<0.001$) and 3.6 times (log-odds ratio 1.27, $p<0.001$) as likely as a HC to have a pathological sonographic result.

Conclusion: This study is the first to describe PBT and PTT imaging techniques that are both feasible and useful for rheumatologists. Perpendicular transducer aim is optimal for imaging the PBT, while cephalad transducer orientation was more effective for evaluation of the PTT. Unlike distal PBT imaging, PTT imaging distinguished HC from disease state, with both RA and SpA patients showing features of PTT enthesopathy much more commonly. This study confirms PTT enthesopathy as a sonographic manifestation of inflammatory arthritis.

	Healthy Control (n=37)	Rheumatoid Arthritis (n=21)	P value	Spondyloarthropathy (n=20)	P value
PBT enthesis diameter, mm (SD)	1.72 (0.43)	1.72 (0.29)	NS	1.72 (0.30)	NS
PTT pre-insertional diameter, mm (SD)	4.55 (0.53)	4.98 (0.98)	0.035	4.74 (0.98)	NS
PTT enthesis diameter, mm (SD)	1.93 (0.49)	2.10 (0.68)	NS	2.02 (0.77)	NS
PBT fiber disruption, %	0	0	NS	3.3%	NS
PTT fiber disruption, %	1%	21.3%	<0.001	22.7%	<0.001
PBT Doppler signal, %	0	6.1%	<0.01	1.7%	NS
PTT Doppler signal, %	0	15.6%	<0.001	5.8%	<0.01
PBT tenosynovial effusion, %	4.5%	5.6%	NS	2.5%	NS
PTT teno synovial effusion, %	7.2%	22.9%	<0.001	12.5%	<0.001

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis is a diseases with diverse skeletal manifestations of which enthesistis is the primary lesion. However, enthesitis may often develop without any symptoms or signs. The primary objective of this study is to evaluate presence of subclinical enthesitis with ultrasonography in patients with psoriasis without any clinical findings of arthritis and/or enthisitis. Secondary objective is to compare ultrasonographic findings with clinical severity of psoriasis and enthesitis.

Methods: 30 patients with psoriasis without clinical findings of arthritis or enthesitis and 30 healthy volunteers as a control group were involved in the study. In the patient group PASI (Psoriasis Area and Severity Index), NAPSI (Nail Psoriasis Severity Index), MASES (Maastricht Ankylosing Spondylitis Entheses Score) and SPARCC (Spondyloarthritis Research Consortium of Canada); in the control group MASES and *SPARCC* scores were calculated. An investigator blind to clinical scores performed ultrasonographic examination on SPARCC scoring sites: bilateral achilles tendon, calcaneal insertion of the plantar fascia, patellar tendon insertion at the base of patella, quadriceps tendon insertion of the upper edge of the patella, trochanter major, supraspinatus tendon insertion at great tuberosity of humerus, medial epicondyle and lateral epicondyle. Acute, chronic and total enthesitis scores were calculated as described in literatures (1,2).

Results: In the patient group the total enthesitis score was significantly higher than the control group.(4.70±3.54SD in the patient group vs 2.90±2.36SD in the control group, p=0.04) There were no significant differences in the acute enthesitis score and chronic enthesitis scores between the groups.(acute enthesitis score the 0.83±1.08SD in the patient group vs 0.37±0.71 in the control group, p= 0.05; chronic enthesitis score 3.87±3.20SD in the patient group vs 2.53±2.09SD in the control group, p=0.14) There was no significant relationship between NAPSI, PASI, MASES, SPARCC scores and the ultrasonographic enthesitis scores in the patient group. In the patient group, there was a low level of statistically significant correlation between MASES and SPARCC scores.(r=0.38 p=0.03) There was no correlation between any of the other clinical scores.

Conclusion: Entheseal changes are common in clinically asymptomatic patients with psoriasis. Ultrasound may be useful in early detection of enthesitis. Reference:

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Dactylitis (DACT) is defined as diffuse swelling of the digit and is included in the ASAS criteria for spondyloarthritis. It is a hallmark feature of psoriatic arthritis (PsA), occurring in 16-24% of cases. One of the main problems with the definition of dactylitis is the existence of a chronic non-tender form. The lack of tenderness suggests inactive disease, but subclinical inflammation may exist. Objective. To assess ultrasound (US) pathological lesions in dactylitic digits of patients suffering from PsA.

Methods: Consecutive PsA patients suffering from at least one DACT in feet or hand were included. The presence of DACT was diagnosed at clinical examination. At US examination, the entire DACT digit was scanned both on dorsal and palmar/plantar sides. The following ultrasound pathological lesions were scored: soft tissue thickness and edema, synovitis of MCP, PIP and DIP joints, inflammatory involvement of both flexor (tenosynovitis) and extensor (paratenonitis) tendons, nail bed vascularity, synovio-entheseal complex at DIP level, enthesitis of flexor tendon, intra-articular and extra-articular bone proliferation. Gray-scale (GS) and power-Doppler (PD) synovitis and tenosynovitis were assessed according to OMERACT scores (0-3). Nail bed vascularisation was scored 0 to 3. The other US lesions were scored 0 (absent) or 1 (present), both in GS and PD. The standard (HAQ) questionnaire, tender and swollen joint count, tenderness of DACT, global disease activity scored by physician and by patient were assessed in all patients.

Results: Twenty-eight DACT from 17 consecutive patients (8 men and 9 women) suffering from PsA were examined by US. Mean age was 43.3±11.2 years. Nine patients presented with hand DACT and 8 patients with foot DACT. Ten patients had single DACT. Seven patients presented with multiple DACT: 3 simultaneous DACT in 4 patients and 2 simultaneous DACT in 3 patients. Seven patients were on non-biologic DMARD, 2 patients were on combined therapy with biologics, one patient was on biologic monotherapy and 7 patients were DMARD naïve. Soft tissue thickness was present in all DACT. Synovitis of at least one joint was present in all DACT (28/28). The MCP synovitis was present in 75% (21/28) of DACT, PIP synovitis in 60% (17/28) of DACT, and DIP synovitis in 43% (12/28) of DACT. Inflammatory involvement of tendons was observed in 75% (21/28) of DACT: more flexor than extensor tendons were involved. Enthesitis was present in 68% (19/28) of DACT. Nail bed hypervascularisation (PD grade 3) was present in 14% (4/28) of DACT. Bone proliferation was present in 46% of DACT (13/28). A significant association between tenderness and the presence of PD and/or edema in the soft tissue was observed ($p<0.01$). The frequency of synovitis, tenosynovitis and enthesitis did not differ significantly between tender and non-tender DACT.

Conclusion: We show that US pathological lesions in DACT are more heterogeneous than previously reported. In particular, DACT is characterized by simultaneous involvement of joints, tendons and soft tissue. A significant amount of joint, tendon and entheseal inflammation persists in non-tender DACT. Tenderness tends to be associated with the presence of edema and/or PD inside the soft tissue, but larger samples are required to confirm these results. The impact of current treatments on inflammation might differ according to joint, tendon or entheseal level involved in DACT.

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the characteristics and differences of the ultrasonic imaging of enthesopathy in the lower extremity in patients with psoriatic arthritis(PsA), psoriasis(Ps) and other inflammatory arthritis, to explore the risk factors of Ps developing into PsA in the long term course, and to investigate the clinical practical value of the musculoskeletal ultrasound (MSUS) as a diagnostic modality in PsA.

Methods: Sex- and age-matched patients with 44 Ps, 44 PsA and 44 healthy controls (HCs) as well as 22 ankylosing spondylitis (AS), 22 rheumatoid arthritis (RA) and 11 osteoarthritis(OA) visting to the dermatological and rheumatic outpatient and ward department of the Chinese PLA general hospital were consecutively enrolled. MSUS of the lower limbs¡¯ entheses were performed, and then a comparation of ultrasonic imaging of enthesopathy between the 6 groups was made.

Results: 304(69.1%) of 440 enthesal sites were abnormal in Ps, compared with 345(78.4%) and 107(24.3%) abnormalities respectively in PsA and HCs (*P*=0.002, 0.000). The presence of erosion and power doppler (PD) signal in Achilles tendon were significantly higher in PsA than in Ps (9 vs 1, 12 vs 1, *P*=0.011, 0.002). Logistic regression results showed that a longer course of Ps may be a risk factor of developing into PsA (regression coefficient was 0.10, OR=1.10, *P*£¼0.001). The Glasgow Ultrasound Enthesitis Scoring System(GUESS) score was higher in PsA than in AS, RA and OA (*P*£¼0.001). The area under the ROC curve revealed that the GUESS accuracy in diagnosing PsA was 88.4 % with sensitivity and specificity of 86.4 and 79.8 %, respectively, at a cutoff value of 4.5.

Conclusion: The frequency of enthesopathy in the lower limbs was significantly higher in Ps and PsA who were absence of extremity musculoskeletal symptoms than HCs when detected by MSUS. Erosion and PD signal in Achilles tendon and a longer course of Ps may be the predictive factors of PsA. MSUS might help to identify entheseal changes in PsA.

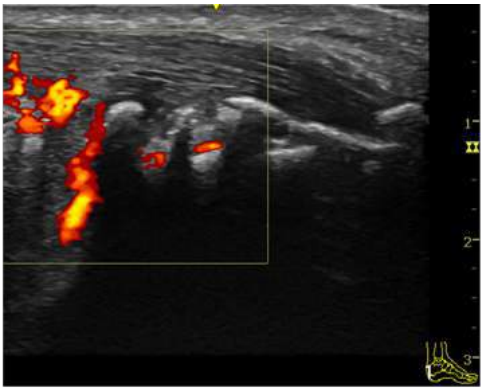

Figure 1 male, 45 years old, diagnosed as PsA for 8 years, representative US findings indicative of enthesopathy on longitudinal scan in left Achilles tendon are: enthesophyte, bone erosion, bursitis and PD signal in acute phase.

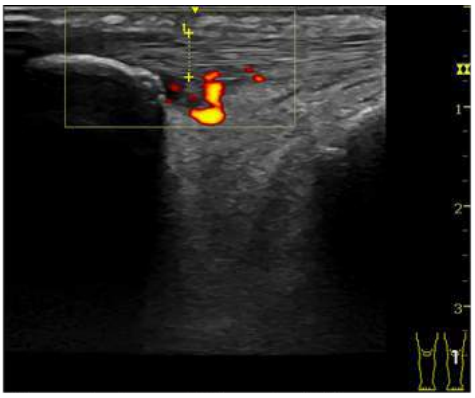

Figure 2 male, 43 years old, diagnosed as PsA for 6 years, representative US findings indicative of enthesopathy on longitudinal scan in left proximal patellar ligament are: entheseal thickness, bone erosion, bursitis and PD signal in acute phase.

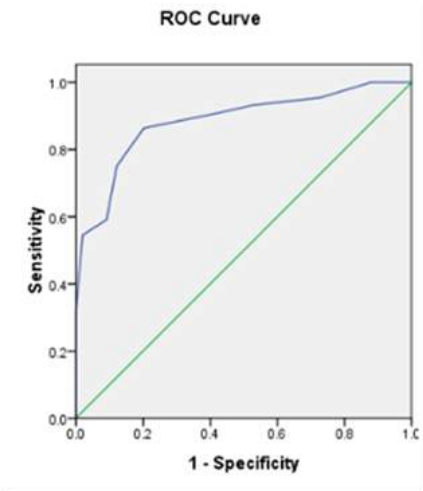

Figure 4 The GUESS accuracy in diagnosing PsA was 88.4 % with sensitivity and specificity of 86.4 and 79.8 %, respectively, at a cutoff value of 4.5.

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical and biological exams are the basis for polymyalgia rheumatic (PMR) monitoring. New imaging techniques such as ultrasound (US) and magnetic resonance imaging (MRI) were recently developed to assess diagnosis and activity of PMR (1). However, concordances between MRI and US, and their sensitivity to change, have never been evaluated. Our objectives were to assess 1- imaging changes of both MRI and US (bursitis and intra articular effusion modifications) in patients treated by tocilizumab and which technique is more able to detect improvements according to the site and 2- the concordance between US and MRI at the first visit.

Methods: 20 glucocorticoid-free patients fulfilling Chuang's PMR criteria, with recent and active disease, were included in a prospective open-label study [ClinicalTrials.gov: NCT01713842] (2). They received three tocilizumab infusions at weeks 0, 4 and 8, without glucocorticoids, followed by oral prednisone from weeks 12 to 24. 18 patients were examined with both US (B and power Doppler mode) and MRI (T1 and T2-STIR weighted sequences) at baseline, week 2 and week 12. A semi-quantitative analysis was performed, scoring from 0 to 3 the disease activity (0= no lesion, 1= mild, 2 = moderate, 3= marked). Imaging were read by one blind reader for MRI and two trained readers for US. Wilcoxon signed-rank test and weighted Kappa coefficient were used for statistical analysis.

Results: 28 shoulders and 30 hips were analysed. No concordance between US and MRI observations was significantly noted at baseline. Activity significantly changed between week 0 and week 12 for hips and shoulders bursitis with MRI (p = 0,005) and US (p=0,029). Considering effusion, imaging lesions of all the joints significantly changed in US (p =0,001) but not in MRI (p=0,231). Bursitis improvement was detected more easily by MRI for the hips (73 %) and by US for the shoulders (57 %). Shoulders and hips effusions significantly regressed in US (improvement 25 to 47%). There was a low proportion of worsening, whether for bursitis (5% with MRI and 17,5% with US) or effusion (10 % with MRI and 3,5% with US).

Conclusion:

US and MRI allow to evaluate the evolution of joints involvement in PMR patients treated by tocilizumab. The two imaging techniques should be used differently, considering shoulders or hips for MRI.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Palindromic rheumatism (PR) is defined as a recurrent, self-abortive arthritis and/or para-arthritis, which progresses to RA in up to 50% patients (pts), particularly those that are anti-CCP+(1). The anatomical basis for the palindromic flare is unclear and may provide insights into the initial phases of RA. We aimed to describe the ultrasound (US) and MRI phenotype of palindromic flare, focussing on intra- and peri-articular inflammation, as compared to early RA.

Methods: Pts were recruited from a prospective PR cohort. Palindromic flares were defined as the presence of ≥2 of pain, swelling, erythema in or around ≥ 1 joint, that later returned to normal. Comprehensive blinded US assessment (wrists, MCPs, PIPs, elbows, knees, MTPs, bilateral ECU and 2nd - 5th finger flexor tendons) was performed during flares. Tenosynovitis (TSV), peri-tendinous oedema (PTO), peri-articular soft tissue inflammation and subcutaneous (s/c) oedema were reported at each joint region. MRI was performed on the most symptomatic region during flare. MRIs were RAMRIS scored and descriptively scored by a blinded experienced reader for TSV, PTO, peri-articular soft tissue inflammation and s/c oedema. The same information was collected in the early RA pts.

Results: Twenty one flares were captured in 15 PR pts and imaged by US (21) and MRI (9) between May 2015 and April 2016 and compared with US and MRI of 16 early RA pts. The mean age of PR pts was 47 years, 10/15 (67%) were anti-CCP+ and 5/15 (33%) anti-CCP-. 13/15 (87%) were DMARD naive. All 15 pts had US (1pt had 3 flares captured, 4 pts had 2, and the remainder had 1) and 8 pts had MRI (4 anti-CCP+, 4 anti-CCP-, 1 had 2 flares captured). On US 10/15 pts (67%) had peri-articular inflammation and/or s/c oedema, in 6 pts this was without synovitis or TSV. Grey scale synovitis was present in 9/15 pts (60%), TSV and/or PTO were present in 5/15 (33%) pts. Power Doppler (PD) synovitis was present in only 3/15 (20%) pts. No erosions were found. On MRI, synovitis was present in 7/8 pts (88%), bone marrow oedema (BME) in 1 (11%) and no erosions were found. US (table 1) and MRI (table 2) lesions are shown for all palindromic flares and early RA pts.

Conclusion: PR has a distinct phenotype with peri-articular soft tissue inflammation and s/c oedema common in PR flares and occurring independently of synovitis and TSV. Synovitis and TSV appear more prevalent on MRI in anti-CCP+ rather than anti-CCP- PR pts in whom s/c oedema seems a prominent finding. The low prevalence of PD synovitis, BME and erosions further distinguishes PR flares from the imaging phenotype in RA. (1)Russell et al. J Rheum 2006

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Carpal tunnel syndrome (CTS) is the most frequent neuropathy of all entrapment neuropathies, believed to be present in 3.8% of the general populatio. Idiopathic CTS is the most common diagnosis in patients with CTS. However, there are a lot of conditions that generate secondary CTS, it is considered that rheumatoid arthritis (RA) is one of the disease generate secondary CTS. The pathophysiology of CTS of RA might be a little bit different from idiopathic CTS. RA is a disease that has the characteristics to generate inflammatory synovial proliferation of the joint and tenosynovitis. Although inflammation of the wrist joint and synovial tissue of the flexor tendons can cause increased pressure in the carpal tunnel, there is a possibility that even RA patients without symptoms of CTS also have subclinical median nerve damage because of the synovial proliferation and inflammation. This aim of this study was to compare the elasticity of the median nerve between patients with RA without symptom of CTS and controls by quantitative elastosonography.

Methods: This study was performed with institutional review board approval and written informed consent from all participants. Four hundred two hands in 201 patients with RA and 222 hands in controls were included. All participants were examined both wrists. Patients were excluded in this study if they had conditions associated with an increased

incidence of CTS (diabetes mellitus, acute trauma, pregnancy, hypothyroidism, hyperthyroidism or connective tissue disease except for RA), history of wrist or hand fracture, surgery, history of other systemic neurologic disorders and radiculopathy. Patients with bifid median nerve, or any mass lesion identified on US examination of the wrist were also excluded from this study. US was performed by using a 5- to18-MHz linear array transducer (HI VISION Ascendus; Hitachi-Aloka Medical,Tokyo, Japan). We attached an acoustic coupler (EZU-TECPL1; Hitachi-Aloka Medical) with a standardized elasticity to the transducer as a reference medium. The inlet of the carpal tunnel at the scaphoidpisiform level and the proximal portion of the carpal tunnel inlet were scanned in a transverse plane. The cross-sectional area (CSA) and the elasticity of the median nerve, which was measured as the acoustic coupler /median nerve strain ratio, were evaluated. The measurements were repeated two times, and the average strain ratio was used for analysis.

Results: Three hundred forty-two hands in 177 patients with RA (139 female, mean age was 63.8 years old) and 158 hands in 81 controls (68 female, mean age was 71.5 years old) were analyzed. The CSA of the median nerve at the level of inlet of the carpal tunnel and proximal portion of the carpal tunnel inlet were not significantly differenced in both groups. Strain ratio in the patients with RA were significantly higher than those in the controls (2.66 vs 2.20; p=0.003 in right hand, 2.59 vs 2.13; p=0.002 in left hand) at the inlet of the carpal tunnel level. However, strain ratio at the proximal portion of the carpal tunnel inlet level was not significantly differenced in both groups.

Conclusion: The median nerve stiffness measured by elastosonography in patients with RA without symptom of CTS is higher than controls. This results suggest that inflammation of flexor tendon and wrist joint may generate fibrotic change for median nerve.

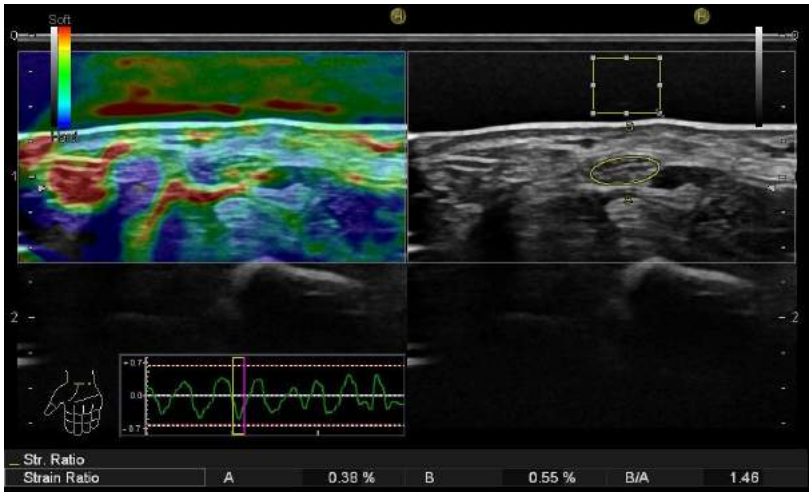

Figure: The images of acoustic coupler /median nerve strain ratio.

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Histological analysis of synovial tissue, despite being a reliable and accurate assessment for synovitis, is not routinely performed. Ultrasonography (US) is a fast, available and low cost imaging tool and has been validated for detecting synovitis. Ultrasonographic and macroscopic findings at arthroscopy have been shown to correlate well. However, a few studies have assessed the correlation of ultrasonographic and immunophenotypic features of synovial tissue, with contradictory results and mostly on long lasting rheumatoid arthritis patients. The aims of this study were (a) to assess the correlation between ultrasonographic and histological scores for inflammation and vascularity in knee joint synovitis; and (b) to evaluate the strength of the correlation for both inflammation and vascularity scores in the 3 major compartments of the knee using US, arthroscopic and histological evaluation.

Methods: Patients of an early arthritis cohort were prospectively included in the study. One operator (AN) performed a knee ultrasonography (B mode and Power Doppler mode) of the three major compartments (medial, lateral and superior) prior the arthroscopy. B mode synovitis grade and Power Doppler activity were scored semi-quantitatively. A different operator (CO/DV) then performed a knee arthroscopy and scored macroscopic aspects with a 100-mm numeric scale (NS) blinded to the US findings. Biopsies were obtained from each compartment, stained with standard H&E, CD68 and Factor VIII, and then analyzed by another operator (UF) blinded to both the US and arthroscopic findings and scored for lining layer hyperplasia, inflammation and vascularity. Statistical analysis was made with non parametric Spearman correlation test.

Results: 26 patients were included. 17 had rheumatoid arthritis (RA) (ACR/EULAR 2010 criteria). 3 patients had psoriatic arthritis (PsA) (CASPAR criteria), 4 had osteoarthritis (OA), 1 had gout and 1 had undifferentiated arthritis. 17 patients (65.4%) were untreated at inclusion. Strong correlations were observed between: US synovitis grade and histological inflammation score (r=0.60; p=0.002), US Power Doppler grade and histological score for vascularity (r=0.69; p<0.001); US measured synovial thickness and lining layer hyperplasia (r=0.61; p=0.002); US synovitis grade and CD 68 score (r=0.49; p=0.02). The findings were homogeneous within the joint as high positive correlations were observed for both histological lining layer hyperplasia and inflammation between lateral and medial compartments (r=0,95; p<0,0001 and r=0.68; p=0.014 respectively), lateral and superior compartments (r=0.78; p=0.001 and r=0.51; p=0.048, respectively) and medial and superior compartments (r=0.69; p=0.004 and r=0.69; p=0.004, respectively).

Conclusion: B mode and Power Doppler US findings strongly correlate with histological inflammation and vascularity scores in actively inflamed knee joints. Ultrasound is therefore an accurate tool for knee joint synovitis assessment of the four most common rheumatic disease diagnoses - RA, PsA, OA and gout.

Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: to date diagnosis of knee osteoarthritis (OA) is based on clinical examination and radiological features. Our objetive was to evaluate the diagnostic test properties of ultrasound (US) for the detection of radiographic knee OA.

Methods: consecutive patients complaining of knee pain were included. Exclusion criteria were: younger than 18 years old, history of knee surgery or trauma, severe knee deformities and corticosteroid injection within the last 2 months. US examinations were performed by an experienced rheumatologist, blinded to clinical and radiological data, using a MyLab 70 machine (Esaote) provided with a multi-frequency linear transducer (4-13 MHz). Standardized scanning method was adopted in order to evaluate the following US abnormal findings: osteophytes (protrusions at the joint margin seen in two planes and visualized as either proximal or distal to the joint) and degenerative femoral hyaline cartilage involvement (presence of at least two of the following: loss of sharpness of the cartilage margins, loss of homogeneity of the cartilage layer and cartilage thinning focal or extend to the entire cartilaginous layer). Weight-bearing anteroposterior (AP) and lateral knee radiographs were read by an experienced rheumatologist, blinded to the clinical and US data, who determine the presence or absence of radiological degenerative changes and classified the severity of knee OA using Kellgren-Lawrence (KL) grading scale.

Results: 281 patients (mean age 64 ± 17 years, 173 (61,6%) female) were included for a total of 322 knees evaluated (41complained of bilateral knee pain). Both the presence of osteophytes and/or femoral hyaline cartilage involvement detected by US were more frequent in those knees with radiographic changes indicative of OA regardless severity acording KL grading scale (Table 1). Table 2 shows the diagnostic test properties of the US abnormal findings for the detection of knee OA using radiological data as reference method.

Conclusion: US demonstrate an excellent sensitivity with an adequate specificity for the detection of radiographic knee OA. US femoral hyaline cartilage involvement and/or US osteophytes showed the best sensitivity while isolated US osteophytes showed the best specificity. US could be used in patients with knee pain when OA is suspected. **Table 1.** Frequency of the US abnormal findings according radiographic features of knee OA.

	Presence of radiological degenerative changes, n: 188				**Abscence of radiological degenerative changes, n: 144**
	KL 1, n: 36	**KL 2, n: 20**	**KL 3, n: 118**	**KL 4, n: 14**	
US femoral hyaline cartilage involvement, % (CI 95%)	77 (64-92)	70 (49-90)	97 (93-99)	100	24 (17-31)

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcium deposition diseases, the disordered calcification of cartilage and/or periarticular soft tissue, are associated with aging, degenerative joint disease, and genetic and metabolic disorders. These conditions are often diagnosed by plain radiography; however, definitive diagnosis requires synovial fluid analysis. Recently Ultrasonography has emerged as a very useful tool for assessment of musculoskeletal disorders. This study was planned to assess the performance of Ultrasonography to detect calcium crystal deposits, as compared to Radiography and Crystal examination, in primary osteoarthritis patients.

Methods: Twenty consecutive primary osteoarthritis patients, who fulfilled ACR criteria for knee osteoarthritis, were enrolled from the rheumatology out patient department of a tertiary care centre. Radiological and sonographic assessment was performed to assess the extent and severity of joint involvement. Presence of crystals in synovial fluid were evaluated by polarized microscope. For the purpose of reproducibility and objectivity in USG findings, the evidence of calcium deposits was taken as presence of chondrocalcinosis of femoral condylar cartilage or meniscal deposits of calcium.

Results: Eight patients were males 12 were females. Average age of patients was 62.6 years. Average duration of illness was 5.5 years. Total 40 knee joints were assessed. Evidence of calcium deposit was seen in radiographs of 11 knee joints (only condrocalcinosis in 5, only meniscus calcification in 4 and both in 2), while USG detected calcification in 35 knee joints (only condrocalcinosis in 2, only meniscal calcification in 12 and both in 21) [p=<0.0005]. The synovial fluid examination revealed Calcium crystals in 16 patients (CPPD in 14 and BCP in 2 patients). The difference between USG analysis and Synovial fluid analysis was not statistically significant.

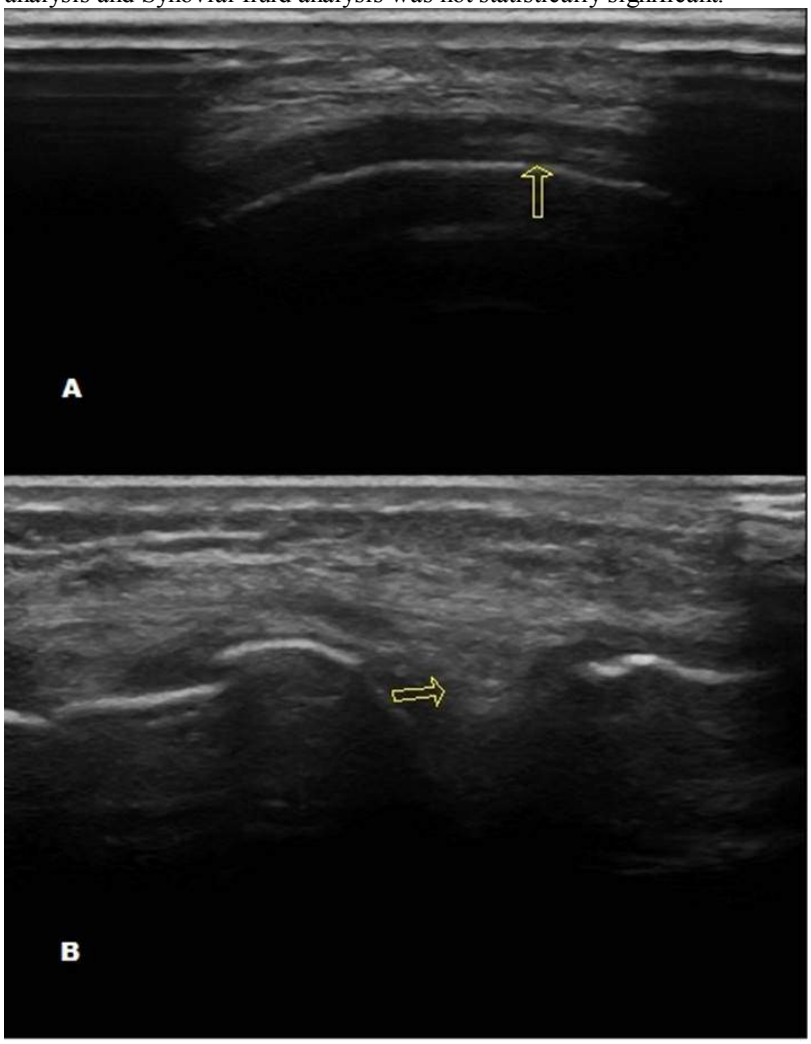

Figure 1. USG images showing A. Chondrocalcinosis in femoral condyle and B. Calcium deposits in Medial meniscus.

Conclusion: Ultrasonography has high sensitivity and specificity for detection of calcium crystal deposits. It is a better modality than plain or digital radiographs, and it appears more sensitive than Synovial fluid crystal examination. However larger studies are needed to be carried out to establish its accurate efficacy.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasound (US) is an emerging technique for the examination of osteoarthritis of the hands (HOA).Bone erosions and osteophytes are hallmarks of advanced HOA. We studied the reliability of US findings in proximal interphalangeal (PIP) and distal interphalangeal (DIP) joints compared to micro computed tomography (µCT) and histology in fingers of dissecting room cadavers.

Methods: We obtained 30 fingers with and without signs of nodal HOA from 15 cadavers donated to the Institute of Anatomy. Written informed consent had prior been given in the lifetime of the individuals. We analyzed PIP and DIP joints using an Esaote MyLabTwice US machine with a 6-18Mhz probe and a Siemens INVEON µCT. The occurrence of erosions and osteophytes was scored for 16 defined regions of each joint (ulnar, radial, dorsal, palmar, dorso-ulnar, palmo-ulnar, dorso-radial, palmo-radial aspect of the joint region of the proximal and distal articulating bone). Thereafter, finger joints were fixed in 4% formalin and embedded in acrylic resin. Serial sections of the joints were stained with haematoxilin/eosin, safranin O, and Pappenheim's solution. Erosions and osteophytes in the different joint regions were assessed. Differences between groups were analyzed using Wilcoxon signed-rank test. Correlations were analyzed with Spearman-Rho test.

Results: In the PIP joints US detected more erosions than µCT (28 vs. 19, p=0.028). The findings of both methods correlated well (r=0.51, p=0.004). The number of erosions in histology correlated significantly with the findings of the µCT (r=0.61, p=0.047) but not with US. US and µCT detected a similar frequency of osteophytes (225 vs. 248, p=0.028) in the PIP joints. Both methods correlated well with each other(r=0.47, p=0.009). Only US correlated with histology (r=0.76, p=0.006). In the DIP joints US, µCT and histology did not yield correlating results. US and µCT detected a similar number of osteophytes in the DIP joints (333 vs. 245, p=0.13) and the findings of both methods correlated significantly (r=0.46, p=0.013). The number of osteophytes on histologic examination did not correlate with osteophytes in US or µCT (r=0.14, p=0.63 and r=0.43, p=0.13, respectively).

Conclusion: US is comparable to µCT in the identification of osteophytes in PIP and DIP joints. Erosions identified by US should be interpreted with caution. Both US and µCT overestimate the frequency of erosions and osteophytes compared to histologic examination.

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovitis-acne-pustulosis-hyperostosis-osteitis (SAPHO) syndrome is characterized by multiple osteoarticular inflammation and dermatologic disorders such as palmoplantar pustulosis. Although the single available study evaluated enthesitis by ultrasound (US), we have been unable to find any study that evaluated abnormalities detected by US of the sternoclavicular joint (SCJ) and peripheral joint (PJ) in patients with SAPHO syndrome. The objective of the present study was to determine the prevalence of US abnormalities of the SCJ and PJ in patients with SAPHO syndrome.

Methods: Thirteen patients with SAPHO syndrome who fulfilled diagnostic criteria proposed by Kahn for SAPHO syndrome 2003 and 13 healthy individuals age- and sex-matched were enrolled. Synovitis, defined by synovial hypertrophy with power Doppler (PD) signals, of the SCJ and the PJ including wrist, MCP, PIP and the other symptomatic joints were evaluated by US.

Results: All of the patients had anterior chest wall symptoms, and spinal and peripheral symptoms were seen in 69.2% and 46.2% of the patients, respectively. Synovitis with PD signals was detected in 16 (61.5%) of the 26 SCJ and 11 (84.6%) of the SAPHO syndrome patients, and none of the controls. Synovitis with PD signals in any PJ was detected in 4 (30.7%) of the SAPHO syndrome patients. Tenosynovitis or tendinitis of the hands was seen in two (15.4%) patients.

Conclusion: Our study has demonstrated that US can detect the abnormalities of the SCJ and PJ in SAPHO syndrome with high sensitivity. US may be a useful method for the early diagnosis of SAPHO syndrome. ADDIN EN.REFLIST

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Correct detection of bone erosions is crucial both for diagnosis and for monitoring of treatment response in patients with inflammatory joint diseases. Musculoskeletal ultrasound (MSUS) is known to have a higher sensitivity than conventional radiography regarding detection of bone erosions (1). Therefore, MSUS is increasingly used as an imaging outcome parameter. Standardization and validation of MSUS is a current task of the OMERACT ultrasound working group. **Aim:** Our study aimed to investigate the sensitivity and specificity of MSUS in the detection of erosions over time compared to HR-pQCT as a gold standard.

Methods: This is a follow-up study on our 2012 cross-sectional comparative analysis on MSUS and HR-pQCT (2). Four of 6 healthy individuals, 6/6 psoriatic arthritis patients and of 9/14 rheumatoid arthritis patients were available for follow-up and received an MSUS and an HR-pQCT scan of the clinically dominant hand. Again, bone erosions at the radial, palmar, and dorsal site of metacarpophalangeal (MCP) joint two, as well as the palmar and dorsal regions MCP joints 3 and 4 were assessed for prevalence and severity. Data were then compared to those taken in 2012. Prevalence and severity of bone erosions as determined by US and by micro-CT were recorded and compared. MSUS was graded as described earlier (2).

Results: After eliminating those datasets without follow-up from the baseline cohort sensitivity of MSUS as compared to HR-pQCT for correct detection of erosions was 95% and specifiity was 74%. For this analysis, grade 1 lesions were included. At follow-up sensitivity was 85% and specifiity 79%. At follow-up, 36 MSUS-lesions were no longer detectable in MSUS; 21/36 were false-positive lesions at baseline. Only one false-positive lesions was detected at both time points. One new lesion was detected by MSUS and confirmed by HR-pQCT. Overall grading in MSUS indicating severity of one erosions regressed; these findings were confirmed by HR-pQCT (p=0.04).

Conclusion: This is the first study assessing change of bone erosions over time using MSUS and HR-pQCT. MSUS was confirmed a sensitive imaging tool able to detect dynamic changes of erosions; it could be used for monitoring of treatment response in inflammatory joint diseases. Knowledge of predilection sites of erosions and physiological cortical breaks might help to correctly differentiate bone erosions from vessel channels and further increases the diagnostic value of MSUS. **References:** 1. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In metatarsalphalangeal (MTP) joints 2-5 of patients with early rheumatoid arthritis (RA), we

aimed to assess the agreement between i) Magnetic Resonance Imaging (MRI) and ultrasound (US) findings of inflammation, and ii) clinical swelling and each of MRI and US findings of inflammation.

Methods: Participants with early RA (ACR criteria) were recruited. Clinical exam was followed by an MRI scan (1.0 Tesla peripheral MRI) and US scan of MTPs 2-5 of the most symptomatic foot. MRI scans were scored by a blinded radiologist using OMERACT RAMRIS criteria for bone marrow edema (BME) (0-3) and synovitis (0-3). Using OMERACT criteria, US images were assessed for synovial thickening (0-3), synovial flow (power Doppler (PD)) (0-3), and erosions (present/absent) in each MTP joint by a rheumatologist, who also assessed swelling (presence/absence) in each MTP. To compare inflammation on MRI versus US, kappa statistics were determined for: MRI synovitis and US synovial thickening, MRI synovitis and US PD, MRI BME and US synovial thickening, and MRI BME and US PD. Agreements between clinical swelling and each MRI and US feature of inflammation (0 = absent, ≥1 on MRI or US = present) were assessed using kappa statistics. The proportions of imaging-detected inflammation also detected clinically were determined.

Results: The study included 33 women, 6 men; mean age 51.6 years (standard deviation=10.2). Table 1 presents weighted kappa statistics for agreement between MRI and US findings of inflammation. Like agreement between synovitis on MRI and US PD, agreement between MRI detected BME and US PD was fair to good. Table 2 presents agreement between clinical swelling and inflammation on MRI and US. Neither US synovial thickness nor MRI synovitis agreed with clinical swelling. There was fair agreement (kappas 0.2322-0.3664) between clinical swelling and each of US PD and MRI BME, but this was stronger in some joints than others. Table 1: Agreement in Inflammation detected by MRI and Ultrasound

Clinical Swelling vs. MRI Synovitis	MTP2	-0.0680	-0.3544, 0.2184	-0.1000	0.2000	31.8
	MTP3	0.1000	-0.1467, 0.3467	-0.3000	0.3000	25.0
	MTP4	0.0625	-0.1601, 0.2851	-0.6500	0.2500	8.3
	MTP5	-0.0843	-0.1799, 0.0113	-0.7750	0.1250	0
Clinical Swelling vs. MRI BME	MTP2	0.2799*	-0.0272, 0.5869	-0.2368	0.0789	50.0
	MTP3	0.2714*	-0.0012, 0.5440	-0.3421	0.2368	35.3
	MTP4	0.0579	-0.1639, 0.2796	-0.6316	0.2632	8.3
	MTP5	0.1857	-0.2098, 0.5812	-0.7895	0.1053	16.7

*denotes kappa is significant ($p<0.05$) There was fair agreement between ultrasound PD and MRI features of BME and synovitis; and ultrasound synovitis and MRI synovitis and BME, but only for MTP4 and 5. There was similar fair agreement between clinical swelling and imaging features of inflammation (BME and PD), but poor for clinical swelling and imaging measures of swelling.

Conclusion: These findings confirm agreements in the imaging parameters of inflammation and suggest that imaging by US and MRI are better than clinical assessment in determining synovial inflammation.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although Ultrasound (US) has demonstrated to be a sensitive and specific tool, its feasibility in daily clinical practice is still under debate. We have developed and validated a fast 4-joints ultrasonographic (US) score to assess disease activity in RA patients. This score named REUMA (***R**apid **E**valuation by **U**S to **M**onitor **A**rthritis*) showed an excellent correlation with 28-joint US assessment and good responsiveness. In order to generalize the utilization of this new and simple US score, we evaluated the performance of this score using an external sample of RA patients and assessed the intra and inter-reader reliability. **Material and**

Methods: We conducted a multicenter cross-sectional study, including ambulatory patients with RA diagnosed according to ACR/EULAR 2010 criteria. Clinical data, demographic and disease characteristics were recorded. The 4-joints US score was calculated for each patient including bilateral radio and intracarpal joint and second metacarpophalangeal. Power Doppler (PD) and gray scale (GS) were graded from 0 to 3, according to OMERACT standards. Total 4-joints US score comes as the result of the addition of PD and GS scores, with a total score ranged from 0–36, being 36 the highest disease activity. Inter and intra-rater reliability were assessed in a web-based exercise using static images from 20 patients, evaluated by 15 ultrasonographers from different centers. Statistical analysis included evaluation of psychometric properties of the 4-joints score including construct validity and internal consistency (Cronbach's α coefficients). The inter and intra-rater reliability were assessed using a two-way random, absolute, average-measures intra-class correlation coefficient (ICC)

Results: 210 RA patients from 9 Rheumatology Centers were included. Mean age was 53 ± 10 years, 89% were female, and disease duration was 8 ± 6 years. Baseline DAS28 score was 3.97 ± 1.47. Mean 4-joints US score was 9 ± 7 (Doppler subscale 3 ± 4; Synovitis subscale 6 ± 4). The score showed an acceptable confiability (Cronbach's α = 0.89) and good correlation with DAS28 (rho spearman= 0.81, $p<0.01$). Floor and ceiling effect were 8% and 0%, respectively. The ICC was excellent for intra [ICC = 0.981 (IC95% 0.955 – 0.999)] and inter-reader reliability [(ICC = 0.994 (IC95% 0.988 – 0.997). Figure 1 shows distribution of US scores and descriptive statistics on the 20 measurements for each of the 15 readers. There is low variation between the means of the readers, with no obvious outliers, and consistent variation within readers (p = 0.84).

Conclusion: The 4-joint US score represents a fast and reliable instrument, with a high degree of absolute agreement between observers from multiple centers. These characteristics make this score an excellent candidate to assess RA patients in daily rheumatology practice. Figure 1. Distribution of 4-joints US scores among 20 patients for each of the

fifteen examiners.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Although there is a consistent body of evidence supporting the use of Ultrasound (US) in Gout, several definitions for US lesions have been proposed. Recently, the OMERACT US Group has proposed a set of 4 definitions, including double contour (DC), aggregates, tophus and erosions. Objective: to evaluate intra and inter-reader

reliability of the US definitions of elementary lesions in gout developed by the OMERACT US Gout Task Force.

Methods: A reliability exercise based on the reading of US images was conducted during the 2016 PANLAR Congress by the PANLAR US Study Group. Fourteen rheumatologists from 6 Latin American countries with different experience in US participated. US images of both normal and gouty elementary lesions were collected by 2 sonographers highly experienced in gout. The image set consisted in 70 static images and 10 videos that were displayed for 20 seconds. Participants were asked to determine the presence of any of the 4 elementary lesions in each image. Nine images was displayed twice to estimate intra-reader reliability. Statistical analysis: Intra and Inter-reader reliability was calculated by the Cohen's kappa coefficient, considering Landis and Koch criteria (<0.2 poor, 0.21–0.4 fair, 0.41–0.6 moderate, 0.61–0.8 good, and 0.81–1 excellent). Furthermore, we stratified sonographers according to their US experience (defining High experience: >5 years of US experience and >50 US gout assessments/year).

Results: A total of 980 image assessment were performed. Aggregates was the more frequent lesions (50%), followed by Tophus (40%), DC (28%) and Erosions (27%). The mean intra-reader values were good to excellent in all lesions: DC= 0.90, aggregates = 0.86, erosions = 0.79 and tophus = 0.76. Mean Kappa inter-reader coefficients showed variability depending on the type of lesion, being moderate for aggregates (K= 0.44) and tophus (K=0.56), good for erosions (K=0.61), and excellent for DC (K=0.87). Kappa estimates and marginal distributions of specific ratings are showed in Figure 1 and Table 2. When comparing high with low experience sonographers, those with high experience showed better intra and inter-reader reliability and lower marginal heterogeneity.

Conclusion: The reliability of the new OMERACT US definitions of elementary lesions in gout varied depending on the type of lesion and evaluator experience. Ultrasonography training programs are necessary to improve the reliability of these new gout US definitions. Figure 1. Marginal distributions of specific ratings among sonographers and relation with personal experience.

Automated Segmentation of Cartilage Provides Comparable Accuracy and Better Responsiveness Than Manual Segmentation: Data from the

Osteoarthritis Initiative

Gwenael Guillard[1], Graham R. Vincent[1], Philip G. Conaghan[2], Alan Brett[3] and Michael A Bowes[1], [1]Imorphics Ltd, Manchester, United Kingdom, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [3]Imorphics Ltd, MANCHESTER, United Kingdom

Automated Segmentation of Cartilage Provides Comparable Accuracy and Better Responsiveness Than Manual Segmentation: Data from the Osteoarthritis Initiative *Guillard G., *Vincent G.R., *Brett, A., **Conaghan, P.G., *Bowes M.A. * Imorphics, Manchester, UK: ** University of Leeds, Leeds, UK

Background/Purpose: A fully automated cartilage segmentation method based on active appearance modelling (AAM), has demonstrated superior performance for a number of tissues including knee and prostate (using MRI), and abdominal, head and neck organs (using CT). Automated segmentation of tissues with minimal change is often insensitive, due to smoothing approximations of such change. In this study we compared the responsiveness of cartilage thickness in the central medial femur region (cMF) using either automatic segmentation or careful manual segmentation, using 565 knees from the Osteoarthritis Initiative over a 2-year period, together with the agreement between the 2 methods.

Methods: 565 knees with OA were analysed at 0,1, and 2 years within the OAI, and results are available on the OAI website (https://oai.epi-ucsf.org/datarelease/ImageAssessments.asp). We compared change from baseline using a pairwise student t-test 0f mean thickness of the manual cMF.ThCtAb region, and a comparable region within an AAM of the femur (Figure 1). Responsiveness was assessed using the standardised response mean (SRM). Agreement between the methods was assessed using a Bland Altman plot (Figure 2). Each image is automatically segmented using AAMs of bone and cartilage through multi-start optimisation. Initially, this fits low-density low-resolution models but ends in a robust matching of detailed high resolution models. Finally, the voxels contained in the cartilage region are assigned with a non–linear regression function, trained with a probably approximately correct (PAC) learning method.

Results: Change in manual cMF at 1 year was 0.037mm, confidence limit (0.028,0.046), $p<10^{-4}$, SRM -0.33; at 2 years was 0.059 (0.047,0.081), $p<10^{-4}$, SRM -0.41. Change in automated cMF at 1 years was 0.061(0.048,0.074), $p<10^{-4}$, SRM -0.39; at 2 years was 0.090 (0.075,0.105), $p<10^{-4}$, SRM -0.49. The methods agreed well, with a systematic bias of -0.034mm, with a 95% confidence limit of 0.37mm, comparable to manual test-retest agreement (unpublished data)

Conclusion: Automated cartilage segmentation using AAMs provides comparable cartilage thickness measures to careful manual segmentation, and improved responsiveness. Manual cartilage segmentation is labour intensive and limits the pursuit of OA clinical trials. Automation now provides an equally accurate alternative, allowing for the segmentation of large datasets such as the OAI.

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Detection of abnormal Rheumatoid Arthritis (RA) related autoantibodies, Rheumatoid Factor (RF) and Anti- Citrullinated Peptide Antibody (ACPA), along with musculoskeletal ultrasound (MSUS) plays a critical role in early RA (eRA) diagnosis. Fluorescence optical imaging (FOI) is an emerging modality that detects subclinical hand joint inflammation[1], and may therefore prove valuable in early RA assessment. Here, we analyzed the FOI results of eRA patients to determine whether patterns of hand joint inflammation were able to distinguish seropositive from seronegative eRA.

Methods: Inflammation on FOI is defined by altered microcirculation (capillary leakage/perfusion), which is seen as abnormal optical signal intensities during visual inspection of a 360-second series of hand and wrist joint images (34 joints per patient). Unsupervised ascending hierarchical clustering was used to identify clusters of patients with different patterns of joint involvement in FOI. The robustness of clustering was verified using k-means, and agreements between the 2 methods were assessed using Cohen's kappa. Baseline clinical and biological characteristics of patients were compared between the clusters using non-parametric tests.

Results: Out of 1326 joints of 39 eRA patients (26 females; 9 with erosive RA; 54% RF+; and 69% ACPA+), 400 (30%) were considered positively inflamed by FOI. The mean (±SD) number of active joints detected by FOI was 10.3 ± 7.2 (Table). Unsupervised hierarchical clustering of joint involvement according to FOI distinguished 2 separate clusters of patients: Cluster1 (n=29) & Cluster2 (n=10). The proportion of seropositive patients was significantly higher in cluster 1 versus cluster 2 (26/29 versus 3/10, $p<0.01$) (Figure). The distribution of inflammation throughout the joints, except for right MCP2, PIPs 5, left MCP1 & DIPs in cluster 2 displayed distinguishable patterns ($p<0.05$) compared to cluster 1, which showed joint inflammation to be largely concentrated around wrists, right MCP2, bilateral MCP3, and to a lesser degree around PIPs 2-4 & left MCP2. The DIPs showed no significant differences between clusters.

Conclusion: Unsupervised hierarchical clustering revealed two distinct inflammatory patterns of joint involvement that may be distinguished in early RA, using fluorescence optical imaging. The proportions of seropositive patients were significantly different between these patterns, suggesting that FOI identifies patterns of joint involvement that are different for seropositive and seronegative RA. Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: This study aimed to analyze the 99mTc-HDP scintigraphic features in hand-arm vibration syndrome (HAVS) and to compare with primary Raynaud's phenomenon (RP) and secondary RP associated with connective tissue disease (CTD).

Methods: 99mTc-HDP digital blood flow and pool scintigraphy were performed in 59 patients with primary RP, 73 patients with HAVS-related RP and 38 patients with CTD-related RP, and clinical features were collected by a retrospective review of medical records. We calculated 6 ratios by using the time-activity curve and static blood pool images; the chilled to ambient hand and wrist ratios of the first peak height, the initial slope, and blood pool uptake. We analyzed 4 morphologic characteristics: an initial spike curve, a slow progress pattern, paradoxically increased uptake pattern in the time-activity curve and the inhomogeneous radioactivity uptake in the blood pool image.

Results: All 73 patients with HAVS-related RP were mine workers. The onset duration of RP after exposure to vibration was 21.8±7.3 years with 6.3±7.0 years of vibration exposure time. The chilled to ambient hand ratios of the first peak height and the initial slope were significantly lower in patients with HAVS-related occupational RP, compared to patients with primary RP. The presence of paradoxically increased uptake pattern of hand was significantly lower in HAVS compared to primary RP.

Conclusion: There were significant differences of both quantitative and morphologic characteristics of 99mTc-HDP scintigraphy between primary RP and HAVS. The results suggest that each disease might have quite different pathophysiology and thus different criteria should be applied to evaluation of each RP. Determination of separate cut off values for 99mTc-HDP scintigraphy is necessary to establish the accurate diagnosis of HAVS.

The Apparent Diffusion Coefficient As a Quantitative Imaging Biomarker of Therapeutic Response in Enthesitis-Related Arthritis

Timothy Bray[1], Kanimozhi Vendhan[1], Nicola Ambrose[2], David Atkinson[1], Shonit Punwani[1], Corinne Fisher[2], Debajit Sen[2], Yiannis Ioannou[2] and Margaret Hall-Craggs[1], [1]Centre for Medical Imaging, UCL, London, United Kingdom, [2]Arthritis Research UK Centre for Adolescent Rheumatology, University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose **:** Early treatment in enthesitis-related arthritis (ERA) may have a disease-modifying effect with consequently improved outcomes. However, disease activity may be difficult to assess, leading to a lack of confidence that inflammation is adequately controlled. Clinical evaluation is helpful in assessing disease activity of peripheral joints in ERA, but is less accurate for assessing sacroiliitis. Magnetic resonance imaging (MRI) is sensitive for detecting sacroiliitis, but current imaging methods are qualitative and rely on visual assessment by a radiologist. Quantitative imaging biomarkers (QIBs) rely on pixel values in the image itself, and may therefore be used to assess inflammation in a more objective, reproducible fashion. This study aims to evaluate diffusion-weighted imaging (DWI) as QIB of therapeutic response in adolescents with enthesitis-related arthropathy (ERA).

Methods **:** 22 adolescents with ERA underwent routine MRI and DWI before and after tumour necrosis factor inhibitor (TNFi) therapy [Figure 1]. Each patientÕs images were visually scored by two radiologists using a modification of the Spondyloarthritis Research Consortium of Canada (SPARCC) system (1). Sacroiliac joint apparent diffusion coefficient (ADC) and normalized ADC (nADC) were measured for each patient using a previously described technique (2). Therapeutic clinical response was defined as an improvement in physician global assessment of more than 30% and radiological response defined as at least a 2.5-point drop in SPARCC score.

Results: For both radiological and clinical definitions of response, reductions in ADC and nADC after treatment were greater in responders than in non-responders (for radiological response: ADC: p<0.01; nADC: p=0.055; for clinical response: ADC: p=0.33; nADC: p=0.089). ADC and nADC could predict radiological response with a high level of sensitivity and specificity (the area under the receiver operating characteristic curves were ADC: 0.97, nADC: 0.82).

Conclusion **:** DWI measurements reflect response to TNFi treatment in ERA patients with sacroiliitis. DWI is more objective than visual scoring, and has the potential to be automated. ADC/nADC could be used as biomarkers of sacroiliitis in the clinic and in clinical trials. **References** 1. Maksymowych WP et al. Arthritis Care Res. 2005;53:703Ð9. 2. Vendhan K et al. Br J Radiol. 2015;18:20150775. **Figures**

Figure 1 Ð Quantitative DWI (left) and conventional STIR imaging (right) in an ERA patient with sacroiliitis. Intensities in the ADC map represent the ADC for each pixel (see colour bar) but pixels in the STIR images have arbitrary values. SIJ ADC is measured using three linear regions of interest (ROIs, solid blue lines) placed on each sacroiliac joint; this is repeated for four consecutive slices. A further ÔreferenceÕ ROI is placed on sacral bone to normalize SIJ ADC for individual patients (dotted blue line).

Prevalence of Radiographic Thymic Alteration and Its Clinical Association in Systemic Autoimmune Diseases

Okinori Murata[1], Katsuya Suzuki[1], Hiroaki Sugiura[2], Yasushi Kondo[1], Hidekata Yasuoka[1], Kunihiro Yamaoka[1] and Tsutomu Takeuchi[1], [1]Keio University School of Medcine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan, [2]Keio University School of Medcine, Division of Diagnostic Radiology, Department of Radiology, Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: While thymic alteration such as hyperplasia, cyst and neoplasia has been precisely studied particularly in myasthenia gravis [1], only a few small-scale studies have been reported in a part of systemic autoimmune diseases [2-4]. We conducted a large-scale cross-sectional analysis on prevalence of radiographic thymic alteration and its clinical association in various systemic autoimmune diseases.

Methods: Consecutive and unbiased 500 patients who had visited at our service and had been evaluated by chest CT scan between January 2013 and December 2015 were enrolled. Thymus size and the radiographic pattern on high-resolution CT

image were quantitatively interpreted. We defined hyperplasia as more than 13mm thickness and graded the patterns by four-point scale (grade 0-3) according to previous study [5,6]. Their association to clinical information was statistically analyzed.

Results: Thymoma and thymic cyst were found in 3 (0.6%) and 1 (0.2%), respectively. After above cases and less than 30 year-old patients were excluded, 488 were served for following analysis. 78% were women and mean age was 63.0 ± 13.9 years old. These included 168 patients with rheumatoid arthritis (RA), 63 with systemic sclerosis (SSc), and 37 with primary Sjögren's syndrome (pSS). Thymic hyperplasia was found in 90 (18%) overall. These included 41 (24%) with RA, 6 (10%) with SSc, and 7 (19%) with pSS. Remarkably, patients with granulated pattern (grade 1 and over) was more frequent (42%) as compared to undiagnosed controls. These included 78 (46%) patients for RA, 32 (51%) patients for SSc, and 17 (46%) for pSS. Regarding clinical association, when RA patients is classified by hyperplasia and granulated pattern, proportion of serum anti-cyclic citrullinated peptide antibody (ACPA)-positivity were significantly higher in alteration group compared to normal group (93% vs. 70% and 89% vs. 63%; *P*=0.004 and 0.0005, odds ratio=6.1 and 5.0). In addition, titer of ACPA was also positively correlated to both hyperplasia and granulated pattern (*P*=0.048 and 0.009).

Conclusion: Thymic alteration was found in quite a few patients with various systemic autoimmune diseases. In RA patients, radiographic thymic alteration, especially granulated pattern significantly correlates to ACPA status and may reflect activation of germinal centers in the thymic medulla. Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Peripheral bone mineral density (BMD) can be decreased in early rheumatoid arthritis but it is unknown if BMD loss emerges already before arthritis is clinically apparent. We aimed to study if BMD loss occurs in patients with clinically suspect arthralgia (CSA), if it is associated with progression to clinical arthritis and if it is associated with MRI-detected subclinical inflammation.

Methods: Patients with CSA had arthralgia for <1 year and were suspect to progress to RA according to their rheumatologists. At baseline a 1.5T MRI was performed of unilateral MCP, wrist and MTP-joints and scored on synovitis, bone marrow edema and tenosynovitis;. summing these features yielded the MRI-inflammation score. Digital X-ray radiogrammetry (DXR) was used to measure BMD on two sequential conventional hand radiographs (mean interval between radiographs 4.4 months). The change in BMD was studied; BMD loss was defined as decrease of ≥2.5 mg/cm^2/month. Patients were followed on arthritis development for median 18.4 months.

Results: In CSA-patients (n=108) change in BMD was negatively associated with age (β=-0.03, p=0.007). Within CSA-patients BMD loss was associated with arthritis development (adjusted for age HR=6.1, 95%CI=1.7;21.4) and was most frequently measured in the months before clinical arthritis development. The MRI-inflammation scores were associated with the change in BMD (adjusted for age β=-0.05, p=0.047). The MRI-inflammation score and BMD loss were both independently associated with arthritis development (HR=1.1 95%CI=1.1;1.2 and HR=4.6 95%CI=1.2;17.2 respectively).

Conclusion: In CSA-patients BMD loss is associated with MRI-detectable subclinical inflammation and with progression to clinical arthritis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of our study was to describe the prevalence of diastolic dysfunction (DD) and structural heart disease (SHD) among a cohort of Axial Spondyloarthritis (AxSpA) patients matched with a healthy control population. Aortic dilation, aortic insufficiency (AI) and DD have been reported in Ankylosing Spondylitis (AS), although their true prevalence remains uncertain. New pharmacologic therapies for AxSpA may have further impacted the prevalence of heart disease in this population. Studies to date have been small and lacked control populations, resulting in controversial recommendations for routine echocardiographic screening in AxSpA patients.

Methods: Prospective transthoracic echocardiograms were performed on 125 AxSpA patients and 56 age-matched healthy controls. Leading edge aortic root (AoR) measurements were made and normalized for body surface area. Measurements were also taken at the aortic annulus, sino-tubular junction and ascending aorta. DD was graded in accordance with the American Society of Echocardiography guidelines. Chi square tests and Wilcoxan rank sum analyses were used in the univariate analysis. A subgroup analysis was also performed in a matched group of 90 AS patients meeting the modified New York criteria and 45 healthy controls.

Results: Participants were 68% male with a mean age of 42.8±12 years. Mean AxSpA disease duration was 18.2 ± 12 years. The modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) for the overall population was 7.1±14.5 units and 9.9±16.5 units for the AS population. Mean AoR diameter was 3.29±0.36 cm for cases and 3.24±0.32 cm for controls. There was no difference in linear aortic measurements, the presence of AI or DD between the two groups. The subgroup analysis of AS patients alone did not show any differences in these outcomes when compared to controls.

Conclusion: While there are differences among individual measurements used in the assessment of diastolic function, there is no clinically relevant difference in the prevalence of DD between cases and controls. Furthermore, there is no significant increase in AoR size or in the presence of AI in AxSpA patients when compared with healthy controls. These

findings are the first basis of evidence to support the current recommendations against routine echocardiographic screening in asymptomatic AxSpA patients. Future subgroup analyses should focus on the impact of pharmacologic therapies on SHD and DD in this population.

Table 1: Baseline Characteristics of the Study Population

Population Characteristics	AxSp Patients n=125	AS Patients n=90
Baseline disease activity (ASDAS - CRP)	2.97 ± 1.25	3.09 ±1.35
Disease activity at time of echo (ASDAS - CRP)	2.0 ± 0.89	1.99 ± 0.94
Baseline CRP (mg/L) Reference range <6.3 mg/L	16.2 ± 22.7	13.6 ± 14.8
CRP at time of echo (mg/L) Reference range <6.3 mg/L	5.5 ± 6.5	6.12 ± 6.84
Treatment with NSAIDs	57.2%	46%
Treatment with TNFi	52%	56%

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Image fusion is an advanced imaging technology, which enables fusion of ultrasound (US) and magnetic resonance imaging (MRI). This fusion gives for each US probe position an exact projection of the corresponding anatomical area on a previously obtained MR image, during a live US assessment. This study is the first to address image fusion of US and MRI tenosynovitis. The aim of this study was to assess and compare US and MRI visualisation of tenosynovitis using image fusion technique.

Methods: Fifteen rheumatoid arthritis patients with US verified tenosynovitis in the wrist or hand had an MRI performed of the affected wrist or hand. A subsequent image fusion was performed, i.e. the MR images and a live US assessment of one tendon sheath were fused. In order to compare the two imaging modalities quantitatively, the area of the tendon and tendon sheath in the transverse axis was measured on US and MRI for each image fusion. Due to partial volume artefacts (voxel containing two different tissues and therefore possessing a signal average of tendon and tendon sheath) on MRI two measures were performed; area 1) the circumference of the black tendon, i.e. excluding voxels containing two types of tissue 2) the circumference of the grey line that surrounds the black tendon, i.e. including voxels containing two types of tissue. Tenosynovitis was assessed using the proposed OMERACT semi-quantitative scoring system for US and MRI. US scoring was therefore based on both grey scale and Doppler, whereas MRI scoring was based only on post-contrast tenosynovial enhancement, measured as distance from the tendon to end of the enhanced tendon sheath.

Results: The median circumference area of the tendons and tendon sheaths on US and MRI 1 and 2 were respectively 0.16 (25;75 pctl: 0.10;0.25), 0.9 (0.06-0.18) and 0.13 of (0.10;0.25) for the tendons and 0.18 (0.13-0.26), 0.27 (0.20-0.45) and 0.23 (0.16-0.40) for the tendon sheaths. Statistically significant differences were found for all measured areas between US and MRI, except for the US tendon area and the MRI tendon area 2 (Wilcoxon's test; p=0.47). Overall agreement between US and MRI tenosynovitis scoring systems was good (see table 1).

Conclusion: In conclusion, we found that US and MRI have good agreement for quantitative assessment of tendons and scoring of tenosynovitis, when comparing the two modalities using image fusion, if the partial volume artefacts on MRI are taken into account.

Table 1 Tenosynovitis scores on tendon level (0-3) for CD, GS and MRI area 1 and 2. Delta scores for MRI area 1 and 2 with CD or GS as reference. Further, percentage of exact agreement and percentage of close agreement is used for comparing the agreement between the scores.

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Raynaud's phenomenon (RP) is a clinical disorder that is characterized by paroxysmal vasospasm of small blood vessel after cold exposure or vibration. Radiopharmaceutical perfusion scintigraphy is a noninvasive and quantitative method for evaluation of RP. Interestingly, the increased perfusion or blood pool activity after cold exposure in one-hand chilling protocol has been reported, they are called paradoxical RP. However, little is known about the paradoxical reaction. In this study, we compared radiopharmaceutical perfusion imaging and thermography in patients with RP for the understanding of paradoxical RP.

Methods: Sixty male patients with secondary RP caused by hand arm vibration syndrome were included in this study. Radiopharmaceutical perfusion scintigraphy and thermography were performed for all patients. Blood flow by radiopharmaceutical perfusion scintigraphy in each hand was measured with one hand chilling protocol. According to the chilled finger to ambient finger ratio (CAR), we divided 60 enrolled patients into low and high ratio groups in each hand.

The finger to palm ratio in the ambient hand (FPRa) and the finger to palm ratio in the chilled hand (FPRc) were analyzed, and the correlations between blood flow ratios by radiopharmaceutical perfusion scintigraphy and temperature by thermography was evaluated.

Results: Among total 60 patients, the numbers of patients with paradoxical RP, that is classified as high ratio group, were 13 (21.7%) and 12 (20.0%) in left and right hand, respectively, and 6 patients showed paradoxical RP in both hands. FPRa showed positive correlations with baseline temperature (Left, $\gamma = 0.276$, $p = 0.033$; Right, $\gamma = 0.424$, $p = 0.001$, respectively), and CAR showed negative correlations with baseline temperature (Left, $\gamma = -0.291$, $p = 0.024$; Right, $\gamma = -0.273$, $p = 0.035$, respectively). In the high-ratio group, the FPRc values after cold exposure were significantly higher than those of ambient state (Left, 65.8 ± 23.2 vs. 49.2 ± 20.7, $p < 0.001$; Right, 61.5 ± 16.4 vs. 49.9 ± 9.6, $p = 0.013$, respectively); while in the low-ratio group, the FPRc values were significantly lower than those of ambient state (Left, 49.9 ± 19.6 vs. 57.0 ± 22.6, $p < 0.001$; Right, 51.5 ± 24.1 vs. 61.3 ± 21.9, $p < 0.001$, respectively). In the high-ratio group, baseline temperatures of the left digit were significantly lower than those in the low-ratio group (Left, 25.2 ± 2.9°C vs. 23.1 ± 3.1°C, $p = 0.037$; Right, 25.2 ± 2.9°C vs. 22.7 ± 3.1°C, $p = 0.018$, respectively) and baseline temperatures of the right digit tended to be lower than those in the low-ratio group (Left, 25.1 ± 2.9°C vs. 23.5 ± 3.1°C, $p = 0.093$; Right, 25.1 ± 2.8 vs. 23.3 ± 3.5°C, $p = 0.100$, respectively).

Conclusion: Paradoxical RP was detected in 20.0 ~ 21.7% of hand perfusion scintigraphy. Low basal blood flow and low baseline temperature of the digit can be related with paradoxical RP in hand perfusion scintigraphy.

Session Title: Imaging of Rheumatic Diseases - Poster I: Ultrasound and Emerging Technologies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RA and PsA result in joint destruction and functional disability if left untreated. Although therapies for patients with RA and PsA are effective and well-tolerated, recent evidence highlighted poor adherence to these anti-rheumatic treatment. Various factors hamper the adherence of patients with (false) medical beliefs and lack of knowledge being the major obstacles. We therefore aim to develop tools that help patients to understand and experience the impact of joint disease. In this study, we used high resolution peripheral quantitative computed imaging (HR-pQCT) to develop a virtual 3D reconstruction of finger joints. We then investigated (i) the feasibility to generate exact 3D models of arthritic and healthy joints, and tested (ii) whether these prototypes are accepted by patients and helped them to better understand and experience their medical condition.

Methods: HR-pQCT (Scanco) measurements were performed in healthy individuals and patients with erosive and non-erosive inflammatory joint disease. Then, a 3D printable file was generated and printed (objet30). Ten healthy participants (HC), 15 RA patients and 15 PsA patients, who were demonstrated printed healthy and arthritic joints, underwent a

detailed, standardized interview to investigate if the “arthro-haptic” experience helped to improve their understanding of the disease. Ethical approval was obtained; all patients and HC consented for the study.

Results: Utilizing HR-pQCT images of MCP heads, high quality and exact 3D models were created. For better visualization and haptic experience, bones were enlarged 3:1. The prototypes achieved a resolution as low as 24 µm. Erosions in different sizes as well as the trabecular network were visualized in detail, demonstrating a structural reduction in arthritic vs healthy bone. The erosions were mainly found at a region close beneath the cartilage area either radial/ulnar or dorsal. No erosions were identified at the palmar location. Artificial truncation separated the MCP head in 2 parts; the print showed a dorsal porous structured cortical defect with irregularly shaped borders, which normally could not be detected in plain X rays. In addition, a cystic structure which was also detected by MRI showed contrast enhancement and contained a new erosion at a two year follow up. After 3D demonstration (healthy vs. erosive joint, visually and haptically) HC and arthritis patients were asked for their emotional opinion. 26/39 (66%) were deeply affected, often quoting “shock”. 13/15 (86%) of the RA and 11/15 (73%) of the PsA patients stated, that they would rethink their attitude regarding medication adherence after being confronted with the 3D models. More importantly, 21/24 (87,5%) of RA and PsA patients expressed that they would have wished to see such 3D prints during their first disease specific conversations. 16/27 (59%) would appreciate seeing their own joint.

Conclusion: Using arthro-haptic 3D joints may help patients to better understand the impact of inflammatory arthritides on bone integrity and long-term damage. Additional studies need to prove that the better understanding will improve adherence of patients.

Session Date: Sunday, November 13, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In response to pro-inflammatory cytokines released locally during osteoarthritis (OA), such as the alarmins S100A8/A9, monocytes can be recruited from the bone marrow (BM) to the site of injury. Monocyte chemoattractant protein-1 (MCP-1) drives monocyte migration via binding with C-C chemokine receptor type 2 (CCR2). In mice, two functionally distinct monocyte populations are described: pro-inflammatory Ly6C-high monocytes ($CCR2^{high}$) and patrolling Ly6C-low monocytes ($CCR2^{low}$). The objectives of our study are to investigate the systemic effects of locally induced OA on BM monocyte populations and their recruitment to the OA joint in collagenase induced OA (CiOA), and the involvement of S100A8/A9 herein.

Methods: CiOA was induced by unilateral-articular collagenase-injection in C57BL/6 mice. At day 7, 21 and 42, mice were sacrificed together with age-matched saline-injected control mice (n=6/group), and expression of several pro-inflammatory cytokines, and MCP-1 and CCR2 were measured in the synovium and serum. During CiOA and control conditions, the absolute amount of cells in the BM of the contralateral femur was measured. Cells from BM, blood and synovial tissue were isolated and analyzed by FACS. Monocyte subsets were identified as

(B220/CD90/CD49b/NK1.1/Ly6G)^{low}CD11b^{high}(F4/80/MHCII/CD11c)^{low} and further distinguished by their Ly6C expression. In addition, we investigated the role of S100A8/A9 on monocyte populations during early CiOA using S100A9$^{-/-}$ mice.

Results: Synovial expression of the pro-inflammatory cytokines IL-1β, IL-6, TNF-α, S100A8 and S100A9 were increased at day 7, but only expression of S100A8 and S100A9 remained high until day 21. Local induction of CiOA resulted in systemic effects within the BM as shown by the significant decrease in total cell numbers at day 7 and 21 (both 14%), which decrease is suggested to be Ly6C high monocytes since the absolute amount of these cells decreases. Concurrently, relative number of Ly6C high monocytes and macrophages were significantly increased (764% and 251%, respectively) locally in the synovium at CiOA day 7, corresponding with the increased synovial mRNA expression of MCP-1 (151-fold) and CCR2 (41-fold). Since S100A8/A9 is sustainably expressed during CiOA and intra articular injection of S100A8 leads to significant induction of MCP-1 (8-fold) in the synovium, we next investigated the role of S100A8/A9 during early CiOA in more detail using S100A9$^{-/-}$ mice. S100A9$^{-/-}$ mice show less synovial activation, less cell influx and less cartilage degradation compared to wild type (WT) mice. Interestingly, there was no decrease in cell numbers or Ly6C high monocytes in the BM of S100A9$^{-/-}$ mice. Moreover, in contrast to WT mice, the patrolling Ly6C low monocytes were significantly increased (205%) in S100A9$^{-/-}$ mice, whereas the pro-inflammatory Ly6C high monocytes were not affected.

Conclusion: Local induction of OA induces systemic release of BM-derived Ly6C high monocytes, which are found subsequently increased locally in the synovium, a process that may be regulated by the sustained release of S100A8/A9 from the synovium via MCP-1.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Innate Immunity and Rheumatic Disease - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Seronegative joint diseases, including psoriatic arthritis and juvenile idiopathic arthritis, are characterized by the lack of autoantibodies, which are relevant biomarkers for predicting disease activity in rheumatoid arthritis. Promising alternative biomarkers are the Damage Associated Molecular Patterns (DAMPs), S100A8, S100A9 and the heterodimer S100A8/A9. These proteins are specifically expressed and released by infiltrating phagocytes and may therefore serve as relevant biomarkers for joint inflammation and destruction in seronegative arthritis. In this study we determined the biomarker potential of serum S100A8/A9 and in vivo imaging of synovial S100A8 to asses joint inflammation and damage in the IL-1 receptor antagonist deficient (IL-1Ra$^{-/-}$) mice, a mouse model for seronegative arthritis in which serum autoantibodies are not correlated to disease activity.

Methods: Serum levels of S100A8/A9 and various cytokines were monitored during arthritis development in IL-1Ra$^{-/-}$ mice using ELISA and Luminex and were correlated to macroscopic and microscopic parameters for joint inflammation and damage. Local S100A9 expression and matrix metalloproteinase (MMP) mediated cartilage damage in the ankle joints were investigated by immunohistochemistry. In addition local S100A8 and activated MMPs were monitored in vivo by optical imaging using anti-S100A8-Cy7 and AF-489-Cy7, a specific tracer for activated MMPs.

Results: Starting at week 8, serum levels of S100A8/A9 were significantly increased (1640 ± 1008 ng/ml at week 16) in IL-1Ra$^{-/-}$ mice compared to WT BALB/c control mice (429 ± 191 ng/ml, $P = 0.005$) and strongly correlated to joint swelling ($r = 0.766$, $P < 0.0001$), while serum levels of IL-1β, IL-6, TNF-α, IL-17, IL-4 or IFN-α did not. In addition, high serum S100A8/A9 levels at week 10 were predictive for increased joint swelling at week 16 ($r = 0.576$, $P = 0.0002$). Next to macroscopic swelling, increased serum S100A8/A9 also correlated to microscopic cell influx ($r = 0.794$, $P < 0.0001$) and was reflected by local expression of S100A9 within the synovium, indicating the activated synovial lining as the source of increased serum S100A8/A9. Local expression of S100-DAMPs could also be monitored non-invasively by in vivo optical imaging using anti-S100A8-Cy7. Next to a biomarker for inflammation, S100-DAMPs may also be used for assessing joint damage. Indeed, arthritic IL-1Ra$^{-/-}$ mice showed increased cartilage damage ($r = 0.687$, $P < 0.0001$) which coincided with MMP-mediated neoepitope (VDIPEN) expression and in vivo imaging of activated MMPs.

Conclusion: These findings underline the potential of S100-DAMPs as a systemic and local biomarker in seronegative arthritis, not only for assessing inflammation but also joint damage.

Session Date: Sunday, November 13, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibodies to citrullinated proteins are highly specific and potentially pathogenic in rheumatoid arthritis (RA). Proteins modified with malondialdehyde-acetaldehyde (MAA) are present in RA synovium where they co-localize with citrullinated proteins. Moreover, MAA-modified proteins are bound and internalized by scavenger receptors (SRs) present on immune cells. However, the mechanism(s) by which citrullinated proteins are recognized by cells of the immune system to initiate antibody and T cell responses remains unknown. Thus, we examined proteins modified with MAA and/or citrulline to determine the impact of these modifications on SR binding.

Methods: Binding studies were performed using Chinese Hamster Ovary (CHO) cells transfected with individual SRs: type A (SR-A), type B-1 (SRB-I), CD36, TLR-2, and TLR-4. Cells were incubated on ice for 90 minutes with 25 µg/ml of human serum albumin (ALB) modified with: MAA (MAA-ALB), citrulline (CIT-ALB), MAA then citrulline (MAA-CIT-ALB), or citrulline then MAA (CIT-MAA-ALB). Cells were washed to remove unbound proteins, incubated with a polyclonal goat anti-human albumin antibody, and detected using a Cy5-conjugated rabbit anti-goat IgG antibody. Cells

were fixed in paraformaldehyde and subjected to Flow cytometry at 650 nm wavelength. Analysis was performed using FlowJo V10. Data is expressed as percent positive compared to isotype control with non-specific ALB binding subtracted as background.

Results: CHO cells expressing CD36 preferentially bound CIT-ALB (P=0.017), but not MAA-ALB (Figure 1). In contrast, SRB-I preferentially bound MAA-ALB (P<0.001), but not CIT-ALB. Interestingly, the MAA-CIT-ALB modification showed slightly less binding than CIT-ALB to CD36 and MAA-Alb to SRB-I, but resulted in binding to both receptors equally, suggesting the double modification results in less specific binding. Additionally, MAA-CIT-ALB binding was increased compared to CIT-MAA-ALB binding on SRB-I (P<0.01) expressing cells. CHO control cells had background binding levels of ~5% for all antigens. Preliminary data using SR-A, TLR-2, and TLR-4 expressing CHO cells demonstrate similar unique binding patterns with these two modifications on albumin (Data not shown).

Conclusion: CHO cells expressing a single SR demonstrated differential binding of MAA-modified and/or citrullinated albumin that was unique to each receptor. Interestingly, co-modifications resulted in a decrease in the binding of ALB as compared to CIT-ALB (to CD36) or MAA-ALB (to SRB-1). However, there was an increase in the binding to both receptors suggesting that co-modification with MAA and CIT may increase the number of different receptors to which they bind. Further studies are underway to evaluate other SR binding of other proteins including histone, vimentin, and fibrinogen modified with MAA and/or CIT.

Session Title: Innate Immunity and Rheumatic Disease - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, systemic autoimmune disease resulting from dysregulated innate and adaptive immune components that result in an inflammatory response. Cytokines produced by inflammatory monocytes are increased in SLE patients and signal through the JAK-STAT pathway. SOCS proteins (suppressor of cytokines signaling), specifically SOCS1 and SOCS3 are upregulated by Jak-STAT signallin and then function to limit JAK-STAT signalling. Thus SOCS proteins assure that the JAK-STAT signals are transient and contain the innate and adaptive immune responses. The expression of SOCS proteins in SLE patients has not been assessed. Reports of SOCS1 and SOCS3 mRNA expression in SLE patients are conflicting and have been obtained from whole peripheral blood (PB), thus the cells with dysregulated SOCS expression could not be determined. Our objective was to assess SOCS1 and SOCS3 protein expression in circulating monocytes subsets from SLE patients, and to determine the relationship between SOCS1 and SOCS3 expression and disease activity.

Methods: PB samples were collected from SLE patients and healthy controls through an IRB-approved protocol. American College of Rheumatology or Systemic Lupus International Collaborating Clinics classification criteria for SLE was used to establish diagnosis. Disease activity was determined by using the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K 30 Days). PB mononuclear cells (PBMCs) were isolated by red blood cell lysis. PBMCs were stained for flow cytometry to identify classical, intermediate, and non-classical monocytes based on CD14 and CD 16 expression. Intracellular staining was used to evaluate SOCS1 and SOCS3 protein expression in monocyte subsets. Median fluorescence intensities (MFI) for SOCS1 and SOCS3 from SLE patients were compared to healthy patients by one-tailed Mann-Whitney U-test $p<0.05$. Spearman's rho correlation was used to test the relationship between SOCS1/3 expression and disease activity, complement proteins (C3 and C4).

Results: Expression of SOCS1 and SOCS3 in monocytes subsets obtained from healthy (n=11) and SLE (n=11) patients were compared. No difference in the monicyre distribution among the subsets was observed between SLE patients and healthy controls. In SLE patients non-classical monocytes showed significantly elevated SOCS1 protein levels (p=0.03) and SOCS1 levelst were positively correlated with disease activity (r=0.56, p=0.04) and negatively correlated with serum C3 (r=-0.56, p=0.04) and C4 (r=-0.79, p=0.003) levels. SOCS3 was also significantly elevated in non-classical monocytes from SLE patients (p=0.01) and negatively correlated with C4 (r=-0.80, p=0.01). The expression of SOCS1 and SOCS3 in classical and intermediate monocytes did not differ between SLE and healthy controls.

Conclusion: In SLE patients SOCS1 is elevated in non-classical monocytes as compared to healtht controls and the levels of SOCS1 in SLE patients correlate with clinical indicators of more active disease. Further studies are needed to determine the role of SOCS1 and SOCS3 in the pathogenesis of SLE and as potential disease activity indicators. _

Session Title: Innate Immunity and Rheumatic Disease - Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Repeated immunization with exogenous antigen such as ovalbumin (OVA) induces SLE in mice otherwise not prone to spontaneous autoimmune diseases, in which autoantibody-inducing CD4 (*ai* CD4) T cell that had undergone *de novo* T cell receptor (TCR) revision was generated. The *ai* CD4 T cells induced varieties of autoantibody including anti-dsDNA antibody and matured CD8 T cells into effector cytotoxic T lymphocyte (CTL) *via* antigen cross-presentation in dendritic cell (DC), after which they caused tissue injuries (Tsumiyama K et al. PLoS ONE 4(12): e8382, 2009; J Immunol. 191: 91, 2013). We here studied the molecular mechanism of antigen cross-presentation to show that accumulation of cross-presentable antigen in the cytoplasm *via*Sec61, translocation channel of protein involved in ER-associated degradation (ERAD), finally induces lupus tissue injury in an experimental model based on our 'self-organized criticality theory' explaining the cause of SLE.

Methods: Bone marrow-derived DC (BMDC) was generated from BALB/c mice. BALB/c mice were repeatedly immunized with ovalbumin (OVA) to induce SLE, and splenic DC (spDC) was isolated from these mice. DCs were cultured with fluorescent-labeled OVA, an inhibitor of Sec61 Exotoxin A and/or an inducer of ER stress Tunicamycin. Immunofluorescent staining, immunoprecipitation and immunoblotting were performed to detect early endosome antigen 1 (EEA1), calnexin, Sec61, OVA and unfolded protein response (UPR)-related molecules. OVA/MHC class I complex was detected under flow cytometry.

Results: Engulfed OVA was co-localized with endosomal marker EEA1, which was then separated from EEA1 in DCs. OVA never co-localized with ER marker calnexin, whereas OVA was co-localized and co-precipitated with translocon Sec61. OVA in the cytoplasm of BMDC became undetectable when co-cultured with the inhibitor of Sec61 Exotoxin A, and thus, antigen was exported directly from endosome to cytoplasm *via* Sec61. When the amount of OVA accumulated in the cytoplasm was decreased dose-dependently by inhibiting Sec61 using Exotoxin A, the amount of OVA/MHC class I complex expressed on BMDC was significantly decreased. Instead, the amount of endosomal Sec61 and cytoplasmic OVA was both increased upon co-culture with an inducer of ER stress Tumicamycin in BMDC. Similarly, in the mice with lupus kidney disease generated upon repeated immunization with OVA, both endosomal Sec61 and cytoplasmic OVA were up-regulated in their spDC. Further, expression of UPR-related molecules including Bip, IRE1, XBP1 and PERK, and phosphorylated eIF2α was significantly up-regulated, which indicated that ER stress increases endosomal Sec61 thereby increasing the amount of antigen accumulated in the cytoplasm. The cytoplasmic antigen which is cross-presentable finally augments lupus tissue injury.

Conclusion: We found in the first that antigen was transported from endosome to cytoplasm *via* Sec61 for antigen cross-presentation. Second, antigen cross-presentation was promoted in proportion to the amount of antigen accumulated in cytoplasm of DC. Third, ER stress increased endosomal Sec61 thereby contributing to the induction of lupus tissue injury by facilitating antigen cross-presentation.

Session Title: Innate Immunity and Rheumatic Disease - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Tolerogenic dendritic cells (TolDCs) are promising tools for therapy of autoimmune diseases such as rheumatoid arthritis (RA). Here we characterise TolDCs from RA patients modulated with dexamethasone and monophosphoryl lipid A (MPLA) concerning gene expression, phenotype, cytokine profile, migratory properties and T cell-stimulatory capacity to explore their suitability for autologous cellular therapy.

Methods: TolDCs were generated from monocytes of 9 RA patients, meeting 2010 ACR/EULAR criteria, and 10 healthy controls, using dexamethasone for tolerization and MPLA for activation (MPLA-tDCs). The phenotype of MPLA-tDCs and their migratory behaviour towards lymphoid chemokines were analysed by flow cytometry and transwell assays. Cytokine secretion of MPLA-tDCs and their ability to activate autologous antigen-specific T cells was determined by flow cytometry and ELISA. Genome-wide transcriptional analysis was performed and differential expression was defined by a false discovery rate of ≤ 0.05.

Results: MPLA-tDCs derived from RA patients, exhibited characteristics of semi-mature DCs (Fig 1), such as: reduced expression of costimulatory and coactivation molecules and the capacity to migrate in response to ligands of lymph node homing chemokine receptors CCR7 and CXCR4. These cells displayed an anti-inflammatory cytokine profile inducing hyporesponsiveness and IL-10 secretion of autologous CD4+ T cells specific to synovial antigens. Global transcriptome analysis demonstrated that treatment with dexamethasone and MPLA overcame RA-associated effects on gene expression profiles of monocyte-derived DCs (Fig 2).

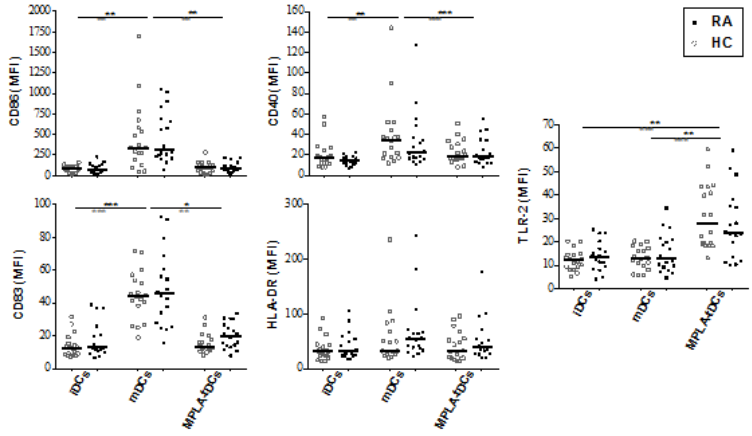

Figure 1. MPLA-tDCs from rheumatoid arthritis patients and healthy controls display low expression of maturation

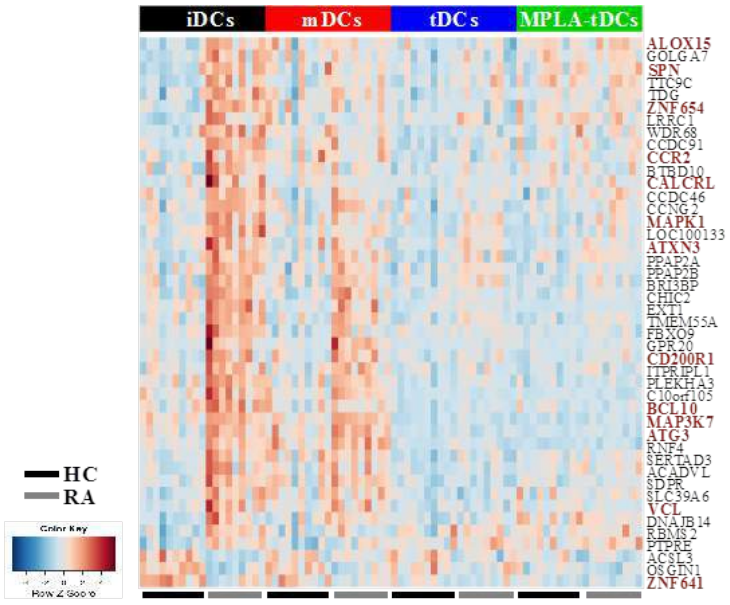

Figure 2. Conditioning with dexamethasone and MPLA induces similar transcriptional profiles on moDCs from RA patients and healthy controls, and reverses disease-associated effects on gene expression in MPLA-tDCs derived from monocytes of rheumatoid arthritis patients

markers and high TLR2.

Conclusion: Monocyte-derived DCs of RA patients have the potential to develop stable tolerogenic features when modulated with dexamethasone and MPLA, irrespective of disease status. The ability of MPLA-tDCs to impair T cell responses to synovial antigens validates their potential for the treatment of RA. Session Date: Sunday, November 13, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatism. RA is multifactorial involving genetic, environmental, endocrine, psychological and immunological factors. In 2002, our research team has discovered alpha-enolase (ENO1) as an autoantigen in RA and has recently demonstrated its effect on monocytes, inducing inflammation mediated through CD14-dependent TLR4 signaling pathway. Monocytes can differentiate into

dendritic cells, osteoclasts or macrophages. Macrophages are involved in RA pathophysiology and can be polarized in different phenotypic profiles, pro-inflammatory (M1 macrophages) or immuno-regulatory (M2 macrophages). The main objective of this study was to determine the effect of ENO1 on monocytes differentiation into macrophages and on their polarization.

Methods: Monocytes of healthy donors were cultured with M-CSF (Macrophage-Colony Stimulating) or GM-CSF (Granulocyte Macrophage-Colony Stimulating Factor) for 5 days for their differentiation into macrophages and for 3 supplemental days with IFN-g and/or LPS or IL-4 and/or IL-10 for M1 or M2 polarization respectively. Monocytes and monocytes-derived macrophages were also cultured with ENO1, or control BSA, to investigate its effect on monocytes differentiation and macrophages polarization. Microscopy, flow cytometry and ELISA were performed to determine the macrophages polarization profile (M1 or M2) induced by ENO1.

Results: Firstly, we showed that ENO1 did not induce monocytes differentiation into macrophages in contrast to M-CSF and GM-CSF. However, in macrophages differentiated with M-CSF or GM-CSF, ENO1 induces M1 polarization in terms of morphology, surface markers and cytokines production. ENO1 can also initiate repolarization in M1 of macrophages previously polarized in M2. Finally, we showed that ENO1 induced a cytokine inflammatory response higher in macrophages differentiated with GM-CSF compared to M-CSF.

Conclusion: These results showed for the first time the potential role of native ENO1 in the inflammatory process of RA through its interaction with macrophages, promoting their polarization into pro-inflammatory M1 profile. Our project, aimed to understand the role ENO1 in RA pathophysiology, opens interesting research perspectives on cell types derived from monocytes.

Session Title: Innate Immunity and Rheumatic Disease - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid lung disease is a prognostic factors of rheumatoid arthritis in human. The pathogenesis and the mechanism of rheumatoid lung disease is unclear. Zymosan A (ZyA)-treated SKG mice develop not only arthritis but also pneumonitis. To clarify the mechanism of rheumatoid lung disease in human, we analyzed the pneumonitis in SKG mice, which is similar to rheumatoid lung disease in human.

Methods: SKG mice were induced pneumonitis by ZyA injection. The severity of pneumonitis three months after ZyA injection was evaluated by the area of diffusely affected lesion in HE stain, as follows: histological score (HS) 0: affected area <10%, HS1: 10-29%, HS2: 30-59%, HS3: ≥60%. Lung-infiltrating cells (T cells, myeloid cells, innate lymphoid cells (ILCs)) were evaluated by flow cytometry. In vitro, lung-infiltrating cells were cultured with GM-CSF (and IL-4) for 5 days and evaluated by flow cytometry. CSFE-labeled naïve T cells were cultured with isolated $CD11b^{+}Gr1^{dim}$cells from lung, and stimulated with anti-CD3 and anti-CD28 monoclonal antibodies. After three days, Cell proliferation was

examined by measuring CFSE fluorescence with flow cytometry.

Results: Histological analysis revealed that ZyA-treated mice developed various severity of pneumonitis; HS1: 30%, HS2: 50%, HS3: 20%. Unique cells with large and bright nucleus emerged only in the specimen of HS3. Flow cytometric analysis revealed that $CD11b^{+}Gr1^{+}$cells, $CD11b^{+}Gr1^{dim}$cells, Th17 cells, regulatory T cells (Treg), and ILC3s were increased, and the proportion of these cells varied depending on the HS: $CD11b^{+}Gr1^{+}$cells decreased as the progression of HS, while $CD11b^{+}$ $Gr1^{dim}$cells emerged only in the lung of HS3 (Figure1). Most of $CD11b^{+}$ $Gr1^{dim}$cells expressed CD11c, and the cells facilitated the naïve T cell proliferation in vitro. GM-CSF (and IL-4) induced the differentiation of $CD11b^{+}Gr1^{dim}$cells from total lung cells. The GM-CSF mRNA was significantly increased in the lung of ZyA-treated SKG mice compared to that of normal saline (NS)-treated SKG mice. Intracellular cytokine staining revealed that GM-CSF-producing Th17 and ILC3s were significantly increased in the lung of ZyA-treated SKG mice.

Conclusion: $CD11b^{+}Gr1^{dim}$cells, which are induced by GM-CSF produced by Th17 and ILC3s, may facilitate the progression of pneumonitis in SKG mice.

Figure1 : $CD11b^{+}Gr1^{dim}$cells emerged in the lung of HS3.

Session Date: Sunday, November 13, 2016
Session Title: Innate Immunity and Rheumatic Disease - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Innate lymphoid cells (ILCs) are a group of lymphocytes that lack antigen-specific receptors and have important roles in mediating immune responses and in regulating tissue homeostasis. ILCs are classified into three subsets, ILCs 1, 2, and 3, based on their patterns of cytokine production and transcription factors (TFs) expression. ILC3s are dependent on Retinoic-acid-receptor-relates orphan receptorγt (RORγt) and produce cytokines such as IL-17, IL-22, and Tumor necrosis factor -α (TNF-α), which play critical roles in inflammatory arthritis. ILC3s are further subdivided into several populations based on the expression of surface markers. LTi cells, which express chemokine receptor 6 (CCR6), are important for development and maintenance of lymph nodes and secondary lymphoid tissues. Another subgroup is natural cytotoxicity receptor (NCR) $^{+}$ ILC3s, which are essential for the epithelial barrier and host protection in the intestine. In rheumatic diseases, the increase of the number of NCR^{+} ILC3s was reported in patients with psoriasis, psoriatic arthritis (PsA) and ankylosing spondylitis (AS). It has also been shown that CCR6^{+}ILC3s have increased in synovium fluid (SF) of patients with PsA. In this study, we tried to evaluate the ILCs 1,2, and 3 both in quantity and quality in various tissues isolated from collagen induced arthritis (CIA) model mice in order to clarify the role of ILCs in the development of rheumatoid arthritis (RA).

Methods: We isolated lymphocytes from bone marrow (BM), spleen, peripheral blood (PB), local lymph nodes (LNs) and joints in normal and CIA model mice. ILC1s, ILC2s, CCR6^{+}ILC3s and NCR^{+}ILC3s were determined by flow cytometry using surface markers, NK1.1 (ILC1), IL-33R (ILC2), CCR6 and NKp46 (ILC3). Gene expression of the TFs and cytokines were measured by quantitative real-time PCR (qPCR) to confirm that ILC subsets are precisely classified by these surface markers. Finally, we compared the absolute cell number, ratio, gene expressions of TFs and cytokines of each ILC sunset in normal and in CIA model mice.

Results: CCR6^{+}ILC3s showed high gene expression of RORγt, IL-17, IL-22 and TNF-α as reported previously. In CIA model mouse, in addition to the increase of ratio of CCR6^{+}ILC3s in PB and joints, the levels of gene expression of TFs and cytokines were significantly elevated. Almost all of NKp46^{+}ILC3s expressed NK1.1, which is a marker for ILC1s. NKp46^{+}ILC3s showed lower gene expression of RORγt, IL-17 and IL22 than CCR6^{+}ILC3, while they showed high gene expression of T-bet and Interferon-γ(IFN-γ), suggesting that NKp46^{+} ILC3s in our purification method may include a fraction of ILC1s. Another marker which can further subdivide NKp46^{+}ILC3 population is required.

Conclusion: CCR6^{+}ILC3 produce IL-17, IL-22 and TNF-α, which are essential cytokines for the development of CIA. CCR6^{+}ILC3s may play roles in pathogenesis of RA through its production of cytokines.

Session Date: Sunday, November 13, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's disease (BD) is a chronic recurrent, multisystem inflammatory disorder. The phenotypic characteristics include oral aphtha, genital ulcers, uveitis and skin lesions. No specific laboratory tests have been known in BD. Reported in BD have been an increased number of γδ T cells in the peripheral blood and hyperactivity of neutrophils. Although a line of evidence has suggested genetic contributions to the disease, etiopathogenesis of BD is still unclear and non-genetic factors, like environment, infection or epigenetics, may play pivotal roles in the pathogenesis. Epigenetic mechanisms including posttranslational histone modifications are known to regulate gene expression without altering the genomic sequence. The association of specific histone modifications with gene expression is very well defined, such as H3K27me3, which may be characteristics of repressed genes, or H3K4me3, which may present in many active genes. Histone modifications in major rheumatic diseases, such as rheumatoid arthritis, have been investigated, while studies on histone modifications in BD are limited. From the functional point of view, it is important to analyze differences of histone modifications in each functional subclass of the entire peripheral blood nucleated cells. To examine the histone modifications of peripheral white blood cells (WBCs) in BD, we have established a novel method analyzing histone methylation in each subset defined by the surface markers using fluorescence-activated cell sorting (FACS).

Methods: WBCs were obtained from patients with active and inactive BD and healthy controls (HC). Six immune cell types were stained with antibodies against surface markers and classified as below : CD4+ T cells, CD8+ T cells, γδ T cells, CD16+CD66b+ neutrophils, CD4+CD25+Foxp3+ Tregs, and CD19+ B cells. All samples were analyzed with a FACSCanto II cytometer. As a quantitative measure of H3K4me3 and H3K27me3, mean fluorescence intensity (MFI) was used and normalized using isotype controls.

Results: H3K27me3 MFI levels of BD in CD4+T cells, CD8+T cells and γδT cells were significantly decreased, compared with HC. H3K27me3 MFI levels of BD in neutrophils were significantly increased. In contrast, H3K4me3 MFI levels of BD in CD4+T cells, CD8+T cells, γδ T cells and Tregs were significantly decreased, compared with those of HC. H3K4me3/H3K27me3 MFI ratio of BD was significantly lower in neutrophils and Tregs, and higher in γδ T cells of BD than that of HC. H3K27me3 MFI of active BD were significantly decreased in γδ T cells as compared to inactive BD. H3K4me3/H3K27me3 MFI ratio of active BD was significantly higher in γδ T cells than in inactive BD.In addition, the similar result was also observed between active and inactive phasesin the same patients. Preliminary observations suggest IL-17 secretion on γδ T cells in BD.

Conclusion: Differences in histone modifications could be detected by FACS in peripheral WBCs in BD patients. Aberrant histone methylation in γδ T cells may be associated with the pathogenesis of BD. It is suggested that histone methylation could be a new candidate-biomarker for BD and that γδ T cells might be a possible therapeutic target in BD.

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis is a chronic inflammatory disease of the skin and is often accompanied by arthritis. The underlying pathogenesis of psoriasis is still unclear, but T-helper 1 (Th1) and Th17 cells are thought to play important roles. Mucosal-associated invariant T (MAIT) cells are innate lymphocytes that are restricted by MHC-related molecule-1 (MR1), express a semi-invariant TCRa chain: Va7.2-Ja33 in humans and Va19-Ja33 in mice. Previously, we have shown that MAIT cells inhibited the progression of autoimmune encephalomyelitis (EAE), and the inhibition of EAE was accompanied by reduced autoreactive Th1 and Th17 responses. Therefore, we sought to investigate whether MAIT cells have a suppressive role in an animal model of psoriasis by using $MR1^{-/-}$ mice lacking MAIT cells.

Methods: A murine imiquimod (IMQ)-induced model of psoriasis (J Immunol. 2009; 182: 5836-45) was induced in $MR1^{-/-}$ and $MR1^{+/+}$C57BL/6J mice at 8 to 10 weeks of age. Mice were topically treated with 62.5mg of 5% IMQ cream (Mochida Pharmaceutical) on the shaved back for 5 consecutive days. Mice were injected with 500ml of phosphate-buffered saline on day 1 and 3. The severity of skin inflammation was monitored every day, and scored by usning linical Psoriasis Area and Severity Index (PASI) score. Erythema, scaling, and thickening of the back skin were scored on the scale from 0 to 4. (J Immunol. 2009; 182: 5836-45). Skin samples were stained with haematoxylin-eosin, and the severity were graded on a scale of 1 to 3 for acanthosis; 1 to 2 for hyperkeratosis, interface liquefaction, inflammation, dermal cellularity, presence of dilated vessels with hemorrhage; 0 to 1 for ulcer or erosion. Differences between groups were assesed using the Mann-Whitney U test, and the significance level was set at $p < 0.05$.

Results: Both $MR1^{-/-}$ and $MR1^{+/+}$C57BL/6J mice equally developed erythema. $MR1^{-/-}$C57BL/6J mice displayed significantly severe scales and thickness of the back skin than $MR1^{+/+}$ mice. The histopathological analysis revealed there was a significant worsening of dermatitis and the higher dermatitis score in $MR1^{-/-}$ mice compared to control $MR1^{+/+}$C57BL/6J mice.

Conclusion: The present study indicated that MAIT cells play a suppressive role for the development of psoriasis. In humans, MAIT cells have recently been found in normal and psoriatic skin. Although further verification for mechanisms of the function of MAIT cells for pathogenesis of psoriasis, regulation of MAIT cell functions may become a novel therapeutic strategy for psoriasis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Innate Immunity and Rheumatic Disease - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Type I IFN expression is known to be upregulated in the salivary glands of patients with SjogrenÕs syndrome, but the upstream stimuli responsible for this IFN signature are not known. IFI16 is a cytoplasmic DNA sensor that stimulates the production of type I IFN in response to cytoplasmic DNA via the STING-IRF3/NFkB pathway. IFI16 expression is also induced by IFN I, and therefore establishes a mutually reinforcing feedback loop. IFI16 is the target of autoantibodies in SjogrenÕs syndrome and is known to be expressed in the salivary gland. We sought to determine whether the elements of this DNA sensing pathway downstream of IFI16 were upregulated in the labial salivary glands of patients with SjogrenÕs syndrome.

Methods: Protein lysates were generated from minor salivary glands obtained from patients with SjogrenÕs syndrome (n=12) and sicca controls (n=7). All patients with SjogrenÕs syndrome met the ACR criteria for SjogrenÕs syndrome; none of the controls met these criteria. Protein lysates were subjected to SDS-PAGE electophoresis followed by Western blotting for the following proteins: IFI16, STING, IRF3, phospho-IRF3, p65, phospho-p65, IFIT3 (as a marker of type I IFN signaling), and vinculin (as loading control). Western blot results were subjected to densitometry analysis and statistical analysis was performed using GraphPad Prism 7.00 (Mann-Whitney analysis for nonparametric variables).

Results: IFI16, STING, IRF3, and p-IRF3 were found to be upregulated in SjogrenÕs patients as compared to controls. The ratio of phosphorylated IRF3/total IRF3 was also increased in SjogrenÕs patients, implying enhanced activation of this signaling pathway. IFIT3, which is a marker of type I IFN expression, was also upregulated in patients. While NF-kB has been proposed to signal downstream of IFI16 in in vitro studies, we did not find p65 to be significantly upregulated nor phosphorylated in SjogrenÕs patients as opposed to controls.

Conclusion: These data indicate that the STING-IRF3-IFN DNA sensing pathway which functions downstream of IFI16 is upregulated and activated in the target tissues of SjogrenÕs patients. These data imply that DNA sensing in the minor salivary gland may be a stimulus for IFN I production in this tissue. Figure 1: Western Blot Analysis of Salivary Gland Protein Lysates

Session Date: Sunday, November 13, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Type 1 interferons, such as interferon-α, are of increasing interest in autoimmunity due to their pleiotropic effects on the immune system. Approximately 20-30% of established rheumatoid arthritis (RA) patients have a positive interferon gene signature (IGS) suggesting active type 1 interferon signalling, While this can predict a poor response to biological therapies, such as rituximab, it has not been shown to correlate with disease activity. Since some treatments, such as steroids, can modify the IGS we wished to examine the prevalence and prognostic value of the IGS in early drug naïve RA.

Methods: 50 DMARD and glucocorticoid naïve early RA patients fulling ACR/EULAR (2010) criteria for RA, 23 established RA patients, 23 SLE patients and 23 healthy controls had whole blood RNA isolated (Tempus, ThermoFisher) and expression of 5 interferon signature genes quantified (MxA, IFI6, OAS1, ISG15, IFI44L) by RT-PCR (Taqman, ThermoFisher) using the Roche Universal probe library. The mean expression of these genes was termed the IGS score and defined as positive if was ≥ 2 standard deviations above that seen in the healthy population. EULAR responses were recorded after 3-6 months on standard DMARD therapy and some early RA patients also had their IGS repeated 1 and 3 months following diagnosis. Statistical analysis included ordinal and nominal logistic regression, multiple regression analysis, Wilcoxon signed rank, Mann-Whitney U and Chi^2 tests (GraphPad Prism v 5.0, San Diego USA and JMP Statistical Visualization Software v 11, SAS Inc, NC). Significance was defined when $p<0.05$.

Results: Twice as many early RA patients as established RA patients exhibited an IGS (42% vs 21%). There was significantly upregulated expression of interferon signature genes in early RA compared with established RA and were at similar levels to those reached in SLE. We observed a significant fall in early RA IGS expression between baseline and 3 months. The baseline IGS score significantly associated with DAS-28 at baseline and 6 months. This association was mainly driven by the CRP and SJC components. The IGS also predicted poorer EULAR response to initial therapies and increased glucocorticoid requirements at both 3 and 6 months (p all <0.05). See table 1 for summary of prognostic findings.

Clinical outcomes at 6 months after diagnosis	**Association with baseline IGS score**	**P value**
DAS-28	positive	0.002
Probability of achieving a "Good" EULAR response	inverse	0.044
Number of additional glucocorticoids administrations	positive	<0.0001

Table 1: Baseline IGS score significantly predicts a poorer response to initial therapy in a range of clinical outcome measures.

Conclusion: We demonstrate an increased IGS in early RA. This mirrors other autoimmune conditions, such as primary sjogrens syndrome and type 1 diabetes where early exposure to type 1 interferons is key in disease pathogenesis. For the first time in RA we show that the IGS correlates with disease activity and in fact has prognostic value in early disease. This could inform management and therapeutic stratification, particularly with regard to therapies that target type 1 interferons and related pathways.

Impact of TLR Stimulation on Cytokine Production in Macrophage Subsets: TLR2 Stimulation Impairs Anti-Inflammatory Activity of M2 Macrophages

Lilian Quero, Anke Gehringer and Diego Kyburz, Department of Biomedicine, Experimental Rheumatology, University of Basel, 4051 Basel, Switzerland

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Toll-like receptors (TLRs) have been shown to contribute to the inflammatory response in rheumatoid arthritis (RA). A number of TLRs have been found to be upregulated in synovial tissue (TLR2, TLR3, TLR4), synovial monocytes (TLR4) as well as macrophages (TLR2, TLR4) in RA versus osteoarthritis (OA). Based on phenotypic and functional differences macrophages can be divided into different subsets. At present there is limited knowledge on the functional role of macrophage subsets in rheumatoid arthritis. Here we investigated the impact of TLR2, TLR3 and TLR4 signaling on monocytes (M0) and monocyte derived M1 and M2 macrophages. We compared inflammatory and anti-inflammatory cytokine release, cell surface marker and TLR gene expression as well as viability of M0, M1 and M2 macrophages.

Methods: Monocytes were isolated from buffy coats of 4-6 healthy donors by CD14 microbead separation and differentiated into M1 and M2 by culturing them in the presence of 50ng/ml GM-CSF and M-CSF, respectively, for 6 to 8 days. For M0, CD14+ cells were kept in standard medium for 3 days. Subsequently, cells were stimulated for 24 hours with Pam3, LPS or PolyIC. Cytokine release was measured by ELISA, gene expression by qRT-PCR and viability by WST-1 assay. Cells were stained with fluorescently labeled antibodies for CD markers and analyzed by FACS.

Results: We demonstrate that stimulation of M2 macrophages with the TLR2-ligand Pam3 but not with the TLR4-ligand LPS leads to a decrease in the IL-10/IL-6 and IL-10/IL-8 ratio. TLR2 and TLR3 basal gene expression levels were similar between the cell types, whereas TLR4 expression was 3.7 fold higher in M2 than M0 or M1. TLR4 was strongly downregulated by LPS and Pam3 in M1 and M2, but not in M0. In contrast, TLR2 was upregulated by Pam3 and LPS. CD14 and CD163 expression was not affected by TLR ligands. CD86 levels were increased in M1 by all TLR ligands tested and in M0 by Pam3 but decreased in M2 by LPS and Pam3. CD80 was increased by Pam3 and LPS in M1 and by LPS in M2. Stimulation with TLR2 ligands was found to significantly increase M2 viability.

Conclusion: We demonstrate that stimulation of in vitro differentiated M2 macrophages with TLR2 ligands leads to increased proinflammatory cytokine production, suggesting that the antiinflammatory activity of M2 macrophages is reduced in an inflammatory milieu with abundant TLR2 ligands as can be found in RA. In line with these observations, Pam3 upregulated TLR2 mRNA expression in M2 macrophages in an autocrine fashion and increased M2 viability, thereby enhancing TLR2-induced proinflammatory effects.

Commensal Microbiota Tune Systemic Toll-like Receptor-Mediated Inflammatory Responses

Lehn K. Weaver[1], Chhanda Biswas[1] and Edward M. Behrens[2], [1]Pediatric Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA, [2]Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Innate Immunity and Rheumatic Disease - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Although commensal microbiota are thought to contribute to the development of autoimmunity, the cellular and molecular mechanisms connecting changes in gut microbiota to the development of autoreactive adaptive immune responses remain elusive. Preclinical models of autoimmunity demonstrate reduced disease severity and defective adaptive immune responses in autoimmune-prone mice treated with antibiotics or housed in germ-free conditions. As many autoimmune diseases show evidence of chronic Toll-like receptor (TLR) activation, we posited that defects in TLR-driven innate immune responses may explain the defective adaptive immune responses and reduced disease severity seen in antibiotic-treated mice.

Methods: We tested our hypothesis by using two murine models of TLR-driven systemic inflammation in mice treated with or without broad-spectrum antibiotics. Analysis of systemic inflammation was performed 10-14 days after a single dose of pristane (TLR7-driven inflammation) or after 5 doses of CpG (TLR9-driven inflammation) in mice treated with or without antibiotics. Systemic inflammation was determined by analysis of diffuse alveolar hemorrhage, cytopenias, hypercytokinemia, hepatosplenomegaly, and inflammation-induced myelopoiesis, which develop in these models of TLR-driven inflammation. TLR9 responsive cells isolated from mice treated with 0-5 doses of CpG were analyzed for production of IL-12 following *ex vivo* stimulation with CpG.

Results: Mice treated with broad-spectrum antibiotics were protected from developing systemic immunopathology following TLR-driven inflammation *in vivo*, as evidenced by lack of diffuse alveolar hemorrhage, cytopenias, hypercytokinemia, and hepatosplenomegaly following injection of pristane or repeated doses of CpG. This was not from baseline defects in innate immune cell numbers or TLR responsiveness, as numbers of TLR responsive cells and TLR-driven cytokine production following a single dose of CpG were preserved in antibiotic-treated mice. However, antibiotics abolished the inflammation-induced myelopoiesis and expansion of peripheral TLR responsive monocytes that accompanies both pristane- and CpG- induced immunopathology.

Conclusion: We demonstrate that antibiotic-treated mice have normal baseline responses to TLR-driven inflammatory signals, but fail to develop end-organ damage or sustained systemic inflammation to chronic TLR triggers *in vivo*. Disease protection in antibiotic-treated mice correlated with defective inflammation-induced myelopoiesis and inhibition of peripheral monocyte expansion that drive ongoing TLR immune responses in these models of sustained systemic inflammation. Our data implicate a novel mechanism for how commensal organisms contribute to the development of autoimmunity by tuning systemic innate immune responses in the setting of chronic TLR stimulation.

Responsiveness to X-Linked Toll-like Receptors Differs Between Mice with XY and XX Sex Chromosome Complement, Regardless of the Gonadal Sex

Brandon Pham, Isela Valera and Ram R. Singh, UCLA, Los Angeles, CA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Males and females differ in mounting immune response to pathogens. Females appear immune privileged, mounting stronger immune response to pathogens and vaccination. While this limits females' susceptibility to infection compared to males, it increases their likelihood, in some cases, by 10-15-fold to develop autoimmune disease. Mechanisms underlying the sex dimorphism in immune/autoimmune responses are not well understood. Since many immune response genes are encoded on sex chromosomes, we posit that a differential expression and/or function of these X/Y-linked genes underlie the differences in immune/autoimmune responses. Here, we investigate the responses of immune cells to two X-linked genes, toll-like receptor 7 and 8 (*Tlr7* and *Tlr8*).

Methods: To dissect the role of sex chromosomes in the absence of confounding hormonal influences, we used the four-core genotype (FCG) mouse model where findings in the XX females (XXF) can be compared with XY females [XYF, XY^{-Sry}]; and XX males [XXM, XX.Sry^{Tg}] can be compared with XY males [XYM, XY^{-Sry}.Sry^{Tg}]. Spleen cells from XYF and XXF mice were stimulated with TLR agonists IMI, R848, Poly I:C, and CpG and then analyzed for cellular proliferation by flow cytometry. Poly I:C and CpG, which stimulate TLR3 and TLR9, respectively, showed similar proliferation patterns to control in both XXF and XYF. IMI and R848, which target TLRs located on the X chromosome (TLR7 and TLR7/8, respectively), were also used to stimulate cells. XYF spleen cells showed increased cellular proliferation in response to stimulation by high concentrations of IMI and R848.

Results: First, we found that as compared to XXF mice, XYF mice had splenomegaly, with increased total cells per spleen ($p < 0.05$, $n = 6$). The proportion of individual immune cells also varied between XXF and XYF mice, with higher proportions of granulocytes and lower proportions of T and B cells in XYF mice as compared to XXF mice, although the absolute numbers of all cell types were higher in XYF vs. XXF spleens. Second, XYF and XYM spleen cells proliferated more vigorously to TLR7 ligand imiquimod and TLR7/8 ligand R848 than XXF and XXM, respectively, whereas the proliferative responsiveness to TLR3 and TLR9 ligands, Poly I:C and CpG, respectively, were not different between XX and XY mice, regardless of the gender. XYF and XXF spleen cells responded similarly to anti-CD3/CD28 stimulation.

Conclusion: These results suggest that the sex chromosome genotype might have consequences for the composition of immune cells and the responsiveness to innate receptors, which in turn could significantly alter immune/autoimmune responses. Ongoing studies will investigate mechanisms underlying these sex-related differences. Nutraceutical Therapy with Polyphenol-Rich Pomegranate Fruit Extract (POMx) Inhibits Systemic NFκB-Mediated Inflammation in a Murine Model of Endotoxemia

Nicholas A. Young[1], Misha Mobeen[2], Tariq M Haqqi[3] and Wael N. Jarjour[4], [1]Immunology and Rheumatology, The Ohio State University Wexner Medical Center, Columbus, OH, [2]The Ohio State University Wexner Medical Center, Columbus, OH, [3]Anatomy & Neurobiology, Northeast Ohio Medical University, Rootstown, OH, [4]Department of Rheumatology/Medicine, Ohio State University, Columbus, OH
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Innate Immunity and Rheumatic Disease - Poster I
Session Type: ACR Poster Session A

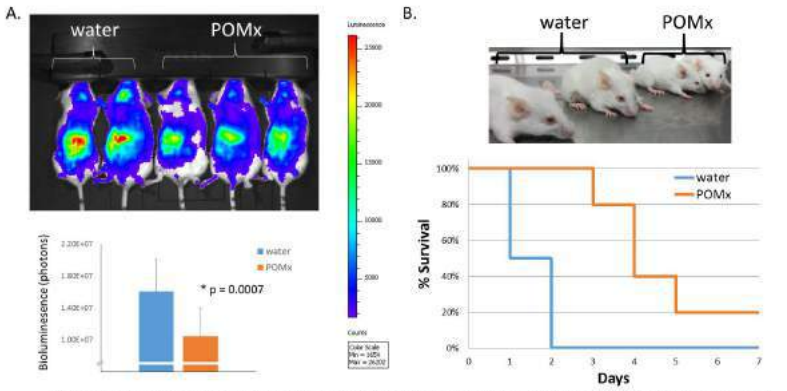
Session Time: 9:00AM-11:00AM

Background/Purpose: The pomegranate fruit is cultivated worldwide for dietary consumption, but has been used therapeutically in Eastern medicine from times dating back to ancient Egypt due to its potent anti-inflammatory properties. Recent studies have attributed this well-documented immunomodulatory influence to anthocyanin and hydrolysable tannins, which are polyphenolic compounds contained in the edible part of the fruit. A commercially- standardized nutraceutical preparation of a polyphenol-rich pomegranate extract (POMx) has previously been created and shown to suppress disease activity in a murine model of rheumatoid arthritis and inhibit NFkB activity in human cell lines. In the present study, our objective was to establish an animal model to longitudinally measure systemic effects of POMx on NFkB-mediated inflammation *in vivo*.

Methods: Endotoxemia was induced in BALB/C-Tg(NFkB-RE-luc)-Xen mice, which have a firefly luciferase cDNA reporter gene under the regulation of 3 kB responsive binding sites, by injection of lipopolysaccharide (LPS). NFkB-mediated inflammation was determined following a sub-lethal dose of LPS (2 mg/kg) by measuring whole-body bioluminescent signals using the Xenogen *in vivo* imaging system (IVIS 200). The emitted photons were quantified for each mouse at baseline, 2 hr, 4 hr, and 24 hr. Lethal endotoxemia was induced by LPS injection (25 mg/kg) for survival curve analysis. Prior to any LPS injection, mice were pre-treated for one week with water or POMx (34mg/kg/day) and continued daily treatment was provided in survival experiments.

Results: Relative to NFkB-RE-luc mice given water, POMx inhibited NFκB-induced luciferase activity after sub-lethal endotoxemia induction with LPS injection. Systemic inflammatory responses measured by IVIS photon quantification of NF-kB activation were significantly suppressed with POMx treatment. Lethal endotoxemia led to 50% survival of control mice receiving water after 24 hr, but POMx treatment resulted in 100% survival. Subsequently, while all controls did not survive past 48 hr, daily dosing of POMx resulted in 20% total survival after 7 days.

Conclusion: This novel application of the NF-kB-regulated luciferase mouse model establishes a system that may facilitate the future therapeutic development of POMx as an anti-inflammatory nutraceutical extract by enabling the longitudinal analysis of systemic NFkB-mediated inflammatory responses and will permit further elucidation of the mechanism of NFkB inhibition *in vivo*.



A) Bioluminescent imaging following sub-lethal LPS stimulation at 2 hr (top) and photon intensity quantitation after 4 hr (bottom). B) Representative photograph of surviving mice at 24 hr (top) and Kaplan-Meier survival curve (bottom) with lethal dose of LPS.

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Verinurad (RDEA3170) is a selective uric acid reabsorption inhibitor in clinical development for the treatment of gout and asymptomatic hyperuricemia. The aim of this study was to evaluate the pharmacokinetics, pharmacodynamics, and tolerability of verinurad following single and multiple doses in healthy adult males.

Methods: This was a Phase 1, randomized, double-blind, placebo-controlled, single- and multiple-ascending dose study. Panels of 8 male subjects (6 active, 2 placebo) received a single oral dose of verinurad or placebo in either a fasted (2 mg, 5 mg, 20 mg, 40 mg) or fed (5 mg, 20 mg) state and panels of 12 male subjects (9 active, 3 placebo) received ascending doses of once-daily verinurad (1 mg, 5 mg, and 10 mg) or placebo in a fasted state for up to 10 days. Verinurad was administered as an oral solution for 1 and 2 mg doses and in tablet form for doses >2 mg. Serial plasma/serum and urine samples were assayed for verinurad and uric acid at predetermined time points. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).

Results: A total of 81 adult males aged 18–54 years enrolled and completed the study. Following single oral doses of verinurad, absorption was rapid and exposure (maximum plasma concentration [C_{max}] and area under the plasma concentration-time curve [AUC]) increased in a dose-proportional manner up to the maximum dose tested; C_{max} was achieved at 0.5–0.75 hours post-dose in the fasted state, and was slightly delayed to 1.25 hours post-dose in the fed state. Food appeared to decrease AUC by about 23% and C_{max} by about 50%. Following multiple daily doses, there was modest accumulation of verinurad. Urinary excretion of verinurad accounted for approximately 2% of the administered dose, suggesting that renal excretion is a minor elimination pathway for unchanged verinurad. Reductions in serum uric acid (sUA) correlated with dose. Under fasted conditions, single-dose administration of verinurad 2, 5, 20, or 40 mg reduced sUA levels by 16%, 24%, 48%, and 62%, respectively. Following multiple once-daily dosing for 10 days, verinurad reduced sUA levels by 22%, 44%, and 61% for the 1, 5, and 10 mg doses, respectively. A persistent pharmacologic effect (>15% fractional excretion of uric acid relative to baseline) was evident for at least 24 hours after dosing for verinurad doses of 2 mg or above. Verinurad was well tolerated at all doses. No serious AEs, severe AEs, discontinuations due to AEs or clinically significant laboratory or ECG abnormalities were reported.

Conclusion: Single and multiple doses of verinurad were well tolerated, absorption was rapid and exposure was dose-proportional. Verinurad increased urinary uric acid elimination and resulted in sustained reductions in sUA. These data support further clinical evaluation of once-daily verinurad as a treatment for gout.

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Verinurad (RDEA3170) is a novel selective uric acid reabsorption inhibitor in clinical development for the treatment of gout and asymptomatic hyperuricemia. This Phase 1, single-blind, multiple dose, drug-drug interaction (DDI) study evaluated the pharmacokinetics (PK), pharmacodynamics, and tolerability of verinurad in combination with febuxostat (FBX) in healthy male volunteers.

Methods: Subjects were randomized to receive once-daily doses of FBX or verinurad or placebo alone for 7 days, FBX + verinurad or FBX + placebo on days 8−14, and the alternative single agent (FBX or verinurad or placebo) on days 15−21. Subjects received either the combination of verinurad 10 mg + FBX 40 mg or verinurad 2.5 mg + FBX 80 mg. Serial plasma/serum and urine samples were drawn at predetermined time points on Days 7, 14 and 21, and assayed for verinurad, FBX, and uric acid. Baseline samples were drawn on Day −1. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).

Results: Of 23 randomized subjects, 20 completed the study. FBX 40 mg had no apparent effect on the plasma C_{max} and AUC for verinurad 10 mg, whereas FBX 80 mg increased the plasma C_{max} and AUC for verinurad 2.5 mg by 25% and 33%, respectively. Verinurad had no effect on FBX PK. Renal clearance of verinurad was unchanged by FBX. The mean maximal reduction in serum uric acid (sUA) was 76% with verinurad 10 mg + FBX 40 mg compared with verinurad 10 mg (56%) or FBX 40 mg (49%) alone (Figure 1A) and was 67% with verinurad 2.5 mg + FBX 80 mg compared with verinurad 2.5 mg (38%) or FBX 80 mg (57%) alone (Figure 1B). Consistent with the mechanism of action (MOA) of verinurad, 24-hr fractional excretion of uric acid (FEUA) increased (2.5 mg: 7.6%; 10 mg: 12.8%) vs baseline (6.5% and 6.0%, respectively). Renal clearance of uric acid (CL_{UR}) increased similarly (2.5 mg: 9.0 mL/min; 10 mg: 12.3 mL/min) vs baseline (8.3 and 7.3 mL/min, respectively). The increases were maintained for 24 hours with verinurad 10 mg + FBX 40 mg (FEUA: 11.8%; CL_{UR}: 13.6 mL/min). Consistent with its MOA, FBX 40 mg and 80 mg decreased the amount of uric acid excreted in urine (246 and 221 mg, respectively, vs baseline: 695 and 818 mg), FEUA (4.8 and 4.2%, respectively, vs baseline: 6.3 and 6.5%), and CL_{UR} (4.9 and 5.0 mL/min, respectively, vs baseline: 7.7 and 8.7 mL/min). No serious AEs, discontinuations due to AEs, or clinically significant laboratory or ECG abnormalities were noted during the study.

Conclusion: No DDI was found with the verinurad 10 mg + FBX 40 mg combination and only a modest one with verinurad 2.5 mg + FBX 80 mg. Both combinations were safe and well tolerated and resulted in greater reduction of sUA than either verinurad or FBX alone. These results support the continued development of this novel approach for the treatment of gout and hyperuricemia.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Verinurad (RDEA3170) is a high-affinity, selective URAT1 inhibitor in development for the treatment of gout and asymptomatic hyperuricemia. This Phase 1, single-dose, open-label study investigated the pharmacodynamics (PD), pharmacokinetics (PK), and safety of oral verinurad in adult subjects with mild, moderate, or severe renal impairment and matched controls with normal renal function (NCT02219516).

Methods: Adult males aged 18-85 years were enrolled with a screening serum uric acid (sUA) 4.5-10 mg/dL and creatinine clearance calculated by Cockcroft-Gault formula of 60 to <90 mL/min (mild renal impairment), 30 to <60 mL/min (moderate impairment), 15 to <30 mL/min (severe impairment), or ≥90 mL/min (matched controls). Oral verinurad 15 mg was administered once under fasted conditions. Serial blood and urine samples were taken 30 min before and up to 72 hours postdose. Safety assessments included laboratory, ECG, and vital sign parameters as well as adverse event (AEs) reporting.

Results: PD data were based on 7-8 subjects per group. Verinurad decreased sUA in all groups, with greatest changes in the normal function and mild renal impairment groups (Figure). Mean (SD) maximal % change in sUA from baseline (Emax) was -38.3(14.8)%, -36.9(13.6)%, -20.5(6.64)%, and -12.6(6.94)%, respectively, in the normal function and mild, moderate, and severe renal impairment groups. Increase in the amount of excretion of uric acid due to verinurad treatment decreased in subjects with moderate and severe renal impairment. Plasma Cmax and AUC of verinurad increased with decreasing renal function. Verinurad at the 15 mg dose was well tolerated, with no serious AEs, no subject withdrawals due to AEs, and no Renal Events Adjudication Committee (REAC)-adjudicated renal events during treatment. One patient in each renal impairment group had treatment-emergent AEs considered possibly related to verinurad, which were categorized as gastrointestinal in nature. There were no clinically meaningful changes noted in laboratory values or vital signs.

Conclusion: The sUA lowering effect of verinurad was observed across the spectrum of renal function. Consistent with the verinurad renal-dependent mechanism of action, decreasing sUA lowering was demonstrated with increasing renal impairment. Verinurad safety and tolerability were similar across all stages of renal impairment.

Figure. Mean % change from baseline in sUA (mg/dL) following single-dose verinurad 15 mg in subjects with mild, moderate, and severe renal impairment and matched controls

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic gout is a significant clinical problem in Asia, including Japan, where many patients remain suboptimally treated with currently available therapies. Verinurad (RDEA3170) is a selective uric acid reabsorption inhibitor in clinical development for the treatment of gout and asymptomatic hyperuricemia. The aim of this study was to evaluate the pharmacokinetics, pharmacodynamics, and tolerability of verinurad in healthy Japanese and non-Asian adult male subjects.

Methods: This was a Phase 1, randomized, single-blind, placebo-controlled study (NCT01872832). Panels of 8 Japanese male subjects were randomized in a 3:1 ratio to receive a modified-release formulation of oral verinurad (2.5 mg, 5 mg, 10 mg, 15 mg) or placebo administered as a single dose in a fasted state and as multiple once-daily doses in a fed state for 7 days. A panel of 8 non-Asian male subjects received single and multiple doses of oral verinurad (10 mg) or placebo. Serial plasma/serum and urine samples were assayed for verinurad and uric acid at predetermined time points. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).

Results: Of 48 randomized subjects, 46 (Japanese: 39, non-Asian: 7) completed the study. Treatment groups were generally well balanced; however, mean body weight and body mass index were approximately 14% and 7% lower, respectively, in Japanese than non-Asian subjects. Following single- or multiple-oral doses of verinurad in Japanese subjects, exposure (maximum plasma concentration [C_{max}] and area under the plasma concentration-time curve [AUC]) increased in a near dose-proportional manner under fasted or fed conditions. The time to C_{max} (T_{max}) was approximately 1.25–2.0 hours post-dose under fasted conditions. A moderate-fat meal delayed T_{max} up to 5 hours post-dose and increased plasma verinurad exposures up to 109%. Following once-daily multiple doses, there was modest accumulation of verinurad. C_{max} and AUC were approximately 38% and 23% higher, respectively, in Japanese versus non-Asian subjects, largely due to the difference in body weight. Mean reductions in serum uric acid following once-daily multiple dosing of verinurad 10 mg were 62% and 58% at maximum reduction and 46% and 44% at 24 hours post-dose in Japanese and non-Asian subjects, respectively. Verinurad was well tolerated at all doses. One Japanese subject discontinued verinurad due to an AE of urticaria that resolved after 11 days. No serious AEs, Grade 3 or 4 AEs, or clinically significant laboratory or ECG abnormalities were noted.

Conclusion: Verinurad significantly lowered serum uric acid and was well tolerated in both healthy Japanese and non-Asian males, despite small differences in plasma pharmacokinetics. These data support further evaluation of once-daily verinurad as a treatment for hyperuricemia with or without gout in the Japanese population.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Verinurad (RDEA3170) is a novel selective uric acid reabsorption inhibitor in clinical development for the treatment of hyperuricemia and gout. This Phase 1, single-blind, multiple dose, drug-drug interaction study evaluated the pharmacokinetics (PK), pharmacodynamics, and tolerability of verinurad in combination with allopurinol (ALLO) in adult male subjects with gout.

Methods: Adult males with gout, aged 18-75 years, with serum uric acid (sUA) ≥8 and ≤10 mg/dL were randomized to receive once-daily oral doses of ALLO 300 mg or verinurad 10 mg alone for 7 days, ALLO 300 mg + verinurad 10 mg on Days 8−14, and the alternative single agent (verinurad 10 mg or ALLO 300 mg) on Days 15−21. Colchicine 0.6 mg was taken once daily from day −14. Serial plasma/serum and urine samples were drawn at predetermined time points on Days 7, 14 and 21 and assayed for verinurad, ALLO, oxypurinol (OXY), colchicine, and uric acid. Baseline samples were drawn on Day –1. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).

Results: Subjects (N=12) were mostly white (58.3%) with mean (SD) age of 51 (10) years. Following multiple doses, ALLO had no effect on C_{max} and AUC of verinurad. ALLO C_{max} was increased 33% but AUC was unaltered by verinurad. The C_{max} and AUC for OXY, the active metabolite of ALLO, were reduced 32% and 38%, respectively, by verinurad. Colchicine plasma exposures were unaltered by verinurad. ALLO had no effect on urinary excretion of verinurad, whereas urinary excretion of OXY was increased 19% by verinurad. The mean maximal decrease in sUA was 65% with verinurad + ALLO compared with verinurad (51%) or ALLO (43%) alone (Figure). Consistent with the mechanism of action (MOA) of verinurad, 24-h fractional excretion of uric acid (FEUA) and clearance of uric acid (CL_{UR}) were increased in the absence (9.2% and 11.5 mL/min, respectively) or presence of ALLO (7.9% and 11.8 mL/min) vs baseline (4.5% and 5.7 mL/min) or ALLO alone (3.7% and 5.0 mL/min). Consistent with its MOA, ALLO decreased the amount of uric acid excreted in 24-h urine (363 mg) compared with baseline (683 mg), verinurad alone (739 mg) or verinurad + ALLO (522 mg) but had no effect on FEUA or CL_{UR}. No serious AEs, discontinuations due to AEs, or clinically significant laboratory or ECG abnormalities were noted.

Conclusion: Although a modest drug–drug interaction was found between verinurad and ALLO, the combination was safe and well tolerated at the studied doses and resulted in greater reduction of sUA than either alone. These results support the evaluation of verinurad + ALLO as an alternative once-daily treatment option for hyperuricemia and gout.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Verinurad (RDEA3170) is a high-affinity URAT1 inhibitor in development for the treatment of gout and asymptomatic hyperuricemia. This Phase 2a, randomized, open-label, single-site study investigated the multiple-dose pharmacodynamics (PD), pharmacokinetics (PK), and safety of oral verinurad in combination with febuxostat versus febuxostat alone and verinurad alone in Japanese male adults with gout or asymptomatic hyperuricemia (NCT02317861).

Methods: Japanese male patients aged ≥20 and ≤70 years with gout or asymptomatic hyperuricemia and serum uric acid (sUA) ≥8 mg/dL were randomized to 1 of 6 cohorts to receive febuxostat (10 mg, 20 mg, and 40 mg) alone; febuxostat in combination with verinurad (dose range 2.5 mg to 10 mg); verinurad (2.5 mg to 15 mg) alone; or benzbromarone (50 mg) alone (4 treatment periods per cohort, each treatment period 7 days). The study drugs were administered once daily in the morning after breakfast. Serial blood and urine samples were measured at preset intervals on Days -1, 1, 2, 7, 8, 14, 15, 21, 22, 28 and 29 for PD and PK endpoints. Safety assessments included adverse events (AEs) and laboratory, electrocardiogram, and vital sign parameters.

Results: Seventy-two patients with gout (n=37) or hyperuricemia (n=35) were randomized in this study. Addition of verinurad (2.5 mg to 10 mg) to febuxostat (10 mg, 20 mg, or 40 mg) decreased sUA in dose-dependent manner (Figure). Verinurad coadministered with febuxostat increased the amount of uric acid recovered in urine (Aeur), compared with baseline and the same dose of febuxostat administered alone, yet comparable with benzbromarone. Plasma Cmax and AUC exposures of verinurad and febuxostat exhibited dose proportional increases within the investigated dose range. No clear PK drug-drug interaction of verinurad and febuxostat with each other was observed. Verinurad at doses from 2.5 mg to 15 mg was well tolerated, with no serious AEs or withdrawals due to AEs. One treatment-emergent AE (diarrhea) was considered possibly related to both verinurad and febuxostat. Laboratory values and vital signs indicated no clinically meaningful changes.

Conclusion: Verinurad coadministered with febuxostat dose-dependently decreased sUA while maintaining Aeur comparable to benzbromarone. All dose combinations of verinurad and febuxostat in this study were generally well tolerated.

Figure. Mean % change from baseline in sUA (mg/dL) following multiple oral doses of febuxostat alone and in combination with verinurad (PD analysis set) .

Session Date: Sunday, November 13, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Verinurad (RDEA3170) is a high-affinity, selective URAT1 inhibitor in development for treatment of gout and asymptomatic hyperuricemia. This Phase 2a, randomized, open-label, multicenter study investigated the multiple-dose pharmacodynamics (PD), pharmacokinetics (PK), and safety of oral verinurad in combination with allopurinol versus allopurinol alone in adults with gout (NCT02498652).

Methods: Patients aged 18-75 years with gout and serum uric acid (sUA) ≥8 mg/dL were randomized to 1 of 2 cohorts to receive allopurinol (300 mg) combined with verinurad (dose range 2.5 mg to 20 mg) and allopurinol 300 mg or 600 mg alone (each treatment period 7 days). Medications were administered once daily ~30 min after breakfast (for allopurinol 300 mg b.i.d. group, the second allopurinol dose was in the evening). Colchicine 0.6 mg for gout flare prophylaxis was initiated at approximately Day -14 (start of urate-lowering therapy [ULT] washout) or Day -7 if not on ULT. Serial blood and urine samples were measured on Days -1, 1, 7, 14, 21, 28, and 35 for PD and PK endpoints. Safety assessments included adverse events (AEs) and laboratory, ECG, and vital sign parameters.

Results: Forty-one patients were randomized (n=20–21 per cohort). Serum PD data pooled across cohorts demonstrated maximal % decrease in sUA from baseline (Emax) at 6-10 h after verinurad and allopurinol combination treatment. Addition of verinurad (2.5 mg to 20 mg) to allopurinol decreased sUA in dose-dependent manner (Figure). Greater sUA reductions were observed for dose combinations of verinurad ≥5 mg with allopurinol 300 mg versus allopurinol 600 mg alone, while allopurinol 600 mg once daily was equivalent to allopurinol 300 b.i.d. Emax was 46.9%, 58.9%, 59.9%, 67.1%, 68.4%, and 74.3% for verinurad at doses of 2.5, 5, 7.5, 10, 15, and 20 mg combined with allopurinol 300 mg, versus 39.7%, 53.8%, and 54.4% with allopurinol 300 mg, allopurinol 600 mg, and allopurinol 300 mg b.i.d. alone. No drug-drug interaction on verinurad and allopurinol plasma PK parameters was observed. Verinurad decreased oxypurinol Cmax by 19.0-32.4% and AUC0-24 by 20.9-39.2%; reductions in oxypurinol Cmax and AUC0-24 were dose dependent, with no further decreases above 15 mg verinurad dose. Verinurad at doses from 2.5 mg to 20 mg was well tolerated, with no serious AEs, withdrawals due to AEs, or renal-related events during combination treatment. Laboratory values and vital signs indicated no clinically meaningful changes. There were no cases of serum creatinine elevation ≥1.5x baseline.

Conclusion: Verinurad coadministered with allopurinol dose-dependently decreased sUA. All dose combinations of verinurad and allopurinol were generally well tolerated with no serious AEs or renal-related events during combination

Background/Purpose: Verinurad (RDEA3170) is a high-affinity, selective URAT1 inhibitor in development for treatment of gout and asymptomatic hyperuricemia. This Phase 2a, randomized, open-label, multicenter study investigated the multiple-dose pharmacodynamics (PD), pharmacokinetics (PK), and safety of oral verinurad in combination with febuxostat versus febuxostat alone in adults with gout (NCT02246673).

Methods: Patients aged 18-75 years with gout and serum uric acid (sUA) ≥8 mg/dL were randomized to 1 of 5 cohorts to receive febuxostat (40 mg and 80 mg) alone and in combination with verinurad (dose range 2.5 mg to 20 mg; 4 treatment periods per cohort, each treatment period 7 days). Medications were administered once daily ~30 min after breakfast. Colchicine 0.6 mg for gout flare prophylaxis was initiated at approximately Day -14 (start of urate-lowering therapy [ULT] washout) or Day -7 if not on ULT. Serial blood and urine samples were measured at preset intervals on Days -1, 1, 7, 14, 21, and 28 for PD and PK endpoints. Safety assessments included adverse events (AEs) and laboratory, ECG, and vital sign parameters.

Results: Sixty-four patients were randomized (n=12–14 per cohort). Serum PD data pooled across cohorts demonstrated maximal % decrease in sUA from baseline (Emax) at 8-12 h after dosing. Addition of verinurad to febuxostat decreased sUA in dose-dependent manner (Figure 1). Greater sUA reductions were observed for dose combinations of verinurad ≥5 mg with febuxostat 40 mg versus febuxostat 80 mg alone. The rate of urinary uric acid excretion was reduced by febuxostat alone, but comparable to baseline levels with verinurad combined with febuxostat (Figure 2). Verinurad plasma exposures increased with verinurad dose and were comparable for febuxostat 40 mg and 80 mg doses. No drug-drug interaction on verinurad and febuxostat plasma PK parameters was observed. Verinurad at doses from 2.5 mg to 20 mg was well tolerated, with no serious AEs, withdrawals due to AEs, or renal-related events. The most frequent treatment-emergent AE possibly related to study medication was pain in extremity, in 2 patients receiving verinurad. Laboratory values and vital signs showed no clinically meaningful changes. There were no cases of serum creatinine elevation ≥1.5x baseline.

Conclusion: Verinurad coadministered with febuxostat dose-dependently decreased sUA while maintaining urine uric acid levels comparable to baseline. All dose combinations of verinurad and febuxostat in this study were generally well tolerated with no serious AEs or renal-related events during combination treatment.

Session Type: ACR Poster Session A

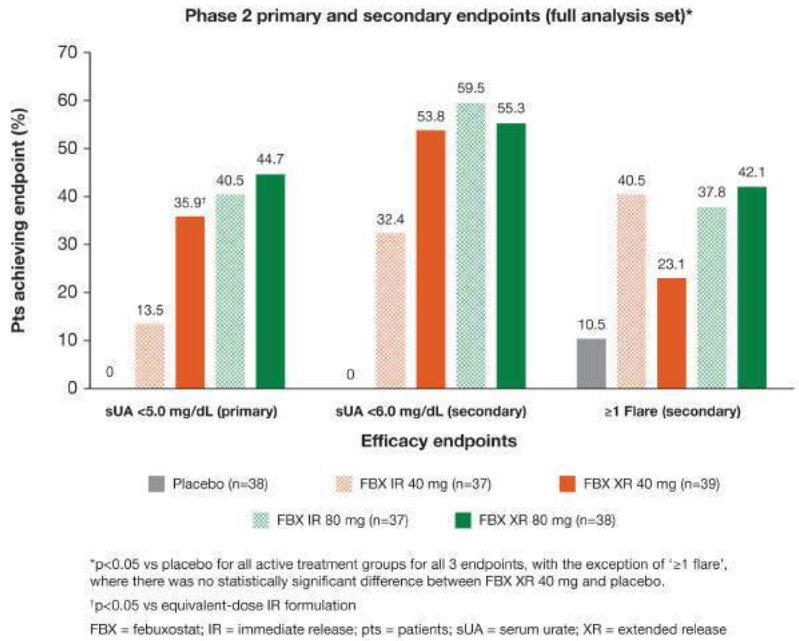
Session Time: 9:00AM-11:00AM

Background/Purpose: Data generated by Phase 1 and 2 studies suggest that the extended-release (XR) formulation of febuxostat (FBX) may provide equal or better reduction in serum urate level (sUA) in patients (pts) with gout, with reduced exposure (C_{max} and AUC), compared with an immediate-release (IR) formulation. This Phase 2 study was conducted to evaluate the efficacy and safety of FBX XR compared with FBX IR in pts with gout and moderate renal impairment.

Methods: In a Phase 2, multicenter, randomized, placebo-controlled, double-blind study, pts with gout (sUA ≥8.0 mg/dL, moderate renal impairment [estimated glomerular filtration rate ≥30 mL/min and <60 mL/min], and ≥1 gout flare within the previous 12 months) received placebo or FBX XR 40 mg, XR 80 mg, IR 40 mg, or IR 80 mg once daily for 3 months. The primary endpoint was the proportion of pts with sUA <5.0 mg/dL at Month 3. Secondary endpoints were proportions of pts with at least 1 flare requiring treatment during the 3-month treatment period and of pts with sUA <6.0 mg/dL at Month 3.

Results: A total of 189 pts received treatment with placebo (n=38) or FBX XR 40 mg (n=39), XR 80 mg (n=38), IR 40 mg

(n=37), or IR 80 mg (n=37). A higher proportion of pts receiving FBX XR 40 mg achieved sUA <5.0 mg/dL versus (vs) IR 40 mg at Month 3 (35.9% vs 13.5%, respectively; p=0.034). All FBX groups showed a higher proportion of pts with at least 1 flare during treatment compared with placebo-treated pts, but a smaller proportion of pts in the FBX XR 40-mg group experienced flares compared with IR 40 mg (23.1% vs 40.5%, respectively). Additionally, a numerically higher proportion of pts achieved sUA <6 mg/dL with FBX XR 40 mg compared with IR 40 mg (53.8% vs 32.4%, respectively). FBX XR 80 mg did not differentiate from IR 80 mg for the primary or secondary endpoints. Primary and secondary endpoint results are shown (**Figure**). Treatment-emergent and treatment-related adverse events were infrequent and generally did not differ among treatment groups.



Conclusion: Significantly more pts receiving FBX XR 40 mg achieved the primary endpoint of sUA reduction to <5.0 mg/dL at the Month 3 visit compared with FBX IR 40 mg. There was a trend toward lower flare rates in the FBX XR 40 mg vs the IR 40 mg group. Overall, incidence rates of treatment-emergent and treatment-related adverse events were low.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

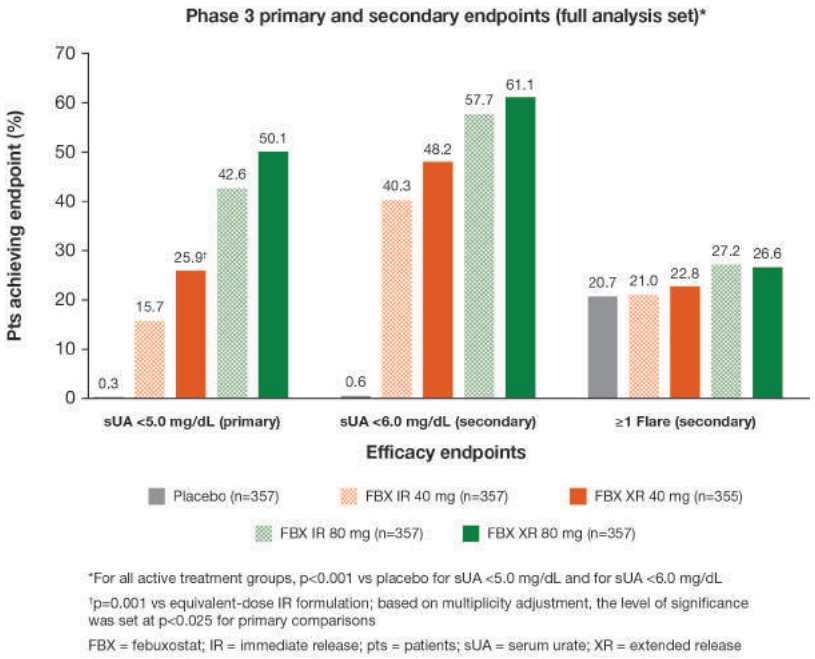
Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Data generated by Phase 1 and 2 studies suggest that the extended-release (XR) formulation of febuxostat (FBX) may provide equal or better reduction in serum urate level (sUA) in patients (pts) with gout, with reduced exposure (C_{max} and AUC), compared with the immediate-release (IR) formulation. This Phase 3 study was conducted to evaluate the efficacy and safety of FBX XR compared with FBX IR in gout pts with normal or impaired renal function.

Methods: In a Phase 3, multicenter, randomized, placebo-controlled, double-blind study, pts with gout (sUA ≥8.0 mg/dL, estimated glomerular filtration rate ≥15 mL/min, and ≥1 gout flare within the previous 12 months) received placebo or FBX XR 40 mg, XR 80 mg, IR 40 mg, or IR 80 mg once daily for 3 months. The primary endpoint was the proportion of pts with sUA <5.0 mg/dL at Month 3. Secondary endpoints were proportions of pts with at least 1 flare requiring treatment during the 3-month treatment period and of pts with sUA <6.0 mg/dL at Month 3.

Results: A total of 1783 pts received treatment with placebo (n=357) or FBX XR 40 mg (n=355), XR 80 mg (n=357), IR 40 mg (n=357), or IR 80 mg (n=357). A higher proportion of pts receiving FBX XR 40 mg achieved sUA <5.0 mg/dL versus (vs) IR 40 mg at Month 3 (25.9% vs 15.7%, respectively; p=0.001). Although the difference was not statistically significant, more FBX XR 80-mg treated pts achieved the primary endpoint compared with IR 80 mg (50.1% vs 42.6%, respectively). Neither FBX XR treatment group differentiated from its respective IR treatment group for the secondary endpoint of proportion of pts with at least 1 flare requiring treatment during the 3-month treatment period. A numerically higher proportion of pts achieved sUA <6.0 mg/dL with FBX XR 40 mg compared with IR 40 mg (48.2% vs 40.3%, respectively), and the observed difference between FBX XR 80 mg vs IR 80 mg for this endpoint was small (61.1% vs 57.7%, respectively). Primary and secondary endpoint results are shown (**Figure**). Treatment-emergent and treatment-related adverse events were infrequent and generally did not differ among treatment groups.



*For all active treatment groups, p<0.001 vs placebo for sUA <5.0 mg/dL and for sUA <6.0 mg/dL
†p=0.001 vs equivalent-dose IR formulation; based on multiplicity adjustment, the level of significance was set at p<0.025 for primary comparisons
FBX = febuxostat; IR = immediate release; pts = patients; sUA = serum urate; XR = extended release

Conclusion: Significantly more pts receiving FBX XR 40 mg achieved the primary endpoint of sUA reduction to <5.0 mg/dL at the Month 3 visit compared with FBX IR 40 mg. Overall, the incidence rates of treatment-emergent and treatment-related adverse events were low. Both FBX formulations were efficacious in lowering sUA and were generally well tolerated.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Benzbromarone is a potent uricosuric, but is not widely available due to concerns about hepatotoxicity. In Aotearoa New Zealand benzbromarone has been available since April 2013, subject to funding restrictions, for patients with inadequate urate-lowering response or intolerance to allopurinol and probenecid. The aim of this study was to assess the safety and efficacy of benzbromarone in a real-life setting.

Methods: All patients who received funding for benzbromarone from 1/4/2013 to 30/9/2014 were identified. Prescribers were sent a questionnaire for each individual. Information on demographics, efficacy of previous urate-lowering drugs and reasons for discontinuation were collected. Specific information about the dose, effect on serum urate, adverse effects and liver function tests after commencing benzbromarone was recorded.

Results: Completed questionnaires were returned for 123/164 (75%) patients. 85 (69.1%) were male, 70 (56.9%) were New Zealand European and 46 (37.4%) were Māori or Pacific Island. The mean (SD) duration of gout was 15 (9.4) years and tophi were present in 70 (56.9%). Mean (SD) SU prior to any ULT was 0.61 (0.11) mmol/l (range 0.36-0.94 mmol/l; n=106). Mean (SD) serum urate prior to benzbromarone was 0.57 (0.12) mmol/l and estimated glomerular filtration rate (eGFR) 50.3 (22.8) ml/min/1.73m^2. The median dose of benzbromarone was 100mg/day (25-200mg/day). Six months after commencing benzbromarone, mean (SD) serum urate was 0.35 (0.12) mmol/l. Renal impairment was common, with 22/112 (19.6%) patients having eGFR <30mls/min/1.72m^2, 55/112 (49.1%) eGFR >30-59 mls/min/1.72m^2 and 35/112 (31.3%) eGFR >60mls/min/1.72m^2. With each drug there was no statistically significant difference in the number of patients who achieved SU<0.36mmol/l based on eGFR. However, at each eGFR numerically more people on benzbromarone achieved SU<0.36 mmol/l, compared with the other two allopurinol and probenecid (Figure 1).

Benzbromarone related adverse events included rash (n=4), diarrhoea (n=9), nausea (n=6), and urate stones (n=3). Liver function tests abnormalities were uncommon and tended to be mild. There were 14 patient deaths; none were considered related to benzbromarone. Allopurinol had been prescribed prior to benzbromarone in 117/123 patients; median maximum allopurinol dose was 200mg/day (range 25-600mg/day), and 19% patients received allopurinol >300mg/day.

Conclusion: Benzbromarone provides useful urate-lowering efficacy and does not appear unsafe in patients with gout. It remains effective even in those with renal impairment. Urate-lowering therapy prescribing requires further optimisation.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess whether allopurinol use reduces the risk of myocardial infarction (MI) in the elderly.

Methods: We used the 2006-2012 5% random sample of Medicare beneficiaries to study the association of new allopurinol initiation and the risk of incident MI, in a cohort study. Multivariable-adjusted Cox regression models adjusted for age, gender, race and Charlson index, in addition to various cardio-protective medications (beta-blockers, ACE inhibitors, diuretics, statins). We calculated hazards ratio (HR) with 95% confidence intervals (CI). Sensitivity analyses adjusted for coronary artery disease (CAD) risk factors including hypertension, hyperlipidemia, diabetes, and smoking.

Results: 1,544 of the 29,298 episodes of incident allopurinol use were associated with incident MI (5.3% episodes). Allopurinol use was associated with reduced hazards of MI, with HR of 0.85 (95% CI, 0.77 to 0.95). Compared to no allopurinol use, longer allopurinol use durations were associated with lower HR of MI: 1-180 days, 0.98 (95% CI, 0.84 to 1.14); 181 days to 2 years, 0.83 (95% CI, 0.72 to 0.95); and >2 years, 0.70 (95% CI, 0.56 to 0.88). Other factors associated with higher hazard of MI were: age 75-<85 and ≥85, male gender, higher Charlson index score and the use of ACE-inhibitor. Adjustment for CAD risk factors confirmed these findings.

Conclusion: Incident allopurinol use was associated with a reduction in the risk of incident MI. Longer allopurinol use durations reduced the risk of incident MI incrementally. Future studies need to assess underlying mechanisms of this association and to assess risk-benefit ratio of allopurinol use for MI prevention.

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess whether allopurinol use reduces the risk of ventricular tachycardia in the elderly.

Methods: We used the 2006-2012 5% random sample of Medicare beneficiary cohort to study the association of new allopurinol initiation and the risk of incident ventricular tachycardia. Multivariable-adjusted Cox regression models adjusted for age, gender, race, and Charlson index, in addition to various cardio-protective medications (beta-blockers, ACE inhibitors, diuretics, statins). We calculated hazards ratio (HR) with 95% confidence intervals (CI).

Results: 2,665 of the 40,004 episodes of incident allopurinol use were associated with incident ventricular tachycardia (6.7% episodes). Allopurinol use was associated with reduced hazards of ventricular tachycardia, with unadjusted HR of 0.84 (95% CI, 0.77 to 0.91); multivariable-adjusted HR 0.81 (95% CI, 0.74 to 0.87) (Table 1). Compared to no allopurinol use, longer allopurinol use durations were associated with lower HR of ventricular tachycardia: 181-365 days, 0.77 (95% CI, 0.67 to 0.89); 1 to 2 years, 0.85 (95% CI, 0.73 to 0.98); and >2 years, 0.75 (95% CI, 0.62 to 0.90). Other factors associated with higher hazard of ventricular tachycardia were: age 75-<85 and ≥85, male gender, higher Charlson index score, and the use of beta blockers. Allopurinol dose was also significant in univariate analysis but not in the multivariate analysis (Table 2).

Conclusion: Incident allopurinol use was associated with a reduction in the risk of incident ventricular tachycardia; allopurinol dose was not. Longer allopurinol use durations reduced the risk of incident ventricular tachycardia incrementally. Future studies need to assess underlying mechanisms of this association and to assess risk-benefit ratio of allopurinol use for ventricular tachycardia prevention. Table 1: Univariate and multivariate adjusted hazard ratios for ventricular tachycardia based on allopurinol use.

Allopurinol Dose Escalation and Mortality among Patients with Gout: A National Propensity-Matched Cohort Study

Background/Purpose: Numerous epidemiologic studies show that hyperuricemia and gout are associated with increased mortality while treatment with allopurinol is associated with reduced mortality. Studies examining surrogate markers of cardiovascular risk indicate that allopurinol may have a beneficial dose effect. Our objective was to determine whether allopurinol dose escalation is associated with decreased all-cause and cause-specific mortality relative to non-escalation.**Methods:** In this 10-year observational, new user, active-comparator study of U.S. Veterans with gout and ≥ 40 years of age, we used propensity score matching with Cox proportional hazards and competing risks regression to compare all-cause and cause-specific mortality between allopurinol dose-escalators and non-escalators. National VA data was linked to the National Death Index to determine dose escalation and mortality outcomes.**Results:** After matching, all characteristics were well balanced between groups. Among 6,009 dose escalators and 6,009 matched non-escalators, there were 2,133 deaths during observation corresponding to a mortality rate of 46.8 per 1,000 person-years. There were

no differences between groups in all-cause mortality (HR 0.97; 95% CI 0.89 to 1.05, Figure 1), cardiovascular mortality (HR 0.99; 95% CI 0.87 to 1.12), or cancer mortality (HR 0.93; 95% CI 0.75 to 1.14). Dose escalation even among dose escalators was limited with only 10% of dose escalators receiving daily allopurinol doses above 300 mg (Table 1). Consistent with incomplete dose escalation, only 31% achieved serum urate (SU) < 6.0 mg/dL after 2-years (Table 2). Sensitivity analyses limited to those achieving SU goal and their matches showed an 8% reduction in cardiovascular mortality for dose escalators relative to non-escalators although this did not reach statistical significance (HR 0.92; 95% CI 0.75 to 1.14). **Conclusion:** Although no association was found between allopurinol dose escalation and reduced mortality, the findings were likely limited by suboptimal dose escalation observed in practice even among dose escalators. Other study designs should be considered for further investigation of the potentially beneficial effect of allopurinol on mortality. Table 1 Baseline and Follow-up Allopurinol Dosing by Group

	Baseline		Follow-up	
	Dose Escalators	Non-Escalators	Dose Escalators	Non-Escalators†
Allopurinol Dose*	(n = 6,009)	(n = 6,009)	(n = 6,009)	(n = 6,009)
≤ 100	75%	76%	1%	78%
> 100 & < 300	20%	19%	38%	18%
300	5%	5%	51%	5%
> 300	<1%	<1%	10%	<1%

Totals may add to more than 100% due to rounding. * Dose represents the average daily dose with allopurinol equivalents used for febuxostat in follow-up calculations. † A small proportion of non-escalators (3.5%) had their dose decreased during the 2-year follow-up.

Table 2 Follow-up Serum Urate (SU) by Group

	Dose Escalators	Non-Escalators
	(n = 6,009)	(n = 6,009)
SU Tested	91%	77%
At SU Goal < 6.0 mg/dL*	31%	12%
Follow-up SU, mean mg/dL	6.9 ± 1.9	7.6 ± 1.7

Values are percentages and mean ± SD. Only the last value on record for follow-up was used if there were multiple. * Calculation includes those missing SU tests. Among only those with follow-up testing 34% of dos e escalators and 16% of non-escalators were at SU goal.

The Safety and Efficacy of Allopurinol Dose Escalation in People with Gout, a Randomised Controlled Trial

Lisa K. Stamp[1], Peter T. Chapman[2], Murray Barclay[3], Anne Horne[4], Christopher Frampton[1], Paul Tan[5], Jill Drake[6] and Nicola Dalbeth[5], [1]University of Otago, Christchurch, New Zealand, [2]Christchurch Hospital, Christchurch, New Zealand, [3]Medicine, University of Otago, Christchurch, New Zealand, [4]Department of Medicine, University of Auckland, Auckland, New Zealand, [5]University of Auckland, Auckland, New Zealand, [6]Rheumatology, Immunology and Allergy, Christchurch Hospital, Christchurch, New Zealand

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Allopurinol is the most widely used urate lowering therapy. Many patients on allopurinol fail to achieve target serum urate (SU), in part due to concerns about the relationship between allopurinol dose and adverse events (AEs). The aim of this randomised controlled trial was to determine the efficacy and safety of allopurinol dose escalation using a treat to target SU approach.

Methods: An open randomised controlled trial comparing creatinine clearance (CrCL)-based allopurinol dose and allopurinol dose escalation was undertaken. Patients with gout, defined by 1977 ARA criteria, receiving at least CrCL-based allopurinol dose for ≥1 month and SU ≥6mg/dL were recruited. Severe chronic kidney disease was not an exclusion. Patients were randomised to continue current dose (control) or dose escalation (DE) for 12 months. In the DE group, allopurinol was increased monthly by 50mg-100mg/d until SU was <6mg/dL. The primary endpoint was reduction in SU and AEs coded according to Common Terminology Criteria for Adverse Events.

Results: One hundred and eighty-three participants (93 control and 90 DE) were recruited. At baseline, mean CrCL was 60 (SD 27) ml/min, urate was 7.2 (SD 1.6) mg/dL and allopurinol dose 269mg/d (range 100-600mg/d). In intention to treat analysis, mean ± SEM SU was 6.7 ± 0.2mg/dL in control participants compared to 5.7 ± 0.2mg/dL DE ($p<0.001$) at 12 months (Figure). SU <6mg/dL at month 12 was achieved in 32% control participants and 69% DE participants ($p<0.001$). During the 12-month period, 58.9% of the control group and 54.3% of the DE group experienced a gout flare ($p=0.58$). There were 43 serious adverse events in 25 controls and 35 events in 22 DE participants. Only one was considered probably related to allopurinol (increased INR in a DE patient on warfarin). Five control participants and 5 DE participants died; no deaths were considered allopurinol related. There were no cases of allopurinol hypersensitivity syndrome. Eleven control participants developed rash; one was thought to be probably allopurinol related leading to allopurinol discontinuation. Eight DE participants' developed rash; 2 were considered possibly related but settled despite continuing allopurinol and 1 was probably related and allopurinol was discontinued. Mild elevations in liver function tests were common in both groups and a few moderate increases in GGT were noted. One DE patient stopped allopurinol due to abnormal LFTs. There was no significant difference in renal function changes between randomised groups.

Conclusion: Higher than CrCL-based doses of allopurinol can effectively lower SU in the majority of patients. Allopurinol dose escalation is well tolerated.

Figure: (A) Mean serum urate, (B) percentage at target serum urate, and (C) mean allopurinol dose.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout patients often suffer from renal disease, some ultimately developing end-stage renal disease (ESRD) and requiring hemodialysis (HD) replacement therapy. Though some reports suggested that tophi disappear after HD, urate-lowering agents are frequently continued, often based on persistent high SUA levels before HD. Also, the impact of SUA levels in the survival of patients on hemodialysis (HD) is under discussion. The aim of the study was to assess the SUA reduction achieved under HD and analyze the kinetics of SUA in a week of intermittent HD.

Methods: SUA levels were determined before and after HD sessions in consecutives 96 patients with end-stage renal disease (ESRD), and compared through paired samples Student's t test. Variables related to HD were analyzed whether associated with SUA reductions ≥80% using Student's t test or ANOVA. Also, a kinetics study on selected 10 patients with hyperuricemia (SUA before HD> 6.8 mg/dL) throughout intermittent HD sessions in a week period was performed; differences in SUA levels were analyzed by repeated measures ANOVA.

Results: Patients were mean aged 66.5 years (SD±13.8), being 62 males (64.6%). Mean time on HD replacement was 7.1 years (±7.2). Before starting HD, 43.0% had hyperuricemia and 21.6% reported gout. Sixteen (16.4%) continued on urate-lowering agents after HD. Mean SUA levels before and after HD session was 5.2mg/dL (± 1.0) and 1.0mg/dL (±0.4), respectively. Mean SUA reduction following HD was 80.2% (95%CI 78.4-82.0); 51 patients (56.7%) showed SUA reduction ≥80%. HD-related variables Kt/v<1.3 (p=0.006) and blood efflux<400mL/min (p=0.004) significantly associated with achieving SUA reduction ≥80%. **Figure** shows the SUA kinetics study: SUA significantly reduced all over the period and persisted below hyperuricemia threshold (p=0.015).

Conclusion: Under HD replacement therapy SUA levels effectively reduced and persisted below saturation point, suggesting that urate-lowering therapy appears unnecessary for patients with gout and ESRD.

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lesinurad is a selective uric acid reabsorption inhibitor approved in the United States and European Union at 200 mg daily dose in combination with a xanthine oxidase inhibitor (XOI) for treatment of hyperuricemia associated with gout in patients unable to achieve target serum uric acid on XOI (allopurinol or febuxostat) alone. Approval of lesinurad was based on three pivotal, placebo-controlled, 12-month phase III (core) studies evaluating lesinurad 200 mg (LESU200) and 400 mg (LESU400) in combination with XOI. Patients completing core studies were eligible to enter extension studies, continuing LESU+XOI at the same dose or randomized from placebo to LESU200 or LESU400 plus XOI.

Methods: Renal-related and kidney stone safety data were pooled from core studies to compare LESU200+XOI and LESU400+XOI with XOI alone and from core studies + extension studies to evaluate the impact on renal safety of extended LESU+XOI treatment. Renal-related treatment-emergent adverse events (TEAEs) were a customized list of 36 preferred terms selected from the Medical Dictionary for Regulatory Activities (MedRA) Renal and Urinary Disorders System Organ Class (SOC), the Investigations SOC and the Acute Renal Failure MedRA Standardized MedRA Query (SMQ). Descriptive statistics are provided for patients receiving ≥1 dose of study medication. To adjust for varying treatment duration, TEAEs are expressed as exposure-adjusted incidence rates (EAIRs; subjects with events per 100 person-years).

Results: In the core studies, EAIRs for any renal-related TEAE, serious renal-related TEAEs, and renal-related TEAEs leading to discontinuation were similar with XOI alone and LESU200+XOI and lower than with LESU400 +XOI (Table 1). Similar results were found for kidney stone and serious kidney stone TEAEs. The most common renal-related TEAE was increased serum creatinine (sCr). EAIRs for sCr elevations ≥1.5x baseline were higher with LESU+XOI than XOI alone (Table 1). Overall, 75% and 84% of sCr elevations in the XOI alone and LESU+XOI groups, respectively, were resolved at last study assessment; 75% and 66% resolved without interruption of medication. Exposure to extended LESU+XOI treatment in core+extension studies did not show an increase from core studies in EAIRs for any renal-related or kidney stone adverse event category (Table 2).

Conclusion: Lesinurad at the approved dose of 200 mg once-daily combined with XOI demonstrated comparable rate of adverse events to XOI alone. There was no clinically relevant increase in these adverse events with the extension of treatment beyond 1 year.

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lesinurad is a selective uric acid reabsorption inhibitor recently approved at 200 mg daily in combination with a xanthine oxidase inhibitor (XOI) for treatment of hyperuricemia associated with gout in patients who have not achieved target serum uric acid on XOI (allopurinol or febuxostat) alone. We integrated safety data for lesinurad (LESU) based on: (1) 3 large, pivotal, placebo-controlled, 12-month phase III (core) trials evaluating LESU 200 mg and LESU 400 mg in combination with an XOI; and (2) 2 extension studies, in which LESU-treated patients continued to receive LESU + XOI at the same dose and initially placebo-treated patients were randomized to receive LESU 200 mg or LESU 400 mg in addition to the XOI provided in the preceding core trial.

Methods: Safety data were pooled from the 3 core studies and 12-month extension studies using descriptive statistics for

patients receiving ≥1 dose of study medication. To adjust for varying treatment durations, treatment-emergent adverse events (TEAEs) are expressed as exposure-adjusted incidence rates (subjects with events per 100 person-years [PY]).

Results: In the core studies, adverse event rates were comparable for XOI alone and LESU 200 mg + XOI groups for any TEAEs, serious TEAEs, and TEAEs leading to discontinuation (Table 1). Adverse event rates were higher with LESU 400 mg + XOI. Major adverse cardiovascular event (MACE) rates, which included cardiovascular death, myocardial infarction, or stroke, in the core studies were 0.71 (95% CI 0.15, 2.08), 0.96 (0.26, 2.47), and 1.94 (0.84, 3.82) per 100 PY for XOI alone, LESU 200 mg + XOI, and LESU 400 mg + XOI, respectively. Renal-related TEAE rates in the core studies were 5.6, 7.3, and 15.4 per 100 PY, respectively. Longer exposure in the core + extension studies did not result in increases in any TEAEs, serious TEAEs, or TEAEs leading to discontinuation (Table 2). MACE rates were low in the core + extension studies, at 1.05 (95% CI 0.50, 1.93) and 1.48 (0.81, 2.48) per 100 PY in the LESU 200 mg + XOI and LESU 400 mg + XOI groups, respectively. Renal events in the core + extension studies were lower in the LESU 200 mg + XOI than LESU 400 mg + XOI group at 8.6 and 14.6 per 100 PY, respectively.

Conclusion: Lesinurad at the approved dose of 200 mg once-daily combined with XOI demonstrated a consistent, acceptable safety profile. There were no new safety concerns in the extension studies.

Table 1. Pooled Analysis of Exposure-Adjusted Adverse Event Incidence Rates in 3 Pivotal Placebo-Controlled 12-Month Phase III Studies Evaluating Lesinurad 200 mg and 400 mg in Combination with Xanthine Oxidase Inhibitors

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Two replicate, randomized, core Phase III trials (CLEAR 1 & 2) reported significantly more subjects treated with lesinurad 200 mg (LESU200) or 400 mg (LESU400), combined with allopurinol (ALLO), achieved target sUA <6.0 mg/dL at 6 and 12 months than with ALLO alone (P<0.0001).[1,2] The safety profile of LESU200+ALLO was comparable to ALLO alone, except for higher incidences of predominantly reversible serum creatinine (sCr) elevations. **Objectives:** Assess long-term safety and efficacy of LESU+ALLO therapy in subjects enrolled in the CLEAR 1 and 2 extension study (NCT01808131).

Methods: Efficacy was assessed for those completing the core study and either continuing core LESU+ALLO treatment (200CONT, 400CONT) or crossing over into extension studies from core ALLO alone to ALLO+LESU200 (200CROSS) or LESU400 (400CROSS). Core LESU200+ALLO or LESU400+ALLO subjects and 200CONT and 400CONT extension groups are reported for safety. Efficacy endpoints included proportion of subjects with target sUA <6.0 mg/dL and mean sUA levels. Treatment-emergent adverse events (TEAEs) were calculated as exposure-adjusted incidence rates (EAIRs; subjects with events per 100 person-years).

Results: For efficacy, 200CONT (n=239) and 400CONT (n=232) groups receiving treatment for up to 24 months, and 200CROSS (n=121) and 400CROSS (n=122) groups, receiving treatment for up to 12 months, were analyzed. Proportion of subjects with sUA <6.0 mg/dL during core and extension are shown (Figure). Mean (SD) sUA (mg/dL) for 200CONT, 200CROSS, 400CONT and 400CROSS groups, respectively, were 6.96 (1.14), 6.92 (1.33), 6.80 (1.20) and 6.99 (1.14) at baseline of core studies, and 5.71 (1.80), 6.68 (1.57), 5.06 (1.94) and 6.68 (1.38) at end of 12-month core studies. After 12 months in the extension study when all patients received LESU, mean (SD) sUA (mg/dL) was 5.75 (1.77), 5.78 (1.92), 5.01 (1.95) and 5.25 (1.77), respectively. For safety, a pooled analysis on a total of 405 (LESU200) and 401 (LESU400) subjects receiving lesinurad in combination with ALLO from the core studies was conducted. During the core and extension study period, EAIRs of TEAEs and serious TEAEs at any time were 54.2 and 5.8 for LESU200 and 57.2 and 8.3 for LESU400. EAIRs of renal-related TEAEs and serious renal-related TEAEs were 7.4 and 0.5 for LESU200 and 14.2 and 0.8 for LESU400. EAIRs of kidney stone TEAEs were 0.5 and 2.0 for LESU200 and LESU400, respectively. EAIRs of sCr elevations ≥1.5x baseline was 7.8 and 17.0 for LESU200 and LESU400, respectively. The majority of elevations (91.7% and 87.8%, respectively) were resolved by analysis cut-off.

Conclusion: Subjects treated with LESU+ALLO therapy through 2 years continued to be at sUA target; those crossing from ALLO monotherapy had increased proportions reach target. Safety during continued treatment in the extension studies was consistent with the profile observed in the core studies.

Figure. Proportion of patients with sUA <6.0 mg/dL during core and extension studies

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Three randomized, double-blind, Phase III trials reported that greater proportions of patients treated with lesinurad 200 mg (LESU200) or 400 mg (LESU400), combined with the xanthine oxidase inhibitor (XOI) allopurinol (ALLO; CLEAR 1 and 2) or febuxostat (FBX; CRYSTAL), achieved serum uric acid (sUA) targets at 6 months versus xanthine oxidase inhibitor (XOI) alone. This analysis evaluated the impact of long-term treatment with lesinurad + XOI on tophus and flares for at least 1 year and up to 2 years.

Methods: Patients completing 12 months in the core CLEAR and CRYSTAL studies could enroll in respective uncontrolled extension studies (NCT01808131; NCT01808144). Patients randomized to LESU200 + XOI or LESU400 + XOI in the core studies who continued on combination therapy in the extension studies were analyzed. Efficacy endpoints included: (1) proportion of patients with complete resolution (CR) of ≥1 target tophus (ie, measurable tophus on hands/wrists and/or feet/ankles 5–20 mm in longest diameter), (2) percent reductions in the total area of all target tophi, and (3) proportion of patients experiencing a gout flare requiring treatment (GFRT).

Results: A total of 239 (LESU200+ALLO) and 232 (LESU400+ALLO) patients continued in the CLEAR extension (n=32 and 33, respectively, with target tophi at baseline); 64 (LESU200+FBX) and 65 (LESU400+FBX) patients continued in the CRYSTAL extension. Proportion of patients with CR of ≥1 target tophus increased from end of core study (1 year) to 2 years: from 25.0% to 43.8% in LESU200+ALLO and 30.3% to 36.4% in LESU400+ALLO, and from 26.6% to 53.1% in LESU200+FBX and 35.4% to 58.5% in LESU400+FBX (LOCF). Percent reduction in the total area of all target tophi versus baseline changed from end of core study to 2 years: from 11.6% to 41.8% in LESU200+ALLO and 42.7% to 49.3% in LESU400+ALLO, and from 54.8% to 68.3% in LESU200+FBX and 58.6% to 72.4% in LESU400+FBX (LOCF). Proportion of patients with a GFRT per month decreased during continued combination treatment in both extension studies (Figure). The proportion of patients with a GFRT during Months 1, 12, and 24 were, respectively, 16.3%, 7.9%, and 5.6% in LESU200+ALLO; 18.1%, 6.9%, and 3.0% in LESU400+ALLO; 26.6%, 10.9%, and 6.3% in LESU200+FBX; and 36.9%, 4.6%, and 1.9% in LESU400+FBX. Extended treatment with LESU + XOI did not result in increased exposure-adjusted incidence rates of adverse events (AEs), AEs leading to discontinuation of lesinurad, serious AEs, or clinical laboratory abnormalities.

Conclusion: The CLEAR and CRYSTAL extension studies showed that patients treated with lesinurad + XOI for up to 2 years exhibited continued increases in the rate of complete resolution of tophi and reduction in tophus area, as well as decreased rates of gout flares.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Allopurinol is the most used urate-lowering agent for patients with gout, but around 10% of patients show intolerance to this drug, often at skin, which can be severe. Febuxostat (FBX) has been proposed for allopurinol-intolerant patients due to its different structure. However, data regarding safety in those with previous skin reactions to allopurinol is still limited (*Chohan.2011;38:1957. Bardin. 2016;83:314*) as these patients were excluded from pivotal trials. The aim was to assess the cutaneous safety of FBX when used in patients with previous skin reactions to allopurinol.

Methods: Retrospective review of patients with crystal-proven gout treated with FBX in our Unit until December 2015. Those with previous skin reaction to allopurinol were selected. We registered epidemiological (age, gender), clinical (skin events), laboratory variables (serum uric acid, glomerular filtration rate), and HLA-B*5801 status. The primary study variable was the rate of patients also presenting skin reactions with FBX. A descriptive analysis with estimation of the 95% confidence interval (95%CI) is presented.

Results: Out 102 gout patients treated with FBX in our Unit, we identified 24 patients with prior allopurinol-related skin events. The median age was 68.5 years (p25-p75 53.7-71.0), being 18 males (75%). Most used starting dose of FBX was 80mg/d (n=16), others were 5mg/d (n=1), 40mg/d (n=4) or 120mg/d (n=3). Median glomerular filtration rate at that time was 77.2 mL/min (62.7-68.6). We identified five patients (20.8%; 95%CI 3-38%) who also developed skin reactions with FBX (see table): in four cases a nonspecific rash, but one suffered from a Stevens-Johnson syndrome. They were HLA-B*5801 negative, and none of these patients presented skin reactions to benzbromarone.

Conclusion: In our series, one out five patients with previous skin reaction to allopurinol also developed after FBX. Larger studies are needed to confirm these results, but this finding strengths caution when using FBX in this subgroup of patients.

Characteristics of five patients developing skin reactions with both allopurinol and febuxostat

Gender	Age	Allopurinol start		Febuxostat start		Rash with febuxostat	Outcome with benzbromarone	HLA-B*5801 status
		Dosage (mg/d)	GFR (mL/min)	Dosage (mg/d)	GFR (mL/min)			
Female	70	50	78	120	77.2	Nonspecific	No rash	N/A
Male	69	N/A	90	40	90.5	Stevens-Johnsons	No rash	Negative
Female	68	100	52	80	80.3	Nonspecific	No rash	Negative
Male	45	50	90	80	90.9	Nonspecific	No rash	Negative
Female	41	300	40	5	40.9	Nonspecific	No rash	Negative

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Dosing adjustments and increased risk of serious side effects of uric acid lowering agents in patients with reduced renal function lead to undercorrection of hyperuricemia in patients with advanced chronic kidney disease(CKD) and gout. Febuxostat is highly effective and well-tolerated to treat hyperuricemia in CKD patients. Although several evidences demonstrated the usefulness of febuxostat in hyperuricemic CKD patients, clinical studies aimed at the CKD patients with inappropriately controlled hyperuricemia by allopurinol have been relatively lacking. The study objective is to evaluate the safety and efficacy of febuxostat in patients, who had CKD with severe renal impairment and did not meet with the target uric acid levels using allopurinol.

Methods: Data were collected from 168 patients who had CKD with more than stage 3b and changed from allopurinol to febuxostat due to uncontrolled hyperuricemia between 2005 and 2014 at Yonsei University Medical Center. Uric acid and creatinine were analyzed at baseline and during the first 6 and 12 months after conversion of febuxostat. Estimated glomerular filtration rate was calculated using the formula of MDRD equation. The patients were defined as a well-controlled state when the uric acid values of the study subjects reached within 6.0 mg/dL.

Results: The mean age was 60.7±14.6 years, and 129 patients (76.8%) were male. The number of patients was 25 (14.9%) in CKD stage 3b, 75 (44.6%) in stage 4, 8 (4.8%) in stage 5, 38 (22.8%) in patients treated with maintenance dialysis, 22 (13.1%) in patients underwent kidney transplantation. The mean estimated GFR (eGFR) and uric acid levels at baseline was 23.1±17.3 ml/min/1.73m^2 and 8.3±2.4 mg/dL, respectively. Most of the patients was treated with 40 or 80mg of febuxostat during the study period. The mean uric acid levels at 6- and 12-month after febuxostat treatment were significantly reduced compared to uric acid levels at baseline (5.2±2.1 mg/dL at 6-month and 4.9±2.2 mg/dL at 12-month, $p<0.001$, respectively). More than 70% of study subjects reached to the target of uric acid levels less than 6mg/dL at 6- and 12-months after treatment of febuxostat [122 (72.6%) patients at 6-month and 133 (79.2%) patients]. The creatinine levels at baseline and 6-month were comparable (3.42±2.03 vs. 3.38±2.16 mg/dL at baseline and 6-month, $p=0.61$), meanwhile, the creatinine levels were significantly increased after 12-month compared to those at baseline (3.69±2.46 mg/dL, $p<0.01$). Abnormality of liver function test was observed in only one patient during the follow up period. None of the patients did not discontinue drug due to adverse events.

Conclusion: Present study demonstrated that substantial hyperuricemic CKD patients treated with febuxostat were achieved the target of uric acid levels without adverse events. Febuxostat is an effective and safe uric acid lowering drug in allopurinol-intolerant patients with advanced CKD.

Pegloticase Provides Clinical Benefit in Patients with Chronic Refractory Gout Who Did Not Meet the Clinical Trial Biochemical Definition of Response

Brian F. Mandell[1], Michael Weisman[2], Anthony Yeo[3] and Peter E. Lipsky[4], [1]Rheumatology, Cleveland Clinic, Cleveland, OH, [2]Rheumatology, Cedars-Sinai Medical Center, West Hollywood, CA, [3]Horizon Pharma, Lake Forest, IL, [4]AMPEL BioSolutions, Charlottesville, VA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pegloticase is a recombinant uricase conjugated to polyethylene glycol approved for the treatment of chronic refractory gout refractory. The pivotal clinical trials for pegloticase defined responders as patients with plasma uric acid (UA) <6.0 mg/dL for ³80% of the time during extensive monitoring from both the week 9 infusion to just before the week 13 infusion and from the week 21 infusion to week 25 (final visit). Nonresponders did not meet this stringent criterion, but had a substantial decrease in UA after the first pegloticase dose followed by a return to a UA level >6mg/dL after ~6 weeks of therapy.[1] Whether these subjects received persistent clinical benefit from the transient reduction in UA is not known and is the subject of this analysis.

Methods: This analysis used results from two randomized controlled trials (RCTs)[1] to assess the clinical efficacy in responders and nonresponders to treatment (8 mg of pegloticase delivered every 2 weeks [q2w]). Serum UA was measured before each infusion and assessment of gout flares, tophus reduction, Patient Global Assessment (PGA), tender and swollen joints (TJC and SJC), pain measured with a 100 mm visual analog scale (VAS) and a variety of Patient Reported Outcomes were determined for four groups: responders, all nonresponders including those who exited the study and were not available for the UA assessments at 3 and 6 months, per-protocol (PP) nonresponders who received all planned pegloticase infusions in the 6-month RCTs, and patients who received placebo.

Results: The analysis included 36 responders, 49 nonresponders, 24 PP nonresponders, and 43 patients who received placebo. Responders exhibited mean reductions in serum UA to <0.5 mg/dL at 3 and 6 months. Both nonresponders and PP nonresponders had a transient decrease in UA that returned to a mean >6mg/dL by 7 weeks. Results for both responders and nonresponders indicated significant reduction in tophi and improvements from baseline in PGA, TJC, SJC, pain, and ASHI (**Table**). Improvements were greatest for responders, but were also significant for both groups of nonresponders. No significant improvements were observed in the patients who received placebo.

Conclusion: These results indicate that chronic refractory gout patients not achieving a protocol-defined biochemical response still have significant clinical benefits with pegloticase treatment. This suggests that the substantial, but transient, reduction in UA achieved in patients categorized as nonresponders in the RCTs can result in sustained clinical benefit. These benefits are not merely a result of being enrolled in a clinical trial or receiving hydrocortisone as prophylaxis for infusion reactions (IR) since they were not observed in patients who received placebo and a similar IR prevention protocol.

Prophylaxis for Infusion Reactions to Pegloticase: An Analyis of Two Different Corticosteroid Pre-Infusion Regimens in US Community Rheumatology Practices

Amar Majjhoo[1], Kome Okposo[2] and Michael Zdanis[3], [1]Shores Rheumatology, St. Clair Shores, MI, [2]Horizon Pharma, Lake Forest, IL, [3]Cetus Group, LLC, Towson, MD

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Corticosteroids are commonly utilized, along with other agents in clinical practice for pre-infusion prophylaxis prior to the administration of therapeutic biologic proteins. Two steroids, methylprednisolone and hydrocortisone, are commonly used. Because of the differing characteristics of these two agents, a chart review evaluating outcomes was performed.

Methods: Nineteen sites completed a retrospective chart review of pegloticase treated gout patients who completed at least three (3) infusions since 1/1/2012. Pegloticase is typically administered at 8 mg every 2 weeks, the FDA approved dose. Data collected included demographics, gout history, contraindications to both infusion reaction prophylaxis and gout flare prophylaxis medications, pre and post treatment serum uric acid (sUA) level, and prior gout treatment. This analysis includes data from 92 patients. Data were analyzed using multiple logistic regression, with number of infusions as a response variable and age, sUA prior to the last infusion, type of infusion prophylaxis corticosteroid (hydrocortisone or methylprednisolone) as treatment outcome predictor variables.

Results: Patient characteristics are similar to the typical pegloticase treated population.

Table 1 – Patient Characteristics

Age (years)	Mean	61.5
	Range	38 – 77
Sex (n, %)	Male	74 (82%)
	Female	18 (18%)
Race (n, %)	Caucasian	73 (79%)
	Black:	11 (12%)
	Asian	6 (7%)
	Other/NA	1 (1%)
Disease Duration (years)	Mean	13.5
	Range	4 – 30
Number of Infusions (n)	Median per Patient	7
	Total	670
Corticosteroid:		
Hydrocortisone	Number of patients (n)	31
	Mean Dose	198 mg
	Modal Dose	200 mg
	Range	150 – 200 mg
Methylprednisolone	Number of patients (n)	61
	Mean Dose	77 mg
	Modal Dose	50 mg
	Range	40 – 120 mg

Use of methylprednisolone as compared to hydrocortisone as pre-infusion prophylaxis was a significant ($p<.001$) predictor of pegloticase therapy duration (number of infusions). Furthermore, the mean number of infusions when methylprednisolone was used (8.48) was significantly higher than when hydrocortisone was used (4.93) ($p<.001$). As previously published, serum uric acid (sUA) drawn immediately prior to infusion was also a significant predictor of continued therapy and remains a key determinant for sustained pegloticase infusions. There was no significant difference between sUA levels prior to initiation of pegloticase therapy for these two groups.

Table 2 – Pre-Infusion Prophylaxis

Corticosteroid		Overall	Infusion Reaction and/or Discontinuation	
			No	Yes
Hydrocortisone	n	31	18	13
	Infusions (mean)	4.935	5.889	3.615
	Infusions (range)	3 – 16	3 – 16	3 – 5
Methylprednisolone	n	61	56	5
	Infusions (mean)	8.475	8.786	5.0
	Infusions (range)	3 – 13	4 – 13	3 – 7

Conclusion: Data from this retrospective chart review indicates that methylprednisolone pre-infusion therapy may allow for longer pegloticase therapy duration as compared with hydrocortisone. However, this modality imposes a significantly higher glucocorticoid load that may suppress symptoms of an infusion reaction rather than inhibit pegloticase drug antibody

formation. The long term use of methylprednisolone prophylaxis may result in glucocorticoid related adverse effects. Methylprednisolone use as compared to hydrocortisone for infusion prophylaxis needs further study to determine efficacy and long-term safety.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcium pyrophosphate crystal-induced arthritis (CPPD) is an acute crystal arthritis, frequently involving the wrist or the knee. Monosodium urate in gout or CPPD in pseudogout have been shown to trigger the release of IL-1β, a strong pro-inflammatory cytokine, through a complex intracellular molecular cascade. IL-1 blockade showed efficacy in treating acute gouty arthritis in phase 3 controlled studies, and there are published retrospectives series and case reports showing a good clinical response in CPPD arthritis in blocking IL-1 with anakinra, an IL-1 receptor antagonist. This randomized controlled trial was designed to evaluate the efficacy and safety of anakinra versus prednisone to treat acute CPPD arthritis.

Methods: Single center, randomized, double blinded controlled study. ISRCTN registration number: ISRCTN46471047. Patients presenting, between 2012 and 2015, with an acute CPPD arthritis (< 5 days duration), were randomly assigned in a 1:1 ratio to a treatment of anakinra 100 mg s.c. + placebo matching prednisone or prednisone 30 mg + placebo matching anakinra s.c. for 3 days. Acute CPPD arthritis was defined as presence of clinical symptoms and CPPD crystals in joint fluid aspiration at screening or in the medical history. Primary outcome was the pain evaluation at 72 hours post dose on a 0-100 mm VAS scale. Secondary outcomes were assessments by the patient and physician of pain intensity and global response over a 28 days period.

Results: Fifteen patients were randomized, 8 assigned to anakinra and 7 assigned to prednisone treatment. Baseline characteristics of both groups were comparable. Three patients (2 in the anakinra group and 1 in the prednisone group) presented a flare 2 weeks after the intervention and were excluded from the study, treated with medication not allowed by the protocol (including open label treatment with anakinra for 1 patient). The study was stopped after 3 years due to a persistent low inclusion rate, reaching only 30% of the 50 expected randomized patients, mainly linked to the short requested delay of symptoms duration for inclusion. Pain reduction at 72 hours on a VAS scale compared with baseline was statistically significant in the anakinra group (-39 mm, p=0.02) but not statistically significant in the prednisone group (-23 mm, p=0.07). There was no statistically significant difference between both groups concerning the primary outcome. All other outcome measures were in favour of the anakinra group, but without being statistically significant due to an underpowered study. No serious adverse events were observed in both groups.

Conclusion: Both anakinra and prednisone seem to be effective in the treatment of acute CPPD-induced arthritis and we observed a trend in favour of anakinra, but non statistically significant, due to an underpowered study. More prospective randomized controlled trials are needed with more patients, probably with a multicentric design.

Anakinra Is Effective and Well Tolerated in Medically Complex Patients Including Transplant Recipients with Gout

Christopher Palma[1], Taylor Topping[2] and Darren Tabechian[1], [1]Medicine, Division of Allergy, Immunology and Rheumatology, University of Rochester Medical Center, Rochester, NY, [2]Pharmacy, University of Rochester Medical Center, Rochester, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anakinra is a biologic response modifier that competitively antagonizes the biologic effects of interleukin-1β. Conventional treatments for the inflammatory response to acute gout are often contraindicated or can exacerbate comorbidities in medically complicated hospitalized patients. We report on the efficacy and safety of Anakinra for treatment of acute gouty arthritis in a medically complex in-patient cohort. Anakinra is not FDA approved for treatment of gout.

Methods: Retrospective chart review of all adult in-patients who received Anakinra in a 1017 bed hospital system from 2011 through 2015 in Rochester, New York. Only those patient treated for episodes of acute gouty arthritis were included. Data collected: demographics, medical comorbidities, prior treatments for gout, duration of hospitalization, concurrent infections, Anakinra dosing, response to treatment, adverse events.

Results: Of 28 adult in-patients receiving Anakinra over 5 years, 18 patients were treated for gout. The average age was 67.7 years. The average length of stay was 21.3 days. The average Charlson Comorbidity index[1] was 7.6. A representative patient with a Charlson Comorbidity index of 7 was scored as follows; age of 78 years old (3 points), CHF (1 point), prior MI (1 point), CKD 3 (2 points). Twelve of 18 cases were crystal proven at time of presentation. Average CRP during peak of symptoms was 163mg/dl. Average calculated GFR was 49ml/min. There were 3 transplant recipients (2 liver, 1 kidney) and 2 patients had implanted portable left ventricular assist devices. Seven patients were also receiving antibiotics at the time Anakinra was administered (Klebsiella pneumonia, 2 Enterococcal uti, C. difficile colitis, toe ulcer, 2 unknown). Thirteen of 18 patients had failed to respond to systemic corticosteroids and one to intraarticular treatment prior to receiving Anakinra. All patients responded to 1 or more doses of Anakinra. (Four of 18 responded to a single dose, 14 of 18 patients required 2 or 3 total doses). There was one adverse event for which Anakinra was a possible cause (worsening encephalopathy in decompensated liver failure patient).

Conclusion: Anakinra is an effective treatment for acute gouty arthritis in medically complex patients including those refractory to corticosteroids. Anakinra appears to be a safe treatment option for patients with extensive comorbid illnesses where conventional gout treatments may exacerbate comorbid diseases. The short half-life of anakinra is of additional utility for immunocompromised patients, such as solid organ transplant recipients, and patients with active infections. 1. Charlson, M et al. SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Because of the large increase in the price of colchicine with the FDA granted market exclusivity the Pharmacy at the Mpls VA HCS asked the Rheumatology Clinic to conduct a QA/QI review related to colchicine prescriptions refillable for up to one year. We intended to evaluate whether the prescribing of colchicine was appropriate related to the certainty of a gout diagnosis or other disorders treated with colchicine. We also evaluated the safety of prescribed colchicine dosing related to renal impairment, control of hyperuricemia in those on chronic colchicine therapy, the presence of co-morbid conditions and potential multiple drug interactions,

Methods: The pharmacy database provided a list of all patients with active, refillable prescriptions for colchicine at the Minneapolis VA HCS. We developed a structured chart review document to gather data from the electronic medical record of those with colchicine prescriptions. Diagnosis of gout was designated as 1) definite gout with urate crystals identified in synovial fluid, tophi, x-ray changes of osseous tophi) 2) probable gout (clinical picture and 6/12 ACR criteria for acute gout), 3) Other diagnoses treated with colchicine included pseudogout, pulmonary fibrosis, pericarditis . 4) Indeterminate reason in the EMR for colchicine yet patient receiving colchicine with/without urate lowering treatment (often in patients co-managed with outside provider 5) No evidence for dx of gout by reported clinical exam, lab tests or x-ray yet taking colchicine. Diagnostic designations 1), 2), 3) were considered appropriate prescribing of colchicine and those with 4) and 5) not appropriate prescribing of colchicine. Laboratory test results, medical history data, x-ray findings, co-morbidities were collected to evaluate the appropriateness of prescribed dosing of colchicine.

Results: 420 patients had prescriptions recorded in the pharmacy database in Nov 2011. The average age was 68.9 yrs (13% <60y; 39% 60-69y; 21% 70-79yr; 25% 80-89y, 3% >90yr) Only 9% of subjects did not have any co-morbidities; 222 had 1 or 2 (53%) and 161 had 3 or 4 (46%). The most common co-morbidities were diabetes, hypertension, chronic kidney disease, and heart failure. 32 patients actually did not have active prescriptions for colchicine and 32 had died before the chart review. Colchicine was designated appropriate in three groups: 1) 128 with definite gout (30%), 87 with probable gout (21%) and 20 with pseudogout and other diagnoses (4.7%). In 134 gout diagnosis was indeterminate (32%) and colchicine prescription was not designated as appropriate. Colchicine dosing was appropriate relative to renal function in 91% of patients. Interestingly concomitant urate lowering therapy was prescribed in only 239 (56.8%) with 170 (40.4%) at target uric acid of <7 and 69 (16.4%) with uric acid >7. Of concern is the lack of urate lowering therapy in 129 (30.7%) of those on chronic colchicine.

Conclusion: Assessment of colchicine prescribing revealed areas of deficient quality of care related to chronic administration of colchicine in nearly one third of patients without a definite or probable diagnosis of gout. These patients may be exposed unnecessarily to risk of adverse drug effects and may be subject to additional costs. There is concern for chronic colchicine treatment to suppress gouty arthritis without treatment of associated hyperuricemia because permanent joint damage may occur. Chart review of the electronic medical record to obtain clinical data presents challenges due to incomplete data recording. There was minimal evidence of ongoing monitoring for potential colchicine side effects. Because of these concerns about quality of gout care, we have set up a Gout management clinic to properly evaluate diagnostic data and to monitor responses and side effects to improve the quality of gout care. Thus far 79 patients came to Gout Clinic, 45 no showed, 64 died before appointment, and 165 declined the appointment. We will continue monitoring the quality of gout care in this new clinic.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The severity of gout is often associated with poor patient compliance and sub-optimal medical treatment. Our objective was to determine the prevalence, characteristics, and factors associated with disability at baseline visit and the effect of regular treatment in patients with gout.

Methods: We analyzed baseline, 6, 12 and 18-months follow-up data of patients with gout from GRESGO, a cohort of 445 consecutive patients with gout seen for the first time at the Rheumatology Department and treated according to published guidelines (urate lowering therapy, acute attacks prophylaxis, NSAID and glucocorticoids) including treatment for associated diseases. Variables included demographic, clinical, and biochemical data; HAQ and EuroQoL questionnaires as well as VAS for pain and health. According to the use of daily life aids, specifically wheel chairs or gait aids (walking frames, canes or crutches) at baseline visit, we made two subgroups: one in need of such aids (GD) and another without them (GNoD). This protocol was approved by the local IRB and patients signed and informed consent for their participation. Statistical analysis included t test, X2, and logistic regression.

Results: Most patients (97%) were males; the mean ages at onset and at baseline were 34.4 (12.7) years and 47.5 (12.7) years; disease duration was 13.1 (10.7) years; 68% had tophi. There were 89 patients (20%) in GD group: 26% required 2 or more gait aids, 48% canes, 10% wheel chairs and 15% other walking frames; and 356 (80%) in GNoD group. GD had lower educational and socioeconomic levels and more severe disease (table 1); although there were no differences in age 47.9 (12.3) VS 47.4 (12.9) and disease duration 14.8 (9.9) VS 12.7 (10.9), p=NS, the frequency of renal and heart diseases was higher in GDAt the six-month follow-up, the effect of proper treatment had improved the clinical condition of 57% of patients in GD; 18 still required daily life aids; and 25% were lost to follow-up. At the 18-months evaluation 36 (40%) patients still had adequate functioning.

	GD %	GNoD %	p	Exp(B)	p
Low socioeconomic level	54	40	0.016	1.60	0.063
>3 Flares/last year	62	43	0.001	0.548	0.022
Previous glucocorticoid usage	67	53	0.017	1.36	0.25
Hypertension	47	35	0.048	1.30	0.30
Lithiasis	21	12	0.048	1.46	0.25
Chronic renal failure*	24	14	0.036	1.71	0.08
Heart failure	3.4	0.8	0.023	4.67	0.07
Hospitalization/gout reasons	33	14	0.001	1.46	0.13
Died during follow-up (n/%)	3/3.4	6/1.7	NS		

As expected, patients in GD had also significantly more or higher frequency of tender, swollen, limited joints, tophi, HAQ, EUROQoL, lost laboral days/6 months and VAS for pain and health. Nine (2%) patients died during follow-up: 3 (3.37%)

from GD and 6 (1.68%) from GNoD.

Conclusion: Disability occurred in 20% of gout patients attending a Rheumatology Department for the first time. These patients were low-socioeconomic level young men with very severe and active disease (> flares/hospitalizations, > tophi) and also associated renal and heart disease. And probably higher mortality.Proper treatment improves functioning in up two 40% of patients with disability in the baseline visit.

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A key factor in the success of gout management is the long-term lowering of serum uric acid (sUA) levels below predetermined targets (5 or 6 mg/dL). Monitoring of uricemia in gout patients is therefore important, especially during drug titration, and is presently done in the laboratory on serum samples obtained after venous puncture. An accurate sUA meter that would allow rapid testing by the health care professionals and self-measurement of uric acid by the gouty patient should improve patient monitoring and management of gout. This study aimed to assess the reliability of immediate uricemia measurement in capillary blood samples obtained from fingertip puncture using the HumaSens-plus point-of-care meter compared with that of a standard laboratory assay.

Methods: Finger-prick blood sUA levels were measured from 238 consenting diabetic patients using the commercially available HumaSens-plus sUA meter (European Conformity marked and approved for EU market use only). Each patient also had a venous sample taken and prepared as Li-Heparin plasma for analysis in the biochemistry laboratory using a uricase automated colorimetric assay. Since the sUA meter has a dynamic range of 3–20 mg/dL, a subject's capillary reading was excluded from statistical analysis when the meter read LO or HI, indicating that the subject's sUA value was lower than or higher than the calibrated range. Statistical analysis included calculation of the Pearson's correlation coefficient (PCC) between the 2 measured values and Bland-Altman graphic representations of means and differences between the 2 measurement results. A total of 206 paired measurements were calculated to be necessary for calculation of a PCC of 80% with a precision of 0.10 and an alpha risk of 0.05%.

Results: Eighteen capillary samples were marked LO by the meter: 15 were confirmed by standard biochemistry to be below 3 mg/dL, and 3 were above (3.2, 3.4, and 7.1 mg/dL). Two capillary samples were read HI and were measured at 5.1 and 3.6 mg/dL by biochemistry. In the remaining 218 samples, PCC was 0.92, and Bland-Altman curve showed acceptable agreement all over the tested values, with the following limits of agreement: [-1.1 mg/dL; 1.39 mg/dL]. On average, plasma measurements were 1.03-fold higher than capillary measurements. Accuracy was 92.7% at the 20% margin. Predictive value was 77.1% for a capillary measurement found to be above the target (6 mg/dL) by biochemistry measurement. For capillary measurement found to be below the target by biochemistry measurement, predictive value was 92.7%.

Conclusion: HumaSens meters were easy to use, and these preliminary results showed that the meters give results that are

reasonably comparable to those of the laboratory assay; as a result, they may be useful in the clinic and in epidemiologic studies. Further studies are underway to better understand discrepancies between the two techniques by looking at drug intakes and other biochemical and hematologic parameters measured in these patients, as well as by comparing results of both techniques to liquid chromatography-mass spectrometry reference measurements.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic hyperuricemia predisposes to deposition of monosodium urate (MSU) crystals in musculoskeletal and other tissues, causing chronic inflammation, acute gout flares, joint damage, and disfiguring tophi. Dual-energy computed tomography (DECT) is a useful imaging tool to detect and quantify MSU crystal deposits. This study assessed the evidence of MSU crystal deposition using DECT scanning among gout patients treated with allopurinol and the potential determinants associated with the observed deposits.

Methods: This multicenter DECT study recruited gout patients from the USA and New Zealand who were taking allopurinol at ≥300 mg daily for at least 3 months. MSU crystal deposition was measured using DECT in hands/wrists, knees, and feet/ankles bilaterally. The presence of MSU crystals as well as the total volume of crystals were assessed according to gout characteristics and serum uric acid (sUA) levels.

Results: Patients (N=147) were predominately male (91.8%), with mean (SD) age 58.7 (10.9) years and gout duration 15.3 (11.1) years. Mean sUA prior to scanning (within 1 month) was 6.0 (1.6) mg/dL, with approximately 46% of patients above the sUA target of 6.0 mg/dL. The median allopurinol dose was 300 mg (range, 300-700 mg) daily. 67.8% of patients had MSU crystal deposits with a total median crystal volume of 0.06 cm^3 (range, 0 to 19.53 cm^3). Those with sUA ≥6.0 mg/dL and palpable tophi showed the highest prevalence of urate deposits (88%), and those with sUA <6.0 mg/dL and no palpable tophi showed the lowest prevalence (47%). Those who reported a gout flare within the prior 3 months (versus none), were prescribed allopurinol doses >300 mg (versus 300 mg), and had palpable tophi (versus none) were more likely to have deposition.

Conclusion: Despite a stable dose of allopurinol for more than 3 months, and even with sUA at the target level, a substantial proportion of gout patients continue to have evidence of MSU crystal deposition by DECT scan. Patients with palpable tophi, sUA levels ≥6.0 mg/dL, and gout flares within the prior 3 months appear to have a higher frequency of MSU crystal deposition. These patients may need continuation and/or intensification of their urate-lowering therapy

Table. Subjects with urate deposition on their DECT scan according to palpable tophus status and sUA level.			
	sUA ≥6.0 mg/dL	sUA <6.0 mg/dL	Total
Palpable tophi			
Presence of urate deposits	15/17 (88.2%)	19/26 (73.1%)	34/43 (79.1%)
Median volume (range) for positive scans*	0.39 (0.01-19.53) cm^3	0.28 (0.05-2.57) cm^3	0.32 (0.01-19.53) cm^3
No palpable tophi			
Presence of urate deposits	39/49 (79.6%)	23/49 (46.9%)	62/98 (63.3%)
Median volume (range) for positive scans*	0.11 (0.01-1.23) cm^3	0.14 (0.01-0.89) cm^3	0.13 (0.01-1.23) cm^3
Total			
Presence of urate deposits	54/66 (81.8%)	42/75 (56.0%)	96/141 (68.1%)

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Detection of double contour sign (DCS) and hyperechoic aggregates (HAG) is a reliable method in detecting urate crystal deposition by ultrasound (US) which has been studied extensively. Worldwide attempts have been made to assess response by measuring Tophi size, but USG has not shown good correlation with other modalities in assessing Tophi size. Our study was aimed at progression / resolution of presence of DCS and HAGs after urate lowering therapy.

Methods: 14 patients of proven gout were followed up for progression / resolution of US findings after one year of urate lowering therapy. US evaluation was done at the beginning of urate lowering therapy and repeat US was done at one year. The ultrasound scans were obtained applying guidelines issued by The Working Group for Musculoskeletal Ultrasound in the EULAR Standing Committee on International Clinical Studies including Therapeutic Trials. DCS was looked for at three articular cartilage sites (first metatarsal, tibiotalar and femoral condyle) whereas HAGs were looked for at three joint sites (radiocarpal, first metatarsal and femoral condyle) and two tendon sites (patellar and triceps). Ultrasound was

done using multifrequency linear array transducer (8–13 MHz) of Logiq E; GE Medical Systems Ultrasound, on B mode gray scale (GS).

Results: In 14 patients, 84 sites were examined for double contour sign (DCS) and 140 sites for hyperechoic aggregates (HAG). In the initial evaluation, DCS was present in 34 out of 84 sites which got reduced to 27 in the follow up (20.5% reduction). HAG were present in 23 out of 140 sites in the initial study which got reduced to 11 out of 140 in the follow up (52 % reduction). Overall there was a 33.3% reduction of US abnormalities over one year follow up after urate lowering therapy. The mean serum uric acid level was 9.44 mg/dl (range- 2.6-13.7mg/dl) before initiation of urate lowering therapy and was 6.7 mg/dl (range 3.9-10.3) at one year follow up. Among the fourteen patients, compliance to drugs and dietary modifications were good for eleven patients and three were non-compliant. The mean serum uric acid levels in the good compliance group was 9.09 mg/dl at the initiation of therapy and mean levels got reduced to 6.0mg/dl after one year of follow up. The resolution of US abnormalities was seen in the compliant group while there was no resolution of US abnormalities in the non-compliant group.

Conclusion: Urate lowering therapy results in marked resolution of DCS and HAGs in gout. Compliance to urate lowering therapy and diet in resolution of US abnormalities is important. Qualitative assessment of presence and absence of DCS and HAGs can be used a guide to successful therapy.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The utility of ultrasound (US) in aiding the diagnosis of gout has been well established. The latest 2015 gout classification criteria have included the US as one of the criteria. However, in a daily hectic outpatients and inpatients practice, with limited resources, the selection of joints for US examination is crucial. Therefore, we aimed to determine the prevalence of positive US findings in joints of the lower limb among gout patients.

Methods: Data was collected prospectively from 15th January 2016 to 31st May 2016. Patients who fulfilled 2015 ACR/ EULAR gout classification criteria were recruited. US examination of the bilateral first metatarsophalangeal (MTP1), midfoot, ankle and knee joints were performed by an experienced rheumatologist. Typical US lesions in gout such as double contour signs (DCS), tophi, and bone erosions were identified according to the international consensus of OMERACT. The frequencies of the positive US findings were analyzed using a descriptive analysis.

Results: There was a total of 78 patients were recruited, the majority (n=76) were male. The mean age of the patient was 52.3 ¡Ó 16.1 years. A total of 624 joints were examined. The frequency of DCS on ankles, MTP1, knees and midfoot were 98.7%, 96.8%, 95.5%, and 17.9% respectively. The majority of tophi were detected via the US on MTP1 (90.4%), while

9.6% of the midfoot, 11.5% of the ankle, and 16.0% of the knee joints had tophi depositions. Of 156 MTP1 joints examined, 68 (43.6%) had erosions.

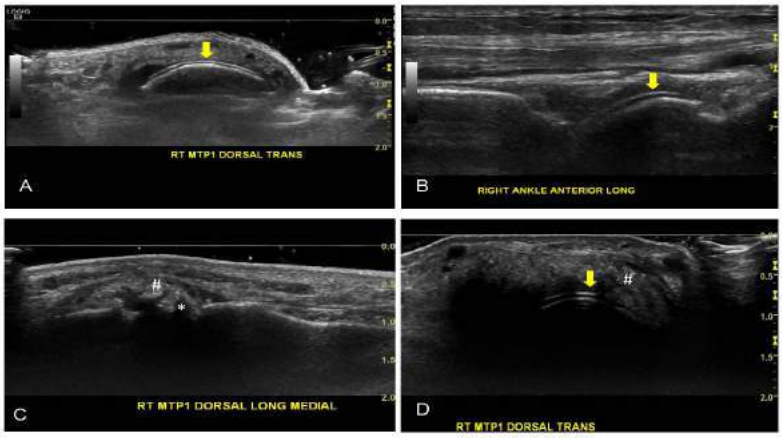
Conclusion: MTP1 consistently demonstrated a high frequency of positive US findings (DCS, tophi and bone erosions). The US of the midfoot showed infrequent gout lesions, especially DCS. In daily practice to detect gout, US examinations of the MTP1 are preferred while the US of the midfoot could be omitted. US examination of the ankle and knee joints could be considered in particular looking for DCS. Bone erosions may not be detected by the US if coexistence of tophi depositions on large joint such as knees and ankles.

Table 1. The distribution of double contour signs, tophi, and bone erosions according to joints.

n (%)	MTP1	Midfoot	Ankles			Knees
			Anterior	Medial	Lateral	
DCS	151 (96.8)	28 (17.9)	149 (95.5)	154 (98.7)	145 (92.9)	149 (95.5)
Tophi	141 (90.4)	15 (9.6)	6 (3.8)	6 (3.8)	18 (11.5)	25 (16.0)
Bone erosions	68 (43.6)	19 (12.2)	-	-	-	-

Abbreviations: DCS, double contour signs; MTP1, first metatarsophalangeal joint.

Figure 1. Typical ultrasound findings on gout patients.



Arrow showed double contour sign. # showed tophi. * showed erosions. Abbreviations: RT, right; MTP1, first metatarsophalangeal joint; TRANS, transverse view.

Role of Synovial Biopsy in Diagnosis of Crystal Arthropathies

Viju Moses[1], Jaya Asirvatham[2], Jonathan McHugh[2] and Robert Ike[1], [1]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [2]Department of Pathology, University of Michigan, Ann Arbor, MI

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Title: Role of Synovial Biopsy in Diagnosis of Crystal Arthropathies

Background/Purpose: Diagnosis of crystal arthropathies (CAs) can be challenging. Advances in arthroscopy and ultrasound guided procedures have enhanced the ease and availability of synovial biopsy as a diagnostic test for rheumatologists, leading us to examine the role of synovial biopsy in CAs.

Methods: We performed word searches on synovial biopsies in the pathology database of a tertiary referral medical center between 1988 and 2015 and identified two groups. (1) A "clinical" group where CA was clinically suspected and listed as a primary or secondary indication for biopsy (with biopsy subsequently either positive or negative for CA); this would be typical of biopsy requests for CA originating from a rheumatology setting. (2) An "incidental" group, where a CA was identified on biopsies submitted from diagnostic and therapeutic procedures without a preoperative suspicion of CA. We reviewed electronic medical records of these cases to extract clinical details.

Results: Of 2786 synovial biopsies reported during the study period, 98 cases were selected for further study (Fig. 1). The mean age was 55 +/-16 years and 45% were female. Biopsy reports in the two groups are summarized in Fig. 1. On restricting analysis of the "clinical" group to only biopsies with CA as the primary clinical suspicion (n=31), the proportion of CA positive biopsies rose to 16% for gout, 13% for CPPD, 10% for unspecified crystal, with 39% overall positive for any crystal, while 22% had an alternate diagnosis and 39% were non-diagnostic. Absolute alcohol was the fixative used for 81% of the specimens in the "clinical" group. Seven of the 33 "incidental" positive biopsies were mass lesions suspected to be neoplastic, but diagnosed by biopsy as gout (n=4) or CPP (n=3). Clinical characteristics of patients from either group with a biopsy diagnosis of gout and CPP respectively were compared with the "clinical" patients negative for CA. (Table 1) Synovial fluid findings could not be analyzed due to a paucity of data.

Conclusion: Synovial biopsy is useful in the diagnosis of CAs, (a) yielding a diagnosis that can influence management in 61% of cases, (b) detecting a CA in 39%, and (c) identifying a specific CA in 29%, when CA is the primary indication for biopsy. Biopsy-positive gout is associated with the presence of bone cysts, while biopsy-positive CPP is associated with older age, monoarticular disease, chondrocalcinosis and bone cysts. An unexpected diagnosis of CA or crystal deposition occurs in 1% of synovial biopsies from procedures with no prior suspicion of a CA, including occasional mass lesions clinically mimicking a neoplasm.

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is the most prevalent inflammatory arthritis worldwide. Within the healthcare setting, gout flares contribute to substantial morbidity and complicated hospital stays. Identifying risk factors and preventing flares are mainstays of therapy. This case-case-control study aims at exploring the risk factors for developing an acute gout flare with special emphasis on inpatient stressors and gout attacks in the hospital setting.

Methods: This is a case-case-control study of all consecutive gout flares from January 2010 to January 2015. The first group of cases comprised patients who developed a gout exacerbation after 48 hours of admission to the hospital. The second group consisted of patients whose gout flare manifested within 48 hours of hospital admission. The control group included chronic gout patients that were hospitalized during the same time frame as cases but did not experience an acute gout attack during their stay. Two multivariable models were constructed, one including predictors of flare-up within hospitalized patients (>48 hrs), and the other including predictors for flare-up upon hospital admission (<48 hrs).

Results: A total of 530 patients were included in this study (184 gout cases >48 hrs of admission, 159 gout cases <48 hrs of admission, and 187 chronic gout controls). There were no significant differences in gender distribution, age means, length of stay, or Charlson comorbidity scores across all study groups. In the first multivariable model (gout attack>48 hrs of admission vs chronic gout controls), recent gastrointestinal bleeding (OR 3.0; CI 1.1-8.2), placement of a urinary catheter (OR 4.1; 95% CI 1.9-8.6), and antibiotic use >3 days (OR 3.2; 95% CI 1.4-7.5) constituted independent predictors of gout exacerbation within hospitalized patients. Subgroup antibiotic analysis revealed that inpatient gout exacerbations were associated with recent use of cephalosporins (p<0.001), quinolones (p=0.01), metronidazole (p=0.03),

and vancomycin (p=0.001). In the second multivariable model, controls were more likely to have the following factors compared to cases: COPD (OR 1.89; 95% CI 1.1-3.3), rheumatoid arthritis (OR 4.2; 95% CI 1.2-15.3), recent infection (OR 2.2 95% CI 1.2-15.3), and a bedrest activity (OR 4.6 95% CI 1.7-12.6) order. In both models, Allopurinol (p<0.001) and Colchicine (p=0.003) use were significantly associated with chronic gout controls compared to cases.

Conclusion: Urinary catheter placement, antibiotic use, and gastrointestinal bleeding within 30 days seem to be unique predictors for gout flares within hospitalized patients. Prior use of cephalosporins (within 30 days) constituted an especially robust risk factor for an acute inpatient gout flare compared to controls. The design of this study permits for a more reliable assessment of inpatient risk factors compared to the classic case-control design.

Patient Perception of Gout Flares as a Measure of Outcome:

Results from an International Study

Background/Purpose: Attacks (flares) are one of the primary manifestations of gout. It is not known how infrequently gout flares need to occur for patients to consider their disease to be in remission, in a state of low activity (LDA), or in an acceptable state (PASS). In addition, it is not clear what time horizon should be used to determine these disease activity states. The aim of this study is to estimate the patient-perceived frequency of gout flares associated with disease activity states along with a clear time-horizon for these estimates

Methods: We enrolled 374 individuals with gout from 15 international sites in a cross-sectional study. We inquired about flare frequencies in the past 6 and 12 months and actual and hypothetical perception of disease states: remission ("gout is gone"), LDA ("gout control is satisfactory") or acceptable state ("gout requires no more treatment") with relation to flares. Data from one half of the group (discovery group) was used to estimate the best discriminatory cutpoints to distinguish remission vs. non-remission, LDA vs. no-LDA, and PASS vs. no-PASS using logistic regression. We then applied these

estimates to the second half of the group (validation group) to calculate sensitivity and specificity of these thresholds. Results at 6 and 12-month recollection intervals were compared. **Results**: The mean age of participants was 52.7 years (SD 13.9), 90.2% were men, and 33.2% had tophi. Participants reported experiencing a median of 2 (IQR 0-4) and 3 (IQR 1-8) flares in the 6- and 12-month preceding period, respectively. From the flare perspective, 24.5% of and 22.6% of participants reported that their gout was in remission. Flare frequency thresholds for disease states were lower with asking the participants about hypothetical (imagined) scenarios than when with their past recollection of disease states within the validation cohort (Table). Recollection of one flare or less in the prior 6 and 12 month periods provided the best predictive cutpoints between a between being or no being in remission, LAD, or PASS (Table). Responses at 6 and 12 months had comparable performance.

Conclusion: Recollection of one flare or less in the previous 6-month period provides the best discrimination for patient-reported gout flare remission state, although the diagnostic performance of this threshold is limited. A 12-month recall period does not outperform a 6-month recall period for assessing gout flare disease states.

Table. Diagnostic performance of cutpoints for different gout flare disease states.

	Scenarios based on recollection of past flares				Hypothetical scenarios			
Disease state	Past 6 months		Past 12 months		Past 6 months		Past 12 months	
Remission vs non-remission	1 or less	SN:79% SP:60%	1 or less	SN: 69% SP:62%	No flares	SN:67% SP:20%	No flares	SN: 53% SP: 22%
LDA vs non-LDA	1 or less	SN:65.0% SP:77.1%	1 or less	SN:50.4% SP:82.4%	No flares	SN:49.8% SP:30.2%	No flares	SN:44.4% SP:40.1%
PASS vs non-PASS	1 or less	SN:71.3% SP:79.7%	No flares	SN:33.7% SP:97.3%	1 or less	SN:60.6% SP:31.0%	1 or less	SN:51.7% SP:31.6%

LDA: low-disease activity, PASS: patient acceptable state, SN: sensitivity, SP: specificity

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout flares are the most common manifestations of gout. Awareness of possible disease

presentations beyond the traditionally recognized podagra is essential for accurate and early diagnosis. Gout flares sparing the first metatarsophalangeal (MTP1) joint may be prone to misdiagnosis as physicians may not consider other patterns of joint involvement in a gout flare. We therefore examined gout flare joint patterns in two large gout cohorts.

Methods: We used data from the Boston Online Gout Study (BOGS), a longitudinal internet-based case-crossover study recruited from the community in the US, and the Study for Updated Gout Classification Criteria (SUGAR), a single time-point international cohort of patients presenting to Rheumatology clinics, to identify patterns of joint involvement and their frequency in gout flares through latent class analysis. In BOGS, we analyzed the joints affected in the first recurrent gout flare reported during the study, while in SUGAR, we analyzed the joints affected at study enrollment. Latent class models with different numbers of classes (patterns) were evaluated, with the optimal number determined by statistical parameters, mean posterior probability of class membership, and clinical judgment.

Results: BOGS included 724 participants, 78% men, mean age 54 years, with mean gout duration of 8 years. SUGAR included 509 subjects with crystal-proven gout, 86% men, mean age 60 years and mean gout duration of 6 years. The optimal model for both studies included four patterns of predominant joint involvement, with mean posterior probability of class membership being ≥79%, indicating a good fit of the group trajectories model. In BOGS, the most common pattern was involvement of lower limb joints (including MTP1), with a prevalence of 49.8%, followed by MTP1 monoarthritis (32.5%), upper limb joint involvement (14.5%), and polyarticular flare (3.1%). Similar patterns were identified in SUGAR, with MTP1 monoarthritis (39.4%) and knee/ankle involvement (37.1%) being the most common, followed by upper limb joint pattern (14.8%) and polyarticular flare (8.6%). (Table) Of note, 43.7% and 64.2% of subjects in BOGS and SUGAR, respectively, had a gout flare in joint(s) other than the MTP1. Upper limb and polyarticular flares appeared to be associated with longer disease duration.

Table. Characteristics of gout flare joint patterns in both cohorts.

Boston Online Gout Study (N=724)	**MTP1 monoarthritis**	**Lower limb[1]**	**Upper Limb[2]**	**Polyarticular**
Prevalence (%)	32.5	49.8	14.5	3.1
N	238	368	97	21
Age, mean ± SD	54.3 ± 12.0	54.7 ± 13.0	55.1 ± 12.1	49.3 ± 10.7
Male, N (%)	187 (78.6)	294 (79.9)	76 (78.4)	11 (52.4)
Gout duration (years), mean ± SD	6.8 ± 9.0	8.1 ± 8.8	10.8 ± 11.4	9.6 ± 9.7
Study for Updated Gout Classification Criteria (N=509)	**MTP1 monoarthritis**	**Knee/ankle**	**Upper limb[2]**	**Polyarticular**
Prevalence (%)	39.4	37.1	14.9	8.6
N	177	217	72	43
Age, mean ± SD	62.4 ± 15.3	57.9 ± 14.7	64.3 ± 13.4	60.6 ± 12.8
Male, N (%)	144 (81.4)	195 (89.9)	62 (86.1)	39 (90.7)
Gout duration (years), mean ± SD	6.5 ± 7.8	8.9 ± 8.4	10.2 ± 9.6	12.0 ± 9.6

1: knee, ankle, heel, instep, first metatarsophalangeal joint, other metatarsophalangeal joint; 2: hand, wrist, elbow. MTP: metatarsophalangeal joint; SD: standard deviation.

Conclusion: We identified similar patterns of joint involvement in two large cohorts of gout patients from both the community and Rheumatology practices. While MTP1 monoarthritis was common, other lower extremity joint patterns were also common. These findings are important to increase awareness of different gout flare presentations among health care providers to improve gout flare diagnosis, including a not uncommon pattern of upper limb involvement. Importantly, lack of MTP1 involvement does not rule out the possibility of a gout flare, especially among patients with longer disease duration.

Session Date: Sunday, November 13, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is the most common form of inflammatory arthritis, with an increasing prevalence worldwide. ACR management guidelines recommend a target serum uric acid (sUA) <6 mg/dL, or <5 mg/dL in patients with tophaceous disease. Patients with significant crystal burden (tophaceous gout) are considered to have higher humanistic and economic burden of illness. These analyses describe patient and treatment characteristics and resource utilization in gout patients with and without tophi.

Methods: Data were assessed from physician surveys and in-depth patient chart audits in France, Germany, Italy, Spain, UK, and USA. Flares, organ/joint damage and tophi were extracted from clinical charts. Type/dose gout treatment, time on current therapy, physician type, and patient sociodemographic factors were identified. Demographic characteristics and comorbidities, sUA levels, and use of colchicine for acute flares during the 12-month study period were compared using chi-square or Fisher's exact tests.

Results: Of the 2505 patients identified, 612 (24. 43%) had physician-confirmed tophaceous gout and 1893 (75.57%) had non-tophaceous gout. Patients with tophi were older (61.6 vs 57.4 years), had gout for a slightly longer period (2.8 vs 2.4 years), reported more flares (3.2 vs 1.7 per year) over the last 12 months, and were more likely to have higher sUA (12-month mean 7.80 vs 7.34 mg/dL) (all $p<0.001$). Levels of comorbidities were significantly higher in patients with tophi including cardiovascular disease, chronic obstructive pulmonary disease, congestive heart failure, diabetes, depression, hypertension, osteoarthritis, and Stage III and Stage IV/V chronic kidney disease (all $p<0.001$). Patients with tophi were more likely to be treated with urate-lowering therapy (87.9% vs 72.4%; $p<0.001$). Of the urate-lowering therapies, patients with tophi were less likely to use allopurinol (52.5% vs 59.0%; $p=0.003$) and more likely to use febuxostat (28.9% vs 11.0%; $p<0.001$). Patients with tophi were more likely to use colchicine (40.7% vs 29.2%; $p<0.001$) and steroids (43.8% vs 18.7%; $p<0.001$), and less likely to use NSAIDs (35.6% vs 42.9%; $p=0.001$) for acute flares. Fewer patients with tophi achieved sUA targets of ≤6 mg/dL and no flares (15.7% vs 27.0%; $p<0.001$) or ≤5 mg/dL and no flares (5.9% vs 12.4%; $p<0.001$) versus patients without tophi. Patients with tophi made more gout-related office visits (5.18 vs 4.42; $p=0.155$) and more made ≥1 gout-related emergency visit (26.8% vs 7.9%; $p<0.001$), hospitalization (12.7% vs 2.2%; $p<0.001$), or had gout-related surgery (4.4% vs 0.1%; $p<0.001$) over 12 months.

Conclusion: Less than 30% of gout patients achieve treatment targets and patients with tophi are less likely to achieve these goals than patients without tophi. Patients with tophi have significantly greater burden of disease and greater frequency of comorbidities than patients without tophi. Preventing development of tophi or resolving crystal burden by treating to guideline targets is an important but rarely achieved goal for patients with and without tophi.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Inadequately treated patients with chronic gout are at risk for an acute attack and many often require hospitalization. An acute attack of gout increases health care costs by an average of $6000 per day. This study was conducted with two main objectives :(1) to assess whether inadequately treated gout or non-compliance with urate lowering therapy (ULT) was responsible for primary gout admission and (2) to determine whether admissions complicated by acute gout resulted in increased in-patient length of stay and how it impacts health care cost.

Methods: Data was collected for adult patients admitted between January 2010 and December 2014 at The Brooklyn Hospital Center with either a primary or secondary discharge diagnosis of Acute Gout using ICD 9 codes. Patient data included demographics, diagnoses, length of stay, gout medications. Patients were placed into two groups: Group A included persons whose primary admitting diagnosis was acute gout and Group B consisted of patients who had gout coded as an active secondary diagnosis. Group B subjects were compared with a matched cohort of 121 subjects with gout whose admission was not complicated by acute gout during the current hospitalization period of January 2010 to December 2014.

Results: 182 subjects were studied, 97(53.3%) were in group A and 85(46.7%) were in group B. 67.0% of the subjects were male with mean age of 64.80, SD +/-12.87 years. 86.3% of the subjects were African Americans. Primary admission diagnosis for Group B subjects were stroke 1.7%, Chest pain 6.0%, acute CHF 8.8%, GI Bleed 3.3%, and other diagnoses 26.9%. Only 37% of Group A subjects were on prior ULT, excluding 8 newly diagnosed cases of gout, with RR: 0.49 (95% CI, 0.37, 0.61). The mean length of stay for Group A subjects was 5.2 days and for Group B it was 8.6 days. The mean length of stay for the matched cohorts was 4.4 days. All data were adjusted for age, gender and race. Centers of Medicare & Medicaid Services, (CMS) reimbursement of primary admission diagnosis for Group B ranged from $8630 to $7900. An additional diagnosis of acute gout did not change the Diagnosis Related Groups (DRGs) resulting in no additional CMS reimbursement. CMS reimbursed $8448 per a primary acute gout admission, a sum of $819,456 for the 5years period.

Conclusion: Inadequately treated chronic gout was the main reason for primary gout admission at the Brooklyn Hospital Center between January 2010 to December 2014.The length of stay for patients whose primary admission was complicated by acute gout was nearly doubled when compared with patients admitted with a similar primary diagnosis. Increase length of stay did not result in a corresponding increase in CMS reimbursement. This study identified the magnitude and the cost associated with primary gout admissions and emphasized the need for initiation of ULT and adequate control of uric-acid levels as per the ACR 2012 guidelines, by primary care physicians in the outpatient setting in conjunction with a rheumatologist.

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is the most common form of inflammatory arthritis with a prevalence of 1.5% in our area in the age group 50-59 years. Gout has a substantial association with several comorbidities. Studies on the impact of gout on indirect costs on a population level are however scarce. The aim of the present study was therefore to describe the yearly difference in absenteeism due to sick leave (SL) and disability pension (DP) in patients with gout and matched population based controls.

Methods: Gout cases were defined in the population based health care database (VEGA) of the Western Swedish Health Care Region (WSHCR) by having a first diagnosis of gout in the years 2003-2009 by ICD-10 codes (M10 and M14.0) in VEGA. Cases were included if their age at the time of the first diagnosis of gout was ≤62 years, to allow for a follow-up period of 3 years before reaching the retirement age of 65 years. Five controls for each case, matched for age, sex and place of residence were chosen from the census register by Statistics Sweden. Data on predefined comorbidities registered previous to the index year was collected from VEGA by ICD-10 codes for cases and controls. Yearly net days of SL and DP for cases and controls were retrieved from Statistics Sweden for a period of 3 years before and after the index year. The difference between cases and controls in yearly net days lost from work due to SL and DP were calculated in the whole population, with a subanalysis of those without predefined comorbidities. Mean values with 95% CI for SL and DP days for the gout cases and controls were calculated by ANOVA, accounting for the matched design and applying non-parametric bootstrapping to calculate confidence intervals.

Results: 4571 gout cases were matched to 22482 population controls. The median age at diagnosis of gout was 53 years and 77% of the study group was male. The total number of work days lost was significantly higher for gout cases compared to the general population at the time of gout diagnosis as well as in the years preceding and following the gout diagnosis. Gout patients were absent from work on average 71 days per year while controls were absent on average 46 days per year (figure 1). In a subgroup analysis of 2546 cases and 10157 matched controls without predefined comorbidities this difference remained but was less pronounced (44 vs 31 days) (figure 2).

Conclusion: Work days lost due to SL and DP were substantially higher in patients with gout compared to controls in a population based setting. Comorbidities explained only slightly more than half of this increase suggesting that socioeconomic or other factors closely related to gout are of importance.

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : Gout is the most prominent clinical manifestation of hyperuricemia, and is the most common cause of inflammatory arthritis. The symptoms of gout (eg, intense joint pain, redness, heat, and swelling) can have a have a significant impact on patients' ability to function, with subsequent decreases in quality of life and increases in healthcare-related costs. Clinicians routinely consider gout severity when making treatment decisions, but the clinical features they use to define severity have not been well characterized. Therefore, we examined patient- and disease-related attributes of clinician-assessed gout severity.

Methods: Data were assessed from a survey of US physicians and in-depth patient chart audits. Gout severity was measured using physician global assessment. Additionally, serum uric acid (sUA) levels, flares, organ/joint damage, tophi, sociodemographic factors, and physician type (eg, primary care, rheumatologist) were identified. Descriptive and multivariate (stepwise logistic regression) statistics described differences among patients with severe vs moderate and mild gout.

Results: A total of 1159 patient charts were abstracted (185 with severe gout, 681 with moderate gout, and 293 with mild gout; 81% male; 38% ≥61 years of age; 71% white). Patients with severe gout had gout for a longer period than those with

moderate or mild disease (66 mo vs 43 mo vs 38 mo; P <0.01). Tophi were reported in almost 74% of patients with severe gout, 19% with moderate gout, but only 3% of patients with mild gout (P <0.01). Patients with severe gout reported an average of ~3 flares per year vs ~2 flares per year for those with moderate gout, and only ~1 flare per year for those with mild gout (P <0.01). There were no differences in most recent sUA levels (7.2 mg/dL severe vs 6.8 mg/dL mild and moderate; P =0.08) or the proportions of patients who reached sUA goal (39% vs 42% vs 40%; P =0.42) by gout severity. The percentage of patients using urate-lowering therapy (ULT) differed by disease severity: 91% with severe, 80% with moderate, and 49% with mild (P <0.01). A model predicting gout severity found that having tophi or a greater number of flares per year, being female or of low social economic status, and having chronic heart failure, diabetes, or osteoarthritis were significant predictors of severe disease.

Conclusion: In this analysis, physician-assessed gout severity was more dependent on gout-specific attributes (tophi and flares), gender, socioeconomic status, and comorbidities than sUA (which was not a good indicator of gout severity). The lack of difference in sUA levels by gout severity may, in part, be a result of more patients with severe gout reporting use of ULT. These results should help physicians identify patients with factors aside from high sUA, who may be at risk of more severe gout, and who may require more careful monitoring and intensive management.

A Survey of Knowledge of Optimal Gout Management in an Academic Primary Care Setting

Stefanie Wade[1] and Micha Abeles[2], [1]Medicine, University of Connecticut Health Center, Farmington, CT, [2]Rheumatology, Consulting Rheumatologist, Midstate Medical Center, Meriden, CT

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We reviewed previous treatment approaches for gout in patients referred to a university rheumatology practice for gout management. All patients met the 2015 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) gout classification criteria. We observed a paucity of concomitant prophylactic treatments that included non-steroidal anti-inflammatories (NSAID's) and colchicine. We also observed that treat to target of serum uric acid levels was lacking. This prompted a survey of primary care physicians and medical residents to evaluate the educational gaps that might be a focus of further medical education.

Methods: A standard questionnaire was developed using input from senior rheumatologists. A core set of principles for the treatment and prevention of gouty arthritis based on the ACR/EULAR recommendations was utilized. All primary care physicians and medical residents from an academic university medical center were invited to participate in an anonymous electronic survey. Participants were requested to avoid researching or reading about management of gouty arthritis prior to survey completion. The survey was sent from the office of the Internal Medicine program director to help in improving response rates.

Results: One hundred and one out of two hundred and eight invitees, (or 48.6 percent,) completed the survey. Ninety-two percent of respondents were resident physicians and 8 percent of respondents were primary care attending physicians. Seventy-two percent of respondents felt comfortable or very comfortable in managing gout. Twenty-six percent indicated that they were very uncomfortable in gout management. Two percent of respondents indicated they would refer to a specialist for all gout management. When asked to identify a treatment target of serum uric acid only 30 percent were able to do so correctly. Fifty-six percent of respondents reported using colchicine in under one-half of the cases. Thirty-four

percent of the respondents had never prescribed concomitant colchicine.

Conclusion: In our academic setting there was a lack of knowledge of the 2015 ACR/EULAR gout classification criteria and the 2012 ACR approach to management. For the most part this was in resident physicians. Too few attending physicians answered the questionnaire to be able to make any conclusions regarding their understanding of treatment for gout. Our data suggests a divergence of current clinic practices in gout treatment by residents from the recommended management guidelines. We suggest that this indicates better dissemination of knowledge to physicians in training is needed.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is the most frequent inflammatory arthritis in males, and therefore a common cause for consultation in both primary care and specialist settings. Despite its frequency, the diagnosis and treatment for this condition are far from desirable. There is evidence of gout management improvement through educational programs targeted at primary care physicians. Objective: To measure the impact in diagnostic and therapeutic attitudes towards patients with gout, in primary care physicians, before and after performing an educational intervention based on a clinical case.

Methods: Through a training program aimed at general physicians with interest in musculo-skeletal diseases, an initiative of the Sociedad Española de Reumatología [Spanish Rheumatology Society] and the Sociedad Española de Médicos de Atención Primaria [Spanish Society for Primary Care Physicians], sessions were held in 6 Spanish locations. In the sessions, a general physician presented a clinical case about a patient with hyperuricaemia, intermittent arthritis, condrocalcinosis in knee joints and several associated comorbidities. In first place, 5 questions with multiple-choice answers were formulated, regarding the diagnosis and treatment deemed appropriate. Later, the case was evaluated and discussed by a rheumatologist, and the same questions were repeated. Answers were recorded by electronic means.

Results: A total of 195 physicians, divided in 6 locations, attended the sessions. Statistically significant results for each evaluated area are summarized below: Diagnosis: initially 21.8% of the attendants deemed arthrocentesis necessary for the diagnosis, but complementary investigations appeared to be more important (67.3%). Afterwards, a significant increase in the need for arthrocentesis was observed (46.7%). Comorbidities: 52.6% of the attendants decided to prescribe a non-steroidal anti-inflammatory drug (NSAID) to the fictional patient, with chronic kidney disease. After the discussion, the broad majority of assistants opted for alternatives such as steroids (41.23%) and only 4.74% still preferred NSAIDs. Initial complexity for diagnosis: a small percentage (12.7%) considered that a solid diagnosis was not possible without a sample of synovial fluid. This percentage rose up to 55.5% after the intervention. Prophylaxis: Colchicine-based prophylaxis was prescribed initially by 57.4% of physicians, and after the session, by most of them (71.6%). Urate lowering drugs: A change was observed in the use of urate lowering medications, from an initial 64.7%, up to 85.1% after the discussion. There was a reduction in the number of referrals to specialists, but it was not statistically significant.

Conclusion: Through educational initiatives for primary care physicians it is possible to optimize the perception of diagnosis and treatment in patients with gout.

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To date, most studies of gout and cardiovascular disease have been cross-sectional or retrospective, and have addressed the outcome of acute coronary syndromes. Less is known regarding the impact of gout on basic vascular health, including arterial endothelial function. We asked whether initiating gout treatment with colchicine and urate-lowering therapy (ULT) reduces inflammation (CRP), and improves endothelial function as measured by brachial artery flow-mediated dilation (FMD).

Methods: Gout patients initiating treatment with their physicians were enrolled. Physicians agreed to follow a care strategy that sequenced colchicine and ULT (allopurinol or febuxostat) initiation. Demographics and cardiovascular risk factors were recorded, and CRP and FMD were measured at baseline, after 6 weeks of colchicine (0.6 mgs daily), and again 4 weeks after ULT had been titrated to clinical target (<6.0 mg/dL; <5.0 mg/dL for patients with tophi) in the presence of continuing colchicine.

Results: 34 untreated male gout patients (mean age 57.9 years) were enrolled. To date, 32 have completed post-colchicine, and 22 have completed post-ULT assessments. CRP decline was observed from baseline to post-colchicine and further to post-ULT (total change from baseline, 0.207 mg/dL) (Figure). Overall we observed no net FMD improvement post-colchicine, but patients who experienced CRP reduction post-colchicine had higher rates of FMD improvement than CRP non-responders (58.8% versus 25.0% FMD response). We stratified the overall cohort based on smoking status, and observed greater rates of post-colchicine improvement in both FMD and CRP in the non-smoker, compared with the smoker group. FMD improvement occurred in 60.0% of non-smokers versus 38.1% of smokers; CRP improved in 75% of non-smokers versus 52.4% of smokers. Non-smokers with CRP improvement were also more likely than non-smoker CRP non-responders to demonstrate FMD improvement (66.7% versus 50% response rate). Baseline to post-ULT trends in CRP improvement were also more pronounced in the non-smoker group, with 75% of non-smokers versus 56% of smokers experiencing a CRP decrease. Analysis of FMD outcomes in patients post-ULT is ongoing.

Conclusion: This prospective observational pilot study suggests that treatment with colchicine and ULT is associated with an overall reduction in CRP. Among patients whose CRP declined, FMD also tended to improve, suggesting a common beneficial effect. Smoking appears to hinder improvement in inflammation and vascular function in response to colchicine and ULT. Data from the third and final (ULT) stage of the study are still being collected with analyses ongoing. Larger and longer studies may be warranted to confirm the anti-inflammatory and pro-vascular benefits of colchicine and ULT in

patients undergoing gout treatment initiation._

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a disease triggered by the crystallization of uric acid in the joints secondary to persistent hyperuricemia, that leads to chronic inflammation. Patients with gout frequently have comorbidities including cardiovascular (CV) disease, kidney failure, diabetes mellitus etc. In fact, some these can increase the levels of uric acid and contribute to develop gout, and also deteriorate the CV profile of these patients. The aim of the present study was to assess the prevalence of unknown cardiovascular risk factors (CVRF) in patients with gout.

Methods : Cross-sectional analysis of a inception cohort of gout patients recruited by consecutive sampling in our rheumatology unit. Gout was diagnosed by visualization of monosodium urate crystals in synovial fluid or tophus sample. A structured CV assessment included CVRF, measurement of blood pressure, anthropometry and lab tests. Arterial Hypertension (AH) was defined by previous diagnosis, blood pressure ≥140/90mmHg and/or use of antihypertensive agents. Type 2 Diabetes Mellitus (DM-2) was defined by previous diagnosis, fasting blood glucose ≥126 mg/dL, glycosylated haemoglobin ≥6.5%; presence of microangiopathic complications was also registered. Dyslipidemia (DLP) was defined by previous diagnosis, use of hypolipidemic agents, or total cholesterol >200 mg/dL and/or triglycerides > 150 mg/dL. A descriptive analysis of the results is presented.

Results : The study involved 199 patients. The mean age was 63.4 (SD+/- 13.2) years, with 171 (85.9%) men. At inclusion the prevalence of CVRF was: AH in 136 patients (68.3%), DLP in 13 (51.8%), and DM-2 in 47 (23.6%). Seventy-six (38.6%) were found obese, smoking background was present in 40 (20.1%), use of diuretics (loop and/or thiazide) in 87 (43.7%), and chronic renal failure in 57 (28.6%). After structured assessment, the following undiagnosed CVRF were found: DLP in 59 patients (29.6%), AH in 20 (10.1%) and DM-2 in 14 (7%) [Figure]. New CVRF were found in 94 (46.7%) patients, among them 52 (26.1 %) had one CVRF, 13 (6.5%) had 2 CVRF, and even 3 CVRF were

identified in 2 cases (1.0%).

Conclusion : Half of our patients showed at least one unknown CVRF, mostly DLP followed by hypertension and DM-2. This finding highlights the need for active screening for new CVRF in patients diagnosed with gout, due to the potential impact on the proper CV management.

Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Coexistent RA and gout were previously believed to be exceedingly rare due to several hypothesized mechanisms encompassing inhibition of crystal formation, deposition, and activation. While now well recognized to coexist, the influence of gout on RA disease measures, medication selection, and long-term outcomes remains unknown. We aimed to assess the associations of comorbid gout with RA measures, treatments, and outcomes.

Methods: Participants in a longitudinal observational cohort of US veterans with RA fulfilling the 1987 ACR criteria were screened for gout within national administrative data for 12 months prior to enrollment using the Healthcare Cost and Utilization Project Clinical Classification Software and within the registry database for urate lowering medications or colchicine. Gout was confirmed by the presence of a physician diagnosis of gout in electronic medical records. Patient characteristics, RA measures, and medications were obtained from the registry, and vital status was determined using linkage with the National Death Index. We compared baseline characteristics using chi-square and independent t-tests. We studied the associations of gout with RA disease characteristics and medication use using multivariable logistic and linear regression models and all-cause mortality with multivariable Cox proportional hazards regression models.

Results: In 2,068 participants (91% male), we identified 107 with coexistent gout (5.2%). At enrollment, RA & gout was associated with older age, higher body mass index, comorbidity, swollen joint count, functional disability, and less frequent shared epitope alleles and NSAID use (Table 1). There were non-significant trends toward less seropositivity and lower autoantibody titers in RA & gout. Odds of ever receiving prednisone, DMARDs, and biologics did not differ between RA and RA & gout (all $p>0.54$). The odds of ever achieving DAS28 (OR 0.72, 95% CI 0.48-1.07, $p=0.11$) or CDAI (OR 0.67, 95% CI 0.41-1.11, $p=0.12$) remission were less common in RA & gout vs. RA alone, although these associations were not statistically significant. Gout was not associated with all-cause mortality (multivariable HR 1.14, 95% CI 0.72-1.80, $p=0.57$) among RA patients.

Conclusion: To our knowledge, this is among the largest studies of coexistent RA and gout described to date. The male predominance, older age, and high comorbidity of participants in the cohort make it an ideal setting for the study of coexistent RA and gout. Gout is associated with demographic and genetic parameters, higher comorbidity burden, and RA measures including higher swollen joint counts and functional disability. These findings highlight the need for identification and treatment of comorbid gout and further study to better understand the mechanisms underpinning these differences and the potential impact that gout therapies might have on RA outcomes.

Session Date: Sunday, November 13, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster I: Clinical Practice
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Calcium pyrophosphate deposition disease (CPDD) is an often un-recognized form of acute and chronic arthritis preferentially affecting the elderly. Some controversy exists about a possible association of rheumatoid arthritis (RA) with CPDD. While early studies suggested that RA and CPDD rarely overlapped, more recent data suggest that CPDD may be more common in patients with RA than in the general population. Possible explanations for this association include diagnostic confusion, higher imaging rates in patients with existing arthritis, or increased deposition of CPP crystals in the damaged RA cartilage. The purpose of our study was to describe a cohort of well-characterized patients with both CPPD and RA, and to generate possible hypothesis about the nature of the relationships between these diseases.

Methods: After approval from the local IRB, a cohort of patients with both RA and CPDD was collected from a university based rheumatology clinic. Patients were identified by participating providers and were included if they satisfied ACR criteria for RA and had CPDD noted radiographically or by synovial fluid crystal identification. A total of 21 such patients seen in the year 2015-2016 were selected for further analysis. Their records were reviewed and analyzed for age, sex, age of RA onset with the diagnosis based on ACR criteria, age of CPDD onset (using either crystal identification or chondrocalcinosis), pattern of joint involvement , joint surgeries, and laboratory values, including rheumatoid factor (RF), cyclic citrullinated peptide antibody (CCP), iron studies, PTH , and calcium levels.

Results: This cohort with both RA and CPDD had a mean age of 75 years, with a mean age of RA onset of 53 years. Two thirds were women and most were seropositive. Medications included typical DMARDs and biologics for 18/21 patients. One was on no medications, and two were on low dose prednisone. The mean age of CPDD onset was 69.9 years, with the mean RA disease duration prior to the onset of CPDD of 13.4 years. One patient had a simultaneous diagnosis of both RA and CPDD. The majority of the patients were diagnosed with CPDD based on the presence of chondrocalcinosis (15/21) and the most commonly involved joint was the knee. Other involved joints were typical of the joint pattern seen with CPDD. Three patients underwent joint replacement of the joints involved with CPDD. No patient had significant abnormalities of PTH levels or elevated iron levels. Calcium supplements were used in about 50% of patients.

Conclusion: The results of our study support existing data that CPDD tends to co-occur with RA after years of disease. The typical demographics of CPDD and its pattern of joint involvement are preserved in patients with RA who develop CPDD, and thus association is not likely to be due to diagnostic confusion. Further studies to understand the connection between these diseases are warranted. Table 1. Patient characteristics

Patient characteristics	
Mean age (years) at study onset	75 (range 57-92)
Women: Men	14:7
Mean age at RA diagnosis (years)	53 (range 20-85)
Mean age at CPDD diagnosis (years)	69.9 (range 47-86)
Mean RA duration prior to CPDD onset (years)	13.4 (range 0-36)
RF +/total available values	12/14
CCP+/total available values	8/8

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The intrathoracic manifestations of IgG4-related disease (IgG4-RD) have been described in only a limited number of patients. No prior studies have provided detailed descriptions of the clinical, radiological, and pathology features of IgG4-related lung disease (IgG4-RLD) in patients from North America.

Methods: We reviewed a cohort of IgG4-RD patients to identify those with intrathoracic disease manifestations. The medical records of 143 subjects with clinicopathologic diagnoses of IgG4-RD were screened to determine which had undergone computed tomography (CT), positron emission tomography (PET), or magnetic resonance (MR) imaging of the thorax. All thoracic imaging studies were reviewed by two thoracic radiologists to document intrathoracic manifestations of IgG4-RD. Data pertaining to patient clinical characteristics, radiologic features, and pathology were collected and analyzed.

Results: Sixty-three subjects had undergone CT, PET, or MRI studies of the chest. Of these, 36 had intrathoracic manifestations consistent with IgG4-RD. Twenty-seven (75%) of these subjects had involvement of the lung, pleura, or both. Intrathoracic manifestations typically occurred in the setting of systemic IgG4-RD, but 75% of the patients with intrathoracic disease had no respiratory symptoms at the time of imaging. Mediastinal/hilar lymphadenopathy, detected in 25 patients (69%), was the most common intrathoracic imaging manifestation. Airway disease consisting of bronchial wall thickening was also commonly noted (50%, 18 patients). Pulmonary nodules were identified in 12 patients (33%). Interlobular septal thickening (28%, 10 patients) and subpleural reticulation (11%, 4 patients) were also observed. Airspace disease consisting of consolidation was also noted in six patients (17%) and ground glass opacity in ten patients (28%). Other intrathoracic manifestations included pleural disease (25%, 9 patients), pericardial disease (8%, 3 patients), vascular involvement (aortitis, pulmonary arteritis, coronary arteritis) (14%, 5 patients), and paravertebral masses (22%, 8 patients). Follow-up with regard to treatment response of intrathoracic findings (defined as improved/stable clinical or radiological findings) to prednisone was available in 12 patients. On prednisone, 8 of 12 patients (66.7%) demonstrated overall improvement or stability of their disease. Follow-up to rituximab treatment was available in 11 cases. On rituximab, ten out of 11 patients (90.1%) demonstrated improvement or stable disease.

Conclusion: In conclusion, the heterogeneity of intrathoracic IgG4-RD manifestations pose significant challenges in diagnosis. The radiologic findings in the lung, in particular, are more diverse than any other organ commonly affected by this disease. Many patients with IgG4-RLD are relatively asymptomatic despite substantial burdens of disease within the lung. The intrathoracic manifestations of IgG4-RD responded well to glucocorticoids and B cell depletion. Because effective treatment is available for IgG4-RD, detection and treatment of disease this asymptomatic stage may lead to better patient outcomes.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

IgG4 related disease (IgG4-RD) is a systemic disease that is characterized by the infiltration of IgG4secreting plasma cells and effector T cells into various organs. However, the characteristics and pathological role of immune cell subsets remain unclear. The aim of this study was to investigate the characteristic phenotype of immune cell subsets in IgG4-RD.

Methods:

Peripheral blood mononuclear cells were obtained from 16 patients with IgG4-RD, 4 with primary Sjogren syndrome (pSS) and 23 healthy donors (HD). The phenotype of circulating B cells, T cells were defined based on comprehensive flow cytometric analysis for human immune system termed 'the Human Immunology Project' by NIH/FOCIS. $CD4^+Bcl\text{-}6^+$ T follicular helper (Tfh) cells were detected by immunohistochemistry in salivary glands obtained by the biopsy.

Results:

Baseline characteristics of patients with IgG4-RD were (means); age 60 years old, symptom duration 19 months, serum IgG 2735 mg/dl, IgG4 694 mg/dl, CRP 0.7 mg/dl. The proportions of $CD3^+CD4^+CD45RA^-CCR7^-$ effector memory T cells, $CD3^+CD4^+CD45RA^+CCR7^-$ effector T helper cells increased, whereas naive T cells decreased in IgG4-RD, compared to HD and pSS. There was no difference in the proportion of well known helper T cell subsets (Th1, Th17, and Treg) between IgG4-RD, pSS and HD. On the other hand, the proportions of $CD4^+CXCR5^+ICOS^+$ Tfh and $CD19^+CD20^-CD27^+CD38^+$ plasmablasts were significant higher in IgG4-RD, compared to pSS and HD. Moreover, the proportion of Tfh in peripheral blood tended to be higher in patients whose Tfh more densely accumulated in the salivary gland. Among multiple immune cell subsets, the proportion of Tfh and that of plasmablasts were positively correlated, revealing statistical clustering. Of note, the percentage of plasmablasts was correlated with serum IgG levels. Furthermore, the proportion of plasmablasts and that of Tfh were higher in patients with extra glandular manifestations, compared to patients without them. After treatment with glucocorticoids, the proportion of plasmablasts and that of Tfh decreased with the improvement of clinical manifestations.

Conclusion: These results revealed that the higher proportion of Tfh cells and plasmablasts is characteristically observed in IgG4-RD. The frequency of Tfh was correlated with that of plasmablasts, and the Tfh/plasmablast axis contributed to

organ manifestation of IgG4-RD. Our findings would clarify the pathogenesis of IgG4-RD through the interaction between Tfh cells and plasmablasts and suggest a potential as the therapeutic target of this disease.

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immunoglobulin G4-related disease (IgG4-RD) is a recently defined entity characterized by a diffuse or mass forming inflammatory reaction rich in IgG4-positive plasma cells. Due to the fact that IgG4-RD was only fully described in the past decade, the epidemiology and prevalence of this disease is still not understood. It is likely that many pathology specimens prior to this time period were not recognized as IgG4-RD.The purpose of this study is to identify IgG4-RD in a by retrieving archived pathological slides originally diagnosed as idiopathic sclerosing masses, fibrosis or chronic inflammation in our tertiary care center.

Methods: This is a retrospective review of archived pathological slides at Westchester Medical Center from the years 2005-2015.We initially retrieved 105 cases using various search criteria from the Pathology database. Of these, 23 cases were included in this study, which fulfilled our final inclusion criteria of biopsy-proven idiopathic sclerosing masses, fibrosis and/or chronic inflammation. Immunohistochemical stains were performed on these specimens including IgG4. In this study we defined IgG4–RD as immunohistochemistry (IHC) > 10 IgG4+ plasma cells/ HPF and IgG4+/IgG ratio>40%, as well as the presence of characteristic histopathology architecture (dense lymphoplasmacytic infiltrate, storiform fibrosis and obliterative phlebitis) [1,2]. Other epidemiological data obtained were age, gender, organ involved and original tissue pathology diagnosis.

Results: Thirty-four percent of the biopsies (n=8/23) were reclassified as IgG4-RD. The most common original histological diagnosis for the eight reclassified specimens was chronic sialadenitis (Table Image) with submandibular gland most frequently involved, followed by parotid gland and retroperitoneal mass. The reclassified specimens were more common in females (5/8) and those above ages 60 (5/8).

Conclusion: This is the only known reported retrospective review study of archived pathological slides for IgG4-RD. The results highlight the ability to reconsider diagnosis, if needed, by performing appropriate immunohistochemical analysis on archived specimens to identify IgG4-RD. Chronic sialadenitis was the most common mimicker of IgG4-RD. **Reference :** 1. Deshpande V, et al. Consensus statement on the pathology of the IgG4-related disease. Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have implicated the increased risk of malignancy in patients with immunoglobulin G4-related disease (IgG4-RD). Hence, we first evaluated the risk and the type of malignancy in Korean patients with IgG4-RD.

Methods: Clinical and laboratory results of patients with IgG4-RD according to the comprehensive diagnostic criteria for IgG4-RD were retrospectively collected using Clinical Data Repository in Severance Hospital, Seoul, South Korea, between January 2006 and November 2015. One hundred and eighteen patients were included, and 35 were classified as having definite, 70 as possible and 13 as probable IgG4-RD. We compared baseline clinical and laboratory variables between patients with definite and those with possible/probable IgG4-RD. Also we calculated the standardized incidence ratios (SIRs) for malignancies using the data from the Korea Central Cancer Registry.

Results: The median age was 60.0 years old, and 91 patients (77.1%) were male. Malignancies were found in 12 of 118 patients (10.1%), and lymphoma (4, (25.0%)) was the most frequent malignancy related to IgG4-RD. Comparison of patients with definite and possible/probable IgG4-RD revealed that definite IgG4-RD patients had higher serum IgG level and frequent multiple organ involvement. Analysis of SIRs elucidated that overall incidence of malignancy was increased in patients with IgG4-RD compared to the general population (SIR 23.08 [95% CI 11.92, 40.31]), and the overall risk of SIRs was highest in Non-Hodgkin lymphoma (SIR 400.00 [95% CI 109.00, 1024.00]).

Conclusion: Our data showed that the increased risk of malignancy, especially lymphomas, was observed in Korean patients with IgG4-RD compared to general population.

The Relationship Between Serum Cholinesterase, Number of Organ

Involvement and Fibrotic Markers in Japanese Patients with IgG4-Related Disease

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the relationship between serum cholinesterase (ChE) level, number of organ involvement, serum fibrotic markers and imaginational outcome in Japanese patients with IgG4-related disease (IgG4-RD).

Methods: The clinical symptoms, laboratory, pathological and FDG-PET/CT findings of Japanese patients with IgG4-RD (n=20) were assessed. Several laboratory data of IgG4-RD with multiple organs' involvements (IM) (n=10), IgG4-RD with limited organ's involvement (IL) (n=10), ANCA-associated vasculitis (AAV) (n=10) and Sjogren syndrome (SjS) (n=10) were comparatively examined. Furthermore, we studied the relationship between the numbers of organ involvement (NOI), several fibrotic markers (ELF score and serum Dkk-1) and imaginational outcome in IgG4-RD group.

Results: Serum ChE levels were significantly lower in IM group than IL, AAV and SjS groups. In total IgG4-RD cases, ChE levels inversely correlated with NOI and fibrotic score, and fibrotic score positively correlated with NOI. Finally, Dkk-1, one of Wnt inhibitors, levels in IM were significantly lower than IL and healthy subjects ($p<0.05$). Moreover, low level of Dkk-1 before and after treatment tended to predict the progression of organ atrophy.

Conclusion: The ELF score and serum Dkk-1 level might be clinically useful indicators of active fibrosis and the extent of IgG4-RD. Notably, continuous lower levels of Dkk-1 were related to organ atrophy and serum ChE levels could predict these phenomena.

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a systemic inflammatory disease characterized by an elevated serum level of IgG4, infiltration of IgG4-positive cells in affected organs and fibrosis, and is becoming widely recognized. Recently, some reports have described the relationship between IgG4-RD and malignancy. However, patient background factors such as affected organs and ethnicity in these reports were different. Furthermore, only a few reports analyzed IgG4-RD patients with malignancy who were treated by rheumatologists. This prompted us to analyze the clinical features of IgG4-RD patients with malignancy.

Methods: Between November 2004 and September 2015, we retrospectively evaluated 84 patients with IgG4-RD in our hospital. We analyzed the prevalence of malignancy, relationship between the appearance of malignancy and diagnosis of IgG4-RD, type of cancer, and related factors. We compared mean age, gender, laboratory data, affected organs and therapy between the malignancy and non-malignancy groups. We also analyzed the standardized incidence ratio (SIR) of newly recognized malignancy after the diagnosis of IgG4-RD.

Results: There were 53 and 31 male and female patients, respectively with a mean age of 64.9 (range 41-81) years. Average observation period was 4.6 years. Mean serum levels of IgG and IgG4 were 2324±1040 mg/dL, 704±644 mg/dL. The mean number of affected organs was 2.8. The affected organs were as follows: salivary glands (53.6%), lacrimal glands (48.8%), lung (36.9%), retroperitoneum/ periaorta (29.8%), kidney (23.8%) and pancreas (21.4%). Twenty-one malignancies developed in 18 of 84 patients (21.4%), before the diagnosis of IgG4-RD in 11 malignancies in 11 patients (mean 4.3 years earlier, range 0.6-14 years), and after 10 malignancies in 9 patients (mean 1.7 years later, range 0-9 years). Colon cancer, prostate cancer and malignant lymphoma (ML) were seen in three patients each, and gastric, lung and renal cancers and in two patients each. ML developed after the onset of IgG4-RD in all patients. Only two patients developed malignancy in the same organ as affected by IgG4-RD. No significant differences were seen in mean age, gender, laboratory data, affected organs and the prevalence of corticosteroid therapy or the mean dose of prednisolone. We analyzed SIR of newly recognized malignancy after the diagnosis of IgG4-RD in 83 patients who were observed for more than one year. We found that SIR within one year of diagnosis of IgG4-RD was 4.62 and that of the total period of observation was 1.92.

Conclusion: The present study clarified the incidence, timing, type of malignancy in patients with IgG4-RD treated by rheumatologists. Malignancies developed at a high frequency. However, no specific characteristics were identified, making periodic screening for malignancy of particular importance.

Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

<span">

Background/Purpose: IgG4-related disease (IgG4-RD) is a recently recognized systemic inflammatory disorder that can affect many organs. It frequently causes retroperitoneal/periarterial lesions, which are referred to as IgG4-related retroperitoneal fibrosis/periarteritis (RF/P). However, clinical and laboratory features of this disease have not been well clarified. This study aimed to clarify the clinical and laboratory features of IgG4-related RF/P. <span">

Methods: We retrospectively evaluated clinical features including subjective symptoms, laboratory data, and imaging findings at diagnosis in 99 patients (pts) diagnosed with IgG4-related RF/P by experienced physicians. The diagnosis of this disease was made principally on the basis of the presence of consistent retroperitoneal/periarterial radiological findings, the fulfillment of the comprehensive diagnostic criteria or each set of organ-specific diagnostic criteria, and exclusion of other diseases. <span">

Results: Eighty-four pts were men, and 15 were women (average age 67.4 years). At diagnosis, 42.4% of pts presented subjective symptoms including pain (23.2%), fever (8.1%), and edema (4.1%). Allergic predisposition was found in 37.4% of pts. Hydronephrosis was detected in 21.2%. Current or past smoking was present in 65.4%.<span">IgG4-related other organ involvement was detected in 69.7%, and the average number of involved other organs was 1.9 (range: 0-8). Serologically, the average serum IgG4 level was 851 mg/dL (range: 59-3610), and 91.8% of pts had serum IgG4 > 135 mg/dL. Hypocomplementemia was observed in 24.4%. An elevated serum C-reactive protein (CRP) level (> 1 mg/dL) was found in 23.6%. The affected aorta/artery comprised mainly 8 thoracic aortas, 67 abdominal aortas, 50 iliac arteries, 8 mesenteric arteries, and 9 coronary arteries. Luminal dilatation of the affected lesions at diagnosis was observed in 26.3% of pts. On the other hand, 24.3% had retroperitoneal, periureteral, or renal pelvic lesions.<span"> Compared with pts without biopsy of the retroperitoneal/periarterial lesions, pts with it showed significantly lower serum IgG4 levels (643 vs 953 mg/dL, *P*=0.011) and IgG4/IgG ratio (23.9 vs 31.1 %, *P*=0.022), higher serum IgE (1,533 vs 543 IU/mL, *P*=0.020) and CRP levels (1.65 vs 0.56 mg/dL, *P*=0.025), lower incidence of other organ involvement (30.3 vs 86.4 %, *P*<0.001) and allergy (21.2 vs 45.5 %, *P*=0.027), and higher incidence of luminal dilatation (42.4 vs 18.2 %, *P*=0.015), pain (36.4 vs 16.7 %, *P*=0.043), and current smoking (58.8 vs 26.6 %, *P*=0.020). Multivariate logistic regression analysis indicated that the presence of other organ involvement [Odds ratio (OR); 0.011, *P*<0.001], serum CRP elevation (OR; 3.81, *P*=0.002), and the presence of iliac artery lesion (OR; 0.049, *P*=0.008) had an independent influence on the performance of biopsies of the retroperitoneal/periarterial lesions.

Conclusion: The present study clarified the clinical and laboratory features of IgG4-related RF/P, and suggested the possibility that biopsy of the retroperitoneal/periarterial lesions was avoidable in pts with other organ involvement.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Eosinophilic angiocentric fibrosis (EAF) is a rare localized fibro-inflammatory lesion involving usually upper respiratory tract and the orbit. It could mimic ENT manifestations of systemic vasculitis particularly GPA. The diagnosis is based on characteristic histologic findings with a mixed inflammatory infiltrate with eosinophils and fibrosis around small caliber arteries with « onion-skin » pattern. Some autors suggest that EAF is a part of the spectrum of IgG4-related systemic disease.

Methods: We report 3 cases of histology-proven EAF. Demographic, clinical, biological, radiologic and histological features are examined. The 3 patients had a 18-fluorodeoxyglucose positron emission tomography (FDG PET) and evaluation of circulating total plasmablast count (CD19low, CD38+, CD20-, CD27+).

Results: table Two females and one male patients were aged from 29 to 50 years. The disease involved the nasal cavity in two cases and the subglottic area in the third case. The demographic, biological and clinical features (table) were consistent with reports of EAF published previously. All cases demonstrated a dense fibrotic stroma with a perivascular onion skin type pattern and an inflammatory infiltrate with eosinophils, lymphocytes and plasma cells. No vasculitis, granuloma formation or necrosis were identified in any of these cases. All patients had a radiological evaluation with a computed tomography (CT) and a FDG-PET. CT evaluations showed expanding soft tissue masses into the maxillary sinus and anterior nasal cavity in 2 cases and soft tissue thickening in the sub-glotting region of the larynx in one case. There was bone destruction in one case. The FDG-PET showed an enhanced FDG uptake of the EAF lesion. No other abnormal hypermetabolic foci were detect on this exam. The serum IgG4 concentration was normal in the 3 cases (from 23 to 50 mg/dL). The circulating plasmablast count was increased in 2 cases (6728/mL et 2958/mL) and normal in the third patient (508/mL). Two patients received glucosteroids associated in one with colchicin without efficiency. Patients with sinonasal lesion underwent partial surgical excision with relapse in the 2 cases. Patient with the subglottic stenosis was improved by endoscopic dilatation.

Conclusion: EAF is an unrecognized entity mimicking a necrotizing vasculitis limited to upper respiratory tract. FDG PET confirms that EAF is a limited pathology without extra-ENT involvment. The anatomopathology examination by an experienced pathologist is the cornerstone of the diagnosis. Despite some differences, EAF share many characteritics with IgG4 related disease like clinical presentation, similar histologic pattern and increase of plasmablast count.

	Patient 1	Patient 2	Patient 3
Sex/Age (years)	F/34	M/50	F/29
Manifestation	Broad nasal ridge	Saddle nose deformity	Erosive rhinitis/suglottic rhinitis
Blood cell count	Normal	Normal	Normal

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

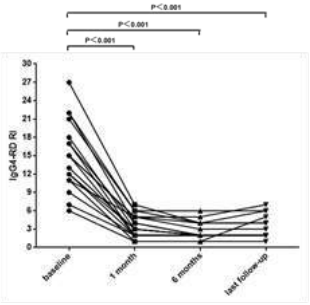
Background/Purpose: Good response could be observed after applying glucocorticoids (GCs) in patients with IgG4-related disease (IgG4-RD), however, the risk of disease relapse was reported relatively high during or after GCs tapering. Recurrent relapses may lead to more damages precipitated in involved organs and high cumulative dose of GCs correlating to severe adverse effects. Hence, it¡¯s important to find an effective immunosuppressive agent (IM) to maintain remission in IgG4-RD. However, to date, studies about IMs in IgG4-RD are all exploratory and the existing evidences are far from enough to identify which IM is more effective. This study was conducted to identify the efficacy and safety of leflunomide (LEF) combined with GCs in treating IgG4-RD.

Methods: Data of patients diagnosed as IgG4-RD between November 2012 and November 2015 were summarized retrospectively. Only patients treated by LEF plus GCs and had been followed up with more than 3 visits and 6 months were enrolled. During all subsequent visits, clinical symptoms, laboratory and imaging findings, changes in treatment, LEF-related adverse events and disease activity reflected by IgG4-RD Responder Index (IgG4-RD RI) were obtained. All available medical records were reviewed combined with additional information through telephone follow-up. Clinical outcomes were assessed by IgG4-RD RI as well as laboratory and imaging examinations.

Results: Eighteen patients including 14 untreated patients and 4 retreated patients with relapsing disease were enrolled. The mean (S.D.) onset age was 54.0 (9.6) years with a male to female ratio of 2.6:1. The mean (S.D.) follow-up period was 11.1 (6.9) months. All patients had active disease with mean (S.D.) IgG4-RD RI of 15.0 (5.6) at baseline and obtained disease response at 1 month. At the last follow-up, the mean (S.D.) IgG4-RD RI was declined to 3.1(1.7) and was 2.5(1.2) in patients without relapse. The mean (S.D.) serum level of IgG4 was declined from 1451.2(1956.8) mg/dl to 254.5(321.1) mg/dl. GCs were all tapered to maintenance dose at 6 months and the mean (S.D.) dose was 7.3 mg/d at the last follow-up. 66.7% (12/18) and 61.1% (11/18) patients were in remission at 6 months and the last follow-up, respectively. 16.7% (3/18) patients relapsed in the clinical course. Adverse effects (AEs) were observed in 1 patient with elevated hepatic enzymes and 1 patient with rashes. These AEs resolved immediately after withdrawn of LEF.

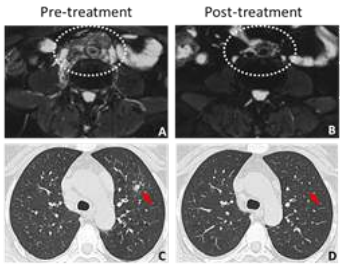
Conclusion: LEF and GCs combination therapy is effective in treating IgG4-RD with a few reversible adverse effects, and LEF is a promising steroid-sparing agent for IgG4-RD.

Figure 1 IgG4-RD RI during the follow-up period



IgG4-RD Responder Index (IgG4-RD RI) decreased at 1 month, 6 months and the last follow-up compared with baseline.

Figure 2 Imaging findings of two patients with IgG4-RD



(A and B) MRI T_2-weighted(T_2W) images of retroperitoneum in a 53-year-old man (Patient 10). A decrease in dimension of retroperitoneal fibrosis (white circle) was observed after treatment for 6 months. **(C and D)** Thin-section pulmonary CT scans of a 48-year-old woman (Patient 17). The round shaped lesion (red arrow) disappeared after treatment for 6 months.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ormond's disease (idiopathic retroperitoneal fibrosis ,IRF) is a rare disease. Main clinical symptom is compression of the ureters leading to renal failure. A majority of patients is believed to have IgG4-related disease causing the symptoms. Until today no therapy is approved for the treatment of IRF. In our center cyclophosphamide bolus therapy over 6 months is used in treating these patients. Only few data is available on treatment approaches for IRF and even less differentiating between IgG4RD and non-IgG4-RD IRF

Methods: Patient data of the last 15 years from our center were evaluated concerning, clinical, serological and radiological response to cyclophosphamide therapy. Patients were differentiated according to the diagnosis of IgG4RD in available biopsies.

Results: In a total of 20 patients 7 patients could be diagnosed with having IgG4RD according to the biopsy, 4 were negative and 1 biopsy remained unclear. For 8 patients no biopsy was available. IgG4 negative patients had a significant higher volume of the retroperitoneal mass than positive and unclear patients at the time of diagnosis. The volume of the

retroperitoneal mass was significantly reduced under therapy only in the group of IgG4RD positive and unclear patients (P=0.003 and 0.0039). Renal function (creatinine) was impaired in all three groups initially and no significant improvement could be observed in any of the groups under therapy. Unfortunately, IgG4 serum levels were only available for very few patients therefore follow up was impossible.

Conclusion: In about 50% of the patients a significant reduction of the retroperitoneal mass in IRF could be observed under treatment with cyclophopshamide bolus therapy, without improvement of renal function in this time frame. IgG4RD negative patients might profit less from the therapy with cyclophosphamide. Prospective studies in larger cohorts and with a longer follow-up are need to get a more accurate idea about the efficacy in IRF.

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean fever (FMF), the most common form of hereditary autoinflammatory diseases, is associated with increased risk for secondary (AA) amyloidosis. We herein aimed to investigate the features of FMF patients with amyloidosis with respect to their responses to current therapies.

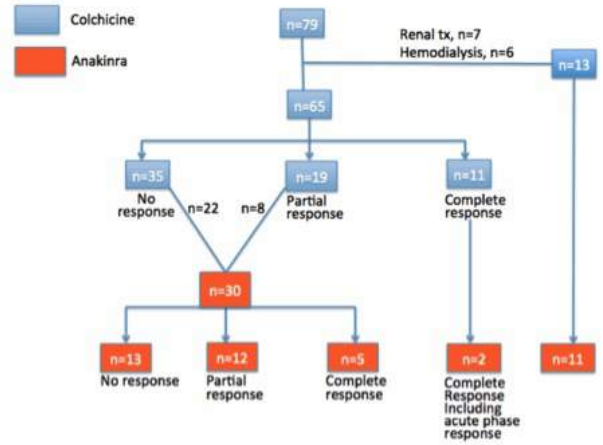
Methods: We enrolled FMF patients with amyloidosis who were regularly followed-up for at least 6 months between 1978 and 2015 into the study. Starting times for colchicine, anakinra or canakinumab and treatment responses were recorded using a standard form. Proteinuria (spot urine protein/creatinine ratio) and C-reactive protein (CRP) levels were measured in every three months during follow-up. Partial response was defined as ³ 50% decrease in baseline proteinuria accompanied by a normal serum creatinine level, whereas complete response was defined as <0.3 gr/d baseline proteinuria and stable serum creatinine. Chi-square test was used to test associations between treatment response and CRP concentrations.

Results: We identified 79 FMF patients with confirmed AA-type amyloidosis, and all were on colchicine treatment. Their demographic features are shown in Table 1. Mean time to diagnosis after the first symptom was 10 years. Patients were evaluated for partial and complete response after mean follow-up period of 66±85 months. Response to full-dose colchicine was observed in 30/65 patients [partial response in 19 (29%), complete response in 11 (17%)]; and 54% was non-responder to colchicine. Anakinra was added to treatment in 22 patients with inadequate response to colchicine, which resulted in partial response in 12, and complete response in 2. Eight patients with partial response to colchicine also received anakinra for better control of attacks and/or elevated acute phase response, and a complete response was achieved in 3 patients. In 3 patients, anakinra was switched to canakinumab because of local injection site reaction (1

patient) and persistence of proteinuria (2 patients). Among those, two patients had partial response, and another underwent hemodialysis due to progressive kidney failure. No significant association was observed between normalized CRP levels and response to treatment with respect to proteinuria and creatinine levels (colchicine; p=0.67, anakinra or canakinumab;p=0.82). No serious infection requiring hospitalization was detected in association with IL-1 blockade.

Table 1. Demographic features of FMF patients with amyloidosis.

Male/Female	40/39
Age of onset (mean±SD)	16±12(2-68)
Age of diagnosis (mean±SD)	27±13(7-70)
Family history of FMF	47%
Time to diagnosis(mo)	121±136(2-576)
Family history of amyloidosis (%)	18%
Arthritis at presentation (%)	60%
MEFV variations (n=46)	M694V,68% V726A,10% M680I,15% Others,7%
IL-1 inhibitors n(%)	43(54%)
Patients on hemodialysis	7(9%)
Renal Transplantation n(%)	17(21%)
High CRP levels in attack-free periods n(%)	31(39%)



Conclusion: Amyloidosis still remains as an important complication of FMF, but patients with amyloidosis comprise a heterogeneous group including those ineffective treated with or refractory to colchicine. Therefore, it is possible to observe a satisfactory response to full-dose colchicine in an important proportion of patients. On the other hand, IL-1 inhibitors, both anakinra and canakinumab, seem to be an effective and safe option for those patients with an inadequate response to full-dose colchicine or with an intolerance to effective doses of colchicine. Efficacy of strict control of inflammatory response by IL-1 blockade on amyloidosis-associated clinical findings such as proteinuria and renal failure needs to be explored in longer series.

Abstract Number: 247

ANTI-Interleukin 1 Therapy in FMF Amyloidosis: A Single Center Experience

Serdal Ugurlu, Bilgesu Ergezen and Huri Ozdogan, Division of Rheumatology, Department of Internal Medicine,

Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Recently there is increasing number of reports pointing out the efficacy of anti-interleukin 1(anti-IL1)therapy to control AA amyloidosis secondary to autoinflammatory diseases. Here we report our experience in IL-1 blockade in patients with AA amyloidosis secondary to FMF.

Methods: Twenty three FMF patients withhistologically proven secondary AA amyloidosistreated with anti-IL1 agents (canacinumab and anakinra). Creatinine, creatine clearance, 24-hour urine protein, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)parameters were measured before and throughout the treatment period in order to evaluate the response. One patient on anakinra for less than a month, therefore the renal functions were not evaluated for her. Patients were closely monitored and adverse events were also reported.

Results: Twenty three (12 female, 11male) patients with AA amyloidosis secondary to FMF who were also on colchicine (mean dose: 1.86±0.58mg/day) were started on anti-IL1 agents (11 on canakinumab, 16 on anakinra).Four patients using Canakinumab were previously on Anakinra. The mean age was 42.5±10.82 years, while the mean duration of FMF was 24.3±8.2 years. The mean follow-up period on anti-IL1 was 14.9±11.5 months (14.5±13.5months on anakinra; 15.45±9.43 months on canakinumab). Fifteen patients are still on anti-IL-1 therapy (9 on anakinra, 6 on canakinumab). Renal functions remained stable after therapy for 9 out of 15 patients (24-hour urine protein from 5754,6±7787.6mg/dlto 4205.286±5717.645 mg/dl, creatinine clearance from 63.41±25.36 to 71.08±31.66 and creatinine from 1.44±0.46 to 1.62±0.69), while CRP (from 21.34±26.40 mg/L to 18.94±32.74 mg/L) and ESR (from 67.44±34.12 mm/h to 34.5±29.16 mm/h) decreased.Renal functions and acute phase reactants improved with therapy in 6 patients (24-hour urine protein from 5153.33±6432.11 mg/dlto1051.733±4571.181 mg/dl;creatinine clearance from 100,76±54.03 to 81.68±40.23 and creatinine from 1.16±0.61 to 1.11±0.60), CRPfrom 22.31±24.66 mg/Lto 2.82±10.65 mg/L; ESR from 64.16±29.73 mm/hto 13.00±14.52 mm/h).Among patients remained stable during anti-IL-1 therapy, 2 were on hemodialysis. In one patient with renal transplantation, amyloidosis was evident in the transplanted kidney and anakinra was introduced and she remained stable.Global patient assessment score of the whole group decreased significantly (from 7.04±3.07 to 1.6±1.94) with IL-1 blockade. Among patients on anakinra, in 5 patients therapy was terminated due to increased proteinuria in 3 and allergic reaction in 2. One patient recieving anakinra with end-stage renal insufficiency died in another center. Treatment was stopped in 5 patients on canakinumab because of increased proteinuria in 3,lichen planus in 1. One patient was lost to follow up despite improvement who was admitted back to the clinic 7 months later with lung adenocarcinoma. A switch from anakinra to canakinumab was made in 4 patients due to allegic reaction in 1 and non-response in 3.

Conclusion: Anti-IL1 therapy can improve or stabilize renal functions in patients with AA amyloidosis secondary to FMF.The efficacy and safety of anti-IL1 therapy in this group of patients in the long-term needs further research.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular (CV) risk assessment is infrequently performed in Familial Mediterranean Fever (FMF), an autoinflammatory disorder with only acute attacks of inflammation. As a surrogate marker of atherosclerosis, carotid intima media thickness (cIMT) is shown to be increased in FMF in previous studies, but the association of cIMT with traditional cardiovascular risk scores is not explored. In this study we aimed to investigate cIMT in FMF and show its relationship to traditional cardiovascular risk scores, disease severity and attack frequency.

Methods: In this cross sectional study, consecutive FMF patients (n=60, M/F: 30/30, mean age= 36.5±9.7 years) were compared to healthy controls (n=60, M/F: 29/31, mean age= 36.8±8.7 years). 10-year CV risk was assesed by 2013 American College of Cardiology/American Heart Association (ACC/AHA) CV risk estimator. FMF severity score-2 (F-SS-2) score was implemented to FMF patients to determine disease severity. Genetic mutations of FMF patients were also recorded.

Results: M694V was positive in 63% of FMF patients, either homozygote, heterozygote or compound heterozygote. 48% of FMF patients had mild, 22% had intermediate and 30% had severe disease according to F-SS-2. Groups were similar in demographic, clinical and biochemical parameters, except for sedimentation rate which was 10±4 mm in control group and 18±11 mm in the FMF group ($p< 0.001$). ACC/ AHA risk scores were similar in both groups: 2.5±2.9) in FMF patients vs. 2.4±2.1 in controls ($p= 0.93$). However, median cIMT was significantly higher in the FMF group compared to controls (FMF: 0.59 mm (IQR= 0.17) vs Controls: 0.52 mm (IQR= 0.13), $p= 0.002$). Patients with severe disease had a higher mean cIMT of 0.62±0.09 mm than those with non-severe disease (0.57±0.09 mm ($p= 0.045$). In multiple regression analysis for all participants, only age and CRP positivity are significantly associated with CIMT ($p< 0.001$ and $p= 0.001$ respectively). In the FMF group, attack frequency while on colchicine treatment (rho= 0.40, $p= 0.002$) correlated with CIMT, whereas attack frequency before starting colchicine was not associated ($r= 0.08$, $p= 0.53$).

Conclusion: cIMT was significantly increased in FMF, but traditional cardiovascular risk scores failed to reflect this change. Attack frequency, which may reflect unsuppressed inflammation, may contribute to the increased cIMT. Therefore, our data suggests that FMF patients, especially those with high attack frequency and severe disease, should be monitored more closely for ischemic CV disease. Further studies are also required to clarify whether better disease control leads to improved cIMT levels.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean fever (FMF) is caused by a number of mutations of the MEFV gene, coding for a protein named pyrin that acts as a major regulatory component of the inflammasome. Accumulating evidence has shown the association of microRNAs (miRNAs) with the development of inflammatory disorders (1). However, little is known about the precise role of miRNAs in FMF. **Objective:** The aim of this study was to identify a serum miRNAs profile and potential biomarkers in FMF and clarify their gene targets for understanding the pathogenesis of autoinflammatory diseases.

Methods: We performed miRNA microarray (Toray 3D-gene miRNA oligo chips) to screen miRNAs in the serum from FMF in attack and in remission. We subsequently examined the effect of candidate miRNAs on cytokine production by using THP-1 cells. Macrophages derived from THP-1 cells were transfected with miRNA mimics or miRNA inhibitor and stimulated with LPS+ATP for 24 hours. We collected the supernatants for the quantification of inflammatory cytokine production. To identify the target genes, we overexpressed its miRNA and performed Agilent expression microarray (SurePrint G3 Human GE 8x60K).

Results: We found that miR-204-3p was greatly decreased in the serum from FMF patients in attack. In vitro study, the expression of miR-204-3p was suppressed by ATP+LPS stimulation in macrophages derived from THP-1 cells. Inhibition of miR-204-3p significantly induced the production of IL-6 whereas overexpression of miR-204-3p inhibited its production. Bioinformatic analysis showed that miR-204-3p is predicted to target genes implicated in Toll like receptor pathway through regulation of PIK3 signaling.

Conclusion: These data suggest that serum miR-204-3p has a potential as a useful biomarker among patients with FMF and that miR-204-3p plays a critical role as a suppressor to regulate the production of IL-6 by targeting PIK3 signaling pathway. **References:**

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophage activation syndrome (MAS) is acute systemic inflammation arising in the context of various autoimmune and autoinflammatory conditions, which is often life-threatening. In 2016, EULAR/ACR/PRINTO Collaborative Initiative group developed new criteria for the classification of MAS in patients with systemic onset juvenile idiopathic arthritis (JIA) (1). Adult onset Still's disease (AOSD) is considered to be an adult counterpart of systemic onset JIA. Therefore, we evaluated the clinical significance of 2016 EULAR/ACR/PRINTO classification criteria for MAS in patients with AOSD.

Methods: We retrospectively reviewed the Severance Hospital's electronic medical records of patients hospitalized with fever and AOSD. From 2005 to 2015, 64 patients were identified. According to the 2016 classification criteria for MAS, patients were defined as having MAS when they had fever, ferritin level of over 684, and fulfilled more than 2 of the following 4 criteria: platelet count ≤181,000, AST > 48 units/L, triglycerides > 156 mg/dL, fibrinogen ≤ 360 mg/dL. Clinical and laboratory data of patients with and without MAS were compared using the two-tailed Student's t-test or the chi-square test. Delta ferritin level was calculated by dividing the maximum level of ferritin level during the admission by i) the initial ferritin level on the date of MAS diagnosis for patients with MAS or ii) on the date of admission in patients without MAS. Univariate and multivariate analysis were used to evaluate factors associated with in-hospital mortality.

Results: Among 64 patients with AOSD, 36 patients (56.2%) were classified as MAS. There were 12 deaths (33.3%) in patients with MAS while there was no death (0.0%) in patients without MAS ($p<0.001$). Comparison of baseline characteristics between patients with and without MAS showed differences in gender, platelet, ESR, AST, ALT, total protein, lactate dehydrogenase (LDH), fibrinogen, triglyceride and ferritin levels (Table 1). In patients with MAS, total protein ($p=0.044$) and delta ferritin≥50% ($p=0.007$) was significantly associated with in-hospital mortality. Multivariate analysis with variables with p-values < 0.05 in univariate analysis revealed that delta ferritin≥50% was associated with in-hospital mortality (OR 8.097, 95% confidence interval, 1.422-46.097, $p=0.018$) (Table 2).

Conclusion: These findings suggest that MAS is a frequent complication in patients with AOSD and is associated with in-hospital mortality. Furthermore, in patients with MAS, delta ferritin levels of over 50% were also associated with in-hospital mortality. Although early recognition is important for the proper management of MAS, there has been no single specific test to detect MAS. We demonstrated that the new 2016 classification criteria, composed of 5 simple laboratory tests, are significantly associated with poor outcome in febrile AOSD. Therefore, patients with AOSD should be monitored carefully for development of MAS based on 2016 EULAR/ACR/PRINTO classification criteria.

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adult-onset Still's disease (AOSD) is an acute and systemic inflammatory disorder that is characterized by high spiking fever, evanescent rash, arthralgia/arthritis and hyperferritinemia. However, recent reports showed that not only typical evanescent salmon-colored rash but also atypical skin lesions, persistent pruritic papules and plaques, could be associated with AOSD. The atypical skin lesions are histologically characterized to have the dyskeratotic cells in upper layer of epidermis.

Methods: We retrospectively assessed clinical and histological findings of skin lesions including persistent pruritic skin lesions in Japanese patients with AOSD (n=7). Moreover, we compared serological and histological finding of AOSD with that of dermatomyositis (DM) (n=6), drug eruptions (DE) (n=6), and Graft versus Host disease (GVHD) (n=6).

Results: AOSD with persistent pruritic skin lesions (n=5) histologically showed dyskeratotic cells only in upper layer of epidermis and horny layer without intraepidermal infiltrations of inflammatory cells. These dyskeratotic cells were positive by TUNEL and ssDNA stainings, suggesting apoptotic cells. AOSD with evanescent rash (n=2) histologically showed no dyskeratosis. On the other side, the pathological findings of DM (n=6), DE (n=6) and GVHD (n=6) had dyskeratotic cells in all layers of epidermis with inflammatory cells infiltrations. Notably, all of AOSD with atypical skin lesions (n=5) had very high levels of serum IL-18 (74,300~307,000 pg/ml).

Conclusion: AOSD with persistent pruritic skin lesions is characterized and specific by prominent epidermal apoptosis, especially involving the upper layers. Therefore, it could play a pivotal role to recognize the atypical skin lesions of AOSD for correct early diagnosis. Finally, the high levels of serum IL-18 might be related with epidermal apoptosis of keratinocyte in AOSD.

Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Adult onset Still's disease (AOSD) is a rare inflammatory disorder of unknown etiology. Several studies have reported that pro-inflammatory cytokines including interleukin (IL)-1, IL-6, IL-18, tumor necrosis factor (TNF)-α, and interferon (INF)-γ, are involved in the pathogenesis of AOSD. Refractory AOSD patients have been treated successfully with anti-cytokine biologics. Herein, we analyzed cytokines to investigate predictors for therapeutic response of biologic drugs in refractory AOSD.

Methods: Twenty two AOSD patients who treated with anti-TNFα agents or anti-IL-6 receptor agent were recruited from a university hospital for rheumatic diseases in Korea. The dosages of anti-TNFα (infliximab in 18 patients, etanercept in 4, and adalimumab in 3) and tocilizumab in 12 were same as those of rheumatoid arthritis. Serum cytokines (TNFα, IL-1β, IL-6, IL-8, IL-17α, and INF-γ) and IL-2 receptor α were analyzed by multiplex flowcytometry. A good response to biologic agents was defined as decreased modified Pouchot score more than 2 score compared to initial treatment of biologic agents. A no response to biologic agents was defined as no decrease of modified Pouchot score. We used the Mann-Whitney test for continuous variable.

Results: Seven (36.8%) patients showed good response to anti-TNFα inhibitors and 3 (13.6%) patients showed partial response. Nine (47.4%) patients did not respond to anti-TNFα inhibitors. Three (25%) patients showed good response to tocilizumab (TCZ), 4 (33.3%) showed partial response, and 5 (41.7%) showed no response. At starting time point of anti-TNFα inhibitors, levels of TNFα, IL-1β, IL-6, and IFNγ in no responders was higher compared to those with good response, but without statistically significant differences (Table 1). At starting time point of TCZ, conversely, the levels of TNFα and IL-6 in no responders was lower compared to responders including good and partial response (Table 2). We didn't raise the dosage of infliximab in no responders, nine patients, in whom TCZ was used as second biologic therapy. Of those, five (55.6%) patients showed improvement in clinical and laboratory findings.

Conclusion: This study showed that AOSD patients who were refractory to biologic agents might have distinct cytokine profiles. Therefore, dosage and sort of biologic agents in AOSD patients might be individualized according to pre-treatment cytokine profiles.

Table 1. Cytokine levels of AOSD patients before anti-TNFα therapy.

	Total (n = 19)	Good response (n = 7)	No response (n = 9)	p
TNFα (pg/mL)	11.19 (20.06)	6.34 (9.71)	14.96 (25.43)	0.632
IL-1β (pg/mL)	6.23 (13.25)	2.32 (2.70)	9.65 (17.79)	0.600
IL-2Rα (pg/mL)	676.47 (593.44)	971.12 (790.92)	447.30 (236.86)	0.101
IL-6 (pg/mL)	54.52 (126.31)	45.34 (77.11)	61.66 (159.13)	0.427
IL-8 (pg/mL)	41.96 (73.61)	69.19 (100.55)	20.77 (37.73)	0.396
IL-17α (pg/mL)	0.77 (1.01)	0.50 (0.32)	0.97 (1.32)	0.745
IL-18 (pg/mL)	42,339.33 (60,876.27)	65,983.73 (79,663.30)	21,650 (30,396.91)	0.165
INFγ	48.27 (117.13)	11.99 (8.87)	76.49 (153.67)	0.708

Values are the mean (SD) unless otherwise indicated. Of 19 AOSD patients, three was partial response. Mann-Whitney test

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

To assess the efficacy and safety of tocilizumab (TCZ) monotherapy for the induction therapy of adult onset Still's disease (AOSD) in a prospective, single-arm, single-center, cohort, pilot study.

Methods: Eight AOSD patients (male 2, female 6) who had agreed with our prospective trial since April 2010 till May 2015 were enrolled. Patients received 8 mg/kg of intravenous TCZ fortnightly for the first two months (five courses), then monthly for the next 5 months and after that TCZ was discontinued and patients were followed up for another 6 month with careful monitoring of clinical symptoms and signs related to AOSD relapses. In this report, we evaluated the efficacy and safety at the sixth month. Efficacy was evaluated by serum markers (WBC, CRP and serum ferritin), clinical symptoms and ratio of patients who required additional therapy, and safety was evaluated by adverse events for six months.

Results: The mean age was 45.2. Fever, arthralgia, rash and sore throat were observed in 100%(n=8/8), 100%(n=8/8), 87.5%(n=7/8) and 75.0%(n=6/8) respectively. LOCF analysis revealed that WBC, CRP and serum ferritin level decreased significantly from 14075 ± 4732/μl to 7042 ± 2939/μl, from 12.2 ± 7.4 mg/dl to 0.32 ± 0.62mg/dl and from 9176 ± 8077ng/ml to 3380 ± 5615ng/ml in 6 month respectively (each, $P<0.01$). The improvement rate of fever, arthralgia and eruption were 100%(n=8/8), 75.0%(n=6/8) and 71.4%(n=5/7). Only 2 patients required additional therapy (prednisolone).The reason of cessation consisted of lack of efficacy (25%, n=2) and adverse event (12.5%, n=1). An adverse event was UTI. There were no other significant adverse events.

Conclusion: TCZ monotherapy may be an alternative treatment strategy for AOSD.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic autoinflammatory diseases (SAIDs) are a genetically heterogeneous group of rheumatic diseases that are driven by abnormal activation of the innate immune system. As one of the SAIDs, the nucleotide-binding oligomerization domain like receptor protein (*NLRP*)12 autoinflammatory disease (NLRP12-AD) is an autosomal dominant disorder associated with the mutations in the *NLRP12* gene. SAIDs have been hardly reported in the Chinese population, and NLRP12-AD has been reported only in Caucasians. We report the first case series of NLRP12-AD in the Chinese population coupled with literature review.

Methods: Three Han Chinese adult patients with clinical phenotype suggestive of NLRP12-AD carrying *NLRP12* variants were treated by the authors in 2015. Their phenotype and genotype were carefully documented and studied. A PubMed search for SAIDs was conducted between January, 1990 and January, 2016, and we focused on NLRP12-AD.

Results: All three adult patients (2 men and 1 woman) developed periodic disease in adulthood. They presented with recurrent fever (n=3), polyarthralgia (n=3), myalgia (n=3), urticaria (n=2), lymphadenopathy (n=2) and erythema nodosa (n=1). All patients carry the *NLRP12* mutation F402L. Based upon our analysis of the clinical data on a total of 26 patients with NLRP12-AD in the literature, both familial and sporadic cases were equally reported, and late-onset cases accounted for 28%. NLRP12-AD patients typically present with periodic fever, urticaria-like rash, arthralgia/arthritis, myalgia, lymphadenopathy and splenomegaly. Genotyping identifies the *NLRP12* gene mutations, notably F402L (55%). Relative to the literature reports, our patients had the similar phenotypic and genotypic features. Patients with NLRP12-AD usually respond to glucocorticoid therapy.

Conclusion: As one of the SAIDs, NLRP12-AD has been sparsely reported in the Caucasian population. Our report is the first to confirm its presence in the Chinese population. An awareness and screening of the *NLRP12* gene mutations in patients with unexplained periodic fever syndrome may reduce misdiagnosis and improper treatment.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS) is a rare auto-inflammatory disease encompassing a spectrum of 3 phenotypes: familial cold auto-inflammatory syndrome (FCAS), Muckle–Wells syndrome (MWS), and neonatal-onset multisystem inflammatory disease (NOMID).[1] The estimated frequency of CAPS ranges from 1 to 3 per million.[2,3] The β-Confident Registry (NCT01213641) is a multicenter, long-term, prospective, observational study with an enrollment period of 5 years (yrs) to monitor the long-term safety and efficacy of canakinumab (CAN) for CAPS. Here we report the overall final results. The primary objective of the Registry was to monitor the safety of CAN, focusing on serious adverse events (SAEs) including serious infections, vertigo, malignancies, and hypersensitivity

reactions.

Methods: : Cumulative safety data were reported as incidence rate per 100 patient-yrs (IR/100 pyrs) from the enrollment of the first patient (November 2009) until end of study (December 2015). After enrollment patients were followed up for at least 1 yr. The Registry protocol did not mandate any visits or procedures; however, all observed and reported AEs and SAEs or AEs potentially related to CAN were recorded. Efficacy was measured using physician's global assessment (PGA).

Results: Overall, 288 patients (FCAS, n=42; MWS, n=170; NOMID, n=34; others, n=42) were enrolled at 39 sites across 13 countries, with a mean patient exposure duration of 3.6 yrs. Of these, 22 (8.0%) discontinued CAN: 5 due to AEs, 10 due to poor efficacy and patient preference, and 7 due to other reasons. The IR/100 pyrs for overall AEs was 100.0. Among the phenotypes of CAPS, patients with FCAS had the lowest IR/100 pyrs (78.1) than patients with MWS (113.4), and NOMID (119.0). The most common AEs were infections and infestations (IR/100 pyrs, 39.1). Overall, 161 SAEs were reported by 86 patients (IR/100 pyrs, 16.3), most commonly, infections (IR/100 pyrs, 5.0). One death (metastatic rectal adenocarcinoma in a 76-yr-old MWS patient) was reported. Of 23 patients who received pneumococcal vaccination (PPV), 15 (65.0%) reported local post-PPV injection site reactions, of which 5 were considered serious. Based on PGA, 31.0% of patients had no disease activity, whereas most (59.0%) of the others experienced mild/moderate disease activity at Month 54. Similarly, disease activity was absent or mild/moderate in patients with *NLRP3* mutation-negative CAPS (n=13) treated with CAN.

Conclusion: The β-confident Registry is the largest CAPS cohort documented in a registry. This Registry showed that the safety profile of canakinumab was consistent with previous findings and efficacy was sustained for more than 5 years. Canakinumab therapy was also effective in patients with *NLRP3* mutation-negative CAPS. References:

Muckle-Wells Syndrome in Chinese Adult Patients

Di Wu, Min Shen and Xiaofeng Zeng, Rheumatology, Peking Union Medical College Hospital, Beijing, China

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Muckle-Wells syndrome (MWS) is a rare autoinflammatory disease, which is categorized as one of the three cryopyrin-associated periodic syndromes (CAPS). MWS is characterized by recurrent episodes of fever, rash and joint pain, and may lead to renal amyloidosis and severe neurological involvements such as hydrocephalus and progressive hearing loss. Here we describe the first cohort of MWS patients in Chinese population, with emphasis on clinical features and gene variations.

Methods: Four Han Chinese patients were diagnosed as MWS from the year 2013 to 2016 at our adult clinic for autoinflammatory diseases. All the diagnoses were confirmed by mutations in the NLRP3 gene. All relevant clinical and genetic data were collected retrospectively and followed up prospectively.

Results: All the four patients were male. The median age at disease onset was 4.5 (ranging from 2 to 46) years and the mean disease duration before diagnosis was 14.25¡À12.63 (ranging from 1 to 29) years. One patient had adult onset disease at the age of 46, and the remaining patients experienced delayed diagnosis into adulthood because of physicians' unfamiliarity with this syndrome in China. All patients denied positive family history. All patients had intermittent febrile episodes with moderate to high temperature. One patient's attacks could be triggered by cold exposure. The mean duration of fever attacks was 3.81¡À2.51 (ranging from 0.25 to 6) days and the interval between attacks ranged from several weeks to several months. Skin rashes were present in all patients, which could be erythematous macular or papular, urticarial, erythema nodosa-like and Sweet disease-like. Two out of 4 suffered from frequent oral ulcers, 2/4 conjunctivitis, 2/4 myalgia, 2/4 headache, 2/4 arthralgia, 1/4 prominent polyarthritis, 1/4 pharingitis, 1/4 abdominal pain, 1/4 severe sensorineural hearing loss, 1/4 epilepsy, 1/4 chronic meningitis with communicating hydrocephalus. All patients had moderately elevated peripheral leukocyte count and systemic inflammatory markers during attacks, which return to normal during intervals. Each patient carried a novel heterozygous mutation in NLRP3 gene, including Q705K, V72M, D31V, T350M, respectively. Three patients had good response to the combination of moderate to high dose of prednisone and conventional DMARDs. Due to economic constraints and unavailability of anti-interleukin 1 therapies in China, only one patient received an anti-TNF¦Áagent. None showed evidence of renal amyloidosis.

Conclusion: Our observational study suggests for the first time that MWS could be identified among adult Chinese patients with intermittent fever of unknown cause, but with unique features compared with previously reported patient cohorts. Our patients are exclusively male without positive family history, with fewer presentations of urticarial rash and hearing loss, and responded better to conventional oral treatments. Considering the lack of amyloidosis, whether our patients had better outcome remains to be seen. The more accurate characterization of Chinese patients suffering from MWS and CAPS needs further studies. Figure 1. A1& A2: erythematous macular and oral ulcer of one patient. B1& B2: resolution of transient arthritis in 1st TMP within one day. C1& C2: new maculopapular rash in the neck and pigmentation after rash disappearance in the forearm.

CNS Manifestations of Patients with Muckle-Wells Syndrome

sara Sebnem KILIC[1], sukru cekic[2] and Juan Arósteguí[3], [1]Pedaitric Rheumatology, Prof Dr, Bursa, Turkey, [2]Dr, Bursa, Turkey, [3]Prof, Barcelona, Spain

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: CAPS is a rare autoinflammatory disease associated with mutations in the NLRP3 gene that result in overactivation of the inflammasome, increased secretion of IL-1beta and IL-18, and systemic inflammation. Muckle-Wells syndrome (MWS) is a rare autosomal dominant disease which causes sensorineural deafness, recurrent hives, and joint pain. CNS manifestations are one of the prominent clinical features in children with CINCA/NOMID, but they have been described only rarely in patients with FCAS and MWS.

Methods: Here we present the imagination findings of CNS involvement in a family whose 11 members have MWS. Clinical data was collected during the course of ongoing patient care.

Results: We evaluated the clinical features of 11 patients who were referred to our center. The median age of the patients was 25 years (range: 9–65years). The ratio of females /males was 1.2 (6/5). All patients had arthritis with exacerbation on exposure to cold and ocular involvement, mostly in the form of conjunctivitis and far less commonly uveitis, irideal synechiae, band keratopathy, cataract, and impaired vision. The median age of onset of arthritis was 7 years (2-30y), the median age of onset of ocular involvement was 8 years (2-45 y). Hearing loss in 73.6% of patients was detected, with a 15 years (12-63 y) as the median age of onset. All patients except one had urticarial rash. The median age of onset of urticarial rash was 8 years (7-30 y). Three patients had recurrent headache attacks. Neurological examination was normal in all and cranial MR was obtained in 8 out of 11 patients. While 4 out of 8 patients had normal MR findings; the enlargement of the ventricles and gliotic focus in the subcortical white matter associated with a deepening of the cerebral sulci in 2 patients; enlarged ventricles and cerebellomedullary cisterns in 2 patients were detected. There was no mutation detected in the study of MEFV (all exons), TNFRSF1A (exons 2-to-7), MVK (all exons), NLRP3 (all exons), NOD2 (exons 4, 8 and 9) and PSTPIP1 (exons 10 and 11) genes. Anakinra was started in 6 patients and two patients were treated with canakunimab . Following anti-IL1 treatment, attacks of arthritis and urticaria are getting fully under control, advances in keratopathy and hearing loss could be partially controlled.

Conclusion: CAPS are usually inherited disorders caused by an autosomal dominant mutation. Neurological manifestations may be one of the major clinical features and were mostly reported in cases with CINCA/NOMID. Currently, there is no fixed demarcation between FCAS and MWS or MWS and CINCA/NOMID. Distinguishing between these cryopyrinopathies may be difficult because they have symptoms in common. During attacks, patients develop severe headaches and will have findings of ‘aseptic’ meningitis in the cerebrospinal fluid (CSF), with predominately neutrophils and eosinophils cellular infiltrate. Our three cases had recurrent headache and two of them had enlarged ventricles and cerebellomedullary cisterns in cranial MR. Although neurological findings was reported rarely in cases with MWS, cranial MR should be requested in patients with MWS who has headache.

Unmet Psychosocial Needs in Patients with CAPS

Jasmin B. Kuemmerle-Deschner[1], Gabi Erbis[1], Tetiana Sergiichuk[1], Sandra Hansmann[1], Iris Haug[1] and Susanne Benseler[2], [1]Pediatrics, University Hospital Tuebingen, Tuebingen, Germany, [2]Pediatrics, University of Calgary, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS) is a rare autoinflammatory disease. Generalized manifestations like recurrent fever and fatigue and organ disease like reduced vision, hearing loss, bone deformities and aseptic meningitis impair the patients' well-being. While most physical complaints are well defined and managed by effective IL-1 inhibition, areas of psychosocial needs are much less explored and often unsatisfied even in treated patients. The purpose of this study was to identify unmet needs in the psychosocial support of children and adults with CAPS.

Methods: A qualitative study of children and adults diagnosed with CAPS cared for at the autoinflammation reference center Tuebingen was performed. Patients and their families were invited to participate in structured focus group interviews grouped according to age and involvement with the disease: children <14 years, adolescents and young adults 14-21 years, adults >21 years; parents; other family members. Open questions were asked to the group. The group discussion was recorded, transcribed to text and analysed for mentioning of certain topics. Frequency of naming and relevance indicated by discussion participants was calculated and graded.

Results: The five focus groups comprised of 42 individuals including 25 CAPS patients; 10 females, 15 males, including five children, eight adolescents/young adults and 12 adults. In addition unaffected individuals included 14 parents and three other family members. Key domains of unmet needs identified included information about the disease, understanding of patients' needs, intervention in social network and exchange of experiences. The area of need identified in all focus groups and named most often was school. Specifically lack of appreciation by teachers (13) and fellow students (21) was named. In adolescents and adults groups other frequently named areas were employment agency, health insurance organizations and general practitioners.

Conclusion: Major unmet needs of children and adults with CAPS were identified as various displays of ignorance by the patients' environment. The need for psychosocial support exists particularly in school.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiac sarcoidosis is a life threatening condition for which there is limited data to guide optimal steroid-sparing agents. B-cells have been reported to be involved in the pathogenesis of sarcoidosis and individual instances of successful rituximab use have been described.

Methods: We identified all patients at a single center with cardiac sarcoidosis (defined by endomyocardial biopsy or biopsy of different organ confirming sarcoidosis plus consistent cardiac imaging) treated with rituximab with at least 1 follow-up.

Results: Mean ± standard deviation age at diagnosis for the 3 men and 2 women identified was 50.9 ± 8.8 years. Median follow-up at our center for sarcoidosis was 2.7 years (range 1.3-7.1). One patient had isolated cardiac sarcoidosis. The remaining 4 had extracardiac involvement: thoracic lymphadenopathy (3, 60%), pulmonary (1, 20%), renal (1, 20%), parotid gland (1, 20%), and neurologic (1, 20%). Endomyocardial biopsies were positive in 2 of 3 patients. All had abnormal findings on PET and/or MRI. Four had cardiac involvement at the time of sarcoid diagnosis. Cardiac

manifestations included both arrhythmia (high grade AV block, ventricular tachycardia) and heart failure. All 5 had an implantable cardioverter defibrillator (ICD) over their follow-up. All 5 received corticosteroids and had failed or were intolerant to at least 1 additional immunosuppressant before rituximab. Mycophenolate mofetil was the most common (4, 80%). Methotrexate was used in 2 (40%), azathioprine 1 (20%), infliximab 1 (20%), and leflunomide 1 (20%). Rituximab 1000 mg IV x 2 doses, 2 weeks apart, was given to 4 patients. One received only 1 dose due to insurance limitations. Three patients received 1000 mg IV x 2 doses after at least 6 month intervals, for a total of 2, 3 and 4 rounds, for each patient, respectively. The median follow-up following first rituximab was 0.8 (range 0.2-1.9) years. All received prednisone with doses successfully reduced over follow-up. Two also received methotrexate with rituximab, with one having to discontinue due to renal dysfunction. All had serial cardiac PETs. In all, there was qualitative improvement in inflammation as assessed by a decrease in FDG uptake. In one patient, all FDG uptake was eliminated in two serial cardiac PETs following the first and second round of rituximab. Due to insurance issues, the third round of rituximab was delayed to 10 months and with recurrence of FDG uptake that stabilized on subsequent cardiac PET. Three had improvement of ejection fraction as measured by cardiac PET following first rituximab infusion: 26% to 54%, 33% to 47%, and 32% to 40%. One had stability and 1 had worsening from 45% to 28% but the latter was performed in the setting of ectopic beats and echocardiogram performed at similar time points demonstrated stability. No individuals died during follow-up. One individual is currently listed as class IB for heart and kidney transplant. No side effects from rituximab were noted.

Conclusion: Rituximab for treatment refractory/steroid-intolerant cardiac sarcoidosis appears to be effective and well-tolerated. Further work is needed to determine its ideal position in a regimen to treat cardiac sarcoidosis.

Risk of Cardiovascular Disease Among Patients With Sarcoidosis: A Population-Based Retrospective Cohort Study

Background/Purpose: Several epidemiologic studies have demonstrated an increased incidence of atherosclerotic cardiovascular disease (CVD) among patients with chronic inflammatory disorders such as rheumatoid arthritis and systemic lupus erythematosus. However, data on sarcoidosis, another relatively common immune-mediated chronic inflammatory disorder, are still limited.

Methods: 345 patients (50% female; 90% Caucasian, 5% African-American; mean age 45.6 years) with incident sarcoidosis in 1976-2013 in a geographically well-defined population were identified based on comprehensive individual medical record review. Inclusion required physician diagnosis supported by histopathology, compatible clinical presentation, and exclusion of other granulomatous diseases. 345 sex and age-matched comparators (50% female; 95% Caucasian, 1% African-American; mean age 45.4 years) were also identified from the same underlying population. Medical records of both cases and comparators were individually reviewed for CVD including coronary artery disease (CAD), congestive heart failure (CHF), atrial fibrillation (AF), cerebrovascular accident (CVA), transient ischemic attack (TIA), peripheral arterial disease (PAD) and abdominal aortic aneurysm (AAA). The prevalence of all and individual CVD prior to index date was compared between the 2 groups using Fisher's exact test. The cumulative incidence of all and individual CVD adjusted for the competing risk of death was estimated. Cox proportional hazards models with adjustment

for age, sex, calendar year, current smoking, diabetes mellitus, hypertension, dyslipidemia and obesity were used to compare the rate of development of CVD, individually and in combination, between cases and comparators.

Results: The prevalence of overall and individual CVD prior to index date was not significantly different between 2 groups (p-value = 0.21 for overall CVD). Adjusting for age, sex and calendar year, the risk of incident CVD after index date was significantly elevated among patients with sarcoidosis with adjusted hazard ratio (HR) of 1.57 (95% CI, 1.15 – 2.16). Further adjustment for current smoking, diabetes mellitus, hypertension, dyslipidemia and obesity yielded adjusted HR of 1.66 (95% CI, 1.09 – 2.55). Sensitivity analysis including only CVD that occurred at least 6 months after index date to reduce the likelihood of detection bias was also performed. The adjusted HR for overall CVD slightly decreased to 1.50 and remained statistically significant (95% CI, 1.06 – 2.06). Significantly increased risk was also observed in some individual CVD as shown in table 1.

Conclusion: Patients with sarcoidosis have a higher risk of CVD. How this risk should be addressed in clinical practice requires further investigation.

Subtype of cardiovascular disease	Number of events after index date for case/comparator	HR (95% CI) for all events after index date, adjusting for age, sex and calendar year	Number of events that occurred after at least 6 months index date for case/comparator	HR (95% CI) for events that occurred at least 6 months after index date, adjusting for age, sex and calendar year
CAD	54/38	1.55 (1.02 – 2.35)	53/38	1.52 (1.00 – 2.31)
CHF	45/24	2.06 (1.25 – 3.38)	43/24	1.97 (1.19 – 3.24)
AF	33/18	1.93 (1.08 – 3.43)	31/18	1.80 (1.01 – 3.24)
CVA	32/14	2.51 (1.34 – 4.71)	31/14	2.45 (1.30 – 4.60)
TIA	6/4	1.68 (0.47 – 5.96)	5/4	1.44 (0.38 – 5.37)
PAD	13/9	1.55 (0.66 – 3.63)	13/9	1.55 (0.66 – 3.63)
AAA	4/4	1.13 (0.28 – 4.53)	3/4	0.86 (0.19 – 3.85)

Sarcoidosis is Associated With Increased Risk of Venous Thromboembolism: A Population-Based Study

Background/Purpose: Chronic inflammation has been increasingly recognized as a risk factor of venous thromboembolism (VTE). Several epidemiologic studies have demonstrated an increased incidence of VTE among patients with chronic inflammatory disorders such as rheumatoid arthritis, inflammatory myositis and vasculitis. However, data on sarcoidosis, another relatively common immune-mediated chronic inflammatory disorder, are still limited.

Methods: 345 patients (50% female; 90% Caucasian, 5% African-American; mean age 45.6 years) with incident sarcoidosis in 1976-2013 in a geographically well-defined population were identified based on comprehensive individual medical record review. Inclusion required physician diagnosis supported by histopathology, compatible clinical presentation, and exclusion of other granulomatous diseases. 345 sex and age-matched comparators (50% female; 95% Caucasian, 1% African-American; mean age 45.4 years) were also identified from the same underlying population. Medical records of both cases and comparators were individually reviewed for both subtypes of VTE including deep venous thrombosis (DVT) and pulmonary embolism (PE). The prevalence of VTE, DVT and PE prior to index date was compared between the 2 groups using Fisher's exact test. The cumulative incidence of VTE adjusted for the competing risk of death was estimated. Cox proportional hazards models with adjustment for age, sex, calendar year, current smoking, diabetes mellitus, hypertension, dyslipidemia and obesity were used to compare the rate of development of VTE between the 2 groups.

Results: The mean length of follow-up was 15.1 years and 16.8 years for cases and comparators, respectively. The prevalence of VTE prior to index date was not significantly different between cases and comparators (1.4% and 1.4%, p-value = 1.0). After index date, 27 VTE events were observed among cases and 10 VTE events were observed among comparators. After adjusting for age, sex and calendar year, the risk of incident VTE after index date was significantly elevated among patients with sarcoidosis with adjusted hazard ratio (HR) of 3.04 (95% CI, 1.47 – 6.29). Increased risk was observed in both DVT (HR 3.14; 95% CI 1.32 – 7.48) and PE (HR 4.29; 95% CI 1.21 – 15.23). Further adjustment for current smoking, diabetes mellitus, hypertension, dyslipidemia and obesity yielded adjusted HR of 3.04 (95% CI 1.25 – 7.39) for VTE, adjusted HR of 3.00 (95% CI 1.05 – 8.58) for DVT and adjusted HR of 4.24 (95% CI 1.11 – 16.18) for PE. Sensitivity analysis including only VTE that occurred at least 6 months after index date to reduce the likelihood of detection bias was also performed. The adjusted HR for VTE slightly decreased to 2.73 and remained statistically significant (95% 1.30 – 5.72). The adjusted HR for DVT and PE decreased to 3.00 (95% CI; 1.25 – 7.20) and 3.58 (95% CI; 0.98 – 13.03), respectively.

Conclusion: Patients with sarcoidosis have a higher risk of VTE. It is possible that this risk is related to the systemic inflammatory nature of the disease, however further investigations are required to address this increased risk in clinical practice.

Seasonal Variation in Incidence of Sarcoidosis: A Population-Based Study 1976-2013

Background/Purpose: Sarcoidosis is a multi-systemic disorder of unknown etiology. Studies of seasonal and regional patterns of incidence of sarcoidosis may provide more understanding of potential environmental triggers of this disease. However, previous studies on the seasonality of sarcoidosis have yielded conflicting results.

Methods: A cohort of adult patients with incident sarcoidosis in 1976-2013 in a geographically well-defined population was identified based on comprehensive individual medical record review. Inclusion required physician diagnosis supported by histopathology and radiologic features of intrathoracic sarcoidosis, compatible clinical presentation and exclusion of other granulomatous diseases. The only exception to the requirement of histopathological confirmation was stage I pulmonary sarcoidosis that required only radiographic evidence of symmetric bilateral hilar adenopathy. Age and sex adjusted incidence rates were calculated using population estimates for adults based on decennial census counts as the denominators. Seasonal variation was compared using Poisson regression models.

Results: The cohort included 345 cases of incident sarcoidosis (mean age 35.4 years, 50% female, 90% Caucasian and 5% African-American). Patients in this cohort were less likely to have incident sarcoidosis in the autumn season with an age and sex adjusted rate of 2.0/100,000 (95% CI 1.5-2.5) compared with winter (3.2/100,000; 95% CI 2.6-3.8), spring (2.8/100,000; 95% CI 2.2-3.4) and summer (2.9/100,000; 95% CI 2.2-3.5; p=0.011; figure 1). Subgroup analysis per decade (1976-1985, 1986-1995, 1996-2005 and 2006-2013) consistently showed lower incidence of sarcoidosis in autumn (rate ratios for autumn compared to spring were 0.53, 0.70, 0.64 and 0.85, respectively), although statistical power was insufficient to demonstrate statistical significance at p <.05.

Conclusion: There is seasonal variation in the incidence of sarcoidosis, with lower rates consistently seen in autumn in the past more than three decades. The results may have implications for the understanding of the etiology of sarcoidosis.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To characterize the main epidemiological, clinical and radiological features at presentation of sarcoidosis in a large multicenter cohort from Southern Europe.

Methods: In January 2016, the Autoimmune Diseases Study Group (GEAS-SEMI) created a national registry (SARCOGEAS) of patients with sarcoidosis. Sarcoidosis was diagnosed in agreement with the criteria proposed by the American Thoracic Society/European Respiratory Society/World Association of Sarcoidosis and Other Granulomatous Disorders (WASOG) 1999 statement on sarcoidosis. Organ involvement was retrospectively determined in each patient at the time of diagnosis using the 2014 WASOG organ assessment instrument. Ethnicity was defined according to the FDA classification. Two outcomes (association with neoplasia and death) were assessed at the end of follow-up.

Results: The cohort consisted of 979 patients (85% biopsy-proven), including 562 (57%) women and 417 (43%) men, with a mean age at diagnosis of 47.02 ± 15.44 years. One hundred twenty-three (13%) patients were born outside Spain. With respect to the FDA ethnic classification, 858 (88%) patients were classified as White, 83 (8%) as Hispanic, 21 (2%)

as Black/African American and 17 (2%) as Asian. Thoracic involvement was present at diagnosis in 910 (93%) patients. With respect to diagnostic tests, data on the radiographic stage at diagnosis was available in all but 15 patients, with stage II (38%) and stage I (30%) being the most frequently-reported patterns. According to the WASOG classification, the most frequently reported extrathoracic involvements at diagnosis were cutaneous in 334 (34%) patients, extrathoracic lymph nodes in 179 (18%), liver involvement in 120 (12%) and ocular involvement in 109 (11%). Potentially life-threatening WASOG involvements were reported in frequencies less than 10%, including neurological involvement in 67 (7%) patients, kidney involvement in 46 (5%) or cardiac involvement in 18 (2%). Therapeutic approaches included the use of oral glucocorticosteroids in 552 (56%) patients, immunosuppressive agents in 76 (8%, mainly methotrexate in 35 patients, azathioprine and 21 and mycophenolate in 7) and biological agents in 13 (1%, including infliximab in 9 cases, adalimumab in 4, rituximab in 2, etanercept in 1 and bevacizumab in 1). After a mean follow-up of 87.9 months, neoplasia was reported in 112 (11%) patients and death in 91 (9%).

Conclusion: This is one of the largest series of sarcoidosis reported out of the US, predominantly composed by White patients in nearly 90% of cases. Clinical presentation is dominated by adenopathies (both thoracic and extrathoracic) and cutaneous features (erythema nodosum), with lower frequencies in the main extrathoracic involvements than that reported in US and Japanese series.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the influence of ethnicity on the clinical presentation of sarcoidosis in a large multicenter cohort from Southern Europe.

Methods: In January 2016, the Autoimmune Diseases Study Group (GEAS-SEMI) created a national registry (SARCOGEAS) of patients with sarcoidosis. Sarcoidosis was diagnosed in agreement with the criteria proposed by the American Thoracic Society/European Respiratory Society/World Association of Sarcoidosis and Other Granulomatous Disorders (WASOG) 1999 statement on sarcoidosis. Organ involvement was retrospectively determined in each patient at the time of diagnosis using the 2014 WASOG organ assessment instrument. Ethnicity was classified according to the FDA classification. Two outcomes (association with neoplasia and death) were assessed at the end of follow-up.

Results: The cohort consisted of 979 patients (85% biopsy-proven), including 562 (57%) women and 417 (43%) men, with a mean age at diagnosis of 47.02 ± 15.44 years. With respect to the FDA ethnic classification, 858 (88%) patients were classified as White, 83 (8%) as Hispanic, 21 (2%) as Black/African American and 17 (2%) as Asian. Epidemiologically, the lowest frequency of women was reported in Blacks/African Americans (24% vs. 58%W, 59%A and 60%H, p=0.018) Radiologically, the highest frequency of radiological stages involving the lung parenchyma was found in Hispanics (79% vs. 71%BAA, 67%W and 56%A, p=0.041). With respect to extrathoracic WASOG involvements, the highest frequencies of cutaneous involvement were found in Hispanics and Whites (41% and 35% vs. 12%A and 9%BAA, p=0.011), ocular involvement in Blacks/African Americans (29%% vs. 14%H, 11%W and 0%A, p=0.021), liver involvement in Blacks/African Americans (38% vs. 16%H, 12%W and 0%A, p=0.021), and kidney involvement in Blacks/African Americans and Asians (14% vs. 11% vs 5%W and 1%H, p=0.037) (Figure 1). After a mean follow-up of 87.9 months, neoplasia was reported in 112 (11%) patients and 91 (9%) patients died. Sarcoidosis was more frequently related to neoplasia in Whites (13% vs. 6%H, 0%BAA and 0%A, p=0.042), who also had the highest mortality rate (10% vs. 5%BAA, 1%H and 0%A, p=0.015).

Conclusion: In a predominantly White Southern European population of patients diagnosed with sarcoidosis, ethnicity played a significant role in the presentation and prognosis of the disease even after taking into account the lower frequencies of ethnicities associated with poor outcomes (Black/African Americans and Hispanics). Consideration of ethnic disparities in the clinical presentation of sarcoidosis may be essential in reaching an early diagnosis, the search for histopathological confirmation and the prompt introduction of specific therapy in Mediterranean patients with sarcoidosis.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Sarcoidosis(Sa) eye involvement is the most common extrapulmonary manifestation and the initial presentation in 5-20% of cases. The definitive diagnosis is histopathological. The sensitivity(S) of the conjunctival biopsy is low,so Ocular Sa(OSa) diagnostic criteria(C.) were proposed:IWOS(First International Workshop on Ocular Sarcoidosis),with high S and specificity(1/0.95), but they have been poorly validated. Our purpose was to apply the IWOS C., to analyze their consistency with the clinical diagnosis of OSa and to asses differential features between patients with OSa and those with systemic involvement

Methods: Cross-sectional study. Clinical records from patients with presumed Sa who had been followed for 10 years in a multidisciplinar Uveitis Unit (Ophthalmology/Rheumatology) were reviewed. Clinical variables and complementary tests results were analyzed. IWOS C. were applied if OSa was suspected. Chi-square test and Kappa coefficient were used

Results: 71 patients included: 47 OSa,13 with ocular-systemic involvement (OS-Sa) and 11 with systemic involvement (SSa). Women/Men 57%/43%, mean follow-up time 9.42 years (±8.55), with no intergroup differences. Significant differences between patients with OSa vs. OS-Sa/SSa were observed: mean age at diagnosis (40.23 ±18.18 vs. 57.54 ±17.65/48.27 ±17 years,p=0.01); mean ESR(16.74 ±12.73 vs. 26.38± 15/19.4 ±31.55 mm/h, p=0.01); mean CRP(3.58 ±4.29 vs. 8.12 ±8.11/10.24 ±14.37 mg/L, p=0.03); CT abnormalities (16.6% vs. 90%/92%, p=0.001); positive biopsy(0% vs. 8/100%, p=0.002); general, joint, respiratory and skin symptoms (OSa 6-12% vs SSa 15-50%,p=0.002). ACE was

increased in 74.6%, with a mean value of 71.98 ±33.59 U/L, no intergroup differences. Altered lacrimal scintigraphy was more often found in the OSa subset (26.7%) vs. OS-Sa/SSa (23.1%/0%), without statistical significance. Comparing OSa vs. OS-Sa patients, ocular involvement was as follows: anterior segment involvement 48% vs 61.5%, intermediate segment 21.3% vs. 15.4%, posterior segment 8.5% vs 0%, panuveitis 21.2% vs. 23.1%, p=0.001. If OSa,bilateral involvement was present in 60% of patients, unilateral involvement was more frecuent in OS-Sa (76%), p=0.06.There were no significant differences regarding uveitis's presentation,course and number of crisis and specific intraocular findings. Applying IWOS Criteria and comparing OSa vs OS-Sa we can classify: Definite OSa 0% vs. 69.2%, Presumed OSa 23.4% vs. 7.7%, Probable OSa 14.9% vs. 15.4% and Possible OSa 2.1% vs. 0%; not fulfilling criteria:59.6% vs. 7.7%(p=0.001). The kappa coefficient between suspicion of OSa/OS-Sa and not fulfilling/fulfilling criteria was 0.30 (p=0.003)

Conclusion: We could classify as Presumed vs. Probable Ocular Sarcoidosis in 25% vs. 15% of patients with suspicion but who hadn't undergone a biopsy. We excluded the diagnosis in 60%. There wasn't a good consistency between the suspected diagnosis/IWOS Criteria fulfillment. Ocular Sarcoidosis patients were younger and had lower ESR/CRP levels. Involvement of the anterior ocular segment was the most frequent one, bilateral in Ocular Sarcoidosis and unilateral in Ocular-Systemic Sa

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Diffuse Idiopathic Skeletal Hyperostosis (DISH) is an incompletely understood condition characterized by new bone formation affecting the spine. Despite reported links between DISH and obesity, the nature of the relationship is unknown. To investigate further, we constructed an obesity genetic risk score (GRS) for BMI and assessed association with DISH.

Methods: A convenience sample of 3,117 patients from the COPDGene Study was used to investigate the association between BMI GRS and DISH. Two readers visually scored spine imaging for DISH based on Resnick criteria. BMI served as the obesity phenotype. Genotyping was performed using the Illumina Omni-Express Chip. A 97 SNP BMI GRS based on validated GWAS loci was calculated. Univariate analyses assessing association of age, sex, race, diabetes status (self-report or taking anti-diabetic medication), BMI GRS with DISH were performed. In addition, a logistic regression model adjusted for age, sex, race, and diabetes, was used to evaluate the association of BMI GRS with DISH. The association of the BMI GRS with BMI served as a positive control. The COPDGene study, initiated 2007-2011, enrolled 10,129 smokers to define subtypes and genetic associations of smoking related lung disease. HRCT of the chest, DNA, demographic and anthropometric data and medical history were obtained.

Results: We analyzed 437 DISH cases and 2,680 controls among men and women in the COPDGene study with available

HRCTs of the chest. See Table 1 for odds ratios (OR) for the univariate and multivariate models. On univariate analysis, DISH correlated with male sex, increasing BMI and increasing age. The correlation between BMI and BMI GRS was significant (p<0.0001). The OR between DISH and BMI GRS was 1.02 (95% CI 1.00-1.04, p=0.019), but when separated by race subgroups, the p-value was not significant in either African Americans or non-Hispanic whites. In the overall multivariate model, there was no significant association between DISH and BMI GRS with OR 1.004 (95% CI 0.99-1.02, p=0.68). **Table 1. Association between DISH and clinical features and BMI GRS**

Variable	Odds Ratio	Adjusted* Odds Ratio	Confidence Interval	P-value
Age (years)	1.06	1.07	1.06-1.08	<0.0001
Gender (male)	2.96	3.50	2.72-4.50	<0.0001
Race (non-Hispanic White)	1.52	0.94	0.71-1.24	0.64
BMI (kg/m^2)	1.09	1.12	1.10-1.14	<0.0001
DM (reported history and medications)	2.64	1.49	1.13-1.97	0.005
BMI GRS	1.02	1.00	0.99-1.02	0.68

***Adjusted for age, gender, race, DM history**

Conclusion: Our results suggest obesity does not share a direct genetic association with DISH. However, it is associated with DISH, which may be due to effects of a shared mechanism such as inflammation. In addition, direct and indirect effects of elevated leptin levels and decreased adiponectin levels, present in obese patients, may play a role to alter bone formation. The role of smoking remains to be elucidated. More studies are needed to further explore the mechanism driving the relationship between obesity and DISH.

Diffuse Idiopathic Skeletal Hyperostosis: Can We Identify Different Clinicoradiological Patterns?

Teresa Clavaguera[1], Ramon Valls[2] and Mari Carmen Rodriguez-Jimeno[2], [1]Unitat de Reumatologia, Hospital de Palamós, Girona, Spain, [2]rheumatology, Hospital de Palamós, Palamós, Spain

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Diffuse Idiopathic Skeletal Hyperostosis (DISH) was described based on vertebral radiological signs (Resnick). Subsequently, Utsinger presented other criteria that add extraspinal involvement that allowed DISH diagnosis even without vertebral signs. Mader et al have tried to develop a new set of criteria without a final consensus about the inclusion of multiple peripheral enthesopathies. **Objective:** Identify clinicoradiological patterns of DIH patients based on the spinal and / or extraspinal involvement and study their distinctive features.

Methods: We conducted a cross-sectional study of patients who fulfilled DISH Resnick's and / or Utsinger's criteria. Demographic, clinical, radiographic and comorbidity data were collected. Exclusion criteria: a) History of spondyloarthropathy, b) HLAB27 +, c) Personal or first degree of psoriasis or Inflammatory Bowel Disease. Variables: clinical, comorbidity and radiological variables were collected. X-rays of spine and joints (pelvis, elbows, knees, feet, hands and shoulders) were reviewed. We defined three clinical-radiological patterns: a) Peripheral: meets Utsinger's but

not Resnick's criteria with > 3 enthesopathies. b) Axial: Resnick and Utsinger's criteria but < 3 enthesopathies. c) Mixed: Resnick and Utsinger's criteria but > 3 enthesopathies. Statistical analysis: We performed a univariate analysis by frequency (categorical) and main statistical and a bivariate descriptive analysis using ANOVA and Fisher's exact test with a confidence level of 95%.

Results: we included 97 patients, 57, 7% were male. The average age at diagnosis was 65.6 y (47-85) but the age of onset of symptoms was 58.2 y (36-80). The delay in diagnosis was 6.36 years (0-25). All patients met Utsinger criteria but 25.8% did not meet Resnick's definition. The symptoms that led to the diagnosis were: 43.7% pain and/or limitation of thoracic-lumbar spine, 16.7% pain and/or limitation cervical spine, 24% a peripheral enthesopathy, 5.2% hip pain and 10.4% was a radiological finding. We identified: a) Axial pattern (30.9%); b) Peripheral pattern (29.4%); and Mixed pattern (30.9%). Although the value of retrospective data is limited, the clinical history of enthesopathy was collected in a 46.2%. 30 patients were not eligible for statistical analysis because of lack of sufficient data. The predominance of female sex (p=0,004) and a younger age of onset (p=0,027) in peripheral pattern were statistically significative. We also found differences in presenting symptoms between those three phenotypes (p=0,014).

Conclusion: We propose three patterns in DISH based on clinical symptoms and characteristic radiological signs. We found statistical differences especially in gender, age at onset and the presenting symptoms. We need prospective studies to elucidate if they correspond to different stages or if they are different phenotypes of the disease.

Session Date: Sunday, November 13, 2016

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept (CTLA4-Ig), a blocking agent for T cell co-stimulation, has been proven beneficial in several autoimmune diseases. The aim of the study was to measure local and systemic immune cell effects of abatacept in the context of polymyositis and dermatomyositis by comparing baseline with 6-month follow-up samples after abatacept treatment.

Methods: 14 patients were included in this substudy of a 6 months' treatment delayed-start design trial. Abatacept was given as intravenous infusions 10mg/kg monthly, in total 7 times. Muscle biopsies and blood samples were taken at inclusion and 6 months of active therapy. Frozen biopsies from the two time points (n=6 patients) were sectioned and

immunohistochemically stained for T cell, macrophage, and B cell markers. Conventional quantification and image analysis were used to calculate the expression of different markers in muscle tissue sections. Frozen PBMCs (n=13 patients) from baseline and 6 months treatment were analyzed with a 29-antibody panel by mass cytometry (CyTOF) focusing on T cell features. Citrus and t-test were used to analyze the CyTOF results.

Results: Following 6 months treatment, the expression ratio of $FOXP3^+/CD4^+$ in muscle sections increased significantly (P=0.03). For peripheral blood CyTOF data, 8 significant different clusters were identified by citrus analysis, which distinguished baseline from follow-up. The proportion of regulatory T cells ($CD3e^+CD4^+CD25^+FOXP3^+$) increased significantly (P=0.04) at follow-up. More specifically, the proportion of effector/memory like Tregs, $CD3e^+CD4^+CD25^+FOXP3^+CCR6^+CD5^+$ cells, increased significantly (P=0.01) while the other Treg subsets did not significantly change.

Conclusion: Our data from peripheral blood suggest that compared to other T cell subsets, regulatory T cells in IIM are relatively resistant to abatacept therapy. Amongst Tregs, the naïve subset were most sensitive. Similarly we observed an increase of Tregs also in affected muscle tissue which could allow more efficient muscle fiber regeneration/healing, implicating that abatacept may be a beneficial drug for myositis.

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are muscle diseases, characterized by inflammatory infiltration and increased expression of MHC class I molecules on myofibers. Immunoproteasome, as a proteolytic complex that shapes the repertoire of antigenic peptides, has been previously demonstrated to be over-expressed in IIMs at mRNA level. In this study, we aim to investigate the functional role of immunoproteasome in the pathogenesis of IIMs.

Methods: Skeletal muscle biopsy specimens from 45 individuals with well diagnosed (ENMC criteria) inclusion body myositis (IBM, n=12), immune-mediate necrotizing myopathy (IMNM, n=12) and dermatomyositis (DM, n=12), in addition to non-IIMs (nIIMs, n=3) and healthy controls (HC, n=6) were included in this study. Immunoproteasome expressions within the muscle fibers and cellular infiltrates were examined by dual immunofluorescence (IF) and immunoblot. Proteasomal activity was measured in the patient muscle biopsies. Primary human myoblasts were used to determine the most effective cytokine in the induction of immunoproteasome expression. Additionally, the role of immunoproteasome during the *in vitro* inflammatory conditions was investigated in myoblasts by using shRNA based gene silencing and

specific chemical inhibitors. The effect of both approaches in MHC-I expression and myokine production was measured by FACS and real time PCR, respectively.

Results: Immunoblots showed significant increase in the expression of relevant players of the immunoproteasome, β1i or β5i in IBM (n=9) and DM (n=9) muscle biopsies compared to HC (n=6). However, the expression in IMNM (n=9) was moderate. In addition, the chymotrypsin-like activity of proteasome reflected the expression of β1i and β5i in the muscle biopsies. Dual IF revealed that both myofibers and muscle infiltrating cells including CD8+ T-cells and CD68+ macrophages in IIMs (n=6 for IBM, IMNM and DM) expressed β1i or β5i. In fact, the expression of β1i and β5i co-localized with the MHC class I expressing myofibers. In contrast, the muscle fibers of HC (n=4) and nIIMs (n=3) were negative for both β1i and β5i. Our *in vitro* study in the cultures of human primary myoblasts showed that pro-inflammatory cytokines, TNF-α, IFN-α, IFN-β and IFN-γ are able to upregulate β1i and β5i expression. Selective inhibition or depletion of β5i amplified the TNF-α or IFN-γ mediated expression of myokines in myoblasts. Furthermore, we found that specific inhibitors of β1i or β5i reduced the cell surface expressions of MHC class I in myoblasts induced by IFN-γ.

Conclusion: We demonstrated that the immunoproteasome expression and activity are increased in skeletal muscle and could involve in pathologic MHC class I expression in IIMs. Therefore, the suppression of the immunoproteasome expression could be an approach to reduce antigen presentation by skeletal muscles and consequently the cytotoxic effect of T-cells. However, functional analyses revealed that immunoproteasome is also important to maintain the myokines that mediate attraction of immune cells in muscles fibers. Thus, the imbalance between two functions may have an impact on the disease phenotype or severity in IIMs.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The dysregulation of innate immunity contribute to pathogeneses of dermtomyositis (DM). Previous study indicated that high expression of retinoic acid-inducible gene-I (RIG-I) in skeletal muscle tissue participated the mechanism of muscle damage. The aim of the study was to determine gene and protein expression of RIG-I in peripheral CD3+T lymphocytes of DM patient and to evaluate the correlation between the RIG-I in T lymphocyte and clinical characteristics.

Methods: The study population included 26 treatment-naive DM patients from Department of Rheumatology at China-Japan Friendship Hospital between July 2015 and February 2016 who fulfilled the criteria of definitive DM proposed by Bohan and Peter. All patients did not have indication of clinical symptom, laboratory and auxiliary examinations of virus infection. 14 age-and sex-matched healthy controls were enrolled. The gene and protein expression of RIG-I in peripheral T lymphocytes were determined by RT-PCR and Western blot. Clinical characteristics such as rash, muscle strength, interstitial lung disease (ILD), esophageal involvement and laboratory examination were recorded. Muscle strength and severity of rash were measured by using the Manual Muscle Test (MMT8) and the modified Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI). 8 patients were followed up after 6 months therapy with glucocorticoid

accompanies with immunosuppressor or not. T-test were used to compare the differences between groups and Spearman's rank was applied to investigate the correlation between the RIG-I expression level and clinical characteristics.

Results: Patients were composed of 9 males and 17 females whose average disease duration was 7.69± 6.39 months. 17 patients and 5 patients were complicated with ILD and esophageal involvement respectively. The average MMT8 score and CDASI were 72.15±6.72 and 19.96 ±10.96 respectively. DM patients had significantly higher level of RIG-I both in gene (0.091 ± 0.051 vs 0.052 ± 0.024; p=0.011) and protein (0.30 ± 0.18 vs 0.18 ± 0.08; p=0.005) expression in T lymphocytes than did healthy control subjects. The levels of protein expression were significantly decreased after therapy with 6 months follow-up (0.32 ± 0.16 vs 0.23 ± 0.17; p=0.017). The gene expression level of RIG-I correlated positively with CDASI score (r=0.455, p=0.02) and negatively with T lymphocyte count (r=-0.466, p=0.016). However, RIG-I level showed no correlation with serum Creatine Kinase (CK) level (p=0.356) and MMT8 score (p=0.284). Patients with ILD had higher gene expression level of RIG-I than that without lung disease involvement (0.107 ± 0.493 vs 0.501 ± 0.029; p=0.006). There was no significant difference between patients with esophageal involvement or not (0.084 ± .0.042 vs 0.093 ± 0.054; p=0.747).

Conclusion: The RIG-I expression level increased significantly in peripheral CD3+T lymphocytes of DM patient and descended after treatment. The increased RIG-I level in T lymphocytes were displaying significant association with rash severity and peripheral lymphopenia. Patients with ILD were more likely to have high level of RIG-I in peripheral T lymphocyte.

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Satellite cells are myogenic stem cells that are essential for myofiber repair, growth and homeostasis in postnatal life. A decline in satellite cell performance has been previously linked with age-associated loss of muscle mass and function; and may also underlie skeletal muscle dysfunction in patients with polymyositis (PM) and dermatomyositis (DM). Successful regeneration of skeletal muscle relies not only on satellite cells, but also on a fine balance between pro- and anti-inflammatory factors. We **hypothesize** that in disease processes such as PM/ DM where chronic inflammation ensues, dysregulated inflammatory responses could lead to inhibition of effective muscle repair and remodeling by inhibiting satellite cell activation and myofiber maturation, and promoting scar tissue formation.

Methods: Skeletal muscle biopsy samples were obtained from 12 treatment refractory DM/PM patients; and 12 generally healthy volunteers who served as age, sex and BMI matched controls. Control biopsy samples were obtained from a skeletal muscle biorepository maintained by the University of Kentucky. Markers of myogenesis, M1/M2 macrophage phenotypes, and pro- and anti-inflammatory markers were assessed by RT-PCR. The data are represented as fold-change compared to controls. Mean values were compared between controls and PM/DM using two sample t-tests. Spearman rank

correlations were used to examine the relationships of markers of myogenesis and immunity with selected disease activity/ damage measures among PM/DM subjects.

Results: In **Figure1**, gene expression of Pax7, a marker of quiescent satellite cells, and embryonic myosin heavy chain (MyH3), a marker of regenerative myofiber formation, are significantly upregulated, while gene expression of MyoD1 and myogenin, markers of activated satellite cells, are either significantly downregulated or not significantly different between PM/DM and controls. Gene expression of pro- (IL6, MCP1) and anti-inflammatory (IL1 Ra, IL4, TGFB and TSP1) markers, as well as both M1 (CD68/11b) and M2 (CD68/206) macrophage markers are significantly upregulated in PM/DM versus controls. Among the markers of myogenesis, only myogenin significantly correlated with MMT-8 muscle testing (r=-0.68, p=0.022), MDAAT muscle disease activity VAS (r=0.82., p=0.002) and serum CK level (r=0.87, p<0.001).

Conclusion: These findings suggest that in PM/DM, the pool of quiescent satellite cells is maintained; regenerative myofiber formation occurs to a certain extent; while activation and terminal differentiation of satellite cells is inhibited. It is interesting to note that gene expression of MyH3 did not correlate significantly with muscle strength. Further studies are needed to determine if embryonic-to-adult myosin heavy chain switch occurs normally in patients with PM/DM, and its effect on functional restoration of myofibers.

Session Date: Sunday, November 13, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Serum cytokines play an important role in the pathogenesis of myositis by initiating and perpetuating various cellular and humoral autoimmune processes. The aim of this study was to measure interferon (IFN)-inducible chemokines (IFNCK), Th1, Th2, Th17, innate, and regulatory cytokines in patients with adult dermatomyositis (DM) and juvenile dermatomyositis (JDM) at multiple visits to identify biomarkers predictive of changes in disease activity.

Methods: Multiplexed immunoassays (Meso Scale Discovery) enabled simultaneous measurement of IFN-regulated chemokines and other pro- and anti-inflammatory cytokines specific to differentiation of specific T cell and innate pathways. Cytokine scores were computed for IFNCK (IP-10, MCP-1), Th1 (IFNγ, TNFα, and IL2), Th2 (IL4, IL10, IL12, and 1L 13), Th17 (IL6, IL17, IL1β), innate (MIP-1α, MIP-1β, IL8), and regulatory (IL10, TNFα) factors. Spearman correlation was used to examine whether cytokines at a previous visit predict change at the next visit, adjusting for disease activity at the previous visit.

Results: The study included 30 patients (13 DM and 17 JDM) with at least 2 visits (68 visits total). Mean age (SD) at inclusion was 53.3 (18.6) years in DM and 9.9 (5.6) years in JDM, 70% female, 87% Caucasian. Most patients were included at their time of diagnosis. The mean (SD) physician global, muscle and extra-muscular disease activity VAS scores at inclusion were 45 (24), 40(30) and 35(20) cm, respectively. The IFNCK score predicted change in physician global (r=0.30; p=0.012), muscle (r=0.29; p=0.016) and extra-muscular (r=0.24; p=0.05) disease activity. The Th17 score also predicted change in physician global (r=0.28; p=0.020), muscle (r=0.25; p=0.041) in DM and JDM, but extra-muscular only in DM (r=0.41; p=0.029). IL6 levels also predicted change in physician global (r=0.31; p=0.011), muscle (r=0.33; p=0.006) and extra-muscular (r=0.33; p=0.007) disease activity, but these associations were predominately among DM.

Conclusion: IFNCK and other cytokine scores may be useful biomarkers to predict changes in disease activity among myositis patients. Differing associations for JDM and DM may indicate biological differences between diseases that warrant specific biomarkers for each to best predict changes in disease activity.

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Monozygotic twins discordant for JDM are rare, composing only 1% of our entire registry of 525 JM patients. These individuals represent a unique opportunity identify persistent gene expression differences in JDM children by allowing for a control with an identical genome, as well as environmental control with respect to early development

Methods: We recruited a pair of monozygotic, white, male twins discordant for Juvenile Dermatomyositis (JDM), age 9.5 years, and a race, sex matched 7.2 year old control for this IRB approved study. The JDM^{+} twin (MSA=probably MJ positive) held his medications (oral prednisone 7 mg, Sub Q MTX 12.5 mg) on the morning of the blood draw. We isolated PBMCs within two hours of blood draw and expanded erythroblasts in culture for 9-12 days. We induced pluripotentcy by transduction with Sendai virus carrying *Oct3/4*, *Sox2*, *Klf4*, and *cMyc*. After documenting normal karyotypic analysis, we profiled the transcriptomes of 3 separate clones from each of the three individuals to detect persistent JDM gene expression differences.

Results: In the comparison of the JDM iPSC clones to the unrelated control, three algorithms only agreed on 11 differentially expressed (DE) genes out of 54 total. This included increased expression of *HLA-DQB1* (FC 7.6-7.8) and *SRD5A3* (FC 2.1), but decreases in expression for *MTRNR2L8* (FC -5.6) and *ZNF718* (FC -2.6) in the JDM-derived cells. 2 of 3 algorithms agreed that the JDM-derived clones also had increased expression of *HLA-DRB1* (FC 4.8). However, virtually the same genes were DE in the unaffected twin compared to the control. Comparing the JDM affected twin and the unaffected twin clones revealed one gene (*ZDBF2*) of only nominal significance for decreased expression in the JDM clones (adj. p-value 0.10, FC -1.6). Clustering of the top 50 genes from the JDM - control comparison along with *ZDBF2* demonstrated that the twins cluster with each other, rather than the unaffected twin clustering with the unrelated control.

Conclusion: 1) iPSC generation reprograms any baseline JDM disease signatures from the original PBMCs. 2) There are inter-individual genetic differences that affect baseline gene expression, as evidenced by the shared expression patterns between discordant twins. **Speculation**: Genetic factors increase risk for developing JDM, but the initiation of the disease process requires a trigger. It remains to be seen if JDM iPSCs manifest persistent epigenetic changes that prime them for an inflammatory response when presented with a suitable antigenic stimulus.

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti- melanoma differentiation-associated gene 5 (MDA5) antibody positive dermatomyositis (DM) and clinically amyopathic DM (CADM) often develop rapidly progressive interstitial lung disesase (RP-ILD), but the pathogenesis is still unclear. We noticed that the sera from many anti-MDA5 antibody positive patients immunoprecipitated the common 110kDa polypeptide. Thus we intended to identify the autoantigen and investigated the clinical significance.

Methods:

Autoantibodies were screened in 340 patients with various connective tissue diseases (CTDs) and 15 healthy controls (HCs) by immunoprecipitation with [^{35}S]methionine-labeled HeLa cells. Immunoabsorbent column chromatography was used to purify the reactive autoantigen and the polypeptide was analyzed by peptide mass fingerprinting.

Results: Anti-110 kDa antibody was detected in 25 DM/CADM patients but not in patients with other CTDs or HCs. All patients with anti-110 kDa antibody were also positive for anti-MDA5 antibody, and had interstitial lung disease. The corresponding polypeptide was identified as splicing factor proline/glutamine-rich protein (SPFQ). Anti-SFPQ antibody was detected at diagnosis and newly appeared in some patients during the disease course. The onsets of DM/CADM had seasonal patterns and showed two peaks according to the temporal appearance of anti-SFPQ antibody. 67% (8/12) of disease onset of patients who had anti-SFPQ antibody at diagnosis were between August and October, whereas 69% (9/13) of those who had newly appearing anti-SFPQ antibody during the disease course were between January and March.

Conclusion:

We identified the anti-110 kDa antibody as DM/CADM specific autoantibody that recognizes SFPQ in patients who also have anti-MDA5 antibody. The onset of DM/CADM with anti-MDA5 antibody had seasonality according to the appearance time of the antibody to SFPQ, which has a role in innate immune responses. These findings may provide new insights into the pathogenesis of DM/CADM with anti-MDA5 antibody.

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The type I interferons (IFN-I) including IFN-a, and IFN-b are key cytokines involved in innate immune response to viral infection. Almost all cells can produce IFN-I, express IFN-I receptor (IFNAR) and induce the transcription of IFN stimulated genes (ISGs), which have anti-proliferative and immunomodulatory activities. Idiopathic inflammatory myopathies (IIMs) are acquired auto-immune diseases. Among the IIMs, Dermatomyositis (DM) is characterized by skin lesions, muscle specific pathologic features combining inflammatory infiltration with HLA-ABC over-expression and vasculopathy. It is known that DM patients express up-regulated ISGs in muscle fibers, endothelial cells (EC), skin tissues and peripheral blood. However, the effect of the IFN-I on myoblasts (MB), myotubes (MT) and EC has not been well determined. Therefore, the aim of this study is to determine if MB, MT and EC present functional changes when exposed to IFN-I.

Methods:

The effect of the activation of IFN-I pathway on the differentiation of MB, and EC and on MT was analyzed *in vitro*. Thus, those cells were cultured with recombinant IFN-I, IFN-a, IFN-β and Poly (I:C) (PIC), an agonist of TLR3 receptor.

Results:

The results on MB showed that PIC, IFN-a and IFN-β abolished myotube formation and decreased myogenin (MyoG) expression. In differentiated MT, all stimuli induced ISGs (MxA and OAS1). Moreover, IFN-a, IFN-β and PIC dramatically reduced myotube surface. Next, IFN-a and IFN-b neutralization and IFNAR blocking experiments confirmed the specificity of the results. Neutralization and blocking experiments in differentiating MB treated with IFN-I, IFN-a and PIC, reverted the myotube formation and myogenin expression. Along the same lines, the surface area in differentiated MT area was restored. In addition, qPCR results showed the upregulation of genes involved in muscle atrophy such as Murf1 and Atrogin with a decrease of MyoG expression. The overexpression of Murf1 and atrogin was confirmed at the protein level *in vivo,* in muscle biopsies from DM patients. The presence of both proteins was detected in perifasicular areas, where atrophic fibers cluster. All stimuli induced HLA-ABC and TLR3 expression in differentiated MT and the presence of IFN-I in the supernatants in MB and MT. The activation of IFN-I pathway in EC, led to a decrease in cell proliferation and ISG up-regulation (MxA, RIG-I, ISG15 and TLR3). Tube formation assay with EC in the IFN-I-activated EC showed a disruption of the vascular network formation, indicating that IFN-I impairs angiogenesis *in vitro*.

Conclusion: In conclusion, *in vitro* treatment with IFN-I or IFN-I pathway activation recapitulates the characteristic pathological features (muscular and vascular damage) defining DM. This emphasizes the key role of the IFN-I pathway in the pathophysiology of DM, results that potentially may lead to new avenues for therapeutic approaches.

Session Date: Sunday, November 13, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Myositis-specific antibodies in patients with inflammatory myopathies are known to be associated with various clinical manifestations, classifications and diagnosis. Among them, recently found anti-transcriptional intermediary factor 1 (TIF1) α, β, or γ antibodies has been reported to be associated with dermatomyositis (DM) accompanied by cancer. Although previous studies have evaluated the association of the antibodies in serum and clinical subtypes, the information about the target antigen is insufficient. The purpose of this study was to confirm the overexpression of TIF1s in the muscle and skin tissues of patients with inflammatory myopathies.

Methods: From February 2004 to November 2014, skin and muscle biopsies were performed on 45 patients diagnosed with dermatomyositis and polymyositis. We stained skin and muscle tissue by immunohistochemistry using anti-TIF1α, β, or γ and compared with the results of healthy control. We analyzed the association between the clinical manifestations and protein expression in each tissue.

Results: When compared with the control group, any antigens showed no significant overexpression in the muscle. However, TIF1α showed higher positive rate in the skin of DM (12/15 [80%]) than in the skin of healthy control (0/7 [0%]) (p=0.001). TIF1γ expression was higher in the muscle of patients with DM while there was no expression in the muscle of healthy controls (DM, 8/19 [80%] vs. healthy control 0/7 [0%], p=0.039). In the tissues of inflammatory myopathies, TIF1α and TIF1γ demonstrated higher positive rates in the skin than in the muscle (TIF1α, muscle, 4/35 [11%] vs. skin, 12/15 [80%], p<0.001; TIF1γ, muscle, 10/35 [29%] vs. skin, 13/15 [87%], p<0.001). When analyzing DM patients only, the result was similar (TIF1α, muscle, 1/19 [5%] vs. skin, 12/15 [80%], p<0.001; TIF1γ, muscle, 8/19 [42%] vs. skin, 13/15 [87%], p=0.013). TIF1β showed strong positivity in all tissues of myositis or healthy control. Analyzing the association with TIF1s expression and cancer, there was no significant difference in the positive rate of TIF1α or γ in the muscle or skin between the myositis patient with or without cancer.

Conclusion: TIF1α was expressed more in the skin of DM patients than that in that of control group and TIF1γ in the muscle of DM patients than in that of control. The expression of TIF1α in the skin and TIF1γ in the muscle of cancer associated DM was not higher than those of DM without cancer. Thus the expression levels of TIF1α in the skin and TIF1γ in the muscle may be associated with myositis rather than with cancer.

Abnormal Composition of Circulating T and B Cells in Patients with Polymyositis and Dermatomyositis Is More Biased in Those with Interstitial Lung Diseases

Hirokazu Sasaki, Akito Takamura, Kimito Kawahata and Hitoshi Kohsaka, Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University (TMDU), Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are systemic inflammatory myopathies. They sometimes accompany interstitial lung disease (ILD), which can lead often to fatal outcome. For PM and DM treatment, high dose corticosteroid and cytotoxic drugs are used as first line therapies. Additionally, the effectiveness of T- and B-cell targeted therapies for refractory PM/DM has been reported. Although the clinical evidence indicates the T- and B-cell involvement in the pathogenesis of PM/DM, the lymphocyte subsets that contribute to the pathogenesis remain unclear. Analyzing peripheral blood mononuclear cell (PBMC) subsets will provide important insights into the understanding of the immune status and the pathogenesis in PM/DM. The aim of this study was to elucidate the lymphocyte subset biases of peripheral blood from the patients with PM/DM.

Methods: PBMCs from 17 (4 PM and 13 DM) patients including 8 patients with ILDs and from 18 healthy donors (HDs) were examined for lymphocyte subsets with flow cytometry according to the standardized immunophenotyping (Nat Rev Immunol 2012;12:191-200). Lymphocyte subsets were compared among patients with ILDs, those without ILDs, and HDs. In 6 DM patients, the lymphocyte subsets before and after the successful treatment were compared.

Results: The PM/DM patients had larger subsets of naïve CD4 T and naïve B cells, and smaller subsets of naïve CD8 T, central memory CD8 T (CD8 T_{CM}), effector memory CD4 T (CD4 T_{EM}), Th1, and memory B cells than HDs. These biased subsets were compared among the patients with ILDs, those without ILDs, and HDs. The patients with ILDs had larger biases in all of these subsets, except for Th1 cell subset, than HDs. Similar trends were also observed in PM/DM patients without ILDs although the differences were not statistically significant. Among the biased subsets in the patients, the naïve B cell subset decreased and the memory B cell subset increased after treatment.

Conclusion: The biases in naïve and memory T- and B- cell subsets suggest abnormal homeostatic regulation or migration of the smaller subsets from the peripheral blood into the inflamed tissues in PM/DM. Normalization of the biases in B-cell subsets after treatment implies B-cell involvement in the pathogenesis. The biases in T- and B-cell subsets in the patients with ILDs may represent intensive autoimmunity.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are systemic autoimmune diseases whose pathogenesis remain unclear. The type I interferon system has recently been suggested to have a role in subgroups of myositis patients, however the triggering factor have not yet been clarified. The anti-microbial peptide, LL-37, carriers numerous immunomodulatory properties in addition to its anti-microbial activity and is implicated in the pathogenesis of several autoimmune diseases through activation of the type I interferon pathway. The aim of this study was to explore a potential role of LL-37 in the pathogenesis of PM and DM.

Methods: Muscle biopsies taken from 6 PM, 6 DM and 5 healthy controls(HC) and skin biopsies taken from both affected (5 DM) and non-affected(3 of DM) areas and 6 HC were immunohistochemically stained for LL-37(monoclonal and polyclonal), CD66b(neutrophil), MxA(type I interferon induced protein) and BDCA-2(pDC). Double immunofluorescence stainings for LL-37 and CD66b was performed. The expression of LL-37 in muscle was confirmed with western blot.

Results: The expression of LL-37 was significantly increased in muscle tissue and symptomatic skin in patients with PM/DM compared to that in HC. LL-37 was mainly expressed by neutrophils as confirmed with double staining. The expression of monoclonal LL-37 positively correlated to CD66b expression in both muscle and skin tissues in PM/DM patients($R=0.9$ and 0.74 respectively, $P<0.01$). BDCA-2 positive pDCs was significantly increased in muscle tissue in patients when compared to HC. MxA was expressed in the same areas as LL-37, CD66b and BDCA-2, and positively correlated with CD66b expression in muscle tissue in all patients($R=0.59$, $P<0.05$). Moreover, the muscular expression of LL-37 and CD66b correlated with increased serum creatine kinase levels($R=0.62$ and 0.71 respectively, $P<0.05$). Monoclonal LL-37 expression in muscle tissue in patients with short disease duration correlated negatively to FI-2 score ($P<0.05$, $R=0.77$).

Conclusion: The data indicated that neutrophil-derived LL-37 may induce type I interferon production in affected muscle and skin tissues in patients with PM and DM and be involved in the pathogenesis of these conditions.

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Heat shock proteins (Hsps) are chaperones playing important roles in skeletal muscle physiology, adaptation to exercise or stress, and activation of inflammatory cells. The aim of our study was to assess Hsp90 expression in muscle biopsies and plasma of patients with idiopathic inflammatory myopathies (IIM) and to characterize its association with IIM-related features.

Methods: Total of 277 patients with IIM (198 females, 79 males; mean age 54.8; disease duration 4.1 years; dermatomyositis (DM, 104)/polymyositis (PM, 104)/cancer associated myositis (CAM, 42)/ necrotizing myopathy (IMNM, 27)) and 100 age-/sex-matched healthy individuals were included in plasma analysis and 50 muscle biopsy samples were stained for Hsp90 (PM-10, DM-10, IMNM-10, myodystrophy-10, myasthenia gravis-10). Patients with PM/DM fulfilled Bohan and Peter criteria and CAM was defined as cancer within 3 years of IIM diagnosis. Plasma Hsp90 was measured by ELISA (eBioscience, Vienna, Austria). Clinical disease circumstances were evaluated by Myositis Disease Activity Assessment (MYOACT), Myositis Intention to Treat Index (MITAX), Myositis Damage Index (MDI), physician and patient global activity using VAS and manual muscle testing (MMT8). CK, LD, ALT, *AST*and CRP were analyzed by routine techniques and IIM-specific autoantibodies by in-line blot and immunoprecipitation. Data are presented as median.

Results: In muscle biopsies Hsp90 expression was higher in IIM than in myodystrophy (myasthenia gravis used as another control was negative). Increased Hsp90 was detected in perifascicular degenerating and regenerating fibers, inflammatory cells (DM, PM), and necrotic and regenerating fibers (IMNM). Plasma Hsp90 levels were increased in IIM patients compared to healthy controls (20.2 vs. 9.2 ng/ml, $p < 0.0001$), and in individual subgroups of IIM vs. healthy controls (PM: 19.4, DM: 22.4, CAM: 19.1, IMNM: 19.6 ng/ml, $p < 0.0001$ for all). Hsp90 levels in all patients positively correlated with LD and AST ($r=0.551$, $p < 0.0001$; $r=0.372$, $p < 0.0001$, respectively), and there was a trend towards correlation with CK ($r=0.111$, $p=0.068$). Increased Hsp90 was associated with decreased MMT8 values ($r=-0.136$, $p=0.029$), in particular in proximal muscles. Hsp90 positively correlated with patient and doctor disease activity ($r=0.222$, $p=0.0004$; $r=0.217$, $p=0.0005$, respectively), pulmonary and muscle disease activity ($r=0.201$, $p=0.001$; $r=0.146$, $p=0.018$, respectively), MITAX and MYOACT ($r=0.175$, $p=0.005$; $r=0.159$, $p=0.012$, respectively), and with MDI extent/severity ($r=0.215$, $p=0.003$; $r=0.120$, $p=0.041$, respectively). Higher Hsp90 was found in patients with interstitial lung disease, cardiac involvement and dysphagia (25.4 vs. 18.9, $p=0.004$; 27.5 vs. 19.3, $p=0.004$; 25.0 vs. 18.2, $p=0.018$, respectively).

Conclusion: We demonstrate increased Hsp90 expression in IIM muscle biopsy samples, specifically in inflammatory cells, degenerating, regenerating and/or necrotic fibers. Increased Hsp90 plasma levels in IIM patients are associated with disease activity and damage, and with the involvement of proximal skeletal muscles, heart and lungs. Session Time: 9:00AM-11:00AM

Increased expression of TIF-1 gamma in duodenal adenocarcinoma from a patient with p155/140 dermatomyositis: a causal relationship?

Background/Purpose: Dermatomyositis is associated with an underlying malignancy in about 24% of cases. Anti-p155/140 antibodies have a strong predictive value for malignancy in adult dermatomyositis patients. The proposed target of the p155/140 antibodies are the TIF-1 family proteins, in particular TIF-1γ. Overexpression of TIF-1γ has been associated with the onset and progression of human hepatocellular carcinoma as well as with poor prognosis and worse survival in breast cancer, which suggests that it may play a role in carcinogenesis and represent a novel prognostic marker. We postulated that TIF-1γ was overexpressed in the duodenal adenocarcinoma of a patient with p155/140 dermatomyositis.

Methods: The patient's intestinal mass was processed following standard protocols for clinical examination and staging of intestinal cancer. After the primary diagnosis was made, formalin/PFA-fixed paraffin-embedded tissue blocks representative of the adenocarcinoma, adjacent normal small intestinal mucosa, as well as small intestinal adenocarcinoma tissue from a patient without dermatomyositis were selected for immunohistochemical staining with an anti-TIF-1γ mouse monoclonal primary antibody (Abcam Inc. Catalog nr. ab57172).

Results: The non-neoplastic small intestinal mucosa (figure 1) adjacent to the tumor showed an expected pattern of staining, with faint nuclear positivity in the regenerating cells of the crypts. The tumor cells (figure 2), however, showed strong diffuse nuclear staining, consistent with high levels of TIF-1γ. The small intestine adenocarcinoma from a patient without dermatomyositis also showed strong diffuse nuclear positivity.

Conclusion: We present the first evidence to our knowledge of TIF-1 overexpression in a solid tissue malignancy from a patient with anti-TIF-1γ (anti-p155/140) dermatomyositis. TIF-1γ was markedly overexpressed in the adenocarcinoma tissue from both the patient with p155/140 dermatomyositis and the patient without dermatomyositis, but showed only faint nuclear expression in the healthy intestinal tissue. The most intriguing question remains why TIF-1γ overexpression in malignant cells does not lead to an autoimmune response in each case and whether genetic alterations in the TRIM33 locus may render TIF-1γ immunogenic in a specific subset of patients.

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies (Abs) to 3-Hydroxy-3-Methylglutaryl Coenzyme A Reductase (HMGCR) identified in adult myositis patients with immune-mediated necrotizing myopathies (IMNM) have been associated with severe weakness, HLA DRB1*11, and statin use. The prevalence and features of juvenile idiopathic inflammatory myopathies (JIIM) patients with this myositis autoantibody (MSA) have not previously been described. Our purpose was to evaluate the prevalence, clinical features and outcomes of JIIM with anti-HMGCR Abs.

Methods: We examined the prevalence of HMGCR Abs in the Childhood Myositis Heterogeneity Study, a nationwide registry of JIIM patients. We also examined demographics and clinical features, outcomes, responses to therapy and associated HLA alleles for this MSA, and whether this MSA can be distinguished from other MSAs in children with myositis.

Results: Of the 441 JIIM patients tested, anti-HMGCR Abs were detected in the serum of 5 patients (1.1%) by ELISA and confirmed by immunoprecipitation. Among these 5 patients, 3 had juvenile dermatomyositis (JDM) and 2 had juvenile polymyositis (JPM). Median age at diagnosis was 8.1 years, 60% were female, 3 were Caucasian, 1 each was Black and Hispanic. HLA typing revealed the DRB1*0701-DQA1*0201 haplotype in 4 patients, and DRB1*0701 allele alone in the 5th (OR =$1.4X10^7$, P≤0.001 vs. healthy controls). None of the patients had a documented statin exposure. All patients had severe disease and were hospitalized at onset, and 2 used a wheelchair. Proximal and distal weakness, falling episodes, muscle atrophy, joint contractures and arthralgias were uniformly present in JIIM patients with anti-HMGCR Abs, and most of these were increased in frequency compared to other MSAs, including anti-synthetase (ARS), p155/140, MJ, and MSA-negative (p = 0.038 – 0.005), but not different from those with anti-SRP Abs. The median highest serum CK in patients with HMGCR Abs was 17,000 U/L [IQ range 441– 17,112 U/L]. Two patients' muscle biopsies showed prominent myonecrosis, myophagocytosis, degeneration, fiber size variation, and mild mononuclear cell infiltration. In 2/3 JDM patients, rashes were frequently mild and improved quickly. Other frequent features were fatigue (5/5), weight loss (4/5), dysphagia, regurgitation, dyspnea (3/5 each), while interstitial lung disease, cardiac involvement and Raynaud's were absent or infrequent, differing from anti-SRP and ARS Abs. The median number of drug received was 8.0 [IQ range 4.0-9.0] in patients with HMGCR Abs, with a median of 9 treatment trials and 2.6 drug therapies per trial over 22 months. All patients received oral prednisone and MTX; 4 IV methylprednisolone, 3 IVIG, 2 cyclophosphamide, and 2 biologics. Patients had partial responses to many of these, and none entered remission. Four patients had a chronic and 1 had polycyclic disease course. On final evaluation, 3 had continued weakness, 2 had elevated serum CK.

Conclusion: Anti-HMGCR Ab is an uncommon MSA in patients with JIIM, and as in adults, is associated with severe weakness, a necrotizing myopathy, and treatment-refractory disease. Interestingly, unlike adults, statin use has not been identified and a different HLA allele, HLA DRB1*0701, is associated in JIIM cases.

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Immune mediated necrotizing myopathy (IMNM) has been recently added as a new entity among dermatomyositis, polymyositis and sporadic inclusion body myositis. IMNM is defined by predominant muscle fiber necrosis and no or few inflammatory infiltrates. Two auto-antibodies are held to be specifically associated with IMNM: the anti-signal recognition particle antibody (SRP) and anti-3-Hydroxy-3-Methylglutaryl-CoA Reductase antibody (HMGCR). Those antibodies target ubiquitous cytoplasmic proteins. The clinical phenotype of SRP and HMGCR patients is characterized by severe proximal weakness of skeletal muscles, whereas extra-muscular manifestations are mild or absent. However, it is unknown to which extent pathological features are similar and muscular immune mechanisms especially those involved in the necrosis are largely unknown. It is crucial to gain insight in pathophysiology of the disease regarding its severity and refractory course.

Methods: Thus, we aim to precisely describe the morphology of skeletal muscle alterations of both conditions in a series of SRP and HMGCR patients, and analyze molecular immune mechanisms at the muscular level. Muscle biopsies from SRP (n=25) and HMGCR (n=19) patients were analyzed and compared to myositis patients (Jo-1, n=21 and dermatomyositis, n=7).

Results: SRP patients have the most important muscle deficit compare to HMGCR, Jo1 and dermatomyositis patients. Along that line, CK levels in SRP patients were the highest whereas the DM group had the lowest values. SRP patients showed the highest proportion of necrotic fibers and strikingly this proportion was similar in HMGCR and Jo1 patients. However, necrosis occurred in perifascicular regions only in Jo-1 patients, whereas it was randomly distributed in SRP and HMGCR patients. Creatine kinase levels correlated with proportion of necrotic fibers. Regeneration of fibers also correlated with necrosis and occurred much more frequently. Inflammation was regularly observed. Macrophages were the most abundant but T cells densities were in a quarter of cases in the same range as myositis controls. In addition, presence of T cells densities in SRP and HMGCR patients correlated with the proportion of necrotic fibers. qPCR and immunohistochemistry analysis showed the presence of classically activated macrophages in a Th-1 immune environment. These M1 macrophages were involved in myophagocytosis. In addition, humoral immunity with activation of the classical pathway of the complement cascade was observed. This was accompanied by a sarcolemmal immunoglobulins depositions and alternatively activated macrophages. Finally, positive membrane staining for SRP and HMGCR proteins were detected both *in vitro* (primary muscle cells culture) and *in vivo*(muscle biopsies for IMNM patients) on some muscle fibers.

Conclusion: SRP and HMGCR myopathies can no longer be considered as non-inflammatory myopathies since the inflammation is correlated with muscle necrosis, which involves humoral immunity including myositis-specific autoantibodies.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Histidyl-transfer RNA synthetase (HisRS, Jo-1) is a major autoantigen in myositis with lung involvement[1-4]. Simultaneous presence of anti-Jo-1 and anti-Ro52 antibodies has been demonstrated in patients with myositis[5-7]. We investigated the presence of HisRS in the extracellular compartments plasma, sera and bronchoalveolar lavage fluid (BALF). In addition, the occurrence of anti-Jo-1 antibody isotypes as well as anti-nuclear antibodies (ANA) was evaluated in BALF and sera from patients with myositis.

Methods: HisRS was measured in sera, plasma and BALF from patients with myositis (in both anti-Jo-1 positive and anti-Jo-1 negative patients), sarcoidosis, rheumatoid arthritis (RA) and healthy controls (HC) by dot-blot, western-blot, immunoprecipitation and mass spectrometry. The presence in BALF and sera of anti-Jo-1 isotypes and ANA was analysed by ELISA and addressable laser bead immunoassay.

Results: HisRS was detected in sera, plasma and BALF of patients with myositis, sarcoidosis and RA, and in HC. Systemic HisRS levels were significantly elevated in anti-Jo-1 positive myositis (14 out of 20 sera) compared to anti-Jo-1 negative myositis (10/18), sarcoidosis (0/8) and RA (3/15) patients, and HC (5/23). In BALF, significant levels of HisRS were detected in 6/8 HC and 5/8 sarcoidosis, compared to 4/8 myositis (2 anti-Jo-1 positive and 2 anti-Jo-1 negative). Our results suggest the presence of a factor in BALF with high binding capacity for HisRS and HisRS complexed with anti-HisRS-N-terminal antibody. C1q-immune complexes (IC) binding HisRS were not the binding factor. However, anti-Jo-1 antibodies as well as anti-Ro52 IgG were identified in myositis BALF (5/8 patients were positive for anti-Jo1 IgG, 3/8 for anti-Jo1 IgA, 3/8 for anti-Jo1 IgM and 4/8 for anti-Ro52 IgG). Furthermore, a positive correlation between the presence of anti-Jo-1 IgG and anti-Ro52 IgG in myositis BALF was identified (r^2=0.881; p=0.007).

Conclusion: HisRS was detected both in blood and BALF. The identification of extracellular HisRS, anti-Jo-1 isotypes and anti-Ro52 IgG in myositis BALF may provide additional clues for the development of autoimmunity in the lungs.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The idiopathic inflammatory myopathies (IIM) are a heterogeneous group of rare autoimmune diseases characterised by muscle weakness and extramuscular manifestations. The most common autoantibody in IIM is anti-Jo-1, present in ~20% of patients and associated with anti-synthetase syndrome; a distinct clinical entity characterised by the presence of myositis, interstitial lung disease, Raynaud's and mechanics' hands. The development of anti-Jo-1 antibodies is also associated with the presence of HLA-DRB1*03:01. Smoking is a risk factor for ACPA+ rheumatoid arthritis in patients possessing the shared epitope. A previous study has suggested an interaction between smoking and DRB1*03 for the development of anti-Jo-1 antibodies in IIM. We sought to replicate this in a large single-country cohort using high resolution HLA imputation data.

Methods: Eight hundred and seventy two UK patients of Caucasian descent were recruited through the UK Myositis Network (UKMYONET) and Juvenile Dermatomyositis Research Group (JDRG) comprising predominantly of adult and juvenile dermatomyositis and polymyositis patients. Juvenile cases were included as a group of patients not exposed to smoking. Smoking was defined as 'having ever smoked at least one cigarette a day for as long as a year' at the time of recruitment. Antibody testing was conducted using immunoprecipitation. DRB1*03:01 was imputed from SNP genotyping information using SNP2HLA. Five hundred and ninety one patients had complete data for smoking, DRB1*03:01 and anti-Jo-1 status.

Results: A strong effect was seen with DRB1*03:01 and the development of anti-Jo-1 antibodies (see table 1). In DRB1*03:01 negative cases, an association was found between smoking and the development of anti-Jo-1 antibodies (p=0.04). In DRB1*03:01 positive cases, an association between smoking and the development of anti-Jo-1 antibodies almost reached statistical significance (p=0.052). No departure from a multiplicative effect between smoking and DRB1*03:01 was observed using anti-Jo-1 as the outcome measure, suggesting that there is no interaction between smoking and DRB1*03:01 status. When repeating the analysis in adult cases only, the effect of smoking did not reach statistical significance for the development of anti-Jo-1 antibodies.

Conclusion: Smoking may be associated with an increased risk of developing anti-Jo-1 antibodies, independent of DRB1*03:01 status. The exposure to smoking in adulthood may contribute to the increased frequency of anti-Jo-1 antibodies in adult compared to juvenile IIM cases.

Table 1 Anti-Jo-1 frequency by smoking and HLA-DRB1*03:01 status using DRB1*03:01 negative non-smokers as the reference group. Includes 591 adult and juvenile patients.

Smoking status	DRB1*03:01 status	Jo-1 +ve, n (%)	Jo-1 –ve, n (%)	OR, 95% CI	P value
Negative	Negative	6 (3)	211 (97)	1.0	
Positive	Negative	7 (8)	76 (92)	3.24, 1.06-9.94	0.04
Negative	Positive	40 (20)	156 (80)	9.02, 3.73-21.80	P<0.0001
Positive	Positive	30 (32)	65 (68)	16.23, 6.22-49.28	P<0.0001

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibodies to small ubiquitin-like modifier activating enzyme (SAE) are associated with diagnosis of dermatomyositis (DM). The aims of this study were to establish the frequency, demographic and clinical characteristics of SAE antibody-positive patients in a referral setting, and to evaluate the performance of a line immunoblot assay (LIA) for detection of SAE antibodies.

Methods: Consecutive samples (n=3,921) received at ARUP Laboratories for myositis antibodies testing were screened by protein immunoprecipitation (IP) of S^{32}-labeled K562 cells. Antinuclear antibodies (ANA) were detected by indirect immunofluorescent antibody (IFA) test. Of these, 13 samples with distinct bands corresponding to approximately 40 and 90 kDa were identified as suspicious of SAE and tested for SAE antibodies by LIA. As controls, 170 disease controls and 44 self-proclaimed healthy controls were also evaluated by LIA. Clinical and laboratory data for all SAE antibody-positive patients were sought to confirm diagnosis.

Results: Twelve out of 13 patient samples with 40 and 90 kDa bands observed in the IP assay were positive in the LIA. SAE antibodies were identified in 2 of the disease control samples, one signal recognition particle (SRP) antibody-positive sample with additional bands at 40 and 90 kDa and one transcriptional intermediary factor 1-γ (TIF1γ) antibody-positive sample with no apparent bands corresponding to 40 and 90 kDa bands (false positive rate = 0.5%). SAE antibodies were not identified in any of the self-proclaimed healthy controls. Overall very good qualitative agreement was observed between the two methods for SAE antibody marker (Cohen's *kappa* = 0.92, 95% CI 0.81-1.00). The positive, negative, and total percent agreements were 92.3% (95% CI 64.0-99.8%), 99.5% (95% CI 97.4-100%), and 99.5% (95% CI 97.5-100%), respectively. SAE antibodies were detected by IP and LIA in 12/3,921 sera (0.3%). Patients positive for SAE in both methods all had a confirmed diagnosis of DM, with characteristic cutaneous manifestations and varying degrees of muscle involvement. Presence of SAE antibodies was mainly associated with homogeneous and/or speckled antinuclear antibody patterns by IFA.

Conclusion: Identification of SAE antibodies is important not only for diagnosis, but also for prognosis and disease management in patients with DM since some of the other DM-associated autoantibodies have been associated with malignancy or rapidly progressive interstitial lung disease. Testing for SAE antibodies is currently only performed by a small number of labs, primarily on a research basis. LIA confirmed the presence of SAE antibodies in patients with 40 and 90 kDa bands observed in the IP assay. Combined use of both methods improves reliability for the diagnosis of DM in patients undergoing evaluation for inflammatory myopathies.

Session Title: Muscle Biology, Myositis and Myopathies - Poster I: Basic/Translational

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have suggested that neutrophil to lymphocyte ratio (NLR) could be an emerging predictive marker of disease activity or mortality in patients with chronic inflammatory diseases, cardiovascular diseases or malignancies. This study was aimed to evaluate the clinical significance and prognostic value of NLR in patients with dermatomyositis.

Methods: We retrospectively reviewed 176 patients with newly diagnosed dermatomyositis who satisfied Peter and Bohan criteria between August 2003 and January 2016. Clinical characteristics and laboratory findings were compared between survivor group and non-survivor group. Using the receiver operating characteristics curves, the cut-off value of NLR for predicting survival was calculated. Univariate and multivariate analyses using Cox proportional hazard model were performed to identify associated factors with survival.

Results: During follow-up (range 0.22-119.4 months), 24 patients (13.6%) died. Non-survivor group had older age (p = 0.011), more interstitial lung disease (ILD, p = 0.015), higher NLR (p = 0.011), lower albumin (p < 0.001), and higher creatinine level (p = 0.005) than survivor group. NLR showed significant positive correlation with C-reactive protein (CRP, r = 0.386, p <0.001), creatine kinase (CK, r = 0.161, p = 0.036), and lactate dehydrogenase (LDH, r = 0.3253, p = 0.001), and negative correlation with albumin (r = -0.298, p <0.001). The optimal cut-off value of NLR for overall survival was 3.8 with the area under the curve of 0.717. According to the cut-off value of 3.8, we classified 87 patients (49.4 %) into the low NLR group and 83 patients (47.2 %) into the high NLR group. The higher NLR group was associated with fever (p = 0.001), the higher muscle enzymes (CK, p = 0.025; LDH, p = 0.001), higher CRP (p < 0.001), lower albumin (p < 0.001), high-dose glucocorticoid therapy (p = 0.031), acute interstitial pneumonia (p = 0.024) and death (p < 0.001). Kaplan-Meier analysis and log-rank test demonstrated a significant difference in survival curves according to NLR of 3.8 (p < 0.001). Cox hazard regression analysis showed that NLR >=3.8, low albumin, the presence of ILD and old age were independent predictors for death (Table 1).

Conclusion: Our results demonstrated that higher level of the NLR was associated with worse overall survival and the NLR may play a role as an independent prognostic marker in patients with dermatomyositis.

- Table 1. Multivariate Cox hazard regression analysis of risk factors for death in patients with dermatomyositis

Variable	Death		
	HR	95% CI	p-value
Age	1.087	1.038-1.137	<0.001
NLR >= 3.8	4.905	1.413-17.025	0.012
Interstitial lung disease	3.421	1.313-8.917	0.012
Albumin	0.498	0.270-0.921	0.026

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (KOA), particularly accelerated KOA, is associated with older age and being overweight. Greater age and weight are associated with impaired glucose homeostasis and elevated inflammation. There is a lot of interest in the role of glucose homeostasis and inflammation in KOA but it is unclear if they are associated with incident accelerated KOA. We aimed to determine if serum measures of impaired glucose homeostasis (glucose concentrations or glycated serum protein, GSP) or inflammation (high-sensitivity C-reactive protein, CRP) are related to incident KOA or incident accelerated KOA.

Methods: We conducted a case-control study using data from baseline and the first 4 annual visits of the Osteoarthritis Initiative. All participants had no radiographic KOA at baseline (Kellgren-Lawrence [KL] < 2). We classified 3 groups: 1) accelerated KOA: ≥ 1 knee progressed to advance-stage KOA (KL Grade 3 or 4) within 48 months, 2) typical onset of KOA: ≥ 1 knee increased in radiographic scoring within 48 months (excluding those with accelerated KOA), and 3) No KOA: no change in KL grade by 48-months. We did 1:1:1 matching based on sex. Weight-bearing, fixed flexion posterior-anterior knee radiographs were obtained at all visits. A laboratory blinded to group assignment conducted high-sensitivity singleplex assay for CRP (Aviscera Bioscience), colormetric/endpoint assay (GSP, MyBiosource), and glucose concentrations with deproteinized samples. Samples were tested in duplicate. Due to nonlinear relationships, we used 3 piece-wise multinomial logistic regression models to determine if baseline CRP, GSP, or glucose were associated with typical onset of KOA or incident accelerated KOA compared with no KOA. We adjusted for age, body mass index, and sex.

Results: We analyzed 54 adults/group and described their characteristics in Table 1. Baseline CRP, GSP, and glucose were not significantly associated with incident accelerated KOA (Table 2). However, lower and higher GSP concentrations were associated with a typical onset of KOA compared with adults with concentrations (log) closer to 5.4 (Table 2, Fig. 1).

Conclusion: Glucose homeostasis may predict individuals at risk of typical onset of KOA but not accelerated KOA. This is further evidence that accelerated KOA may be a distinct disorder from KOA.

Table 1. No Significant Baseline Differences Among Those with Accelerated Knee Osteoarthritis (AKOA), Typical Onset of Knee Osteoarthritis (KOA), and no KOA			
Baseline variable	**No KOA (n = 54)**	**KOA (n = 54)**	**AKOA (n = 54)**
Females (n, %)	24 (63%)	24 (63%)	24 (63%)
Presence of Diabetes (n, %)	1 (2%)	0 (0%)	4 (8%)
Age (years)	59 (8)	57 (8)	62 (9)
Body Mass Index (kg/m^2)	27.3 (4.9)	27.9 (4.6)	28.9 (4.7)
Fasting Time (hrs)	12 (2)	12 (3)	12 (2)
C-reactive Protein (mg/L)	3.53 (1.09)	3.16 (1.15)	3.70 (1.05)
Glycated Serum Protein (ln)	5.47 (0.58)	5.51 (0.83)	5.48 (0.77)
Glucose (mg/dL)	111.25 (24.34)	106.38 (24.90)	107.27 (32.16)
Frequencies were analyzed with Chi-Square test and group means with paired-sample t-tests.			

Table 2. Baseline Glycated Serum Protein Concentrations are Associated with a Typical Onset of Knee Osteoarthritis (KOA)			
Predictor	**No KOA**	**KOA (n=54) Adjusted OR**	**Accelerated KOA (n=54) Adjusted OR**
C-Reactive Protein < 3.4 mg/L	**REFERENCE**	0.70 (0.37,1.34)	1.27 (0.58,2.79)
C-Reactive Protein > 3.4 mg/L	**REFERENCE**	0.69 (0.33,1.45)	0.91 (0.46,1.79)
Glycate Serum Protein (log) < 5.4	**REFERENCE**	**0.14 (0.03,0.74)**	0.20 (0.04,1.09)
Glycate Serum Protein (log) > 5.4	**REFERENCE**	**2.40 (1.02,5.63)**	1.78 (0.73,4.30)
Glucose <115 mg/dL	**REFERENCE**	0.99 (0.97,1.02)	0.98 (0.96,1.00)
Glucose >115 mg/dL	**REFERENCE**	0.99 (0.95,1.03)	1.02 (0.98,1.05)
All analyses are based on piece-wise regression models with cutpoints defined by graphing splines. All analyses are adjusted for age, body mass index, and sex (matching variable). There were no interactions with body mass index.

Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rotator cuff tear (RCT) and hand osteroarthritis (HOA) are commonly accompanied because they share a similar pathogenesis. However, there was no previous study investigating the relationship between RCT and HOA. The aim of this study was to estimate the prevalence and associated factors of developing RCT in patients with HOA.

Methods: In this study, we enrolled 1150 individuals who lived in Gyeongnam province in Korea from June 2013 to December 2015. Physical examinations were performed by rheumatologists and orthopedists. Plain radiography of hands and magnetic resonance imaging (MRI) of shoulders were performed in all participants. Serum levels of high sensitive C reactive protein (hsCRP) and high density lipoprotein (HDL) were checked. RCT was diagnosed by clinical examination and MRI findings. Diagnosis of HOA was made by the 1990 American College of Rheumatology classification criteria. Severity of radiographic HOA was assessed by sum of Kellgren–Lawrence (KL) grades of total involved joints on plain radiographs.

Results: The prevalence of RCT was higher in patients with HOA group (192/307, 62.5%) than those without HOA (410/827, 49.5%, $p < 0.001$). Among 307 with HOA, patients with RCT were older (62.69 ± 7.04 vs. 59.11 ± 7.69, $p < 0.001$) and showed higher hsCRP (1.51 ± 3.78 vs. 0.67 ± 0.70, $p = 0.004$) and lower HDL levels (55.66 ± 15.46 vs. 60.48 ± 12.45, $p = 0.003$) compared to those without RCT. There were no significant differences in gender, smoking, comorbidities, work period, body mass index, a number of affected joints, HOA severity, and prevalence of erosive HOA between both groups. Multiple logistic regression analysis showed significant associations of age (odds ratio [OR] 1.06; 95% confidence interval [CI] 1.02 - 1.10), serum levels of hsCRP (OR 1.37, CI 1.04 - 1.80), and HDL (OR 2.13, CI 1.14 3.98) with RCT in HOA patients.

Conclusion: The prevalence of RCT is high and age and serum levels of hsCRP and HDL have predictive roles in the development of RCT in HOA patients.

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyaluronic acid (HA) viscosupplementation is widely used in patients with knee osteoarthritis (KOA), but variable reported outcomes have impacted its incorporation into treatment algorithms. The current study examined clinical predictors of response to HA injections.

Methods: Patients receiving HA injections during routine visits were enrolled if they had KOA pain for ≥1 month and VAS pain ≥30. Baseline assessments included BMI, the Knee Injury and Osteoarthritis Outcome Score (KOOS) questionnaire, and standing knee xrays scored for Kellgren-Lawrence grade. The use of single vs multi-week HA products, anatomic injection approach, and use of ultrasound guidance were additional variables. Patients completed the KOOS at 2 months post-treatment to evaluate improvement from baseline.

Results: We screened 384 and enrolled 287 patients (65.5% female, age 62 years ±11, 28-88; BMI 31.0 kg/m^2±6.7, 18-54) with a baseline mean KOOS pain score (0 to 100) of 51.5 ±17.4, We obtained 2 month follow-up from 226 patients, with a mean KOOS pain improvement of 9.6 (Fig. 1) and similar results with other KOOS subscores. After 2 months, younger patients reported significantly better ΔKOOS pain improvement. Those <60 benefitted more than the 60-69 age group, with the mildest response from those 70 and older (11.9±16.7 vs 10.3±17.8 vs 4.8±14.4, p=0.042). A similar trend followed for the % of patients who showed any improvement in these subgroups (73.0%, 65.4%, 60.7%).

Patients with less severe radiographic disease trended towards more improvement, with KL0 vs KL1/2 vs KL3/4 ΔKOOS pain scores of 13.0±17.4, 11.7±17.7 and 7.9±16.0, p=0.205 and response rates of 76.9%, 71.9%, and 66.4%.

Those receiving a single-dose injection had similar ΔKOOS pain results than the traditionally-used multi-week versions (10.3±15.0 vs 9.2±17.5, p=0.674). This single-dose group displayed a higher % of any improvement (76.8% vs 63.1%). Obese (BMI>30) and non-obese patients responded similarly with ΔKOOS pain averages of 10.2 and 8.9 and response rates of 68.7% and 65.8%. Further breakdown into smaller BMI subgroups was similarly unrevealing, as was a linear regression of BMI vs ΔKOOS Pain (R=0.178, p= 0.674). In addition, we found no significant difference in outcome from various anatomic needle approaches (medial, lateral, flexed knee) or from the use of ultrasound guidance.

Conclusion: Younger KOA patients responded better 2 months following a course of HA viscosupplementation, and there was a trend towards more improvement in patients with less severe radiographic disease. Obesity, anatomic approach and ultrasound guidance did not appear to impact response. Single-injection formulations provided as much improvement as multi-injection products by KOOS scores – with less time and expense. These results could tailor future algorithms for more appropriate and cost-effective use of HA in KOA management.

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Foot pronation can lead to lateral patellofemoral (PF) maltracking with reduced tibiofemoral (TF) varum, inciting speculation that the highly pronated foot reported in knees with osteoarthritis (OA) could increase risk of worsening lateral PF joint damage, while reducing risk of worsening medial TF damage. Yet, longitudinal data is lacking and dynamic foot pronation measured during the early, mid, and terminal phases of walking may differ from measures in static standing. Our purpose was to explore the relation of foot pronation measured during each phase of walking to the 2-year risk of worsening lateral PF and medial TF cartilage damage. Pronation effects on PF tracking and knee varus moment tend to be maximal during the early stance phase.

Methods: The Multicenter Osteoarthritis Study (MOST) includes adults aged 50-79 years with or at risk of knee OA. At the 60 month exam, high-resolution plantar pressure profiles were acquired during 5 trials of self-paced walking. From

these, we measured foot pronation during the early, mid, and terminal stance phases using the Pronation-Supination Index (PSI), as described by Motooka, et al. (same-day retest ICC 0.46 to 0.94), where lower values indicate greater pronation. From 1.0 T MRIs, readers scored (0-6) one knee per subject for cartilage damage in each sub-region of the lateral PF (2 sub-regions) and medial TF (5 sub-regions) compartments using WORMS (weighted kappa > 0.63). Among sub-regions with submaximal scores at 60 months, worsening damage was any increase in WORMS score at 84 months. Separate logistic regression models estimated the relative odds of worsening lateral PF and medial TF cartilage damage within quintiles of increasing foot pronation compared to feet with the least pronation. Adjustments were made for age, sex, and BMI. GEE accounted for non-independent knee sub-regions.

Results: 1067 and 1104 subjects (mean age 66.8 ± 7.6 years, BMI 29.6 ± 4.8 kg/m2, 60.7% female) contributed to the analysis of worsening lateral PF and medial TF cartilage damage, respectively. Compared to feet with the least pronation, odds of worsening lateral PF damage were 2.35 (95% CI: 1.38, 4.01) times greater in limbs with the greatest foot pronation during early stance ($p < 0.002$). A non-significant trend suggested a possible relation between greater early phase foot pronation and reduced odds of medial TF worsening. There was no association between foot pronation during other phases of walking and risk of worsening knee damage (Table).

Conclusion: In adults with or at-risk of knee OA, feet with the greatest foot pronation during the early stance phase of walking are at increased risk of worsening knee cartilage damage in the lateral PF compartment. These findings could inform efforts to refine preventative footwear interventions for compartment-specific knee OA.

Table. Relative odds (OR) of worsening lateral patellofemoral and medial tibiofemoral cartilage damage in quintiles of increasing foot pronation (PSI) during the early, mid, and terminal stance phases walking.

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Falls are the leading cause of injury-related morbidity and mortality in older adults. To our knowledge no studies have examined the association between knee OA and fall injuries.

Methods: Using data from the Health ABC Knee Osteoarthritis Substudy, a community-based study of white and black adults ages 70-79 (42% black; 48% men) at baseline (1997-1998), we tested the associations (at the person-level) between knee pain without radiographic OA (ROA), knee ROA without pain, and knee symptomatic ROA (sROA) and incident fall injuries among 962 adults mean (SD) age 74.7 (2.9) years. We also examined whether these associations differed by sex, obesity status, and fall injury type (fracture vs. non-fracture). Knee ROA was defined as having a Kellgren-Lawrence grade of ≥2 in at least one knee. Knee sROA was defined as having both ROA and pain symptoms (during the last 30 days) in the same knee. Fall injuries were defined using a validated diagnoses code algorithm from linked Medicare claims (99.2% linkage) as any unique event with a fall code (E880-888) and/or non-vertebral fractures (800-804, 807-829). Cox regression modeling was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs). Covariates associated with the exposure or outcome at $p<0.1$ were included in multivariate adjusted models.

Results: The mean (SD) follow-up time was 7.50 (3.02) years. The prevalence of sROA, pain without ROA, ROA without pain, and no ROA or pain was 34.4%, 40.0%, 4.8%, and 20.8%, respectively. Of the 962 participants, 274 (28.5%) had an incident fall injury. Compared with those without ROA or pain, individuals with pain without ROA (HR= 1.28; 95% CI: 0.89, 1.85), ROA without pain (HR= 1.18; 95% CI: 0.59, 2.39), and sROA (HR=1.24; 95% CI: 0.83, 1.85) did not have a significantly increased risk of fall injuries (Table). Among men only, and compared with men without ROA or pain, those with pain without ROA (HR= 2.13; 95% CI: 1.01, 4.50, p-value=0.048) and sROA (HR=2.28; 95% CI: 1.00, 5.18, p-value=0.049) had a significantly higher risk of fall injuries (Table). The association between knee OA and fall injuries did not differ by obesity status or fall injury type.

Conclusion: Both knee sROA and knee pain without ROA were independently associated with a borderline increased risk of incident fall injuries in men only. **Table.** Adjusted risk of fall injuries associated with knee pain without ROA, knee ROA with pain, and knee sROA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a chronic and progressive degenerative disease. While management of OA should be directed to long-term control of symptoms and joint structure changes, existing pharmacological agents are mostly studied for their effects on symptoms for short-term periods. This is the first systematic review and meta-analysis investigating the effects of available medications over long-term treatment courses on symptoms and structure in knee OA.

Methods: The Cochrane Central Register of Controlled Trials (CENTRAL), PubMed, Embase, Scopus and Web of Science were searched for randomized controlled trials (RCTs) of pharmacological interventions in knee OA published until February 29, 2016. Reference lists of retrieved articles were also screened for additional trials. Only RCTs with treatment/follow-up of at least one year were eligible. The primary outcome was knee OA pain change from baseline to the endpoint (≥ 12 months) on a validated scale. Secondary outcomes were changes in physical function and joint structure expressed as radiologic medial tibiofemoral joint space narrowing (JSN). We performed a random-effects network meta-analysis within a Bayesian framework. Imputation methods for mean changes and variability measures were adopted to include papers with incomplete data. Quality of evidence was rated based on the GRADE approach.

Results: Out of 5992 articles for RCTs of drug therapy in knee OA, 38 RCTs involving 18833 patients met the long-term

eligibility criteria and included virtually all available pharmacological intervention categories: 27 interventions including placebo for pain (Figure), 13 for physical function and 17 for JSN, with trial duration ranging between 1 and 3 years. There was no evidence of efficacy for most interventions vs placebo, with the exception of prescription glucosamine sulfate that was significant on pain (Figure) and physical function, with a Glass' Delta Effect Size (ES) of -0.29 [95% credibility interval: -0.49; -0.10] and -0.32 [-0.52, -0.12], respectively, and high quality of evidence rated by GRADE. Glucosamine sulfate, chondroitin sulfate and strontium ranelate were the only interventions able to significantly reduce radiologic JSN (ES 0.42 [0.20; 0.64], 0.20 [0.08; 0.31] and 0.20 [0.06; 0.35], respectively).

Conclusion: This network meta-analysis shows no evidence of efficacy in the long-term management (at least one year) of knee OA for available medications including NSAIDs, corticosteroids, acetaminophen, putative disease-modifiers, most bone acting agents or Slow Acting Drugs in OA. The only exception is prescription glucosamine sulfate, that is consistently effective on symptoms and joint structure changes, while chondroitin sulfate and strontium ranelate are effective only on structure. Additional long-term RCTs of available and new medications are needed in OA.

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) etiopathogenesis includes an inflammatory component. Published reports indicate that synovial fluid urate levels, even in patients without gout, associate with OA prevalence/severity. Whether serum urate (sUA), the precursor for gout and a biomarker for cardiovascular and kidney disease, may serve as a biomarker to convey or predict OA risk is not known. We investigated whether sUA levels associate with knee OA radiographic severity and contrast MRI-measured quantitative synovial volume (SV), and whether sUA levels predict radiographic progression, in a gout-free knee OA cohort.

Methods: We assessed sUA in 88 gout-free subjects who completed a 24-month prospective, natural history knee OA study. Subjects had symptomatic medial knee OA, met ACR knee OA criteria and had BMI <33 at study entry. sUA was measured (enzyme-colorimetry) in serum frozen and banked at baseline. At baseline and 24 months, patients underwent standardized weight-bearing fixed-flexion posteroanterior knee radiographs (SynaFlexer™). Twenty-seven subjects additionally had a dynamic gadolinium-enhanced 3.0T knee MRI that was read for quantitative synovial volume (SV). A musculoskeletal radiologist, blinded to subject data, determined joint space width (JSW) and Kellgren-Lawrence (KL) grades at each time point. Joint space narrowing (JSN) was determined as JSW change from baseline to 24 months. Pearson's correlations, student's t-tests, one-way ANOVA with post hoc Tukey-Kramer tests, ROC and AUC curves were used in statistical analyses, as appropriate.

Results: sUA correlated with JSN in both univariate ($r=0.40$, $p\leq0.01$) and multivariate analyses (adjusting for age, gender and BMI, $r=0.28$, $p=0.010$). There was a significant difference in mean JSN after dichotomization of sUA at 6.8mg/dL, the solubility point for serum urate, even after adjustment for age, gender and BMI (JSN [±SEM] of 0.90mm±0.20mm for sUA≥6.8; JSN [±SEM] of 0.31mm±0.09mm for sUA<6.8, $p<0.01$). Baseline sUA distinguished progressors (JSN>0.2mm), and fast progressors (JSN>0.5mm), from non-progressors (JSN≤0.0mm) in multivariate analyses (area under the receiver operating characteristic curve [AUC] 0.626, $p=0.027$; AUC 0.620, $p=0.045$, respectively). sUA also correlated with SV ($r=0.44$, $p=0.0040$), a possible marker of JSN, though this correlation did not persist after controlling for age, gender and BMI ($r=0.13$, $p=0.562$).

Conclusion: In non-gout patients with knee OA, sUA levels predict JSN and may serve as a biomarker for OA progression.

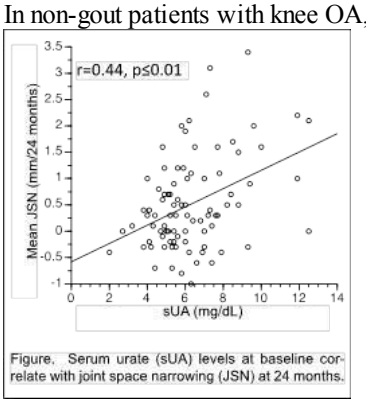

Figure. Serum urate (sUA) levels at baseline correlate with joint space narrowing (JSN) at 24 months.

Efficacy and Safety of Fasinumab for Osteoarthritic Pain in Patients with Moderate to Severe Osteoarthritis of the Knees or Hips

Jennifer Maloney[1], Alan Kivitz[2], Thomas J. Schnitzer[3], Paula Dakin[1], Catherine Stehman-Breen[1] and Greg Geba[1], [1]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [2]Altoona Center for Clinical Research, Duncansville, PA, [3]Northwestern University, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is an important cause of chronic pain in older adults. Fasinumab is a fully-human, high-affinity monoclonal antibody directed against the nerve growth factor (NGF). By selectively blocking NGF, fasinumab has the potential to effectively modulate NGF associated pain without causing some of the well-known adverse side effects of commonly used analgesic medications such as opioids and NSAIDS. We assessed the efficacy and safety of fasinumab on pain due to OA in patients with intolerance or inadequate pain relief from analgesics.

Methods: Adult patients were required to have a diagnosis of OA of the knee or hip based on American College of Rheumatology classification criteria. Eligible patients had an inadequate response or were intolerant to standard-of-care pain medications. Patients were required to have a Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale score of ≥4 and a Kellgren-Lawrence X-ray grading of ≥2 in at least one hip or knee joint. Patients were excluded if they had evidence of joint instability on screening imaging or if they had significant concomitant medical conditions that could interfere with the efficacy or safety assessments. Eligible patients were randomized to receive placebo or 1 mg, 3 mg, 6 mg, or 9 mg of fasinumab subcutaneously every 4 weeks through Week 12. Primary efficacy was measured as a change from baseline to week 16 for the WOMAC pain subscale. WOMAC physical function and Patient Global Assessment (PGA) were measured as secondary endpoints. The primary efficacy variables were analyzed using a mixed-effect model repeated measure approach.

Results: Four hundred and nineteen subjects received at least one dose of study medication. At week 16, LS mean changes from baseline in the WOMAC pain subscale in patients were -2.25 for placebo, -3.35 (1 mg), -3.33 (3 mg), -3.03 (6 mg), and -3.65 (9 mg) for the fasinumab groups; all fasinumab groups showed significant improvement vs placebo ($p \leq 0.05$). Improvements were also observed for WOMAC physical function and PGA. Fasinumab was generally well tolerated. As expected for the class of NGF antibodies, certain neuromuscular events, including arthralgia, paraesthesia, hypoaesthesia, and peripheral edema, occurred more commonly in fasinumab treated patients. During the study period, there were the following number of subchondral insufficiency fracture cases: 1, 0, 2, 0, and 4 in the placebo, 1 mg, 3 mg, 6 mg and 9 mg groups, respectively. There was 1 case of rapidly progressive osteoarthritis in each of the 3 mg, 6 mg, and 9 mg fasinumab groups.

Conclusion: <span",'serif'; mso-fareast-language:="mso-fareast-language:" mso-ansi-language:="mso-ansi-language:" mso-fareast-theme-font:="mso-fareast-theme-font:" font-size:="font-size:" ar-sa;"="AR-SA;"" mincho';="Mincho';" mso-fareast-'ms="mso-fareast-'MS" 12pt;="12pt;" minor-fareast;="minor-fareast;" en-us;="EN-US;" mso-bidi-language:="mso-bidi-language:">These 16-week results suggest that fasinumab provided significant clinical benefit in relieving osteoarthritic pain compared with placebo in patients with moderate to severe OA who have inadequate pain relief or are intolerant to other analgesics. Fasinumab was generally well tolerated in the majority of patients in this study. Clinicaltrials.gov NCT02447276

Knee osteoarthritis as risk factor for hip osteoarthritis

Background/Purpose: While the hip and knee are linked biomechanically, the risk of hip osteoarthritis (OA) in persons with knee OA has not been well studied. Knee OA is associated with weak hip girdle muscles which may predispose to hip OA. Furthermore, persons with painful knee OA may alter their gait and abnormally load other lower extremity joints. We examined the risk of hip OA in those with knee OA in the Multicenter Osteoarthritis Study (MOST).

Methods: MOST is a NIH funded cohort study of risk factors for knee OA. To evaluate hip OA, we used long limb films which included hip imaging obtained at baseline and 60 months follow-up. Radiographic hip OA was defined using the modified Croft definition, and we defined incident radiographic hip OA as development of OA at 60 months. To evaluate knee OA, PA and lateral weight bearing films were obtained at baseline. A knee had radiographic OA if that knee had either tibio-femoral or patello-femoral OA (Kellgren and Lawrence score >=2). Symptomatic knee OA was defined as knee with radiographic OA and knee pain on most days in a month. For the 1st analysis, the exposure groups were knees with or without (either unilateral or bilateral) radiographic knee OA at baseline. For the 2nd analysis, the exposure groups were knees with or without symptomatic knee OA at baseline. The outcomes for both analyses were incident radiographic hip OA. For both analyses, we compared the risk of incident radiographic hip OA in hips with or without (radiographic or symptomatic) knee OA. The analyses were adjusted for hip OA risk factors including age, sex, BMI, knee injury/surgery. We carried out subanalyses among those with unilateral prevalent radiographic and symptomatic knee OA to compare the risk of incident ipsilateral vs contralateral hip OA at 60 months.

Results: In the 1st analysis, the risk of incident radiographic hip OA with any radiographic knee OA was not significantly greater than risk of incident radiographic hip OA without any radiographic knee OA (see table 1). For the 2nd analysis, there was an increased risk of incident radiographic hip OA with any symptomatic knee OA (see table 1), and this increased risk was limited to the subset of subjects with unilateral symptomatic knee OA (adjusted OR 1.99, $p = 0.01$). Among those with prevalent radiographic or symptomatic knee OA, we found no predilection for ipsilateral vs. contralateral incident hip OA (see table 2).

Conclusion: Pre-existing radiographic knee OA did not increase risk for incident radiographic hip OA, but symptomatic knee OA may increase risk for incident radiographic hip OA.

Table 1

1st Analysis: Incident Radiographic Hip OA in subjects with **radiographic** knee OA

	n/n (%)	Crude Risk Ratio	Crude p value	Adjusted Risk Ratio*	Adjusted p value
Subjects without knee OA	30/907 (3.31%)	1.00 (reference)	(ref)	1.00 (reference)	(ref)
Subjects with **any** knee OA	44/889 (4.95%)	1.50 (0.94, 2.38)	0.09	1.55 (0.94, 2.55)	0.08
Subjects with **unilateral** knee OA	20/439 (4.56%)	1.38 (0.78, 2.43)	0.27	1.36 (0.75, 2.45)	0.31
Subjects with **bilateral** knee OA	24/450 (5.33%)	1.61 (0.94, 2.76)	0.08	1.71 (0.93, 3.13)	0.08

2nd Analysis: Incident Radiographic Hip OA in subjects with **symptomatic** knee OA

	n/n (%)	Crude Risk Ratio	Crude p value	Adjusted Risk Ratio*	Adjusted p value
Subjects without knee OA	52/1374 (3.78%)	1.00 (reference)	(ref)	1.00 (reference)	(ref)
Subjects with **any** knee OA	22/380 (5.79%)	1.59 (0.96, 2.62)	0.07	1.67 (0.99, 2.80)	0.05
Subjects with **unilateral** knee OA	21/301 (6.98%)	1.91 (1.15, 3.18)	0.01	1.99 (1.17, 3.36)	0.01
Subjects with **bilateral** knee OA	1/79 (1.27%)	0.35 (0.05, 2.51)	0.29	0.38 (0.05, 2.83)	0.35

n/n = hips with outcome/subjects total
* Adjusted for age, sex, BMI, knee injury/surgery

Table 2

Incident radiographic hip OA in subjects with unilateral **radiographic** knee OA

	Hip, *n/n* (%)	Crude RR (95% CI)	p value	Adjusted RR* (95% CI)	p value
Ipsilateral Side	10/428 (2.34%)	(Ref)		(Ref)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) may affect multiple joint sites, including the hands, knees, and spine. Studies have suggested high heritability for hand OA, but OA in the major diarthrodial joint affected in the back, the facet joint, is unknown. Also, the heritability of OA has been found to be joint specific especially for hand and knee OA, but it is unknown whether facet joint OA shares heritability or even occurrence with OA elsewhere. Our goals were to determine whether there are shared genetic and environmental components to OA across distinct joint sites; we determined the heritabilities, genetic correlations, and environmental correlations between hand, knee, and facet joint OA.

Methods: Analyses were based on the Framingham Study, a community-based study in the US in which subjects were studied irrespective of OA status. We created a summary index score for hand OA by summing bilateral Kellgren-Lawrence (KL) scores at the 2^{nd}-5^{th} distal interphalangeal, 2^{nd}-5^{th} proximal interphalangeal, 1^{st}-5^{th}metacarpophalangeal, thumb interphalangeal, and 1st carpometacarpal joints from posteroanterior hand radiographs. We assessed knee OA by summing KL scores from bilateral anteroposterior knee radiographs. We obtained measures of facet joint OA from thoracic CT imaging and summed Pathria and Weishaupt semi-quantitative scores at bilateral facet joints from T4 to L4 to obtain a summary index score. There were 1,259 individuals from the second generation cohort that underwent both hand and knee OA assessments. A total of 1,191 individuals from the second and third generation cohorts underwent facet joint OA assessments, of which 500 also had knee and hand OA assessments. We used a variance components method based on familial pedigrees to estimate heritability of hand, knee, and facet joint OA and bivariate models to estimate genetic and environmental correlations between OA at each joint site. All models were adjusted for age and sex.

Results: Mean age was 69±8 years and mean BMI was 29±5 kg/m^2. About 54% were women. Mean summary index score for hand, knee, and facet joint OA was 7±12 (range=0 to 69), 1±2 (range=0 to 8), and 28±13 (range=3 to 66), respectively. There were 266 families, ranging in size from 1 to 30 individuals. Estimated heritabilities for hand, knee, and facet joint OA were 62±9%, 13±9%, and 62±8%, respectively. Phenotypic correlation was significant between hand OA and knee OA (ρ_P(SE)=0.20 (0.03), p<0.01), but not between hand OA and facet joint OA (ρ_P(SE)=0.05), p=0.52). Neither genetic correlation (ρ_G(SE)=0.27 (0.24), p-0.28) nor environmental correlation (ρ_E(SE)=0.22 (0.11), p=0.07) was significant between hand and knee OA. For knee OA and facet joint OA, phenotypic correlation was significant (ρ_P(SE)=0.09 (0.04), p=0.04), but neither genetic (ρ_G(SE)=-0.12 (2.27), p=0.94), nor environmental correlation (ρ_E(SE)=0.19 (0.20), p=0.29), was significant.

Conclusion: Heritability was high (>60%) for OA at the hands and facet joints, and low (<15%) for OA at the knees. While knee OA commonly occurs with hand and facet joint OA, we found little evidence of genetic or environmental correlation across joint sites, suggesting that the genetic and environmental influences on OA are site-specific.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: There is a need for successful drug development in osteoarthritis (OA) as there are currently no disease modifying drugs approved for OA. This may be due to: patient heterogeneity resulting from different disease drivers, clinical studies are complicated by unintended inclusion of patients with little or no disease activity (DA)/progression, lack of surrogate markers for DA in OA. The aim was to investigate clinical characteristics of an RA-like phenotype in OA in 2 OA phase III studies.

Methods: Biochemical DA was assessed in serum from RA and OA patients by the acute reactant CRP and its proteolytic product CRPM[1]. Association between CRPM and DA scores was investigated by spearman's rho in the placebo group of the LITHE study (n=193, a phase III RA RCT[2]). OA patients were divided into 4 groups: patients with no inflammation [CRPM<9nM], local inflammation [CRPM>9nM/hsCRP<3g/L], acute inflammation [CRPM<9nM/hsCRP>3g/L], and active disease [CRPM>9nM/hsCRP>3g/L] (table). Biomarkers of soft tissue degradation (C1M, C3M), cartilage degradation (C2M, UCTX-II), bone balance (CTX/OC) and macrophage activity (VICM) were measured in the placebo groups of 2 phase III OA clinical trials (SMC1 and SMC2) including patients with radiographic knee OA[3]. Kellgren-Lawrence grade (KLG), joint space width (JSW) and WOMAC were recorded at baseline and 2 years

Results: *Association between DA and CRPM in RA.* There was a significant correlation between DA and CRPM: HAQ (0.24. p=0.0007), VAS pain (0.16, p=0.023) and DAS28 (0.29, p<0.0001). CRP accounted for about 30% of the biological variation in CRPM, indicating CRP and CRPM reflect different biological processes, and provide independent information. *Identification of OA phenotypes.* The mean CRPM level was significantly high in RA than OA patients (17.1 vs. 8.5, p<0.0001); however, 31-40% of OA patients had CRPM>9nM, thus overlapping with 75% of the RA. *Tissue degradation in OA.* In SMC1, C1M and VICM were significantly increased in patients with high DA (p<0.0001). C2M was higher (p=0.006) in patients with local inflammation. C3M was higher in patients with local inflammation, but without acute inflammation (table). The results was replicated in SMC2. *OA phenotypes and progression.* There were no difference in 2-year progression of KLG, JSW, WOMAC amongst the 4 groups.

Conclusion: This study provides a major finding: Clinical outcome measures were not different between the groups. Consequently, these data indicate that each different phenotype progress at a comparable rate; however, the underlying pathogenesis is likely to be different, thus should be targeted differently.[1]Siebuhr OAC,22,44,2014.[2]Bay-Jensen, SAR,43,470,2014.[3]Karsdal OAC, 23, 532,2015.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-Reported Outcomes Measurement Information System (PROMIS) provides reliable, valid measures of health status to resolve many challenges with comparability and interpretability in OA. Minimally important differences (MID) allow for meaningful interpretation of patient-reported outcomes, however, MIDs of PROMIS scores are unknown for OA. Our purpose was to establish a range of MIDs for 4 PROMIS Short Forms: Physical Function, Pain Interference, Depression, and Anxiety for knee OA following the guidelines of the PROMIS Instrument Validation Standards.

Methods: We performed a longitudinal analysis using the pooled, similar treatment effects that resulted from a randomized trial comparing Tai Chi with physical therapy in adults with symptomatic knee OA (ACR criteria). Participants completed surveys before and after 12-week intervention (**Table**). We used legacy anchors as a reference to estimate the MIDs. We paired a set of legacy anchors with each PROMIS instrument based on similarity of their target constructs or clinical relevance (**Table**). We further defined important change in each anchor measure based on previously published MID (range = MID to 2 times MID). Among participants with important change for each anchor we calculated the absolute mean change in corresponding PROMIS T-scores to determine an individual MID estimate. We then used distribution-based methods to evaluate the quality of each MID, and only selected MIDs that met 3 *a priori* criteria: 1) Spearman correlations between the anchor and PROMIS change scores ≥0.3; 2) subset sample sizes ≥10; and 3) the absolute values of the effect sizes (Cohen's *d*) between 0.2–0.8. The lowest and highest selected-MID estimates created the lower and upper bound of an initial MID range for each PROMIS instrument. When the lower bound estimate was smaller than the standard error of measurement (SEM, i.e. smallest change score exceeding measurement error), the lower bound would be set to the SEM.

Results: We had 165 participants (mean age 61 years, 70% female, 53% white, 92% KL Grade ≥ 2). Of 14 estimated MIDs, 8 met all criteria. Four MIDs did not meet criterion #3 (described above); 2 MIDs did not meet criterion #1; and 1 MID did not meet criterion #2 (**Table**). The SEMs for PROMIS Depression, Anxiety, Physical Function, and Pain Interference were 2.3, 2.3, 1.9, and 1.8, respectively. The final MID ranges were: PROMIS Depression = 2.8 to 3.0; PROMIS Anxiety = 2.3 to 3.4; PROMIS Physical Function = 1.9 to 2.2; and PROMIS Pain Interference = 2.4 to 3.1. These correspond to 20-33% of the normalized standard deviation units per scale.

Conclusion: We established the first estimates of MID for PROMIS Physical Function, Pain Interference, Depression, and Anxiety Short Forms among those with symptomatic knee OA. This information will be an important standard of reference to better apply or interpret PROMIS instruments in future studies. < td width="126" valign="top">

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Mindfulness is the ability to maintain a heightened awareness of one's moment-to-moment experiences without judging or reacting. Recent evidence suggests that mindfulness may improve outcomes in chronic pain, but no study has examined whether mindfulness is a predictor of treatment response in OA. Our objective was to evaluate whether OA participants with higher baseline mindfulness are more likely to achieve OMERACT-OARSI treatment response after exercise intervention.

Methods: We performed a longitudinal analysis of pooled participants from a randomized trial comparing Tai Chi mind-body exercise to standard physical therapy regimen with similar treatment effect among adults with symptomatic knee OA (ACR criteria). A participant subset completed the WOMAC, Patient Global Assessment, and Five Facet Mindfulness Questionnaire (FFMQ) before and after 12-week intervention. Those among this subset were stratified into tertiles based on their total mindfulness score. Treatment response was defined based on OMERACT-OARSI criteria: 1) ≥ 50% improvement in pain or function and change of ≥ 20 points on a scale of 0 to 100 in WOMAC pain or function, or 2) ≥ 2 of the following criteria: improvement of ≥20% and change > 10 points in WOMAC pain, improvement of ≥ 20% and change > 10 points in WOMAC function, or improvement of ≥20% in Patient Global and change > 10 points. We calculated risk ratios for each paired tertile comparison, and analysis of variance or chi-square tests to check for characteristic differences among the tertiles at baseline.

Results: We measured 76 of 86 baseline participants (mean age 60 years, 74% female, 48% white, 87% KL Grade ≥2, and 85% college-educated), for their follow-up visit. **Table 1** summarizes the baseline characteristics of participants by tertile. The only difference in baseline characteristics was that higher mindfulness had higher BMI ($p = 0.01$). **Table 2** summarizes the distribution of treatment response. Those with higher mindfulness were 1.4-fold more likely to meet responder criteria than those with either medium (95% CI: 1.1, 1.8; $p = 0.01$) or lower mindfulness (95% CI: 1.1, 1.8; $p = 0.01$). No difference was found between medium and lower mindfulness (1.0; 95% CI: 0.7, 1.4; $p = 0.98$).

Conclusion: Knee OA participants with higher mindfulness are 40% more likely to respond to exercise intervention. Higher mindfulness may be a novel predictor of non-pharmacological treatment response among people with symptomatic knee OA. This finding may help optimize the design of exercise interventional trials in OA.

Table 1. Demographic and Clinical Characteristics of Participants by Mindfulness Levels					
Variable		**Lower Mindfulness**	**Medium Mindfulness**	**Higher Mindfulness**	***p*-value**
Age, years		63.1 (10.5)	57.4 (9.5)	60.5 (10.8)	0.11

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate predictive factors for good outcome of ultrasound intra-articular glucocorticoids in knee osteoarthritis (OA).

Methods: We conducted a prospective monocenter cohort study including 116 patients with knee OA, after failure to standard treatments, with pain > 4 (numerical rating scale NRS 0-10). Patients received an ultrasound-guided injection of 40 mg triamcinolone acetonide in their most painful knee. We exhaustively collected demographic and clinical data at inclusion, as well as lab, radiographs and ultrasound parameters of the included knees. WOMAC score was calculated at inclusion and after 4 weeks. Responders were defined as patients with at least 40% improvement of their WOMAC score. Univariate analysis was performed in order to select possible predictive factors, and stepwise multiple logistic regression analyses were conducted to identify predictors of response.

Results: Among the 116 patients, 101 were females. Median age was 64 years (40-85) and mean duration of the disease was 14.1 ± 14,8 years. Mean BMI was 29.9 ± 3.8 Kg/m^2. Mean NRS of pain was 8.4 ± 1.2 and mean WOMAC was 73.3 ± 11,8 at inclusion. 70.0% of the knees were grade 3 or 4 of Kellgren-Lawrence. 98% of knees expressed ultrasound synovial effusion and/or hypertrophy at inclusion. After 4 weeks, 61.2% of patients were responders. Regression analysis showed that patients with a BMI < 30 Kg/m^2(OR=0.38, 95%CI 0.16-0.89) and an ESR < 20 mm (OR=0.27, 95%CI 0.08-0.90) were more likely to respond to ultrasound-guided glucocorticoids injection. Having both predictive factors of good response increases the response rate to 73.5%, whereas having no predictive factor decreases the response rate to 25.0%.

Conclusion: Our study is the largest study evaluating predictive factors of response for intra-articular glucocorticoids injections in knee OA. Also, it is the first study of predictive factors for ultrasound-guided injections. Patients with high BMIs and high ESR seem less likely to respond to intra-articular injections.

Long-Lasting Local Knee Structural Pathology Is Associated with Persistent

Multi-Site Pain

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Knee pain is the most common manifestation of knee osteoarthritis (OA) and typically accompanied by pain at other sites. Knee structural pathology in MRI, such as bone marrow lesions (BMLs), effusion and cartilage defects, appear to be strongly associated with knee OA-pain through abnormal excitability in peripheral and central pathways. However, whether persistent multi-site pain (MSP) is maintained by long-lasting peripheral structural pathology remains unknown. This study, therefore, aimed to determine whether long-lasting knee structural pathology--BMLs, effusion and cartilage defects is associated with persistent MSP and explore the underlying mechanisms.

Methods: Data from the prospective Tasmanian Older Adult Cohort study was utilized. Knee pain and pain at other sites (neck, back, hands, shoulders, hips and feet) was measured by a questionnaire at baseline and 2.6 years later. T1-weighted or T2-weighted fat saturated MRI of the right knee was performed to assess the BMLs, effusion and cartilage defects at baseline and 2.6 years. Knee radiographic OA was assessed by X-ray at baseline. Long-lasting structural lesion was defined as the presence of a lesion at both baseline and follow-up. Persistent MSP was defined as the presence of knee pain plus other site pain at both baseline and follow-up. Logistic regression modelling was used with adjustment for potential confounders.

Results: In 394 participants (mean age 63 years, mean BMI of 27.3 kg/m^2 and 51% women), 25% of participants with knee pain had pain present in at least one other site at baseline and 2.6 years. The presence of BMLs, effusion and cartilage defects at both baseline and follow-up were: 38%, 26% and 30% of the participants, respectively. Persistent knee pain plus other site pain was respectively associated with long-lasting BMLs (OR 1.94, 95% CI 1.13 to 3.33), effusion-synovitis (OR 2.24, 95% CI 1.24 to 4.03), and cartilage defects (OR 2.33, 95% CI 1.31 to 4.13) in multivariable analyses. However, there was no significant association of the presence of knee structural pathology only at either baseline or follow-up with persistent knee pain plus other site pain (all P>0.05).

Conclusion: Longer duration of the presence of BMLs, effusion and cartilage defects is associated with persistent knee pain plus other site pain, suggesting that nociceptive input induced by knee structural lesions may be a key factor in the maintenance of persistent multi-site pain in which sensitization may be implicated. The importance of this to clinicians and researchers is that the timing of treatment of knee structural pathology may normalize the increased sensitivity (sensitization).

Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammation has been implicated in the pathogenesis of KOA, but the relevance of physical exam findings and patient-reported symptoms of inflammation is unknown. Our objectives were to examine the association between physical exam findings, including bulge sign and patellar tap, as well as participant-reported symptoms, with MRI-detected effusion-synovitis (ES) in two samples: knees that developed radiographic OA (ROA) and knees that went on to knee replacement (KR).

Methods: The Osteoarthritis Initiative (OAI) is a longitudinal cohort study of participants with or at risk for ROA. Two samples with available MRI readings were utilized: 355 knees that developed incident ROA within 4 years of follow-up (323 participants) and 225 knees that underwent KR within 5 years of follow-up (195 participants). The bulge sign and patellar tap were conducted by trained examiners at baseline, 2 years, and 4 years. Questionnaires assessing participant-reported knee swelling and knee pain when straightening fully, in the last 7 days, were administered at the same visits. MRI was performed with 3-T systems (Trio; Siemens, Erlangen, Germany). Non-contrast effusion-synovitis (ES) was scored using the MRI Osteoarthritis Knee Score (MOAKS). Logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI) to assess the association between physical exam findings and participant-reported symptoms with MRI-detected ES, with generalized estimating equations to account for two knees in an individual and multiple time points.

Results: The 323 participants in the ROA group were predominantly female (66%), overweight and obese (42%, 39% respectively), white (81%), with mean age 60 years. The 195 participants in the KR group were also largely female (58%), overweight and obese (37%, 47% respectively), white (86%), with mean age 65 years. Among knees that developed ROA, those with bulge sign or patellar tap had significantly higher odds of ES, compared to those without these findings (OR=3.67 [95%CI: 2.43, 5.54]). In addition, among knees that went on to KR, a modest association was found with presence of these findings (OR=1.91 [95%CI: 1.28, 2.85]). Knees with participant-reported swelling in the last 7 days, and pain when straightening fully had significantly higher odds of ES, with evidence of dose-response based on the frequency of swelling, and severity of pain, in both ROA knees, and KR knees (Figure 1).

Conclusion: A bulge sign and patellar tap on physical exam were associated with MRI-detected ES, as well as participant-reported knee swelling and knee pain when straightening fully in participants who developed ROA as well as those who progressed to KR. The magnitude of association was greater for frequent and severe self-reported symptoms, compared to physical exam findings, and among early OA knees compared to end-stage OA knees when ES was more prevalent.

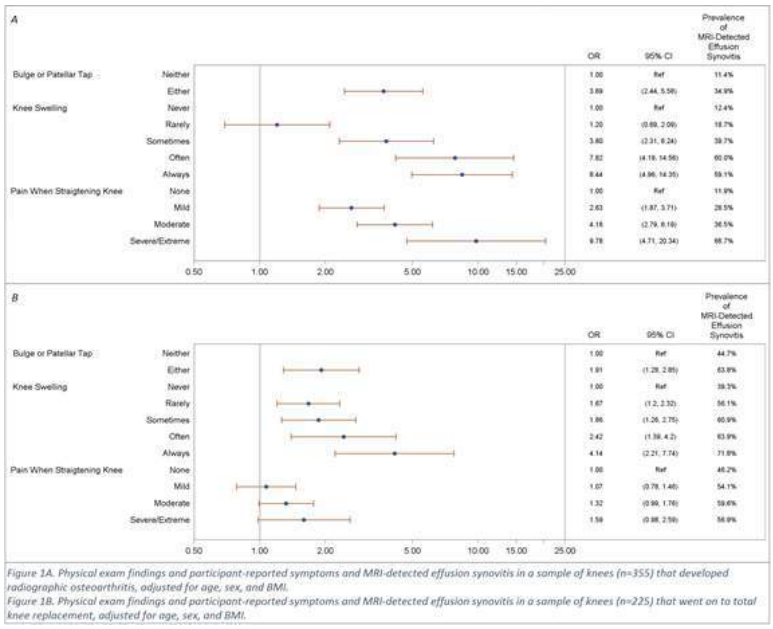

Figure 1A. Physical exam findings and participant-reported symptoms and MRI-detected effusion synovitis in a sample of knees (n=355) that developed radiographic osteoarthritis, adjusted for age, sex, and BMI.
Figure 1B. Physical exam findings and participant-reported symptoms and MRI-detected effusion synovitis in a sample of knees (n=225) that went on to total knee replacement, adjusted for age, sex, and BMI.

Gait Abnormalities Due to Hip Osteoarthritis Are Different in Men and Women

Kharma C. Foucher, Orthopedic Surgery, Rush University Medical Center, Chicago, IL
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Gait mechanics are different in healthy men and women.[1] It is unknown whether or not the gait changes associated with hip osteoarthritis (OA), also differ in men and women. The goal of this study was to investigate sex differences in hip OA-related gait mechanics, using a previously described[2] cohort of subjects with and without hip OA. The hypotheses tested were (1) gait kinematics and kinetics are different in asymptomatic men and women, but not in men and women with hip OA and (2) the extent of hip OA gait abnormalities are different in men and women.

Methods: An IRB-approved data repository was used to identify 150 subjects with symptomatic, radiographically-verified hip OA (age 62 ± 10, 86 F/64M, BMI 28±5) and 159 asymptomatic subjects (age 56 ± 9, 104 F/55 M, BMI 27 ± 5). All subjects had undergone gait analysis using standard published methods. The gait variables used for this study were the dynamic hip range of motion in the sagittal plane, and peak external moments about the hip in the sagittal, frontal, and transverse planes. Variables were averaged from trials collected at subjects' self-selected normal walking speeds. Analysis of variance was used to compare gait variables for men and women, with and without hip OA.

Results: H1 – The peak hip adduction moment was higher but the peak external rotation moment was lower in healthy

woman compared to healthy men (p = 0.037, p = 0.026). These differences were not seen in the hip OA group (Fig. 1.) H2 – All gait variables were lower in people with hip OA compared to healthy subjects. However, the magnitude of the OA vs healthy group difference in the peak adduction moment was 43% larger for women than men. The OA vs. healthy group difference in the peak external rotation moment was 55% larger for men than women (p < 0.001). There were no other sex-specific differences (p = 0.395-0.948).

Conclusion: Both hypotheses were supported. Sex differences in gait kinetics were seen in the healthy subjects, and were similar to those previously reported. [3,4] These differences were not preserved in subjects with hip OA. Moreover, compared to men, women with OA had greater deficits (vs. asymptomatic women) in the peak hip adduction moment, which is balanced by the hip abductors. Men, had greater deficits in the peak hip external rotation moment, which is balanced by muscles that internally rotate the hip during midstance. The hip abductors participate in this function during this phase of gait. Thus, these findings demonstrate that hip OA may result in different gait adaptations in men vs. women, particularly with respect to the role of the hip abductors. A better understanding of sex-specific gait adaptations could lead to new rehabilitation-based approaches to address the utilization and outcomes disparities in OA and THA. **References:** [1]Ko et al., J Biomech, 44:1974-9, 2011. Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies show differences between self-report measures and performance/functional measures following total knee arthroplasty (TKA). We investigated the hypothesis that this trend would hold true in a large prospective cohort of patients (no exclusion criteria) undergoing primary unilateral TKA.

Methods: De-identified data from 345 patients (age 63.8 y/o, 44% male, BMI of 32.37), undergoing primary unilateral TKA, were included in this study. Data were drawn from a clinical registry of all patients seeking rehabilitation services at ATI Physical Therapy, (Greenville, SC) from January 2014-January 2016. The performance measure used was the Timed Up and Go (TUG). The self-report measure used was the disability subscale of the Western Ontario and McMaster Universities Arthritis Index (WOMAC). All measures were collected at baseline (pre-TKA), early post-TKA (<20 days after TKA) and later post-TKA (30 to 45 days after TKA). One-way repeated measure ANOVA's were then performed on each outcome (TUG and WOMAC separately) to test for the effect of time. Post-hoc contrasts compared the change in outcomes from baseline scores. Secondarily, Pearson product moment correlations were calculated by using change scores from baseline ([initial-final/initial]*100) to evaluate the relationship across time points between TUG and WOMAC disability subscale.

Results: TKA resulted in a significant worsening of mean TUG times from baseline to early post-TKA (3.16 sec; $p<0.001$), while WOMAC disability subscale scores demonstrated functional improvement (-5.22; $p<0.005$). At the later post-TKA time point, mean TUG times significantly improved from baseline (-2.56 sec; $p<0.001$) and WOMAC disability subscale scores had a large significant improvement (-20.52; $p<0.001$). Pearson product moment correlations revealed that change in the WOMAC total disability subscale was not significantly correlated ($p>0.05$) with change in TUG times from baseline to the early or later post-TKA time points.

Conclusion: At early post-TKA, patients reported improved scores from baseline on the WOMAC while poorer times were observed on the TUG. Similarly, for later post-TKA, the lack of correlation between changes in WOMAC and TUG measures from baseline, further suggests that patient-reported and performance outcomes may be measuring different constructs. Therefore, they should both be used for assessment as they provide different, but complementary information. Using only patient-reported outcomes is likely to disguise critical deficits impairing patient function. This is particularly true during the early post-TKA period when patients perception of their physical function (self-report) contrasts with more objective assessments (performance testing). Failure to identify underlying functional deficits, not captured using self-report measures, may result in inappropriate discharge planning and long term functional decline.

MRI-Detected Cartilage Damage, Meniscal Damage, and Meniscal Extrusion Prior to Incident Radiographic Osteoarthritis and the Subsequent Trajectory of Joint Space Loss

C. Kent Kwoh[1], Frank Roemer[2,3], Erin L. Ashbeck[4], Charles Ratzlaff[4], Jeffrey Duryea[5] and Ali Guermazi[6], [1]1501 N. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Loss of joint space width (JSW) on x-ray is the recommended standard to define osteoarthritis progression. However, both cartilage and meniscal damage contribute to JSW loss, yet neither are seen on radiographs. The extent to which JSW loss on x-ray reflects cartilage damage vs. meniscal damage/extrusion is unknown. Our objective was to evaluate the impact of medial cartilage and meniscal damage/extrusion 1 year prior to incident radiographic osteoarthritis (ROA) on the subsequent trajectory of medial JSW.

Methods: Knees (n=327) from the OAI that developed incident ROA (IROA) through 48 months of follow-up were identified based on Kellgren-Lawrence grade (KLG) ≥2. MRI Osteoarthritis Knee Score (MOAKS) was used to assess cartilage damage (≥1.1 vs. <1.1) and meniscal damage/extrusion (i.e., tears and maceration [≥2 vs. <2] or extrusion [≥3mm vs. <3mm]) in the year prior to incident ROA. Annual fixed JSW (fJSW) (x=0.250 mm) on x-ray was assessed over three years of follow-up. The sample included n=1,289 fJSW measures in 327 knees from 301 participants between 2 years prior to IROA and up to 2 years after IROA detection. Trajectories of mean medial fJSW and change in medial fJSW, with 95% confidence intervals (CI), were estimated using mixed models with participant and knee treated as random effects.

Results: As seen in Figure 1, knees with medial cartilage damage one year prior to IROA (compared to knees without damage) had a significantly lower mean medial fJSW in the three years following, with a difference in mean fJSW of 0.393mm [95%CI: 0.182, 0.604; p<0.0003] one year later, 0.454mm [95%CI: 0.233, 0.676; p<0.0001] two years later, and 0.754mm [95%CI: 0.508, 1.000; p<0.0001] three years later. Similarly, knees with medial meniscal damage one year prior to IROA (compared to those without damage) had significantly lower mean medial fJSW in the 3 years following, with a difference in mean fJSW of 0.238 [95%CI: 0.002, 0.474; p<0.0483] one year later, 0.288 [95%CI: 0.041, 0.534; p<0.0223] 2 years later, and 0.448 [95%CI: 0.180, 0.716; p<0.0011] 3 years later. Although those with meniscal extrusion had less fJSW one year prior to IROA, there was no significant difference in trajectory of fJSW loss for knees with meniscal extrusion vs. those without. There was no significant difference in the trajectory of fJSW loss among those with cartilage and meniscal damage/ extrusion vs. those with only cartilage damage.

Conclusion: Knees with medial tibiofemoral cartilage damage in the year prior to IROA, with or without meniscal damage/extrusion, had significant loss of mean medial fJSW over the following 3 years. Meniscal extrusion was associated with differences in concurrently measured fJSW, but not the future trajectory of fJSW. While loss of fJSW reflects both cartilage and meniscal damage, the magnitude of the differences suggests cartilage damage is the predominant factor in the future loss of fJSW.

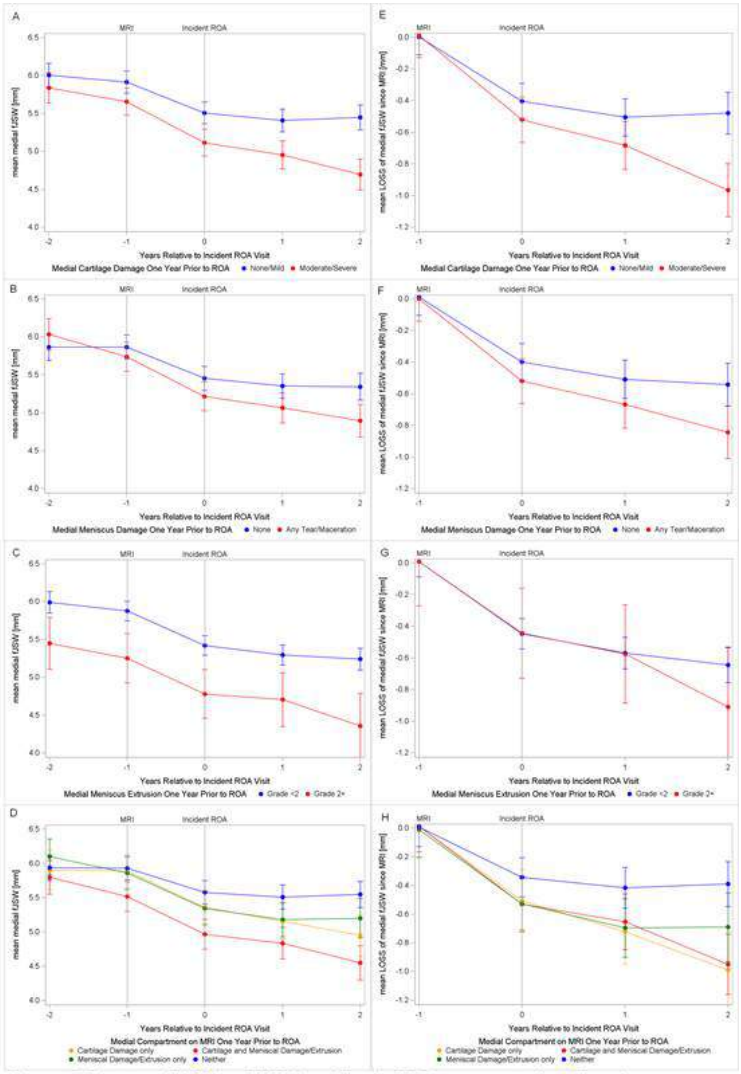

Figure 1. Trajectory of fJSW and fJSW loss following MRI assessment of cartilage damage, meniscal damage, and meniscal extrusion

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Traditionally, regions of the knee that are assessed in clinical trials are selected based on anatomy or responsiveness to change. However, it is unclear whether there are regions of the articular cartilage that are changing together over time. The purpose of the study was to visualize and explore which regions of cartilage change together longitudinally.

Methods: To determine the locations of greatest longitudinal cartilage change, we measured a convenience sample of 100 knees with baseline and 24-month MRIs from the Osteoarthritis Initiative. Sample included knees that were primarily Kellgren-Lawrence grades 2 or 3, with few progressing over 24 months. One reader (MZ) (intraclass correlation coefficient [ICC] 3,1 model > 0.86 at baseline) used customized software to measure the Cartilage Damage Index (CDI) in the medial and lateral compartments of the femur, tibia, and patellar cartilage on paired baseline and 24-month double echo steady state MRIs. For the whole knee CDI, cartilage thickness is measured in 12 informative locations for the medial and lateral patella, and in 9 locations for the medial and lateral femur and tibia (total of 60 CDI sites per knee). Using changes in CDI measures at each location over 24 months, we performed a factor analysis to identify sites that changed together. Factors with an eigenvalue > 1 were retained.

Results: The factor analysis produced 20 factors (Figure 1) accounting for 74% of the variance in CDI changes. To visualize the findings of the factor analysis, we created a figure that identifies the CDI points with factor loadings greater than or equal to 0.4 based on their anatomic location within the knee (medial and lateral patella, femur, and tibia). The factors are listed from greatest to smallest eigenvalues, or those explaining the largest percent of variability to those explaining the smallest percent of variability. Notably, the first 3 factors, that account for 23% of the total variation, only involved CDI locations in the patella. Surprisingly, very few of the factors (4) represent a combination of the articular surfaces that anatomically are adjacent to one another. Many of the factors (13) only involve one articular surface.

Conclusion: Factor analysis **on this sample** suggests that much of the variation in CDI change measures comes from regions on the patella. The patellofemoral joint is often overlooked in OA research, but our results suggest more research on this region of the knee is needed. Also, we found that it is uncommon for articular cartilage to change in conjunction with the adjacent articular surface (e.g. medial tibia cartilage does not necessarily change when the medial femur cartilage changes). These findings suggest that new strategies that evaluate change in cartilage may improve our understanding of OA progression.

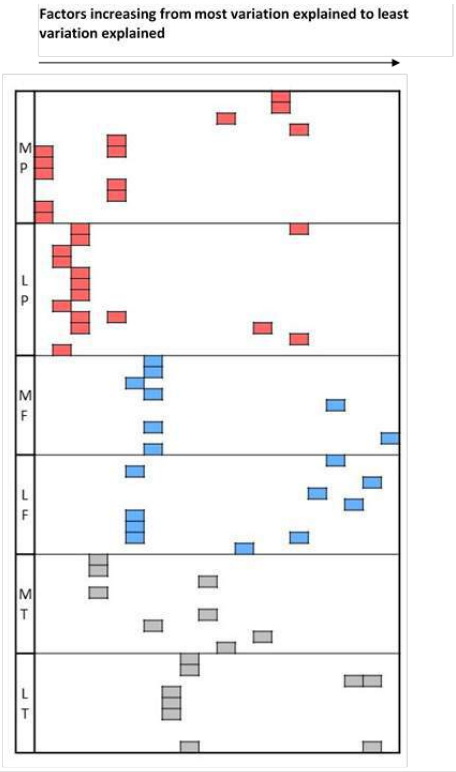

Figure 1. Sites with patterns of change stratified by knee cartilage location. Sites with color represent factor loadings with an absolute value of > .4. Sites are ordered from most anterior to most posterior regions within the cartilage. Abbreviations used: MP, medial patella; LP, lateral patella; MF, medial femur; LF, lateral femur; MT, medial tibia; LT, lateral tibia.

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Incident symptomatic OA is a common outcome of interest in epidemiologic studies of risk factors for OA. We postulate that evaluating this outcome in those who do have radiographic OA (ROA) at baseline but do not have frequent knee symptoms will be more informative than the other at-risk groups. Crepitus is the complaint of hearing

grating, cracking or popping sounds in and/or around a joint. This is a common symptom in the clinical setting and is possibly predictive of incident knee OA. Our purpose was to evaluate whether the association between crepitus and incident knee symptomatic osteoarthritis (SOA) is better detected in a group with ROA but without frequent knee symptoms than other at-risk groups.

Methods: This was a person-based longitudinal study using data from the Osteoarthritis Initiative (OAI). We evaluated the right knee only and specifically focused on people at baseline without SOA. Crepitus was assessed using the Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire at baseline. PA semi-flexed knee radiographs and frequent knee pain ("During the past 12 months, have you had pain, aching, or stiffness in or around your right knee on most days for at least one month? By most days, we mean more than half the days of a month" were assessed at baseline and 48-month visits.) were assessed at baseline and 48-month visits. ROA was defined as Kellgren and Lawrence (KL) grade ≥ 2. We performed logistic regression with crepitus as the predictor and incident SOA by the 48 month visit as the outcome. Subgroup analyses were performed by three groupings: (1) +ROA, -Sx: those with ROA, but no frequent symptoms at baseline, (2) –ROA, +Sx: with frequent symptoms but no ROA at baseline, and (3) -ROA, -Sx without ROA or frequent symptoms at baseline.

Results: 2936 people each contributed one observation with a mean age of 61.1 (9.3) years and mean BMI of 28.2 (4.7) kg/m². 42% were male. Incident SOA was least common in knees that never had crepitus and most common in those who always had crepitus (p for trend <0.0001) (Table 1). More than 75% of incident SOA cases originated from the +ROA, -Sx subgroup, despite it constituting about a third of the total number of observations.

Conclusion: Subjective knee crepitus strongly predicts incident SOA over 4 years. Crepitus evaluated as a subjective assessment, therefore offers utility for identification of at-risk individuals, predictive modeling, and future research. Selecting those with ROA but without frequent knee symptoms, may optimally power studies to evaluate incident SOA.

TABLES

Periarticular Tibial Knee Bone Mineral Density is Associated with Knee Symptoms Lo GH, Driban JB, LaValley M, Strayhorn M, Price LL, Eaton CB, McAlindon TE

Background/Purpose: Relative local knee periarticular bone mineral density (paBMD) as measured by dual x-ray absorptiometry (DXA) has been associated with features of radiographic knee osteoarthritis (OA). We postulated that this measure is associated with knee pain and measures of quality of life. To address this question, we evaluated the association of paBMD with pain and quality of life.

Methods: We performed a cross-sectional study of a subgroup of the incidence subcohort of the Osteoarthritis Initiative (OAI) who had knee DXA scans from the 72-month visit. We evaluated the right knee using identical GE Lunar Prodigy scanners, generating knee medial:lateral paBMD ratios focused on the tibial plateau. Frequency of knee pain was assessed using the 72-month visit question, "In the past 12 months, have you had pain, aching or stiffness in or around your knee on most days for at least one month?" The Knee injury and Osteoarthritis Outcome Score quality of life (QOL) assessments were also evaluated as outcomes – each item was dichotomized with a high score considered a symptomatic outcome. We performed logistic regression with a predictor of medial:lateral paBMD groups based on biologic cut points (1) low paBMD Ratio group with scores < 1.02, (2) neutral group (referent) with scores ≥ 1.02 and < 1.17, (3) high group with scores ≥ 1.17 and < 1.24 and (4) very high group with scores ≥ 1.24. Analyses were adjusted for age, sex, and BMI.

Results: 985 participants, 51% female, were included with a mean age of 65.4 (8.4) years and BMI of 28.1 (4.9) kg/m^2. The very high paBMD Ratio group had more pain compared to the neutral group (Table 1).

Table 1. Medial:Lateral paBMD Ratio Groups as predictors for frequent knee pain.			
Medial:Lateral paBMD Ratio groups	Prevalence of Frequent Knee Pain	Unadjusted OR	Adjusted OR*
Low (<1.02)	41/193 (21%)	1.0 (0.7 – 1.6)	1.0 (0.7 – 1.6)
Neutral (≥1.02, <1,17)	107/517 (21%)	Referent	Referent
High (≥1.17, <1,24)	32/142 (23%)	1.1 (0.7 – 1.7)	1.1 (0.7 – 1.7)
Very High (≥1.24)	33/106 (31%)	***1.7 (1.1 – 2.8)***	***1.7 (1.1 – 2.8)***
	Prevalence of QoL Q1 How Often Aware of Knee Problems		
Low (<1.02)	96/193 (50%)	***1.4 (1.0 – 1.9)***	***1.5 (1.4 – 2.1)***
Neutral (≥1.02, <1,17)	217/515 (42%)	Referent	Referent
High (≥1.17, <1,24)	72/140 (51%)	***1.5 (1.0 – 2.1)***	***1.4 (1.0 – 2.1)***
Very High (≥1.24)	57/106 (54%)	***1.6 (1.1 – 2.4)***	***1.7 (1.1 – 2.6)***
	Prevalence of QoL Q2 How Often Modified Lifestyle		
Low (<1.02)	32/194 (17%)	1.0 (0.6 – 1.5)	1.0 (0.6 – 1.6)
Neutral (≥1.02, <1,17)	88/516 (17%)	Referent	Referent
High (≥1.17, <1,24)	41/141 (29%)	***2.0 (1.3 – 3.1)***	***2.0 (1.3 – 3.1)***
Very High (≥1.24)	23/106 (22%)	1.4 (0.8 – 2.2)	1.3 (0.8 – 2.3)
	Prevalence of QoL Q3 How Often Troubled by Lack of Confidence in Knee		
Low (<1.02)	26/194 (13%)	1.3 (0.8 – 2.1)	1.4 (0.8 – 2.3)
Neutral (≥1.02, <1,17)	55/515 (11%)	Referent	Referent
High (≥1.17, <1,24)	23/141 (16%)	1.6 (1.0 – 2.8)	1.5 (0.9 – 2.6)
Very High (≥1.24)	17/106 (16%)	1.6 (0.9 – 2.9)	1.4 (0.8 – 2.6)
	Prevalence of QoL Q4 How Much Difficulty Have with Knee?		
Low (<1.02)	31/194 (16%)	1.3 (0.8 – 2.1)	1.4 (0.9 – 3.0)
Neutral (≥1.02, <1,17)	65/515 (13%)	Referent	Referent
High (≥1.17, <1,24)	28/141 (20%)	***1.7 (1.1 – 2.8)***	***1.7 (1.0 – 2.8)***
Very High (≥1.24)	22/106 (21%)	***1.8 (1.1 – 3.1)***	***1.7 (1.0 – 3.0)***
*Adjusted for Age, sex, and bmi.			

Conclusion: Relative local paBMD is associated with contemporaneous knee pain and some quality of life assessments. These findings may suggest that changes within the local bone have a clinically relevant influence on knee pain. Modification of the medial:lateral paBMD Ratio may improve knee pain and assist in identifying new targets of therapy.

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: , The discovery of MSCs in the synovium and synovial fluid (SF) provided a potential mechanism for repairing cartilage “from the top down”. Indeed, we have shown in a canine model that MSCs injection into synovial fluid in canine OA is associated with MSC adhesion to damaged cartilage which may potentially contribute to subsequent joint repair (Baboolal T et al ARD 2015). Moreover, it is possible that SF-MSCs may be lost under joint irrigation at arthroscopic procedures. The purpose of this work was threefold; first to test the hypothesis that SF-MSCs can be replaced, and also their numbers further increased by synovial agitation, second that these cells were capable of rapid adhesion to clots and third that the clot composition improve MSC migration.

Methods: , Initially, ex-vivo mechanical agitation of both excised porcine and human synovium was tested using a panel of cytology brushes and custom made prototypes. Based on the prototype devices a “synovial brush” for human in vivo intra-operative MSC release in patients undergoing arthroscopy was developed and compared to a conventional cytology brush. Colony-forming unit-fibroblast (CFU-F) assay was performed to quantify released MSCs. Adhesion to clots was studied by comparing Platelet Rich Plasma (PRP), Whole Blood (WB) and Fibrin Glue (FG) to evaluate the effect of this adjunctive therapies on MSC function. Migration studies were performed using passage 2-4 synovial MSCs in trans-well migration assay. MSC migration, over a five hour period, was compared between PRP and pooled human Platelet Lysate (hPL). The functional integrity of brushed MSCs was confirmed using trilineage assays for bone, fat and cartilage differentiation.

Results: Ex-vivo mechanical agitating of the synovium with the cytology brush compared to irrigation alone increased MSC number 2.7-fold (n=10, p=0.002). Based on in vitro studies, we selected a custom designed synovial brush for in vivo studies in patients and compared to the cytology brush, the custom designed brush resulted in a median 65-fold increase in the number of CFU-Fs (n=8, p=0.0148). Trilineage differentiation of released synovial MSCs was at least comparable to donor match synovial fluid MSCs. We also noted that existing standard arthroscopic procedures with irrigation during arthroscopy effectively removed the majority of CFU-Fs from the joint cavity. Released synovial MSCs adhered to clots within 30 minutes with no difference seen between clot compositions. These MSCs demonstrated a trend for a better migration towards hPL compared to PRP.

Conclusion: Conventional arthroscopy procedures wash away SF-MSCs. Using a novel brushing technique and a custom designed synovial brush, synovial MSCs can be mechanically released in vivo, and these cells were capable of rapid migration and adhesion and had excellent preservation of chondrogenesis. Collectively these findings show that endogenous minimally manipulated MSCs can be readily increased, and provide a one-stage procedure combining synovial brushing with arthroscopy towards a low cost simple procedure in developing endogenous MSCs for joint repair in OA. This knowledge may aid in the development of a Rheumatological medical arthroscopy strategy.

Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Ayurveda is used to treat knee osteoarthritis (OA) despite limited evidence. We aimed to evaluate the effectiveness of complex multimodality Ayurvedic treatment in comparison to conventional care in OA knee patients.

Methods: Patients with OA of the knee according to ACR criteria were included in a multicenter randomized, controlled trial and treated in 2 hospital outpatient clinics and 2 private outpatient clinics with a total of 5 physicians and 20 therapists participating. Patients received either Ayurvedic treatment (n=77) or conventional care (n=74) with 15 treatments over 12 weeks. Primary outcome was the change on the Western Ontario and McMaster University Osteoarthritis (WOMAC) Index after 12 weeks. Secondary outcomes included the WOMAC subscales, a pain disability index, numeric rating scales for pain and sleep quality, a pain experience scale, a quality-of-life index, a profile of mood index, rescue medication use, and safety issues.

Results: A total of 151 patients (Ayurveda n=77, conventional care n=74) were included. Changes of the WOMAC Index from baseline to 12 weeks were more pronounced in the Ayurveda group (mean difference 61.1 [95% CI 52.4;69.6]) than in the conventional group (32.0 [95% CI 21.4;42.6]) resulting in a significant difference between groups ($p<0.001$) and a clinically relevant effect size (Cohen's d 0.68 [95% CI 0.35;1.00]). Similar tendencies were observed for all secondary outcomes at week 12. Effects were sustainable at follow-ups after 6 and 12 month.

Conclusion: The results suggest that a complex Ayurvedic treatment might be clinically superior to a complex non-surgical conventional intervention in the treatment of OA of the knee.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Although some studies have shown a negative relationship between grip strength and hand osteoarthritis (OA), little is known about how grip strength is related to specific radiographic features of hand OA, such as osteophytes, joint space narrowing, and erosion. In addition, no reported study has examined whether grip strength, as a measure of muscle activity, is related to knee OA, which may also show a one-way effect of reduced muscle strength on OA. In this large, population-based cohort study, we took advantage of the availability of subjects without hand pain to evaluate the effect of grip strength on OA using a novel, semi-quantitative grading system. We also examined whether grip strength was related to detailed radiographic features of OA.

Methods: Data from 2,251 subjects enrolled in the Dong-gu study, who had no hand joint pain, were analyzed to investigate the relationship between grip strength and OA. Hand grip strength was measured using a hand-held dynamometer, and radiographs of the hand and knee were scored according to a semi-quantitative grading system. Multiple linear regressions were used to explore associations between grip strength and radiographic features of OA.

Results: Grip strength in men and women was negatively related to hand (both $p < 0.001$) and knee (men, $p < 0.001$; women, $p = 0.010$) OA after adjusting for confounders. Hand (men, $p < 0.001$; women, $p = 0.001$) and knee (both $p < 0.001$) joint space narrowing showed the strongest associations with low grip strength, regardless of sex. Moreover, the severity of hand osteophytes in women ($p = 0.001$), knee osteophytes in men ($p = 0.006$), hand malalignment (men, $p = 0.008$; women, $p = 0.041$), and subchondral cysts (men, $p < 0.001$; women, $p = 0.007$) was correlated with low grip strength in both sexes.

Conclusion: Among subjects without hand joint pain, low grip strength was associated significantly with hand and knee radiographic OA, regardless of sex. Among all types of OA radiographic damage, low grip strength showed the strongest association with joint space narrowing.

The Relation of Serum Urate to Radiographic Knee and Hand Osteoarthritis

Ana Beatriz Vargas-Santos[1], Na Lu[1], Jingbo Niu[1], David T. Felson[2] and Tuhina Neogi[1], [1]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, [2]Clinical Epidemiology Research & Training Unit, Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Increasing evidence suggests a role for uric acid as a danger signal for the innate immune system,

which could contribute to OA development and/or progression. If serum urate (SUA) is a true risk factor for OA, urate-lowering drugs could help prevent incident or progressive OA. However, SUA and knee OA are both associated with obesity; thus any association may be confounded by body mass index (BMI). Hand OA, in contrast, may be less affected by BMI, and may provide a better reflection of the systemic metabolic effects of urate. We therefore evaluated the relation of SUA to radiographic knee and hand OA (ROA) in a large community cohort unselected for OA, accounting for BMI.

Methods: We performed a cross-sectional study among subjects of the Framingham Original Cohort 50 years and older. SUA was assessed at exams 20 and 21 (1986-1992) and ROA at exam 22 (1990-1994). ROA of each tibiofemoral joint and of each hand joint was defined as KL ≥2. We categorized SUA as: <5mg/dL, 5-<6mg/dL, 6-<7mg/dL, 7-<9mg/dL, and ≥9mg/dL. We evaluated the sex-specific relation of SUA to the prevalence of ROA using logistic regression, adjusted for age and BMI, with generalized estimating equations to account for the correlations of joints within individuals. We repeated these analyses with SUA as a continuous variable, and categorized as quintiles.

Results: There were 329 men and 575 women with SUA and radiographic data available, among whom 89 and 156 had knee OA, and 252 and 500 had hand OA, respectively. Men with SUA >9 mg/dL had 3.3 times significantly higher prevalence of knee ROA compared with those with SUA <5 mg/dL, though the number of individuals in this category was small (table). The other SUA levels were not associated with knee or hand ROA in men or women (table), nor was there a significant test for linear trend. When SUA was assessed as a continuous variable, the prevalence of knee ROA among men and women was 1.1 times higher (95% CI 0.88-1.25 and 0.93-1.31 for men and women, respectively) for each mg/dL increment of SUA, and for hand ROA it was 1.0 (95% CI 0.94-1.10 and 0.95-1.10, respectively) (table). There was also no relation of SUA quintiles with knee or hand ROA (data not shown).

Conclusion: There was no dose-response relationship between SUA and ROA of the knee or hand. While men in the highest SUA level (>9 mg/dL) had significantly higher prevalence of knee ROA, given the small numbers and lack of replication in women or in hand ROA, this could be a chance finding. On the other hand, this sample had very few individuals with very high SUA levels; thus, we cannot rule out a possible threshold effect. Repeating this study in a sample with greater numbers of individuals with higher levels of SUA is warranted. Nonetheless, it is possible that systemic urate is not wholly biologically relevant for the risk of OA, and rather urate in the joint micro-environment must be evaluated to gain insights into the role urate may play on OA pathogenesis.

Table: Relation of serum urate to prevalent radiographic tibiofemoral and hand osteoarthritis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gumiganghwal-tang (GMGHT) is a traditional herbal medicine consisted of nine different herbs. GMGHT inhibit the production and mRNA expression of inflammatory cytokine production TNF IL B on LPS-stimulated peritoneal macrophages in a dose-dependent manner. It is empirically used for the treatment of inflammatory disease including common cold and various pain, but there are few reports on clinical trials to clarify its efficacy and safety. The current study aimed to investigate the clinical efficacy and safety of GMGHT in patients with knee OA.

Methods: This was a 6-week, multicenter, phase 2, double-blind, randomized, and placebo controlled study of GMGHT vs placebo. Eligible patients who fulfilled American College of Rheumatology criteria were randomized to receive either GMGHT or placebo. Clinical assessments included measurement of knee pain and function with the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), patient global assessment (PGA), and knee pain scores every 2 weeks.

Results: A total of 128 patients enrolled (female n=117, 91.4%; mean age 58.7 ¡¾ 8.1 years) was enrolled. At baseline, pain VAS was 67.2¡¾1.4, 71.3¡¾1.6 (treatment and placebo group, respectively, p=0.84) and total WOMAC score was 55.2¡¾1.6, 55.6¡¾1.5 (p=0.84). At 6-week, pain VAS was 43.0¡¾2.5, 61.6¡¾2.5 (treatment and placebo group, respectively, p<0.01) and total WOMAC score was 34.1¡¾2.4, 46.9¡¾1.8 (p<0.01, Figure 1). None of patients discontinued because of treatment emergent adverse events. Expected adverse event including dyspepsia, liver function abnormality, and low extremity edema was comparable between both groups (Table1).

Conclusion: Treatment of GMGHT resulted in significant improvement in pain, function and global assessment, and it was generally safe and well-tolerated in patients with OA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess predictors of response, according to hip MRI inflammatory scoring system (HIMRISS), in a sample of patients with hip osteoarthritis (OA) treated by hyaluronic acid (HA) injection (HAnox-M-XL).

Methods: 60 patients with hip OA were included. Clinical outcomes were assessed at baseline and three months after HAnox-M-XL injection by WOMAC50 scoring. On hip MRI performed just before HA injection, bone marrow lesion (BML) and synovitis were assessed by HIMRISS by four readers. The inter-reader reliability of HIMRISS, and associations between MRI features and clinical data were assessed. Logistic regression (univariate and multivariate) was used to explore associations between MRI features and response to HA injection, according to WOMAC50 response at three months.

Results: Inter-reader intra-class correlation coefficients for HIMRISS varied from 0.64 [0.52-0.74] for acetabular bone marrow lesion (BML), to 0.86 [0.81-0.89] for HIMRISS total. 45.5% of patients met WOMAC50 response. At baseline,

WOMAC-function correlated significantly to HIMRISS synovitis-effusion (r=0.27, p=0.03). In univariate analysis, BML femoral according to binary assessment (p=0.025), HIMRISS BML femoral (p=0.0038), HIMRISS BML acetabular (p=0.042) and HIMRISS total (p=0.0092) were associated negatively with WOMAC50 response. In multivariate analysis, adjusted for age and BMI, HIMRISS femoral BML (p=0.02) and HIMRISS total (p=0.016) were negatively associated with response. At a HIMRISS threshold of <15, 82% of patients were responders, with specificity SP=0.97, sensitivity SN=0.39, and positive and negative predictive values of 0.91 and 0.64 respectively.

Conclusion: HIMRISS is reliable for total scores and sub-domains (acetabular and femoral BML, and synovitis-effusion). It permits identification of responders to HAnox-M-XL injection in hip OA patients.

Postural Stability Is Associated with Lower Pain, Lower Stiffness, and Higher Muscle Power Among Adults with Symptomatic Knee Osteoarthritis

Wei Liu[1], Augustine C. Lee[2], William F. Harvey[2], Lori Lyn Price[3], Jeffrey B. Driban[2] and Chenchen Wang[2], [1]Osteopathic Rehabilitation and Biomechanics, 1Edward Via College of Osteopathic Medicine, Auburn, AL, USA, Auburn, AL, [2]Rheumatology, Tufts Medical Center, Boston, MA, [3]Clinical Care Research, Tufts Medical Center, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Postural stability is an indicator of static standing balance and a critical component of physical function and fall prevention among those with knee OA. Examining associations between postural stability and physical or functional health outcomes can inform the better monitoring of disease progression and design of ideal treatments. There is limited research on the association between postural stability and outcomes of physical health and functional status in knee OA. The purpose of this study was to investigate the relationships between postural stability and pain, stiffness, physical function, walking ability, and muscle strength and power in a large population of adults with symptomatic knee OA.

Methods: We performed a cross-sectional analysis of baseline data collected as part of a randomized trial comparing Tai Chi with physical therapy. Participants who met the ACR criteria for symptomatic knee OA completed the WOMAC and a battery of physical performance tests (Berg Balance, 6 Minute Walk, 20 Meter Walk, muscle strength and power) at baseline (**Table**). Postural stability was quantified using a standardized balance force plate to measure center of pressure (COP) excursions in Anterior–Posterior (A-P) and Medial-Lateral Direction (M-L), with eyes open and closed. Greater excursion amplitude indicates greater postural instability.

Results: There were 173 participants (mean age: 60 years, BMI: 33, 69% female, 55% white, and 93% Kellgren/Lawrence Grade ≥ 2). Greater COP excursion amplitude, with eyes open or closed and in the A-P or M-L direction, was associated with higher pain (r=0.15-0.16, P<=0.05) and stiffness (r=0.24-0.25, P<=0.002). Greater COP excursion amplitude in the M-L direction (eyes open or closed) or A-P direction (eyes open) was also significantly associated with lower peak power at low (r=-0.15- -0.17, P<=0.05) or high resistance (r=-0.16- -0.19, P<=0.04). COP excursion variables were not significantly associated with BMI, WOMAC function, dynamic balance (Berg balance), muscle strength, or the walk tests (**Table**).

Conclusion: Participants with symptomatic knee OA who had greater postural stability tended to have less pain, less stiffness, and more muscle power. Our findings indicate that therapeutic interventions that positively modulate postural stability may reduce pain and stiffness among those with knee OA. In addition, static postural stability may be an

informative performance metric to assist researchers and clinicians to better monitor symptoms, design novel treatment, or prevent future falls.

Table. Correlation Coefficients between Postural Stability and Health Outcomes

Session Title: Osteoarthritis – Clinical Aspects - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis**(**OA) has been recognized as a progressive disease resulting from stress in synovial joint tissues including periarticular muscles. In knee OA, quadriceps muscle mass and strength were shown to be associated with knee OA symptoms, prevalence and progression. As one of the measures to evaluate periarticular muscles in knee OA, muscle mass imbalance or difference in both leg muscles has not been investigated. Therefore, we examined if leg muscle imbalance is related to higher prevalence of knee OA and its radiographic grade as well as symptoms.

Methods: We conducted a cross-sectional study using data from the Fifth Korean National Health and Nutrition Examination Survey (KNHANES V). Males or females aged 60 years or older who underwent both knee radiographs and DXA scans were included. Patient characteristics, bilateral knee x-rays with KL grade readings, body composition by DXA scans were obtained as part of KNHANES V. Muscle imbalance index was defined as |(left leg muscle mass)/(both legs muscle mass) x 100 -50|. Statistical analyses were performed to examine the relationships between muscle imbalance index and radiographic grade and knee symptoms.

Results: Total 2,548 patients (1,126 of men and 1,422 of women) were included in the analysis. The characteristics of males and females were significantly different. Males were younger, had smaller BMI but bigger muscle mass and lesser fat mass in both legs, exercised more than female patients. Muscle imbalance index was averaged at 0.94¡¾0.03 in males and 1.04¡¾0.03 in females. The index was significantly greater in women (p=0.01). The imbalance index was positively associated with the KL grade as well as knee pain especially in males. The most imbalanced group had 2.3 times worse radiographic grade and 2.8 times more likely to have knee pain than the least imbalanced group in males. In males with radiographic knee OA (KL grade >=2), those with the highest quantile of muscle imbalance were 3 times more likely to have knee pain compared with those in the lowest quantile. When subjects were divided into 4 different groups by obesity (BMI>=25kg/m^2) and the muscle imbalance index (4^{th} quantile vs. the rest) – balanced normal, balanced obese, imbalanced normal, and imbalanced obese, those with imbalanced obese were 1.8 times or 3.6 times worse radiographic grade of knee osteoarthritis in males or females, respectively (Figure). In males, having leg muscle imbalance irrespective of their weight status related to significantly worse radiographic grade of knee OA compared with normal males.

Conclusion: Leg muscle imbalance was associated with radiographic knee OA grade as well as prevalent knee pain. In males, muscle imbalance was significantly related to worse radiographic knee grade or knee pain, whereas obesity alone was not related to neither of them.

Observer Variability of Joint Space with Measurements Is Subject Related in Medial Knee Osteoarthritis

Berna Goker[1], Seminur Haznedaroglu[1], Abdurrahman Tufan[1] and Joel Block[2], [1]Internal Medicine-Rheumatology, Gazi University Medical School, Ankara, Turkey, [2]Division of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Assessment of structural progression of knee osteoarthritis (OA) requires quantitative evaluation of the radiographic joint space width (JSW). Significant reduction in the rate of narrowing of JSW represents a crucial readout in the evaluation of potential disease modifying agents for OA. However, as the knee is geometrically complex, quantitative JSW readings can only be performed on radiographs obtained using special techniques, and even in such cases, the variability in measurements (both intra-observer and inter-observer) is often large. Thus, to confidently demonstrate significance, longitudinal OA studies often require very large group sizes to achieve satisfactory power. Reducing observer variability at baseline could be a useful strategy to permit smaller or shorter structural OA studies. It has long been clear that observer variability is observer-related. However, we observed that the geometry of individual knee joints often predisposes to exagerrated measurement variability. Here we tested the hypothesis thatthere is

a study subject–related component to observer variability of JSW mesurements, and that this can be assessed at baseline to minimize the risk of observed variability in longitudinal studies.

Methods: With IRB approval and after obtaining informed consent, 20 subjects with symptomatic medial compartment knee OA (Kellgren-Lawrence grade 2-3, pain on ambulation >30 mm on a 100 mm visual analog scale) were evaluated at baseline and longitudinally as part of a larger trial. Subjects underwent semi-flexed fluoroscopic-guided PA knee radiography (Schuss view) at baseline and at 12 months. Medial compartment JSWs were quantified using Image J software (US NIH, Bethesta, MD, http://rsb.info.nih.gov/ij/) twice by the same observer, and these measurements were repeated after 8 years. The difference in the measured medial JSWs between the measurements made at baseline and those repeated after 8 years of the baseline x-ray for each subject was calculated (baseline observer variability for the individual subject). Similarly, the difference between two measurements of 12-month xrays were calculated for each subject (follow-up observer variability). Pearson's correlation test was used for analysis.

Results: Baseline observer variabilities ranged from -1.55 to 0.88, with a mean ±SD of -0.05 ± 0.44. Similarly, the variability of the 12 month measurements ranged from -1,13 to 1.35, with a mean ±SD of 0.13 ± 0.44. The discrepancy at baseline was related to the measured discrepancy of the subjects at 12 months, (Pearson's r=0.51, p=0.02), and these measurements were consistent when re-assessed 8 years later (intraclass correlation coefficient 0.97 (95 % CI 0.93-0.99)).

Conclusion: These data suggest that some knees are subject to greater measurement variability than other knees, and that these differences remains constant over time. It may be possible to identify knees that are highly prone to measurement error at baseline, and to thereby reduce groups sizes in OA trials by excluding such knees. . Selecting patients with radiographs resulting in better observer variabilty at baseline might allow performing disease modifying OA studies with smaller number of patients or shorter duration.

Incident Participation Restriction in Adults with Knee Osteoarthritis: Do Positive and Negative Affect Matter? the Multicenter Osteoarthritis Study

Molly Vaughan[1], David T. Felson[2], Michael P. Lavalley[3], Gael Orsmond[4], Jingbo Niu[5], Cora E Lewis[6], Neil Segal[7], Michael Nevitt[8] and Julie J. Keysor[9], [1]635 Commonwealth Avenue, Room 651, Boston University College of Health & Rehabilitation Sciences, Boston, MA, [2]Clinical Epidemiology Unit, Boston University School of Medicine, Boston, MA, [3]Biostatistics, Boston University School of Public Health, Boston, MA, [4]Department of Occupational Therapy, Boston University, Sargent College of Health & Rehabilitation Sciences, Boston, MA, [5]Department of Nephrology, Baylor College of Medicine, Houston, TX, [6]Preventive Medicine, University of Alabama at Birmingham, Birmingham, AL, [7]University of Kansas, Shawnee, KS, [8]Department of Epidemiology & Biostatistics, University of California San Francisco School of Medicine, San Francisco, CA, [9]Physical Therapy, Boston University, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Participation restrictions, common among people with knee osteoarthritis (OA), may be due to psychological factors. Many people with OA experience chronic pain, which can alter levels of positive and negative affect. Positive affect consists of emotional vitality and optimism, whereas negative affect is defined by unpleasant engagement or distress. Positive and negative affect may impact participation restriction over time; however, little is known of their long-term effects. We investigated the risk of incident participation restriction over 84 months with positive

and negative affect among adults with or at risk of knee OA.

Methods: Data are from the Multicenter Osteoarthritis Study (MOST). Participants with participation restriction at baseline or who underwent total knee replacement during the 84 months were excluded. Participation restriction was measured using the Instrumental Role Limitation subscale of the Late Life Disability Index at 0, 30, 60, and 84 months. The Center for Epidemiological Studies Depression Scale was used to measure positive and negative affect at baseline. Scale values were dichotomized at the median to create high and low positive and negative affect groups. The risks of incident participation restriction over 84 months due to low positive affect, high negative affect, and combinations of low and high positive and negative affect were calculated in binomial regression analyses, adjusting for demographic factors, disease factors, and function. We tested the interaction between low positive and high negative affect.

Results: Of the 1810 participants at baseline, 470 (26%) (m=62.1 years, 56% female) had incident participation restriction over 84 months. In adjusted analyses, participants with low positive affect had 20% greater risk of incident participation restriction, and participants with high negative affect had 50% greater risk (Table 1). In the combination analysis, participants with both low positive affect and high negative affect had the highest adjusted risk of incident participation restriction [RR=1.8] compared to other combinations of positive and negative affect, but the interaction between positive and negative affect was not significant.

Conclusion: People with or at risk of knee OA with low positive and high negative affect are at increased risk of participation restrictions over time and efforts aimed at preventing participation restriction in this population should consider these psychological profiles.

Table 1. Risk ratios (RR) of incident participation restriction over 7 years (N=1810)

	Subjects n (%)	Crude RR [95%CI]	Multivariable Adjusted RR [95%CI]†

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Measures of chronic pain typically do not account for individuals' physical activity (PA) levels. Although PA is essential for managing conditions like osteoarthritis (OA), some people may reduce activity to manage their pain. Recent research showed that a PA-adjusted pain measure was more strongly associated with radiographic OA severity than an unadjusted pain measure. We extend this area of research by examining whether PA-adjusted pain is also more closely associated with key function and quality of life outcomes.

Methods: In a subset of 140 Veterans (M age=61.8 years, 87.1% male) enrolled in a clinical trial of group vs. individual physical therapy, we used the Western Ontario and McMaster Universities Osteoarthritis (WOMAC) Pain Scale and calculated four composite **WO**MAC pain and **P**hysical **A**ctivity (WOPA) scores using accelerometer-derived data. Specifically, WOMAC pain scores were adjusted for: 1) step counts, 2) time in sedentary activity, 3) time in moderate-intensity activity, and 4) energy expenditure (kilocalories). All data were from baseline assessments. We examined associations of WOMAC pain score and each of the four WOPA scores with six OA-related outcomes: 6-minute walk test, 8-foot walk test, chair stand test, self-reported satisfaction with physical function, fatigue (brief fatigue inventory), and anxiety / depressive symptoms (single item). Analyses were partial correlations, controlling for age, gender and body mass index.

Results: Significant ($p<0.05$) associations were found between WOMAC / WOPA scores and OA-related outcomes in the majority (22/30) of models (Table 1). In all cases greater pain was associated with poorer outcomes. For the four OA-related outcomes that measure aspects of physical function (six-minute walk, chair stands, 8-foot walk, satisfaction with function), the step-count adjusted and energy expenditure adjusted WOMAC pain scores had stronger associations (partial r's=0.24-0.45) than the unadjusted WOMAC pain scores (partial r's=0.15-0.25). For fatigue, unadjusted WOMAC pain and energy expenditure adjusted WOMAC pain scores had similar associations (partial r's=0.27 and 0.28), and for anxiety and depressive symptoms, the unadjusted WOMAC pain score had the strongest association (partial r=0.31).

Conclusion: Results suggest PA-adjusted pain measures may add increased value in predicting some OA-related outcomes and should be explored further, particularly in longitudinal studies. Step-count adjusted pain (which was associated with radiographic OA severity in previous research) and energy expenditure adjusted pain may be particularly useful in predicting functional outcomes.

Table 1. Partial Spearman Correlations (r) of Pain / Physical Activity Measures with OA-Related Outcomes

	WOMAC Pain r (p-value)	WOMAC-Step Count r (p-value)	WOMAC-Sedentary / Light Activity r (p-value)	WOMAC-≥ Moderate Intensity Activity r (p-value)	WOMAC-Energy Expenditure r (p-value)

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment with romosozumab (Romo) has been shown to rapidly increase BMD in postmenopausal women with low BMD through a dual effect on bone, increasing bone formation and decreasing bone resorption (McClung *NEJM* 2014), and is being investigated for anti-fracture efficacy in postmenopausal women with osteoporosis. Here we report the results of the primary analysis of a phase 3 placeBo-contRolled study evaluatIng the efficacy anD safety of Romo in treatinG mEn with osteoporosis (BRIDGE; NCT02186171).

Methods: This randomized, double-blind, multicenter study enrolled ambulatory men age 55–90 with a lumbar spine (LS), total hip (TH), or femoral neck (FN) T score ≤ –1.5 and a history of fracture after age 45, or a T score ≤ –2.5. Men were randomized 2:1 to receive Romo 210 mg or placebo (Pbo) SC once monthly for 12 months. All subjects received daily calcium and vitamin D. The primary endpoint was the percentage change from baseline in LS BMD by dual x-ray absorptiometry (DXA) at month 12. Secondary and exploratory endpoints included the percentage change from baseline in BMD by DXA at months 6 (LS, TH, and FN) and 12 (TH and FN), and the percentage change from baseline in the serum bone turnover markers P1NP and CTX, respectively. Safety endpoints included incidence of adverse events (AEs).

Results: A total of 245 men were enrolled (163 Romo, 82 Pbo). Subjects had a baseline mean (SD) age of 72 (7.3) years, baseline mean LS, TH, and FN T-scores of –2.3, –1.9, and –2.3, respectively, and 54% had a historical fracture. In the Romo group, statistically significant gains in BMD from baseline were observed at all sites evaluated at months 6 and 12 (month 12: LS [12.1%] [Figure], TH [2.5%], and FN [2.2%]) (all $P < 0.05$ vs Pbo). Romo treatment also resulted in a rapid and transient increase in the bone formation marker P1NP that peaked at month 1 (median increase from baseline 86%) and gradually returned toward baseline. The bone resorption marker CTX decreased after the first dose of Romo, with the greatest decrease observed at month 1 (median decrease from baseline 31%), and remained below baseline through month 12. The overall subject incidence rates of AEs and serious AEs were balanced between treatment groups. Injection site reactions were reported in 5.5% and 3.7% of subjects in the Romo and Pbo groups, respectively; most reactions were reported as mild in severity. The subject incidence of positively adjudicated cardiovascular serious AEs was 4.9% (8/163) in the Romo group and 2.5% (2/81) in the Pbo group. The subject incidence of positively adjudicated cardiovascular death was 0.6% (1/163) in the Romo group and 1.2% (1/81) in the Pbo group.

Conclusion: In men with osteoporosis, treatment with Romo for 12 months demonstrated a dual effect by increasing bone formation and decreasing bone resorption resulting in significant gains in BMD at the spine and the hip compared with Pbo, and was generally well tolerated.

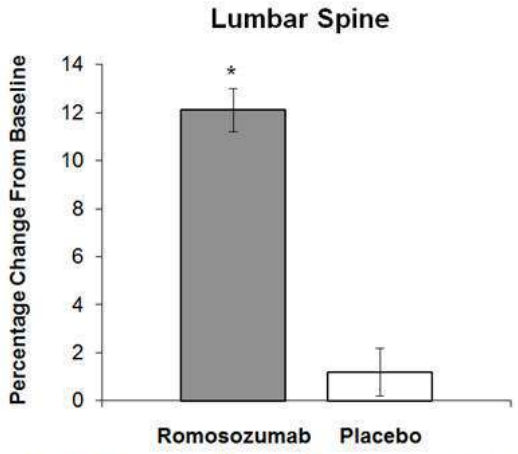

Figure. Percentage change from baseline in bone mineral density at month 12 in men receiving romosozumab 210 mg or placebo subcutaneous once monthly. Data are least-squares means and 95% confidence intervals. *$P < 0.0001$ vs placebo.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To improve the rate of osteoporosis medication use in women with a prior fracture we developed and implemented a tailored, educational, direct-to-patient video intervention to provide information about reducing fracture risk with osteoporosis medications.

Methods: We conducted a controlled, randomized clinical trial of our novel intervention among US women in the Global Longitudinal Study of Osteoporosis in Women cohort with self-reported fracture history who were not currently using osteoporosis therapy. The primary outcome at 6 months follow-up was self-report of osteoporosis medication use. Secondary outcomes included self-reported use of calcium and vitamin D supplementation and bone density testing. Missing data were treated with multiple imputation and the outcomes (proportions) were compared by chi square test using intent-to-treat analysis.

Results: We randomized 2684 women to receive the intervention materials or usual care. Study participants were 92.6% Caucasian, with a mean (SD) age 74.9 (8.0) years, had some college education (76.7%), in good health (84.6%), and a self-reported lower than average risk for osteoporosis (40.0%). In the 12 months prior to randomization, 1390 women reported talking with their doctor regarding osteoporosis, 7.4% reported a fracture, vitamin D or calcium supplementation were reported as 83.5% and 68.6%, respectively. We observed no differences in sociodemographic characteristics and no significant differences in the primary (11.7% vs 11.4%) and secondary (calcium, 31.8% vs 32.6%; vitamin D, 41.3% vs 41.9%; bone density, 61.8% vs 57.1%) end points between the intervention and usual care groups. Exploratory post-hoc analyses demonstrated that women in the intervention arm had more favorable views towards osteoporosis medications compared with the usual care arm and a lower proportion were in the unaware and uninvolved stages of behavior change regarding osteoporosis medications (64.1.% vs. 68.8%, raw p =0.028). We found that barriers to treatment were higher in the intervention, as compared to usual care arm at 6 months: concerns regarding osteonecrosis of the jaw (28.9% vs 24.6%, raw p=0.031) and difficulty in taking/remembering to take osteoporosis medications (22.0% vs 18.1%, raw p=0.03).

Conclusion: This randomized study testing a novel, personalized educational intervention, did not increase the use of osteoporosis therapy at 6 months. The intervention appeared to have influenced participants' readiness for behavior change.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Denosumab (DMAb) has been associated with low incidence of spine and non-spine, including hip, fractures through 10 years of treatment (Bone *ASBMR* 2015). Questions about bone safety arose in response to the FREEDOM transiliac crest biopsy findings: low numbers of tetracycline labels were observed with low dynamic parameters of remodeling (Reid *JBMR* 2010). In the FREEDOM Extension, bone biopsies were performed in subjects with 5 years of DMAb treatment and findings were similar to those in subjects with 2 or 3 years of DMAb treatment in FREEDOM (Brown *JBMR* 2014). We now report bone biopsy findings in subjects with 10 years of DMAb treatment.

Methods: A subset of subjects with 10 years of DMAb exposure (3 years FREEDOM + 7 years Extension) participated in a transiliac bone biopsy substudy. Subjects underwent a tetracycline/demeclocycline labeling procedure prior to their bone biopsy visit (6 months after their last DMAb dose); samples were prepared and analyzed according to standard procedures by the Mayo Clinic as previously described (Reid *JBMR* 2010). Continuous and categorical variables were summarized using descriptive statistics.

Results: There were 22 biopsies evaluable for qualitative histology in subjects with 10 years of DMAb exposure; all specimens showed normally mineralized lamellar bone. There was no evidence of pathologic findings, including osteomalacia, woven bone, or marrow fibrosis. There were 21 biopsies evaluable for histomorphometry; these showed that the antiresorptive effects of DMAb were maintained over time. In addition, indicators associated with bone formation and structure (including osteoid surface, osteoid width, and eroded surface) were generally similar to those at years 2/3 and 5 (Table). As part of the analysis of dynamic parameters, the presence of tetracycline labels was reviewed in all biopsies. The percentage of samples with any tetracycline label in trabecular bone has steadily increased over time from 34% in year 2/3, to 43% in year 5, and 77% in year 10; the percentage of samples with any label in cortical bone has remained steady from 57%, to 64%, and 55%, respectively. Double tetracycline labeling of trabecular or cortical bone was found in 7 (32%) subjects at year 10.

Conclusion: Bone histology showed normal bone microarchitecture, and histomorphometry was consistent with DMAb mechanism of action. There was no evidence of progression in the degree of low remodeling with long-term exposure to DMAb. **Table 1:** Bone histomorphometry in FREEDOM and its extension

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Evaluation of efficacy and safety of percutaneous vertebral fill technique vertebroplasty in subjects with acute vertebral fracture (symptom duration less than six weeks) .

Methods: Randomized, parallel group, placebo controlled trial. The proceduralists utilized a vertebral fill cement technique, achieving cement distribution from the superior to the inferior end plate. Primary outcome measure patient rated pain intensity less than 4 (Numerical Rating Scale) measured at two weeks. Secondary outcome measures recorded at time points 3 days, 14 days, 28 days, 3 months and 6 months were functional disability (The Roland-Morris Low Back Pain and Disability Questionnaire (RDQ), The Quality of Life Questionnaire of the European Foundation for Osteoporosis (QUALEFFO. Effectiveness analyses by intention-to-treat principle. Proportions compared using a two-sided chi-squared or exact (conditional binomial) test. Changes in quality of life measures (pain/ functional disability scores) analysed using *t*-tests enabling comparisons with published studies. All comparisons were two-sided with a significance level of 5% considered as being statistically significant.

Results: 120 subjects were enrolled (59 control arm, 61 vertebroplasty arm). Female 73%, Male 27%. Mean age 80 years (SD 7.2) The proportion of patients achieving an NRS <4 at 14 days was 43.6% in the vertebroplasty group and 21% in the control group (p=0.011). Mean decrease in change in NRS pain score from baseline greater in the vertebroplasty group at all time points (p<0.05). Mean reduction in RDQ from baseline favoured vertebroplasty from day 14 to month 6. (p<0.05). There was minimal difference Mean QUALEFFO l between groups. Four serious adverse events occurred; 2 in the placebo group and 2 in the vertebroplasty group.

Conclusion: Percutaneous Vetebroplasty performed during the first six weeks post fracture utilizing a vertebral fill technique, is more effective than placebo in reducing pain, and improving function in patients with vertebral fracture. Serious adverse events were the same in both groups. Figure 1: Primary outcome measure – percentage (%) of patients with NRS < 4) all time points p<0.05)

Ebselen Is a Potential Anti-Osteoporosis Agent By Suppressing RANK Ligand-Induced Osteoclast Differentiation in Vitro and Lipopolysaccharide-Induced Inflammatory Bone Destruction In Vivo

Changhoon Lee[1], Jong Min Baek[2], Ju-Young Kim[2], Won-Seok Lee[3], Wan-Hee Yoo[4], Myeung Su Lee[5] and ACR authors group, [1]Division of Rheumatology, Department of Internal Medicine, Wonkwang University Hospital, Iksan, Korea, The Republic of, [2]Department of Anatomy, School of Medicine, Wonkwang University, Iksan, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine of Chonbuk National University Hospital-Chonbuk National University, jeonju, South Korea, [4]Division of Rhuematology, Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine of Chonbuk National University Hospital-Chonbuk National University, Jeonju, South Korea, [5]Division of Rheumatology, Department of Internal Medicine, Wonkwang University Hospital, Iksan, Chonbuk, South Korea

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ebselen is a non-toxic seleno-organic drug with anti-inflammatory and antioxidant properties that is currently being examined in clinical trials to prevent and treat various diseases, including atherosclerosis, stroke, and cancer/We investigated the effects of ebselen on RANKL-induced differentiation of osteoclasts and their functions and the underlying molecular mechanisms. Furthermore, we determined the effects of ebselen on LPS-induced bone erosion in vivo.

Methods: We cultured BMMs for 4 days in the condition of M-CSF and RANKL pretreated with ebselen. The cells were then stained with TRAP solution, rhodamine-conjugated phalloidin for F-actin ring labeling and DAPI solution to detect apoptotic body formation. The change of F-actin ring on mature osteoclasts induced by ebselen was quantified by calculating the ratio of actin ring positive (AR+) osteoclasts versus actin ring negative (AR-) osteoclasts. to detect the formation of apoptotic osteoclasts, we performed TUNEL (TdT-mediated dUTP-biotin nick endlabeling) assay. Primary calvaria osteoblasts and BMCs were co-cultured and were re-seeded in hydroxyapatite-coated plates or dentin slices with or without ebselen. ICR mice were divided into 4 experimental groups comprising 5 mice each: phosphate-buffered saline-treated (control) group, ebselen only-treated group, LPS only-treated group, and LPS and ebselen-treated group. Ebselenor PBS was administered orally every 8 days, and LPS was injected intraperitoneally on days 1 and 4. μ-CT data containing 3D images and bone parameters and histological data were acquired

Results: Ebselen suppressed the formation of TRAP-positive multinucleated cells in an osteoblast/osteoclast co-culture by regulating the ratio of RANKL/osteoprotegerin secreted by osteoblasts. In addition, ebselen treatment in the early stage of osteoclast differentiation inhibited RANKL-dependent osteoclastogenesis by decreasing the phosphorylation of IκB, PI3K, and Akt in early signaling pathways and by subsequently inducing c-Fos and nuclear factor of activated T-cells c1. Further, ebselen induced apoptosis of osteoclasts in the late stage of osteoclast differentiation. In addition, ebselen treatment suppressed filamentous actin ring formation and bone resorption activity of mature osteoclasts. Reflecting these in vitro effects, administration of ebselen recovered bone loss and its μ-CT parameters in lipopolysaccharidemediated mouse model. Histological analysis confirmed that ebselen prevented trabecular bone matrix degradation and osteoclast formation in the bone tissues. Finally, it was proved that the anti-osteoclastogenic action of ebselen is achieved through targeting N-methyl-D-aspartate receptor.

Conclusion: These results indicate that ebselen is a potentially safe drug for treating metabolic bone diseases such as

osteoporosis.

Cortical Bone Changes in Pre- and Postmenopausal Healthy Women Measured with HR-pQCT

Jackeline Couto Alvarenga[1] and Rosa M R Pereira[2], [1]Division of Rheumatology, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Rheumatology Division, Faculdade de Medicina da USP, São Paulo, Brazil

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased fracture rates are well-recognized in adults with trabecular and cortical bone deficits, but cortical evaluation has been poorly studied. The aim of this study is to analyze the cortical bone parameters using high-resolution peripheral quantitative computed tomography (HR-pQCT, Scanco Medical AG, Switzerland) parameters in a cohort of 450 healthy women and compare these cortical parameters in pre- and postmenopausal.

Methods: The distal radius (DR) and distal tibia (DT) of 228 premenopausal women and 222 postmenopausal women were scanned using HR-pQCT. The entire volume of interest (VOI) was automatically separated into cortical and trabecular regions using a threshold-based algorithm and the following cortical parameters were obtained: cortical volumetric bone mineral density (Ct.vBMD), cortical thickness (Ct.Th). Moreover, cortical porosity (Ct.Po) was calculated as the percentage of void space in the cortex. Stiffness was analysed with a software specific finite element analysis (Scanco Medical AG, Switzerland). Significance was accepted at $p < 0.05$.

Results: At distal radius, the density (Ct.vBMD) and thickness (Ct.Th) showed an important decrease of these parameters up to 10 years after menopause, and remained stable after this period. Differently, Ct.Po showed a continue alterations (increase) linearly with age. Regarding distal tibia site, the deterioration of the Ct.vBMD, Ct.Th and Ct.Po were observed linearly with aging. The Pearson correlation demonstrated that density and thickness cortical parameters at DR and DT showed a moderate significant correlation (Ct.vBMD: DR: r= 0.521, DT: r=0.316; Ct.Th: DR: r= 0.619, DT: r= 0.392, $p<0.01$) and a weak correlation with cortical porosity (Ct.Po- DR: r= -0.162, DT: r= -0.273 ($p<0.01$) with stiffness parameter.

Conclusion: Our results showed that cortical parameters of the distal radius have a different behavior during aging comparing to distal tibia site. Moreover, cortical density/thickness showed better correlation with strength parameter, suggesting that density/thickness parameter are better for predicting cortical bone quality comparing to cortical porosity.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: As rheumatoid arthritis (RA) is a well-established risk factor for osteoporosis and compression fracture, non-adherence to bisphosphonate (BP) therapy in patients with RA can adversely affect clinical outcome. Our study aimed to investigate the drug retention rate of oral BP and analyze the associated factor for this rate in RA patients under routine care.

Methods: In this retrospective longitudinal study, 410 RA patients in whom the first oral BP such as ibandronate (150 mg/month), risedronate (35 mg/week) and alendronate (70 mg/week) initiated from April 2003 to September 2015 at a university-affiliated rheumatology center in South Korea were included. Seropositve RA was defined as having for a positive test result for presence of either rheumatoid factor or anti–cyclic citrullinated peptide antibody. The drug retention rate was calculated using the Kaplan-Meier method and the predictors of this rate were identified by Cox-regression analyses.

Results: The mean age was 65.9 ¡¾ 11.3 years and 399 (96.6%) and 332 (81%) patients were female and seropositive RA, respectively. During the study period, 283 (69%) patient discontinued oral BP. The cause of BP discontinuation was as follows: treatment failure, 35.7%; adverse events, 6.4%; patients¡¯ decision, 43.1%; drug holidays, 2.8%; cost, 12%. The 2-year drug continuation rate was 65.8, 40 and 42.1% and the median retention was 39.2, 13.1 and 18.8 months for ibandronate, risedronate and alendronate, respectively. The drug retention rate significantly differed among the 3 oral BP (p<0.001, Fig. 1). In multivariable Cox regression models, risedronate demonstrated a worse retention rate than ibandronate (HR=2.34, 95% CI=1.79-3.06, p<0.001, Table 1). Additionally, seropositve RA patients showed a better BP retention rate than those without this feature (HR=0.59, 95% CI=0.42-0.84, p=0.004).

Conclusion: Persistence of BP treatments was suboptimal in RA patients under routine care. Monthly ibandronate showed better retention rate than weekly risedronate, suggesting that a longer dosing interval may improve the adherence of BP treatment in RA patients.

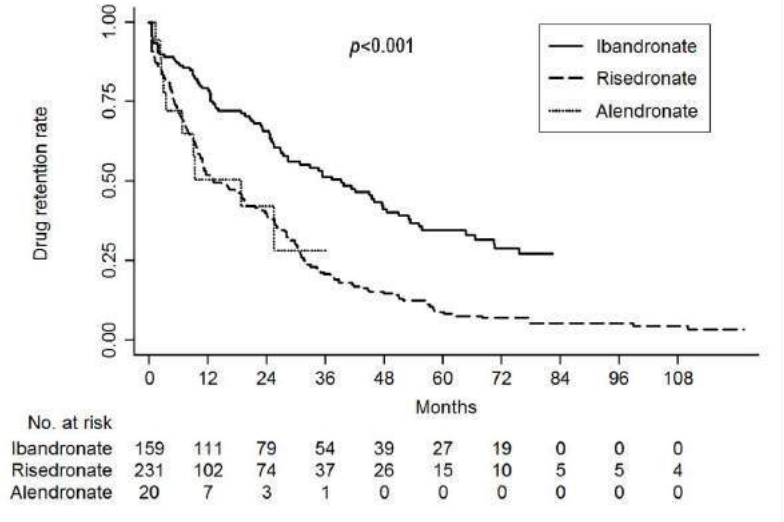

Figure 1. Kaplan-Meier survival curve of oral bisphosphonate in patients with rheumatoid arthritis Table 1. Cox-proportional hazard regression analyses with backward model selection for tacrolimus discontinuation according to causes.

A Study of Serum Electrolyte Levels after Denosumab Administration

KEN NAKASEKO, TAKAO SUDO and TAKAHIRO ASANO, KUWANA CITY MEDICAL CENTER, Kuwana Mie, Japan

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Denosumab is an antiresorptive drug used for the treatement of postmenopausal osteoporosis. One of the major and critical adverse events of denosumab injection is hypocalcemia, which is most often observed in the one-week period following administration. Examination of albumin-adjusted calcium (Ca) level after one week is recommended to exclude the presence of hypocalcemia. Although hypophosphatemia has been reported to be an adverse event with a frequency of more than 1% in patients subcutaneously administered 120mg of denosumab for tumor treatment, there have been no reported data regarding its frequency in patients administered 60mg for osteoporosis. The purpose of the present study was to evaluate the occurrence of denosumab adverse events, focusing on serum electrolyte levels soon after administration, as well as to confirm its efficacy.

Methods: Forty-three women between the ages of 55 and 91 years with postmenopausal osteoporosis were enrolled and treated with a 60mg subcutaneous injection of denosumab and an oral calcium tablet combined with native vitamin D and magnesium (Mg).Serum Ca and phosphorus (P) were measured at baseline and at 1,2,3,and 4 weeks after administration. Serum Mg, bone formation marker intact serum procollagen type 1 N-terminal propeptide (P1NP), and bone resorption marker tartrate-resistant acid phosphatase-5b (TRACP-5b) were also evaluated at baseline and 4 weeks after

administration. Laboratory investigations after a second injection were performed in 33 patients in the same manner. Bone mineral density (BMD) was measured at baseline and 6 months after administration.

Results: Both serum Ca and P electrolyte levels significantly decreased soon after administration. Hypocalcemia was detected in 3 patients: 2 patients 1 week after administration, and 1 patient 2 weeks after. Hypophosphatemia was observed in 10 patients: 8 patients 1 week after administration and 2 patients after 2 weeks. Hypocalcemia was observed 1 week after the second administration in 1 of the 33 patients. Hypophosphatemia was detected in 1 patient 1 week after. Serum Mg levels were within normal limits on all examinations. There were no patients who discontinued the treatment due to adverse events in the present study. All serum electrolyte levels recovered within 4 weeks of each administration. At 4 weeks, P1NP level was decreased by 24.0% and TRACP-5b was decreased by 66.9 %. At 6 months, BMD of the lumbar spine was increased by 2.5%, the femur by 1.5%, and the distal radius by 0.6%.

Conclusion: Adverse events were not observed clinically throughout the duration of the study period. However,hypocalcemia and hypophosphatemia were observed within 1 or 2 weeks after the first and/or second administration of denosumab. Therefore, measuring serum electrolyte levels of Ca and P within in 1 or 2 weeks is strongly recommended for the detection of hypocalcemia and hypophosphatemia. Furthermore, denosumab administration resulted in a low bone remodeling ratio reflected by decreases in both P1NP and TRACP-5b levels, and increase in BMD, which may reduce fracture risk.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In our previous study, several conclusions are reached like: (1) IL-22 can promote inflammation and osteoclast formation in the process of RA;(2) 1,25(OH)2D3 decreases serum IL-22 level in RA patients, and acts as a dose-dependent inhibition of expression of RANKL;(3) 1,25(OH)2D3 may inhibits the expression of RANKL by blocking IL-22-mediated JAK-2 /STAT-3and p38MAPK/ NF-κB transduction pathways.In this study, we will compare the formation of osteoclasts in different treatment groups to explore whether the 1,25(OH) 2D3 can inhibit the formation of osteoclasts by affecting the IL-22-mediated JAK-2 / STAT-3 and p38MAPK/ NF-κB signal transduction pathways.

Methods: 1. In this trial all the osteoclast precursors PBMCs came from the peripheral blood of healthy volunteers, the consentrations of RANKL, M-CSF, 1,25(OH)2D3 respectively: 30ng/mL、25ng/mL、1nM. All the samples were devided into the following groups: GroupA: PBMC+M-CSF；GroupB: PBMC+M-CSF+RANKL；GroupC: PBMC+M-CSF+RANKL+1,25(OH)2D3. Detected the levels of the osteoclasts' marker TRAP, cathepsin K, matrix metalloproteinase (MMP)-9 mRNA by RT-PCR to assess the effect of the agents. 2.Isolate FLS from RA synovial tissue of patients and culture them to generation 4~8, add IL-22 to stimulate the secretion of RANKL. Isolate PBMC from the peripheral blood of healthy volunteers, add the M-CSF pretreatment after 24h when the cells adherent, co-culture the two kind cells. At the same time, add RANKL, M-CSF, IL-22, 1,25(OH)2D3 and different signal transduction protein inhibitors according to the experimental groups.The consent rations of RANKL and M-CSF are the same to part1, the consentration of IL-22 is

10ng/ml. We devided all the samples into the following 5 groups: Group a: PBMC+RA-FLS+M-CSF; Group b: PBMC+RA-FLS+M-CSF+RANKL; Group c: PBMC+RA-FLS+M-CSF+IL-22+1,25(OH)2D3; Group d: PBMC+RA-FLS+M-CSF+1,25(OH)2D3+IL-22+AG490; Group f: PBMC+RAFLS+M-CSF+1,25(OH)2D3+ IL-22+SB203580.

Results: 1.In the part1 the number of osteoclasts (multiple nuclear TRAP positive cells)in groupA, B, C respectively 7±>0.816, 30±2.944, 5±2.16. There was statistically significant difference between groups(P<0.05). 2.The mRNA of the three makers to osteoclast is higher in group B compared with the other two groups (P<0.05). But the difference between group A and C has no statistically significance(P>0.05). 3.In the part 2 the number of osteoclasts in the Groups a,b,c,d,f respectively 7.5±1.732, 38.5±3.416, 0.5±0.477, 21.75±3.775, 9±2.944. The number in the Group b is higher than in Group a, The difference was statistically significant(P<0.05); the difference between Groups c,d,f and Group b also has statistically significant(P<0.05); the difference between Groups d,f and Group c also has statistically significant (P<0.05). 4.The expression of the target genes in the Groups a,c,d and the Group f are lower than the Group b. There has no statistically significant difference between Group a and c, d and f (P>0.05). The differences between other groups are statistically significant(P<0.05).

Conclusion: 1,25(OH)2D3 can inhibit the formation of osteoclasts by blocking the IL-22-mediated JAK-2/STAT-3 signaling pathway.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Denosumab is a RANK ligand antibody and the first biologic agent used for the treatment of post-menopausal osteoporosis (OP) and prevention of bone metastases complications. The aim of this meta-analysis was to assess the safety of Denosumab.

Methods: Data sources included MEDLINE, EMBASE, Cochrane Library, and recent abstracts from ACR and EULAR congresses were searched until March 2016. Randomized controlled trials comparing the safety of Denosumab to placebo or bisphosphonates (BP) in postmenopausal OP and in cancer (either cancer with bone metastases or with hormone therapy) were selected. Data were extracted by one investigator, confirmed by another, and pooled in meta-analysis using Review Manager software (Cochrane collaboration).

Results: 6136 articles were of potential interest, and 19 met the inclusion criteria. 7 articles (3859 patients) compared the safety of Denosumab to BP in post-menopausal OP. There was no significant difference when comparing Denosumab with bisphosphonates in any adverse events (AAE) (RR=0.98, 95% CI=0.95-1.01) serious adverse event (SAE) (RR=1.04, 95% CI=0.81-1.33) and all infections (AI) (RR=1.11, 95% CI=0.98-1.25). Regarding Denosumab versus placebo in post-menopausal OP, 7 studies (8724 patients) were included and there was no significant difference in AAE (RR=0.98, 95% CI=0.94-1.01), SAE (RR=1.03, 95% CI=0.96-1.11), AI (RR=1.11, 95% CI=0.98-1.25), however cellulitis was more frequently found with Denosumab (RR=8.03, 95% CI=1.44-4.00). No cases of osteonecrosis of the jaw (ONJ) has been reported. 5 articles were pooled to compare Denosumab with BP in patients with bone metastases and no significant difference was found in AAE (RR=0.99, 95% CI=0.98-1.00), SAE (RR=0.99, 95% CI=0.95-1.03), AI (RR=1.01, 95% CI=0.89-1.13) and ONJ (RR=1.40, 95% CI=0.92-2.13). 4 articles were selected concerning patients treated with placebo or Denosumab in breast and prostate cancer without bone metastases. Although no significant difference was found in AAE (RR 1.01, 95 % CI=0.99-1.03), use of Denosumab was associated with a significantly increased risk of hypocalcemia (RR 5.20, 95 % CI=1.34-20.13) and of cholecystitis (RR 3.43, 95 % CI= 1.01-11.69).

Conclusion: In post-menopausal OP, Denosumab had a relatively good safety profile although significantly more cellulitis occurred when compared with placebo. For patient with cancer, Denosumab was associated with more hypocalcemia and cholecystitis than placebo; that could be explained by a relative immunosuppression and a higher dose of Denosumab used in these patients. Patients with bone metastases treated with Denosumab tended to have a higher risk of ONJ although not significant.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Previous U.S. and Canadian studies [1-3] have suggested that no significant associations exist between use of biologic disease-modifying anti-rheumatic drugs (DMARDs) and risk of non-vertebral fractures in patients with rheumatoid arthritis (RA), although previous small studies reported that biologic DMARDs preserve bone mineral density. Our objective was to determine the association between biologic DMARD use and the risk of non-vertebral osteoporotic fractures in Japanese patients with RA.

Methods:

The Institute of Rheumatology Rheumatoid Arthritis (IORRA) study, which began in 2000, was a prospective cohort study of Japanese patients with RA conducted at the Institute of Rheumatology, Tokyo Women's Medical University (Tokyo, Japan). More than 116 publications have described various characteristics including fracture rate [4], fracture site, and

risk factors for fractures [5] in Japanese patients with RA using this cohort. A nested case-control study was conducted using the IORRA cohort. RA subjects were followed from cohort entry until the earliest non-vertebral osteoporotic fracture at elbow, forearm, hip, humerus, pelvis, shoulder, and wrist. Controls were matched to cases (4:1 ratio) by age, sex, and date of cohort entry. Biologic DMARD exposure was defined as being on treatment for ≥ 180 days pre-fracture (index). Conditional logistic regression was used to assess the association between biologic DMARD use and the risk of non-vertebral osteoporotic fractures.

Results:

Over the study period, 565 cases were identified (2,822 controls). The most common fracture sites were hip (25.3%), wrist (21.1%), and shoulder (15.2%). In total, 230 subjects (51 cases and 179 controls) were exposed to biologic DMARDs. The median duration of exposure was 2.5 (interquartile range [IQR], 1.0-4.0) and 2.5 (IQR, 1.0-4.5) years in cases and controls, respectively. We were unable to demonstrate an association between biologic DMARD use and fracture risk (hazard ratio [HR] 1.11; 95% confidence interval [CI], 0.75-1.65) (Table). Baseline Japanese health assessment questionnaire disability index (JHAQ-DI), daily prednisone (PSL) dose, and bisphosphonate use were significantly ($P < 0.001$) associated with fracture risk.

Conclusion: Despite the positive impact of biologic DMARDs on bone remodeling observed in small studies, we were unable to demonstrate a reduction in the risk of non-vertebral osteoporotic fractures in Japanese patients with RA as reported in U.S. and Canadian patients with RA.

Table. Hazard ratios (95% confidence interval) of non-vertebral osteoporotic fractures in Japanese patients with RA: Multivariate analyses.

Factor	HR (95% CI)	*P*
RA disease duration	1.00 (0.99-1.01)	0.49
Body mass index	1.02 (0.99-1.05)	0.17
JHAQ-DI	1.59 (1.39-1.81)	< 0.001
NSAIDs use	1.06 (0.86-1.31)	0.56
Daily PSL dose, mg/day	1.06 (1.03-1.10)	< 0.001
Bisphosphonate use	1.51 (1.21-1.88)	< 0.001
Active vitamin D3 use	1.20 (0.92-1.58)	0.18
Proton pomp inhibitor use	0.76 (0.57-1.01)	0.059
Biologic DMARD use	1.11 (0.75-1.65)	0.59

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis-related fractures contribute to increased morbidity and mortality in those affected and substantial economic burden to society. Effective screening for osteoporosis with fracture risk assessment tools (FRATs) is crucial to allow for needed preventive therapies. Electronic medical records (EMRs) present an important opportunity to identify patients at high risk for osteoporosis-related fractures. We compared the performance of four FRATs in identifying patients with osteoporosis by bone mineral density (BMD) T-score: The Veterans Affairs Fracture Absolute Risk Assessment Tool (VA-FARA), The World Health Organization's Fracture Risk Assessment Tool (FRAX) based on patient-reported risk factors, the electronic FRAX (e-FRAX) which obtains inputs from the EMR, and the Osteoporosis Self-Assessment Screening Tool (OST). VA-FARA, FRAX, and e-FRAX are designed to identify fracture risk, which correlates with osteoporosis. OST is designed to identify osteoporosis.

Methods: We performed a cross-sectional analysis of all patients enrolled in the VA Salt Lake City Bone Health Team (BHT) from February 1, 2012 through February 1, 2013 who had a DXA. Patients were eligible for BHT intervention if they were males age 70+ or females age 65+. BMD scores were obtained by chart abstraction for each patient. Osteoporosis risk factors were obtained from a screening questionnaire which patients completed prior to DXA scan for calculation of FRAX. For VA-FARA and eFRAX risk factors were derived from the EMR. Clinical risk scores were then calculated and compared against the gold standard of DXA-based osteoporosis. Receiver operator characteristic (ROC) curves were plotted for each test and areas under the curve (AUC) were compared.

Results: A cohort of 473 patients met eligibility criteria (mean age 80.3 years, 98% male). Of these, 118 patients (25%) had osteoporosis as defined by DXA score < -2.5. There was no statistically significant difference between FRATs in identifying DXA-based osteoporosis. ROC curves are shown in figure 1. ROC statistics are shown in Table 1.

Conclusion: Our study suggests that FRATs perform similarly in identifying osteoporosis defined by BMD T-score among elderly Veterans. Electronic osteoporosis screening methods have a significant ease-of-use advantage by passively collecting risk factor data from the EMR. If these tools perform similarly for fracture outcomes as well, they could replace manual FRAX and thus improve efficiency in identifying individuals who should be sent for DXA scan to screen for osteoporosis.

Figure 1: ROC curves for FRAX, VAFARA, and OST to predict osteoporosis diagnosis by DXA score.

		95% CI	
	ROC statistic	LL	UL
FRAX w/o DXA	0.73	0.68	0.78
VAFARA	0.65	0.60	0.71
OST	0.71	0.66	0.77
eFRAX	0.66	0.60	0.72

Session Date: Sunday, November 13, 2016
Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Bariatric surgery is the most effective treatment for severe obesity.[1,2] Increased bone resorption has been demonstrated after bariatric surgery.[3] However, there have been limited and conflicting reports as to the prevalence of osteoporosis and occurrence of fractures after surgery.[3,4] Existing clinical practice guidelines for the perioperative nutritional, metabolic and nonsurgical support of the bariatric surgery patient recommend checking pre- and post-operative vitamin D and post-operative PTH among other tests. Furthermore, bone density measurements is recommended at 2 years post-surgery. [5] This study aimed to describe the incidence of significant bone loss and fractures in the post-bariatric surgery population in an urban medical center. In addition, it also aimed to assess whether our physicians were following current practice guidelines for the monitoring of bone health in bariatric patients.

Methods: This retrospective observational study included chart review (SD, LM, AI) from electronic medical records. Patients who had undergone bariatric surgery at MetroHealth Medical Center since January 1, 1999 to December 31, 2015 were identified by ICD-9 code gastric bypass 43664 and 43665, sleeve gastrectomy 43775 and gastric banding 43770, and were included in the study. Data were collected using Research Electronic Data Capture (REDCap). The following data were reviewed: demographics; date and type of bariatric procedure; pre- and post-surgery vitamin D, parathyroid hormone (PTH), C-terminal telopeptide (CTX), N-terminal telopeptide (NTX) and bone alkaline phosphatase; bone density survey [Dual-energy X-ray absorptiometry (DXA)] dates & results; and fractures if any, including type (fragility or traumatic) and location. Descriptive analyses were performed and included measures of central tendency (mean and median) and variability (standard deviation, minimum and maximum). Wilcoxon signed rank test was used to assess statistical significance between certain distributions such as race and body mass index (BMI) or vitamin D levels.

Results: Five hundred twenty-three patients were included in the study. There were 437 females and 86 males, with a mean age of 45.39; 48.76% were identified as White and 39.77% were identified as African-American (Table 1). The most common surgical procedure was gastric bypass 80.31%, followed by sleeve gastrectomy 16.63%, and gastric banding 3.06%. Average days of patient follow-up after bariatric surgery were 1162 days. Pre-surgical mean BMI was 48.98 kg/m^2, with African-Americans having a significantly greater BMI than Whites and Hispanics ($p = 0.0009$). Post-surgical weight loss median percent difference was 22.60% loss 6 months after surgery, 29.96% 12 months after surgery, and 26.12% at 3 or more years after surgery. Vitamin D was checked in 83.4% of patients before surgery, but was only checked in 41.87% of patients within 1 year after surgery. Vitamin D levels were within normal range (30.0 - 100.0 ng/mL) up to 1 year after surgery for patients who have had their levels checked. There was no significant difference in post-surgical vitamin D levels among races ($p = 0.1770$). PTH was checked in only 6.70% of patients 6 months after surgery, and in only 5.16% at 1 year post-surgery. CTX, NTX and bone alkaline phosphatase were rarely measured. Only 19 patients (3.63%) had DXA prior to surgery. Eleven patients (2.10%) had DXA within 2 years after surgery, and 16 patients (3.06%) had DXA more than 2 years after surgery. Four of the 19 patients who had DXA pre-surgery had repeat scans post-surgery (1 within 2 years, and 3 after 2 years), all showed significant bone mineral density (BMD) decrease (Table 2). Only 10 fractures were observed in the study; 3 were fragility and 7 were traumatic. Mean time to fracture for those who had a fragility fracture was 4.93 years. The location of the 3 fragility fractures were the wrist (n=1) and fibula (n=2). All of the 3 patients underwent gastric bypass procedure.

Conclusion: There is considerable discrepancy between current physician practice at our urban medical center and recommended clinical practice guidelines for bone health monitoring in the bariatric population. Vitamin D, PTH and DXA were infrequently checked in our bariatric surgery patients. In the few patients who had pre- and post-operative bone density measurements, significant bone loss was observed. Despite this large survey of bariatric patients, there is a low incidence of fractures post-bariatric surgery over a follow up time of 3 years. **Demographics (n=523)** Age (Mean): 45.39 N Observed Percent Sex Female Male 437 86 83.56 16.44 Race White Black Hispanic Unavailable/ Declined 255 208 31 29 48.76 39.77 5.93 5.54 Table 1. Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased fracture risk, however, this is confounded by a coexisting use of steroids. This study aims to quantify the association between fragility fracture risk and traditional risk factors, including bone mineral density (BMD), in an RA population that have never used steroids; further, we aim to differentiate the associations that trabecular (lumbar spine) and cortical bone (femoral neck) have with fracture risk.

Methods: Data was collated from all patients referred for a DXA scan at a North West of England hospital between 2004 and 2015. Patient's baseline characteristics and BMD were recorded and body mass index (BMI) measured. Only patients with RA were included and those who had previous used steroids were excluded. The population was divided by previous fragility fracture status. Baseline variables were compared using the Student T-test (continuous variables) and chi-squared test (categorical variables). Patients details recorded at time of scan included age, sex, BMI, and the presence of risk factors including smoking, alcohol, and family history of osteoporosis. The predictors of fracture were modelled using traditional risk factors including lumbar spine and femoral neck BMD. This was quantified using logistic regression analysis, adjusted for age, gender and BMI.

Results: 669 patients, 85% female and of median age 65 years (IQR 57.9, 71.9) were included in the analysis. 189 (28%) of patients had previously sustained a fragility fracture. Traditional risk factors were not associated with previous fragility fracture sustainment, as shown in table 1. However, the number of risk factors incrementally increased risk of fracture (OR 7.21, 95% CI 5.22, 9.94). Higher BMD of both the lumbar spine and femoral neck was associated with reduced fragility fracture sustainment, as shown in table 2.

Table 1: Risk of Fracture in Patients with Traditional Risk Factors	
Traditional Risk Factors	**Risk of Fracture** **OR, 95% upper and lower CI**
Smoker	1.21 (0.86, 1.71)
Alcohol	1.72 (0.83,3.58)
Sex	1.36 (0.82, 2.24)
Family History	1.59 (0.97, 2.59)
Secondary Osteoporosis	1.18 (0.73, 1.91)
BMI	0.97 (0.94, 1.00)
Age At Scan	1.02 (1.00, 1.04)
Cumulative Number of Risk Factors	7.21 (5.22, 9.94)

Table 2: BMD in the Non-Fracture vs. Fracture Cohorts		
	BMD in the Non-fracture vs Fracture Cohorts, Adjusted for Age, Gender and BMI **(OR, 95% upper and lower CI)**	**BMD in the Non-fracture vs Fracture Cohorts, Not Adjusted for Age, Gender and BMI** **(OR, 95% upper and lower CI)**
L1-L4 BMD	1.16 (1.06, 1.47)	1.14 (1.05, 1.36)
Left Femoral Neck BMD	1.08 (1.02, 1.36)	1.07 (1.02, 1.26)
Right Femoral Neck BMD	1.04 (1.01, 1.19)	1.04 (1.01, 1.18)

Conclusion: This study of a large population of RA patients without steroid exposure revealed that low lumbar spine and femoral neck BMD was associated with fragility fracture sustainment, whereas individual traditional risk factors, were not associated with fragility fracture sustainment; rather, only the number of traditional risk factors was associated. Therefore, it may be that BMD is the only important predictor of future fragility fracture risk in RA patients without steroid exposure. Because lumbar spine BMD is not included within the FRAX tool, we would advocate its use when estimating risk.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is a heterogeneous group of chronic inflammatory arthritides. JIA is the most common cause of musculoskeletal disability in children, and greater than 1/3 of children with JIA have persistent disease into adulthood. JIA is associated with decreased bone mineral density, growth abnormalities and erosive joint damage. We aimed to determine the prevalence of clinical osteoporosis and related outcome measures in adults with a history of JIA at Penn State Hershey Medical Center.

Methods: We performed a retrospective analysis of 67 adult patients with a history of JIA, age of onset ≤ 16 years, treated at Penn State Hershey from January 1st 2013-June 1st, 2015. After medical record extraction with review by two physicians, covariates focusing on JIA and osteoporosis risk factors were recorded in a REDCap database. Clinical osteoporosis was defined as a clinical diagnosis of osteoporosis by the physician and/or fragility fracture. Standard descriptive statistics were used to calculate means, standard deviations and frequencies. Covariates were compared between subjects with and without clinical osteoporosis using nonparametric tests. Statistical significance was determined by P values of <= 0.05.

Results: Patients had a mean age of 26 years, disease duration of 19 (+/- 9.5) years and were 85% female with 67.2% having polyarticular disease. Twelve percent (8/67) had clinical osteoporosis. Clinical osteoporosis was associated with longstanding disease features including disease duration and current age ($p=0.05$), increased disability scores on the health assessment questionnaire ($p=0.035$), history of orthopedic and joint replacement surgery ($p < 0.0001$ for both), increased frequency of current glucocorticoid use ($p=0.0052$), erosive joint disease ($p=0.01$) and there was a trend for association with ETOH use ($p=0.07$). More clinical osteoporosis subjects were using calcium and vitamin D ($p=0.0052$), had DEXA scans ordered ($p < 0.0001$) and vitamin D levels within the past year. No significant difference was observed for JIA classification subtype, gender, BMI, tobacco use, current or history of methotrexate or Tumor Necrosis Factor α-inhibitor use.

Conclusion: Adult patients with a history of JIA have a high prevalence of clinical osteoporosis, which is associated with both long standing JIA and glucocorticoid use. Adult Rheumatology providers should have increased awareness of poor osteoporotic outcomes in this unique patient population. Table: **Univariate Analysis of Osteoporotic vs Non-Osteoporotic subjects with a History of JIA**

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

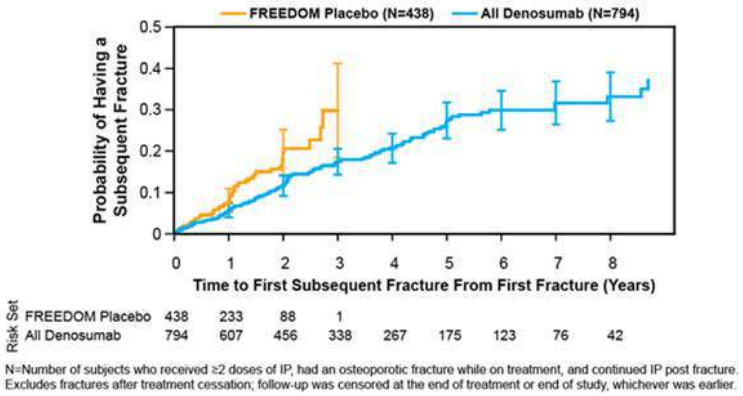
Background/Purpose: Osteoporosis is a common, progressive condition leading to increased bone fragility and susceptibility to fracture. Although osteoporosis therapy decreases fracture risk, fractures while on any current treatment can occur and do not necessarily represent treatment failure. It is therefore of interest to assess whether patients who fracture on denosumab (FREEDOM and FREEDOM Extension) experience a lower risk of subsequent fracture continuing on therapy than those on placebo who have fractured.

Methods: During FREEDOM, postmenopausal women with osteoporosis were randomized to placebo or denosumab for 3 years. During the 7-year Extension, all participants were allocated to receive denosumab. In this analysis, we report subsequent osteoporotic fractures (new vertebral or nonvertebral) in subjects who received ≥2 doses of denosumab during FREEDOM or the Extension, had an osteoporotic fracture while on treatment, and continued treatment post-fracture, compared with subsequent fractures in FREEDOM placebo subjects. These subsequent fractures were analyzed as recurrent events using the stratified Cox model with the robust variance estimation adjusting for prior fracture.

Results: During FREEDOM, 438 placebo and 272 denosumab subjects had an osteoporotic fracture (mean age at first on-study fracture: 74.1 and 74.5 years, respectively). Of these, there were 54 (12.3%) and 24 (8.8%) subjects who had ≥1 subsequent fractures in the placebo and denosumab groups, respectively. Adjusted subject incidence per 100 patient-years was lower for denosumab (6.7) vs placebo (10.1). Combining all subjects on denosumab from FREEDOM and the Extension for up to 10 years, 794 (13.7%) subjects had an osteoporotic fracture while on denosumab (mean age at first on-study fracture: 76.5 years). Of these, one or more subsequent fractures occurred in 144 (18.1%) subjects, with an adjusted subject incidence of 5.8 per 100 patient-years, similar to FREEDOM denosumab (6.7 per 100 patient-years). Among subjects with ≥1 subsequent fracture, 90% had only 1, and spine fracture was most frequent. The risk of having subsequent on-study osteoporotic fractures was lower in all denosumab subjects compared with placebo subjects (HR 0.60 [95% CI: 0.43–0.81]; p=0.0012; Figure).

Conclusion: The risk of a second fracture with continued denosumab treatment remains lower than placebo, thus suggesting that a fracture sustained while on denosumab is not necessarily indicative of a treatment failure, and continuation of treatment should be considered.

Figure: Time to First Subsequent Osteoporotic Fracture Among Placebo and All Denosumab Subjects Who Had an Osteoporotic Fracture in FREEDOM and the FREEDOM Extension



N=Number of subjects who received ≥2 doses of IP, had an osteoporotic fracture while on treatment, and continued IP post fracture.
Excludes fractures after treatment cessation; follow-up was censored at the end of treatment or end of study, whichever was earlier.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Denosumab is approved for treating postmenopausal women with osteoporosis at high risk for fracture. The placebo-controlled FREEDOM trial and its active-treatment Extension investigated the efficacy and safety of denosumab for up to 10 years. The lack of a long-term control group in the Extension, however, limits the ability to evaluate long-term efficacy. We used two approaches to put denosumab's 10-year anti-fracture efficacy into perspective. First, we compared the 10 year observed cumulative incidence of major osteoporotic (MOP; hip, clinical spine, forearm, or humerus) and hip fracture in subjects who completed the Extension with the 10-year fracture probability predicted at baseline by FRAX (a computer-based algorithm assessing fracture probability from clinical risk factors).[1] The 10-year MOP fracture rate was also compared with that estimated for a hypothetical cohort of 10 year placebo controls (virtual twins).

Methods: Subjects in this analysis received 10 years of denosumab (3 years FREEDOM; 7 years Extension; 60 mg Q6M), completed the 10-year visit, and missed ≤1 dose in FREEDOM and ≤1 dose in the Extension (n=1,278). Kaplan-Meier estimates of cumulative 10-year incidence of MOP and hip fracture were determined. Ten-year probability of fracture predicted by FRAX (calculated with femoral neck BMD) at FREEDOM baseline was also estimated. Rate of MOP fracture in a hypothetical cohort of 10-year placebo controls (virtual twins) was estimated using a previously described simulation method and baseline characteristics identical to the 10-year denosumab completer group.[2,3]

Results: The observed cumulative 10-year fracture incidence (95% CI) was lower than the 10 year mean (SD) fracture probability predicted by FRAX for both MOP (10.75% [9.05%–12.46%] vs 16.42% [9.06%]; Figure) and hip (1.17% [0.58%–1.76%] vs 6.14% [6.52%]) fractures. The observed cumulative 10-year MOP fracture incidence was also significantly lower than the estimated virtual twins fracture rate (10.75% [9.05%–12.46%] vs 23.13% [17.76%–28.87%]; RR=0.49 [0.36–0.64]).

Conclusion: Fracture incidence with 10 years of denosumab treatment in postmenopausal women with osteoporosis was lower than the 10-year probability predicted by FRAX for both MOP and hip fractures. It was also lower than the fracture rate estimated in a hypothetical cohort of 10-year placebo controls for MOP fracture. These data support the long-term efficacy of denosumab in reducing MOP and hip fractures. **References:** [1]https://www.shef.ac.uk/FRAX/index.aspx; [2]Vittinghoff *Stat Med* 2010; [3]Papapoulos *Osteoporos Int* 2015

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Abaloparatide is a novel 34 amino acid peptide created to be a potent and selective activator of the PTH 1 receptor signaling pathway and is under investigation for use in the treatment of postmenopausal women with osteoporosis.

Methods: ACTIVE (Abaloparatide Comparator Trial In Vertebral Endpoints) was a trial of 2463 postmenopausal women

with osteoporosis (aged 49-86 years; mean=69 years old) who were randomized to double-blinded abaloparatide-SC 80 µg or placebo, or open-label teriparatide 20 µg SC for 18 months. Prespecified subgroup analyses were performed to evaluate if fracture risk reduction was consistent across different levels of baseline risk. Risk factor subgroups were defined categorically by BMD T-score of the lumbar spine, total hip and femoral neck (≤-2.5 vs >-2.5 and ≤-3.0 vs >-3.0), fracture history (yes vs no), prevalent vertebral fracture (yes vs no) and age (<65 vs 65 to <75 vs ≥75 years old) at baseline.

Results: Abaloparatide-SC increased BMD from baseline at the lumbar spine 9.2%, total hip 3.4% and femoral neck 2.9% (all p<0.0001 vs placebo). Abaloparatide-SC reduced morphometric vertebral fractures 86% (p<0.0001), nonvertebral fractures 43% (p=0.049) and major osteoporotic fractures 70% (p=0.0004) compared to placebo and reduced major osteoporotic fractures compared to teriparatide by 55% (p=0.031). Results of forest plots show consistent fracture reduction in the abaloparatide arm for new morphometric vertebral or nonvertebral fractures without any interactions caused by baseline risk factors. In addition, there were no meaningful interactions among any of the baseline risk factors and magnitude of BMD accrual by abaloparatide-SC.

Conclusion: These data suggest that abaloparatide-SC may have potential to provide protection against fractures consistently across a wide variety of ages and baseline risks, including those with and without prior fractures, and will likely be useful for a broad group of postmenopausal women with osteoporosis.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Bone mineral density(BMD) by dual X-ray absorptiometry(DXA) is currently standard clinical tool for predicting osteoporotic fracture. However, DXA doesn't allow studying abnormalities that predict different fracture risks independent of areal BMD, such as trabecular and cortical bone compartments and bone microarchitecture. High-resolution peripheral quantitative computed tomography(HR-pQCT) is non-invasive method to assess cortical and trabecular microarchitecture and bone mechanical competence in clinical studies on postmenopausal women with low

bone mass. However, there are no studies on HR-pQCT in general elderly population. Thus, we sought to verify the association between fragility fractures and bone microarchitecture and strength using HR-pQCT and markers of bone turnover in older adults.

Methods: 276 older adults were assessed by questionnaire. Lateral scans of spine obtained from Vertebral Fracture Assessment (VFA) by DXA were done to assess vertebral fractures (semiquantitative method). HR-pQCT was performed at the distal radius and tibia and following parameters were analyzed: volumetric bone mineral density(vBMD) - total(Tt), trabecular(Tb) and cortical(Ct), structural parameters - trabecular number(Tb.N), trabecular thickness(Tb.Th.), trabecular separation(Tb.Sp), cortical thickness(Ct.Th) and strength variables - Stiffness(S), Estimated ultimate failure load(Fult) and Apparent modulus(Epp). Serum levels of aminoterminal propeptide of procollagen type I(PINP) and C-terminal telopeptide of type I collagen (CTX) were evaluated.

Results: The mean age was 79.4± 4.1 years. According to DXA, osteopenia and osteoporosis were observed in 44.2% and 38.9%, respectively. At least one vertebral fracture was observed in 56.2% of subjects. At distal tibia, individuals with vertebral fractures had lower vBMD(Tt.vBMD, $p=0.001$; Tb.vBMD, $p<0.001$), lower Tb.N, $p<0.001$, higher Tb.Sp, $p<0.001$ and lower strength parameters(S, $p=0.002$; F.ult, $p=0.002$; E.app, $p=0.034$). At distal radius, subjects with vertebral fractures had lower volumetric density(Tt.BMD,$p<0.001$; Tb.BMD,$p<0.001$; Ct.BMD,$p=0.021$), lower structural parameters(Tb.N,$p<0.001$; Tb.Th, $p=0.030$; Ct.Th,$p=0.013$), higher Tb.Sp,$p<0.001$; and lower bone strength(S, F.ult, E.app). Bone turnover markers were significantly different between fracture and non fracture groups: CTX (0.25 ± 0.16 vs. 0.30 ± 0.18 ng/mL, $p=0.004$) and P1NP(38.2 ± 29.2 vs. 40.6 ± 19.5 ng/mL, $p=0.035$). After adjusting for potential confounding variables, logistic regression model revealed that Tb.vBMD at distal tibia (OR 0.98, 95%CI 0.98–0.99, $p<0.001$)) and CTX (OR 0.821, 95%CI 0.697–0.966, $p=0.017$) were independently associated with vertebral fractures

Conclusion: HR-pQCT detected marked differences on bone microstructure between older adults with vertebral fractures and those without fractures independent of areal BMD by DXA. Lower trabecular volumetric BMD was independently associated with vertebral fracture in community-dwelling elderly. Moreover, lower CTX was also linked to vertebral fracture and could indicate low bone turnover as risk factor for fractures in advanced-aged population.

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

We recently showed that patients with primary Sjögren Syndrome (pSS) have significantly higher bone mineral density (BMD) in the lumbar spine and femoral neck compared with healthy controls. The majority of those patients (69%) were using hydroxychloroquine (HCQ), which may have favourable effects on BMD. The aims of this study are to evaluate the effect of HCQ on osteoclast function and to identify a potential mechanism of action.

Methods:

Osteoclasts were cultured from PBMC-sorted monocytes for 14 days. All cultures were treated with different HCQ doses (0, 1 and 5 µg/ml). At multiple time-points, staining with an acidification marker (acridine orange) was performed as measure for intracellular pH. The ratio of FITC (neutral pH) vs. TRITC (acidic pH) fluorescence intensities were analyzed. Additionally, a fluorescent cholesterol uptake assay was performed and fluorescence intensities were analyzed as measure for cholesterol uptake.

Results :

The difference in surface resorption by osteoclasts was significant between HCQ dose 1 and 5 µg/ml vs. control (4.3 ± 1.0% for HCQ dose 1 µg/ml and 1.6 ± 0.8% for HCQ dose 5 µg/ml vs. 16.2 ± 3.2% for the controls, P = 0.037 and P = 0.011 respectively). We also found that the FITC:TRITC ratio of the HCQ 5 µg/ml group was significantly reduced (lower intracellular pH) at day 12 and day 14 following continuous HCQ treatment compared to the controls (day 12: 1.06 ± 0.05 for the control vs. 0.87 ± 0.03 for HCQ 5 µg/ml, P = 0.034 and day 14: 0.92 ± 0.03 for the controls vs. 0.59 ± 0.03 for HCQ 5 µg/ml, P = 0.037). Furthermore, cholesterol uptake was significantly increased in HCQ 5 µg/ml compared to control (day 7: 31673 ± 1922 RU for HCQ 5 µg/ml vs. 14583 ± 3217 RU for the control, P = 0.0015 and day 11: 18297 ± 229.7 RU for HCQ 5 µg/ml vs. 4902 ± 259.6 RU for the controls, P = 0.0003). In addition, the LDL receptor gene expression was significantly increased in the HCQ 5 µg/ml cells compared to the controls (P = 0.03).

Conclusion :

In agreement with our clinical data, we demonstrate that HCQ suppresses bone resorption *in vitro*. We hypothesize that women (with pSS) benefit from HCQ since their BMD decreases dramatically in the first few years following menopause due to enhanced osteoclast activity.

We also showed that HCQ decreases the intracellular pH in mature osteoclasts and stimulates cholesterol uptake. We postulate that HCQ induces osteoclastic lysosomal membrane permeabilization (LMP) leading to apoptosis and associated decreased resorption. However, the osteoclast tries to decrease LMP by increasing cholesterol uptake and LDL expression **(Figure)**.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous evidence indicates an association between vitamin D deficiency and autoimmune diseases. The aim of this study was to evaluate serum 25 hydroxyvitamin D (25OHD) and bone mineral density (BMD) in patients with rheumatologic diseases (RD) in Argentinean patients. In addition, 25OHD levels were analyzed in function of disease activity.

Methods: This retrospective study evaluated 106 patients with RD (64 with rheumatoid arthritis (RA), 12 spondyloarthropathies (SA), 13 systemic lupus erythematosus (SLE) and 17 other collagenopathies (OC) [vasculitis, scleroderma, indiferenciateted disease connective tissue, superposition syndrome of connective tissue disease]) and was compared with a control group (CG, n=102) matched by age (CG= 55.82±1.48 years; RD= 55.28±1.30, sex and body mass index. All the patients were from Rosario (32º52´18´´S) and Buenos Aires (34º36´14´´S) cities. Exclusion criteria: supplemented with vitamin D, pregnancy, intestinal malabsorption, chronic liver or kidney disease or cancer. Date are expressed as mean±SEM. Differences between groups were analyzed using the Mann–Whitney or Kruskal–Wallis test. Correlations were performed with Spearman's correlation test. The difference was considered significant if $p<0.05$.

Results: No differences between groups were observed in serum calcium, phosphatemia, urinary calcium, parathormone and urinary deoxipiridinoline. Significant differences were found in alkaline phosphatase (CG= 102.90±5.40 UI/l; RD= 167.2±8.59) and 25OHD (CG= 25.64±1.06 ng/ml; RD= 19.17±0.66). 25OHD significantly correlated with erythrocyte sedimentation rate (ERS) [r= -0.26] and reactive C-protein (RCP) [r = -0.27] as acute phase reactants. RD patients had significant lower 25OHD levels (RA= 19.89±0.81; SA=15.64±1.76; SLE= 19.81±2.49; and OC= 18.44±1.48) than CG (25.64±1.06 ng/ml). No correlation between 25OHD levels and DAS-28 and HAQ-DI scores were found. However, lower values of 25OHD were found at higher scores: HAQ-20 ≤2= 22.41±1.45 ng/ml, HAQ-20 >2= 18.80±0.95, p=0.047; DAS28 ≤3.2= 21.43±1.62 ng/ml, DAS28 >3.2= 19.78±0.95l, p=0.157. Activity scores in others RD couldn´t be analyzed because small number of patients. No significant differences were found in lumbar spine BMD between premenopausal or postmenopausal (postM) patients, but femoral neck BMD was significantly lower in postM RD patients (0.775±0.026 g/cm^2; T-score −1.94±0.20) than in postM CG patients (0.802±0.020; T-score −1.24±0.16).

Conclusion: In both groups 25OHD levels were under 30 ng/ml. However, 25OHD levels were lower in RD patients (deficiency) than CG (insufficiency). Lower values of 25OHD were found at higher ERS and RCP in all RD and at higher activity disease scores in RA.

Presence of Vertebral Fractures and Disc Disease in Post Menopausal Females with Height Loss As a Possible Screening Method for Osteoporosis

Nicola Berman[1], Gregory Chang[2] and Stephen Honig[1], [1]Rheumatology, New York University Department of Rheumatology, New York, NY, [2]Radiology, New York University Department of Radiology, New York, NY
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The presence of non-traumatic vertebral fracture can identify a patient who has clinical osteoporosis. However, approximately 75% of vertebral fractures are asymptomatic and as many as 45% of vertebral fractures in North America go unrecognized. As a result, a significant number of cases of osteoporosis are missed and left untreated, leaving patients vulnerable to future fractures and morbidity and contributing to the economic burden of osteoporosis related fractures in the United States. We investigated whether women with 2 or more inches of height loss have a high incidence of fractures, whether the degree of height loss correlates with presence of fractures, and how these findings correlate with bone density, in order to test whether height loss could be a potential screening tool for osteoporosis. Additionally, we assessed how many of these patients with 2 or more inches of height loss had been treated for osteoporosis in the past.

Methods: From among all postmenopausal female patients seen at our academic Osteoporosis Center, we prospectively enrolled a cohort of 100 subjects self-reporting two or more inches of height loss from maximum height. Enrollment occurred over a two-year period. Patients with a history of spinal surgery or significant scoliosis (>10% spinal curvature) were excluded. At intake, all patients had radiographs of the lumbar and thoracic spine (AP and lateral). A vertebral fracture was defined as >20% vertebral height loss based on the guidelines from the Vertebral Fracture Initiative by the International Osteoporosis Foundation. Intervertebral disc disease was classified based on the Genant modification of the Sharp method.

Results: Of 100 patients with height loss, 76 had a fracture of the thoracic or lumbar spine, or both. 58 women had fractures of their thoracic spine and 50 of their lumbar spine. Among the 76 women with a diagnosis of fracture, 21 (28%) had never been treated for osteoporosis. Among the 24 patients without fractures, the average T-Score was -2.0 of the spine. Among all the patients, 96 had intervertebral disc disease (94 had thoracic and 75 had lumbar disc disease). When evaluating the degree of height loss in all of the patients, there was no significant difference between the patients who had sustained a fracture and those who had not.

Conclusion: In this study, 2 or more inches of height loss was explained by vertebral fracture and presence of disc disease, or both, with the majority of subjects demonstrating fractures pathognomonic for osteoporosis. Individuals with 2 or more inches of height loss and no fractures had T scores mainly in the osteopenic-osteoporotic range. Our data therefore suggest that any patient with 2 or more inches of height loss should be evaluated for both vertebral fractures and osteoporosis. Significantly, 28% of women with radiographic findings of compression fracture had not previously been treated for osteoporosis, underlining the need for better screening and treatment.

Session Date: Sunday, November 13, 2016
Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Low bone mass at metacarpal (MC) diaphysis measured by radiogrammetry (DXR) has been described as a poor prognostic factor in rheumatoid arthritis (RA). However, this technique is not available in our environment. Our group has previously described the measurement of bone mineral density (BMD) at metacarpophalangeal joints (MCP) by dual X-ray absorptiometry (DXA). This measurement showed an acceptable correlation with the DXR at MC bones. However, DXR at MC bones mainly assesses cortical bone, whereas DXA at MCP mainly analyzes trabecular bone. Therefore, we have developed a procedure to evaluate MC's (2nd to 4th) bone mass of the nondominant hand through DXA. The aim of our study was to evaluate the correlation between BMD at 2nd to 4th MC of the nondominant hand measured by DXA with data obtained by DXR in patients with early arthritis (EA).

Methods: We studied 171 patients belonging to the Princesa Early Arthritis Reginster Longitudinal (PEARL) Study (84% women, 55.4 years at symptoms onset; 56.7% fulfilled RA 2010 criteria; 52% RF+ and 43.5% ACPA+). Demographic, clinical and laboratory data were collected per protocol. Hand X-rays were performed at baseline and after one year of follow-up, as well as nondominant hand BMD assessment by DXA (Hologic © QDR4500, Elite). The standard Hologic© software allows to design regions of interest (ROI) tailored to the researcher needs. In order to develop ROIs in DXA similar to that in DXR, the ROI generator was placed on every MC mid third of the diaphysis (aprox 17x17 mm). The ROI was rotated to be aligned to the MC longitudinal axis, avoiding overlap between adjacent ROIs. The BMD by DXA was the average of 3 successive measurements. The BMD by DXR was measured with standardized software by Sectra (Linköping, Sweden) on hand digital X-ray (GE © DX Definium 8000). Statistical analysis was performed using Stata 12 for Windows, including linear correlations according to the Spearman test between the BMD values of MC by DXA and DXR and BMD by DXA at global hand and MCP joints. In addition, a multivariate analysis was performed to determine which variables accounted for the differences between MC bone mass measured by DXR and DXA.

Results: 248 BMD measurements (154 at baseline and 94 at second visit) of the 3 regions described whose values are shown in Table 1.

	MC-DXR	MC DXA	Total Hand DXA	MCP DXA
BMD (g/cm2; mean ± SD)	0.529±0.074	0.427±0.060	0.327±0.041	0.265±0.040
Difference with MC-DXR	-	0.104±0.074*	0.206±0.060*	0.268±0.053*
Correlation with MC-DXR	-	0.865*	0.824*	0.717*

As shown in table 1, MC bone mass measured by DXA shows the lowest absolute difference and the best correlation with MC bone mass by DXR. Female gender (beta coefficient = 0.013; p = 0.039), patients older than 65 years (beta coefficient = 0.014; p = 0.019) and patients with higher body mass index (beta coefficient = 0.002 by kg/m2; p = 0.019) were significantly associated with lower differences between the values of MC by DXA and DXR.

Conclusion: There is an excellent correlation between BMD evaluated by DXA and by DXR at cortical level of the MC bones. Our findings open the possibility of exploring the value of MC-BMD assessment through DXA as a prognostic marker in patients with EA. Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a known risk factor for osteoporosis. There are many factors that contribute to this increased risk, including the use of glucocorticoids, systemic inflammation due to the disease process and relative physical inactivity. Only a few studies have assessed the risk of fractures in RA. The objective of this systematic review was to assess the risk of fractures in adults with RA compared with controls from the general population.

Methods: Two authors screened citations from the following electronic databases: MEDLINE (1946 to July 2015), EMBASE (1947 to July 2015), Cochrane Database of Systematic Reviews (2005 to July 2015) and CINAHL (1981 to July 2015). Included citations had to be written in English, only include patients greater than or equal to 18 years of age and compare fracture incidence/prevalence between RA patients and a control group. Case control, cohort and cross-sectional studies were included. Abstracts and conference proceedings were not searched. The primary outcome was fracture incidence and/or prevalence. Two authors abstracted data using a standardized data abstraction form. The quality of the studies was assessed using the Newcastle-Ottawa Scale (NOS).

Results: The searches resulted in 3451 citations, and after applying the inclusion criteria, we selected seventeen observational studies comparing fracture incidence and/or prevalence between RA and controls. Overall, the results demonstrated that the risk of fracture was elevated in RA compared to controls in 14 of the 17 studies. Thirteen studies were adjusted for glucocorticoid use and there was an increased risk of fracture with glucocorticoid use in 4/13 of these studies. Seven studies analyzed RA severity or functional impairment as a risk factor for fracture and the risk of fracture was elevated in 2/7 of these studies. Fracture ascertainment was performed by searching medical records in seven studies, analyzing spine radiographs in six studies, self-reported history in two studies and by multiple methods in two studies. Eight studies evaluated fractures at multiple sites, whereas nine studies evaluated fractures only at a single site (spine in 6 and hip in 3). Only two studies reported specific data on fragility fractures, whereas in the remaining studies, the fracture mechanisms were not defined. Assessment using the NOS revealed that the studies were of high quality. Scoring by NOS criteria revealed that 14/17 studies scored 4/4 on selection, all studies scored 2/2 on comparison and 13/17 studies scored 3/3 on outcome/exposure. Limitations of the studies included the following: studies enrolled a diverse range of patient and control group populations, and generally included all types of fractures determined by various methods and involving multiple sites. Some studies only included women while others included both genders. The studies took place in different countries. These differences between the studies made it difficult to directly compare them. Due to the marked study heterogeneity, a meta-analysis was not performed.

Conclusion: The risk of fracture in RA is elevated when compared to the general population.

Session Date: Sunday, November 13, 2016
Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To explore the relationship of anti-CCP levels with BMD or fragility fracture in patients with RA

Methods: This is a prospective cross sectional study. Consecutive RA patients who visited Rheumatology clinic at Chang Gung Memorial Hospital in Kaohsiung between 01-Sep- 2014 and 31-May-2016 were enrolled in this study. Those patients who fulfilled the classification criteria of RA (ACR 2010) and inclusion criteria were registered as participants. During the period, we checked anti-CCP, ESR, CRP, DAS28 for each participant at enrollment and collected demographics, evidence of prevalent fragility fracture (history or radiography), personal life style and behaviors, risk factors of fragility fracture in FRAX tool, and medication history. We also measured BMD when anti-CCP checked. The descriptive summary is presented in the form of mean ± standard deviation. Continuous variables were evaluated by one-way ANOVA or Kruskal-Wallis test. Chi-square test or Fisher's exact test were used for the qualitative variables. A level of statistical significance of $p < 0.05$ was used for all statistical tests performed.

Results: A total of 521 participants were enrolled during the period. Demographics are presented in Table 1. The participants were categorized into 4 groups according to quartiles of anti-CCP levels(QI -IV). There were 130, 127, 132, and 132 participants in group I to IV, respectively. There was no obvious difference between ages, gender, body mass index, disease duration (Table 1), prevalence of fragility fracture (Table 2) between groups. However, the levels of RF ($p<0.0001$), ESR ($p<0.0001$), CRP ($P= 0.009$), and DAS28 ($p<0.0001$) was significant different between the groups. The BMD (g/cm^2) of lumbar spine (total), from QI to IV, of each group was 0.902±0.177, 0.836± 0.155, 0.859±0.167, and 0.866±0.190 ($p=0.0244$), respectively. While, the BMD (g/cm^2) of femoral neck was 0.661±0.129, 0.599±0.107, 0.623±0.126, 0.620±0.121, respectively ($p=0.0011$) (Table 2).

Conclusion: The levels of anti-CCP in RA patients are related to levels of RF and disease activity, in terms of ESR, CRP, and DAS28. The BMD, either lumbar spine or femoral neck, is significantly different between anti-CCP levels, while, there is no obvious difference in prevalence of fragility fracture between the groups. Via this investigation, it suggests that increased risk of fragility fracture in RA patients may not be related to the disease activity or anti-CCP levels. Table 1 Demographics of participants

Groups	I	II	III	IV	p

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis in kidney transplant is complex and multifactorial. We studied the evolution of Trabecular Bone Score (TBS) and bone mineral density (BMD) in kidney transplant recipients as well as concurrent factors to their variations.

Methods: Transplant patients at Rouen University Hospital between August 2008 and January 2013 were selected. They must have received two bone densitometry exams measured by absportiometry dual-energy X-rays (DEXA). The TBS was calculated retrospectively.

Results: 66 patients were included. The change in the TBS was not significant between the two visits. The BMD increased significantly at three sites, lumbar spine + 3.3%, + 3.7% total hip, femoral neck + 2.2% ($p < 0.01$). The duration of corticosteroid therapy was negatively correlated with the TBS ($r = 0.41$) and BMD at the lumbar spine ($r = -0.52$) ($p < 0.0001$). Hyperparathyroidism or corticosteroid or chemotherapy induced diabetes was associated with poorest evolution of TBS (-0.046 95% CI [-0074, 0016] versus 0.031 95% CI [-0002, 0059], $p = 0.02$ and -0.048 95% CI [-0075, 0017] versus 0.038 95% CI [-0016, 0065], $p < 0.01$) while the results on BMD were not significant. Regarding bisphosphonates, there was a positive correlation with BMD at the total hip ($r = 0.33$, $p = 0.02$).

Conclusion: TBS provides additional information with BMD in the osteoporotic risk assessment in transplant recipients, particularly in relation to glucocorticoid therapy, hyperparathyroidism and diabetes.

Clinical Analysis of Tumor-Induced Osteomalacia Misdiagnosed As Spondyloarthritis: A Report of 18 Cases

Na Sui[1], Jian Zhu[2] and Fei Sun[1], [1]Chinese PLA General Hospital, Beijing, China, [2]Rheumatology, Chinese PLA General Hospital, Beijing, China

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To study and summarize the clinical features of tumor-induced osteomalacia(TIO) misdiagnosed as spondyloarthritis(SpA), aiming to explore the reasons of misdiagnosis and raise the correctness of TIO diagnosis.

Methods: A total of 18 TIO patients misdiagnosed as SpA from March 2002 to January 2016 in Department of Rheumatology of Chinese PLA General Hospital were enrolled. The clinical manifestations, laboratory examinations data, imaging features, Localization of tumors and histological characteristics were analyzed.

Results: 18 patients were included (11 males and 7 females) with a median age of 33 years (range 19-60). The mean disease duration was 3.8 years (range 0.17 to 20 years). All patients presented with persistent low back pain. The pain could not be relieved by rest or exercise, all patients had a history of taking nonsteroidal anti-inflammatory drugs and showed no obviously improvement. The inflammatory markers such as erythrocyte sedimentation rate and C-reactive

protein were usually normal. The level of serum calcium was normal or slightly lower, nevertheless, all patients had hypophosphatemia and increased level of alkaline phosphatase. Sacroiliac joint lesions were found in X-ray, CT or MRI, however the lesions in sacrum or ilium were predominant rather than in joints. Abnormal bone imaging in ribs, long bones and soft tissues in addition to joints could be detected by bone scintigraphy. And the technetium-99m octreotide scintigraphy (Figure 1a) was completed to detect the causative neoplasms, then targeted images with radiographs (Figure 1b), CT or MRI were used for further localization of the tumors. Successful localization of tumors was followed by surgical resection (13 of these 18 patients) and analysis by pathology studies. The pathology results indicated that the majority (46.2 %,6 of 13) were characterized as phosphaturic mesenchymal tumors (PMTs). After tumor resection, serum phosphorus levels normalized in all 13 surgical patients after a mean of 16 days (range 3-57 days), and Clinical symptoms were alleviated within 3 months (Figure 2).

Conclusion: TIO can be easily misdiagnosed as SpA because of the atypical clinical features and imaging changes of sacroiliac joint, however, the laboratory findings and response to the NSAIDs of the two conditions are different. Considering the complete surgical resection leading to normalization of parameters in laboratory tests and relief of symptoms of TIO patients, prompt diagnosis and surgical treatment is extremely essential. Comprehensive laboratory examinations and the technetium-99m octreotide scintigraphy can contribute to the timely diagnosis of TIO.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are diagnosed with osteoporosis earlier than those without, and are therefore exposed to bisphosphonates for longer. However, the increasing use of bisphosphonates has raised concerns about atypical femur fracture. While patients with RA are at risk of atypical femur fracture, the impact of RA on the occurrence of atypical femur fracture is unclear. Here, we investigate the contribution of RA and other clinical factors on the development of bisphosphonates-related atypical femur fracture.

Methods: We conducted a retrospective case-control study in patients who have taken bisphosphonates for at least 1 year in Seoul St. Mary's Hospital, between 2008 and 2015. We identified patients with atypical femur fracture by reviewing surgical and radiographic records. Atypical femur fracture was classified based on the 2013 American Society for Bone and Mineral Research task force criteria. Three age- and sex- matched controls without the history of atypical femur fracture were randomly selected to each patient with an atypical femur fracture. Cox proportional hazards models were used to analyze the independent contribution of risk factors for bisphosphonates-related atypical femur fracture occurrence.

Results: In 35,104 patients who were prescribed BPs for at least a year during 8 year period, 43 female patients (mean age, 68 years) suffered atypical femur fracture (0.12%). Patients with atypical femur fracture exposed to bisphosphonates for 7.3 years. Patients with atypical femur fracture had exposed to bisphosphonates longer and continued bisphosphonates treatment without cessation. Twenty-eight percent of patients with atypical femur fracture were comorbid with RA. Glucocorticoids and disease modifying anti-rheumatic drugs were frequently used in patients with atypical femur fracture. Multivariate Cox regression analyses estimated that the hazards ratio of atypical femur fracture increased by 9.2 for long-term glucocorticoids use at least one year, 7.2 for prolonged bisphosphonates exposure without cessation and 1.3 for every kg/m^2 of the increased body mass index (BMI).

Conclusion *:* The incidence of bisphosphonates-related atypical femur fracture is very low. Although there is an association between atypical femur fracture and long-term bisphosphonates use, clinicians should remember that bisphosphonates significantly reduce the risk of osteoporotic fracture. We suggested that long-term bisphosphonates use without cessation, prolonged glucocorticoids use and higher BMI are risk factors for atypical femur fracture. These patients should be carefully followed up with X-rays or dual-energy bone densitometry during bisphosphonates treatment.

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporotic patients with no evidence of fractures sometimes experience vague lower back pain. However, there have been few reports regarding the correlation between osteoporosis and pain-related behavior. Our previous studies have indicated that hindlimb-unloading induced bone loss and mechanical hyperalgesia in hindlimb of mice. We investigated the effects of osteoporosis treatments on bone mass and pain-related behaviors in osteoporosis model mice with hindlimb unloading.

Methods: Male ddY mice (8 weeks old) were tail-suspended for 2 weeks and assigned to 4 groups; hindlimb-loaded mice treated with vehicle (control=HL), hindlimb-unloaded mice treated with vehicle (HU), hindlimb-unloaded mice treated with ALN (HU-ALN), hindlimb-unloaded mice treated with PTH (HU-PTH) (n=8/group). After 2 weeks tail-suspension, mice were reloaded and started treatment. For 2 weeks, mice were injected subcutaneously with 40μg/kg ALN twice a week, 40μg/kg PTH five times a week, or saline as vehicle. The bilateral distal femoral metaphyses and proximal tibial metaphyses were analyzed three-dimensionally by micro-computed tomography (μCT) 2 weeks after reloading and treatment. Mechanical sensitivity was also tested using von Frey filaments 2 week after reloading. The withdrawal threshold, the 50% withdrawal threshold and the frequency of the withdrawal response to the application of von Frey filaments to the plantar surface of the hind paws was examined. Measurement of pain-related behavior with von Frey filaments was interpreted as indicative of mechanical allodynia.

Results: μCT analysis of the distal femoral metaphysis and the proximal tibial metaphysis showed that significantly decreased bone volume/tissue volume (BV/TV) was significantly decreased in HU group compared with HL group. However, ALN treatment and PTH treatment increased BV/TV compared with saline in HU mice. (Fig.1) The paw withdrawal threshold and the 50% paw withdrawal threshold were significantly lower in HU group than in HL group, whereas it was significantly higher in HU-ALN group than in HU group. Similarly, it was tend to be higher in HU-PTH group than in HU group, but not significantly. (Fig.2) The paw withdrawal frequency stimulated by von Frey filaments with strength of 0.4-1.0 g was significantly higher in HU group than in HL group. Whereas it was significantly lower in HU-ALN group and HU-PTH group than in HU group with strength of 0.4-0.6g.

Conclusion: In this study, treatment of ALN or PTH recovered bone loss and mechanical hyperalgesia in disuse osteoporotic animal models by hindlimb-unloading. The results suggest that low bone volume itself is one of the causes of osteoporotic pain.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, we showed that treatment with COBRA-light therapy including prednisone with initially 30 mg/day, was as effective as the original COBRA scheme, with initially 60 mg/day [1], in the treatment of rheumatoid arthritis (RA). Since high-dose glucocorticoids are associated with bone loss, we investigated the differences in bone mineral density (BMD) after one year of treatment in both arms. Therefore, this study aims to determine whether there is a significant difference in BMD between COBRA and COBRA-light, and to determine the difference in change in BMD between baseline and 52 weeks between these groups, at the lumbar spine (L1-L4), total hip, and femoral neck.

Methods: An open-label, randomised controlled, non-inferiority trial of patients with active, newly diagnosed RA following a treat-to-target protocol.

Results: BMD data were determined in 144 out of 164 included RA patients, all randomized to either COBRA (n=71) or COBRA-light (n=73) therapy. Both at baseline and after 52 weeks, no significant difference in BMD was found between COBRA and COBRA-light, at all sites. Changes between baseline and week 52 are shown in *Table 1*. No significant difference in change in BMD between COBRA and COBRA-light was found, at all sites. However, COBRA-light showed a significant decrease in BMD in the lumbar spine and total hip after 52 weeks, whereas the femoral neck and the COBRA group did not.

Conclusion: No difference in change in BMD between COBRA and COBRA-light was found. The overall bone loss was small, which suggests that the negative effects of (high-dose) prednisone on bone might be counteracted by the large reduction in disease activity as a result of combination therapy and tight control treatment. **References:** [1] Ter Wee MM, et al. Ann Rheum Dis 2015.

Table 1.
Changes in bone mineral density between baseline and week 52 during COBRA and COBRA-light therapy

	COBRA (n=71)			COBRA-light (n=73)		
	baseline	week 52	change	baseline	week 52	change
Lumbar spine	1.12 (0.17)	1.12 (0.17)	0.01%	1.10 (0.15)	1.09 (0.15)	-1.02%*
Total hip	0.95 (0.14)	0.95 (0.14)	0.05%	0.95 (0.12)	0.94 (0.13)	-1.16%*
Femoral neck	0.90 (0.16)	0.89 (0.17)	-0.59%	0.88 (0.12)	0.87 (0.11)	-0.98%

** Significant change between baseline and week 52 (p<0.05); Values are reported as mean (SD), unless otherwise specified.*

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The high rates of readmission among patients with osteoporotic vertebral fracture have reduced quality of life and increased mortality. This study aimed to determine predictors of readmission in such patients using magnetic resonance imaging (MRI).

Methods: This study reviewed records of osteoporosis patients with acute vertebral fractures proven by MRI between 2004 and 2007 for pre-operative MRI, subsequent readmission, and possible factors that increase readmission within two years. Clinical information like co-morbidities, previous hip fracture, and number of vertebral fractures were recorded. Primary outcome was readmission (within two years of discharge). Predictor variables were categorized and compared between readmissions and non-readmissions. Logistic regression was used for multivariate analysis.

Results: There were 106 patients with MRI-proven acute vertebral fractures who underwent vertebroplasty, including 33 with readmission within two years. There were no differences in age, BMI, sex, number of vertebral fracture, and underlying co-morbidities between readmissions and non-readmissions. However, the MRI signal intensity (SI) at the non-enhancement area parameter was different between the two groups (70.97±66.51 vs. 108.62±98.31; p=0.008). After adjusting for potential confounders, those with higher SI at the non-enhancement area had lower readmission risk (p=0.005; OR: 0.984, 95% CI: 0.973-0.995).

Conclusion: Pre-operative MRI may be predictive of readmission in patients with osteoporotic vertebral fracture. Recognizing the need to optimize primary and secondary prevention in these patients to improve quality of life is mandatory.

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: This study investigated whether bone mineral density (BMD) affects readmission risk in patients with CKD who received denosumab therapy.

Methods: The study design was a retrospective case review of CKD patients. Baseline age, sex, and body mass index (BMI) were recorded for all patients included in the study. All comorbidities were recorded. All subjects underwent dual energy X-ray absorptiometry assay of the lumbar spine and right hip for BMD. The primary outcome was readmission. Predictive variables were categorized and compared between readmitted and non-readmitted patients. Logistic regression was used for multivariable analysis.

Results: A total 121 patients with CKD who received denosumab therapy were enrolled. Of these, 29 were readmitted within 2 years, and 92 had no readmission. The lumbar BMD differed between the readmission (-2.94±0.68) and non-readmission group (-2.09±1.48). The readmission group had a lower T score than the non-readmission group. When adjusted for potential confounding factors, a decreased lumbar BMD had a higher readmission risk. When the cut-off points determined by receiver operating characteristic (ROC) curve analysis were applied, the most precise point was set at a T score of -3(Table).

Conclusion: Osteoporosis in CKD patients is associated with a high risk of readmission; the best predictor after denosumab therapy was the lumbar spine T score. A lower T score (especially if less than -3) was associated with a higher probability of fracture readmission. It is essential to optimize primary and secondary prevention in these patients to improve their quality of life.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: This study investigated the effect of different severities of CKD on bone mineral density (BMD) in patients treated with denosumab.

Methods: This study was a retrospective case review of CKD patients treated with denosumab. Baseline age, sex, and body mass index (BMI) were recorded for all patients. All comorbidities such as diabetes, hypertension, and liver and estimated glomerular filtration rate (eGFR) serum collagen type 1 cross-linked C-telopeptide (CTX) were also recorded. All subjects underwent dual energy X-ray absorptiometry assay of the forearm, lumbar spine, and total hip and femoral neck to determine the BMD. Changes in BMD between baseline and 1 year after denosumab administration were recorded. The correlation between the changes in BMD and eGFR was assessed.

Results: A total 108 patients with CKD who had received denosumab therapy were enrolled. The mean age was 71.04 ± 9.64 years, and 96 patients (88.9%) were women. Baseline eGFR correlated negatively with changes in the BMD of total hip (Rho = 28.7, P=0.01) and femoral neck (Rho = 40.6, P < 0.01) but not those in the spine and forearm. The lower the eGFR, the more was the improvement in BMD in the femoral neck after denosumab therapy. When changes in femoral neck BMD were assessed as outcome measures using linear regression, young patients (p = 0.001) and those with a low eGFR benefitted more from denosumab therapy (p = 0.029).

Conclusion: Denosumab therapy is effective in cases of low eGRF and young age. Aggressive medical attention is needed in these patients.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In recent years, denosumab, a monoclonal antibody against RANKL, has been proven for effective treatment of primary osteoporosis. However, effects of denosmab for glucocorticoid-induced osteoporosis(GIOP) were not clearly resolved. We conducted a longitudinalcohort study to clarify effects of denosmab when compared with bisphosphonates on osteoporotic vertebral fractures in GIOP.

Methods: Patients with connective tissue diseases at Tokyo Medical Center was subjected for one year longitudinal cohort study. The number of subjects was 210 (female; 184, age; 65+/-14 (mean +/- SD), prednisolone dosage during 1yr; 6.2+/-5.1mg/day, disease duration; 11.7+/-11.3yr). Lumbar bone mineral densities (lBMD) were measured with Lunar 3030 (GE). Incident vertebral fractures were defined from XP with the semi-quantitated method (Genant, H. 1993). Prevalent vertebral fractures were seen in 97（46％） patiets. Bisphosphonates and denosmabwere used in 150 and 60 patients, respectively.

Results: 1) The value of lBMD (%YAM) at the base line was 81.7+/-14.7%. The rate of incident fractures during the follow-up period was 12.3%. 2) The group of denosmab showed higher values in age and prevalent fracture and lower value in lBMD than the group of Bisphosphonates ($p<0.05$). Increases in lBMD after 1 yr were not different in these two groups. Incident vertebral fractures were lower in the patients with denosmab (3.3%) than in those with bisphosphonates (16.0%), even though the denosmab group were at higher risk in age, prevalent fracture, and lBMD. 3) A logistic regression analysis revealed that statistically significant factors for incident fractures were lBMD (1% increase, OR; 0.95; 95%CI; 0.91-0.99, $p<0.01$), prednisolone dosages (1mg/day increase, 1.13, 1.03-1.25, $p<0.01$), prevalent fractures (3.61, 1.29-10.13, $p<0.01$), and denosmab treatment (vs bisphosphonates, 0.17, 0.03-0.54, $p<0.01$).

Conclusion: Our results suggested that denosmab might be effective for prevention of osteoporotic fractures in patients treated with glucocorticoids.

Background/Purpose: Transplants increase risk of bone loss and fractures and reduce quality of life. Information on fracture incidence is important when making clinical decisions about initiating anti-osteoporotic treatment and when assessing treatment success. No existing fracture assessment tool accounts for the additional risk transplant patients may experience over time. With this study, we aimed to estimate fracture incidence rates in transplant patients and present them in a uniform way, which could aid clinicians in making personalized patient care decisions.

Methods: We searched MEDLINE and PubMed from inception to May 2016 for all observational studies and randomized controlled trials (RCTs) involving solid organ transplant recipients and reporting on osteoporotic fractures. We included RCT data from groups which received no anti-osteoporotic treatment or were treated with calcium and vitamin D. Studies involving >50% bisphosphonate users were excluded. Two independent reviewers extracted data on hip, vertebral (morphometric /clinical), non-vertebral, and total fractures. We calculated fracture incidence rates per 1000 patient-years (PY) for each study and combined them using a random effects meta-analysis model.

Results: We included 42 studies (N=280,066, 99% were kidney transplant) (Table 1). Time since transplantation varied across studies (3 months-11.5 years; median 1 year). A majority of transplant recipients were started on pulse IV steroids, followed by high dose oral corticosteroids, which were tapered within 3-6 months. Most incident fractures were reported within one year post-transplant across all studies. Kidney transplant recipients experienced high risk of hip fracture (4 per 1000 PY) (Table 2). We also found a very high risk of vertebral (morphometric/clinical) fracture (81 per 1000 PY) in heart transplant recipients. Liver transplant recipients experienced high risks of vertebral and non-vertebral fractures (86 and 31 per 1000 PY, respectively).

Conclusion: This study found a high fracture risk in transplant recipients, especially within the first post-transplant year. Our results will support informed decision-making regarding anti-osteoporotic treatment and will aid policy makers in formulating standards of care. Current evidence is heterogeneous in terms of variables such as patient characteristics and follow-up. Researchers studying post-transplant care should aim for a homogeneous study design, which will enable precise estimation of fracture rates and treatment effects, as well as investigation of factors relating to variability in fracture risk among transplant recipients.

Table 1: Patient Characteristics							
Author, year	**N of patients, Female (%)**	**Mean age, years**	**Steroid regimen**	**Other Immunosuppressant use**	**Calcium and Vitamin D use**	**Bisphosphonate use (%)**	**Mean time from transplant, years**

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis (OP) in males under 70 years is less common than postmenopausal and senile, but generates significant social and health costs associated with morbidity and mortality from fractures. It´s common in patients with inflammatory rheumatic diseases and hepatic, bowel and endocrine pathologies, also in COPD patients and in those undergoing chronic corticosteroid therapy. Sometimes clinical risk factors of male OP go unnoticed, so the diagnosis is delayed and is done when one or more fractures by low energy mechanism have already produced, which is a late diagnosis. Bone Metabolism Unit at Basurto University Hospital receives from 2010 male patients with suspected OP. The objective of this study is to describe demographic and clinical characteristics of men ≤70 years evaluated in our OP consultation, with referral protocols according to risk factors.

Methods: A retrospective, descriptive study based on a review of database of these patients. We analyze origin of derivation, risk factors, presence of fractures at the moment of diagnosis, primary diagnoses and occurrence of refractures. All statistical analyses were performed using SAS for Windows statistical software, version 9.2.

Results: 199 patients, with a mean age of 57.74 years (18-70), from Primary Care (73), and general rheumatology (57), up to 65% of the total; 23 patients (11.5%) from traumatology; 15 from endocrinology (7.5%); 9 from gastroenterology (4.5%). 59.8% were smokers or former smokers, 25% had drinking habit. 20.1% had received prednisone doses ≥ 7.5 mg for more than 3 months. 12 patients had family history of fracture (6%), and 70 already had one or more fractures (35.1%): 57 one or more vertebral fractures, 5 hip fracture and 12 wrist fracture. 99 patients had OP with treatment indication by bone agent. 59.3% had secondary OP, main cause digestive disorders (malabsorption syndromes and inflammatory bowel disease) by 21%, 10% endocrine disorders and rheumatic inflammatory diseases also by 10%. Presence of fractures was associated with decreased DXA spine ($p = 0.027$) and hip ($p = 0.004$). A very weak correlation between higher FRAX fracture and number of risk factors was detected, on the other hand a moderate correlation was observed with the number of fractures (Spearman Rho = 0.472; $p < 0.001$). So does to the hip FRAX (Spearman Rho = 0.417; $p < 0.001$). Low levels of D vitamin showed association with decreased DXA in spine. Drinking habit showed statistically significant association ($p=0.032$) with a decrease in the T - score of hip. Among 70 patients with previous fractures, only 15 (21%) had received prior treatment with bone agent. 7 patients suffered refracture after starting treatment and during follow-up (74.2 months) (6-129).

Conclusion: For the correlation found with spine bone density, it seems important to keep enough D vitamin levels in this population. Almost 1/3 of our patients were referred for low energy mechanism fractures, which is an important failure in early diagnosis, and reveals an unmet need among different specialties of awareness on risk factors for male osteoporosis. Therapy with bone agent (oral biphosphonate mainly), seems useful in preventing new bone fractures in these patients.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Women with breast cancer are at an increased risk for the development of bone loss and osteoporosis mainly due to adjuvant therapies, such as aromatase inhibitors (AI). AI therapy fully suppresses estrogen synthesis, further exacerbating the increased bone resorption and leading to an excess fracture risk. Thus, a close monitoring of bone mineral metabolism is recommended in these cases. The aim of the present study was to analyze bone health status and clinical characteristics of women with breast cancer referred by oncologist to a specialized clinic and their outcomes during follow-up.

Methods: Retrospective analysis of consecutive female patients with recent breast cancer (BC) and low bone mineral density (BMD) referred to the osteoporosis outpatient clinic for assessment, as agreed with oncologists. A descriptive analysis of epidemiological, clinical, laboratory, imaging, and dual energy x-ray absorptiometry (DEXA) data is presented, both at baseline and last visit. 95% confidence intervals (95%CI) were estimated for rate of fragility fractures (FF) at baseline and during follow-up.

Results: A total number of 122 female patients have been assessed up to May 2016; median aged 60.9 (SD±10.6) years old, 91.5% postmenopausal. BC was non-methastasic in 89 (70.3%), and 89 (70.3%) patients were on aromatase inhibitors (66 on letrozole). At baseline, 26 patients (21.0%, 95CI% 20.9-21.1) had previous FF, mostly vertebral (13) or non-vertebral (9), and two cases had suffered from multiple FF. BMDs were at osteoporotic range at the lumbar spine and osteopenic at both the femoral neck and hip. Median 25-hydroxyvitamin D levels were 23.9ng/mL (p25-75 18.1-45.1) at baseline. Regarding antiosteoporotic therapies, bisphosphonates were prescribed in 62 cases (66.6%), denosumab in 16 (17.2%), and raloxifene in one case (1.0%); the others were only on calcium plus vitamin D supplementation. A total of 102 patients were followed a median of 1.5 years (0.8-2.5), and 20 (16%) discontinued controls. During follow-up, new FF occurred in nine patients (9.0%, 95%CI 8.9-9.1), that were vertebral in 6, non-vertebral in 2, both in one case, while no hip FF were detected.

Conclusion: The outcomes of a structured assessment of female patients with BC and low BMD are reported here. Despite this, almost 10% of cases developed a new FF, highlighting the need for special attention to this singular, secondary form of osteoporosis.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with autoimmune diseases are at increased risk of early onset osteoporosis due to multiple reasons including prolonged exposure to corticosteroids and the disease process itself in RA patients. Same patients are more likely to be on TNF inhibitors or other biologics, which causes them to be at an increased risk of infections. Denosumab, an anti-RANK ligand inhibitor used to treat osteoporosis, is associated with increased infection risk as Receptor activator of nuclear factor kappa-B ligand (RANKL) is also expressed on activated T and B lymphocytes(1). It is unknown if there is an added risk of infections when TNF inhibitors/biologic agents and denosumab are used concomitantly.

Methods: Data was collected and analyzed on 40 patients in the rheumatology clinic who had been on denosumab and TNF inhibitor/ other biologic for 5 years at the Keck Medical Center of USC.

Results: The mean age of the population was 70 ± 9.8 SD years, among which 98% were females. 75% had RA, 10% SLE, 2.5% SLE and Sjogren's, 2.5% SLE with Antiphospholipid Syndrome(APLS), 2.5% RA and SLE, 2.5 % Microscopic Polyangiitis, 2.5% Psoriatic arthritis, and 2.5% Neurologic Behcet's disease. We noted a 17.5% cumulative infection rate before denosumab over 2 years, which is 8.75 cases per 100 person-years. 9% hospitalization rate for infections was noted prior to denosumab. Importantly no infections developed within the first year of initiating denosumab. After 5 years of denosumab with TNF/other biologics, cumulative infection rate was 62.5 % and incidence rate was 12.5 cases per 100 person-years. In the FREEDOM Trial at 3 years, cumulative incidence rate of infections was 52.9%. In our study, 70% patients were on TNF inhibitors and 30% were on other biologics. At 5 years, Cumulative Infection rate was 71.4% among the TNF group and was 50% in the other biologics group. Urinary tract infection (UTI) accounted for the most common infection (17.5%). Other common infections: Pulmonary(15%), skin and soft tissue(12.5%), GI(5%), Tinea(5%)Herpes zoster(2.5%), HSVII(2.5%), sialadenitis(2.5%) . No opportunistic infections, and no reactivation of latent TB found in our patients.

Conclusion: No infections developed within the first year, suggesting a cumulative effect of increased infection risk, if any. We cannot attribute the overall infection rate solely to the combination of denosumab and biologics as patients who developed infections either had Diabetes Mellitus, urinary incontinence, recent surgery, underlying pulmonary disease. Whether prophylactic antibiotics are indicated in patients with recurrent infections PRIOR to denosumab is uncertain, but may be a consideration in certain patients. References: 1. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Scheuermann's disease is one of the most frequent illnesses of the spine in teenagers. Its evolution over time is poorly understood. Spinal deformities, by impairing the biomechanics of spine, may be a new risk factor for osteoporotic vertebral fracture. Recently, prospective studies have demonstrated that disc space narrowing (DSN) and thoracic kyphosis could be new vertebral fracture risk factors and similar abnormalities are frequently observed in Scheuermann's disease. Our objective was to examine whether Scheuermann's disease is predictive of vertebral fracture in elderly men.

Methods: We assessed the Scheuermann's disease using the Berlin criteria (Armbrecht & al. Osteoporos Int, 2015, 26, 2509) among 766 spinal radiographs, made of men aged from 50 to 85 years old. Bone mineral density (BMD) was measured at baseline using a HOLOGIC 1500 QDR device. Data on incident vertebral fractures have been prospectively collected for 7,5 years and non-vertebral fractures for 10 years. We analyzed the relationship of Scheuermann's disease and each of its diagnostic criteria with BMD and with the risk of fracture.

Results: Scheuermann's disease prevalence was 25,2%. Scheuermann's disease was associated with lower BMD at the hip and higher BMD of lumbar spine and whole body after adjustment for age, weight, 17b-estradiol and 25-hydroxycholecalciferol. Vertebral fractures occurred in 27 men, peripheral fractures occurred in 60 men. Scheuermann's disease was not associated with an increased risk of vertebral fracture. However, vertebral endplate irregularity, one of its diagnostic criteria, was associated with an increased vertebral fracture risk after adjustment for the age, weight, lumbar spine BMD, prevalent vertebral fractures, prior falls, overall score of DSN due to osteoarthritis (Odds ratio= 2.69, 95% CI: 1.16; 6.26, $p<0.05$). In individuals with Scheuermann's disease, peripheral fracture risk was lower after adjustment for the age, weight, femoral neck BMD, prior fragility fracture (self-reported non-vertebral fractures and vertebral fractures), prior falls, overall score of DSN due to osteoarthritis, severe abdominal aortic calcification (Odds ratio= 0.47, 95% CI: 0.23; 0.99, $p<0.05$).

Conclusion: In this prospective cohort study in elderly men, Scheuermann's disease was not associated to an increased vertebral fracture risk, but with a decreased non vertebral fracture risk. Endplate irregularity, however, was substantially predictive of new vertebral fracture risk, which may be taken into account in the evaluation of the risk of fracture in elderly men.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis prevalence in lung transplantation candidates is between 16-21%. In the last years, the survival rate after lung transplantation has definitely improved, due to the improvement of the surgical techniques, of the treatment in the intensive care unit and the development of better immunosuppressive therapy. In spite of this, it was observed that there is a rapid loss of bone mass in these patients in the first year post-transplantation, probably due to prolonged immobilization post-surgery, to high doses of glucocorticosteroids used to prevent acute rejection and to the immunosuppressive regimen. Prospective studies have been conducted which demonstrated changes in bone mass and a

major incidence of fractures in lung transplant patients. Our objectives were to determine the prevalence of osteopenia, osteoporosis and fractures in lung transplantation candidates and lung transplant patients in a reference center as well as to evaluate the change of bone mass pre and post transplantation.

Methods: We included 179 patients from the cohort of lung transplant patients of Vall d'Hebron University Hospital, whose femoral and lumbar bone mineral density determinations pre and post-transplant were available. Since it is a retrospective study and the moment of the post-transplant bone densitometry couldn't be standardized, the patients were stratified depending on the moment of the realization of the densitometry: less than 6 months, between 7 and 12 months and more than 12 months after the transplant.

Results: Out of the 179 patients, 110 were men and 69 were women, and their average age was 51±10.4 years. The prevalence of pre and post-transplant osteoporosis, osteopenia and symptomatic fractures is shown in table 1.

Table 1. Pre and post-transplant osteoporosis prevalence

Prevalence	Pretransplant(%)	Post-transplant(%)
Osteoporosis	38	38.5
Osteopenia	45.8	48.6
Normal	16.2	12.8
Fracturas	9.5	11.2

No significant differences were observed when comparing the percentage of men and women with osteoporosis and osteopenia before and after the transplant, in relation to the patients' sex or age. The change of bone mass post-transplant, expressed in gr/cm^2 was of 1.3% (±15.3) in the lumbar spine, -2.1 (±11.3) in the femoral neck and 2.1(±9) in the total femur. The patients' diagnostic change after lung transplant is shown in table 2.

Table 2. Change of bone density between pre and post-transplant

		Post-transplant		
		Normal	Osteopenia	Osteoporosis
Pre transplant	Normal	18 (62.1)	11 (37.9)	-
	Osteopenia	4 (4.9)	62 (75.6)	16 (19.5)
	Osteoporosis	1 (1.5)	14 (20.6)	53 (77.9)

More than 60% of the patients didn't have a diagnostic change after the transplant. Out of the 11 patients with normal pre transplant bone densitometry and post-transplant osteopenia, 9 had previously received osteoporosis treatment. Out of the patients with pre transplant osteopenia, 16 had osteoporosis afterwards, 8 of whom had not received previous treatment. 14 patients that had pre transplant osteoporosis improved to osteopenia post-transplant, out of which 12 had been previously treated.

Conclusion: In our series the prevalence of osteoporosis and osteopenia was of 38% and 45.8%, respectively. The prevalence of pre-transplant symptomatic fractures was of 9.5%. The prevalence of post-transplant osteoporosis and osteopenia was of 38.5% and 48.6%, respectively. The prevalence of post-transplant symptomatic fractures was of 11.2%. In our cohort, the majority of patients whose bone densitometry worsened from normal/osteopenia to osteoporosis had not received pre transplant prophylactic treatment. The post-transplant bone mass loss was between 1-2%, and the most affected regions were the total femur and the femoral neck.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis is a very frequent complication in recipients of a lung transplant . The factors that intervene can be previous to the transplant, such as the individual risk, the underlying disease, the treatments received but also the ones related to the lung transplant, like the prolonged post-surgery immobilization. The rate of bone mass loss in the lumbar spine and the femoral neck in the first year is around 2-5% and fracture prevalence is between 18-37%. The objectives of this study were to evaluate the effect of antiresorptive, glucocorticosteroids and other immunosuppressive treatments on bone mineral density in lung transplant patients.

Methods: This is a retrospective study on a cohort of 179 patients who were submitted to lung transplant between 2004 and 2014 in the Vall d'Hebron University Hospital. A bone densitometry was practiced to all patients before and after the lung transplant. The comparison between the determinations was made by calculating the percentage of change in bone mass expressed in g/cm^2 at each of the explored region: the lumbar spine (L2-L4), the femoral neck and the total femur. For the analysis of the effect of immunosuppressant therapy on bone mineral mass, a subgroup of 136 patients was selected, who were receiving a standard treatment regimen: glucocorticosteroids, tacrolimus and mycophenolate. 3 groups were established, depending on the moment of the densitometry realization: in the first 6 months, between 6 and 12 months and more than 12 months after the lung transplant. The correlation between bone mineral loss in the regions of interest and the accumulated dose of each of the treatments was evaluated using logistic regression and multivariate analysis.

Results: Out of the 179 patients, 121 received treatment for osteoporosis after the lung transplant (89 were previously receiving it). Table 1 shows the number of treated patients as well as the received treatments. The average time (rank) between the start of the treatment and the realization of the bone densitometry post-transplant was of 24 months (5-120).

Table 1. Osteoporosis treatment after post-transplant

	Treated (n=121)	Not Treated (n=58)	p
Osteopenia	61 (50.4)	26 (44.8)	0.272
Osteoporosis	46 (38)	23 (29.7)	0.480
Normal	14 (11.6)	9 (15.5)	
Drug type			
Oral byphosphonate	64 (52.9)		
Intravenous byphosphonate	46 (38)		
Strontium ranelate	2 (1.7)		
Teriparatide	1 (1.7)		
Calcitonin	1 (0.8)		
Denosumab	3 (2.5)		

Among the 136 patients (58.8% men) who were selected for the study of the effect of immunosuppressants on bone mineral mass, 49 (36%) had been diagnosed of Chronic Obstructive Pulmonary Disease, 64 (47%) of Interstitial Lung Disease and 23 (17%) of other pulmonary diseases. The average percentage of variation of the bone mineral mass in all 136 patients was of +1.3% in lumbar spine, -3.4% in femoral neck and -2.3% in total femur. The percentage of variation of bone mineral mass pre and post-transplant in the treated patients was of 2.8% for the lumbar spine, -0.5% for the femoral neck and -1.3% for the total femur, in comparison to the group of untreated patients where the variation was of -2.5, -5.4% and -3.9, respectively. There was no significant difference in the average accumulated dose of glucocorticosteroids and immunosuppressants between patients whose post-transplant bone mineral mass improved or worsened, in none of the studied regions, nor in the global study or in either of the subgroups of studied diseases. In the multivariate analysis, feminine sex was the only variable which was associated to bone mineral loss in all the studied regions, except for the femoral neck.

Conclusion: The patients who received antiresorptive treatment pre transplant have a major increment of bone mineral mass at the lumbar spine and a lower post-transplant bone mineral mass loss than the not treated ones. No association was observed between glucocorticosteroid and other immunosuppressants and post-transplant bone mineral mass.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with a terminal lung disease have a great number of risk factors for the development of osteoporosis. Although much has been learned about the factors that contribute to bone mass loss, in our study we try to determine the risk factors in groups of similar diseases. The study´s objective is to determine if the known risk factors for low bone mass are more prevalent in each of the studied lung diseases and if these correlate with the presence of osteoporosis in lung transplantation candidates.

Methods: 179 patients were included, from the cohort of lung transplant patients of the Vall d'Hebron Univesity Hospital, whose pre transplant bone densitometry at lumbar spine and femoral neck were available. 3 groups of lung diseases were selected, due to the differences related to the grouping of risk factors and the glucocorticosteroid doses required before transplantation. The groups were: Chronic Obstructive Pulmonary Diseases (COPD), Interstitial Lung Diseases (ILD) and Other Diseases (Lymphangioleiomyomatosis, cystic fibrosis, primary and secondary pulmonary hypertension). The glucocorticosteroid dose was stratified as follows: high dose if it was more than 5mg/day for more than 3 months (or prednisone equivalent) or more than 3 times a year, and low dose if it didn't meet these conditions.

Results: 179 patients were included, with an average age of 51±10.4 years, without sex related differences. 69 were women (66% of them were at menopause at the moment of the transplantation). 12.3% (22 patients) of the patients had a low body mass index, 57% were smokers with an average of 24.7 packages/year, 5% consumed more than 40 grams of alcohol per day, 44% were sedentary, 8.4% had first degree relatives with an osteoporotic fracture, 15.6% had osteopenia and 86% had received glucocorticosteroids, 56.4% of them at high dose. The risk factors more prevalent in Chronic Obstructive Pulmonary Disease in comparison with the other groups as well as the prevalence of each of them are shown in Table 1.

Table 1. Risk factors for low bone mass and fractures for all the patients, in each of the lung disease

Risk factor	Total	COPD (n=65)	ILD (n=82)	Other (n=32)	COPD versus ILD		COPD versus Other	
					OR (CI)	p	OR (CI)	p
Menopausse	46 (66.6)	14 (77.8)	24 (82.7)	8 (36.4)	0.93 (0.71-1.2)	0.426	2.16 (1.2-3.89)	0.007
Calcium intake	41 (22.9)	19 (29.2)	17 (20.7)	5 (12.2)	1.23 (0.81-1.87)	0.235	1.44 (0.71-2.9)	0.213
Low body mass index	22 (12.3)	8 (12.3)	5 (6.1)	9 (28.1)	2.01 (0.69-5.88)	0.153	0.44 (0.19-1.03)	0.053
Smoking	102 (57)	58 (89.2)	38 (46.3)	6 (18.8)	1.92 (1.5-2.46)	0.000	4.75 (2.3-9.83)	0.000
packages/year	24.7(32.4)	51.1 (37)	12.1 (17)	3.4 (8)		0.000		0.000
Alcoholism	9 (5)	5 (7.7)	4 (4.9)	0	1.57 (0.44-5.64)	0.356	-	0.128
Sedentarism	79 (44.1)	37 (56.9)	34 (41.5)	8 (25)	1.37 (0.98-1.91)	0.045	2.27 (1.2-4.3)	0.003
Previous fracture	17 (9.5)	7 (10.8)	10 (12.2)	0	0.88 (0.36-2.19)	0.5	-	0.054
Fracture in a relative	15 (8.4)	5 (7.7)	5 (6.1)	5 (5.6)	1.26 (0.38-4.17)	0.475	2.03 (0.63-6.51)	0.195
Osteopenia producing disease	28 (15.6)	9 (13.8)	7 (8.5)	12 (37.5)	1.62 (0.64-4.12)	0.220	0.37 (0.17-0.78)	0.009
Oral glucocorticosteroids	154 (86)	62 (95.4)	75 (91.5)	17 (53.1)	1.04 (0.96-1.14)	0.270	1.79 (1.29-2.49)	0.000
High dosis	101 (56.4)	29 (46.8)	59 (78.7)	13 (76.5)	0.59 (0.44-0.80)	0.000	0.61 (0.42-0.89)	0.027
Vitamina D (ng/ml)	18.1 (12.3)	16.2 (11.3)	19.2 (11.3)	19.4 (15.7)		0.388		0.092
Parathormone (pg/ml)	66.7 (39.2)	73.2 (48)	59.8 (28)	71.1 (40.2)		0.060		0.521

The risk factors associated with osteoporosis in all the patients were a low body mass index, smoking and previous fracture. In the different groups of lung diseases, the risk factor associated with osteoporosis in the Chronic Obstructive Pulmonary Disease group as well as in the Interstitial Lung Disease group was the presence of a previous fracture, with an OR of 1.81 (1.44-2.28) and 3.31 (1.07-10.24), respectively. In the group of other diseases the risk factor associated to osteoporosis was the glucocorticosteroid treatment, with an OR of 1.95 (1.08-3.52), without differences related to the dose.

Conclusion: In our cohort, the risk factors for low bone mass, depending on the disease, were smoking and sedentarism in the Chronic Obstructive Pulmonary Disease group. In the same group there was a major prevalence of menopause and glucocorticosteroid treatment, in comparison to the other groups. But the prevalence of high glucocorticosteroid dose in this group was lower than in the others. The risk factors for osteoporosis in lung transplantation candidates were previous fractures, smoking and a low body mass index. In the Chronic Obstructive Pulmonary Disease and Interstitial Lung Disease groups the factor with greater association to osteoporosis was the presence of previous fractures and in the other diseases group glucocorticosteroid treatment.

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis represents a preventable and often treatable condition that is responsible for 1.5 million fractures annually in the United States. Proper patient knowledge represents a crucial aspect of disease management and has potential implications in treatment adherence and lifestyle modification. By examining how much patients know about their own diagnosis, their disease knowledge, and what resources they would like to use we aim to lay the groundwork for developing efficient patient education resources.

Methods: We surveyed 52 individuals and collected data on demographics, bone density test results, disease knowledge (using a validated survey), and educational sources both used and preferred. This was done to learn how much patients know about their condition on a fundamental level.

Results: 50% of participants diagnosed with osteoporosis correctly self-reported their condition, as did 21.1% diagnosed with osteopenia. Between the normal, osteopenia and osteoporosis groups there were no significant differences between their scores on the patient-knowledge questionnaire. The resources most used by patients were Handouts/Brochures and Internet/Personal Research, and patients reported a preference for learning directly from their Doctor/Nurse.

Knowledge Questionnaire (True/False)	**Percent Correct**
1) Osteoporosis means having a worse bone density than osteopenia. **T**	74.5%
2) Osteoporosis leads to an increased risk of bone fractures. **T**	98.1%
3) Osteoarthritis is another term for osteoporosis. **F**	75.0%
4) Osteoporosis causes joint pain. **F**	46.8%
5) Osteoporosis is more common in men. **F**	97.9%
6) If my mother has osteoporosis, then I am at a higher risk of getting it too. **T**	81.6%
7) Heavy drinking/alcohol use has been linked with osteoporosis/osteopenia. **T**	63.0%
8) Cigarette smoking can increase risk of osteoporosis. **T**	89.1%
9) Regular exercise especially walking is known to weaken bones and cause osteoporosis. **F**	96.0%
10) Decreased levels of sex hormones can increase the risk of getting osteoporosis. **T**	59.1%
11) Calcium is important for bone health. **T**	100%
12) Sardines and broccoli are good sources of calcium for people who cannot take dairy products. **T**	89.1%
13) A woman's risk of developing osteoporosis **decreases** after menopause.	93.6%
14) Taking prednisone regularly can **increase** risk of developing osteoporosis. **T**	81.8%
15) Taking Fosamax (alendronate) can **decrease** the risk of developing osteoporosis. **T**	66.7%

Conclusion: The majority of fractures occur in patients with osteopenia because they have not yet been treated or diagnosed. Our study confirms the lack of disease awareness in patients with osteopenia. We confirmed the invaluable role of medical personnel in teaching patients about bone density loss. It is through efficient learning that patients can be empowered to take charge of their health.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Sclerostin, an osteocyte secreted protein encoded by SOST gene, is an important regulator of Wnt pathway. It prevents bone formation by blocking Wnt binding to its receptor. High levels of sclerostin have been reported in post-menopausal women with osteoporosis. Sclerostin can be induced during inflammation and may also inhibit repair of bone erosion in patients with rheumatoid arthritis (RA). There are few studies demonstrating the role of sclerostin on bone mass and disease activity in RA patients. This study aims to assess the serum sclerostin level in patients with RA and to correlate its level with disease activity and bone mineral density.

Methods: Forty-seven patients of RA fulfilling the ACR/EULAR (2010) criteria, attending the department of Rheumatology, King George Medical University, Lucknow, India were included in the study. Twenty-eight age- and sex-matched healthy controls were enrolled from the same geographic area. Apart from routine blood investigations; rheumatoid factor (RF), anti citrullinated protein antibody (ACPA), 25 hydroxy vitamin D, radiographs and bone mineral density (BMD) were also done. Disease activity was assessed by CDAI. Serum sclerostin levels of both cases and controls was assayed by using enzyme-linked immunosorbent assay (ELISA) assay [Elabscience, coefficient of variation (CV) < 10%] and compared with disease activity and bone mineral density.

Results: Mean age of RA patients was 32.7+6.8 yrs with mean duration of disease 4.2+2 yrs. Mean age of the control group was 28.7+6.3 yrs. Rheumatoid factor was positive in 29 out of 38 patients and anti citrullinated protein antibody was positive in 44 out of 47 patients. Mean sclerostin level among patients was 8422+3655 and that of control group was 6479+1510 (p value 0.002). Serum sclerostin level did not correlate significantly with ESR (r:-0.31, p:0.048), CRP (r:-0.11, p:0.65), CDAI (r:-0.11, p:0.45), BMD at lumbar spine(L1-4, r:.14, p:0.35) and femur (r:0.06, p: 0.67).

Conclusion: Serum sclerostin level did not correlate with disease activity and BMD in RA patients.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteonecrosis of the femoral head (ONFH) is characterized by epiphyseal necrosis that can lead to sub-chondral fracture, femoral head collapse and hip replacement. Osteoporosis (OP) and ONFH share common clinical and pathophysiological features such the occurrence of fracture, risks factors (GC and alcohol) and altered bone cells functions. This study was undertaken to study BMD in patients with pre-fractural (stage 1 and 2) and fractural stages (stage 3 and 4) of ONFH and to determine whether ONFH at a fractural stage was associated with an increased prevalence of OP

Methods: We included 243 patients with ONFH and 399 age and sex-matched healthy controls in this prospective controlled trial. Data was gathered including demography, risk factors, ARCO staging of ONFH and bone mineral density (BMD). Patients were stratified according to the staging (pre-fractural and fractural stages) of ONFH at diagnosis and BMD.

Results: BMD (defined by the T-score) was significantly lower in the ONFH group at both the femoral head (-0.96 ± 1.11) and the lumbar spine (-1.22 ± 1.47) compared to the control group (-0.55 ± 0.97 and -0.73 ± 1.31) ($p<0.01$). The ONFH group depicted a significantly higher proportion of osteopenia (50.39% vs 40.87%, $p =0.027$) and of OP (18.78% vs 7.33%, $p <0.001$) relative to the control group. Furthermore, we analyzed BMD of ONFH patients according to the stage of ONFH at diagnosis. We observed that stage 1-2 ONFH patients (53.86%) (but not stages 3-4) were at a higher risk of osteopenia than the control group (40.88%, $p =0.0203$) with an odds ratio of 1.27 (95% CI: [0.78; 2.06]). Moreover, stage 3 and 4 ONFH patients (25.31%) were at a higher risk of osteoporosis (with an odds ratio of 4.89 (95% CI: [2.77; 8.76]) than patients in the stage 1 and 2 group (7.24%, $p <0.001$) and compared to the control group (with an odds ratio of 4.89 7.33%, $p <0.001$).

Conclusion: Fractural stages ONFH were associated with a 5-fold risk of osteoporosis. Therefore, we advise that patients suffering of ONFH should be screened for low bone mass.

Peripheral Osteoclastogensis Is Coming Back Along with Inflammation Twelve Months after Rituximab Therapy

Session Date: Sunday, November 13, 2016
Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: We investigated change of bone turnover markers in peripheral blood before, 6 and 12 months after rituximab therapy in seropositive RA patients.

Methods: Ten seropositive RA patients were enrolled. They had been refractory to antirheumatic drugs and anti TNF-¥á therapy, thus received rituximab, monoclonal anti-CD 20 antibody treatment. Rituximab 1000mg were infused on days 1 and 15. Peripheral blood mononuclear cells were collected before, 6 and 12 months after rituximab treatment. They were

cultured and number of osteoclasts was counted. In addition, CD 19 cells and complete blood count (CBC) along with ESR, CRP and RA disease activity such as DAS28 were assessed. Bone turnover markers including c-terminal telopeptide (CTX), osteocalcin, bone specific alkaline phosphatase (BSALP) were also measured using enzyme linked immunosorbent assay.

Results: The number of cultured osteoclasts from peripheral blood and serum level of CTX were lowered, six months after rituximab therapy (Table 1). BSALP which is bone formation marker also increased after the treatment. The acute phase reactants and RA disease activity, measured 6 months after rituximab therapy markedly responded to the treatment as CD 19 cells were depleted (Table 2). On the other hand, twelve months after rituximab therapy, the serum level of acute phase reactants began to rise and CD 19 cells increased in numbers. RA disease activity also got worse. Bone resorption pits by osteoclasts cultured from peripheral blood at 12 months after rituximab treatment significantly increased than bone resorption pits by osteoclasts from peripheral blood at 6 months after the treatment.

Conclusion: Peripheral osteoclastogenesis decreased when systemic inflammation is improved in RA patients 6 months after B cell depletion treatment. However, one year after rituximab treatment, systemic inflammation increased as peripheral B cell counts began to normalize. The area of bone resorption pit by cultured osteoclasts from peripheral blood increased as well. Therefore, we think peripheral osteoclastogenesis is coming back along with the inflammation, 12 months after rituximab treatment and rituximab therapy should be resumed within a year.

Session Date: Sunday, November 13, 2016
Session Title: Pain – Basic and Clinical Aspects - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Destabilization of the medial meniscus (DMM) in the mouse knee results in slowly progressive joint damage, accompanied by pain-related behaviors. Secondary mechanical allodynia develops by week 4 after surgery, but is not maintained after sham surgery while it is maintained for 16 weeks after DMM. Eight weeks after DMM but not sham surgery, mice develop activity-induced pain. Development of chronic pain is characterized by molecular changes in the dorsal root ganglia (DRG), where the cell bodies of sensory neurons reside. Therefore, we sought to perform an unbiased discovery study on DRG cells at different time points after DMM in order to uncover pathways that may be involved in generating acute *vs.*persistent pain associated with experimental osteoarthritis (OA).

Methods: DMM or sham surgery was performed in the right knee of 10-week old male C57BL/6 mice. Age-matched naïve mice were also included. Four, 8, or 16 weeks after surgery, ipsilateral L3-L5 DRG (innervating the knee) were collected and pooled from each mouse, RNA was extracted, and an Affymetrix Mouse Transcriptome Array 1.0 was performed following manufacturer recommendations. A total of 3 mice (3 arrays) were used for each treatment per time point. Sham 8-week samples did not amplify well and were excluded from the study. Two types of analyses were performed, one looking for genes involved in post-surgical pain (called “early pain”), and one looking for genes involved in persistent pain (called “late pain”). “Early pain” compared naïve 4-week samples to data pooled from sham and DMM 4 week-samples. “Late pain” compared data pooled from naïve 8- and 16-week and sham 16-week samples to data pooled from DMM 8- and 16-week samples. Ingenuity pathway analysis software was used to identify pathways of interest among the differentially expressed genes ($p<0.01$).

Results: In the “early pain” analysis, 345 genes were differentially regulated, using a $p<0.01$ cut-off. The top 3 networks included genes related to 1) Cell morphology/Protein synthesis/Cellular function and maintenance; 2) Hematological system development and function/Hypersensitivity response/Inflammatory response; and 3) Cell cycle/Cell death, which were enriched in the pooled DMM/sham 4-week samples relative to the naïve 4-week controls. In the “late pain” sets, 227 genes were differentially regulated. The top networks included genes related to 1) Nervous system development/Cell-to-cell signaling; 2) Cell-mediated immune response/Cell function & maintenance; 3) Amino acid metabolism/Molecular transport; 4) Humoral immune response; and 5) Cell cycle, which were enriched in the pooled DMM 8- and 16-week samples relative to sham/naïve 8- and 16-week controls. In general, there was little overlap (10 genes) between the differentially expressed genes in the “early” *vs.*“late” pain set, supporting our choice for separating these sets as such.

Conclusion: This molecular study represents the first unbiased analysis in the DRG in a model of chronic OA-pain. Findings support behavioral data suggesting that distinct phases exist in the pain developing after DMM surgery. Future work will seek to validate these pathways with the aim to identify new analgesic targets for treating osteoarthritis pain.

Session Date: Sunday, November 13, 2016

Session Title: Pain – Basic and Clinical Aspects - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pain is often the most troubling feature of musculoskeletal disease in children and young people (CYP). In paediatric pain research, recent attempts to standardise the assessment of chronic pain for CYP have been pivotal in establishing *which* measures should be used. However, guidance about *how* pain assessments should be administered is extremely limited. Furthermore, inconsistencies exist in pain scoring systems used to classify chronic pain as mild, moderate or severe in CYP. The aim of this review was to evaluate current evidence on pain assessment administration, scoring and pain classification in CYP with chronic pain.

Methods: Medline, EMBASE, CINAHL and PsycInfo were searched (inception to 18th January 2016) for studies in which uni-dimensional, self-report, pain assessments were used with CYP (aged 5-18 years) who suffered from a chronic pain condition (or illness conditions in which chronic pain was a feature). Two researchers reviewed full-text articles independently of each other for inclusion. Disagreements were identified and reviewed for inclusion by a third reviewer. Selected studies were critically appraised by the two independent reviewers. Quality criteria were adapted from existing recommendations for the selection, administration and interpretation of self-report scales with children. The maximum possible score was 8.

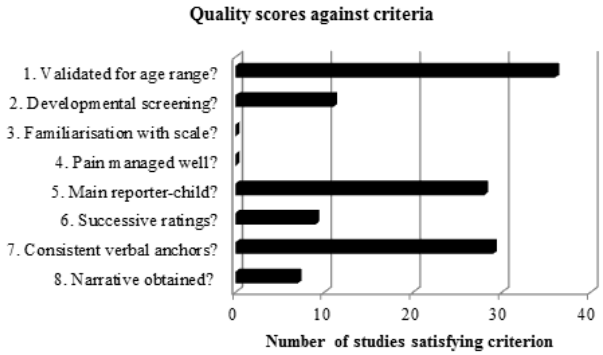
Table 1: Quality criteria used to evaluate the selection, administration and interpretation of pain scales in selected studies.

Quality of measure selection
1. Has the tool been validated for the age range with which it was used?
2. Were children screened for developmental delay or was a measure of competency conducted prior to pain assessment?
Quality of measure administration
3. Did the child have a chance to become familiar with the pain scale used e.g. by rating hypothetical scenarios?
4. Were children introduced to the scale at a time when they were not distracted by the level of pain they were experiencing?
5. Was the child the main reporter of pain at assessment?
6. Were successive pain ratings observed?
7. Were consistent verbal anchors used across patients?
Quality of measure interpretation
8. Was a narrative explanation of pain scores also obtained, at least at the first data collection point?

(adapted from von Baeyer 2006; 2014)

Results: Thirty-five studies were included from a sample of 628. Five papers reported the use of several scales. A total of 40 reports met the inclusion criteria for full review and used one or more of the following assessment types; Visual Analogue Scales, Numerical Rating Scales, Faces Pain Scales, Body Maps. None of the pain assessments undertaken met all quality criteria. The highest score achieved was 5 out of a maximum of 8, the lowest was 0 (median=3, IQR=3-4). Key administrative details were missing from the majority of reports with 22 failing to provide details of how the assessment was scored. Only two articles provided details of how pain scores were classified.

Table 2: Quality scores against criteria



Conclusion: Pain assessments were rarely administered in accordance with existing administrative guidance. The rationale for *how* pain measures were utilised with CYP with chronic pain was seldom provided and the reporting of pain assessments was poor. Details on the systems used to score and classify pain were missing in most published papers. Lack of standardisation remains a problem in chronic pain research. The finding of this review suggest that implementation of guidance for *how* to use, score and report pain assessment tools with CYP in chronic pain is necessary for both clinical practice and research.

Session Title: Pain – Basic and Clinical Aspects - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: There is a well-described epidemic of deaths and hospitalizations related to opioid prescriptions in adults. However, little is known about opioid toxicity in children. We investigated the incidence of opioid toxicity and compared the safety of the most frequently prescribed opioid, codeine, to that of other opioids used by children and adolescents without serious diseases.

Methods: We studied a Tennessee Medicaid cohort of 424,382 children aged 2–17 years, who filled 1,133,089 opioid prescriptions for non-cancer pain. We excluded children with prior encounters indicating serious diseases (cancer, sickle cell anemia, congenital anomalies, hospitalization for a total of more than 30 days in the preceding year, or history of organ transplant), institutional residence, and history of drug abuse. The primary study endpoint was opioid toxicity, defined as an emergency department visit, hospitalization, or death attributed to opioid analgesic use. Medical records were reviewed to adjudicate the outcomes.

Results: The median length of opioid prescription was three days. Most prescriptions were for acute, self-limited conditions including dental procedures (31%), outpatient procedure/surgery (24%), trauma (18%), and minor infections (17%). There were 365 confirmed cases of opioid toxicity with a median follow-up time of opioid exposure of 17 days. At 17 days, the cumulative incidence of opioid toxicity was 33.2/100,000 prescriptions. Children taking any opioid at doses in the highest tertile had higher risk of toxicity than those in the lowest tertile (IRR=1.85, 95% CI=1.36-2.51). The use of tramadol [incident rate ratio (IRR)=3.03, 95% confidence interval (CI)=2.0-4.60] and oxycodone (IRR=1.87, 95% CI=1.19-2.95) was associated with increased risk of opioid toxicity compared to codeine. An analysis restricted to events leading to deaths, hospitalizations or escalation of care showed increased risk with meperidine (IRR=3.43, 95% CI 1.05-11.24) and tramadol (IRR=4.73, 95% CI 2.07-10.82).

Conclusion: We studied a cohort of children without serious underlying conditions who received opioid analgesics for mostly minor and self-limited outpatient disorders. The cumulative incidence of opioid toxicity was 33.2/100,000 prescriptions at 17 days of follow-up. The use of tramadol, oxycodone, and meperidine, and higher doses of opioids in general increased the risk of toxicity.

Session Title: Pain – Basic and Clinical Aspects - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: As many as 25% of chronic pain patients use alcohol to manage pain.[1] Preliminary studies in fibromyalgia patients have shown that low to moderate alcohol consumption was associated with lower symptoms compared to no alcohol consumption.[2] We assessed a large cross-sectional chronic pain sample for associations between severity of symptoms and alcohol consumption.

Methods: 2585 patients (58% female) presenting to a university chronic pain clinic completed a survey battery and reported number of alcoholic drinks consumed per day. Patients were grouped by level of alcohol consumption (drinks per day): none, low (≤1), moderate (>1 and <3) and heavy (≥3). Associations between alcohol consumption and fibromyalgia symptom severity (SS) scale were assessed using analysis of covariance (ANCOVA). Univariate analysis was used to determine significant covariates, using chi-square (X^2) tests and one-way analysis of variance (ANOVA) for categorical and continuous variables, respectively. Bonferroni's post-hoc test was used to assess pairwise differences. Adjusted means ± standard deviation and pairwise differences (x) ± standard error are reported. Analysis performed using IBM SPSS 22.

Results: 1991 (70%) subjects did not consume alcohol; 594 subjects consumed alcohol and were grouped into low (n= 444), moderate (n= 120) and high (n= 30) levels. Univariate analysis revealed significant differences in gender (X^2= 41.4), fibromyalgia status (X^2= 29.8), smoking status (X^2= 26.4), opioid therapy (X^2= 47.7) and age (F= 3.4), all $p< .001$. After controlling for covariates, alcohol level had a significant effect on symptom severity (F= 5.8, $p< .001$). Adjusted mean SS scores were 6.8 ± 0.1, 6.5 ± 0.1, 5.9 ± 0.3 and 7.0 ± 0.4 for the no alcohol, low, moderate and high levels, respectively. Post hoc tests showed that the moderate alcohol consumers had significantly lower SS scores compared to

low alcohol consumers (x= 0.9 ± 0.3, p= .015) and non-drinkers (x= 1.3 ± 0.3, p< .001); no other significant pairwise differences were observed. These data represent a U-shaped curvilinear relationship (Figure 1).

Conclusion: The results suggest that consumption of moderate amounts of alcohol in chronic pain patients is associated with lower symptom severity compared to low or no alcohol consumption. These findings are similar to previous studies examining this relationship in fibromyalgia patients. These results should be further investigated for associations between alcohol consumption levels and other chronic pain symptoms.

Session Title: Pain – Basic and Clinical Aspects - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal (MSK) pain syndromes are common and the most prevalent type of chronic pain in the pediatric population. The chronic pain syndromes include central pain sensitization conditions such as Reflex Neurovascular Dystrophy, Reflex Sympathetic Dystrophy, Juvenile Fibromyalgia, Allodystrophy, and Complex Regional Pain Syndrome. The mean annual cost per child of care with chronic pain at tertiary pain centers was estimated at $11,787. To our knowledge, there is no robust data characterizing pediatric patients with chronic MSK pain syndromes prior to diagnosis at non-specialized pain centers. We describe the length to diagnosis, the healthcare utilization patterns, and economic burden of chronic MSK pain syndromes in pediatric populations. We hypothesized that the cost of MSK pain syndromes prior to diagnosis is similarly burdensome due to delayed diagnosis.

Methods: A retrospective chart review was conducted at a general pediatric rheumatology clinic at Nationwide Children's Hospital (NCH) in Columbus, OH. We included subjects with a diagnosis of primary chronic musculoskeletal (MSK) pain including Juvenile-Onset Fibromyalgia, RSD, and CRPS seen between 2010 and 2014. We excluded patients with primary rheumatologic disorders, with a chronic MSK pain syndrome diagnosed outside of the Nationwide Children's Hospital system or by a non-rheumatologic specialist. Of 118 with a primary diagnosis of chronic MSK pain 80 met inclusion criteria and were analyzed. We only evaluated visits within the NCH system. Data relating to MSK pain prior to diagnosis were collected from the NCH electronic medical records: date of symptom onset and diagnosis, number of emergency visits, number of hospital admissions, length of hospital admissions, number of outpatient visits, medications used, and imaging studies. Pain scores rated on a visual analogue scale (VAS) from 1-10 and functional disability using the Childhood Health Assessment Questionnaire (CHAQ) scores were recorded at the initial visit and at the time of diagnosis. The Medical Expenditure Panel Survey (MEPS) provided nationally representative data on health care service unit costs. Specifically we used the MEPS annual total expenses per visit mean estimates for office based visits, emergency room visits and inpatient admissions.

Results: The mean (±SD) age was 14.6 ±3.0 years. 89% were female and 86% were white. The average length of time from symptom onset to diagnosis was 18.2 ± 24.9 months. At diagnosis mean pain intensity was 6.45± 2.7 and mean CHAQ score were 0.74± 0.6. 29% went to the emergency room at least 1 time and 52% of those with 1 visit had diagnostic laboratory testing. 5% were admitted as inpatients. 81 % sought out one specialty consultation, 38% sought out two specialty consultations, and 35% sought out 3 or more specialty consultations. The most commonly visited specialist was rheumatology followed by orthopedics prior to a diagnosis. The mean cost estimate hospital, ED and office visits between 2009-2014 was $1910.66 ± 3807.6 (range: 213 -21216). 53% had xrays and 21% had MRI's while other imaging studies were not as frequently performed. 65% were prescribed Nsaids and 15% were prescribed Narcotics. There were no strong correlations between length of time diagnosis and costs.

Conclusion: Children with chronic MSK pain are undiagnosed for greater than 12 months and utilize multiple health services, undergo diagnostic testing and use several medications resulting in high costs even before diagnosis. Our estimate is likely an underestimate as our data only represented data from one site when many of children are being seen in multiple health care systems. Healthcare providers must be attuned to this diagnosis in patients with a long history of chronic MSK pain, high pain scores, and who are seen frequently by healthcare professionals.

Session Title: Pain – Basic and Clinical Aspects - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Background/Purpose: Osteoarthritis pain remains a significant health problem due to a growing elderly population and the need for newer effective medical therapies. Osteoarthritis pain does not correlate well with radiographic severity, and loss of function in patients with osteoarthritis may result from pain, from altered biomechanics or from toxicity of analgesics. Previous studies of mice with osteoarthritis demonstrated evoked pain behaviors but no consistent change in gait or wheelrunning. Age may also alter pain behaviors in mice with arthritis. In order to better define the relationship between osteoarthritis, pain and function, we measured different types of pain behaviors in mice with osteoarthritis at a uniform age as a function of duration of arthritis and in response to different analgesic treatments.

Methods: Chronic non-inflammatory arthritis was produced by intra-articular (IA) injection of 10 µl collagenase (COL) (10IU) into the left knee of C57BL6 male mice 4 or 6 weeks prior to pain behavior testing using evoked pain score (EPS) and automated dynamic weight bearing (ADWB) device. EPS was a tally of fights and vocalizations/min with knee palpation at 15.6 psi. Percent weight and time on each limb was measured with ADWB apparatus (Bioseb, Vitrolles, France). IA vanilloids resiniferatoxin (RTX) or capsaicin (CAP) (10µl of 0.001%RTX or 0.01% CAP) were given 7 days prior to pain testing. IA botulinum toxin A (BTX) (10µl 0.02 IU) was injected 3 days before testing. Mice underwent pain behavior testing either 4 weeks or 6 weeks after COL injection. All mice were 12 weeks old at the time of testing.

Results: Arthritis pain behavior was low in naïve mice - EPS (0.57) and ADWB proportions for weight (40.9%) and time (97.4%) were normal. IA COL arthritis significantly increased EPS (4.0) after 4 weeks of arthritis and but had very little effect on ADWB for weight (39.7%) and time (98.0%). All IA therapies normalized EPS in arthritic mice. Forepaw compensatory weight bearing increased only from 9.3% in naïve mice to 10.9% in COL arthritic mice at 4 weeks (NS). However after 6 weeks of COL induced arthritis, the EPS was not significantly different from naive (0.8). ADWB measures for left hind-limb weight-bearing at 6 weeks dropped (to 37.6%) and time on the limb was reduced (to 95.2%). These differences were not statistically significant. However there was an increase in forepaw weight-bearing. After 6 weeks COL mice placed 15.8% weight on the forepaws (p=0.02). Both IA RTX and IA CAP normalized this compensatory forepaw weight-bearing in the 6 week arthritic mice.

Conclusion: IA COL monoarthritis increased evoked pain behaviors in mice after 4 weeks but had little effect on spontaneous pain measured by ADWB at this timepoint. After 6 weeks of chronic arthritis, EPS measures were no longer increased, but compensatory forepaw weight-bearing was increased significantly. This compensatory weight-bearing normalized after treatment with IA neurotoxin treatment. These results suggest that both neuroadaptive and behavioral adaptive mechanisms may be at play. Normalization of weight-bearing with analgesia suggests that alterations in weight-bearing are not just due to mechanical factors.

Session Date: Sunday, November 13, 2016

Session Title: Pain – Basic and Clinical Aspects - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic temporomandibular disorders develop with persistent pain in other areas of the body in some patients, suggesting a predisposition to a generalized pain phenotype. The objective of our study was to evaluate whether there is an association between temporomandibular joint (TMJ) pain, and pain in other joints, or a generalized pain phenotype.

Methods: The Osteoarthritis Initiative is a cohort study of participants with or at risk for knee osteoarthritis. TMJ pain was assessed via self-reported pain or aching across the face, cheek, or jaw, in the past 30 days at the 4-year visit. Logistic regression was used to estimate the association between recent TMJ pain and knee pain on most days of the month in the past 30 days, as well as hand pain and hip pain. Depression was ascertained using the Center for Epidemiologic Depression Scales (CES-D), and the number of reported body areas with pain was assessed using a homunculus (see figure legend for locations). Mean CES-D scores and number of body areas with pain were compared between participants reporting recent TMJ pain and those without using a two-sample t-test. All analyses were cross-sectional (n=3,852), and due to previously reported sex differences in TMJ pain, all analyses were conducted sex-stratified.

Results: Participants had a mean age of 61 years (SD 9.1), with 80% White and 17% African American. Recent TMJ pain was reported by 11% of females (n=2,225) and 5% of males (n=1,627). Females with TMJ pain had significantly higher odds of reporting knee pain (OR=1.40 [95%CI: 1.14, 1.72]), hand pain (OR=1.81 [95%CI: 1.39, 2.37]), and hip pain (OR=2.13 [95%CI: 1.62, 2.79]), compared to females without TMJ pain; and while the odds of knee, hand, and hip pain was higher among males with TMJ pain compared to males without TMJ pain, the associations were not significant (OR=1.23 [95%CI: 0.86, 1.77]; OR=1.37 [95%CI: 0.81, 2.32]; OR=1.26 [95%CI: 0.73, 2.17], respectively). Females reporting TMJ pain had higher levels of depression on average compared to those without TMJ pain (9.2 vs 7.0; difference of 2.2 [95%CI: 1.1, 3.4], p=0.0002) though we did not observe a significant difference among males (7.9 vs 6.2; difference of 1.7 [95%CI: -0.5, 3.8], p=0.13). Both females and males with TMJ pain had significantly higher mean counts of body pain areas compared to those without TMJ pain (4.2 vs 2.5; difference of 1.7 [95%CI: 1.3, 2.2], p< 0.0001, and 2.9 vs. 1.8; difference of 1.1 [95%CI: 0.4, 1.8], p=0.004, respectively; Figure 1)

Conclusion: Males and females reporting recent TMJ pain also reported pain in more body areas than those who did not have TMJ pain, suggesting a generalized pain phenotype. Females with TMJ pain were significantly more likely to have knee, hand, and hip pain. The management of patients with TMJ pain and pain in other joints may require a broader pain assessment and treatment strategies tailored to address a generalized pain phenotype.

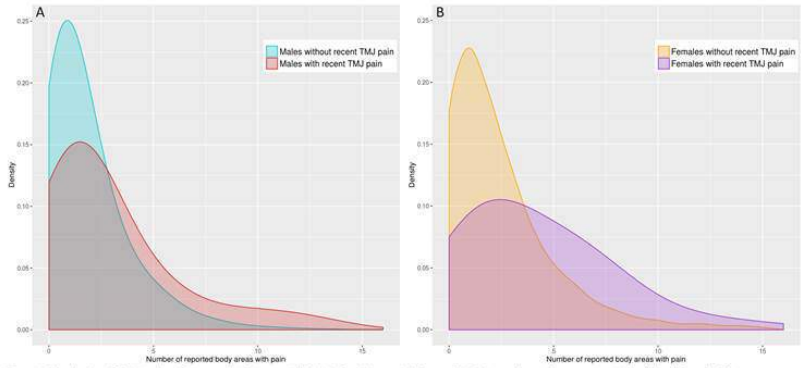

Figure 1. Distribution of the Number of Reported Body Areas with Pain in Participants with Recent TMJ Pain vs. those without, among Males (A) and Females (B).
The number of reported body areas with pain included: right and left shoulders, right and left elbows, right and left wrists, right and left hands, right and left ankles, right and left feet, neck, four locations on the back, and one area for other, for a total of 18 possible body areas.

Session Title: Pain – Basic and Clinical Aspects - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Anxiolytic Effects of the Novel Alpha-2-Delta Ligand Mirogabalin (DS-5565) in Sluka Model, an Experimental Animal Model of Fibromyalgia Yuki Domon[a], Naohisa Arakawa[a], Hiroyasu Murasawa[b], Hiroyuki Kobayashi[b], Kensuke Saeki[b], Yutaka Kitano[a] [a] Biological Research Laboratories, Daiichi Sankyo Co., Ltd., Tokyo, Japan [b] Hashima Laboratory, Nihon Bioresearch Inc., Gifu, Japan

Background/Purpose: Mirogabalin (DS-5565) is a novel ligand of the alpha-2-delta subunit of voltage-gated calcium channels. Mirogabalin possesses unique binding characteristics to alpha-2-delta subunits, and potent and long-lasting analgesic effects in fibromyalgia models and neuropathic pain models. Phase III clinical trials of mirogabalin in patients with fibromyalgia, diabetic peripheral neuropathic pain and postherpetic neuralgia are ongoing. Fibromyalgia is often associated with anxiety and depressive symptoms. In the present study, we investigated the anxiolytic effects of mirogabalin in intramuscular acidic saline injection model (Sluka model) in rats, an experimental animal model for fibromyalgia.

Methods: Male SD rats received two repeated intramuscular injections of acidic saline (pH 4.0) into the gastrocnemius muscle. After development of hyperalgesia, the animals received the test compound orally and the anxiolytic effects were determined in open field test and elevated plus maze test at 2 h after administration. Dose levels of mirogabalin were set at 3 and 10 mg/kg, and the normal and model control groups received vehicle (distilled water).

Results: Sluka model rats showed mechanical hyperalgesia demonstrated by decreased pain thresholds to von Frey filaments. In the open filed test, Sluka model rats significantly preferred the wall-area to the central-area compared with normal rats. In the elevated plus maze test, Sluka model rats exhibited significant decreases in the number of entries and time spent in the open-arm, and significant increases in time spent in the closed-arm. Taken together, Sluka model rats showed anxiety-related behaviors. A single oral administration of mirogabalin (3 and 10 mg/kg) significantly alleviated and normalized above anxiety-related behaviors in both tests.

Conclusion: Sluka model rats showed anxiety-related behaviors in open field test and elevated plus maze test. Mirogabalin alleviated the anxiety-related behaviors in Sluka model rats. Mirogabalin may provide effective anxiety relief for patients with fibromyalgia, as well as pain relief.

Figure 1 Effects of mirogabalin on anxiety-like behavior in open-field test in Sluka model rats.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Pain – Basic and Clinical Aspects - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Joint pain is the primary reason individuals with arthritis seek medical care. Unfortunately, arthritic pain is difficult to treat and current treatments are fraught with undesirable side effects. It is commonly thought that pain is evoked by inflammation and / or joint damage, leading to a peripheral and central sensitization. However, the severity of pain often does not correlate well with these factors. We hypothesize that, while inflammation leads to sensitization of joint terminals, over time, changes occurring within the joint itself may contribute to the ongoing pain state. Therefore, our goal was to characterize the time-course of changes occurring within cortical and trabecular bone of the femur, tibia, and ankle joint of arthritic mice using μCT analysis. Further, we examined the ankle joint for the presence of nerve sprouting of sensory and sympathetic nerve fibers as it has been shown that this sprouting may contribute to ongoing pain in other musculoskeletal diseases.

Methods: Using the K/BxN serum transfer model of arthritis, we have shown that male C75Bl/6 mice develop clinical signs of arthritis accompanied by a robust tactile allodynia. Importantly, male, but not female mice, show tactile allodynia persisting beyond the resolution of inflammation. For this reason, bones of arthritic male and female mice were analyzed on days 0, 10, and 28. We quantified arthritis-induced changes in the femur, tibia, talus, and calcaneus. For trabecular bone, we determined trabecular bone mineral density (tBMD), percent bone volume (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), trabecular separation (Tb.Sp), the degree of anisotropy (DA); while for cortical bone, BMD (cBMD), cortical area (Ct.Ar), and cortical thickness (Ct.Th) were examined. Following μCT analyses, bones were decalcified, processed for immunohistochemistry as frozen sections and immunostained with anti-CGRP (peptidergic C-fibers), anti-NF200 (myelinated sensory fibers), anti-GAP43 (sprouted nerve fibers), anti-TH (sympathetic nerve fibers), and anti-CD68 (macrophages).

Results: In the distal femur and proximal tibia, arthritic mice showed decreased tBMD, BV/TV, Tb.N at day 28 as compared to age-matched naive mice. There were no major changes in the cortical bone of the femoral or tibial mid-diaphyses. In the talus, there were no significant changes in any trabecular bone parameters in female or male arthritic mice as compared to naïve. In the calcaneus, tBMD and BV/TV are significantly decreased in male and female arthritic animals as compared to naïve, with females showing greater bone loss at day 28. While there was no difference in Tb.Th or Tb.Sp, we found a significant decrease in Tb.N over time in arthritic females. In addition to these changes in bone parameters, a semi-quantitative analysis revealed greater density of CGRP+, TH+, NF200+, and GAP43+ innervation in ankles of male mice at day 28, relative to female animals.

Conclusion: Together, these results suggest that K/BxN serum transfer-induced arthritis results in sex-dependent changes in tactile allodynia, which are reflected in underlying differences in peripheral sensory innervation, but not bone loss.

Session Title: Pain – Basic and Clinical Aspects - Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The Patient Reported Outcomes Measurement Information System(PROMIS) is a publicly available assessment system offering multiple measures to assess physical, mental and social health. PROMIS measures are developed based on a rigorous mixed-methods approach, and modern measurement methods, including use of item response theory (IRT). Measures are developed for use across a spectrum of chronic conditions. The purpose of the project is development and calibation of instruments to measure aspects of pain in children as part of PROMIS. PROMIS Pediatric Pain Interference, Pain Behavior and Pain Quality measures were previously developed. The primary objective of this study is to evaluate the dimensionality and validity of the PROMIS Pediatric Pain Intensity Scale.

Methods: The initial pool of the pediatric PROMIS pain related items were developed based on literature reviews, clinician interviews, and qualitative research with patients with pain. In addition to the three item banks previously developed to assess various dimensions of pain in children, four items were identified as pain intensity items measuring worst pain, usual pain, average pain and current pain on a 5-point likert scale. We conducted confirmatory factor analysis (CFA) to assess dimensionality of these 4 items and looked correlations of the pain intensity scale with other pediatric PROMIS pain scales (pain interference and pain behavior), as well as a legacy pain intensity numeric rating scale.

Results: The sample populations included pediatric patients with juvenile idiopathic arthritis, fibromyalgia, and sickle cell disease, ages 8 to 18 recruited from outpatient hospital clinics in Ohio, Pennsylvania, and Georgia for a total sample size of N = 447. CFA shows good fit of the four items to a unidimensional model: comparative fix index (CFI)=1.00, Tucker-Lewis index (TLI)=1.00, and root mean square error of approximation (RMSEA)=0.013. The IRT slope parameters of the four items were 1.55, 2.06, 1.51, and 1.15. The category threshold parameters ranged from -2.92 to 2.97. Correlation with legacy pain intensity numeric rating scale is r = .94. Correlations with PROMIS pain interference short form is r = .75 and with PROMIS pain behavior short form is r = .74. “Usual” and “average” pain items provided similar information. Based on cognitive debriefing with study participants, the item worded with reference to “usual pain” was preferred over the“average pain” item. The measure perfomed well after exclusion of the “average pain” item, yielding a three item scale.

Conclusion: The pediatric PROMIS pain intensity scale provides a short, three-item unidimensional measure of pain and demonstrates convergent validity with other PROMIS pain measures. The pediatric PROMIS pain intensity scale provides a measure of self-reported pain intensity that can be used in pediatric clinical research or clinical practice settings.

Session Title: Pain – Basic and Clinical Aspects - Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

ABSTRACT

Background/Purpose: Among the symptoms of Rheumatoid Arthritis (RA), pain is often regarded as a critical factor related to quality of life (QoL) by patients, and the fact of having pain confers subjects with RA a 5 year mortality twice as high when compared with RA patients without pain (1,2). There are different causes of pain in RA patients, and the level of compromise in the QoL may vary among them too (3). The aim of this study is to identify different pain profiles in association to the QoL in Colombian RA patients.

Methods: This was a cross-sectional study involving 1395 patients with diagnosis of RA, all of whom had a registered EuroQoL, MDHAQ, CDAI and DAS-28 at the time of their involvement to a rheumatology specialized center, and a complete patient inclusion form which included data on disease characteristics, comorbid conditions and current treatment. A mixed-cluster analysis based on multivariate descriptive methods such as multiple factor analysis and k-means cluster analysis was done to summarize sets of related variables with strong associations and common clinical context. The variables used for the cluster analysis were the five dimensions of the EuroQoL, the Visual Analog Scale of the EuroQoL and the EuroQoL result (4).

Results: Four clusters were identified with varying degrees of pain and compromise on QoL (see figure 1). Due to the fact that cluster 2 was characterized by more severe pain and discomfort without severe compromise in the other dimensions, it was used as the reference group. When compared with the patients with the least compromise of their QoL as well as pain (cluster 4) this patients were identified to be older, whit a higher proportion of females, and they had a lower education level. Regarding treatment, this patients used significantly less methotrexate, and significantly more glucocorticoids and biologic therapy. When evaluating comorbid conditions, Cluster 2 had significantly more Fibromyalgia, Cardiovascular Disease and Diabetes, and they also had a higher CDAI and DAS-28. Finally, regarding disability, we identified that cluster 2, in spite of its association with severe pain, was the one with the second best disability profile according to the MDHAQ. All the results mentioned above were statistically significant.

Conclusion: In spite of the fact that the results of a study come from a single population, they underlie the importance of identifying different pain profiles in RA patients which may benefit from specific therapies. These findings also highlight the importance of personalized medicine, which may translate into better outcomes for our patients.

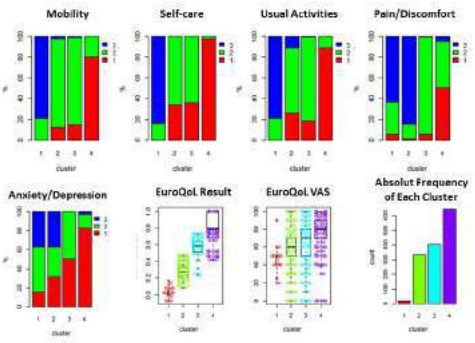

Figure 1. *Profile of each group with respect to the original variables used to build the groups.* Red bars represent the percentage of individuals in each cluster with no compromise for the given dimension, green the percentage of subjects with moderate compromise and blue the percentage of subjects with severe compromise.

Session Title: Pain – Clinical Aspects - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The inflammatory response has an initiation phase and a resolution phase. Ideally, inflammation leads to complete resolution that enables tissue healing and a return to previous healthy condition. However, if it is left unresolved, the surrounding tissues can be damaged over time. Chronic unresolved inflammation has been linked to many chronic diseases, and clinically often manifests as pain in joint-related conditions. During the resolution phase, specialized pro-resolving mediators (SPMs) are produced from polyunsaturated fatty acids at the affected tissue site, orchestrating the resolution activities and expediting the return to homeostasis. Some individuals may not produce desirable levels of SPMs —due to lifestyle behaviors, dietary choices, age, or health status—and the inflammatory response is left unresolved. The objective of this study was to observe the effect of a natural product (LM-O3) containing standardized SPMs on select inflammatory biomarkers and on overall well-being assessed by multiple questionnaires in subjects with OA, RA, or other chronic inflammatory conditions.

Methods: The 8-week, IRB-approved, open-label case series was conducted at 6 clinical sites from where participants were recruited. Main inclusion criteria included individuals with (1) chronic pain lasting ≥ 3 months, (2) OA, RA or other joint-related conditions, or (3) fibromyalgia. LM-O3 contained fractionated lipid concentrate from natural sources standardized to 2 SPMs (18-hydroxyeicosapentaenoic acid and 17-hydroxydocosahexaenoic acid). After baseline assessment, all participants consumed 750 mg of LM-O3 as 6 softgels once daily taken with a lipid-containing meal. After Week 4, the dose of LM-O3 was titrated up to 1000 mg as 8 softgels once daily. Participants returned to the clinic at Weeks 4 and 8 for clinical evaluation (biochemical measurements, clinical symptomology and quality of life assessments relevant to clinical condition, compliance, and adverse events). Changes from baseline to Week 4 and Week 8 were analyzed separately using two-sided paired t-test.

Results: Thirty-four participants completed the study. Levels of hs-CRP were significantly reduced from 9.2±15.8 mg/L (mean±SD) at baseline to 5.2±9.5 mg/L at Week 4 (p=0.031) and to 6.3±10.6 mg/L at Week 8 (p=0.007). PGE_2 levels were also significantly reduced from 590.6±802.0 pg/mL at baseline to 350.6±334.3 pg/mL at Week 8 (p=0.039). Total scores on the Brief Pain Inventory, the American Chronic Pain Association Quality of Life Scale, and other subject-reported scales reflective of clinical diagnoses were significantly reduced at Week 4 and 8 compared with baseline. Results at the Week 4 and 8 assessments were comparable. No serious adverse events were reported. A subgroup analysis of 14 subjects diagnosed with OA or RA showed comparable results, including reduced pain and improved activities of daily living.

Conclusion: A SPM-containing natural product exerted beneficial effects on inflammatory biomarkers and reduced the severity of pain as well as the impact of pain on activities of daily function in subjects with health conditions associated with chronic unresolved inflammation.

Session Title: Pain – Clinical Aspects - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In individuals with RA, catastrophizing is associated with poor pain outcomes. It is not known whether catastrophizing can be altered by treating RA with DMARDs, or if pain can predict changes in catastrophizing associated with DMARD treatment. The objective of this analysis was to identify changes in catastrophizing associated with DMARD therapy and to examine associations between baseline pain and subsequent catastrophizing levels. We also analyzed the opposite relationship to determine if baseline catastrophizing is associated with future pain.

Methods: We examined baseline (before DMARD initiation) and follow-up data (12-24 weeks after DMARD initiation) from the first 115 subjects in a prospective cohort of RA patients with active disease starting or switching DMARDs. Pain was measured by the Numeric Rating Scale (NRS) from 0-10, and pain catastrophizing was measured by the Pain Catastrophizing Scale from 0-52. We used paired t-tests to determine if pain catastrophizing changed over 12-weeks of DMARD treatment. Multivariable linear regression models were used to examine the association between: a) baseline pain catastrophizing as the independent variable and 12-week pain intensity as the outcome, and b) baseline pain intensity as the independent variable and 12-week pain catastrophizing as the outcome. These models controlled for age, gender, disease duration, swollen joint count and depression. In addition, baseline pain intensity was included as a covariate in the model examining the relationship between baseline catastrophizing and 12-week pain, and baseline catastrophizing was included in the model examining the relationship between baseline pain and 12-week catastrophizing.

Results: In this cohort of RA patients, median age was 54.9 years, and 78.1% were women. 38.8% started a non-biologic DMARD, and 61.2% started a biologic DMARD. Both pain and catastrophizing decreased after 12-weeks, from 5 to 3 on a 10-pt NRS (P <0.0001) and from 16 to 10 on the 52-point Pain Catastrophizing Scale (P <0.0001). High baseline pain was associated with greater catastrophizing at 12 weeks (β=0.92, p=0.04) (Figure). Baseline catastrophizing was not associated with pain at 12 weeks (β=0.02, p=0.36).

Conclusion: These findings demonstrate that after initiating a new DMARD, pain catastrophizing decreases in RA patients, suggesting that catastrophizing may have state-like properties, which can be altered by DMARD treatment. However,

despite DMARD treatment, individuals with high baseline pain had higher pain catastrophizing at 12-weeks, compared to those with low baseline pain. These findings suggest that aggressive initial treatment of pain may be useful in preventing future catastrophizing.

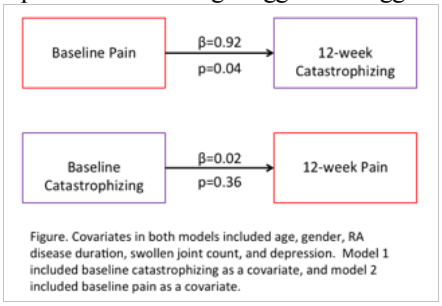

Figure. Covariates in both models included age, gender, RA disease duration, swollen joint count, and depression. Model 1 included baseline catastrophizing as a covariate, and model 2 included baseline pain as a covariate.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The goal of this project is the identification of informative synovial biomarkers to predict which children with oligoarticular juvenile idiopathic arthritis (JIA) will have a persistent course, with no more than 4 involved joints, vs those who will have an extended course, with a cumulative total of ≥5 affected joints after the first 6 months of disease.

Methods: As part of a separate ongoing IRB approved protocol, remnant synovial fluid was obtained from patients undergoing medically indicated arthrocenteses. All patients satisfied ACR classification criteria for JIA. Using our clinical database, JIA samples were separated into two groups: (1) oligoarticular JIA with persistent course (PR), (2) oligoarticular JIA with extended course (E). All samples were from steroid-naïve joints and most samples from E were obtained prior to extension. Primary cultures of fibroblast-like synoviocytes (FLS) were established for each subject. RNA from cultured passage 3-6 FLS were isolated, amplified and hybridized to Affymetrix Human GeneChips using the Affymetrix protocol. Expression values were determined with GC-RMA. Global gene expression of FLS from 12 PR and 11 E samples were obtained. Data was filtered for log2 expression >4 in all samples of either E or PR, then for absolute value of 1.5-fold change. Bioconductor package Linear Models for Microarray Analysis (LIMMA) revealed 83 probesets with statistically significant differential expression between E vs PR FLS (7% false discovery rate), shown in heatmap.

Results: Hierarchical clustering of the 83 probesets revealed samples from the different courses cluster together, with most of the PR to the left of the heatmap. Importantly, the all of the E were taken from the very first sample available,

which preceded extension in the majority of patients, highlighting that there are detectible differences in the gene expression of the FLS early in the course in the patients whose disease is destined to extend. Of these 83 probesets, 9 corresponded to genes with secreted proteins. We performed mathematical modeling with linear discriminant analysis (LDA) on these 9 genes to reveal 6 genes (KLHL13, MAMLD1, ANKRD44, CD14, HSPBAP1, and MBP) which could correctly predict group, E or PR, 100% of the time using leave-one-out cross validation. ELISA was used to confirm expression of these secreted proteins in synovial fluids.

Conclusion: We were able to demonstrate differential gene expression in FLS from JIA patients who remained PR vs those who were destined to extend, demonstrating detectible difference early in disease which may be useful for prediction. The differentially expressed genes, especially for secreted proteins, provide a starting point for development of biomarkers to distinguish between PR and E JIA using aspirated synovial fluid.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lack of specific diagnostic, prognostic or response to treatment markers in juvenile idiopathic arthritis (JIA) leads to study new potential markers, as serum calprotectin (S100A8/A9). This heterodimer, part of the S100 protein family, is directly released by activated leukocytes during inflammation, serves as an agonist of TLR4, activates endothelial cells and stimulates transendothelial migration of phagocytes at the site of inflammation. Increased serum calprotectin levels have been described in many inflammatory chronic diseases.To assess the use of serum calprotectin (sCal) as a marker of disease activity and its monitoring, as a classification and prognosis tool of response to treatment or risk of flares in patients with JIA.

Methods: Ninety-five patients with JIA from the CAP48 multicentric cohort were included in this study (mean age ± SEM: 14,3 ± 0,6 years; F/M sex ratio: 1,4/1; mean disease duration: 2,1 ± 0,6 and 5,0 ± 1,4 years for the newly-diagnosed and well-established JIA respectively), as well as 11 healthy controls (mean age ± SEM: 26,2 ± 0,2; F/M sex ratio: 1,7/1) obtained from the biobank of the Rheumatology department of the Erasme hospital. Enzyme-linked immunosorbent assay (ELISA) method was used to quantify sCal, with a commercial kit. This ELISA had first been adjusted in order to assess the quality of the detection method in sera matrix with spiking recoveries and to elaborate internal positive controls with sera of patients with active Crohn's disease.

Results: Patients with inactive JIA had a 4-fold increased level of sCal (6.555 ng/mL) compared to healthy controls (1.737 ng/mL), while patients with active JIA had themselves a 2-fold increased level of sCal (11.403 ng/mL) compared to patients with inactive disease. sCal was found to be slightly correlated to the Tender Joint Count and CHAQ (r/p = 0,2/0,04 and 0,3/0,006 respectively), moderately with the CRP (r/p = 0,2/0,05 and 0,5/0,04 for abnormal values) and strongly with the ESR (r/p = 0,8/0,0003. As for the CRP, sCal could differentiate forms with active oligoarthritis (persistent or extended oligoarthritis or enthesitis-related arthritis) (7.515 ng/mL) from polyarthritis (14.714 ng/mL) or systemic forms (26.976 ng/mL). However, sCal brought an added value compared to the CRP as a prognosis marker. Indeed, patients with active disease had higher serum levels if they were going to be future good-responders (pediACR> 30) at 6 months following the sample test, while patients with inactive disease had higher serum levels if they were going to flare up to 3 to 9 months following the sample test.

Conclusion: This study confirms potential uses of serum calprotectin as a prognosis marker of response to treatment and risk of flares. However, larger studies designed to evaluate sCal in JIA are needed. Attention should also be called in future studies to assess the possible role of sCal in the differential diagnosis of fevers of unknown origin in children.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease of childhood and an important cause of disability. Its cause remains unknown, but likely includes complex interactions between genes and environmental exposures resulting in dysregulation of the immune system. TNF-α is a cytokine with an important role in inflammation and immune function. Several single nucleotide polymorphisms (SNPs) have been identified within the region of the TNF-α gene but only very small minority have proven functional consequences and were associated with JIA susceptibility. The aim of this work was to evaluate the clinical significance of serum levels of tumor necrosis factor alpha (TNFα) and -308 A/G promoter polymorphism in JIA patients and find any association to the subsets, clinical and laboratory features, disease activity and damage as well as functional disability.

Methods: Forty-eight JIA children and 30 controls were included in the present study. Juvenile arthritis disease activity score in 27 joints (JADAS-27) was calculated, juvenile arthritis damage index (JADI) assessed and Childhood Health Assessment Questionnaire (CHAQ) to measure the functional status. *Serum TNF-α* was assayed by ELISA and *gene (-308) promoter polymorphism* determined by polymerase chain reaction.

Results: The 48 JIA children (mean age: 11.5±2.8 years) were 13 systemic, 17 oligoarticular and 18 polyarticular onset. The serum TNF-α was significantly higher in patients (90.4±6.3 ng/ml) compared to control (3.5±2.6 ng/ml) ($p<0.0001$) with a tendency to be higher in the polyarticular subtype. All controls had TNF-α -308GG alleles. The frequency of GG genotype tended to be higher in systemic onset compared to oligoarticular and polyarticular subtypes. The serum TNF-α significantly correlated with JADAS-27 ($r=0.32, p=0.03$) and CHAQ ($r=0.37, p=0.01$) and negatively with the presence of GG alleles ($r=-0.48, p=0.001$). The GG alleles were significantly negatively associated with C-reactive protein ($r=-0.32, p=0.03$) with a tendency to negatively correlate with JADAS-27, CHAQ and JADI-extrarticular ($r=-0.28, p=0.06$; $r=-0.25, p=0.09$ and $r=-0.25, p=0.09$ respectively).

Conclusion: There is evidence of a possible influence of the −308 SNP promoter position on the production of TNF-*α*, the severity of JIA which may consequently influence the response to anti-TNF-*α* treatment.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The classical inflammatory markers, C-reactive protein and erythrocyte sedimentation rate often do not adequately reflect JIA disease activity. Our objective was to assess the serum levels of DKK1, OPG, SOST, RANKL, greline, BAFF, leptine, APRIL, ACPA, CTD, RF IgA and IgM, INFy, IL1β, IL6, IL10, IL17 and TNF in patients with JIA, and detect their relation to disease activity.

Methods: Serum levels of selected cytokines were determined by ELISA in JIA patients registered in Reuma.pt. The Juvenile Arthritis Disease Activity score in 27 joints (JADAS27) and Childhood Health Assessment Questionnaire (CHAQ) were calculated. Multivariate linear regression was used for analyzing the relation between the potential serum biomarkers levels and JADAS27 and CHAQ, adjusting for gender, body mass index, age, disease duration and JIA categories.

Results: 281 patients, 66% female, mean age 17.3±10 years and mean disease duration 10.9±8.7 years. Ninety-eight were persistent oligoarticular (OligoP), 48 extended oligoarticular (OligoE), 45 polyarticular RF negative (poly RF-), 26 Poly RF+, 22 systemic, 28 enthesitis-related arthritis (ERA) and 14 psoriatic arthritis. The global analysis including all JIA patients revealed that APRIL, RF IgA and IL17 levels were correlated with JADAS27 (β=0.14, p=0.02; β=0.12, p=0.006; β=0.36, p=0.014; respectively) and IL6 was inversely correlated with JADAS27 (β=-0.06, p=0.03). Regarding CHAQ, we have found that APRIL, INFγ and TNF were correlated with CHAQ (β=0.01, p=0.001; β=0.003, p=0.02; β=0.003, p=0.04; respectively). In the separate analysis by JIA category, in OligoP, RF IgM, INFy, IL1β, and TNF were correlated with CHAQ (β=0.007, p=0.005; β=0.004, p=0.019; β=0.008, p=0.033; β=0.007, p=0.038; respectively), and, on the other hand, IL10 was inversely correlated with CHAQ (β=-0.007, p=0.023). In OligoE, RF IgA levels were correlated with JADAS27 and CHAQ (β=0.91, p=0.016; β=0.05, p=0.037). In patients with Poly RF+ the serum levels of OPG and ACPA were correlated with JADAS27 (β=0.06, p=0.024; β=0.03, p=0.05), and OPG was also correlated with CHAQ (β=0.004, p=0.032). In PolyRF- patients, DKK1 was correlated with JADAS27 (β=0.014, p=0.047), and serum levels of APRIL and RF IgM were associated with CHAQ (β=0.03, p<0.001; β=0.03, p<0.001). In systemic JIA, CTD lev els were correlated with JADAS27 (β=82.67, p=0.002), and DKK1 was inversely associated with JADAS27 (β=-0.009, p=0.035). In ERA category we have found leptin was correlated with JADAS27 and CHAQ (β=0.9, p=0.005; β=0.05,

p=0.029), and ACPA with CHAQ (β=0.005, p=0.031). Lastly, for psoriatic arthritis patients, APRIL and RF IgA levels were correlated with CHAQ (β=0.17, p=0.046; β=0.13, p=0.008), and DKK1 and SOST were inversely correlated with CHAQ (β=-0.0003, p=0.037; β=-0.001, p=0.030).

Conclusion: Our data underline the heterogeneity of different juvenile idiopathic arthritis categories. Interestingly, we have identified potential biomarkers of disease activity/functional status in JIA categories. Larger studies are needed in order to validate these results.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adalimumab (ADA) is a tumor necrosis factor (TNF) inhibitor used for treatment of chronic immune diseases. The safety of ADA treatment in pediatric patients (pts) is particularly important since prolonged treatment for these conditions is often required. The objective of this study is to evaluate the safety of ADA, alone or in combination with concomitant therapy, in pediatric pts with polyarticular juvenile idiopathic arthritis (pJIA), enthesitis-related arthritis (ERA), psoriasis (Ps), and Crohn's disease (CD).

Methods: Safety data from 6 clinical trials and their open-label extension studies were analyzed. Pts treated for pJIA (NCT00048542, NCT00775437, and NCT00690573) and ERA (NCT01166282 [interim week-52 data]) received ADA 24 mg/m^2 body surface area every other week (eow) or 20 mg eow (<30 kg) to 40 mg eow (≥30 kg). Pediatric pts treated for Ps (NCT01251614) received ADA 0.4 mg/kg (up to 20 mg) or 0.8 mg/kg (up to 40 mg) at week 0, then eow from week 1. Pediatric pts treated for CD (NCT00409682) received open-label ADA induction therapy (160 mg and 80 mg at weeks 0 and 2, respectively, if ≥40 kg; 80 mg and 40 mg if <40 kg), followed by double-blind maintenance dosing (high dose: 40

mg eow if ≥40 kg or 20 mg eow if <40 kg at week 4; low dose: 20 mg eow if ≥40 kg or 10 mg eow if <40 kg at week 4); weekly dosing was allowed for disease flare at week 12 or later; pts received high-dose eow or weekly ADA during an open-label extension (NCT00686374). Events (E) per 100 pt-years (PY) were calculated using adverse events (AEs) reported after the first ADA study dose through 70 days after the last study dose.

Results: The analysis included 577 pediatric pts, representing 1440.7 PY of ADA exposure **(Table)**. Over 90% of pts across indications reported treatment-emergent AEs. Common AEs were headache (13.6, 46.9, and 23.4 E/100 PY for pJIA and ERA, Ps, and CD, respectively), nasopharyngitis (12.4, 58.4, and 15.2 E/100 PY, respectively), and upper respiratory tract infection (30.2, 24.7, and 14.8 E/100 PY, respectively). The rates of serious AEs (E/100 PY) were 13.5 for pts with pJIA and ERA, 7.4 for pts with Ps, and 32.2 for pts with CD. One death was reported from an accidental fall (pt with Ps). There were no reports of malignancies, demyelinating disorders, pulmonary embolism, reactivation of hepatitis B, Stevens-Johnson syndrome, or erythema multiforme.

Conclusion: The safety profile of ADA in pediatric pts with pJIA, ERA, Ps, or CD was similar across indications, and no new safety signals specific to the pediatric population were identified. **Table. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Enthesitis-related arthritis (ERA) is a JIA category primarily affecting entheses and peripheral joints but can involve the axial skeleton. Disease activity and structural change can adversely affect long-term physical function and quality of life of ERA patients (pts)**.** Adalimumab (ADA) has been previously demonstrated to be effective in children with polyarticular JIA and ERA. Objective of this study is to evaluate the persistence of efficacy and long-term safety of ADA compared to placebo (PBO) in children and adolescents with ERA.

Methods: This is a phase 3, multicenter, randomized, double-blind (DB) study in ERA pts aged ≥6-<18 years (yr) at baseline (BL). Methods have been previously described. Pts were randomized 2:1 to receive blinded ADA (24 mg/m^{2}BSA up to 40 mg every other week (wk) [eow]) or PBO for 12 wks followed by open-label (OL) ADA eow for up to an additional 192 wks. Primary endpoint was % change from BL in number of active joints with arthritis (AJC) at wk 12. Secondary variables assessed included enthesitis count (EC), tender (TJC) and swollen joint (SJC) counts, and American College of Rheumatology (ACR) Pediatric (Pedi) 30/50/70 responses. Kaplan Meier analysis was used to determine time to achieve SJC=0, TJC=0, and EC=0 from time of first ADA injection.

Results are summarized through 156 wks of treatment for efficacy and 204 wks for safety. Safety was assessed in terms of adverse events (AE). Results: 46 pts were randomized (ADA, n=31; PBO, n=15). No pts discontinued during DB period; 7 pts early escaped to OL ADA. 17 pts discontinued from OL period prior to wk 204 including 4 pts achieving remission. Percentage change from BL at wk 12 in AJC was greater in ADA group vs. PBO (-62.6±59.5 vs -11.6±100.5, *P*=0.039) with response maintained with continued ADA therapy through 156 wks (-88.3±27.7). During treatment with ADA 95.7%, 89.1%, and 89.1% of pts achieved SJC=0, TJC=0 and, EC=0, respectively. Median time from first dose of ADA to achieving SJC=0, TJC=0, and EC=0 was 41, 108, and 56 days, respectively. At wk 12 ACR Pedi70 was statistically significant in favor of ADA while EC, TJC, SJC, and ACR Pedi30/50 showed numerically greater, but not statistically significant improvement in favor of ADA with responses maintained through wk 156. During DB period AE incidence rates were similar [ADA/PBO (%)]: any AE (67.7/53.3), serious AE (3.2/0), and infectious AEs (29.0/20.0). Among pts who received at least 1 dose of ADA, any AE, serious AEs, infectious AEs, and serious infections were reported in 100%, 21.7%, 89.1%, and 8.7% respectively. Ten pts reported a total of 19 serious AEs through 204 wks of treatment. No deaths or malignancies were reported.

Conclusion: ADA reduced the signs and symptoms of ERA at wk 12 and efficacy was sustained through 156 wks. Safety profile observed through 204 wks of treatment in pediatric pts with ERA was consistent with that observed in children

aged ≥2 yrs treated for polyarticular JIA.

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Selective peripheral B-cell depletion by rituximab (RTX) is a relatively recent advance in rheumatic diseases. RTX is an approved treatment in RA. Although very few studies have examined RTX in JIA, evidence in adults for its better effectiveness in seropositive compared to seronegative RA, may have led to reluctance for the use of RTX in RF negative poly-articular JIA. The aim of this study was to describe the use and outcomes among children with

JIA, including RF negative polyarticular subtype treated with RTX in the UK.

Methods: The UK Biologics for Children with Rheumatic Diseases (BCRD) study is a prospective register capturing information on JIA patients treated with biologic therapies. Demographic, disease information, disease activity before and after (median 5.5 months) rituximab (2 doses at 750mg per m^2, 2 weeks apart) and adverse events were analysed. Effectiveness of RTX was evaluated from the change in core set measures. The ACR pediatric (Pedi) criteria were applied for cases with complete information on disease activity.

Results: A total of 49 JIA patients treated with RTX were identified, 80% female, median (IQR) age at disease onset and start of RTX was 5 (3, 7) years and 15(6, 12) years respectively. RF (-) polyarticular was the commonest subtype (n=20) followed by RF (+) polyarthritis (n=12), oligoarticular extended (n=9), oligoarticular persistent (n=4), psoriatic (n=2) and 1 patient each with systemic-onset and enthesitis related arthritis. Most (n=46) had received treatment with at least 1 prior biologic before RTX, an anti-TNF being the most common (n=42), 16 received concomitant MTX. Most children started RTX following inadequate response to prior therapy (n=45). There were significant improvements in active and limited joint counts, physician assessment of disease activity and ESR; median functional ability (CHAQ score) did not improve (table1). The ACR Pedi criteria could be applied only in 20 children due to missing individual data items. ACR-Pedi30/50/70 were achieved in 65%, 56% and 20% overall, and in 73%, 56% and 43% of RF (-) polyarthritis. Most did not experience any adverse events related to RTX over the first 6 months of therapy, with 2 reported infusion reactions and 2 infections (1 serious).

Conclusion: In this small but varied JIA cohort, RTX therapy resulted in meaningful improvements in physician recorded outcomes in many children with JIA, including those with RF (-) arthritis with limited adverse effects, suggesting RTX may be an effective treatment option for children with subtypes other than RF(+) polyarthritis. Disability scores did not improve overall although this may reflect the severity of disease in this longstanding disease cohort.

Concomitant / previous therapies	**Value (n=49)**		
Concomitant DMARD therapy	19(38.9%)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor that is being investigated for juvenile idiopathic arthritis (JIA). Here, we report the pharmacokinetics (PK), safety, and taste acceptability of tofacitinib following multiple oral doses in patients (pts) 2–<18 years (yrs) old with active JIA.

Methods: Data were obtained from an open-label, non-randomized, multicenter, Phase I study (NCT01513902) where JIA pts were given 5 mg adult equivalent (based on body weight) of tofacitinib (tablet or solution) twice daily (BID) for 5 days (Table). There were 3 cohorts (COH) based on pt age, COH1: 12–<18 yrs, COH2: 6–<12 yrs, and COH3: 2–<6 yrs, with a target enrollment per group of ≥8 JIA pts for N=≥24 evaluable pts completing the study. Pts were enrolled in a step-wise approach beginning with the older age COH first. Subsequent younger age COH were enrolled following confirmation of safety and PK from the previous COH. PK parameters of tofacitinib were calculated using non-compartmental analysis of plasma concentration (conc)-time data. Taste acceptability of the solution formulation was listed and categorically summarized (frequency and %).

Results: 26 pts (COH1 [N=8], COH2 [N=9], and COH3 [N=9]) were included in this analysis. Pts' age ranged from 2–17 years; all were white except for one; there were 17 females and 9 males. Baseline disease characteristics were similar across all COH. All exposure metrics including geometric mean (GM) area under the conc-time curves (AUC_{tau}), maximum (C_{max}), minimum (C_{min}) and predose (C_{trough}) conc were lower in COH2 relative to those in COH1; however, due to higher doses in COH3 (modified after interim analysis of COH1 and 2), the mean AUC_{tau} in COH3 was comparable to COH1. GM apparent volume of distribution (V_z/F) decreased with age (COH1=104.9 L, COH2=71.0 L, COH3=51.4 L). Average terminal half-lives ($t_{½}$) were COH1=2.62 h, COH2=1.95 h, and COH3=1.77 h. GM tofacitinib CL/F were 53%, 39%, and 11% higher in COH1, COH2, and COH3 pts, respectively, vs adult RA pts (18.4 L/h) receiving tofacitinib 5 mg BID. GM CL/F and V/F parameters were similar between males and females. Tofacitinib, administered over 5 days as multiple dose tablets or solution formulation, was well tolerated and taste for the solution formulation was found acceptable in children with active JIA. No serious adverse events or new safety signals were identified.

Conclusion: PK results from this study established dosing regimens for pts aged ≥2 years to be used in the upcoming efficacy and safety studies of tofacitinib in JIA pts. Tofacitinib was well tolerated in this study in JIA pts. Overall, pts found the taste of the tofacitinib solution formulation to be acceptable.

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept is a widely approved and used biologic in children with juvenile idiopathic arthritis (JIA). The purpose of this study was to describe the longitudinal effectiveness and safety of abatacept in JIA patients.

Methods: Using a standardized protocol, clinical sites in the Pediatric Rheumatology Collaborative Study Group (PRCSG) and Paediatric Rheumatology International Trial Organization (PRINTO) enrolled patients with JIA currently on or starting abatacept in this longitudinal registry. Planned duration of follow-up is 10 years and data shown are those collected through 31 March, 2016 (up to 3 years of follow-up).

Results: *Overview.* Of 315 enrolled patients with JIA, 308 contributed data. The total mean person-years of observation were 231.9 years on abatacept. In this registry, 35 (11%) patients were new starters on abatacept (≤ 1 month of treatment), 207 (67%) had received abatacept for 1 month–1 year, 52 (18%) for 1–2 years and 14 (4%) >2 years. During follow-up, 224 (73%) patients continued abatacept. *Baseline.* Of the 308 patients with data, 246 (80%) were female, mean/median age at enrollment was 13.2/13.8 years, disease duration was 5.4/4.4 years, and the active joint count was 2.7/0. Baseline clinical, functional and health-related quality of life scores are shown in Table 1 based on results up to 3 years. A history of uveitis was recorded in 40 (13%) patients and 12 (4%) had active uveitis. JIA subtype was: systemic (2%), oligoarticular (21%), polyarticular RF– (53%), polyarticular RF+ (10%), psoriatic (4%), enthesitis-related (4%), undifferentiated (6%). Concomitant JIA medication was taken by 86% of patients (64% MTX, 49% NSAIDs, 17% systemic steroids, 5% leflunomide, 5% hydroxychloroquine, 1% cyclosporine, 1% sulfasalazine). *Follow-up safety.* A total of 30 AEs were reported (18 serious; all single occurrences) in 25 patients (0.8% of study population), resulting in an overall AE rate of 12.9 per 100 patient-years (95% CI 8.8, 18.2). There were 12 infections of special interest (5.0/100 patient-years, 95% CI 2.8, 8.8). Two patients discontinued abatacept due to a safety event (anaphylaxis). No new autoimmune diseases, deaths, malignances or tuberculosis cases were reported.

Conclusion: In this JIA cohort, abatacept demonstrated persistent effectiveness with low MD global disease activity, low number of active joints and over 30% of patients were in clinical inactive disease. Abatacept was well tolerated and no new safety signals were observed. 1. Wallace C, et al. *Arthritis Care Res* 2011;**63**:929–36. 2. Filocamo G, et al. *J Rheumatol* 2011;**38**:938–53.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Reference Adalimumab is not available in our country but biosimilar ZRC 3197 is(1). This is lower priced and as healthcare is primarily self funded in India, it is now a practical option for many children with JIA and uveitis. This is the *first study* to analyse the use, safety and efficacy of ZRC 3197 in pediatric rheumatology patients.

Methods: Records of 29 children, who have been given ZRC3197 from Dec '14 till 15th June '16 were analysed to assess i.)Use, safety and efficacy in children with JIA ii.) Use, safety and efficacy in children with Uveitis. A predesigned proforma captured the demographic details, medications, 74 joint count and SUN classification for uveitis.

Results: 29 children (16 males) have received ZRC 3197 to date. **Indications:** JIA: (n=15) ERA 12, IBD and Psoriatic arthritis 1 each, PJIA 1.Median age at commencing ZRC 3197: 14.66yrs.(10.08-23.66) Uveitis (n=14); idiopathic:4, PJIA:4, OJIA:4,ERA:1,Behcets with uveitis:1.Median age at commencing ZRC 3197:8.66yrs.(5.16-20.16) All patients were on methotrexate/ and/or oral steroids/topical steroid eye drops. Median duration of therapy with ZRC3197:6 mths (0.5-17 mths) **Safety**: **Prebiologic screen:** Tuberculosis screening positive in 4: 2 drug anti tubercular therapy(ATT) for latent TB given to 3; 1 treated for TB disease. **Post biologic**: 1 child had multi dermatomal herpes zoster after 1 dose and drug was discontinued. **Efficacy**: a.)In 13 children with JIA, (2 patients's follow up <3 mo) ZRC3197 was effective in all domains noted at 3mo.and 6mo.of use(Table1) as determined by the Wilcoxon Signed Ranks test. Median duration to achieve inactive disease in 12 children was 3 weeks (2-32weeks), 3 were still active at last follow up, none flared till last follow up. **Table1: Efficacy of ZRC 3197 in children with JIA**

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cost is a major impediment for use of biologic response modifiers (BRMs). Biosimilars/Intended copies, priced at almost half the reference molecule might be the answer. There is limited data on safety & efficacy of these in pediatric rheumatology. This study was thus undertaken to i.) Assess efficacy/safety of Cipla Etanercept(CE) &Intas Etanercept(IE) ii.)Compare efficacy of CE& IE with reference Etanercept & with each other

Methods: All children with JIA who were given CE & IE till 15.6.16 were included. CE/IE/Reference Etanercept was used in disease resistant to Methotrexate, NSAIDs & steroids. Age matched 39 children who received reference Etanercept were taken as control arm. Data was analysed by Wilcoxon Signed Ranks test at 0, 3 & 6 mths for: 74 joint count, joints with limited range of movt., ESR & CRP. Patients were also categorised as per Wallace criteria into active disease, inactive disease & clinical remission on & off medications.

Results: Total 69 children – 30 given CE & IE, 39 given reference Etanercept. Demographics –CE & IE given to 30(53% males).ERA: 60%,Polyarticular JIA:30% & others 10%. Median age of starting CE & IE: 8.41yrs. Reference Etanercept given to 39(61%males).ERA:66.6%, Polyarticular JIA:20% &13.4% others. Median age at starting :10.66 yrs Efficacy– Table 1 shows significant efficacy of CE & IE in all tested domains. Table 2 shows no difference in all tested domains of reference Etanercept when compared to CE &IE.Table 3 shows no significant difference in efficacy of CE vs IE.

Median(range)	12 (3-35)	3 (3-24)	3 (3-3)
(p value)	**0.56**	**0.80**	**1**

Safety**:** CE/IE were safe with few side effects. Pre CE/ IE: HbsAg +ve:1; Screening for tuberculosis(TB) infection +ve in 5 Pre Reference Etanercept – Screening for TB +ve in 3 Post CE & IE: 12 weeks after starting IE, 1(3.33%) had cellulitis of the right foot. Reference Etanercept: 3 (Hemolytic anemia-1,Varicella-1,New onset uveitis-1).

Conclusion: CE & IE licensed for use in India are safe &effective in a cohort of 30 children with JIA. They are comparable to each other & the reference Etanercept with a similar efficacy& safety profile. This is the first comparative study of these two agents against reference Etanercept from a single centre & needs to be replicated in other centres with a longer follow up.

Abstract Number: 392

Safety and Clinical Response of Weekly Adalimumab in the Treatment of Juvenile Idiopathic Arthritis, Pediatric Chronic Uveitis and Other Childhood Rheumatic Diseases

Colleen K. Correll[1], Danielle R. Bullock[1], Rachel Cafferty[1] and Richard K Vehe[2], [1]Pediatrics, University of Minnesota, Minneapolis, MN, [2]University of Minnesota Masonic Children's Hospital, Minneapolis, MN

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Every other week adalimumab is used to treat juvenile idiopathic arthritis (JIA) and other pediatric rheumatic diseases. It is common for pediatric rheumatologists to escalate to weekly dosing to achieve better disease control when needed. Weekly adalimumab has been demonstrated to be safe and effective in several autoimmune diseases in adults; however, to our knowledge, there have been no studies demonstrating the safety and effectiveness of weekly adalimumab in children with rheumatic diseases. We conducted a retrospective chart review of pediatric patients on weekly adalimumab to assess safety and clinical responsiveness.

Methods: Sixty-nine patients at the University of Minnesota or Gillette Children's Hospital were identified as treated with weekly adalimumab. Sixty (87%) were eligible for the chart review. Demographic and clinical data were collected. Basic descriptive analysis was performed to assess for adverse events and clinical response to weekly adalimumab.

Results: Sixty-three percent (38/60) of patients on weekly adalimumab were females, and the mean age at initiation of weekly dosing was ~14 years. Weekly adalimumab was used most commonly to treat uveitis and rheumatoid factor-negative polyarticular JIA. Most of the patients were also on a nonsteroidal anti-inflammatory drug (NSAID) and methotrexate (Table 1). Only three patients (5%) had an infection requiring hospitalization. One patient with sepsis was concurrently taking an NSAID, methotrexate, and cyclosporine for treatment of chronic uveitis with JIA. Two patients (3%) developed autoimmune disease (Table 2). Most children dislike the pain associated with adalimumab injections, and, thus, the common practice at our clinics is to stop weekly dosing by three months if it is not helpful in treating the disease. Therefore, for this chart review, if the patient continued the weekly dosing for at least three months we determined they had a positive clinical response. Ninety-percent (53/59) of patients were determined to have a positive clinical response. One patient was lost to follow-up prior to the three month point.

Conclusion: The use of weekly adalimumab in children in our centers was determined to be safe and effective. Ninety-percent of patients had a positive clinical response. Minor infections were common, but serious infections requiring hospitalization were uncommon. Two patients on weekly adalimumab developed autoimmune disease. Adalimumab-induced autoimmunity is a recognized issue, but further studies are needed to determine if weekly dosing increases this risk in children.

Table 1. Characteristics of patients on weekly adalimumab	
Characteristics	**N (%)**
Male	22 (36.7)
Age (in years) at diagnosis (mean ±SD)	7.7 (5.3)
Age (in years) at start of adalimumab (mean ±SD)	13.28 (4.9)

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: JIA patients are predominantly non-Hispanic white and studies have shown that race and ethnicity may be associated with worse disease. This study assesses the associations of sex, race and ethnicity with disease outcomes in children with JIA in the Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) Registry. PR-COIN is a multicenter network that uses quality improvement methods to develop and evaluate specific JIA management strategies to improve outcomes in JIA.

Methods: A cross sectional analysis of children with JIA enrolled in the PR-COIN registry from 6/2010 and 7/2015 was done. Univariate statistics and tests of association were performed to compare patient characteristics associated with sex, race (White, African American (AA) and Asian) and ethnicity (Hispanic/Latino, non-Hispanic). One-way ANOVAs were used for all normally distributed continuous data, Wilcoxon Rank Sum for all non-normal continuous data, and Fischer's exact test for all categorical data.

Results: Race information was available for 2436/3192 children (90% white, 6% African American (AA) and 4% Asian). Ethnicity data was available for 2431 children (8% Hispanic/Latino. Characteristics of JIA patients by sex (F:M 2.5:1), race, and ethnicity are reported in tables 1-3. AA children were noted to have worse disease outcomes compared to other races ($p<0.0001$ for all observations). Asian children had the best overall disease outcome scores for all variables ($p<0.0001$). Hispanic children had a higher median JADAS score (3 vs 2.5 in non-Hispanics, $p<0.001$) and a lower median pain score (0.5 vs 1, $p<0.001$). Males, Asians and Hispanics started DMARDs and biologics significantly sooner than other groups ($p<0.0001$).

Conclusion: Race and ethnicity are associated with different disease outcomes in children with JIA. Similar to other studies, AA and Hispanic patients had worse outcomes with higher disease activity scores. However, patients overall tended to have good outcomes with minimal morning stiffness, and low GA, pain and disability scores. Understanding the etiology and clinical significance of outcome variations between sex, race and ethnicity may enable early identification of patients at risk for worse disease and help to improve the care of JIA patients.

Table 1: JIA Patient Characteristics

Outcome	Full Sample
Number	3192
JIA Subtype: n (%)	
Systemic Arthritis	182 (5.70)
Polyarticular, RF (+)	211 (6.61)
Polyarticular, RF (-)	901 (28.83)
Oligoarticular, persistent	840 (26.32)
Oligoarticular, extended	226 (7.08)
Psoriatic Arthritis	217 (6.80)
Enthesitis Related Arthritis	334 (10.46)
Undifferentiated Arthritis	73 (2.29)
Patient Characteristics: n (%)	
Male	779 (28.2)
Female	1983 (71.8)
Hispanic	246 (9.04)
Not Hispanic/Latino	2357 (86.59)
Not Documented	119 (4.37)
White	2327 (90.54)
Black	149 (5.80)
Asian	94 (3.66)
JIA Disease Outcome Measures: Median [IQR]	
CHAQ Score	0 [0-0.38]
Duration of Morning Stiffness	1 [1-2]
MD-GA	1 [0-2]
PGA	1 [0-3]
JADAS	2 [0-6]
Pain Score	1 [0-4]
Joint Count	0 [0-2]
Treatment: Mean (SD)	
Month to 1st Biologic	144.37 (130.36)
Month to DMARD	118.08 (121.86)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Children with JIA are at risk for cardiovascular disease and obesity compounds this risk. There is limited data on the prevalence of elevated BMI in JIA patients (pts) and its effects on disease activity and physical function. This study aims to assess the prevalence of obesity and its effects on JIA pts in the Pediatric Rheumatology Care and Outcome Improvement Network (PR-COIN). We hypothesized that the pts with a high BMI would have worse outcomes.

Methods: We evaluated the de-identified data of JIA pts entered between 6/2010 and 7/2015. Data collected included demographics, height, weight, and pain, CHAQ, Juvenile Arthritis Disease Activity Score (JADAS), and pt and physician global assessment scores (PGA, MDGA). BMI measures body fat based on height and weight (kg/m^2). The average BMI is compared to typical values for other children of the same age and gender. Univariate statistics were used to describe the sample. To compare outcomes across subgroups and across time, a Wilcoxon Rank sum test and a Wilcoxon Sign Rank test was performed, respectively.

Results: 3317 pts were enrolled in the database across 13 sites in the US and Canada [Tables 1,2]. 125 pts were excluded due to missing data for a final sample of 3192 (17,451 visits). Mean age was 7.7 ± 4.9 years, and mean disease duration was 5.4 ± 4.4 years. Table 3 compares the outcome measures of overweight/obese (ov/ob) to normal/underweight JIA pts. All ov/ob except systemic and undifferentiated pts had higher pain scores ($p<0.0001$). Ov/ob oligo-, psoriatic, and ERA pts had higher CHAQ and MDGA scores ($p<0.05$). Ov/ob polyarthritis pts had worse disease activity, MDGA, CHAQ scores and more office visits ($p<0.0001$). Ov/ob systemic pts had the shortest disease duration prior to starting MTX ($p=0.001$) and more office visits ($p<0.0001$). Ov/ob undifferentiated pts had the shortest disease duration prior to the first course of steroids ($p<0.04$) and a longer disease duration prior to starting MTX ($p<0.003$) and biologics ($p<0.0001$) (data not shown). There was no difference in years to start steroid, MTX or biologic based on overweight status.

Conclusion: Results suggest that ov/ob pts have worse pain, disease, function and more office visits than underweight/normal weight JIA pts. Goals of treatment should not only include arthritis control, but dietary and exercise treatment and recommendations.

Table 1: Demographic Characteristics of Patients in the PR-COIN Registry

	Patients		Patient Visits	
Demographic Characteristic	N	%	N	%

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Different definitions of clinically inactive disease (CID) for JIA have recently been shown to identify different groups of children. It is unclear whether long-term outcomes, such as low disability, differ between children who, early in disease, have no objective inflammatory signs (CID on Wallace's preliminary criteria) versus those who also have good global wellbeing (CID on clinical Juvenile Arthritis Disease Activity Score (cJADAS)). It is also unclear whether achieving CID is more beneficial to long-term outcomes than achieving minimal disease activity (MDA). This study assessed whether functional outcome within five years, measured by the Childhood Health Assessment Questionnaire (CHAQ), differs according to disease activity state at one year following presentation in children with JIA.

Methods: Children recruited to the Childhood Arthritis Prospective Study (CAPS), a multicentre UK inception cohort, prior to 1st January 2011 and with a physician's diagnosis of JIA (limited to oligoarticular, RF negative or positive

polyarticular subtypes) were selected. At one year following presentation, children were categorised into three disease states: i) CID using both Wallace's preliminary criteria and cJADAS, ii) CID using Wallace's preliminary criteria only and iii) No CID. In addition, children were assessed for MDA using the cJADAS. CHAQ scores were compared between each disease state group via univariate and multivariate zero-inflated negative binomial regressions with robust clustering at the patient level. Multivariate models adjusted for age and symptom duration at presentation, gender and ILAR subtype. Multiple imputation accounted for missing data.

Results: Of 832 children, 70% were female and the most common subtype was oligoarthritis (68%), followed by RF-negative (27%) and RF-positive polyarthritis (5%). At one year, 22% had achieved CID according to Wallace's preliminary criteria and cJADAS, 7% according to only Wallace's preliminary criteria and 56% to neither. Compared with those who had not achieved CID, children who had achieved CID on both tools at one year had 21% lower CHAQ scores (95% CI 10, 31%) and double the odds of zero disability (95% CI 1.5, 2.6) within the first five years. However, those who had achieved CID only on Wallace's preliminary criteria had similar CHAQ scores to the no CID group. There was no difference in functional ability between children who had achieved MDA or CID using JADAS at one year, with both achieving 27% lower CHAQ and having three times the odds of zero disability compared with children not in these states (Table 1).

Conclusion: Better long-term functional ability was only observed to increase when both objective measures of inflammation and subjective measures of the global picture of disease were taken into account. MDA may be an equally valid, but more feasible, treatment target to CID in patients with JIA.

Table 1. Associations between achievement of CID and MDA at one year and CHAQ scores within the first five years following initial presentation

Outcome definition at one year following presentation	IRR of higher CHAQ (95% CI)	P-value	IRR of CHAQ=0 (95% CI)	P-value
Combined states				
Not in CID on either tool	Reference	-	Reference	-
CID on Wallace's preliminary criteria only	1.1 (0.9, 1.3)	0.260	0.70 (0.43, 1.1)	0.139
CID on both Wallace's preliminary criteria and cJADAS10	0.79 (0.69, 0.90)	0.001	2.0 (1.5, 2.6)	<0.001
CID vs MDA				
MDA cJADAS10 (versus no MDA)	0.73 (0.65, 0.82)	<0.001	2.8 (2.2, 3.7)	<0.001
CID cJADAS10 (versus no CID)	0.73 (0.65, 0.82)	<0.001	2.7 (2.1, 3.5)	<0.001

IRR: Incidence rate ratio, CHAQ: Childhood Health Assessment Questionnaire, CID: Clinically inactive disease, MDA: Minimal disease activity, cJADAS10: Clinical Juvenile Arthritis Disease Activity Score weighted to 10 joints.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several outcome measures in trials with juvenile-onset spondyloarthritis (Jo-SpA) have been borrowed from trials in juvenile idiopathic arthritis and from adult spondyloarthritis, but a proper psychometric analysis has never been conducted in patients with Jo-SpA. We aimed at assessing discriminatory aspects of several disease activity outcome measures and response criteria for Jo-SpA.

Methods: Data from a previously reported 12-week RCT comparing infliximab (IFX) and placebo (PBO) in patients <18 years with Jo-SpA and onset <16 years of age were analyzed. The primary endpoint of the trial was the number of active joints (both swollen and tender). Several other disease activity measures and response criteria were also tested (Table). Statistics to determine how well disease activity measures could discriminate between IFX and PBO included 'standardized mean difference' (SMD) and 'Guyatt's effect size. Both statistics are standardized measures to compare change from baseline per group. For categorical response criteria, the chi-square test (χ^2) was used. Higher numbers indicate better discriminatory capacity.

Results: Patients were randomised to IFX (n=12) and PBO (n=14). Of the continuous measures, the ASDAS showed the best and very good discrimination between IFX and PBO (SMD:1.98; Guyatt: 4.28) (Table). The physician's global, CRP, JADAS and JSpADA also discriminated well. The BASDAI (or its separate items), BASFI and spinal mobility measures performed worse. Of the response criteria ASAS40 and ACR Pedi 90 discriminated best between IFX and PBO (Table). ASDAS response criteria and ACR Pedi 30-70 also performed well. **Table: Discrimination between patients on infliximab and placebo at week 12**

0.005

CONTINUOUS OUTCOME MEASURES				
	Infliximab mean change (SD)	**PBO mean change (SD)**	**Guyatt's effect size**	**SMD**
ASDAS	2.4 (1.3)	0.5 (0.6)	4.28	1.98
Physician's global assessment, 0-10 mm VAS	5.2 (2.4)	1.6 (2.2)	2.34	1.56
JADAS27 (0-57)	12.7 (5.9)	4.3 (5.7)	2.22	1.46
JSpADA (0-8)	2.8 (1.2)	0.5 (1.4)	1.98	1.73
CRP (mg/L)	21.1 (8.4)	2.3 (10.9)	1.93	1.90
Total enthesitis (0-51)	8.5 (10.6)	1.6 (5.0)	1.71	0.85
Patient's global assessment, 0-10 mm VAS	4.3 (3.8)	0.8 (2.8)	1.55	1.08
BASDAI total (0-10)	3.3 (3.1)	0.9 (2.3)	1.41	0.90
Pain, 0-10mm VAS	3.3 (2.1)	-1.7 (3.2)	1.03	1.80
Active joint count (0-72)	4.4 (1.7)	2.6 (4.6)	0.96	0.51
	Infliximab mean change (SD)	**PBO mean change (SD)**	**Chi-square**	**p-value**
ACR Ped 90	8 (67%)	1 (7%)	10.12	0.001
ASAS40	6 (55%)	0 (0%)	10.05	0.002
ACR Ped 70	9 (75%)	2 (14%)	9.76	0.002
BASDAI50	8 (73%)	2 (14%)	8.77	0.003
ASDAS-MI	5 (63%)	0 (0%)	8.65	0.003
ACR Ped 50	11 (92%)	5 (36%)	8.55	0.003
ASDAS-CII	7 (88%)	2 (20%)	8.10	0.004
ASDAS-ID	7 (64%)	1 (8%)	7.74	
ACR Ped 30	11 (92%)	6 (43%)	6.80	0.009
JADAS27 MDA (≤2)	6 (50%)	1 (7%)	6.03	0.014
JADAS27 inactive disease/remission (≤1)	3 (25%)	0 (0%)	3.96	0.047
ASAS20	7 (64%)	4 (29%)	3.07	0.080

Conclusion: Of all continuous measures tested in adult axial SpA the ASDAS discriminates best between active treatment and PBO in patients with Jo-SpA. But the child specific JSpADA also performs well. Of all response criteria tested the child-specific ACR Pedi 30 to 90, as well as the adult ASAS40 and ASDAS response criteria work well. One of these measures should be used as primary endpoint in trials with Jo-SpA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In adults, psoriatic arthritis (PsA) is associated with an increased prevalence of obesity, hypertension, and diabetes. It is not yet known if pediatric patients with PsA also have a higher prevalence of these comorbidities. We evaluated the association of obesity, hypertension, and diabetes with PsA and psoriasis in children.

Methods: We conducted a cross-sectional study of children with PsA and psoriasis enrolled in The Health Improvement Network (THIN) database between 1994 and 2013. All psoriasis and PsA cases in the cohort had ≥ 1 READ code for psoriasis, or psoriasis and arthritis, respectively. The index date was defined as the first READ code entry for psoriasis or PsA. Controls were matched on age, sex, and practice at a 5:1 ratio. Prevalence of hypertension, diabetes, and obesity were calculated among patients in these groups. Hypertension and diabetes were identified using ≥ 1 READ code for these diagnoses. Age- and sex-specific z-scores for BMI (zBMI) were calculated. Differences in demographic and clinical characteristics were assessed using the t-test and Wilcoxon rank sum test, as appropriate.

Results: 6366, 1786, and 13351 children were identified as having juvenile arthritis (excluding PsA), PsA, and psoriasis, respectively. Among children with psoriasis, 280 (2.1%) had PsA. The mean age at PsA diagnosis was 7.7 (SD 4.5) years and psoriasis diagnosis was 9.8 (SD 4.0) years. 62.4% of the PsA, 56.7% of the psoriasis, and 56.5% of the controls were female. Table 1 summarizes characteristics of each patient population at the time of data collection. PsA patients were significantly more likely to have hypertension and diabetes than patients with psoriasis, but did not have a higher prevalence of hypertension and had a lower prevalence of diabetes compared to controls. zBMI was significantly higher in PsA compared to controls (1.1 vs 0.07, p-value 0.03) and psoriasis compared to controls (0.9 vs 0.07, p-value 0.01), but not significantly different between children with PsA and psoriasis (p-value 0.3).

Conclusion: PsA was found to be associated with an increased prevalence of hypertension and diabetes compared to patients with psoriasis, but not compared to healthy controls. Children with PsA and psoriasis also had a significantly higher mean zBMI compared to healthy controls.

Table 1: Comorbidities in Patients with Pediatric Psoriatic Arthritis and Psoriasis

	PsA (n=1,786), N(%)	Psoriasis (n=13,071), N(%)	Controls (n=64,339), N(%)	PsA vs. psoriasis p-value	PsA vs. Controls p-value
Hypertension	24 (1.3)	49 (0.4)	599 (0.9)	P<0.001	0.07
Hypertension w/out CKD	18 (1.0)	44 (0.3)	426 (0.7)	P<0.001	0.08
Diabetes	32 (1.8)	91 (0.7)	1,949 (3.0)	P<0.001	0.01
zBMI*, mean (SD)	1.1 (2.0)	0.9 (1.8)	0.7 (1.9)	0.3	0.03

Legend. The psoriasis group excludes patients with psoriatic arthritis. Psoriatic arthritis (PsA); chronic kidney disease (CKD); BMI z-score (zBMI).

* zBMI data only available for PsA for N=105; psoriasis for N=627; controls for N=11,174.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Etanercept (ETN) is approved in the EU for the treatment of children with juvenile idiopathic arthritis (JIA) categories of polyarticular, extended oligoarticular (eoJIA), enthesitis-related arthritis (ERA), and psoriatic arthritis (PsA), but little evidence is currently available regarding predictors of clinical remission. We evaluated

characteristics that may have predicted the achievement of clinical remission with ETN in the CLIPPER study.

Methods: In this ongoing, Phase 3b, open-label study, pediatric patients with eoJIA (2–17 y), ERA (12–17 y), or PsA (12–17 y) received ETN 0.8 mg/kg once weekly (maximum, 50 mg) for up to 96 weeks. Baseline demographic and disease characteristics that were significantly different ($p<0.05$) between children in remission or with active disease were analysed post hoc as categorical predictors (i.e., dichotomized continuous characteristics) in univariate logistic regression models; response and disease activity status after 12 weeks of ETN treatment were also considered as predictive factors. Clinical remission was defined with the JIA ACR Wallace 2011 remission criteria or Juvenile Arthritis Disease Activity Score 71-joint reduced count (JADAS71) clinical remission criteria (≤1) persisting for ≥24 weeks.

Results: Of the 127 patients enrolled in the trial, 42 (33%) and 54 (43%) achieved JIA ACR or JADAS71 clinical remission over 24 weeks, respectively. In univariate analyses, patients who had lower BMI and were shorter at baseline and those who were younger at the time of disease onset were significantly more likely to achieve JIA ACR and JADAS71 remission (table). Age >11 vs ≤11 years at baseline and C-reactive protein level >2.4 mg/L vs ≤2.4 were significant predictors of JIA ACR remission; HLA-B27+ vs HLA-B27– status and >11 vs ≤11 joints with limitation of motion at baseline were predictors of JADAS71 remission. Induction of JIA ACR and JADAS71 responses at 12 weeks was also predictive of sustained ACR and JADAS71 responses for 24 weeks.

Conclusion: Clinical remission after 12 weeks of etanercept treatment was the most important predictor of sustained clinical response over 24 weeks in pediatric patients with eoJIA, ERA, or PsA JIA subtypes. **Trial registration identifying number:** NCT00962741/NCT01421069

Enthesitis in Juvenile Idiopathic Arthritis (JIA)

Background/Purpose: The characteristics of enthesitis, a feature in some children with juvenile idiopathic arthritis (JIA), t has not been well described in large prospective inception cohorts. We used data from a Canadian cohort to describe the characteristics of patients with enthesitis, the sites most commonly affected, and the temporal changes in the number of sites of enthesitis, relative to changes in active joint counts.

Methods: Children newly diagnosed with JIA at 16 Canadian centers from 2005 to 2010 were followed in the ReACCh-Out cohort for up to 5 years. For this analysis, all patients with >1 visit (n=1406) were included. The presence and location of enthesial tenderness on examination were recorded by pediatric rheumatologists in all children present at 0, 6, 12, 18, 24, 36, 48 and 60 months after enrolment. For this study, a child was said to have enthesitis if enthesial tenderness was present on >1 occasion and/or at >1 body site. The characteristics of patients with an without enthesitis were compared using univariate logistic regression on each characteristic. The number of tender enthesial sites was analyzed over time and compared to the number of active joint counts using linear mixed models for longitudinal data.

Results: A total of 219 patients (16% of the cohort) fulfilled our criteria for enthesitis; 8% fulfilled criteria at enrolment and 15% fulfilled criteria within 2 years. The most frequent sites of involvement were the calcaneal plantar insertion (39%), Achilles insertion (31%), and tibial tuberosity (30%). The characteristics of children with and without enthesitis are presented in Table 1. Children with enthesitis were older, more often male and 141 (64.4%) were categorized as enthesitis related arthritis; 57.1% had polyarticular involvement and 30% had sacroiliac involvement at some point during follow-up. The mean number of tender enthesial sites decreased dramatically over the follow-up period, roughly in parallel with the number of active joints (see Figure 1, p=0.16 for whole group). A mixed linear model analysis showed no significant difference in active joint counts over time in children with or without enthesitis (p=0.73).

Conclusion: The number of patients with enthesitis and their characteristics were generally as expected, except that over half the patients had polyarticular involvement. The number of tender enthesial sites and active joints decreased similarly over time in the enthesitis group, and the active joint counts decreased similarly over time in children with and without enthesitis. **Table 1: Characteristics of Patients With Versus Without Enthesitis**

Characteristic	Patients with Enthesitis	Patients without Enthesitis	OR (95% CI)

Foot Involvement in Enthesitis-Related Arthritis Subtype of Juvenile Idiopathic Arthritis: Clinical, Radiological and Functional Assessment

Sanat Phatak[1], Namita Mohindra[2], Abhishek Zanwar[1] and Amita Aggarwal[1], [1]Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, [2]Radiodiagnosis, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Though foot involvement is common in juvenile idiopathic arthritis (JIA), it is often neglected by patients and physicians alike. The involvement could occur due to arthritis, enthesitis or tenosynovitis. Tarsitis is thought to be a harbinger for spondyloarthropathy. Thus this study was done to assess clinical and radiological involvement of feet as well as its impact on function in children with JIA-Enthesitis related arthritis (ERA).

Methods: We enrolled consecutive patients newly diagnosed with JIA ERA of age less then 18 years and disease duration less than 5 years seen during 2015. All patients underwent clinical examination of the feet and answered the Juvenile arthritis foot index (JAFI) questionnaire to assess functional impact. Radiological assessment included plain X-rays of the feet, US of the joints and entheses and MRI scan of one foot. HLAB27 was done by PCR.

Results: Fifty-five patients, with a median age of 14 years and duration of disease 1.9 years were included in the study. Eighty percent (37/46) were HLAB27 positive and 18 (32.7%) had radiographic sacroiliitis. Forty six (83.6%) patients had a history of foot pain while 36 had abnormal clinical exam: 15 had ankle, 8 had subtalar 24 had midfoot and 10 had forefoot joint involvement. Tendoachilles enthesitis was present in 21 whereas plantar fasciitis was seen in 7 patients. The median JAFI score was 4 (0-11) and the score correlated with history of foot pain ($r=0.66$; $p<0.01$) and foot swelling ($r=0.58$; $p<0.01$). On plain X-ray (N=40) 3 had midfoot joint space reduction and 3 had midfoot joint fusion. On US (N=55), 16 had ankle, 8 had subtalar and 19 patients had midfoot arthritis with the talonavicular (TN) joint being the most commonly involved. 27 had US active tendoachilles enthesitis and 11 had plantar fasciitis. On MRI (N=50) tarsitis was seen in 27 patients and TN was the most commonly involved joint. Bone marrow edema was seen in 33 patients with the calcaneum being the most commonly affected bone. Midfoot enthesitis was found in 14 patients and tenosynovitis in 17 patients. Clinical and US had 82% concordance at midfoot and 90% at tibiotalar joint. MRI had lower concordance rates (74% with clinical exam and 72% with ultrasound at midfoot) as it picked up additional findings in 12 patients.

Conclusion: Foot joints and entheses are involved in a substantial proportion of patients with JIA ERA patients and lead to functional disability. Early recognition and treatment may decrease damage.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Pertussis cases have increased worldwide and knowledge on immune response after adult Tdap vaccine is scarce. This study evaluated the humoral immune response profile after Tdap in children and adolescents with Juvenile Idiopathic Arthritis and in healthy controls.

Methods: After written informed consent, children and adolescents with Juvenile Idiopathic Arthritis (JIA) using anti-TNF and healthy controls (control) with three previous whole-cell DTP plus two booster vaccine doses received a Tdap dose. Blood samples were collected immediately before and 28 days after Tdap. Tetanus, diphtheria and pertussis antibodies were tested by ELISA. Antibodies>0.100 IU/mL were considered protective for tetanus and diphtheria. There isn't a consensus antibodies level considered protective for pertussis.

Results: JIA group (n=10) was represented for 7 (70%) female, with median age 13 (8-18), 4 (40%) with positive anti-nuclear antibodies (ANA), 1 (10%) with positive rheumatoid factor. Control group (n=9) was represented for 4 (44.4%) female, with median age 15.2 (9-15.6). JIA and control groups presented an increase in response to tetanus (p=0.0004, p=0.002) and diphtheria (p<0.0001, p=0.002) antibodies after Tdap booster dose on day 28 and were comparable in the proportion of immune subjects on day 0 (p=0.1226, p=0.3322) and on day 28 (p=0.3493, p=0.5). Everyone in both groups seroconverted to tetanus and diphtheria. In JIA group median antibodies level for pertussis were 10.796 IU/mL (2.4-197.09) and 83.8 IU/mL (8.4-196.69) on day 0 and day 28. In the control group median antibodies level for pertusis were 8.47 IU/mL (1.08-108.88) and 59.73 IU/mL (13.87-138.04) on day 0 and day 28.

Conclusion: In this preliminary study, children and adolescents with JIA using anti-TNF and healthy controls showed adequate humoral immune response to tetanus, diphtheria and pertussis after Tdap. Future research include increasing sample size correlating T follicular cells population with improved humoral immune response.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The comparative risk of infection with newer biologic agents, such as abatacept (ABA), in the treatment of juvenile idiopathic arthritis (JIA) has not been reported. We used claims data to compare rates of hospitalized infection among JIA patients initiating ABA or tumor necrosis factor inhibitors (TNFi).

Methods: We combined data from national U.S. Medicaid claims from 2000-2010 and MarketScan claims from 2010-2014. Patients with a physician diagnosis code for JIA before age 16 years and prior to new use of ABA or a TNFi were included. New use of ABA and of each of the 5 TNFi agents was defined by a 6 month baseline period of non-use prior to first observed use. Follow-up began on the day of the new prescription fill or infusion claim and was extended for 90 days beyond the days supplied for each subsequent fill. Study outcome was hospital discharge with any infection as the primary diagnosis. We calculated crude infection rates per 100 person-years and stratified results according to clinical factors during the baseline period: use of oral glucocorticoids (GC), use of a different biologic agent, and inpatient or outpatient infection. We also stratified by systemic JIA (SJIA) as defined by any diagnosis for macrophage activation syndrome or any use of relatively SJIA-specific medications (e.g., anakinra). Multivariable regression analyses were precluded by few observed outcomes.

Results: We identified 5,933 and 257 initiators of TNFi and ABA, respectively. The baseline patient characteristics are in Table 1, and the overall and stratified crude infection rates are in Table 2. ABA was strongly associated with SJIA and with use of a different biologic agent during baseline compared to TNFi. The overall crude infection rates were higher for ABA (4.14 [2.07-8.28]) compared to TNFi (1.50 [1.22-1.85]). SJIA was associated with much higher infection rates among ABA users, and, to a lesser extent, among TNFi users. All 8 ABA patients with infection outcomes had infections during the baseline period, but the overall proportions of patients with baseline infections were similar with ABA and TNFi.

Conclusion: Crude hospitalized infection rates following initiation of ABA were higher compared to TNFi. This may be partially explained by higher proportions of patients with SJIA and recent use of other biologics among ABA initiators compared to TNFi. Infection during baseline was a risk factor for subsequent infection and may importantly be the reason for initiation of ABA in some patients. Evaluation of the comparative safety of non-TNFi biologics in JIA is challenging due to small sample sizes and requires careful consideration of prescriber channeling.

Table 1.

Characteristic	TNFi	ABA
Number of patients	5933	257
Median age (25-75%)	13 (9-16)	14 (10-17)
Female (%)	4093 (69%)	204 (79%)
Median days of follow-up (25-75%)	245 (121-495)	186 (109-368)
SJIA (%)	455 (8%)	35 (14%)
Oral GC use during baseline (%)	2337 (39%)	143 (56%)
Biologic use during baseline (%)	1397 (24%)	152 (59%)
Infection during baseline (%)	2624 (44%)	126 (49%)

Table 2.

	Number of infections & Infection rate per 100 person-years [95% CI]	
Patients	TNFi	ABA
All	91 1.5 [1.2-1.9]	8 4.1 [2.1-8.3]
With SJIA	9 2.2 [1.2-4.3]	4 23.5 [8.8-62.5]
Without SJIA	82 1.5 [1.2-1.8]	4 2.3 [0.9-6.0]
With GC use during baseline	44 1.9 [1.4-2.5]	4 3.9 [1.5-10.4]
Without GC use during baseline	47 1.3 [1.0-1.7]	4 4.4 [1.7-11.8]
With biologic use during baseline	21 1.8 [1.2-2.8]	6 5.3 [2.4-11.9]
Without biologic use during baseline	70 1.4 [1.1-1.8]	2 2.5 [0.6-9.9]
With infection during baseline	60 2.3 [1.8-2.9]	8 8.2 [4.1-16.4]
Without infection during baseline	31 0.9 [0.6-1.3]	0 0.0 [0.0-3.9]

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Most data about infections associated to biologic therapy in juvenile idiopathic arthritis (JIA) derive from registries designed to identify general adverse events that have not focused on risk factors for this condition. In addition, previous publications of biological therapies were performed in distinct settings regarding endemic area and infection surveillance protocol. Therefore, our objectives were to assess the rate of serious/opportunistic infections in JIA patients from a single tertiary center under biologic therapy using a standardized electronic protocol in order to identify possible risk factors associated to theses complications.

Methods: From August 2004 to March 2016, 107 consecutive JIA patients were longitudinally followed at the biologic therapy center of the Rheumatology Division of our tertiary university hospital using a standardized electronic database protocol including demographic data, clinical and laboratorial findings and treatment at baseline and at the moment of infection. Serious infections were defined as those requiring hospitalization or intravenous antibiotics and opportunistic infections included tuberculosis(TB), herpes zoster(HZ) and systemic mycosis. All subcutaneous and intravenous biologic agents are regularly administered in our center with previous infectious screening.

Results: The mean age at baseline was 14.6±5.7yrs, 71% were females and median disease duration prior to biologic therapy was 4.8yrs (0.1-21). A total of 398 patient-yrs (py) were included: 179py for etanercept (ETN), 92py for adalimumab (ADA), 22py for infliximab (IFX), 78py for abatacept (ABA) and 27py for tocilizumab (TCZ). The median time of biologic exposure was 3.0 years (0.15-11.5). We observed 35 serious/opportunistic infectious events in 27 (25%) patients:31 (88.6%) were serious infections and 7 (20%) opportunistic (1 TB, 5 HZ, 1 systemic candidiasis). The median time of total biologic exposure until infection was 18 months (1–91) and most common sites were: 34% skin/soft tissue, 23% urinary tract and 20% respiratory tract. No patient died due to infectious complications. Serious/opportunistic infections rates were 10.6/100py for ETN, 10.9/100py for ADA, 2.6/100py for ABA and 14.8/100py for TCZ. Comparison of 27 patients with and 80 without infection showed a higher frequency of systemic-onset JIA (44 vs. 20%,p=0.021), lower age at biologic therapy initiation (12 ± 6 vs. 16 ± 5yrs,p=0.005) and a history of previous serious infection (33 vs. 14%,p=0.042) in the former group. Further analysis of 35 patients with and 80 patients without infectious complications balanced for mean time of biologic exposure revealed a significantly higher frequency of lymphopenia (17 vs. 1%,p=0.003) during infection events. Disease activity parameters and concomitant treatment had no influence on infections rate (p>0.05).

Conclusion: This single center study demonstrated a high rate of serious infections in JIA patients under biologic therapy in a real life setting, except for ABA. Systemic-onset JIA, lower age at biologic therapy start, history of previous serious infections and lymphopenia were important risk factors for these complications.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The introduction of biologic agents at the beginning of the 2000s has represented a major advance in the management of juvenile idiopathic arthritis (JIA). These medications have been shown to be effective in a sizeable proportion of patients refractory or intolerant to methotrexate. However, in order to document the impact of the recent therapeutic progress on the prognosis of JIA there is the need to compare the long-term outcomes achieved with previous therapies with those obtained with the newer medications. We aimed to compare the level of disease activity and the amount of articular and extra-articular damage between patients treated in the "methotrexate" era and "biologic" eras.

Methods: Data for the "methotrexate" era were extracted from a previous study on disease outcome in 310 patients with disease onset before 2002 and disease duration of ≥5 years (Solari et al. A&R 2008;59:1571-9). Data for the "biologic" era were obtained with the present study by examining all consecutive patients with JIA who had disease onset between January 2002 and June 2011 and a disease duration of ≥5 years. Outcome assessments included joint counts, physician global assessment of overall disease activity on a visual analog scale, Juvenile Arthritis Disease Activity Score-10 (JADAS10), Juvenile *Arthritis* Multidimensional Assessment Report (*JAMAR*) completed by a parent, and acute phase reactants. The amount of articular and extra-articular damage was assessed through the Juvenile Arthritis Damage Index (JADI).

Results: Demographic and clinical features of patients seen in the two study periods were overall comparable. As compared to the older sample, patients treated more recently had received more frequently methotrexate (84.6 vs 64.5%) and biologic medications (60.4% vs 11.3%), and had undergone more commonly intra-articular corticosteroid injections (97.6% vs 79%). The comparison of disease activity and damage between the two cohorts is presented in the table. All items of JADI articular and extra-articular were decreased in the recent sample, with the exception of temporo-mandibular damage and leg-length discrepancy, whose frequency was comparable in the two datasets.
file:///C:/Users/23667/Desktop/Table.htm

Conclusion: Compared with patients treated in the "methotrexate" era, those treated in the "biologic" era have a higher frequency of inactive disease and less articular and extra-articular damage. These findings highlight the improvement in disease outlook achieved with the newer therapeutic modalities.

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry is a multicenter, prospective observational study collecting data from children with rheumatic diseases in order to characterize disease patterns, treatments, and outcomes. The current Registry began enrolling children with JIA in July 2015. This abstract describes patterns of medication use among children with JIA enrolled through March 31, 2016.

Methods: Children were enrolled into the CARRA Registry by participating centers in the US and Canada. Children with the following characteristics were eligible for enrollment: 1) new diagnosis of JIA within previous 6 months; 2) systemic JIA; 3) history of polyarthritis (≥ 5 joints involved during disease course); 4) newly starting or re-starting methotrexate or biologic. In the categorization of medication use, current and past medication use were combined, and non-biologic DMARDs included methotrexate, leflunomide, and sulfasalazine. Patients with incomplete data entry at the time of analysis were included, and missing data were not imputed.

Results: 1155 children were enrolled from 46 centers; 244 were newly diagnosed (29% of those with sufficient data to determine). Patient characteristics are summarized in the Table. Receipt of non-biologic DMARDs only (without receiving biologics) was observed in 18% of all children, and there was an increased proportion of newly diagnosed patients in this group (30%). Receipt of any biologic agent was present in 56% of all children, and this was less common among patients with persistent oligoarthritis (30%). Non-TNF inhibitor biologic use was common among systemic JIA (71%) and was very uncommon among ERA (2%) and psoriatic arthritis (0%), although smaller numbers of children with these JIA categories have been enrolled into the Registry to date. Any use of systemic glucocorticoids was present among 44% overall, and was increased among systemic JIA (81%) and RF+ polyarthritis (69%). Among newly diagnosed children, 38% were treated with biologics, 30% had received DMARD only, and 29% received systemic glucocorticoids.

Conclusion: By design, this large cohort of children with JIA from North America includes a high proportion of biologic users. Children with systemic JIA had the most frequent use of non-TNF inhibitor biologics and systemic glucocorticoids, consistent with treatment efficacy data. Longitudinal data generated from the long-term follow-up of Registry participants will provide important data on medication usage, as well as comparative safety and effectiveness.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) persisting into adulthood is associated with articular damage, increased disability and mortality. Approximately 100,000 polyarticular JIA patients will enter adult practices over the next 10-15 years and represent a distinct population for these providers. We initially searched the electronic medical record (EMR) for adult patients with JIA, but found that only physicians with pediatric training used the JIA diagnosis while the rheumatoid arthritis (RA) diagnosis was used by the adult rheumatologists. Considering differences in clinical features, we hypothesized that the 2010 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) RA criteria would have lower sensitivity than the 1987 RA criteria for classification of polyarticular JIA patients, compared to an adult-onset RA cohort.

Methods: Patients > 18 years of age with an established JIA diagnosis made ≤16 years who were seen by adult rheumatology between January 1st 2013-June 1st2015 were evaluated. EMR extraction with rheumatologist review was performed and disease features were recorded. A prospective observational cohort of RA was used for comparison. JIA was retrospectively classified using the International League of Associations for Rheumatology (ILAR) JIA classification criteria and RA was classified using the ACR/EULAR 2010 and the 1987 criteria. McNemar's test, chi-square, and Welch's t-test were used to test for group differences between polyarticular JIA and RA.

Results: 67 adult subjects had JIA, with 45 having polyarticular disease, were compared to 66 subjects with RA. Polyarticular JIA subjects had a mean age of 27 years, 89% were female, with mean disease duration of 20.6 years. 29% (9/31) were rheumatoid factor (RF) positive. While 71.1% (32/45) met the 1987 RA criteria, only 46.7% of polyarticular JIA subjects met the 2010 RA criteria ($p<0.0001$). RA subjects had a mean age of 56 years, were 78% female, with mean disease duration of 11.2 years. 74% (43/58) were RF positive. 81.8% (54/66) met the 1987 criteria whereas 87.9% met the 2010 RA criteria. Patients with RA were approximately 1.88 times (95% RR 1.36, 2.61) more likely to meet the 2010 ACR/EULAR RA criteria than those with polyarticular JIA.

Conclusion: Adults with polyarticular JIA have unique clinical characteristics from RA, highlighted by less than half meeting the 2010 ACR/EULAR RA classification criteria. Accurate classification is the first step to define optimal evaluation and treatment in this unique patient population. Rather than blurring the clinical picture, adult rheumatologists should have increased awareness of JIA disease subtype.

Demographics and Disease Characteristics: Polyarticular JIA vs. RA			
Variable	**Poly JIA** Mean ± SD or % (n)	**RA** Mean ± SD or %	**p-value**

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is unclear which tool should measure functional ability in adolescents with JIA. The proxy-completed Childhood Health Assessment Questionnaire (P-CHAQ) is completed on the adolescent's behalf and an adolescent version (A-CHAQ) has not been validated. Since adolescence parallels transfer to adult care, the adult HAQ may be preferable to capture functional ability throughout transition. However, it is unclear how the HAQ compares with the two CHAQ tools. Agreement between the P-CHAQ, A-CHAQ and HAQ was assessed in adolescents with JIA during the three years following presentation to rheumatology.

Methods: Adolescents aged 11 to 17 years recruited before 1st January 2013 to the Childhood Arthritis Prospective Study (CAPS), a UK multicentre JIA inception cohort, were selected. Adolescents had complete data on proxy-completed P-CHAQ and adolescent-completed A-CHAQ and HAQ at presentation. These assessments were continued annually. At baseline, Wilcoxen signed-rank tests compared median scores, Spearman's correlations assessed pairwise correlations and percent agreement (defined as cores within 0.25 points) was assessed. Univariate and age and sex-adjusted associations between scores were assessed via zero-inflated negative binomial models. Multiple imputation accounted for missing data for longitudinal models, which had robust clustering at the patient level.

Results: Of 94 adolescents included, median age at diagnosis was 13 years (IQR 12 to 15) and 61% were female. Median disease duration at diagnosis was seven months (IQR 5 to 14) and the most common subtype was oligoarticular JIA (40%). Median baseline HAQ (0.5) was marginally lower than both CHAQ scores (both 0.6), although this difference was not clinically significant. In accordance, the highest agreement was between the two CHAQ tools (78%) and lowest between the HAQ and P-CHAQ (71%). Where discordant, the majority of HAQ scores fell below those from either CHAQ. Discordance between CHAQ scores was more evenly distributed (Table 1). Despite marginally different medians, the strongest correlation was between the HAQ and the A-CHAQ (0.91), with the lowest between the two CHAQ tools (0.83). After adjustment for age and sex, there was around 11% difference in scores at baseline and 8% over the course of three years (Table 2).

Conclusion: There was strong correlation, good concordance and similar associations between the P-CHAQ, A-CHAQ and HAQ in adolescents with JIA. The strong relationship between the HAQ and either CHAQ tool indicate the utility of HAQ in adolescents with JIA.

Table 1. Comparisons of the P-CHAQ, A-CHAQ and HAQ in adolescents with JIA at baseline

Score	Median score (IQR)	Comparison	Correlation	Percent agreement (%)	Percent discordant scores (%)	
					Higher	Lower
P-CHAQ	0.625 (0.125, 1.375)	**Vs. A-CHAQ**	0.84	77	10	12
A-CHAQ	0.625 (0.125, 1.250)	**Vs. HAQ**	0.93	76	20	4
HAQ	0.500 (0.000, 1.125)	**Vs. P-CHAQ**	0.85	71	9	20

P-CHAQ: Parent-assessed Childhood Health Assessment Questionnaire (CHAQ); A-CHAQ: Adolescent-assessed CHAQ; IQR: Interquartile range.

Table 2. Associations between P-CHAQ, A-CHAQ and HAQ at baseline and during the first three years of disease in univariate and multivariate regression models adjusting for age and sex

Comparison	Univariate IRR	95% CI	Multivariate IRR	95% CI
Baseline assessments				
P-CHAQ vs. HAQ	1.11	1.09, 1.13	1.12	1.10, 1.14
A-CHAQ vs. HAQ	1.11	1.09, 1.13	1.11	1.10, 1.13
P-CHAQ vs. A-CHAQ	1.11	1.09, 1.13	1.11	1.09, 1.13
Longitudinal assessments over the first three years following presentation				
P-CHAQ vs. HAQ	1.06	1.02, 1.10	1.09	1.06, 1.12
A-CHAQ vs. HAQ	1.05	1.02, 1.09	1.07	1.05, 1.11
P-CHAQ vs. A-CHAQ	1.07	1.04, 1.11	1.09	1.06, 1.11

P-CHAQ: Parent-assessed Childhood Health Assessment Questionnaire (CHAQ); A-CHAQ: Adolescent-assessed CHAQ; IRR: Incidence rate ratio; CI: Confidence interval

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Incorporation of parent-/child-reported outcomes in patient assessment is deemed increasingly important in the managment of children with juvenile idiopathic arthritis (JIA). Aim of the study is to develop and to validate parent-centered and child-centered versions of the Juvenile Arthritis Disease Activity Score (JADAS), named parJADAS and chiJADAS, respectively.

Methods: The parJADAS and chiJADAS include 4 measures: 1) parent/child assessment of disease activity; 2) assessment of pain intensity; 3) self/proxy assessment of joint disease; 4) assessment of morning stiffness (MS). Disease activity and pain are assessed on a 0-10 VAS. The active joint count is based on the count of any swollen or painful joint up to a maximum of 10 joints. MS duration is assessed on a Likert scale, ranging from no MS (0 points) to > 2 hours of MS (10 points). Validation was conducted on a dataset of 602 children with JIA who underwent 1749 visits at study unit. To account for repeated measurements in a single patient, construct validity was assessed by calculating between-subject and within-subject correlations of parJADAS and chiJADAS with cJADAS, JADAS10, physician global assessment of disease activity, number of active joints, parent/child rating of well-being and ESR. Discriminant ability was evaluated by comparing score levels between patients with active or inactive disease according to current criteria, and between patients who were satisfied or not satisfied with disease outcome. Sensitivity to change was tested using standardized response mean (SRM) in 2 subsequent visits performed no more than 6 months apart. Internal consistency was assessed with Cronbach‘s alpha coefficient and inter-rater reliability was assessed using the intraclass correlation coefficient (ICC).

Results: Between-subject correlations of parJADAS and chiJADAS were high (>0.70) with JADAS10, cJADAS10, parent/child rating of overall well-being, and moderate (0.40-0.70) with the other measurements. Moreover, in the same subject, changes over time of the parJADAS and chiJADAS corresponded to changes in disease activity, as indicated by high within-subject correlations with JADAS10, cJADAS10, physician global assessment of disease activity, parent/child rating of overall well-being, and active joint count. Both parJADAS and chiJADAS discriminated well between inactive and active disease and between satisfied and not satisfied patients ($p<0.001$). The responsiveness to clinical change of parJADAS was good (SRM = 0.84). The internal consistency was satisfactory, with Cronbach‘s alpha >0.80 for both PARJADAS and CHIJADAS. The inter-rater reliability between the parJADAS and the chiJADAS measured at the same visit was high, with ICC 0.92 (95% CI 0.90-0.93).

Conclusion: The parJADAS and chiJADAS were found to be valid and reliable for assessment of disease activity in JIA and may therefore be suitable for use in clinical practice, observational studies, and therapeutic trials. Both scores may potentially surrogate physician assessments when these are not available.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Global assessment scores are increasing important in assessing disease activity by physicians and patients/parents (PGAmd, PGApatient/parent). The purpose of this study was to determine and characterize the discordance between these assessments JIA patients and to distinguish which patient and disease characteristics contribute to this discordance.

Methods: Patients in this study were part of the Pediatric Rheumatology-Care & Outcomes Improvement Network (PR-COIN) and data collected from the registry. Patient and disease characteristics were collected including PGAmd and PGApatient/parent scores (each on a 21-point visual analog scale from 0-10) from 202 established JIA patients at Stanford Children's Health, ages 2-18. PGA discordance was calculated as [PGApatient] – [PGAmd], could range from -10 to 10, and was classified as positive, negative, or none. No discordance was defined as agreement within 1 point. Negative discordance was defined as the patient's PGA being underrated by >1 point compared to the MDs, whereas positive discordance was the reverse. Discordance was "marked" if the difference was greater than three. Validated instruments were administered to specific age groups: 2-4, 5-7, 8-12, and 13-18. Descriptive statistics were calculated and logistic regression used to evaluate the association between the discordance category and the patient/disease characteristics for all positive and then all negative discordance, each with no discordance as the reference. We also compared MD and parent PGA scores (198 pairs), as well as patient-parent agreement (147 pairs).

Results: 138 (68.3%) patients were female with a mean (SD) age of 11.4y (4.5) and disease duration of 4.3y (3.8). Oligoarticular (31.7%), rheumatoid factor (RF) negative polyarticular (24.3%), and enthesitis-related arthritis (ERA) (17.8%) were the most common JIA subtypes. For physician-patient pairs, 82 (54%) had no discordance, 54 (36%) had positive/marked positive discordance, and 15 (10%) had negative/marked negative discordance. The results were similar for physician-parent discordance. When patient and parent responses were compared, there was greater concordance (69% agreement) than compared to MD-patient (54%) and MD-parent (65%). After age and sex adjustment, pain, morning stiffness, and elevated CHAQ scores were associated with increased odds of positive discordance. Patients with RF negative polyarticular and ERA had lower odds of negative discordance when compared to patients with oligoarticular disease in the MD-patient comparison and with increased odds of positive discordance in the MD-parent comparison.

Conclusion: It is important to understand what patients and parents perceive as important to their disease status and health outcomes. Discordance was seen in approximately 50% of MD-patient and MD-parent comparisons with the majority of the discordance being positive/marked positive (78% of MD-patient and MD-parent discordant pairs). Pain, the presence of morning stiffness, and higher CHAQ scores were found to be statistically significantly associated with positive discordance.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis is a broad term that describes a clinically heterogeneous group of arthritis of unknown cause, which begin before 16 years of age. Sleep problems are common among children with chronic illnesses such as JIA. However, little is known about the frequency and severity of sleep disturbance(s) and the factors that are associated with sleep problems in children with JIA. The aims of this study were to primarily investigate sleep quality and to secondarily examine possible associations of pain, disease activity, sleep disturbance in Turkish children and adolescent with JIA.

Methods: 96 patients with JIA (age range 8-18) participated in this study. Disease activity was assessed with The Juvenile Arthritis Disease Activity Score-27 (JADAS27). Pain severity was evaluated with a 100-mm Visual Analog scale (VAS). Sleep quality was evaluated with Pittsburgh Sleep Quality Index (PSQI). The PSQI is a self-rating questionnaire resulting in a global score between 0 and 21, which consists of seven subscores (sleep quality, sleep latency, Sleep efficiency, daytime dysfunction, sleep disturbance, use of sleeping medication, sleep duration). A global PSQI score above 5 indicates poor sleep.

Results: A total of 96 eligible patients with JIA (61 female, 35 male) were enrolled including 42 (43.8%) with polyarticular onset, 33 (34.8%) with oligoarticular subtype, 14 (14.6%) with systemic onset and 7 (7.3%) with other subtypes. The mean of age, duration of sleep and pain severity was 12.93±3.36, 8.43±1.59 and 23.80±24.82, respectively. 39.6% of participants were poor sleepers. Table 1 shows comparisons of the results of JADAS and VAS pain in patients with good/poor sleep quality groups. JADAS and VAS-pain were statistically significant worse in patients with poor sleep than in patients with good sleep ($p<0.05$). 96.1% of patients have reported that they have experience of sleep disturbance (65.6% of them; less than once a week, 30.2% of them; once or twice a week, 1% of them; three or more time week). Sleep quality was very good only for 29.2% of them. 84.4% of them have reported they sleep >7 hours. 66.7% of participants reported needed more than 15 minutes to fall asleep each night (sleep latency). Sleep efficiency was found as >85% for almost all patients.

Conclusion: The results of this study suggest that poor sleep are significant widespread in Turkish children and adolescent with JIA and poor sleep quality is associated with greater pain severity and disease activity among patients with JIA. Future research should investigate whether reducement in pain and disease activity can improve sleep quality in patients with JIA **Table 1.** Comparisons of the results of JADAS and VAS pain in patients with good/poor sleep quality groups

	Good Sleep n=58 (60.4%)	**Poor Sleep n=38 (39.6%)**		
	Mean (SD)	**Mean (SD)**	**t**	**p**
JADAS	4.65 (4.31)	6.96 (4.96)	-2.418	0.018
VAS-pain	16.81 (22.25)	34.47 (25.00)	-3.620	0.000

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Children with JIA are increasingly being encouraged to be physically active and are participating in organized and competitive sports as youth athletes. These youth are at risk of experiencing pain and dysfunction related to their underlying rheumatic disease, as well as the sports-related injuries observed in the general population. Our objective was to describe the demographic characteristics as well as the physical activity level and health-related quality of life of a cohort of youth athletes who have a diagnosis of JIA.

Methods: The JIA Sport and Exercise Medicine Clinic at Alberta Children's Hospital is a multidisciplinary clinic run by a pediatric rheumatologist, physiatrist, and physiotherapist. All practitioners have a special interest and experience in pediatric sport and exercise medicine. The clinic includes children with a diagnosis of JIA followed in the hospital's Pediatric Rheumatology Clinic, who self-identify as athletes and are interested in attending a Sport and Exercise Medicine clinic. Prior to the clinic visit, each child is asked to complete a series of questionnaires which includes validated measures of level of physical activity (Hospital for Special Surgery Pediatric Functional Activity Brief Scale (HSS Pedi-FABS) (scores 2-30) and Physical Activity Questionnaire for Adolescents (PAQ-A) (scores 1-5)) and health-related quality of life (Pediatric Quality of Life Generic Core Scale (Version 4.0, Adolescent) (PedsQL GCS-A) and Pediatric Quality of Life (Version 3.0) Rheumatology Module (PedsQL-Rheum)).

Results: A total of 11 youth with JIA participated in the JIA Sport and Exercise Medicine Clinic between October 2014 – April 2015. Children had a median age of 14 years (range 10-17) and 64% were male. The median time since diagnosis was 4 years (range 1-14). The sub-types of JIA included oligoarticular, 7, enthesitis-related arthritis, 3, and polyarticular RF negative, 1. All children took at least one arthritis medication, including NSAIDs (8), non-biologic DMARDs (5), and biologic DMARD (1). Children were involved in a variety of primary sports including ice-hockey, soccer, baseball, football, running, gymnastics, ringette, and dance. The children indicated that they were active a median of 13 hours per week (range 3-22). The measures of physical activity revealed moderate to high mean scores (SD) on the PAQ-A, 2.84 (0.84), and HSS Pedi-FABS, 22.45 (6.27). Health-related quality of life was found to be low with mean scores (SD) on the PedsQL GCS-A of 81.03 (11.08), (Physical Health, 73.58 (18.77), and Psychosocial Health, 85.00 (9.37)). The mean scores (SD) on the PedsQL-Rheum were low to moderate for Pain and Hurt, 58.52 (24.25), Treatment, 76.62 (18.38), Worry 75.00 (23.86), and Communication, 71.97 (23.94). The score was high for Daily Activities, 95 (9.22).

Conclusion: Youth athletes with JIA are involved in a variety of sports. They are physically active for an above average number of hours per week but experience a significant degree of pain and have decreased scores of physical and psychosocial functioning. Additional support may need to be targeted to youth athletes with JIA to help them achieve their sports goals.

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Diabetes mellitus (DM) and hypertension (HTN) are well-known toxicities of glucocorticoids (GCs), but the risks of these complications are unclear in children with JIA. We studied rates of new-onset DM and HTN after oral GC exposure compared with non-users separately in children with JIA and children with attention-deficit/hyperactivity disorder (ADHD), a non-immune reference population.

Methods: Using Medicaid claims data (2000-2010), we identified children ages 1-18 diagnosed with JIA (based on diagnostic codes ± pharmacy claims) or ADHD (based on diagnostic codes). We studied oral GCs as time-varying exposures based on pharmacy claims after a ≥9-month GC-free baseline period. Incident DM was defined by new use of insulin or oral antidiabetic drugs; secondary type 2 DM definitions combined diagnoses and pharmacy claims. Incident HTN was defined by new use of antihypertensive drugs combined with diagnoses. We compared absolute rates of new DM and HTN in each cohort and used Cox regression to estimate hazard ratios (HRs) between GC-exposed and -unexposed children.

Results: Children with JIA contributed ~2,600 person-years (py) of GC-exposed time and ~38,000 py of unexposed time; children with ADHD had ~7,500 py exposed to GCs and ~1.6 million py unexposed. Compared with non-users, GC users were younger and more likely to be recently hospitalized before study entry. Within disease cohorts, exposed and unexposed groups were similar in terms of sex, race/ethnicity, and prior comorbidities. Compared with the unexposed, incremental rate differences of new DM drug use and type 2 diabetes were 10.4/1,000 py and 4.5/1,000 py in GC users with JIA, respectively, and 5.1/1,000 py and 1.7/1,000 py in GC users with ADHD, respectively (Table). The rate differences for new antihypertensive drug use were of similar magnitude: 15.4/1,000 py greater in GC users with JIA and 4.8/1,000 py greater in GC users with ADHD. After adjusting for age, sex, race/ethnicity, year of study entry, prior comorbidities and medications, and baseline healthcare utilization, GC exposure was associated with new DM drug use in children with JIA: current GC use, aHR 3.4 (95% CI 2.4, 4.8); any prior GC use, aHR 1.7 (95% CI 1.2, 2.4). The associations of GC use with type 2 DM in JIA, and with DM among children with ADHD, were similar (Table). The strength of association between GCs and HTN was even greater: current GC use, aHR 4.5 (95% CI 3.2, 6.2); any prior GC use, aHR 2.4 (95% CI 1.6, 3.6). Results for children with ADHD were also similar (Table).

Conclusion: In children with JIA, current oral glucocorticoid use is associated with a 3-fold increased rate of new treatment for diabetes mellitus and over 4-fold increased rate of new treatment for hypertension. These findings are similar among children with ADHD, but the absolute rates of these complications are higher in children with JIA. More work is

needed to clarify how GC dose and duration relate to these toxicities.

Table. Absolute and relative (hazard) rates of new diabetes mellitus and hypertension among GC-exposed and -unexposed children with JIA and ADHD

	Diabetes mellitus				Hypertension	
	New DM drug use[1]		New type 2 DM[2]		New HTN drug use[3]	
	JIA	ADHD	JIA	ADHD	JIA	ADHD
No. of outcomes/ person-years

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: According to a recent expert panel, in refractory juvenile idiopathic arthritis (JIA)-related uveitis, infliximab or adalimumab may be considered (Levy-Clarke et al. Ophthalmology 2014; 121:785-796). In some cases these biologic agents are not effective, or not tolerated. Golimumab (GLM) is a novel fully humanized anti-TNF-α monoclonal antibody. Our aim was to assess the efficacy of GLM in refractory uveitis associated with JIA.

Methods: Multicenter study of uveitis related to JiA and refractory to at least **a)** one standard synthetic immunosuppressive drug and, **b)** one anti-TNFα drug**.** The results were expressed as mean±SD or as median (25,75 interquartile range [IQR]) as appropriate. The Wilcoxon signed-rank test was used to compare continuous variables. Also a review of the literature regarding the effectiveness of GLM in uveitis related to JiA was performed.

Results: We assessed 7 (5 women/2 men) patients with 13 affected eyes; mean age 21.7±7.5 years. Uveitis was bilateral in 6. Cystoid macular edema (CME) was present in 3 patients (5 eyes). Besides corticosteroids and synthetic immunosuppressive drugs, patients had received a median of 2 biological agents (range 0-3): adalimumab (n=6), etanercept (n=1), infliximab (n=3), abatacept (n=2). GLM dosage regimen was 50 mg/sc every 4 weeks. GLM yielded an improvement in all ocular parameters. After 6 months of therapy the number of anterior chamber cells decreased from a median of 1 [0.25-1.5] to 0 [0-0.5] (p=0.02), vitritis from 0 [0-1] to 0 [0-0] (p=0.6); and optical coherence tomography (in 3 patients with CME) from 313.6±77.05 to 261.4±75.1 µm (p=0.03). Moreover, the best-corrected visual acuity increased from 0.5 to 0.62 (p=0.018). After a mean follow-up of 16.8±11.4 months, a complete remission of uveitis was achieved in

4 of 7 patients. The only observed adverse effects were local erythema at the injection site in 2 patients. A literature review of refractory JIA related uveitis treated with GLM is summarized in **Table.**

Conclusion: GLM appears to be a useful therapy in refractory JIA-related uveitis. **TABLE**

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) associated uveitis is the most common extraarticulare comorbidity of juvenile idiopathic arthritis. Nowdays it occurs in about 10-15% of JIA patients. As effective treatment options are emerging, is it extremely important to propose validated definition of inactivity, which is main aim of the treatment.

Methods: Multinational Interdisciplinary Working Group for Uveitis in Childhood Group (MIWGUC) had prospectively evaluated the validity of the proposed outcome measures(1). Based on these data, we proposed a definition of inacitivity using the nominal group technique in a consensus meeting in Barcelona, Spain, in November 2015.

Results: The following items were selected to define inacitivity. It is required, that in both eyes the following condition is reached: 1. Slit lamp total number of AC cells: 0 inflammatory cells *In aphakic patients ,some cells may be present, in the anterior vitreous 2. Absence of Optic disc edema *The presence of isolated optic disc edema may not be a sign of activity 3. Absence Macular edema *The presence of isolated macular edema may not be a sign of activity 4. Absence of Vitreous haze *The presence of isolated vitreous haze may not be a sign of activity 5. VAS score of activity physician 0-100: must be 0

Conclusion: We proposed items to define inactivity of JIA associated uveitis, which is a major goal of treatment. This proposal will be validated from the MIWGUC group in prospective study. References:

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) associated Uveitis is the most common extraarticulare comorbidity of juvenile idiopathic arthritis. Nowdays it occurs about 10-15% of JIA patients. As innovative effective treatment options are emerging, it is extremely important for defining validated damage index in order to assess the effectivity of drugs to preventing damage, one of the main aims of the treatment.

Methods: Multinational Interdisciplinary Working Group for Uveitis in Childhood Group (MIWGUC) had prospectively evaluated the validity of the proposed outcome measures(1). Based on the data, we proposed a damage index using the nominal group technique in a consensus meeting in Barcelona, Spain, in November 2015.

Results: Following items were selected for assessing damage: Vision related permanent damage per eye /per patient - yes / no **Right eye Left eye** 1. flare 2. synechiae 3. cataract 4. maculopathy 5. Opticopathy 6. Decreased Visual acuity 7. Ocular hypertony – >21 mmHg 8. Ocular hypotony - <6 mmHg 9. Glaucomatous field loss and /or glaucomatous optic atrophy 10. Band-keratopathy 11. Epiretinal membrane formation 12. Visual deterioration – less then 0.3 in any eye 13. Uveitis related disability VAS 0-100 by ophthlamologist 14. Uveitis related disability VAS 0-100 by pediatric rheumatologist

Conclusion: We proposed items for assessing the damage index of JIA associated uveitis. The damage index should be a valid instrument for assessing the effectivity of a given drug in order to preventing damage. This proposal will be evaluated from the MIWGUC group in prospective study. References:

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Approximately 10-15% of patients (pts) with juvenile idiopathic arthritis (JIA) experience comorbid uveitis. The objective of this study is to explore events of uveitis and associated safety in pts with moderately/severely active polyarticular or polyarticular-course JIA (pJIA) who were prescribed and treated with adalimumab (ADA) and/or methotrexate (MTX) in routine clinical practice.

Methods: STRIVE is an ongoing, multicenter, non-interventional, observational registry of up to 10 years duration in pts with moderately/severely active pJIA who are treated with either ADA±MTX or MTX alone as part of routine clinical care. Pts could initiate ADA and/or MTX within 24 months prior to registry entry. Pts that completed ADA studies (DE038, M10-444) had option to roll-over into this registry. Ophthalmologists performed slit-lamp examination for uveitis at registry entry and specified visits in 3-6 month intervals through 5 yrs. Beyond 5 yrs, uveitis events were collected solely through adverse event (AE) reporting. Observational ocular AEs (e.g. cataract, glaucoma) were recorded from registry entry through yr 6.

Results: As of 1 June 2015, a total of 21/303 (6.9%) and 68/543 (12.5%) enrolled pts reported at least 1 case of JIA-associated uveitis at any visit in the MTX and ADA±MTX groups, respectively. In the JIA-associated uveitis population, 10 (47.6%) in MTX and 42 (61.8%) in ADA±MTX group presented with documented uveitis at registry entry. In the population without uveitis at registry entry, 11/293 (3.8%) and 26/501 (5.2%) pts in MTX and ADA±MTX arms, respectively had first documentation of uveitis post-enrollment. Most pts in the JIA-associated uveitis sub-population were female (73%), white (96%), with a mean age of 8.1 yrs; mean pJIA disease duration was 1.8 and 4.8 yrs for MTX and ADA±MTX groups at registry entry, respectively. Nine (42.9%) MTX and 48 ADA±MTX (72.7%) pts were positive for antinuclear antibodies at registry enrollment. For vast majority of pts,uveitis was localized to anterior layer. In ADA group, 45 (66.2%) pts with documented uveitis received concomitant MTX during the course of the registry. Through Month 42, majority of JIA-associated uveitis sub-population had either no new manifestation of uveitis or stabilized uveitis. A higher proportion of MTX vs ADA±MTX pts discontinued registry drug (15/21 [71.4%] vs. 21/68 [30.9%]), but continued to be monitored for safety follow-up. Of these, 2 (9.5%) and 1 (1.5%) in MTX and ADA±MTX group, respectively, discontinued the registry drug due to an AE, and 4 of the 15 pts in the MTX group discontinued MTX group and switched to ADA±MTX registry group. Two (0.4%) pts with glaucoma and 1 (0.2%) pt with cataract were reported in ADA±MTX group and none in MTX group; 2 of these patients had documented uveitis at registry enrollment.

Conclusion: Among pJIA pts with uveitis documented at registry entry, a higher percentage of pts were enrolled in ADA ±MTX group as per investigator judgment. No new safety signals for adalimumab were observed in JIA-associated uveitis sub-population treated per standard of care. Based on this interim analysis, JIA-associated uveitis appeared well-controlled during the course of this registry for pJIA pts with existing uveitis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster I: Juvenile Idiopathic Arthritis, Uveitis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pediatric HLA-B27-associated uveitis is a common form of non-infectious uveitis (NIU) that can lead to ocular complications and vision loss. Methotrexate (MTX) is the usual first-line systemic treatment in NIU. Tumor necrosis factor-α inhibitors (TNFi) are primary therapy in other HLA-B27-associated diseases such as ankylosing spondylitis and inflammatory bowel disease. There is no standard treatment protocol for pediatric HLA-B27-associated uveitis. Given the success of TNFi in other HLA-B27-associated diseases, our aim is to describe MTX and TNFi use in pediatric HLA-B27-associated uveitis.

Methods: We reviewed medical records of 21 children with HLA-B27-associated uveitis. We compared demographics and clinical characteristics based on treatment with TNFi.

Results: There were 12 (57%) children with HLA-B27-associated uveitis alone (U), and 9 (43%) with JIA-associated uveitis (JIAU) that was all enthesitis related arthritis (Table 1). Most were non-Hispanic (86%) White (95%) males (52%), diagnosed at a median of 10.5 (8.1-11.8) years, with anterior (90%), unilateral (67%) disease and several complications. Of these, 14 (67%) did not require TNFi (8 topical steroids alone, 6 MTX alone,) and 7 (33%) required TNFi. There was a clinical trend of earlier treatment with TNFi in JIAU (0.5 vs. 2.6 years of MTX) despite similar uveitis duration before MTX start (0.2 vs. 0.3 years). Comparing by TNFi use, more females were treated with TNFi (60% vs. 9%, $p = 0.02$) (Table 2). There was no difference in race, age at uveitis diagnosis, uveitis type, laterality, or complications. Comparing by gender, more females 8/10 (80%) then males 5/11 (45%) also needed MTX. Although they had similar uveitis type (40% associated with ERA), complications (80%), and age at diagnosis (10.8 vs. 9.7 years), more females needed TNFi and MTX.

Conclusion: Usual treatment for pediatric NIU includes MTX and then TNFi if MTX fails, ocular complications arise/worsen or uveitis persists. Based on our results, it appears reasonable to treat pediatric HLA-B27-associated uveitis with MTX prior to TNFi. However, we demonstrate the increased use of TNFi in females despite a similar uveitis course. We were unable to determine clinical factors that explained this difference due to our sample size, but this requires further study. There may be an inherent gender difference in immune pathway response which may mitigate uveitis course and improve visual outcomes.

Table 1. Demographics and Clinical Characteristics of Children with HLA-B27-associated Uveitis

Discrepancy in Reported and Actual Rates of Counseling on Teratogenicity and the Need for Contraception When Initiating Mycophenolate in Women of Childbearing Age

Jenna Thomason[1] and Alison Bays[2], [1]Medicine, University of Washington, Seattle, WA, [2]Rheumatology, University of Washington, Seattle, WA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Many women of childbearing potential with autoimmune diseases require terotogenic medications, such as mycophenolate. On October 29, 2007 the FDA deemed mycophenolate a pregnancy class D medication given the risks of first trimester abortion and congenital malformations.[1] The encounter when mycophenolate is initiated is arguably the most important time to counsel patients on its risks and the need for effective contraception. We compared reported rates versus actual documentation of counseling in the electronic medical record (EMR).

Methods: We developed a 10 question, anonymous survey that was distributed to all rheumatology providers at our institution. The survey asked respondents at how often they provide and document adequate counseling when initiating mycophenolate in women of childbearing age. Subsequently, using our institution's De-identified Clinical Data Repository, we identified women aged 17-45 on mycophenolate who had been seen in one of our rheumatology clinics since October 29, 2007, and assessed actual documentation of counseling at initiation of mycophenolate.

Results: Fifteen faculty and fellows (83%) responded to the survey. On average, respondents reported providing and documenting adequate counseling when initiating mycophenolate in 74% and 64% of encounters, respectively. Of 219 charts reviewed, 65 patients met inclusion criteria; the patients included were predominately Caucasian (38%) with an average age of 35. In 5 encounters (8%) providers documented advising the patient that mycophenolate is a teratogen and in only 1 encounter did a provider discuss the specific risks (**Table I**). The need for contraception while taking mycophenolate and 6 weeks afterwards, as well as the type of contraception utilized were also scarcely documented (n=6, 9%; n=0, 0%; n=9, 14%, respectively). In 22 (34%) encounters providers documented discussion of other side effects or that information was provided. Barriers to effective counseling identified by the survey included lack of time (50%) and inadequate knowledge (33%).

Conclusion: Documentation of counseling on teratogenicity and the need for contraception at the initiation of mycophenolate was reported at much higher rates than was actually observed on chart review, despite higher documentation of other side effects. By educating providers and using the EMR to prompt them to provide counseling when prescribing mycophenolate, we may be able to increase documentation rates. Additionally, "dot phrases" with risks and contraception information could be imported into the provider note and patient instructions as a time saving strategy. **Table I.** Mean reported rates of counseling on the teratogenicity of mycophenolate and the need for contraception as compared to actual documentation of counseling

	Reportedly discussed	***Reportedly documented***	***Actually documented***
	(Reported % of initial encounters)	*(Reported % of initial encounters)*	*N=65 (%)*
Counseling point			
Mycophenolate use in pregnancy carries an increased risk of 1st trimester abortion	*49%*	*16%*	1 *(2%)*
Mycophenolate use in pregnancy carries an increased risk of congenital malformations	*83%*	*45%*	1 *(2%)*
The patient should use contraception during her entire treatment with mycophenolate	*84%*	*65%*	6 *(9%)*
The patient should continue contraception 6 weeks following cessation of mycophenolate	*37%*	*15%*	0 *(0%)*
The type(s) of contraception utilized (or to be utilized) by the patient	*55%*	*38%*	9 *(14%)*
The patient should alert her doctor when considering pregnancy	*87%*	*60%*	2 *(3%)*

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: chronic inflammatory diseases are at a substantially increased risk of cardiovascular disease. Framingham risk score (FRS) underestimates cardiovascular risk in many inflammatory diseases. Our objective was to assess the predictive ability of Framingham score model for the 10-year risk of fatal and non-fatal CV diseases in patients with Polymyalgia Rheumatica (PMR).

Methods: we retrospectively reviewed electronic medical records of patients registered in our hospital after year 2000 with the diagnosis of PMR. Patients fulfilling ACR PMR 2012 criteria or with a clinical diagnose made by a rheumatologist were included. Patients with history of cardiovascular event before diagnosis, age greater of 80 years at diagnosis or with less than 10 years of follow up after diagnosis, were excluded. Framingham score was calculated at diagnosis, and based on the FRS, patients were classified into low, intermediate and high-risk categories. Cardiovascular (CV) events such as stroke, transient ischemic attack, coronary arterial disease and peripheral vasculopathy were identified during follow up. Discriminatory ability for CV risk prediction was estimated by the area under the receiver operating characteristic (ROC) curve. Global cardiovascular risk was calculated at 10 years after PMR diagnosis and compared with FRS estimated at diagnosis.

Results: A total of 97 patients were included. Patients characteristics are described in table. Among the 97 patients followed up for a total of 981.5 person-years, 18 CV events occurred with an incidence rate of 1.83 per 100 patient-years (95% CI: 1.1-2.9). There were no differences in clinical characteristics among patients with and without CV events (table). The area under the ROC curve for FRS was 0.61 (95% CI: 0.47- 0.74), indicating low discrimination between patients with and without a CV event. According to FRS 17 (17.5 %), 46 (47.4%) and 34 (35%) patients were classified into low, intermediate and high risk categories respectively. Across the three predicted CV risk groups the observed/predicted CV events (%) were:0.059/0.065; 0.2/0.13; and 0.24/0.26 for low, intermediate and high risk categories respectively. When observed vs predicted CV events in quintiles of CV risk were compared, the following values were obtained: 0.1 vs 0.072; 0.16 vs 0.12; 0.20 vs 0.16; 0.31 vs 0.34.

Conclusion: FRS showed low discrimination capacity between patients with and without a CV event. FRS primarily underestimated CV risk at low and intermediate risk levels, and mostly overestimated CV risk at higher risk levels. Table 1. Patients characteristics

Session Title: Quality Measures and Quality of Care - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking is a both a risk factor for developing rheumatoid arthritis (RA) and a predictor of severe, treatment-refractory disease in RA and other rheumatic conditions, yet, little is systematically done in rheumatology clinics to help patients quit smoking. We previously reported that only 10% of eligible RA visit notes documented tobacco counselling by rheumatologists; only one in 175 notes recommended quit line phone services. Quit line services are free in every state and recommended by US guidelines to improve quit rates four-fold, but are rarely leveraged in rheumatology clinics.

Methods: We designed a prospective study to examine the feasibility of a staff-led tobacco cessation intervention in three academic rheumatology clinics over six weeks in 2016, compared to 2012-2015. Medical assistants and nurses were educated on tobacco cessation and rehearsed evidence-based care in a one hour session. During clinic rooming, electronic health record (EHR) alerts prompted documentation of tobacco use, assessment of 30 day readiness to quit among users, and offers for electronic referral for quit line to phone the patient within one week. Process measures for assessing tobacco use and readiness to quit were compared (pre- post-) using standard EHR documentation fields. We compared quit line referral events to historic abstracted rates. Chi-square tests and logistic regression models were used to obtain odds ratios between the groups pre-intervention and during protocol implementation.

Results: Over the six week protocol pilot, 123 rheumatology visits with patients who smoke were compared to 4078 baseline visits with patients who smoke. Process measures showed that the protocol increased tobacco status documentation to 97% (OR 1.40, 95% CI 1.02-1.92) **Table 1**. Assessment of 30 day readiness to quit robustly increased from 3% before to 76% during the protocol intervention (OR 105, 65.7-167). Moreover, 32% (n=30) of those asked reported readiness to quit or cut back in the next 30 days. In total during the intervention, 12% (n=15 of 123 eligible visits) agreed to tobacco quit line electronic referral compared to 0.57% being offered referral (n=1 of 175) in our prior report ($p<0.001$).

Conclusion: The rheumatology staff protocol intervention for tobacco quit line electronic referral was feasible and tobacco cessation care improved by week six. A marked gain in assessing quit readiness, despite prior existence of this field in the EHR, shows that tools alone are ineffective and supports the need to study systematic implementation of such tools. A full six month pilot study is under way to assess protocol effectiveness including actual tobacco cessation rates. Given the importance of tobacco cessation for inflammatory disease activity and long term cardiovascular risk, methods should be studied to deliver tobacco cessation care or connect patients to proven quit resources.

Table 1. Tobacco use and quit readiness assessment and quit line referrals by visit before vs. during intervention

	Pre-Protocol n= 47,098 (n (%))	Protocol n= 1498 (n (%))	p	Protocol Unadjusted OR (95% CI)	Protocol Adjusted* OR (95% CI)
Tobacco Status Assessed	45,337 (96%)	1458 (97%)	0.031	1.41 (1.03, 1.94)	1.40 (1.02, 1.92)
Tobacco User (current)	4078 (9%)	123 (8%)	0.54		
Readiness to Quit Assessed	135 (3.3%)	94 (76%)	<.0001	94.7 (60.3, 148)	105 (65.7, 167)
Quit line referral	(<0.57% historic)	15 (12%)	<.0001

Educating Patients on the Cardiovascular Risks of Rheumatoid Arthritis: Usual Care Versus a Structured Approach

Marcia Genta[1] and Robert M. Genta[2], [1]Dallas Arthritis Center, Dallas, TX, [2]Laboratory, Dallas Arthritis Center, Dallas, TX

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) carries a considerable increase of the risks for cardiovascular (CV) disease. It is unclear how well patients with RA understand such risks and what they do to minimize them. This study was designed to determine whether a structured approach (detailed explanation and a concise brochure) is more effective than a verbal explanation delivered to the patient when the diagnosis of RA is made.

Methods: Existing patients with an established diagnosis of RA followed at the Dallas Arthritis Center were administered a questionnaire. These patients had been given the traditional verbal explanation of CV risks. In the interventional phase of the study, newly diagnosed RA patients were given a simple brochure that illustrated CV risks associated with RA and suggested strategies to minimize them. The contents of the brochure were discussed with the patients in a structured fashion, *i.e.*, by rigorously following the scheme in the brochure and by answering patients' questions as each point was presented. In a follow-up visit after the diagnosis, the questionnaire was administered to patients who had received the structured explanation and the brochure. Responses of the two groups were compared using unadjusted odds ratios and the chi-square test.

Results: A total of 53 patients completed the questionnaire in the first phase and 33 completed the second phase. In group 1 (non-structured explanation with no brochure) 22 of the 53 patients (41.5%) indicated that they could recall having been given an explanation of the CV risks associated with RA and being encouraged to make appropriate life-style changes. However, 31 patients (58.5%) had no such recollection. In group 2 (structured explanation and brochure) 22 of 33 patients (66.7%) indicated that they could recall having been given an explanation of the CV risks associated with RA and being encouraged to make appropriate life-style changes, while 11 (33.3%) had no such recollection. This represents a highly significant change with respect to group 1, where only 41.5% recalled having received instructions (OR 2.82 95% CI 1.14 – 6.98; $p<0.05$). Patients' responses regarding lifestyle changes made are depicted in Table 1.

Conclusion: A brief structured explanation of CV risks associated with RA was more effective than a less formal unstructured explanation given as part of the initial or follow up encounters with regards to smoking behavior and switching to a healthier diet. Approximately half of the patients reported increasing their commitment to exercise, irrespective of how the suggestion was delivered and whether they recalled or not being given the advice. A high proportion of patients (4 out of 5) reported seeing their primary care provider (PCP), and structured or unstructured recommendations seemed to have little effect on this behavior.

Patients	Smokers (%)	Stopped Smoking (%)	Increased exercise (%)	Healthier diet (%)	See PCP (%)
Non-structured (n = 53)	**17** (*31.1*)	**8** (*47.1*)	**27** (*50.9*)	**29** (*54.7*)	**43** (*81.1*)
Recall instructions (n = 22)	**9** (*40.9*)	**4** (*44.4*)	**12** (*54.5*)	**13** (*59.1*)	**19** (*86.4*)
Do not recall (n = 31)	**8** (*25.8*)	**4** (*50.0*)	**15** (*48.4*)	**16** (*51.6*)	**24** (*77.4*)
Structured (n = 33)	**12** (*36.4*)	**9** (*75.0*)	**9** (*66.7*)	**26** (*78.8*)	**26** (*78.8*)
Recall instructions (n = 22)	**9** (*40.9*)	**8** (*88.9*)	**8** (*68.2*)	**19** (*86.4*)	**19** (*86.4*)
Do not recall (n = 11)	**3** (*27.3*)	**1** (*33.3*)	**1** (*63.6*)	**7** (*63.6*)	**7** (*63.6*)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Quality Measures and Quality of Care - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) have an increased risk of premature cardiovascular disease (CVD), making comorbid risk factors like smoking a prime intervention target for rheumatology patients who smoke. Primary care clinics have systems to promote cessation, but rheumatology clinics rarely address smoking adequately (Vreede 2015). Resources like free telephone quit lines exist that have already been shown to improve the odds of quitting, but patients must first be connected to them. The Ask-Advise-Connect model has been shown to increase the proportion of patients being referred to quit lines 13-fold (Vidrine 2013), but this model has not been studied thoroughly in specialty clinics. These tools show great promise for encouraging tobacco cessation, but they should be tailored for use in rheumatology in order to maximize their effectiveness. Our goal was to work with rheumatology clinic staff to 1) understand current tobacco cessation care practices and obstacles and 2) use that information to customize and implement a quit line referral intervention based on the Ask-Advise-Connect model.

Methods: We conducted participatory work system redesign with medical assistants (MAs) and nurses from three rheumatology clinics at a large, academic health system in 2015. Building on prior patient and provider interviews and staff focus groups, we held two hour-long focus groups using semi-structured interview questions to assess current processes, needs, and a proposed electronic health record (EHR)-based quit line referral process. The results were organized according to the Systems Engineering Initiative for Patient Safety (SEIPS) work system domains.

Results: 80% (9 MAs, 5 nurses) of the clinic staff participated in the focus groups. We found that smoking assessment was standard, but follow-up actions were rare. Barriers to assessing smoking and referring patients to cessation resources included discomfort discussing cessation with smokers and the absence of an easy referral process (Table 1). Using these findings, we developed a new staff-driven tobacco quit line referral process for MAs and nurses that leverages our EHR system. The process uses two decision-support EHR alerts with conversation prompts to assess use and 30-day readiness to quit (Ask), encourage cessation (Advise), and refer the patient to the state tobacco quit line using an electronic interface (Connect). We also created a rheumatology-specific educational brochure and an hour-long staff training program to support the workflow.

Conclusion: By working directly with our rheumatology MAs and nurses, we developed a new smoking assessment and referral protocol that addresses major obstacles to delivering consistent, effective care to rheumatology patients who smoke. We are testing the effectiveness of this intervention in a 6-month pilot.

Table 1. Results of Participatory Work System Redesign (n=14 MA and nurse participants)

Work System Components	Before Redesign	Protocol Redesign Components
People	Staff uncomfortable with tobacco conversations	1-hour education and rehearsal session with trained tobacco cessation experts
Organization	No tobacco care follow-up procedure	Standard protocol supported by clinic staff and leadership
Technology	No use of reminders to assess readiness to quit; no easy way to refer to quit line	EHR alert and order set with talking points for quit line referral; electronic interface to/from quit line
Environment	No physical cues for tobacco cessation conversations	Patient brochure on tobacco cessation tailored to rheumatology clinics discussing links with diseases
Tasks	Assessment of tobacco use only	**Ask** about tobacco use and 30-day readiness to quit, **Advise** quit line support, and **Connect** via e-referral to quit line who will call the patient within 48 hours
Staff Quotations	*"I never had the verbiage to continue… I never asked [about tobacco cessation] because I didn't know where to go from there."—Medical Assistant*	*"It doesn't seem like this [protocol] would be hard to do."—Medical Assistant*

Session Date: Sunday, November 13, 2016
Session Title: Quality Measures and Quality of Care - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Meta-analyses of observational studies showed that RA patients' morbidity and mortality risks stemming from cardiovascular (CV) causes were, respectively, close to 50% and 60% higher than those of the general population. It has been proposed that high-grade inflammation affects multiple tissues and leads to endothelial dysfunction, dyslipidemia, more oxidative stress, increased levels of homocysteine, and insulin resistance. These effects accelerate atherogenesis and myocardial microvascular abnormalities. Research has shown that the tools used for risk assessment in the general population underestimate the true risk when they are applied to patients with proatherogenic diseases such as diabetes mellitus (DM) or chronic kidney disease (CKD). Evidence suggests that this is also the case with RA.

Methods: We reviewed the electronic medical records (EMR) of patients with the diagnosis of RA based on the ICD 9 codes, that were followed at the University of Virginia Rheumatology outpatient clinic in the 7/2014 – 5/2015 period. We reviewed age, gender, RF/CCP positivity, disease duration of more than 10 years, current smoking status, systolic blood pressure (SBP) and treatment, lipid panel (date, total cholesterol, HDL, LDL), cholesterol medications, DM status, aspirin use. We calculated the cardiovascular risk by multiplying the Framingham risk score by 1.5 as per EULAR recommendations.

Results: A total of 460 charts were reviewed. 78% of patients were female and 22% were male. 44.56% had lipid levels available in the EMR. Of the patients with documented lipid levels 49.75% had levels checked more than 2 years ago. Only 22.39% of the total patients reviewed had recent lipid levels documented in the EMR (less than 2 years old). Of the 359 female patients, 28.91% were on cholesterol medications although 60.84% had an LDL level greater than 100. 15.32% were smokers, 14.2% had a diagnosis of DM, while 29.24% had an SBP of more than 140. Of the 101 male patients, 56.41% were on cholesterol medications and 43.58% had an LDL level greater than 100. 22.77% were smokers, 19.8% had a diagnosis of DM, and 29.7% had an SBP of more than 140. Our data for female patients shows that the Framingham risk score is higher than the average population in all age groups except for the 55 - 64 years old age group and significantly higher in all age groups when multiplied by 1.5. Our data for male patients shows that the Framingham risk score is higher than the average population in all age groups except for the 60-69 years old age group and significantly higher in all age groups when multiplied by 1.5.

Conclusion: Studies have shown that RA patients have an increased cardiovascular risk, similar to DM and CKD population and twice as high as the general population. Our chart review shows that our RA patients have a number of CV risk factors and have an increased risk compared to the normal population based on calculated Framingham risk score as well as multiplication for RA. Additionally it appears that lipid screening and aggressive treatment for hypertension is underutilized in this population. We propose to send letters to the primary care practitioners to increase awareness of the CV risk assessment in RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: American College of Rheumatology (ACR) 2015 guidelines for the treatment of rheumatoid arthritis (RA) include recommendations for immunization against influenza, pneumococcus, hepatitis B (Hep B) and herpes zoster (HZV). The guidelines also recommend the indications and timing of administration of these killed vaccines (pneumococcal, influenza and Hep B), and live attenuated HZV vaccinations. The aim of our study is to measure adherence rates to these ACR immunization recommendations in rheumatoid arthritis patients in our tertiary health care system based rheumatology practice and to identify opportunities to close the gap, if any.

Methods: A retrospective review of the electronic health record (EHR) was performed to identify consecutive adult RA patients from January 1, 2016 to March 31, 2016 whose primary care physician (PCP) was within the affiliated health care system. Influenza vaccinations were captured only for the 2015-2016 flu season. In addition to the ACR recommendations for pneumococcal vaccinations, we determined the number of RA patients receiving the entire Advisory Committee on Immunization Practices (ACIP) recommended pneumococcal vaccination series. EHR review keywords included "vaccination," "immunization," "pneumococcal", "flu", "hepatitis", "zoster" and whether vaccinations were offered, or refused by the patient.

Results: A total of 85 adult RA patients were identified. The mean age was 61.5 yrs, 84.7% were female, 85.9% were Caucasian, and the mean duration of RA was 7.3 yrs. 82.4% were on a traditional DMARD, and 27.1% on a biologic DMARD. One patient was allergic to the influenza vaccination and was excluded. Of the remaining 84 patients who met the indications for influenza vaccination, 60.7% received the vaccination. 3.6% patients were offered the influenza vaccination but did not end up receiving it, and 10.7% refused vaccination. 52.9% of all RA patients received the pneumococcal vaccine. Of the three patients identified as being both at risk for Hep B (i.e. healthcare workers, intravenous drug abuse history and/or multiple sexual partners in last 6 months)and susceptible (anti-Hep B surface antibody negative), only one patient was subsequently vaccinated (33%). 29.2% of RA patients ≥ 50 years of age received the HZV vaccination. One HZV vaccine was deferred by the PCP secondary to prior initiation of immunosuppressant therapy. 16.7% received the entire ACIP recommended pneumococcal vaccination series.

Conclusion: At our tertiary health care system rheumatology clinic, rates of adherence to ACR recommendations for vaccinations are sub-optimal. Some limitations of our data include vaccinations potentially received outside the clinic setting (e.g. pharmacies and retail stores), individual clinic vaccine stocking schedules and supplies, and vaccinations recorded prior to the July, 2015 launch date of our EHR, leading to attrition of data. Analysis of care gaps and future steps include vaccination guideline education, EHR integration of reconciliation and new vaccination orders, and subsequently re-measure adoption and adherence.
