Background/Purpose: Systemic sclerosis (SSc) carries high risk for progressive interstitial lung disease (ILD), but there are no valid methods for early detection of SSc-ILD or algorithms for ILD progression available. The aim of this study was to assess the impact of baseline FVC on lung fibrosis, fibrosis progression and mortality.

Methods: Paired pulmonary function tests (PFT) and high resolution computed tomography (HRCT) images were obtained at baseline and follow-up in consecutive SSc patients (n=305) from the prospective Oslo University Hospital (OUH) cohort. All patients met the 2013 ACR/EULAR classification criteria. Extent of fibrosis was scored on 10 sections from every HRCT and expressed as percentage of total lung volumes. The annual fibrosis progression was defined as the difference in extent of fibrosis between the baseline and follow-up HRCT divided by the actual follow-up period in years.

Results: At baseline, 186/305 patients (61%) had a baseline FVC <100% (Table 1). Lower baseline FVC (<90, 80 and 70%) was associated with male gender and higher extent of fibrosis at baseline and follow up (Table 1). In multivariate cox regression analyses, all baseline FVC thresholds (<100, 90, 80 and 70%) were significantly associated with mortality (Table 2). Other parameters significantly associated with mortality were age at onset (HR 1.1, 95% CI 1.1-1.2, p-value<0.001) and diffuse cutaneous SSc (HR 2.2, 95% CI 1.2-3.6, p-value 0.002). All baseline FVC thresholds were also associated with annual fibrosis progression in univariate cox regression analyses (Table 2). In multivariate analyses, only baseline FVC <80% was associated with annual fibrosis progression (HR 1.8, 95% CI 1.0-3.0, p-value 0.042), as well as male gender (HR 1.9, 95% CI 1.1-3.4, p-value 0.023) and anti-Topoisomerase I (HR 2.2, 95% CI 1.3-3.9, p-value 0.006). Of the 119 patients with baseline FVC>100%, 56 had no lung fibrosis. These 56 patients were predominantly female (90.4%); most of them had limited cutaneous SSc (91%) and anti-centromere antibodies (76%) and 18% died during the observation period.

Conclusion: These prospective cohort data suggest that baseline FVC%, including normal range values, predict mortality and fibrosis progression in SSc. Based on these data, we suggest that all SSc patients should be assessed with PFT and HRCT at baseline, and followed with PFTs on a regular basis. **Table 1:** Demographics, extent of fibrosis at baseline and follow-up, annual fibrosis progression and pulmonary function segregated by baseline FVC% in 305 SSc patients

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The gastrointestinal tract (GIT) is frequently affected in SSc patients as a consequence of a reduction in enteric propulsive forces. Due to intestinal involvement, patients may experience diarrhea, constipation, bloating, weight loss and a general reduction in well-being. The use of prokinetics proved effective in treating some SSc patients with GIT. Serotonin (5-HT4) receptor agonists with only moderate affinity for the 5-HT4 receptors were however withdrawn due to cardiac toxicity. Prucalopride is a high-affinity 5-HT4 receptor agonists with no major cardiac issues, whose efficacy in SSc has not been assessed yet.

Methods: Forty patients with self-reported mild-to-moderate enteric symptoms were enrolled in a cross-over 2 x 2 study. Subjects were given prucalopride 2 mg/day or no treatment for one month and vice versa after a 2 weeks washout period, according to the ABBA sequence. Before and after each sequence the patients compiled the UCLA GIT 2.0 questionnaire and Likert scales to rate the severity of GIT involvement or constipation; the number of complete intestinal movements and the number of used laxatives were also recorded. Mixed linear models, were used to compare responses correcting for the number of laxatives.

Results: Seven patients did experience side effects (headache and dizziness, diarrhea, abdominal pain) and 4 patients were not compliant to study procedures (inadequate drug intake); 29 subjects did complete the study. Baseline GIT parameters and main results are reported in the Table. Prucalopride treatment was ranked as moderately-to-extremely effective by 22 patients (72.4%).

Conclusion: The safety profile of Prucalopride in SSc is similar to what had already reported in the literature. In SSc patients with mild-to-moderate GIT problems, prucalopride may be effective in treating dismotility symptoms, increasing the number of complete bowel movements, partially reducing reflux disease and improving the patents' well-being.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a complex autoimmune disease with extensive fibrosis of the skin and internal organs in which extracellular matrix (ECM) remodeling is a key pathogenic process. Given the clinical heterogeneity and the individual disease course of SSc, biomarkers to allow personalized medicine are highly needed. We evaluated the potential of selected ECM neoepitopes as serological biomarkers for diagnosis, prognostic of progression and prediction of clinical outcomes.

Methods: Stable SSc patients (n=151), SSc progressors (n=21, either 10% decrease in FVC% predicted or increase in mRSS ≥25% and 5 points on 1 year clinical follow up) meeting the ACR/EULAR classification criteria and healthy controls (HC; n=29) were analyzed. Longitudinal clinical assessment, data recording and sera collection were done according to EUSTAR standards. ECM-degradation (C3M,

C4M2, BGM, VICM) and ECM-formation biomarkers (P1NP, Pro-C3, Pro-C6) were measured in serum using ELISA-based assays. Differences in biomarker levels were analyzed with respect to several fibrosis-related clinical outcomes as well as the Valentini disease activity score (VDAS). Statistical analysis was performed by Man-Whitney U, Kruskal-Wallis and Spearman tests, as well as multivariate logistic regression, adjusted for sex and age. Biomarkers' sensitivity and specificity was examined by ROC analysis.

Results: The expression of C4M2, Pro-C3, BGM and C3M was significantly increased in SSc patients compared to HC ($p<0.0001$, AUC=0.93; $p<0.0001$, AUC=0.74; $p=0.003$, AUC=0.67; $p<0.0001$; AUC=0.93, respectively). Furthermore, Pro-C3, VICM and Pro-C6 levels were significantly higher in SSc progressors vs. HC ($p<0.0001$, AUC=0.85; $p=0.003$, AUC=0.75; $p=0.0002$, AUC=0.81, respectively), whereas P1NP was significantly lower ($p=0.04$, AUC=0.67). Interestingly, ECM-degradation markers C4M2, BGM and C3M were significantly lower in SSc progressors vs. SSc patients ($p<0.0001$; $p<0.005$; $p<0.0001$, respectively), whereas the formation marker Pro-C3 was slightly higher, but without reaching statistical significance (Figure 1). Pro-C3 was significantly higher in patients with DLCO SB <70% ($p=0.03$), moderate-severe dyspnea ($p=0.02$) and active disease (VDAS ≥3, $p=0.02$) and showed a mild correlation to the VDAS ($r= -0.29$; $p=0.000$).

Conclusion: These data indicate that ECM neoepitopes could not only differentiate between HC and SSc patients but, even more, could help identify patients prone to progress at 1 year clinical follow up. The significant decrease in ECM-degradation markers in SSc progressors compared to stable patients suggests an impairment of collagen degradation in this group. ECM neoepitopes arise as potential new biomarkers in SSc. Figure 1.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Effective treatments for systemic sclerosis (SSc) related Raynaud's phenomenon (RP) are badly needed but clinical trials have been hampered by the lack of objective outcome measures. Laser speckle contrast imaging (LSCI) and thermography are two non-invasive measures of blood flow that show excellent potential but require further investigation to prove their suitability as outcome measures in multi-centre clinical trials. The main aim of this multi-centre study was to determine the validity and reliability of LSCI and thermography. This abstract reports the first step in a more comprehensive analysis; the repeatability of the techniques as assessed by a local assessor at each site.

Methods: 158 patients with RP secondary to SSc were recruited from 6 specialist SSc centres in the UK. Patients attended their local centre on 2 consecutive days. They underwent a cold challenge; 15^{o}C water submersion of gloved hands for 1 minute, then un-gloved reperfusion and rewarming at 23^{o}C room temperature. Baseline and changes in blood flow and temperature over 15 minutes post challenge were imaged simultaneously using LSCI (relative perfusion) and thermography (skin temperature, an indirect measure of perfusion), respectively. Parameters for both perfusion and temperature were calculated locally and data analysis was performed centrally. The distal dorsal differences (DDD) of each hand were calculated from baseline images. The area under curve (AUC), maximum value (MAX), and gradient (GRAD) in first two minutes were calculated from the post challenge data of the fingers. Data were averaged across 8 digits for each patient to obtain a single measurement for each parameter for each technique at both visits. Test-retest reliability was assessed using intra-class correlation coefficients (ICC) using linear mixed models (R version 3.2.3) where an ICC of 0.60 is regarded as substantial reliability (Landis and Koch 1977).

Results: Median age was 63.3 years (IQR 53.8–69.8), 84% were female, median SSc symptom duration was 9.6 years (IQR 4.5 – 17.4), and 77% had limited cutaneous SSc. Both techniques had substantial reliability for AUC. Thermography reliability across all parameters varied from moderate to strong (GRAD 0.56 to MAX 0.72) and LSCI varied from moderate to substantial (GRAD 0.46 to AUC 0.67) (table 1). Reliability of the two techniques has higher overall ICCs for thermography, suggesting marginally greater reliability of thermography in this sample.

Conclusion: This is the first multi-centre study examining reliability of LSCI and thermography in patients with RP secondary to SSc, and these are the preliminary findings from local analysis. The results and analysis are encouraging, overall, LSCI and thermography demonstrated moderate to strong reliability (and therefore good potential as outcome measures of digital vasculopathy), although thermography appears to be marginally superior to LSCI. **Table 1.** ICCs (Logged for non-normality where necessary) for summary measures of response to cold challenge under LSCI and thermography.

ICCs	LSCI	Thermography	Difference (LSCI-Thermography)
AUC	0.67 (0.54 to 0.76)	0.68 (0.58 to 0.80)	-0.01 (-0.17 to 0.11)
DDD	0.67(0.56 to 0.76)	0.66 (0.56 to 0.76)	0.01 (-0.12 to 0.11)
MAX	0.64 (0.52 to 0.75)	0.72 (0.64 to 0.81)	-0.09 (-0.21 to 0.03)
GRAD	0.46 (0.40 to 0.69)	0.56 (0.40 to 0.74)	-0.09 (-0.24 to 0.18)

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Autologous fat tissue grafting (AFTG) has been successfully used in the treatment of different sclerotic conditions, including scleroderma. We evaluated in patients with SSc who complained of a reduced mouth opening, the long-term efficacy of AFTG of the lips in improving mouth opening in comparison with hyaluronic acid (HA) filler. We also investigated whether these procedures may induce some changes in the microvascular architecture and dermal structure of the treated skin area.

Methods: We studied 36 patients with dcSSc, (median age 37+12 yrs, disease duration 11+8yrs): 18 were treated by topical perioral AFTG according to Coleman technique and 18 by HA filler. The filler was repeated after 3 months. Baseline and after treatment (at months 3, 6, and 12) mouth opening changes were assessed by measuring inter-incisal distance and oral perimeter. Pre- and post-treatment modifications of microvascular architecture were assessed by counting capillaries in the inferior lip videocapillaroscopy (VC) images. Similarly, histological sections of perioral skin biopsy were examined at baseline and 3 months to evaluate dermo-epidermic junction (DEJ), the collagen content (by Masson's Trichrome staining) and microvessel density (MVD) (by anti-CD34/CD31staining).

Results: . 3 months after treatment both the inter-incisal distance and oral perimeter significantly increased ($p < 0.001$). At the same time, a significant skin neovascularization became evident, both considering the VC images ($p < 0.001$) and MVD scores in IH sections ($p < 0.0001$). Finally, some skin histological aspects also improved, as shown by the significant changes in DEJ flattening scores ($p < 0.0001$) and collagen content with less abnormal and denser collagen bundles. At 6 and 12 months, despite the disappearance of filling effect, both the functional improvement in mouth opening and the increased number of capillaries were maintained. No effect either on the mouth opening, VC images and skin histological aspects was observed in SSc patients treated by HA filler.

Conclusion: The present study shows that, in SSc patients, AFTG can improve mouth opening, induce a neovascularization, and partially restore the skin structure. All these effects were confirmed in the long-term observation. The lack of functional and biological effects in the control group treated by HA filler, suggests that the observed therapeutic effect of lipostructure may be specifically ascribed to the on site transplantation of fat tissue.

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune fibrotic disorder characterised by collagen and extracellular matrix deposition in the skin and internal organs, such as the lung. Interstitial lung involvement (ILD) is frequent in SSc and represents the most frequent cause of death. Gold nanoparticles (GNPs) have a great potential in biomedical applications among which drug-delivery. Previously, we proved that GNPs containing everolimus and functionalized with anti-CD44 antibody targeted to mesenchymal cells from patients with chronic lung allograft rejection (CLAD) specifically inhibited these cells. We proved that also fibroblastoid-like cells (FLCs) isolated from bronchoalveolar lavage (BAL) of ILD-SSc patients express CD44. Here, we loaded in the same nanoparticles the drug imatinib (GNP-HCim) with the aim to specifically inhibit FLCs from ILD-SSc patients.

Methods: GNPs with imatinib and exposing an anti-CD44 antibody were engineered. GNP-HCim were incubated 2h with FLCs from three patients with ILD-SSc. Cell apoptosis (Annexin V) and proliferation (CFSE) were evaluated at different times by flow cytometry. Cell viability was assessed by MTT test. As control, functionalized GNPs without imatinib (GNP-HC) or imatinib alone (IM) were used. Fluorescent GNP-HC were generated to assess cell uptake by confocal microscopy and flow cytometry. Statistical differences were evaluated using ANOVA by Graph Prism 5.0 program.

Results: Fluoresce experiments showed that only HC-functionalized nanoparticles were entered into FLCs within 1 h. The results showed that GNP-HCim inhibited cell proliferation without significant differences between the three cell lines. In particular, the effect of GNP-HCim was significant at 48 ($p<0.001$) and 72h ($p<0.01$). A significant inhibition was also observed in presence of GNP-HC both after 48 ($p<0.01$) and 72h ($p<0.05$). These results suggest that an unspecific effect of the nanoparticles itself or, by interaction with the antibody anti-CD44. No changes were produced by IM alone. MTT assay confirmed the results obtained by CFSE since a significant reduction ($p<0.001$) of cell viability was observed with GNP-HCim and GNP-HC starting from 48 h. IM treatment affected the FLCs viability ($p<0.05$ at 48h; $p<0.001$ at 72h). Functionalized nanoparticles were able to significantly increase apoptosis after 8 ($p=0.0051$) and 24 h ($p<0.001$) compared to uFLCs. However, only drug-loaded nanoparticles still significantly increase apoptotic rate after 48 h ($p=0.004$).

Conclusion: We proved that specifically engineered GNPs significantly inhibit proliferation and induce apoptosis of FLCs from ILD-SSc patients, as already described for CLAD patients. FLCs treatment with imatinib alone was not effective as GNP-HCim demonstrating the superiority of the nanoparticles. These experiments confirm the possibility to use engineered nanoparticles to develop a new pharmacological treatment for patients with pulmonary fibroproliferative disorders.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies can be characterized in up to 95% of patients with systemic sclerosis (SSc) and provide enormous diagnostic and prognostic value in the clinical setting. We have recently identified a novel autoantibody in patients with SSc targeting Eukaryotic Initiation Factor 2B (anti-eIF2B). Earlier work identified an association with diffuse cutaneous systemic sclerosis (dcSSc) and interstitial lung disease (SSc-ILD), although the majority of samples had originated from a large tertiary referral respiratory unit managing patients with SSc-ILD. Anti-eIF2B positive sera has a cytoplasmic staining pattern on indirect immunofluorescence (IIF), but anti-nuclear antibody (ANA) staining is negative. The objectives of this study were to explore the prevalence and clinical associations of anti-eIF2B antibodies in ANA-negative samples obtained from a large US prospective study of SSc.

Methods: ANA-negative samples from the Scleroderma Family Registry and DNA Repository were tested by routine serological techniques followed by radiolabelled protein immunoprecipitation (IPP). Sera that immunoprecipitated a 30kDa band (consistent with anti-eIF2) underwent immunodepletion studies to confirm antigen specificity for eIF2B. The clinical phenotype of patients carrying anti-eIF2 was assessed.

Results: Of the 128 ANA-negative samples, a 30kDA band was identified on IPP in 10 samples (7.8%). Immunodepletion studies confirmed eIF2B as the antigen target in 9 samples. No other SSc-specific autoantibodies were identified in these 9 samples (suggesting mutual exclusivity). The clinical features of anti-eIF2B positive patients are presented (Table). All patients had Raynaud's phenomenon (9/9, 100%). The majority of patients had dcSSc (8/9, 89%) although the mean modified Rodnan Skin Score (documented 7/9, 78%) was only 17.7. All patients with previous chest imaging (7/9, 78%) had radiographic evidence of SSc-ILD; either on computed tomography (6/6, 100%) and/or plain radiograph (4/4, 100%). Pulmonary function tests (documented in 7/9, 78%) revealed a mean FVC of 63.4% predicted and mean DLco of 64.3% predicted. The prevalence of digital ulcers and gastro-esophageal reflux disease was low (2/9, 22% for each). No patients had evidence of pulmonary arterial hypertension on echocardiography or right heart catheterization (when reported).

Conclusion: Anti-eIF2B is a novel, rare (estimated total prevalence in SSc ~1%) and mutually exclusive cytoplasmic autoantibody identified in approximately 7% of ANA-negative samples of patients with SSc. Our findings would support the previously reported clinical association of anti-eIF2B autoantibodies with dcSSc and SSc-ILD in a larger and more representative SSc patient population. **Table. Clinical phenotype and outcome of pulmonary investigations of anti-eIF2B positive SSc patients** * na, not available

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

No objective measure is presently available to assess digital ulcer (DU) in SSc patients apart from “healed/non healed” and experience-based clinical judgment. The aim of the current study is to propose a composite DU clinical assessment score (DUCAS) and to lend it, test

its face validity by correlating it with commonly used disease related patient-reported outcomes (PROs) and physician evaluation.

Methods:

SSc patients presenting at least one DU and attending the Rheumatology Wound Care Clinic of the Florence University Hospital or the London Royal Free Hospital were enrolled. Patients were assessed with HAQ-DI, Cochin scale, Visual analogic scale (VAS) for DU-related pain (DU_pain, 0-100 mm), patient VAS for global DU status (ptGDU, 0-100mm) and patient global assessment (PtGA, 0-100 mm) as PROs and physician VAS for DU status (phyGDU, 0-100mm). The DUCAS included 7 DU related variables selected by a committee of 8 SSc DU experts - they are outlined in table 1. Each variable was weighted on a clinical basis and the DUCAS score was the sum of the values for the 7 variables (max=19,5). Spearman's correlation tests were calculated for to examine face validity. A linear regression model with forward and backward stepwise analysis was used to determine the relationship of individual variables with the primary clinical parameter, phyGDU.

Results:

44 SSc patients (9 males, mean age 54,3±15,6 years, mean disease duration 9,9±5,8 years) were enrolled in the study. Mean phyGDU was 44,3±23mm, mean ptGDU was 54±30mm (Wilcoxon p=0.022, phyGDU VAS vs ptGDU) and mean DUCAS score was 4,2±2. Overall DUCAS showed significant positive correlations with all PROs, but when all the individual clinician and patient's variables were modelled, only the overall DUCAS significantly predicted PhyGDU; after backwards stepwise analysis overall DUCAS and ptGDU best predicted PhyGDU, with an adjusted R^2=0,437 and AIC=380,3 (Table 2).

Conclusion:

DUCAS is a newly proposed clinical score for SSc related DU which has face validity and which may reflect DU statusas judged by SSc experts. Further validation of this score will be undertaken.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

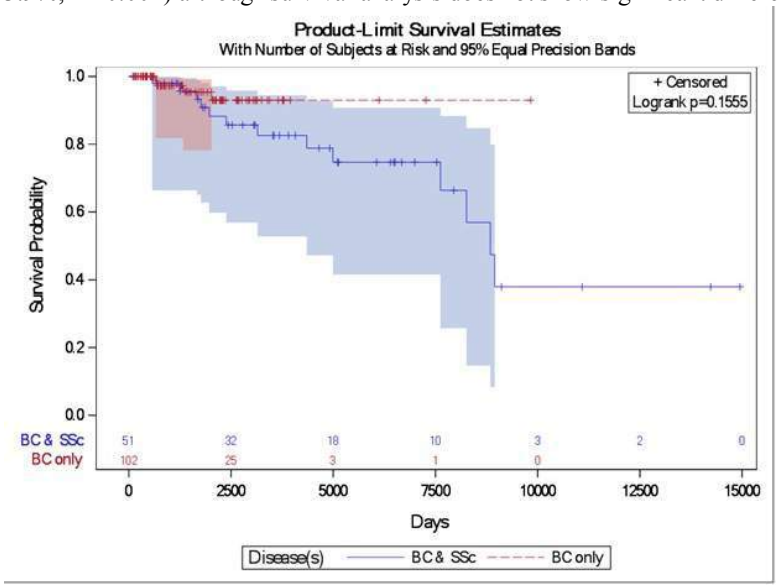
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Breast cancer has been shown to be more prevalent in patients with systemic sclerosis (SSc) compared to that in the general population. A close temporal correlation between the onset of SSc and breast cancer has been demonstrated, particularly in patients with anti-RNA polymerase III antibody, suggesting a possible pathogenic or paraneoplastic association in this subset of patients. Certain chemotherapeutic agents and radiotherapy may be avoided in patients with SSc. The goal of this study was to demonstrate the impact of scleroderma on breast cancer treatment options and outcomes. We also wanted to assess the association of SSc to the specific histopathologic subtype, hormone receptor status and human epidermal growth factor receptor 2 (HER2) oncogene status of breast cancer.

Methods: A retrospective chart review was performed to compare patients with breast cancer with and without SSc that were seen within the last 10 years at our institution. For comparison, a random number generator was used to select 102 out of 9157 breast cancer patients without SSc who were diagnosed and treated at our institution over the same time period. Data on demographics, clinical characteristics, breast cancer treatments, and survival rate were collected. Numerical variables are compared between groups using ANOVA and two sample t-tests. Categorical variables were compared using either Pearson's chi-squared test or Fisher's exact test. Survivor functions were estimated using the Kaplan-Meier method and differences in survivor functions were tested for with log-rank tests.

Results: Fifty-one patients with SSc with a history of breast cancer were identified; 43.1%, 3.9% and 7.8% of patients with SSc had anti-centromere, anti-Scl-70 and anti-RNA polymerase III antibodies respectively. Patients with RNA polymerase III antibody had shorter interval between SSc and breast cancer onset compared to the patients with anti-Scl-70 (11.7 vs 51.2 months, P 0.43) and anti-centromere (11.7 vs 66.5 months, P 0.07) antibodies. Patients with breast cancer and SSc less frequently had invasive ductal carcinoma compared to breast cancer patients without SSc (47.1% vs 63.7%, P 0.049). The percentage of estrogen and progesterone receptor positivity as well as HER2 oncogene positivity were similar in the two groups. There was a trend towards receiving less radiotherapy in patients with SSc and breast cancer (52.9% vs 68.6%, P 0.058). The decision to receive chemotherapy, hormonal therapy and immunotherapy were similar between the two groups. Mortality rate was much higher in breast cancer patients with SSc compared to those without SSc (25.5% vs 3.9%, P <0.001) although survival analysis does not show significant difference (Figure1).



Conclusion: Breast cancer patients with SSc have higher mortality rate compared to those without. Further studies are needed to identify specific treatment strategies for this group of patients.

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Aberrant rho-kinase (ROCK) activity is implicated in pathogenesis of several vascular and immunologic disorders. We previously demonstrated evidence of increased ROCK activity in histopathologically negative temporal artery biopsies (TAB) of subjects with clinical giant cell arteritis (GCA) compared to those without GCA. The aim of this study was to validate a ROCK activity score in a large cohort of GCA patients.

Methods: TAB obtained as part of an international study examining the role of ultrasound in GCA were utilized. Only histologically negative TABs were used for this study. Subjects were categorized into 2 groups, those who were diagnosed with GCA despite negative TAB at 6 months after biopsy and those with negative TAB ultimately felt not to have GCA. Paraffin-embedded TAB were stained for phosphorylated ezrin/radixin/moesin (pERM), a surrogate of ROCK activity, and reviewed by a pathologist blinded to clinical diagnosis. Three areas of the vessel (intima, adventitial and vasa vasorum) were scored for staining intensity on a scale of 0–2, with a maximum possible score of 6 for each TAB. As determined a priori, scores ³4 were considered a high pERM intensity score suggesting ROCK activity. TAB sections were also stained for unphosphorylated ERM, the inactive protein.

Results: Biopsies of 36 subjects with TAB-negative GCA were identified and compared to biopsies of 43 subjects without GCA. There were no differences between the 2 groups in age, sex and corticosteroid dose. The mean pERM intensity score in non-GCA subjects was 3.9 ± 1.4 compared to mean pERM intensity score of 5.0 ± 1.4 in those with GCA, p = 0.002. Using the predetermined cut-off of 4 to define high pERM intensity, subjects with GCA were nearly4 times more likely to have a high pERM intensity score compared to non-GCA, OR 3.67, 95%CI :1.19,11.36; p= 0.019. The sensitivity of high pERM intensity score for the diagnosis of GCA in histologically negative TAB was 86%, 95%CI: 70,95. In GCA subjects, the ERM staining was less intense in all areas of the TAB specimens compared to the pERM staining, suggesting activation of the ROCK pathway.

Conclusion: In this large cohort of well characterized subjects, those with GCA and negative biopsies had significantly higher pERM intensity scores in TAB specimens compared to subjects without GCA. These results are concordant with previously published pilot data. pERM staining has diagnostic significance in enhancing the sensitivity of TAB, and helps to define the clinically important group of biopsy-negative GCA. The ROCK pathway warrants further investigation in GCA and may be a potential therapeutic target.

Session Time: 9:00AM-11:00AM

Abstract

Background/Purpose: Ultrasound (US) is increasingly used in the diagnosis of giant cell arteritis (GCA). US findings mainly rely on morphology ("halo-sign" and "compression sign"). Increasing resolution of modern US probes allows exact intima-media thickness (IMT) measurement of normal and vasculitic temporal arteries. No data have yet been published on IMT of temporal, facial and axillary arteries in GCA patients compared to healthy controls.

Methods: Fourty newly diagnosed GCA patients of a fast-track GCA clinic and 40 age- and sex-matched controls were included between October 2014 and December 2015. The diagnosis of GCA was established by two very experienced rheumatologists (WAS or AJ) on the basis of clinical presentation, laboratory tests and US results. The diagnosis was confirmed after 6 months in patients who were included until July 2015. IMT measurement was performed at or within 24 hours after the first visit. The common superficial temporal arteries with their frontal and parietal branches and the facial arteries were bilaterally examined with a 10–22 MHz probe (Esaote MyLab Twice). A 6–18 MHz probe was used for both axillary arteries. In total, IMT measurement was performed at 800 sites. The mean IMT values of the different arteries were compared between controls and patients with active vasculitis of the corresponding artery by means of a Mann-Whitney test. ROC analysis was performed to determine the best cut-off value, balancing sensitivity and specificity, to discriminate between a normal and a vasculitic artery.

Results: Both groups consisted of 40 participants each and included 27 females. The mean age was 72 years (SD 9). Of the 40 GCA patients, 22 (55%) had indurated temporal arteries on clinical examination, 16 (40%) had symptoms of polymyalgia rheumatica. The mean duration of symptoms was 15 weeks (SD 19). Five patients (13%) had visual impairment (anterior ischaemic optic neuropathy, 3; amaurosis fugax, 1; diplopia, 1). Twenty-eight patients (70%) described headache; and 17 (43%) had jaw claudication. The mean ESR was 82 mm/h (SD ± 28); and the mean CRP was 107 mg/l (SD 79). In 26 patients (65%) the axillary arteries were involved of whom 9 had no involvement of temporal arteries. Table 1 shows IMT of affected arteries in GCA patients compared to controls and cut-off values for distinguishing normal from inflamed arteries.

Artery	Vasculitic arteries considered	IMT patients in mm (SD)	Control arteries considered	IMT controls in mm (SD)	Cut-off (mm)	Sensitivity	Specificity	Correctly classified
Common superficial temporal arteries	44	0.65 (0.18)	80	0.23 (0.04)	0.42	100%	100%	100%
Frontal branches	42	**0.54 (0.18)**	80	0.19 (0.03)	0.34	100%	100%	100%
Parietal branches	36	**0.50 (0.17)**	78	**0.20 (0.03)**	0.29	97.2%	98.7%	99.3%
Facial arteries	24	**0.53 (0.16)**	80	**0.24 (0.05)**	0.37	87.5 %	98.8%	96.2%
Axillary arteries	46	**1.72 (0.41)**	80	**0.59 (0.10)**	1.0	100%	100%	100%

Conclusion: IMT measurement of temporal, facial and axillary arteries can correctly distinguish vasculitic from normal arteries in suspected GCA in addition to morphological parameters. Data for wall diameters are needed for future longitudinal trials to monitor GCA treatment.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Positron emission tomography combined with computed tomography (PET/CT) with ^{18}F-fluorodeoxyglucose (FDG) can be used to assess large-vessel inflammation in giant-cell arteritis (GCA) and has demonstrated high sensitivity in detecting extra-cephalic forms of the disease, notably in patients without vascular-related symptoms. Few data exist on the merits of repeating this procedure as part of treatment monitoring during follow-up. It remains to be seen whether a repeated procedure during patient follow-up for GCA-related large-vessel involvement demonstrated on FDG-PET/CT is clinically helpful. Our aim was to determine the value of repetitive FDG-PET/CT in giant-cell arteritis (GCA) with large-vessel involvement.

Methods: We conducted a retrospective multicenter study between 2000 and 2015. Patients were included if 1) GCA was diagnosed according to the American College of Rheumatology criteria. 2) large-vessel involvement was demonstrated on FDG-PET/CT at diagnosis; 3) FDG-PET/CT was repeated at least once during follow-up. We separated the cohort into two groups, according to the indication of the repeated procedure, i.e. for evaluating vascular uptake in patients with disease remission or with disease relapse.

Results: Thirty-seven patients (24 [65%] women, median age: 68 [55-85]) with large-vessel inflammation on baseline FDG-PET/CT were included. During a median clinical follow-up of 50 [12-162] months, 63 new FDG-PET/CT were performed, including 34 scans in 25 patients with controlled disease and 29 scans in 22 relapsing patients. In patients with controlled disease, repeated FDG-PET/CT showed fewer involved vascular territories than on the previous one in only 15/34 (44%) scans (median involved territories: 2 [0-4] vs. 4 [1-6], respectively; $p<0.001$), including five (15%) with total disappearance of vascular uptakes, 12 [6-63] months after diagnosis. At the end of the study, 20 patients (80%) still had vascular uptakes on repetitive scans, which did not alter the therapeutic decision unless clinical symptoms and/or an elevated acute phase had resumed. Of the patients with disease relapse, the PET/CT showed increased number of vascular uptakes in 5 cases (17%), whereas the others showed reduced or unchanged vascular uptakes.

Conclusion: In patients with GCA-related large-vessel involvement, repetitive FDG-PET/CT during follow-up did not provide any reliable additional information, beside clinical and laboratory assessment. Therapeutic management was actually not influenced by the PET/CT results. A prospective study is required to confirm these findings.

Session Time: 9:00AM-11:00AM

Long-term Outcomes of Renal Artery Involvement in Takayasu Arteritis

Background/Purpose: Takayasu arteritis (TA) involving the renal artery can result in hypertension, renal dysfunction, and premature death. Some patients with renal artery stenosis underwent revascularization procedures including stent insertion. The aim of this study was to investigate the long-term outcomes and factors that predict outcomes in TA patients with renal artery stenosis.

Methods: The medical records of patients diagnosed with TA between January 1997 and December 2014 were reviewed retrospectively. Renal artery involvement was based on CT and/or angiography findings. Poor outcome was defined as uncontrolled hypertension, chronic renal insufficiency, or death.

Results: Of the 62 TA patients with renal artery involvement, 11 (17.7%) underwent renal artery revascularization. Younger age, male gender, and more severe (>70%) stenosis were associated with vascular intervention. After a median follow-up of 90.6 months, 11 (17.7%) of the 62 patients had uncontrolled hypertension and six (9.7%) had chronic renal insufficiency, but these outcomes were not significantly associated with vascular intervention. Renal insufficiency (5/15 [33.3%] vs 3/47 [6.4%], p=0.016) and bilateral involvement (12/15 [80.0%] vs 23/47 [48.9%], p = 0.041) were significantly more frequent in patients with poor than good outcomes. Multivariate Cox analysis revealed that renal insufficiency at presentation (hazard ratio [HR]=13.778, 95% confidence interval [CI]=3.530–53.786; p=0.000) and bilateral renal artery involvement (HR=5.053, 95% CI=1.179–21.661; p=0.029) were significant risk factors for poor outcomes at follow-up, but revascularization procedure was not (HR=0.663, 95% CI=0.176–2.498; p=0.543) (Table 1).

Conclusion: Bilateral lesions and renal functional impairment at presentation, but not implementation of revascularization procedures, were significant factors for outcomes in TA patients with renal artery involvement.

Table 1. Multivariate analysis of clinical factors predictive of poor outcome in TA patients with renal artery involvement

	HR	95% CI	P-value
Renal impairment at presentation[a]	13.778	3.530–53.786	**0.000**
Bilateral involvement	5.053	1.179–21.661	**0.029**
Revascularization	0.663	0.176–2.498	0.543

[a]Renal insufficiency was defined as an estimated glomerular filtration rate < 60 ml/minute. CI: confidence interval; HR: hazard ratio.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Accelerated atherosclerosis associated with chronic inflammation is one of the major complications of systemic inflammatory diseases. Takayasu arteritis (TAK) is a rare, systemic large-vessel vasculitis predominantly affecting the aorta and its major branches. The prevalence of atherosclerotic risk factors and cardiovascular (CV) disease in patients with TAK has not been well defined. The purpose of this study was to assess the frequency of CV risk factors and the incidence of CV events (CVE) in patients with TAK.

Methods: Patients fulfilling the 1990 American College of Rheumatology criteria for TAK from Mayo Clinic, Rochester, USA and Marmara University, Istanbul, Turkey were included in this retrospective cohort study. Data on CV risk factors at the time of TAK diagnosis and incident CVE during follow-up were abstracted from the medical records. Patients with TAK were compared to age, sex and calendar year–matched controls from the same geographic region without TAK. The 2008 Framingham 10-year general CV risk score (FRS) was used for the evaluation of CV risk at the time of TAK incidence/index date. For patients without lipid profiles, the office-based FRS, which does not require lipid values, was computed according to previously published algorithms.

Results: A total of 175 patients with TAK and 175 non-TAK controls were included in the study (115 from Mayo Clinic, 60 from Marmara University for each group). Among patients age ≥ 30 years at index date (107 TAK,109 non-TAK), complete data to calculate FRS were available in 93 (87%) TAK and 91 (83%) non-TAK subjects. Hypertension diagnosis and lipid-lowering treatment were significantly more frequent in the TAK group compared to non-TAK. Prior to the incidence/index date, the occurrence of CVE was significantly higher in the TAK group The overall Framingham 10-year CV risk score was significantly higher in the TAK group compared to non-TAK at incidence/index date (Table 1). After excluding patients with prevalent CVE, 18 TAK and 3 non-TAK patients developed CVE during a mean follow-up of 7.4 years in TAK and 7.9 years in non-TAK groups. The cumulative incidence of CVE was 16.4% at 10 years in TAK group vs. 6.0% in non-TAK group and the risk of CVE was increased among patients with TAK (hazard ratio: 4.52; 95% CI: 1.29, 15.78 adjusted for age, sex and country).

Table 1: Baseline characteristics of TAK and non-TAK cohorts in index dates.

	TAK (n=175)	Non-TAK (n=175)	P value
Age (Years)*	34.1±32.7	34.9±32.9	0.70
Sex (female/male)	157 / 18	160 / 15	0.58
Hypertension, n (%)	69 (40%)	22 (13%)	**<0.001**
Diabetes mellitus, n (%)	12 (7%)	8 (5%)	0.35
Lipid profile (mg/dl)*			
Total cholesterol, mg/dL	200±50 (n=113)	190±37 (n=60)	0.23
Low density lipoprotein, mg/dL	119±42 (n=101)	108±35 (n=51)	0.12
High density lipoprotein, mg/dL	52±17 (n=103)	54±15 (n=53)	0.50
Triglycerides, mg/dL	137±90 (n=108)	126±96 (n=60)	0.13
Lipid lowering treatment, n (%)	22 (13%)	7 (4%)	**0.004**
Obesity (BMI >30 kg/m^2), n, (%)	32 (22%)	37 (23%)	0.78
Smoking status, ever, n, (%)	80 (47%)	70 (41%)	0.36
Framingham risk score, %†	3.6 (2.2-10)	2 (1.2-5)	**0.001**
Any prior atherosclerotic vascular event	37 (21%)	6 (3%)	**<0.001**

*Mean ±SD †Median (Interquartile range); BMI, body mass index; n = number; SD = standard deviation; TAK = Takayasu arteritis; bolded p-values statistically significant at <0.05

Conclusion: CV risk factors are more common in patients with TAK, and the Framingham 10-year cardiovascular risk score is higher in patients with TAK at the time diagnosis compared to non-TAK subjects of similar age and sex. The cumulative incidence of CVE was also significantly higher during follow-up in the TAK group. Patients with TAK should undergo careful assessment of CV risk factors, and an aggressive risk modification approach is warranted.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

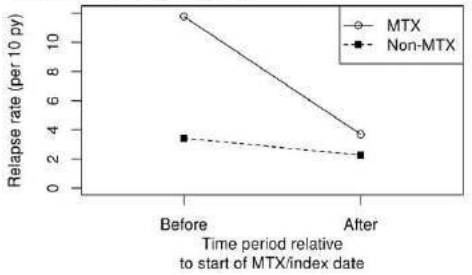
Background/Purpose: Prospective trials evaluating methotrexate (MTX) as adjunct immunosuppression in giant cell arteritis (GCA) have provided evidence of a modest benefit for reducing risk of relapse and decreasing glucocorticoid (GC) use. Limited information is available regarding the use of MTX in routine clinical practice. The purpose of this study was to determine the effect of MTX on relapse risk and GC use in a large, single-institution cohort of patients with GCA.

Methods: A retrospective review of patients diagnosed with GCA from 1998-2013 was performed. Patients diagnosed with GCA were ≥ 50 years and had either a temporal artery biopsy (TAB) that was consistent with GCA or radiographic evidence of large-vessel vasculitis. Each patient with GCA treated with adjunct MTX (case) was matched to a similar GCA patient without MTX (control). Cases and controls were matched on age, sex, disease duration at start of MTX and initial GC dose. Each control was assigned an index date that matched the start date of MTX in cases. Baseline demographics, disease characteristics and relapse events were abstracted. GC requirements and relapse events before and after MTX initiation (or corresponding index date) were compared using rate ratios.

Results: A total of 84 patients with GCA receiving MTX were identified and compared to 84 patients with GCA receiving only prednisone. Mean age at diagnosis 69.5±7.0 years in cases and 70.3±6.9 in controls. No significant differences in demographics, laboratory parameters or baseline disease characteristics were observed between groups. Mean initial prednisone doses were similar (53.5±15.8 mg/day in cases, 55.0±13.5 mg/day in controls). The median (interquartile range [IQR]) time from GCA diagnosis to MTX initiation in cases was 0.7 (0.3, 1.6) years and the median (IQR) starting dose was 13.5 (10, 15) mg per week.

Prior to MTX initiation the observed relapse rate was 11.8 relapses per 10 person-years and decreased to 3.69 relapses per 10-person years following initiation. The rate ratio comparing relapse rates observed after MTX to the rate prior to MTX initiation was significantly reduced; rate ratio (95% CI): 0.31 (0.24, 0.41). In the control group the relapse rate was 3.42 relapses per 10 person-years before the index date and 2.27 relapses per 10 person-years following the index date [rate ratio (95% CI); 0.66 (0.45, 0.99). Although both groups had a reduction in relapse rate ratios, the rate of decrease in relapse rate was significantly greater in patients on MTX than those not on MTX (p=0.002) [Figure]. Patients receiving MTX discontinued GC significantly later than patients without adjuvant MTX (p=0.014).

Figure: Rate of decrease in relapse rate is greater in patients on methotrexate (MTX) than those not on MTX (interaction p=0.002).



Conclusion: In this large single-institution cohort, the addition of MTX to GC decreased the rate of subsequent relapse by 2-fold compared to patients on GC alone. MTX should be considered as adjunct therapy in patients with relapsing GCA to decrease the risk of further relapse events.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: FDG-PET may have a role in diagnosing and monitoring disease activity in large vessel vasculitis (LVV). Studies that assess the diagnostic accuracy of PET in LVV often use patients with cancer as a comparator group. There are limited data regarding use of serial FDG-PET imaging to monitor disease activity, and most assessments are performed during periods of clinically apparent disease. This study assesses the diagnostic performance of PET to differentiate LVV from mimics of vasculitis, examines the role of PET as a measure of disease activity, and determines the clinical characteristics associated with abnormal vascular FDG uptake.

Methods: 42 patients with LVV and 50 comparators (15 with systemic inflammation, 35 with atherosclerosis) were recruited in this prospective, observational cohort. Patients with LVV underwent FDG-PET every 6 months. Clinical and imaging assessments were performed blinded to each other and to levels of acute phase reactants. FDG-PET/CT was performed with 120 min uptake time (256 matrix, 3 mm slice). Active vasculitis on PET was defined by agreement of two nuclear medicine experts and inter-rater agreement was assessed by the kappa statistic. Multivariable regression, adjusted for repeated measures, assessed associations between active vasculitis on PET and clinical characteristics.

Results: 125 FDG-PET scans were performed in 92 patients: giant cell arteritis (n=22; mean age 68.4±9.4 years; disease duration 2.4±2.5 years), Takayasu arteritis (n=20, mean age 34.9±11.2 years; disease duration 13.4±11 years) and comparators (n=50, mean age 53.6±15.3 years). Inter-rater agreement was high (kappa = 0.84). In patients with LVV with clinically active disease, the performance characteristics of PET as a diagnostic test were good (sensitivity 90%; specificity 86%); however, 17% of patients with atherosclerosis had PET scan findings indistinguishable from active vasculitis. 26 of 45 PET scans (58%) performed in patients with LVV during apparent clinical remission suggested ongoing active vasculitis. Clinically apparent active disease and shorter disease duration were significantly associated with an abnormal PET scan. There was no association between levels of acute phase reactants and PET abnormalities; treatment with immunomodulating medications had a non-statistically significant protective effect (Table).

Conclusion: FDG-PET is useful to distinguish active LVV from mimics of vasculitis, but patients with atherosclerosis can have PET scan findings that closely resemble LVV. The majority of patients with LVV have abnormal PET scans while in clinical remission. An inverse association between disease duration and PET abnormalities suggests that scan abnormalities observed during clinical remission are not due to accrued vascular damage. FDG-PET may be an important modality to detect and monitor subclinical inflammation in LVV.

Table: Clinical Predictors of Abnormal FDG-PET Scan in Large Vessel Vasculitis

	Univariable		Multivariable	
	Odds Ratio	**P value**	**Odds Ratio**	**P value**
Disease Status (Active vs. Remission)	6.58 (1.74 – 24.90)	<0.01	9.29 (1.89 – 45.68)	<0.01
Disease Duration (Per year)	0.99 (0.99-1.00)	0.02	0.99 (0.99 – 1.00)	0.03
Diagnosis (GCA vs. TAK)	2.38 (0.86 – 6.67)	0.09	7.32 (0.35 – 151.69)	0.20
Age (Per Year)	1.02 (0.01 – 2.74)	0.10	1.05 (0.98 – 1.12)	0.20
Prednisone (Per 1mg / day)	0.99 (0.96 – 1.03)	0.72	0.96 (0.92 – 1.01)	0.10
Other Immune Medications (Yes vs. No)	0.56 (0.11 – 1.61)	0.28	0.56 (0.15 – 2.13)	0.39
Sex (Male vs. Female)	2.13 (0.62 – 7.25)	0.23	Not included in Multivariable model	
Patient Global Assessment (Range 0-10)	1.11 (0.90 – 1.38)	0.32		
Fibrinogen (Per 10)	1.02 (0.99 - 1.07	0.50		
ESR (Per 10 mm/h)	1.06 (0.92 – 1.35)	0.67		
CRP (Per 10 mg/L)	1.02 (0.91 - 1.26)	0.85		
Endothelin 1 (Per 1 mg/dl)	0.99 (0.88 – 1.12)	0.86		

GCA: giant cell arteritis; TAK: Takayasu's arteritis;
ESR: erythrocyte sedimentation rate; CRP: C-reactive protein

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: This study aimed to describe large arterial lesions among patients with giant cell arteritis (GCA) and to understand what clinical characteristics are associated with development of new arterial lesions during follow-up.

Methods: Patients with GCA enrolled in a prospective, multicenter, longitudinal study and/or a clinical trial were included. All patients were followed with standardized clinical assessments, including data from arterial imaging (stenoses, occlusions, aneurysms, and dissections). New lesions were defined as any new findings in a previously unaffected arterial segment.

Results: Data on imaging of the aorta and its branches were available for 187 patients with GCA: 146 (78%) female, mean (±SD) age at diagnosis 68.5 (±8.5) years. Mean (±SD) duration of follow-up was 3.8 (±2.3) years. Disease duration at entry into the cohort was within 1 year for 124 subjects (56%). At least one arterial lesion was present in 110 (58%) patients on entry into the cohort; 72 patients (65%) with disease duration <1 year. Subclavian (62 patients, 33%) and axillary arteries (47 patients, 25%) were the most frequently involved (**Table 1**). Serial imaging was available in 108 (58%) of the entire cohort; 76 (69%) of 110 with any lesion at baseline. Median (range) number of imaging studies was 3 (1-10). New arterial lesions were noted in 39 (36%) with new axillary and/or subclavian artery involvement being the most frequently observed (**Table 1**). Only 33% of 18 patients with new subclavian and/or axillary lesions had symptoms of upper extremity claudication since the prior visit or at the time of the visit. Clinical symptoms of any active disease since the last visit or at the day time of the visit were present only in 14 of the 56 visits (25%) where a new angiographic lesion was first reported. There were no differences in age, sex, disease duration, duration of follow-up, or presence of any disease activity during follow-up between patients with and without new lesions (**Table 2)**. Medication use including adjunctive immunosuppressive treatment at last follow-up is in **Table 2.**

Conclusion: New arterial lesions on serial imaging are common in patients with GCA, especially among patients with established large-vessel involvement. The majority of new lesions identified through use of serial angiography occur in patients who do not have symptoms of active disease at the time new findings were noted. Additional studies are needed to further understand the role of serial imaging, significance of new arterial lesions, and impact of treatment on large-vessel disease in patients with GCA.

Table 1: Distribution and frequency of arterial involvement at first and on follow-up imaging in patients with giant cell arteritis

Arterial Territory	Number of patients with any involvement on baseline imaging (Total = 187)	Number of patients with any *new* lesions on follow-up imaging (Total = 108)
Thoracic Aorta (overall)	20	6
· Thoracic Root	13	6
· Arch	6	2
· Descending Thoracic Aorta	6	1
Abdominal Aorta (overall)	6	1
· Suprarenal Abdominal Aorta	2	0
· Infrarenal Abdominal Aorta	6	1
Common carotid	13	9
External Carotid	3	2
Internal Carotid	16	4
Vertebral	17	4

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The American College of Rheumatology 1990 criteria for the classification of Takayasu arteritis (TAK) include age at disease onset ≤ 40 years. We aimed to investigate the clinical characteristics of TAK that developed over the age of 40 (TAK > 40).

Methods: We retrospectively analyzed 43 patients with TAK in three foundation hospitals from April 2000 to March 2016. We collected baseline variables at diagnosis including clinical symptoms and laboratory data, and subsequent relapses using medical records. We compared the above indices of TAK > 40 to those of TAK ≤ 40 years old at disease onset (TAK ≤ 40). Multiplex cytokine/chemokine bead assays were performed using preserved sera supernatants of 24 patients with TAK at disease onset (10 TAK > 40 and 14 TAK ≤ 40) of total 43 patients and Milliplex MAP Human Cytokine/Chemokine Panel 1 Pre-mixed 41Plex (Merck Millipore, Darmstadt, Germany) analyzed with a Bio-Plex® MAGPIX™ Multiplex Reader (Bio-Rad, Hercules, CA). Seventeen sera samples of healthy donors (HD) were used to compare to sera of patients with TAK.

Results: Of 43 patients, twenty patients were TAK > 40. TAK > 40 had significantly fewer orthostatic hypotension, carotid bruit and chest pain at disease onset compared to TAK ≤ 40 (2 [10%] (TAK > 40) vs. 10 [43%], p=0.019, 7 [35%] vs. 16 [70%], p=0.034, 0 [0%] vs. 6 [26%], p=0.023). There are no differences in C reactive protein, erythrocyte sedimentation rate, angiographic classification types, frequency of positive HLA-B52, chronic renal diseases, surgical interventions and aortic regurgitation in both groups. Initial prednisolone dose was lower in TAK > 40 [median, 30 mg vs. 40mg per day, p=0.024]. Body weight at disease onset and tapering speed of prednisolone were not different in both groups. Assessed by a log-rank test, the relapse free survival rate after remission was significantly higher in TAK > 40 (p=0.029) (Figure 1A). Median interleukin 6 levels of TAK > 40, TAK ≤ 40 and HD were 26.9 pg/mL, 23.4 pg/mL and 0.7 pg/mL, respectively (TAK > 40 vs. HD: p<0.01, TAK ≤ 40 vs HD: p<0.01, TAK > 40 vs. TAK ≤ 40: p=0.98) (Figure 1B). Median interferon gamma levels were 3.1 pg/mL, 20.5 pg/mL and 12.6 pg/mL, respectively (TAK > 40 vs. HD: p<0.01, TAK ≤ 40 vs HD: p=0.77, TAK > 40 vs. TAK ≤ 40: p=0.040) (Figure 1C). Median interleukin 17 levels were 1.1 pg/mL, 8.4 pg/mL and 5.1 pg/mL, respectively (TAK > 40 vs. HD: p<0.01, TAK ≤ 40 vs HD: p=0.77, TAK > 40 vs. TAK ≤ 40: p=0.018) (Figure 1D).

Conclusion: Our study suggested that TAK > 40 years old can be treated with lower prednisolone dose for remission and had fewer relapses after remission compared to TAK ≤ 40. Decreased levels of interferon gamma and interleukin 17 at disease onset were seen in TAK > 40. Difference of cytokine profiles at disease onset may associate with clinical characteristics of TAK > 40.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Histological findings of intima-media or transmural inflammation in temporal artery biopsies (TABs) have undisputed high value for diagnosis of giant cell arteritis (GCA). Conversely, the diagnostic significance of isolated adventitial or periadventitial cell infiltrates (e.g., inflammation limited to the adventitia [ILA], vasa vasorum vasculitis [VVV], and small vessel vasculitis [SVV])-remains unclear. We investigated the diagnostic value of isolated ILA, VVV or SVV in TABs for GCA and for the combined GCA/polymyalgia rheumatica (GCA/PMR) spectrum because of the close clinical connection of GCA and PMR.

Methods: All TABs performed in a single center over 7 years (2009–2015) were independently reviewed by 2 experienced pathologists blinded to the clinical diagnoses and with particular attention to isolated (peri)adventitial cell infiltrates. VVV was defined as a perivascular infiltrate within or in close contact with the adventitia and SVV as infiltrates of a periadventitial vessel. Medical charts were reviewed and diagnoses were classified as GCA, PMR and other by the final clinical diagnosis, with a follow-up of at least 6 months, as the gold standard. For TABs that did not show a classical histological picture of GCA with intima-media or transmural inflammation, we calculated the specificity and positive predictive value (PPV) of ILA, VVV or SVV for GCA and for GCA/PMR diagnoses. These variables were calculated for findings observed by at least 1 or by both pathologists. Cohen's kappa statistics were used to measure inter-observer agreement.

Results: We analyzed TABs for 100 patients; 6 were discarded because they did not allow for proper morphologic analysis of all vessel layers and 19 had classical histological features of GCA. For the remaining 75 TABs (mean age of patients, 69±12 years, 59% female), the diagnosis was GCA (n=8), PMR (n=7) and non-GCA/PMR (n=60). The frequency of (peri)adventitial TAB findings and their respective specificities and PPV for clinical diagnosis of GCA or GCA/PMR are in the Table. Inter-observer agreement was good for ILA (kappa 0.63 [95% CI 0.42–0.84]) and fair for SVV (0.31 [95% CI 0.09–0.52]) and VVV (0.21 [95% CI -0.01–0.43]).

	GCA (n=8) vs. non-GCA (n=67)			**GCA/PMR (n=15) vs. non-GCA/PMR (n=60)**		
	Frequency	Spec (95% CI)	PPV (95% CI)	Frequency	Spec (95% CI)	PPV (95% CI)
ILA						
At least 1 reader	2/8 vs. 10/67	85% (74–93)	17% (2–48)	4/15 vs. 8/60	87% (75–94)	33% (10–65)
Both readers	1/8 vs. 5/67	93%(84–96)	17% (0–64)	1/15 vs. 5/60	92% (82–97)	17% (0–64)
VVV						
At least 1 reader	0/8 vs. 7/67	90% (80–96)	0% (0–41)	0/15 vs. 7/60	88% (77–95)	0% (0–41)
Both readers	0/8 vs. 1/67	99% (92–100)	0% (0–98)	0/15 vs. 1/60	98% (91–100)	0% (0–98)
SVV						
At least 1 reader	2/8 vs. 27/67	60% (47–72)	7% (1–23)	7/15 vs. 22/60	63% (50–75)	24% (10–44)
Both readers	1/8 vs. 8/67	88% (78–95)	11% (0–48)	4/15 vs. 5/60	92% (82–97)	44% (14–79)

ILA: isolated inflammation of the adventitia, PPV: positive predictive value, Spec: specificity, SVV: small vessel vasculitis, VVV: vasa vasorum vasculitis

Conclusion: Isolated (peri)adventitial infiltrates in a TAB do not reliably predict a diagnosis of GCA and should not be considered relevant GCA-defining histological criteria. More general consensus is needed on the histological criteria defining GCA.

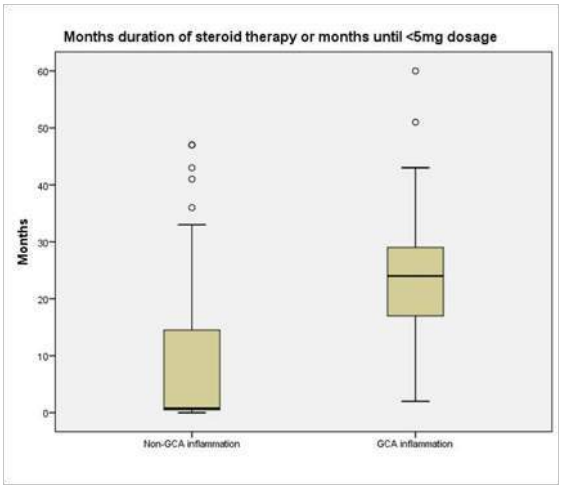
SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis of giant cell arteritis (GCA) by temporal artery (TA) biopsy requires pathologic identification of arterial inflammation, usually with giant cells. However, some biopsies may show lymphocytic infiltrates without arterial involvement (nonGCA-i). The prognostic significance of these findings is uncertain and virtually no long term follow-up studies have been done.

Methods: We identified 218 TA biopsies performed from 2010-2012 and 123 were available for blind slide review by a pathologist (RLH). Of these cases, 88 had medical records reviewed for long-term outcome. Chart review included: demographics, comorbidities, clinical presentation (constitutional symptoms, craniofacial symptoms, PMR symptoms, change in vision), and laboratory parameters. Using SPSS software, the associations between two categorical variables were analyzed with Chi-Square or FisherÕs Exact test. Mann-Whitney U test was used to analyze continuous variables.

Results: Based on assessment of symptoms at presentation and during long-term follow-up, patients with nonGCA-i were significantly less likely to have constitutional symptoms, craniofacial symptoms, CRP elevation, and vision loss ($P<0.05$). The frequency of temporary or permanent vision loss of any etiology among the 3 groups was as follows: 8/18 (44.4%) patients with TA biopsy positive for GCA, 1/34 patients with nonGCA-i, (2.9%) and 5/35 (14.3%) patients with negative TA biopsy. There was a trend towards less PMR among patients with nonGCA-i ($P=0.088$). The frequencies of the 3 groups meeting the 1990 ACR classification criteria (excluding biopsy result) were as follows: 16/18 (88.8%) patients with TA biopsy positive for GCA, 25/35 (71.4%) patients with nonGCA-i, and 19/35 (54.3%) patients with negative TA biopsy. Patients with nonGCA-i received a shorter duration of corticosteroids compared to those with positive TA biopsy ($P = 0.001$). While 13/33 (39.4%) patients with non-GCA-i and 13/35 (37.1%) patients with negative biopsy were treated with steroids for at least 4 months, all 14 patients with TA biopsy positive for GCA were treated for at least 4 months (excluding patients lost to follow-up or deceased).



Conclusion: In this cohort, patients with nonGCA-i rarely developed clinically evident GCA-like symptoms requiring corticosteroid therapy >= 4 months. Most importantly, patients with nonGCA-i did not develop complications of visual loss acutely or in long-term follow-up. Based on our findings, nonGCA-i in a temporal artery biopsy is an incidental finding and is not a harbinger of GCA clinically, even with long-term followup. Treatment on the basis of nonGCA-i alone may expose the patient to unnecessary corticosteroids. No new cases of GCA were identified in the pathological review. However, dose and duration of corticosteroid therapy for patients with nonGCA-i should always be guided by clinical judgement.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: As published in The Lancet online, March 4, 2016, the first RCT about tocilizumab (TCZ) in GCA showed clinical efficacy of the anti-IL-6 biologic agent in the induction and maintenance of remission for up to 52 weeks. This study analyzed the long-term outcome after termination of the RCT.

Methods: 30 patients with Giant Cell Arteritis (GCA) were randomized in this RCT in a 2:1 ratio into receiving intravenously (i.v.) TCZ 8mg/kg bodyweight plus Glucocorticoids (GC) or Placebo (PB) plus GC. They received infusions in 4-weekly intervals for 52 weeks. Thereafter TCZ medication was stopped, further treatment was prescribed by the treating physicians, patients were followed up clinically.

Results: By week 52 of the RCT all patients of the TCZ arms were in sustained complete remission, of these 18 without GC co-medication. 2/20 patients received GC after the last infusion due to premature stop of TCZ, one patient with Stevens-Johnson-syndrome and one with diverticulitis. Median follow-up time was 12.5 months (range 3-32). After the last infusion of TCZ 11/20 patients relapsed with a median time to relapse of 5 months (range 2-14). In the placebo arm all but one patient relapsed and/or continued GC treatment. Remarkably, 1/10 PB patients remained in remission throughout the study and was without medication at last follow-up, 10 months after the end of study. None of the relapsing patients experienced blindness, aortic rupture, aortic stenosis or other major vascular complications. In case of

relapse, dose of GC was 1mg/kg bodyweight in signs of major relapse and 20-40 mg/d in minor relapse according to the average dose during the study period that was sufficient to control symptoms in PB patients prior to relapse. Additionally, in 6/11 TCZ patients relapsing after the last study infusion, TCZ was re-administered with 8mg/kg bodyweight i.v. in monthly intervals after a median time of 6.5 months (range 3-14). In 2/6 patients with TCZ re-introduction, TCZ was stopped after 4 and 6 months, respectively, with lasting remission. In 1/6 patients TCZ was again given for 2 months, stopped in remission yet had to be re-introduced 6 months later due to a second relapse.

Conclusion: Clinical and serologic remission in response to TCZ for 52 weeks does not result in relapses-free survival after termination of treatment. Although IL-6 blockade using TCZ controls clinical disease, it may not control pathogenesis in all cases. The fact that 45% of patients remained in lasting remission may help to design treatment protocols to determine appropriate maintenance dosage regimens of TCZ after achievement of remission.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : Alterations in the immune system and infections are suspected to increase susceptibility to giant cell arteritis (GCA). Recently herpes zoster has been raised as a potential candidate pathogen for GCA. We examined the association between prior infections, in particular herpes zoster, and incident GCA in a population-based cohort.

Methods : A nested case-control study was performed using The Health Improvement Network (THIN) database, an electronic database originating from general practices in the United Kingdom. Cases with newly-diagnosed GCA were identified using a validated algorithm and compared to age-, sex-, and practice-matched controls using incidence density sampling. Patients with a prior diagnosis of polymyalgia rheumatica were excluded. Infections, including herpes zoster, that occurred prior to the onset of GCA were identified using diagnostic codes. Conditional logistic regression was used to examine the relationship between any infection or herpes zoster infection on the development of GCA and expressed as incidence rate ratios (IRR). All analyses were adjusted for prior use of glucocorticoid and non-glucocorticoid immunosuppressive therapies, alcohol use, smoking history, and the Charlson Comorbidity Index. Patients were analyzed according to the time period prior to index date in which the infection occurred to determine if recent infections were more strongly associated with GCA compared to earlier infections. A sensitivity analysis excluding patients who previously received at least 1 prescription for an oral glucocorticoid or immunosuppressive medication was performed.

Results : There were 4,559 cases of GCA and 22,795 controls. Any prior infection and herpes zoster was associated with incident GCA (IRR 1.26 [1.16, 1.36] and 1.17 [1.04, 1.32], respectively) (**Table 1**). A greater number of infections was associated with a higher risk of developing GCA. A sensitivity analysis excluding patients who received immunosuppressive medications produced similar results. The risk of developing GCA was greatest among those who experienced an infection within a year of the index date but was also significantly associated with infections that occurred in earlier time periods (**Table 2**).

Conclusion : Antecedent infections and, to a lesser extent, herpes zoster infections are modestly associated with incident GCA. These data provide population-level support for the hypothesis that longstanding alterations of the immune system are associated with susceptibility to GCA and suggest that herpes zoster is unlikely to play a major causal role in the pathogenesis of GCA.

Table 1: The Association of Infections with Incident Giant Cell Arteritis

Exposure	Unadjusted IRR (95% CI)	*P*-value	Adjusted IRR (95% CI)*	*P*-value
Herpes zoster infection	1.24 (1.10, 1.39)	< 0.01	1.17 (1.04, 1.32)	< 0.01

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is the most frequent inflammatory disorder in persons older than 50 years of age. Biomarkers like ESR and CRP may be associated with a relapse [1-2] but are not disease-specific. Monocytes play an important role in the pathogenesis of PMR and are detected in inflamed tissues (synovia and bursa) of PMR patients. The expression of CD16 (FcR-III) identifies pro-inflammatory monocytes that increase with age, produce IL-6, and are prone to migrate to areas of tissue damage [3]. We hypothesized that down-modulation of peripheral CD16+ monocytes is associated with an emerging relapse in PMR.

Methods: Twenty consecutively recruited, newly-diagnosed, steroid naïve PMR patients fulfilling the Chuang/Hunder criteria were included. Patients were prospectively followed for a median of 3.12 years (range 0.87-4.83 years). Relapses were defined as recurrence of PMR signs and symptoms associated with an increase in ESR (>30mm/h) and/or CRP (>10mg/L) which could not be explained otherwise. Peripheral CD16+ monocytes were enumerated by flowcytometry. Patients were divided into 2 groups based on the median value of CD16+ monocyte counts.

Results: ESR was significantly higher in the group with low CD16+ monocytes compared to the group with high CD16+ monocytes. Therefore, the relation between the numbers of CD16+ monocytes and the ESR was examined and a significant inverse correlation was found (Spearman's rho=-0.51, $p<0.05$). Also, PMR patients with low CD16+ monocyte counts were 6-fold more likely to relapse than patients with high CD16+ monocyte counts (HR: 5.96) (Figure 1).

Conclusion: PMR patients with low CD16+ monocyte counts demonstrated a shorter time to relapse. **References** 1. Kremers HM, Reinalda MS, Crowson CS, Zinsmeister AR, Hunder GG, Gabriel SE. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There are no estimates of the prevalence of giant cell arteritis (GCA) or polymyalgia rheumatic (PMR) in a United States population in the current millennium. The purpose of this work was to estimate the 2015 point prevalence of GCA and PMR in a population-based study performed in a US population.

Methods: Study populations of incident cases of GCA in 1950-2009 and incidence cases of PMR in 1970-2014 were previously identified among residents of a well-characterized geographically defined area. Prevalence estimates were obtained from the incidence rates assuming no increased mortality associated with GCA or PMR, which has been previously shown, and assuming migration in and out of the geographically defined area was independent of disease status. Age, sex and calendar year specific indigence rates and population lifetables were used to derive prevalence estimates. Prevalence estimates were age- and sex-adjusted to US white 2010 population aged ≥50 years. Bootstrap sampling was used to obtain 95% confidence intervals [CI] for the prevalence estimates.

Results: A total of 248 incident cases of GCA were diagnosed in 1950-2009 and 790 cases of PMR were diagnosed in 1970-2014. The

overall age and sex adjusted prevalence rate of GCA on January 1, 2015 was 204 (95% CI: 161, 254) per 100,000 population aged 50 years and older. The prevalence rate of GCA among women was 304 (95% CI: 229, 375) per 100,000 population aged 50 years and older and among men was 91 (95% CI: 46, 156) per 100,000 population aged 50 years. The overall age and sex adjusted prevalence rate of PMR on January 1, 2015 was 744 (95% CI: 694, 793) per 100,000 population aged 50 years and older. The prevalence rate of GCA among women was 907 (95% CI: 824, 994) per 100,000 population aged 50 years and older and among men was 557 (95% CI: 475, 638) per 100,000 population aged 50 years.

Conclusion: Prevalence rates of GCA and PMR in the new millennium to 2015 are similar to previously published prevalence estimates in the late 1990s. For GCA this reflects the fact that the incidence of GCA has been stable for the past 20 years. For PMR there have been slight increases in incidence of PMR in recent years, which have not yet affected the prevalence of PMR, but may lead to future increases in the prevalence of PMR. The health burden of these diseases among older persons continues to be substantial and reflects the need for continued efforts to better manage it.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Large vessels vasculitis (LVV) include Takayasu disease (TD) and Giant Cell Arteritis (GCA). Interleukin 33 (IL-33) is a cytokine which controls immune responses and has also an important vascular impact. We aimed to analyse the role of IL-33 and its receptor ST2 in the pathogenesis of LVV.

Methods: TD and GCA patients fulfilling the ACR criteria, with active or inactive disease and age-matched controls (HD) were included. We performed quantitative measurement of IL-33 in sera by ELISA, analysis of cytokine production by flow cytometry and Luminex. Immunohistochemical analysis of inflamed aorta and temporal arteries from TD and GCA patients was also performed.

Results: IL-33 and soluble ST2 were overexpressed in sera of LVV patients as compared to age-matched controls ($p=0.03$ in TD and $p=0.013$ in GCA for IL-33 and $p=0.0002$ in GCA for ST2). By immunofluorescence in inflamed vessels, we found endothelial IL-33 expression pattern mainly in the adventice together with the expression of its receptor ST2 restricted to inflammatory infiltrate. In both diseases, we highlighted in the vascular inflammatory lesions, the expression of Th2 cytokines (IL4) and of IL10. We have shown that IL-33 induced an increase of CD4+ T cells secreting IL-4 after 3 and 5 days of culture in GCA patients ($p=0.01$). In both disease, we have found that IL-33 led to an increased IL-5 and IL-13 secretion in the supernatants of mononuclear cell cultures. Besides anti-inflammatory properties of IL-33 in LVV, we demonstrated in mice that IL-33 led to an increased vascular permeability in both diseases ($p=0.004$). As

mast cells represent one of the main targets of IL-33, we have repeated a Miles assay in mice KO for mast cells. Vascular permeability was significantly decreased in KO mice injected with the same TA patients as compared to WT mice (p=0.007). In vitro, the exposure of TA sera to HUVECS led to the increase of VeCad phosphorylation compared to controls sera (p=0.03). Sera from TD patients also significantly increased the migration of endothelial cells whereas the exposure of serum to anti-IL-33 significantly decreased the number of transmigrated cells.

Conclusion: These findings open new perspectives for the role of IL-33 in the pathogenesis of LVV. IL-33 may regulate the inflammatory immune response by promoting Th2-polarization and increases vascular permeability, though mast cells.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is an immune-mediated polygenic disease characterized by inflammatory lesions in medium- and large-sized arteries. The aim of the present study was to perform the first unbiased genome-wide association study (GWAS) of GCA in order to identify the most relevant genetic factors contributing to disease predisposition.

Methods: We obtained genome-wide genotypes of 2,134 cases of GCA and 9,125 unaffected controls from 10 different populations of European ancestry (Spain, UK, North America, Italy, Germany, France, Norway, Netherlands, Switzerland, and Ireland). After imputation and tight quality filters, a total of 1,844,133 single-nucleotide polymorphisms were analyzed by logistic regression under an additive model using sex and ten first principal components as covariates. The inverse variance weighted method under fixed effects was used to meta-analyze the different studies.

Results: Two independent signals within the HLA class II region were strongly associated with GCA: rs9268905 (P = 1.94E-54, OR = 1.79, 95% CI = 1.67-1.93), located between the *HLA-DRA* and *HLA-DRB1* genes, and rs9275592 (P = 1.14E-40, OR = 2.08, 95% CI = 1.87-2.32), located between *HLA-DQA1* and *HLA-DQA2*. Outside the HLA region, different genetic variants of plasminogen (*PLG*) and prolyl 4-hydroxylase subunit alpha 2 (*P4HA2*), which encode proteins with relevant roles in vascular remodeling and neoangiogenesis, were associated at the genome-wide level of significance (top hits: *PLG* rs4252134, P = 1.23E-10, OR = 1.28, 95% CI = 1.19-1.39; and *P4HA2* rs128738, P = 4.60E-09, OR = 1.32, 95% CI = 1.20-1.45). Using publicly available functional annotation data, we observed that the associated signals correlated with eQTLs and histone marks specific for cell types and tissues involved in GCA pathology.

Conclusion: Consistent with previously published data, our results confirm the HLA class II as the most relevant genetic region for GCA. Additionally, we have identified *PLG* and *P4HA2* as novel GCA risk *loci*, highlighting the importance of the angiogenesis processes in the development of this form of large vessel vasculitis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common form of systemic vasculitis. The pathogenesis of GCA remains incompletely understood. Current evidence suggests that dendritic cells are key regulators of the inflammatory pathways involved in GCA. Dendritic cells secrete the T-cell regulating cytokine interleukin-23 (IL-23) which stimulates Th17 cells. The aim of this study was to evaluate the effect of IL-23 on inflammatory and proliferative pathways in GCA.

Methods: Temporal artery (TA) explant, peripheral blood mononuclear cell (PBMC), and myofibroblast outgrowth models were established from patients with GCA. All patients met the ACR classification criteria for GCA. TA explants were stimulated for 24 hours with recombinant IL-23 (10ng/ml). PBMCs were stimulated with recombinant IL-23 (10ng/ml) after priming with anti CD3 (0.5μg/ml) and anti-CD28 (1μg/ml). Levels of the pro-inflammatory cytokines IL-6 and IL-8 were quantified by ELISA. Myofibroblast outgrowths were established from TAs embedded in Matrigel, stimulated with IL-23 (10ng/ml) with media changed every 3 days, and number of outgrowths per high-power field (hpf) counted after 28 days. Data were reported as mean (standard deviation (SD)). Wilcoxon Signed Rank test was used to compare between group differences. Statistical significance was set at $p<0.05$. Analyses were performed using SPSS.

Results: IL-23 stimulated IL-6 from TA explants from a basal level of 7595 (11726) to 12468 (15194) pg/ml/mg ($p=0.007$, $n=40$), and IL-8 from a basal level of 6859 (13454) to 11820 (21685) pg/ml/mg ($p=0.003$, $n=39$). IL-23 stimulated IL-6 from PBMCs from a basal level of 2830 (3568) to 4637 (5739) pg/ml ($p=0.0001$, $n=19$), and IL-8 from a basal level of 201075 (116367) to 248228 (152195) pg/ml ($p=0.02$, $n=14$). IL-23 significantly increased the number/hpf of myofibroblast outgrowths compared to basal conditions from 7.01 (6.66) to 12.71 (10.55) ($p=0.0008$, $n=22$). Results are demonstrated in Figure 1.

Conclusion: IL-23 upregulated pro-inflammatory cytokines in temporal artery explants and PBMCs from GCA patients, including IL6, suggesting that IL23 may be upstream of IL-6 in the pathogenesis of GCA. IL-23 may play a central role in stimulating inflammatory and proliferative pathways and constitutes a therapeutic target in GCA. Figure 1: (A) IL-6 levels in IL-23 stimulated TA biopsies; (B) IL-8 levels in IL-23 stimulated TA biopsies; (C) IL6 levels in IL-23 stimulated PBMCs; (D) IL-8 levels in IL-23 stimulated PBMCs; (E) Myofibroblast outgrowths from IL-23 stimulated TA sections.

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: GCA has been considered a Th1-mediated disease. In recent years it has become apparent that Th17-mediated mechanisms may also play a role in GCA pathogenesis. Interleukin-12 is a heterodimeric cytokine (p35/p40) involved in Th1 functional differentiation of T lymphocytes. When combining with p19 subunit, p40 compose IL-23, a powerful pro-inflammatory cytokine that promotes Th17 response. P40, p35 and p19 are known to be expressed in GCA lesions but their distribution, association and functional roles have not been investigated. The aims of this study were 1) to investigate IL12p40, IL12p35 and IL23p19 subunit expression in GCA lesions and their combination to conform different cytokines 2) to investigate the effect of glucocorticoid treatment on subunit expression 3) to explore functional roles of p40 by culturing temporal artery sections with a neutralizing anti-human IL12/IL23p40 antibody.

Methods: IL-12/IL23p40, IL12p35 and IL23p19 mRNA were measured by qRT-PCR in temporal arteries from 50 patients with biopsy-proven GCA and 20 patients with negative temporal artery biopsies, eventually diagnosed with other conditions. 36 patients were treatment naïve and 14 had received glucocorticoid treatment for 7 days (range 2-12) before the performance of temporal artery biopsy. Cytokine subunit distribution was assessed by immunofluorescence. Proximity ligation assay (PLA) was used to assess spatial relationship between subunits to conform different cytokines. Temporal arteries from 10 patients and 10 controls were cultured on 3D-matrix (Matrigel) and exposed to a neutralizing goat anti-human p40 antibody (R&D Systems) or dexamethasone (0.5 µg/mL) .Mann-Whitney test was used for statistical analysis.

Results: p40 and p19 mRNA concentrations were significantly higher in patients than in controls .No significant differences were found in constitutively expressed p35 mRNA levels between patients and controls. P40 and p19 mRNA expression was significantly decreased in treated GCA patients versus those treatment-naïve. Interestingly, immunofluorescence staining revealed intense p19 expression by inflammatory cells, independent from p40 expression. Although p40 expression was less abundant than other subunits, association between subunits to conform IL-23 could be confirmed by PLA in GCA lesions. Neutralization of IL-12/IL-23p40 tended to reduce IFNg mRNA production in cultured temporal arteries from GCA patients with no effect on IL-17, TNFa or IL-6. Dexamethasone significantly down-regulated IFNg, IL-17, TNFa and IL-6 in cultured arteries.

Conclusion: p40 and p19 mRNA expression are increased in active lesions from patients with GCA and decrease with glucocorticoid treatment. P19 subunit is much more expressed than p40 in GCA temporal arteries, indicating an independent role for p19 or its potential association with unidentified subunits. Neutralization of IL12/IL23p40 seems to mainly inhibit the Th1-mediated pathway by reducing IFNg levels. Supported by SAF 2014 57708-R , PIE13/00033 and FEDER.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In GCA, cranial artery involvement is particularly frequent and underlies the classical manifestations and complications of the disease. Symptomatic pericarditis has been occasionally described as part of the presenting symptoms. However, the frequency of imaging-detected pericardial involvement has not been systematically evaluated. The aim of our study was to assess the prevalence of pericardial involvement detected by CTA in patients with newly diagnosed GCA, as well as the potential relationship with pericardial symptoms, GCA manifestations, laboratory data, or the presence of large-vessel vasculitis (LVV). The outcome of pericardial involvement with GC treatment was also analyzed.

Methods: From July 2007 to January 2015, 63 patients diagnosed with biopsy-proven GCA at our institution were subjected to CTA according to a defined protocol as part of a prospective study assessing LVV [*Prieto-González S et al; Ann Rheum Dis 2012*]. These patients were treatment-naïve or had received GC for ≤ 3 days. A follow-up CTA was scheduled to evaluate the outcome of imaging-detected lesions with GC treatment. Post-hoc assessment of CTA images was performed in order to detect pericardial abnormalities including pericardial thickening (thickness of the pericardial membrane of at least 4mm) and/or pericardial effusion (presence of liquid between the pericardial membrane and the heart). Specific GCA symptoms and laboratory features, as well as classical pericardial manifestation were recorded.

Results: Among the 63 patients included, 45 were women and 18 men, aged 78 years (range 56-92). At the time of GCA diagnosis, pericardial involvement was present in 18 patients (29%), consisting of thickening (4-7mm) in 8 patients (13%) and effusion (4-18mm) in 10 (16%). Forty-six patients completed the follow-up CTA assessment after a median follow-up of 16 months (range 12-135). At the

second imaging, 8 of them (17%) still had pericardial involvement: thickening in 5 (11%) and effusion in 3 (6%). All patients were asymptomatic regarding classical pericarditis symptoms. No relationship was observed between the presence of pericardial involvement and GCA manifestations, laboratory data or the detection of LVV.

Conclusion: In our series, about one third of patients with newly diagnosed GCA have pericardial involvement, consisting of a subclinical mild to moderate pericardial thickening or effusion that improves during the follow-up with GC treatment. Supported by SAF14/57708-R.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) requires treatment with high dose corticosteroids with attendant significant adverse events. There is a critical need for alternative therapies. Interleukins 12 (IL-12) and 23 (IL-23) stimulate Th1 and Th17 responses respectively, both hypothesized to be important in GCA pathogenesis. We have recently reported preliminary evidence of efficacy of IL-12/23 blockade with ustekinumab in 14 GCA patients. In this study we report outcomes in a larger cohort of 25 patients.

Methods: We performed a prospective open label study of ustekinumab in patients with refractory GCA. Ustekinumab was administered subcutaneously at a dose of 90mg at week 1 and week 4 followed by every 12 weeks. Patients underwent standardized clinical assessments. Disease activity was based on a combination of clinical assessment, acute phase reactants (ESR, CRP) and available imaging studies. Descriptive statistics were reported as mean and standard deviation (SD), median and interquartile range (IQR) or number (n) and percentages as appropriate, Wilcoxon Signed Rank test was used to compare between group differences. Statistical significance was set at $p<0.05$. All patients gave written informed consent and ethical approval obtained.

Results: 25 patients commenced ustekinumab having failed to taper corticosteroids and a median of 1 other immunosuppressant, with a median (IQR) of 2 (1, 3) prior relapses of GCA. 84% had experienced significant corticosteroid side effects. Full demographic and clinical details are shown in Table 1. Median (IQR) duration of ustekinumab treatment at last follow-up was 15 (6, 22) months. Efficacy outcomes are detailed in Table 2. Median (IQR) steroid dose decreased significantly from 15mg (5, 20) to 5mg (3.8, 10) ($p=0.002$). 7 patients with large vessel vasculitis had follow-up imaging performed with improvement of wall thickening in all and no new stenoses or aneurysms. No patients experienced a relapse of GCA during ustekinumab treatment. 11 adverse events were recorded, 2 respiratory tract infections, and 1 case each of pancreatitis with infected pseudocyst, bell¡¯s palsy, thyroid goitre, alopecia, parasthesia, tinea pedis, urinary tract infection, dental abscess, and cold extremities. 3 patients discontinued ustekinumab due to adverse events or personal preference, 2 subsequently had flares of polymyalgia rheumatica.

Conclusion: Ustekinumab led to significant reductions in steroid dose and acute phase reactants in patients with refractory GCA. The efficacy of ustekinumab in GCA warrants investigation in a randomized controlled trial.

Session Time: 9:00AM-11:00AM

Risk of Coronary Artery Disease in Patients with Polymyalgia Rheumatica: A Systematic Review and Meta-analysis

Background/Purpose: Several chronic inflammatory disorders, such as rheumatoid arthritis and systemic lupus erythematosus, are associated with an increased risk of coronary artery disease (CAD) as a result of accelerated atherosclerosis. However, the data on polymyalgia rheumatica (PMR), one of the most common chronic inflammatory disorders in older adults, remain unclear due to limited number of epidemiological studies. To further investigate this possible association, this systematic review and meta-analysis of observational studies was conducted to compare the risk of CAD in patients with PMR versus participants without it.

Methods: Two investigators independently searched published studies indexed in MEDLINE, EMBASE and the Cochrane database from inception to March 2016 using the terms "polymyalgia rheumatica" combined with the terms for coronary artery disease. A manual search of references of selected retrieved articles was also performed. The inclusion criteria were: (1). observational studies published as original studies to evaluate the risk of CAD among patients with PMR; (2). published odds ratios (OR), relative risk (RR) or hazard ratio (HR) or standardized incidence ratio (SIR) with 95% confidence intervals (CI) in the studies. Study eligibility was independently determined by the two investigators noted above. The quality of each study was assessed using Newcastle-Ottawa scale. RevMan 5.3 software was used for data analysis. Point estimates and standard errors were extracted from individual studies and were combined by the generic inverse variance method of DerSimonian and Laird. Given the high likelihood of between-study variance, random-effect model rather than fixed-effect model was used. Statistical heterogeneity was assessed using the Cochran's Q test and I^2.

Results: Out of 176 potentially relevant articles, four studies (three retrospective cohort studies and one cross-sectional study) with 34,569 patients with PMR were identified and included in this meta-analysis. The pooled risk ratio of CAD in patients with PMR was 1.72 (95% CI, 1.21 to 2.45). The statistical heterogeneity of this meta-analysis was high with an I^2 of 97%.

Conclusion: The risk of CAD among patients with PMR is 70% higher than in patients without PMR. This finding has importance for the assessment and management of cardiovascular disease in these patients.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Our aim was to describe patients with Giant-Cell Arteritis (GCA)-related stroke and to compare them to a control group of GCA patients without cerebrovascular involvement.

Methods: We created a retrospective multicenter cohort of patients with 1) GCA diagnosed according to the American College of Rheumatology (ACR) criteria between 1995 and 2015; 2) stroke revealing vasculitis or occurring within four weeks of starting GCA therapy. The control group comprised GCA patients with no history of stroke from patient-reporting centers. For each patient included with stroke, five randomised patients without stroke were included in the control group. All of them satisfied the ACR criteria

Results: Forty patients (21 (53%) women, median age 78 [60-91] years) with GCA-related stroke were included and were compared to 200 control patients with GCA. The stroke revealed GCA in 29 (73%) patients, whereas it occurred after diagnosis in 11 patients, 6 [1-14] days after the initiation of glucocorticosteroids (GC). No differences were observed between patients whose stroke revealed GCA and those suffering a stroke following GCA diagnosis. Vertebrobasilar territory was involved in 29 (73%) patients. Seven patients died within a few hours or days following a stroke. Compared to the control group, the stroke patients were older (78 [60-91] vs. 74 [50-94] years old, p=0.03), displayed more ophthalmic ischemic manifestations (25 (63%) vs. 50 (25%), p<0.001), had fewer anemia (22/37 (59%) vs. 137/167 (79%), p=0.03) and a higher level of hemoglobin at diagnosis (12.0 [9.4-16.1] vs. 11.1 [7.8-15.8] g/dl, p=0.02). Conversely, PMR was less frequent (8 (20%) vs. 76/198 (38%), p=0.03) and biological inflammatory parameters were lower at GCA diagnosis in patients with GCA-related stroke (ESR: 68 [10-119] mm vs. 80 [10-140], p=0.003; CRP: 61 [28-185] mg/l vs. 99 [6-400], p=0.04). Multivariate logistic regression revealed that the best predictors for the occurrence of stroke were the presence of ophthalmic ischemic manifestations at diagnosis (OR = 5, 95% CI, 2.14—12.33; p=0.0002) and absence of anemia (OR = 0.39, 95% CI, 0.16—0.99; p=0.04).

Conclusion: Stroke, especially in the vertebrobasilar territory, is more likely to occur in GCA patients who experience recent ophthalmic ischemic manifestations and who display low inflammatory parameters.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Case reports and series suggest that Takayasu's arteritis (TA) can co-exist with various inflammatory disorders.

Inflammatory bowel disease [(IBD; Crohn's disease (CD) or ulcerative colitis (UC)] has been the most common association. We conducted a formal study to look specifically at the frequency of such inflammatory disorders in a large cohort of TA followed by a single tertiary center.

Methods: There were 226 (200 F/ 26 M) patients registered with a diagnosis of TA. Of these, 17 (8 %) had died and 15 (7 %) were lost to follow-up. The remaining 194 patients were called back at the outpatient clinic for an interview and for a physical examination. A standardized form sought whether the patient was also diagnosed as IBD, ankylosing spondylitis (AS), Behçet's syndrome (BS), amyloidosis, uveitis, rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (pSS), Sjögren's syndrome, psoriatic arthritis, inflammatory myositis, small vessel vasculitis, autoimmune/demyelinating or any other inflammatory disorder. In addition to the self-reported information, patient charts and all medical documentation available were used as a source of information.

Results: 153 (136 F/ 17 M) patients were studied. The mean age at the onset of symptoms was 31±11 years and at the time of TA diagnosis was 34 ± 12 years. Subclavian artery was the most common involved artery (83%), followed by common carotids (75%) and aorta (64%). Currently, while 25 (16%) patients were off treatment, 72 (47%) patients were using glucocorticoids, 47 (31%) azathioprine, 32 (21%) methotrexate and 44 (29%) biological agents. We identified in total 31 (20 %) patients with inflammatory diseases (IBD: n= 11; AS: n = 11; and BS: n = 9). Table shows their demographic characteristics. Among the remaining 122 patients, inflammatory back pain was present in 44 (36 %) recurrent oral ulcers were present in 19 (16%), erythema nodosum in 13 (11%), arthritis in 12 (10%), papulo-pustular lesions in 5 (4%), uveitis in 5 (4%) and genital ulcer in 1. It was noted that inflammatory back pain was mostly located on the dorsal area (n=40). Apart from these diseases, we also observed secondary amyloidosis (n=3), psoriasis (n=3), autoimmune hepatitis (n=2), RA (n=1) and morphea (n=1). None of the patient had SLE, Sjögren's or myositis.

Conclusion: TA does co-occur with IBD, AS or BS in about 1/5 of the patients, at least in a hospital setting and without a clear temporal pattern. This could be due to the close association of TA with MHC class-1 diseases. In addition, the high prevalence of inflammatory back pain in the dorsal spine in TA needs further scrutiny.

Table. Demographic features of 31 TA patients with inflammatory bowel disease (IBD), ankylosing spondylitis (AS) or Behçet's syndrome (BS)

Concomitant disease	F/M	Mean age at TA diagnosis (SD)	Mean age at concomitant disease (SD)	The time of TA diagnosis in relation to concomitant disease
AS (n=11)	9/2	31 ±8	27±11	TA preceded (n=6) AS preceded (n=5) Simultaneous (n=6)
IBD (n=11)	10/1	33±9	31±9	TA preceded (n=2) IBD preceded (n=3) Simultaneous (n=4)
BS (n=9)	7/2	35±13	32±13	TA preceded (n=1) BS preceded (n=4)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A key unmet need in the monitoring of disease activity in large vessel vasculitides (LVV), i.e., giant cell arteritis (GCA) and Takayasu arteritis (TAK), is the ability to differentiate active vasculitic disease activity from atherosclerotic damage through the use of noninvasive imaging modalities. In LVV, the inflammatory process begins at the vasa vasorum in the adventitia, with vasa vasoritis and inflammatory cell recruitment. Thickened adventitia and medial fibrosis are key features that differentiate vasculitis from atherosclerosis. A novel imaging modality that can noninvasively detect increased neovascularization and thickening in large vessels' adventitia is microbubble contrast-enhanced carotid ultrasonography (CU). In animal and human studies using CU, higher densities of vasa vasorum correlated with plaque vulnerability and atherosclerosis progression. Our objective was to establish feasibility of measuring adventitial vasa vasorum density (aVVD) in LVV patients; to compare aVVD in clinically active vs. inactive LVV patients; and to examine various serum vascular and inflammatory biomarkers in these patients.

Methods: We performed a preliminary analysis of an ongoing cross-sectional study of 7 LVV patients (2 active, 5 inactive) to illustrate feasibility of the novel CU technique. All subjects met ACR criteria for GCA or TAK. All subjects underwent CU with measurement of carotid intima-media thickness (cIMT, using maximum of both sides) and mean common carotid artery (CCA) adventitial to lumen videointensity ratio (using maximum of both sides) to quantify aVVD. Data on demographics and disease characteristics were collected on all subjects. Serum biomarkers of CD40L, matrix metalloproteinase-9, myeloperoxidase, E-selectin, intercellular adhesion molecule-1, and vascular cell adhesion molecule-1 were measured in all subjects by enzyme-linked immunosorbent assay (ELISA). The inflammatory markers high sensitivity C-reactive protein and erythrocyte sedimentation rate were also measured in all patients.

Results: Table 1 shows results of type of LVV, disease activity status, demographic data, cIMT, and aVVD of all 7 subjects. The mean cIMT of the two active LVV subjects was 1.23 mm, and the mean cIMT of four inactive subjects was 0.91 mm. The maximal aVVD of the CCA's far wall for the two active LVV subjects was 0.58, versus 0.50 for the five inactive LVV subjects. Wide variation in serum biomarker levels were seen in the inactive subgroup, and statistical testing will be performed when the study of n=20 participants is completed to compare if the levels are higher in the active vs. inactive subgroups.

Conclusion: Measurement of aVVD in LVV patients is feasible utilizing the novel CU technique. In this pilot study, the aVVD was slightly higher in active vs. inactive subjects. Our study is ongoing, with plans for targeted enrollment of larger numbers and comparison with control (non-LVV) subjects. **Table 1.**

Subject Number	Type of LVV	Active vs. Inactive	Age (years)	Gender	BMI (kg/m^2)	cIMT (mm)	Left aVVD	Right aVVD
LV01	GCA	Inactive	64	Female	35.1	0.65	0.095	0.276

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Takayasu arteritis (TAK) is an inflammatory large-vessel vasculitis of unknown etiology affecting the proximal aorta and its primary branches. Heart disease is a major cause of death in patients with TAK but studies evaluating coronary/pulmonary artery involvement and myocardial dysfunction in this population have been limited.

Methods:

A retrospective cohort of patients with newly diagnosed TAK from 1984 to 2009 was assembled. All patients included met 1990 American College of Rheumatology classification criteria for TAK. Demographics, baseline disease characteristics, relapse events, surgeries and mortality were abstracted from direct medical record review. Angiograms (invasive and non-invasive), echocardiograms, nuclear medicine scans, and electrocardiograms (ECG) were reviewed for evidence of CP involvement. For the purpose of this study, CP abnormalities were defined as coronary or pulmonary artery vasculitis, left ventricular (LV) dysfunction, left atrial (LA) enlargement, moderate-severe valvular disease, pulmonary arterial hypertension (PAH), regional wall hypokinesis/akinesis, LV hypertrophy or persistent ECG axis deviation. Cox models with time-dependent covariates were used to assess the association between CP involvement and outcomes.

Results:

A total of 117 patients with TAK were identified. Forty-five (38%) patients had at least one objective CP abnormality observed within 6 months of TAK diagnosis. Age at diagnosis was higher in those with CP involvement than those without (34.6 vs 30.1 yrs, respectively; p=0.04). Baseline characteristics and symptoms were similar, except shortness of breath, which was more frequently observed at TAK diagnosis in patients with CP involvement compared to those without (53% vs 21%, respectively; p=0.001). PAH was identified in 7, pulmonary arteritis in 9, coronary arteritis in 3, aortic valve insufficiency in 10 (6 moderate, 4 severe), LV systolic heart failure in 4, LV enlargement in 17, and LA atrial enlargement in 17 patients. Seventy-seven patients had at least 1 year of follow-up [median (IQR): 5.5 (2.9-10.1) years]. Of these 77 patients, 44 had at least one vascular or valvular surgery during the follow-up period. Composite CP involvement was not associated with risk of first surgery [Hazard ratio (95% CI): 1.21 (0.64-2.30); p=0.56]. However, PAH on echocardiogram was significantly associated with risk of first surgery [HR (95% CI): 12.9 (1.86-89.14); p=0.01]. During follow-up 7 patients died. CP involvement was not significantly associated with mortality [HR (95% CI): 2.51 (0.45-14.02); p=0.29].

Conclusion:

Cardiopulmonary abnormalities in TAK are common. In this population, the presence of PAH predicted a 13-fold increased risk for vascular or valvular surgery. In this cohort, the presence of CP involvement did not increase mortality.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Disease activity of polymyalgia rheumatica (PMR) (1, 2) may be evaluated using the PMR activity score (PMR-AS). For patients without measure of CRP, or patients having a treatment modifying its measure (i.e. anti-IL6), the PMR-AS could be unmeasurable or biased. Three options should be suggested: 1-to use ESR instead CRP but anti IL6 may also modify ESR; 2- to use PMR-AS without CRP (clin-PMR-AS) as an item but its validation is mandatory; 3- to replace CRP by a virtual value imputed on the basis of the other parameters (CRP-imputed-PMR-AS). Our goal was to build a PMR-AS using imputed value of CRP.

Methods: We used two independent cohorts of patients: the CRI cohort (137 visits of 89 PMR patients without any treatment or treated by corticosteroids) (2) and the TENOR cohort (20 patients, 20 visit at inclusion without any treatment, 20 visit at W4, 8, 12 during tocilizumab infusions, and 20 visit at 16, 20 and 24 weeks with treatment by steroids) (2). In the CRI cohort, we evaluated the correlation (Spearman) between the items of the PMR-AS to define which of them may be the best to perform an imputation of CRP. Then we built a scatter plot representing PMR-AS and clin-PMR-AS. Their correlation could be represented by an equation y=ax+b. We verified that the CRP-imputed-PMR-AS in patients of the TENOR cohort without treatment by tocilizumab gave a good correlation with PMR-AS with CRP. Finally, we evaluated the difference of PMR-AS without CRP and the CRP-Imputed-PMR-AS in the TENOR cohort during the visit 4, 8 and 12.

Results: On the CRI cohort, we observed a good correlation between the items of the PMR-AS, the clin-PMR-AS and PMT-AS. Agreement between PMR-AS with and without CRP was excellent (using cut off 0-7-17-∞; only 5/137 were discordant, kappa: 0.93) but as anticipated, the clin-PMR-AS was lower than the PMR-AS. On a scatterplot representing the PMR-AS (y) according to the clin-PMR-AS (x), a straight line y=1.12 x clin-PMR-AS + 0.26 represented their association, and with use it for CRP imputation. The mean +/- SD was very close between the PMR-AS, clin-PMR-AS, and CRP-imputed-PMR-AS, respectively. Using cut off 0-7-17-∞, we obtained a slightly higher concordance for the CRP-imputed-PMR-AS (kappa=0.95). This suggested that it was not really necessary to do an imputation to separate patient in groups of PMR-AS except for high clin-PMR-AS. The replication in the TENOR cohort before and after treatment by tocilizumab confirmed that CRP-imputed-PMR-AS did not modify the results using the original PMR-AS (during treatment by tocilizumab, means for PMR-AS, clinPMR-AS, and CRP-Imputed-PMR-AS were 11.3+/-8,1, 11+/-8.1 and 12.0+/-9, respectively).

Conclusion: This study supplies evidence that a CRP-imputed-PMR-AS may be used to monitor PMR activity for patients without available CRP or treated by anti IL6. Nevertheless, use of PMR-AS (or Clin-PMR-AS) in patients treated by tocilizumab lead to a very small proportion of false classification of patient splited in low-disease activity or high-disease activity. Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a chronic immune-mediated vasculitis of large and medium vessels characterized by a chronic relapsing course with no good biomarkers that can predict activity and response to treatment. Fortunately, the accessibility of the temporal artery for tissue biopsy allows novel mechanistic studies that can characterize pathogenic macrophages which possess pro-inflammatory and pro-angiogenic properties which depend on their cross talk between the microenvironment of the compartments/layers of the vessel wall. The localization of particular activated macrophage subtypes (AMs) in a particular vessel compartment can provide insight on how AMs influence endothelial activation in the intima, and neoangiogenesis in the media and adventitia. In this pilot study, we evaluated the expression of 2 novel AM subtypes- folate receptor beta (FRB) and endothelin receptor beta (ETB) which are potential pathogenic populations and druggable targets for existing medications like methotrexate/new generation antifolates and endothelin receptor blockers We assessed their predominant distribution across the intima media and adventitial layers.

Methods: Formalin-fixed paraffin embedded hematoxylin-eosin stained tissue sections were examined from 6 patients with GCA and 2 controls with no disease and normal temporal artery biopsies. Immunohistochemical stains were performed using FRB, CD68 and CD3 antibodies to enhance recognition of AMs, their distribution along the intima media and adventitial layers and composition of inflammatory infiltrates. We compared the expression of FRB and ETB in GCA versus controls and mild (no visual loss) versus severe disease (positive visual loss).

Results: In GCA patients, overall inflammation was moderate to severe with >90% destruction of the internal elastic lamina. AMs comprised 36.3 ± 4.1% of total leukocyte infiltrate while CD3(+) lymphocytes accounted for 61.7 ± 4.1%. FRBs were selectively expressed in AMs, which predominantly localized in the media/adventitia with a median of 9.8 cells/hpf (IQR = 7-12). ETBs were expressed predominantly in intimal macrophages- with a median of 20.5 cells/hpf (IQR = 15.2 – 21.5), smooth muscle and endothelial cells. There were no macrophages nor FRB expression demonstrated in the controls. A trend towards higher FRB and ETB expression was seen in GCA with complications of vision loss versus those without but did not reach statistical significance.

Conclusion: FRBs macrophages are potential biomarkers that localize to the media/adventitia and may contribute to vasa vasorum angiogenesis. ETB is more ubiquitously expressed, and ETB macrophages localize to the intima where they may affect endothelial activation. FRB and ETB macrophages should be analyzed for pathogenicity, antifolate-binding properties and clinically correlated in larger samples in future and prospective studies.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate health-related quality of life (HRQoL) in a large cohort of patients with giant cell arteritis (GCA) as measured by the 36-item Short Form Health Survey (SF-36).

Methods: Patients with GCA enrolled in a multicenter, longitudinal cohort were included. Subjects were followed with standardized clinical assessments which include symptoms attributed to vasculitis at diagnosis and follow-up, physician global assessment (PGA, 0-10 visual analogue scale), patient global assessment (PtGA, 0-10 visual analogue scale), vasculitis damage index (VDI), SF-36. Physical component scores (PCS) and mental component scores (MCS) were calculated from SF-36 and normalized to the general population (mean ± SD=50 ± 10) with lower scores indicating poorer outcomes. Active disease at a study visit was defined as presence of any symptom attributable to vasculitis in the prior 28 days.

Results: Data from 281 patients with GCA were included: 197 (70%) women; mean age at diagnosis = 72.1±8.4 years. Median (25^{th}, 75^{th} quartiles) time from diagnosis to entry in the cohort was 25 (7, 88) weeks. 108 subjects (39%) were enrolled into the cohort ≤ 12 weeks from diagnosis. Manifestations at time of diagnosis: positive temporal artery biopsy 180 of 224 (80%) patients in whom it was performed; visual manifestations in 109 patients (38%); limb claudication (upper or lower) in 59 patients (20%). VDI at entry into the cohort was 1 (0-2) with 149 subjects (60%) having at least 1 item of damage. Means±SD PCS and MCS were lower in patients with GCA compared to the general population at 39±11 and 47±13, respectively. Mean PCS was significantly lower in women, patients with active symptoms on the day of evaluation, those with elevated inflammatory markers, those with at least 1 damage item on VDI, and patients with PtGA ≥ 1 and/or PtGA ≥ 3 (**Table**). Mean MCS was lower in patients with active symptoms or with a PtGA≥1 or PtGA ≥ 3 (**Table**). Subjects with newly-diagnosed disease had similar PCS but lower MCS compared to the patients with established disease. When analysis was restricted to the subset with newly-diagnosed GCA, PCS was statistically lower in women, those with elevated acute phase reactants and the subset presenting with limb claudication or PtGA ≥ 3 while MCS was similar across these comparisons (**Table**). PCS and MCS was similar in patients with visual symptoms at diagnosis even when restricted to subjects with newly-diagnosed disease.

Conclusion: Patients with GCA have reduced HRQoL, as measured by the SF-36. PCS appears sensitive to changes in disease status or health status while MCS did not appear to differentiate between the variables measured. SF-36 may be a useful tool in assessing patient reported outcomes in patients with GCA. These findings highlight the importance of measuring the burden of disease from the patient's perspective when evaluating GCA.

Giant Cell Arteritis and Malignancy – More Than Just a Coincidence?

Rok Jese[1], Alojzija Hocevar[1], Ziga Rotar[1], Sonja Praprotnik[2] and Matija Tomsic[1], [1]Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, [2]Department of Rheumatology, University Medical Centre Ljubljana, Slovenia, Ljubljana, Slovenia

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Malignancy associated vasculitis represents 2–5% of systemic vasculitides. While there have been reports of increased incidence of malignancy in patients with giant cell arteritis (GCA) no definite association has yet been established. Our objective was to determine the proportion patients with GCA and past/concurrent/subsequent malignancy.

Methods: We conducted a prospective longitudinal analysis of patients diagnosed with GCA from September 2011 to May 2016 at a single secondary/tertiary rheumatology centre. The proportion of patients with past, concurrent, and successive malignancy (diagnosed within 1 year of follow-up) was determined. Crude incidence rate (CIR) of malignancy in general population aged 50 years and above from the same geographical region in year 2011 and 2012 (final accessible reports based on complete yearly data) was acquired from Slovenian Cancer Registry for comparison.

Results: During the observation period 119 new GCA cases were identified (median age 73.8 (IQR 70.0–78.8) years, 71% female, 39.5% ever smokers). Ninety-eight (82.4%) patients fulfilled the 1990 ACR classification criteria for GCA; the remaining 17.6% had imaging evidence of large vessel vasculitis. Thirteen patients (10.9%) had past history of malignant disease; one of these patients had an active urinary bladder cancer at the time of GCA diagnosis. There was 1 death due to cancer during the follow-up. In 8 patients (6.7%) malignant disease was found concurrently with GCA (4/8) or within one year of follow-up (4/8) (Table 1). With respect to location of the 8 newly diagnosed malignancies, there were 3 cases (2.5%) of urinary bladder cancer (Table 2). CIR for malignancy in population aged 50 years and above of the same geographical region was 1.51%, with specific CIR for bladder cancer of 0.04%.

Table 1. Age-stratified comparison of malignancy incidence rate in GCA patients vs. the general population.

Age group (years)	No. of patients with malignancy			No. of GCA patients with C/S malignancy	Total No. of GCA patients	Incidence rate (C+S)	CIR for general population
	P	C	S				
50–59	1	1	0	1	7	14.3 %	0.75 %
60–69	2	1	2	3	35	8.6 %	1.59 %
70–79	6	0	2	2	55	3.6 %	2.31 %
80+	4	2	0	2	22	9.5 %	2.56 %
Total (50+)	**13**	**4**	**4**	**8**	**119**	**6.7 %**	**1.51 %**

Legend: P – past; C – concurrent; S – successive; CIR – Crude Incidence Rate

Table 2. Location of malignancy and temporal relationship to GCA.

Location	P	C	S
Renal	1	0	0
Bladder	1	2	1
Stomach	0	1	1
Colon	3	0	0
Ovarian/uterine	3	0	0
Haematologic	1	1	0
Breast	2	0	1
Prostatic	1	0	0
Melanoma	1	0	1
Total	**13**	**4**	**4**

Conclusion: In our study, incidence rate of malignant disease was distinctly higher in GCA patients compared to general population for all age groups; ultimately, 6.7% of GCA patients were diagnosed with concurrent/successive malignant disease – compared to 1.5% of

similarly aged general population. Additionally, we detected an increased incidence of urinary bladder cancer in our GCA cohort.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: FDG-PET can be used to detect vascular inflammation in large vessel vasculitis (LVV). The study objective was to determine if therapies currently used to treat LVV impact vascular FDG uptake.

Methods: Patients with giant cell arteritis (GCA) or Takayasu's arteritis (TAK) were recruited into a prospective, observational cohort of LVV. All patients underwent FDG-PET/CT at 6-month intervals (256 matrix, 3mm slice, 2 hour uptake time). Change in cumulative glucocorticoid (GC) dose between interval visits was calculated. Treatment status between interval visits was categorized as increased, decreased, or unchanged. Change in treatment was defined as change in average daily dose of prednisone over past 7 days by $\geq$ 5 mg, addition of a new DMARD or biologic agent or a 50% change from the baseline dose. Standardized uptake values (SUVs) were measured in 3 regions: 1) ascending aorta and arch; 2) descending aorta; and 3) liver. Vascular FDG uptake was quantified as a target to background ratio (TBR) standardized to the liver (TBR = SUV_{max} Aorta Region / SUV_{mean} Liver). Change in TBR in each region of the aorta was calculated between interval study visits. Kruskal-Wallis test was performed to compare change in TBR across treatment status categories. Spearman correlation between change in TBR, change in cumulative GC dose, and change in methotrexate (MTX) dose was calculated. Linear regression was performed to evaluate relationship between change in MTX and GC dose with change in TBR.

Results: FDG-PET/CT was performed in 20 patients with LVV (GCA=14; TAK=6) over 49 study visits. 15 patients were treated with GCs, 10 patients were treated with MTX, and 8 patients received another DMARD or biologic during the study. Increased therapy was recorded over 11 visit intervals, decreased treatment was noted in 5 visit intervals, and there was no change in therapy for 11 visit intervals. There was a simultaneous decrease in the GC dose with increase of DMARD over 2 treatment intervals, which were excluded from further analysis. Change in TBR of the descending aorta significantly differed among the 3 treatment categories (p=0.01). Post hoc analysis showed significant reduction in TBR in the group with increased treatment versus the unchanged treatment group. A similar trend was observed in the TBR of the ascending aorta and arch among the 3 treatment groups but differences between groups were less pronounced and did not reach statistical significance (p=0.08). There was no change in the SUV_{mean} of the liver with change in treatment. Change in TBR of the descending aorta was inversely correlated with change in cumulative dosage of GC (r=-0.40, p=0.03) and with change in daily dose of methotrexate (r=-0.67; p=0.01). In multivariable regression, change in GC dose and change in methotrexate dose were independently associated with a change in TBR of the descending aorta ($p<0.05$).

Conclusion: Therapies commonly used to treat LVV, including glucocorticoids and methotrexate, can reduce FDG vascular uptake in the aorta. Interval change in PET activity is more pronounced in the descending aorta compared to the ascending aorta and arch. FDG-PET might be useful to monitor vascular disease activity as an outcome measure in clinical trials of LVV.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Physical function is an established outcome measure for many rheumatic diseases and fatigue is a common disease manifestation across most, if not all, systemic inflammatory diseases. These two domains are often rated among the most important disease manifestations by patients. For giant cell arteritis (GCA), there exists limited data as to how the disease affects health-related quality of life, including fatigue and physical functioning.

Methods: Data from subjects with GCA participating in a multicenter longitudinal cohort from December 2014 to April 2016 were used. Fatigue and physical functioning were assessed using the Patient-Reported Outcomes Measurement Information System (PROMIS) instruments administered through computer adaptive testing (CAT). PROMIS instruments are calibrated so that scores are normally distributed with a mean of 50 and standard deviation of 10 in the US population. Higher scores signify better physical functioning and increased fatigue. Active disease was defined as physician global assessment > 0. Scores were compared to age-stratified population norms and a one sample t-tests was done. To assess whether PROMIS measures discriminated between active disease and remission in GCA, a mixed linear model was constructed with a random intercept introduced for each study subject.

Results: Data from 194 subjects that came for 435 study visits were used. The mean age of the participants was 73.7 (sd 7.9) years and 135 (70%) were women. At baseline 167 patients with GCA were in disease remission but nonetheless had substantially reduced physical functioning and increased fatigue compared to age-stratified population norms (Table). Thirteen patients had a total of 25 visits with active disease. Active disease was associated with a higher score of fatigue by 5.69 points (95% CI: 2.65; 8.73) and lower score of physical functioning by -1.76 points (95%CI: 4.14; 0.61).

Conclusion: Patients with GCA have substantially increased fatigue and reduced physical functioning compared to age-stratified population norms. PROMIS measures for fatigue and physical functioning can discriminate between active disease and remission in GCA. These

results highlight the benefit of combining patient-reported outcomes with physician-reported assessments in the evaluation of patients with GCA. **Table. Age-stratified scores for PROMIS instruments among patients with GCA during remission**

	Patients with GCA	Population Norms	P-value
Fatigue			
45-54	---	51.6	
55-64	54.6	49.7	0.04
65-74	52.9	48.1	0.001
≥75	53.8	48.0	<0.001
Physical functioning			
45-54	---	49.0	
55-64	42.4	47.5	0.03
65-74	42.6	47.2	<0.001
≥75	39.6	45.2	<0.001

PROMIS = Patient Reported Outcome Measurement Information System; GCA = giant cell arteritis

Abstract Number: 888

Prevalence of Takayasu Arteritis in Young Women Presenting with Acute Ischemic Heart Disease

Giulio Cavalli, Alessandro Tomelleri, Elena Baldissera and Lorenzo Dagna, Internal Medicine and Clinical Immunology, Vita-Salute San Raffaele University, Milan, Italy

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ischemic heart disease (IHD) is classically considered a disease of older men. However, 10% of myocardial infarctions occur in patients aged <45; also, in up to 25% of cases, these young patients are females. Classic atherosclerosis represents the most common etiology in young patients with IHD; additional causes include coronary vasospasm, coronary artery dissection, or vasculitis. Takayasu arteritis (TA) is a rare, large vessel vasculitis characterized by granulomatous inflammation of the aorta and its major branches, usually occurring in female patients aged ≤40. Purpose of this study was to evaluate the prevalence of TA in young women presenting with acute IHD in the Emergency Department.

Methods: We evaluated the hospital records of 172,790 consecutive young female patients (aged <45), who accessed the Emergency Department of our institution, a University Hospital serving a population of 1.5 million, over 8 consecutive years (2007-2015). The diagnosis at discharge was confirmed by either outpatient clinic or a telephone interview. Diagnosis of TA was established based on the 1990 ACR criteria.

Results: We identified 2,090 women aged <45 who presented with chest pain, dyspnea, palpitations, angina, heart failure, or cardiac arrest. Of these patients, 40 had IHD, as confirmed by elevated serum troponin T and compatible electrocardiographic changes. Seven additional patients, who died either before or shortly after accessing the Urgent Care department and in whom autopsy was not performed, were excluded from the study since their cause of death was not univocally identifiable. The etiology of IHD was 'classic' atherosclerosis in 24 cases, TA in 4 cases, vasospasm and sympathomimetic drug abuse in 3 cases each, coronary artery dissection and microvascular angina in 2 cases each, Takotsubo and radiation-induced cardiomyopathy in 1 case each.

Conclusion: In spite of an extremely low incidence in the general population (1-3 new cases/million/year in Europe or the United States), TA accounted for 10% of cases of acute IHD in female patients aged <45 in our study group. Since our Institution serves a population of 1.5 million, and coronary involvement may appear in up to a third of TA patients, the number of observed cases is compatible with the *a priori* expectations based on TA estimated incidence. Although 'classic' atherosclerosis remains the leading cause of IHD, in our study cohort TA was more frequent a cause than vasospasm and drug abuse. This finding is important, as while the latter two etiologies are commonly considered in young patients with cardiac ischemia, TA is very likely to be overlooked. Our data indicate that TA is not infrequent in younger females presenting with acute IHD. The development of TA in a young woman marks the onset of a severe, chronic disease characterized by recurrences and significant morbidity and mortality in the most productive years of life. Thus, it is crucial that a diagnosis of TA is not overlooked in a young woman presenting with IHD, in order to provide optimal care of the patient besides the management of the acute event.

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu's arteritis (TAK) is a relapsing large vessel vasculitis. There are currently no reliable predictors of disease relapse. This study explored whether changes in patient-reported outcomes (PROs) during periods of remission are associated with future disease relapse in TAK.

Methods: Data from patients with TAK participating in a longitudinal cohort and/or a clinical trial in TAK were available for this analysis; quarterly assessments were made. Patients completed a patient global assessment (PtGA) on a 100-mm visual analog scale with higher scores indicating worse disease activity, and the 36-item Short Form Health Survey (SF-36) from which the physical component

scores (PCS) and mental component scores (MCS) were calculated and normalized to the general population (mean ± SD=50 ± 10) with lower scores indicating worse outcomes. ESR and CRP were measured at each visit. Physicians determined disease state (remission or active) at each visit and whether a relapse had occurred since last visit. The 2 visits preceding relapse (remission visits) and the study visit following or concurrent with relapse (relapse visit) were used for analysis. Robust generalized estimating equations in logistic regression models evaluated associations between changes in PtGA, PCS, MCS, ESR, and CRP in the 2 remission visits preceding relapse and disease relapse, adjusting for intra-subject correlations, age, and sex.

Results: 207 patients with TAK were seen at a total of 1,077 study visits (881 remission and 196 relapse visits); 97% were female with a mean age at entry (± SD) of 38.7 ± 12.9 years. Table 1 shows the mean PtGA, PCS, MCS, ESR and CRP during remission and relapse visits. An increase of 10 mm in PtGA or a decrease in PCS scores by 1 point between the 2 visits preceding relapse were associated with disease relapse (OR [95% CI]= 1.23 [1.05-1.45], p=0.011 for PtGA and 1.07 [1.02-1.13], p=0.016 for PCS). Changes in MCS, ESR, or CRP were not associated with disease relapse (OR=1.10 [0.96-1.05, p=0.638, OR=1.01 [0.97-1.04], p=0.546, OR=1.00 [0.95-1.03], p=0.864 for MCS, ESR and CRP respectively).

Conclusion: Changes in patient global assessment and the SF-36 physical component scores, but not the SF-36 mental component scores, during periods of remission are associated with future disease relapse. Changes in ESR or CRP during periods of remission do not predict future disease relapse. These findings suggest that patients are good predictors of disease relapse and the current measures of disease activity and definitions of relapse in TAK are problematic and should incorporate patient-reported outcomes.

Table 1. Measurements of patient-reported outcomes and acute phase reactants during periods of remission and relapse among patients with Takayasu's arteritis

Assessment	Remission visits (n=881)	Relapse visits (n=196)	p value
PtGA (mm) (mean ± SD)	28 ± 22	45 ± 23	<0.001
PCS (mean ± SD)	43.3 ± 10.1	39.0 ± 10.0	<0.001
MCS (mean ± SD)	46.5 ± 12.3	47.0 ± 11.0	0.593
ESR (mm/hr) (mean ± SD)	21.0 ± 17.9	25.6 ± 24.6	0.002
CRP (mg/dl) (mean ± SD)	5.8 ± 10.1	10.1 ± 19.2	<0.001

PtGA: Patient Global Assessment; SD: standard deviation;
PCS: SF-36 Physical Component Score; MCS: SF-36 Mental Component Scores;
ESR: erythrocyte sedimentation rate; CRP: C-reactive protein

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The need to include patients' perspectives as key outcomes in clinical research is now widely recognized. This project was designed to describe the experience and burden of disease in patients with Takayasu's arteritis (TAK) during remission and active disease, and determine its effect on their daily lives.

Methods: Patients with TAK from the United States and Turkey were recruited to participate in semi-structured, one-on-one interviews or focus groups. The interviews and group sessions were recorded, transcribed, and entered into an Nvivo database. Patient-reported outcome themes were identified. Patients in the USA were invited to free-list terms that they associated with disease states. The Smith's Salience Index (SSI) was used to identify the most salient terms. SSI Scores range from 0 to 1 with higher scores indicating terms frequently mentioned and highly ranked by patients.

Results: 31 patients with TAK were involved in the qualitative research. 12 patients participated in individual interviews in the US and a total of 19 patients participated in three focus groups in Turkey. The most common themes that emerged were pain and discomfort, fatigue and low energy levels, and emotional impact. 75% of the study patients reported additional disease-specific domains of illness, most of which were similar between the two countries and only differed with regards to impact on finances (Table 1). The most salient terms identified by free-listing and ranking were pain/discomfort and emotional effects (SSI=0.51 and 0.37, respectively) during remission and pain/discomfort and fatigue/energy levels (SSI=0.56 and 0.33, respectively) during active disease (Figure 1).

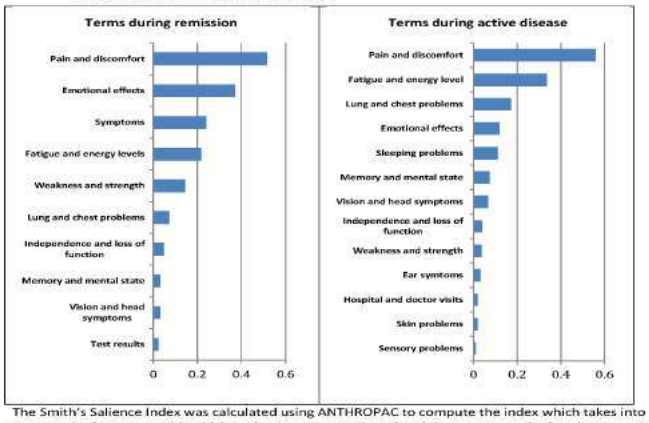
Conclusion: Patients with TAK report a range of disease-specific symptoms across different cultures and disease states that are generally not well or specifically captured by generic patient-reported outcome tools currently used in research and not at all addressed by physician-reported outcome measures. Patients identify different outcomes that are important during periods of active disease. Developing methods to capture outcomes of high importance to patients would advance research methodology to best capture the full spectrum of disease activity in TAK.

Table 1: Domains of illness commonly reported by patients with Takayasu's arteritis in the United States and Turkey

Domain	Definition	United States	Turkey
Pain/discomfort	Pain and discomfort associated with TAK	✓	✓
Fatigue/Low-energy	Fatigue and reduced energy felt secondary to having TAK	✓	✓
Impact on participation	Symptoms of TAK affect ability or desire to participate in activities	✓	✓
Impact on self-care	Symptoms of TAK affect ability to conduct personal care activities	✓	✓
Impact on finances	Financial burden associated with insurance/medication related to TAK	✓	
Impact on future	How TAK affects patient's future and plans for the future	✓	✓
Impact on school or work	Symptoms of TAK affect performance or ability to carry out specific tasks at work.	✓	✓
Limited interactions	Impact of TAK limits quantity or quality of interactions with family members or friends	✓	✓
Depression and anxiety	Impact of TAK leads to depression or anxiety	✓	✓
Stress and frustration	Stress and or frustration brought on by symptoms, diagnosis, or treatment of TAK	✓	✓

TAK: Takayasu's arteritis; "✓" indicates whether patients in that country mentioned the domain

Figure 1. Smith's Salience Indices of patients' free-listed and ranked terms in remission and active disease in Takayasu's arteritis



The Smith's Salience Index was calculated using ANTHROPAC to compute the index which takes into account the frequency with which each term was mentioned and the average rank of each term on an individual list. Scores range from 0 to 1 with higher scores indicating terms more frequently mentioned and highly ranked.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the characteristics and diagnosis of patients with negative temporal artery biopsy (TAB) for whom a final diagnosis of giant cell arteritis (GCA) was excluded.

Methods: We performed a prospective bicentric cohort study from January 2010 until December 2014. Patients with a clinical suspicion of GCA who underwent TAB were included. ACR criteria for the diagnosis of GCA, clinical and biological parameters, final diagnosis and glucocorticoids treatment were collected. Patients final diagnosis was (1) GCA with histological proof (TAB^+-GCA) ; (2) GCA without an histological proof (TAB^--GCA); (3) isolated polymyalgia rheumatica (PMR) and (4) another diagnosis (neither GCA nor PMR) (GCA^-PMR^-).

Results: 248 patients with a mean age of 73.7 years were included. Among them, 69 patients (27.8 %) had a final diagnosis of TAB^+-GCA; 65 patients (26.2%) had TAB^--GCA; 23 patients (9.2%) had PMR and 91 patients (36.7%) had another diagnosis (GCA^-PMR^-).

Among GCA$^-$PMR$^-$ patients, 9.8% fullfilled 3/5 ACR Criteria for the diagnostic of GCA. GCA$^-$PMR$^-$ patients less often had clinical signs of GCA: headaches (37% vs 65.8%, p <0.0001), scalp tenderness (18.6 % vs 39 %, p=0.0019), jaw claudication (13.7% vs 30%, p=0.0073) and temporal artery abnomalities (2.3% vs 18.9%, p=0.0006). These patients presented a lower C-reactive protein (CRP) and erythrocyte sedimentation rate (51.7 vs 70.5 mg/L, p=0.03; 53.6 vs 74 mm/hour, p=0.0003 respectively). The proportion of patients with CRP < 5 mg/L was more important in GCA$^-$PMR$^-$ patients (27.4% vs 10.8%, p=0.0014). The main final diagnoses for these patients were ophthalmologic (17%, n=16), systemic inflammatory (16.7%, n=15) and infectious diseases (13.1 %, n=12). No diagnosis was made in 20 of them (21.9%). Ophthalmologic causes included: non-arteritic anterior ischemic optic neuropathy (n=4), isolated ocular nerve palsy (n=4), papilledema, optic atrophy and macular degeneration (n=2 for each), retrobulbar neuritis and central retinal artery occlusion (n=1 each). Systematic diseases included: connective tissue diseases (Sjögren's syndrome (n=2), Sharp syndrome (n=1), Antiphoslipid syndrome (n=1)); systemic vasculitis (ANCA vasculitis (n=4), Takayasu arteritis (n=2), cryoglobulinemia (n=2)), Still's disease (n=2) and a diffuse infiltrative pneumonia. Infections consisted of intracellular infections (n=4), endocarditis, cellulitis, dental infection, urinary tract infection and pneumonia (n=1 each) and three suspected infections without documentation. Glucocorticoids were prescribed in 45% of GCA$^-$PMR$^-$patients.

Conclusion: Data available on the clinical characterisitics and diagnosis of GCA$^-$PMR$^-$ patients are scarse. Ophthalmologic signs and persistent inflammatory syndrome were the two main circumstances leading to a clinical suspicion of GCA. GCA$^-$PMR$^-$ patients have a significantly lower rate of specifical symptoms of GCA than TAB$^+$-GCA and more often a normal CRP. In almost half of these patients, glucocorticoids were initiated in the setting of an ophthalmologic emergency or suspected systemic disease. An algorithm combining GCA symptoms and CRP rate could be helpful to decide if TAB should be performed in patients with a clinical suspicion of GCA.

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu arteritis (TAK) is a large-vessel vasculitis in which assessment of disease activity is challenging. Recent studies support that 18F-fluorodeoxyglucose (FDG)-positron emission tomography (PET)/computed tomography (CT) is useful for disease activity assessment in TAK. In this study, we examined FDG/PET CT activity in clinically active, persistent and inactive TAK patients according to the physician's global assessment (PhGA).

Methods: A total of 42 FDG/PET CT images of 31 TAK patients (F/M: 25/6, mean age 41±15 yrs, disease duration 90±71 months) from were evaluated by visual and semiquantitative analysis (vascular SUV_{max}/liver SUV_{max}) for vascular inflammation. For the visual analysis using the liver as reference, 18F-FDG uptake was graded from grade 0 to 3. No uptake (grade 0) or any uptake lower than liver (grade 1) in major vessels were regarded as "inactive". Any uptake that is equal to or higher than liver (grade ≥2) was accepted as "active". PhGA, Kerr's criteria, and ITAS2010 and ITAS-A (both with ESR and CRP) were used for disease activity assessment. Persistent disease is defined as either elevated acute phase reactants (APR) without any clinical signs or symptoms or presence of only one of the Kerr's criteria regardless of the APR.

Results: At the time of FDG/PET CT imaging 14 (33.3%), 22 (52.4%), and 6 (14.3%) patients were regarded as active, persistent and inactive, respectively. Overall, 24 patients (57.1%) were active by FDG/PET CT visual grading with a median (range) of 2 (1-8) active vascular lesions per patient. Comparison of clinical and FDG/PET CT findings of patients who were regarded as active, persistent and

inactive by physician's assessment revealed higher ITAS2010 and ITAS-A scores, ESR and CRP levels in active and persistent patients (*Table*). PET-positivity by visual grade was observed in 78.6%, 45.5% and 50% of clinically active, persistent and inactive patients, respectively. In semiquantitative analysis, parallel with the clinical disease activity, an increasing trend was observed in SUV_{max} (inactive: 2.26, persistent: 3.22, active: 3.44) and SUV_{max} ratios (inactive: 1.00, persistent: 1.25, active: 1.43). When PET-positive and negative patients were compared, except for APR, no difference in disease activity by ITAS2010 scores were observed.

Conclusion: FDG/PET CT evaluated by visual analysis is useful in demonstrating vascular inflammation and its extent in active TAK patients. However, visual grading of FDG/PET CT is not sufficient enough to differentiate persistent and inactive patients. In these patients semiquantitative analysis should also be considered for further information about vascular inflammation. Further research is also needed to determine whether the increased FDG/PET uptake observed in persistent and inactive patients is associated with actual vascular inflammation that may lead to vascular damage.

Table. Clinical and FDG/PET CT findings according to disease activity by physician's assessment

	Active, n=14	**Persistent, n=22**	**Inactive, n=6**	**p value**

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

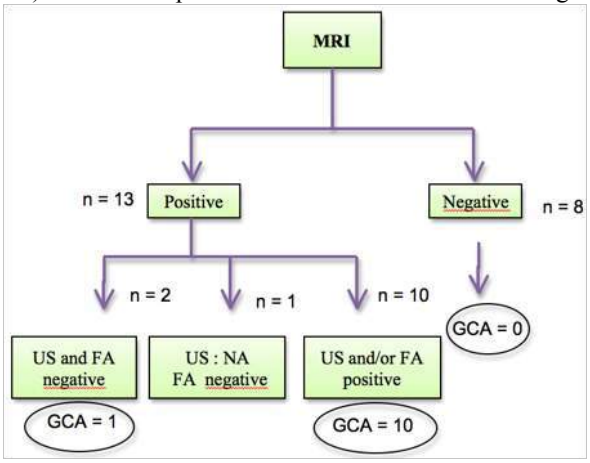
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant Cell Arteritis (GCA) is the most common systemic vasculitis in patient over 50 years of age. It is a medical emergency as it may lead to ischemic complications, including permanent visual loss in 20 % of untreated patients. Early diagnosis enabling a rapid initiation of treatment is of critical importance. Positive Temporal Artery Biopsy (TAB) is the gold standard test. However, a negative TAB does not rule out the disease. Encephalic high-field MRI, temporal arteries ultrasonography (US) or fluorescein and indocyanine green angiogram (FA) have been widely studied as diagnostic tests. However, there is currently no consensus nor clearly identified algorithm for their use in a current practice, either alone or in combination. Our objective was to evaluate the accuracy and potential diagnostic value of a multi-modal imaging combination of encephalic high-field (3T) MRI, ultrasonography and fluorescein and indocyanine green angiogram (FA).

Methods: All patients referred for suspected GCA at our center between Dec 2014 and Mar 2016 were prospectively included in this study. The study was approved by an official external Ethical Review Board. PatientÕs informed consent was obtained upon inclusion. For each patient, encephalic 3T MRI, cervical and temporal arteries US and fluorescein and indocyanine green angiogram (FA) were performed. Subsequently, a TAB was performed. TAB-positive patients were considered cases of GCA ; TAB-negative patients files were reviewed by an expert in internal medicine using to determine (based on ACR criteria) whether they were not cases of GCA, or cases of TAB-negative GCA. Diagnostic accuracy of the combination of MRI, US and ICGA was statistically evaluated against this gold standard, first separately for each imaging modality, then using a multimodal classification tree.

Results: Twenty-two patients were included in this preliminary analysis. GCA was diagnosed in 11 patients. Fourteen patients presented a partial vision loss and 7 a visual acuity < 1/10, reflecting severe disease. MRI was positive in 13/22 patients and negative in 8/22 patients. No patient with negative MRI had GCA. When MRI was positive, if either US and/or FA was also positive, all patients were GCA (10/13 patients) (p=0,001). If MRI was positive and both US and FA were negative, final diagnosis was undetermined (two cases, one GCA and one no GCA).



Conclusion: This preliminary analysis suggests that a negative encephalic high-field MRI might be sufficient to rule out GCA, whether in cases of positive MRI the addition of the two other imaging modalities may have a good accuracy to rule-in the disease in cases at least one of them is positive. Such preliminary results have to be confirmed in the final analysis of the ongoing study.

Laboratory Tests in Giant Cell Arteritis – Do They Make the Cut?

Alexis Jones[1], Joe Li[2] and Charles Li[3], [1]Rheumatology, University College London, LONDON, United Kingdom, [2]Rheumatology, Royal Surrey County Hospital, Guildford, United Kingdom, [3]Royal Surrey County Hospital, Guildford, Great Britain

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The initial suspicion of Giant cell arteritis (GCA) is often made in the setting of primary care or casualty by a non-rheumatologist. Whilst temporal artery biopsy (TAB) is the gold standard for diagnosis, this is not readily available and can be difficult to organise outside a teaching hospital setting. Furthermore, the reliability of this test is reduced by concomitant steroid use and the presence of skip lesions in vessel wall inflammation. Clinical features combined with biochemical markers of inflammation are often the most important tools in the diagnosis of giant cell arteritis. In this study, we evaluate the association of CRP, ESR, platelet count and alkaline phosphatase (ALP) with the results of temporal artery biopsy in a regional setting involving three District General Hospitals in the UK. As it has been over 5 years since the British Society for Rheumatology guidelines were published, we also audited whether our local practice follows them. Particularly, with regard to biopsy length which has been shown to influence the sensitivity of the test.

Methods: A retrospective analysis of all patients referred with suspected temporal arteritis to three centres in South East England between Feb 2010 and May 2015 was performed. Data regarding age, sex, date of biopsy, length of biopsy, biopsy result and ESR, CRP, platelet count and Alkaline Phosphatase (ALP) within 14 days prior to biopsy was collected.

Results: 542 patients were referred with suspected giant cell arteritis between Feb 2010 and May 2015. 119 patients were excluded owing to inconclusive biopsy findings and lack of laboratory results within 14 days prior to TAB. The majority of excluded patients had blood tests performed at other sites. 422 patients (131 men 291 women) were included. Mean age was 72.4. 95 TABS were positive and 327 negative. Mean biopsy length was 13.9mm. 32.2% of biopsies were less than 10mm. The mean ESR for positive biopsies was 58.6 versus 40.1 in negative biopsies ($p < 0.001$). 84.3% of patients with a positive temporal artery biopsy were associated with an ESR >10. The mean CRP in those with positive biopsies was 91.1 compared with 50.3 in those with a negative TAB ($p < 0.001$). 95.8% of patients with a positive TAB had a CRP >10. Patients with positive TABS also had higher platelet counts: mean platelet count was 424 in positive biopsies versus 334 in negative biopsies ($p < 0.001$). There was no statistical difference in ALP between those with positive and negative biopsies.

Conclusion: Laboratory correlates of inflammation remain good predictors of a positive temporal artery biopsy. A positive biopsy is associated with increased CRP, ESR and platelets. Our study shows that improvements need to be made locally to ensure the recommended temporal artery biopsy length (>10mm) is taken.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is an inflammatory disease associated with older age and long term use of glucocorticoids. As such a high incidence of osteoporosis and osteoporosis related fractures is expected. There is scarce information on incidence of osteoporotic-fractures in PMR in developing countries.The objective of this study was to identify the incidence rate and risk factors for osteoporotic-fractures in PMR patients.

Methods: we retrospectively reviewed electronic medical records (EMR) of patients registered in a large University hospital between years 2000-2015 with the diagnosis of PMR. Patients fulfilling ACR PMR 2012 criteria or with a clinical diagnose made by a rheumatologist were included. Patients with previous history of fractures, or with traumatic fractures were excluded. The major osteoporotic fractures (hip, wrist, and clinical spine) retrieved from the EMR, during the follow up period were taken as the endpoint event. Global, and sex-specific incidence rate with their 95% CI was calculated. A Cox proportional hazards models was fitted to analyze variables associated with suffering a fracture, including age, sex, smoking, hypertension, obesity, time on steroids, and steroids initial dose.

Results: 998 patients contributing a total of 4283 patient-years were included. Patient characteristics are shown in the table. During follow up 93 fractures were observed, for an overall incident rate (cases per 1000 patient-years) of 21.7 (95% CI: 17.7-26.6), 26.3 (95% CI: 21.2-32.5) for women, and 8.3 (95% CI: 4.3-15.9) for men. Forty-three incident osteoporotic hip fractures were observed for an overall incident rate of 10 (95% CI: 7.4-13.5) per/1000 patient-years, 12.5 (95% CI: 9.2-17) for women, and 2.8 (95% CI: 0.9-8.5) for men. The incident rate (cases per 1000 patient-years) for wrist and clinical vertebral fractures were: overall: 7 (95% CI: 4.9-10); 9 (95% CI: 6.3-13) for women, and 0.9 (95% CI: 0.13-6.5) for men; and 4.7 (95% CI: 3-7.2), 4.7 (95% CI: 2.8-7.8) for women, and 4.6 (95% CI: 1.9-11) for men, respectively. In the univariate analysis patients with fractures were significantly more females, of older age, and received steroids for a longer period (table). In the multivariate Cox proportional hazards model, the only variables associated with osteoporotic fractures were female sex (HR: 2.7 (95% CI: 1.6-4.6), and older age at diagnosis (HR: 1.1 (95% CI: 1-1.1).

Conclusion: There was a high incidence rate of major osteoporotic fractures among patients with PMR. Females and patients with older age were at higher risk. This risk should be taken into account when treating this disease. **Table 1** Patients characteristics

Variable	Patients with Fractures (n=93)	Patients without Fractures (n=905)	P Value
Females, n (%)	84 (90)	654 (72)	<0.001
Mean age at diagnosis (SD)	77.1 (6.6)	75.3 (7.9)	0.0280

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: chronic inflammatory diseases are at a substantially increased risk of cardiovascular events (CVE). Scarce data is available in patients with Giant cell arteritis (GCA) and Polymyalgia Rheumatica (PMR). Our objective was to analyze the incidence of CVE in these patients seen at a large University hospital.

Methods: we retrospectively reviewed electronic medical records (EMR) of patients registered between years 2000-2015 with the diagnosis of GCA or PMR. Patients fulfilling ACR 1990 criteria for GCA or ACR PMR 2012 criteria or with a diagnose made by a rheumatologist were included. Patients with history of CVE before diagnosis were excluded. Data regarding smoking status, blood pressure, obesity, diabetes, dyslipidemia, disease characteristics and treatments were recorded. CVE such as stroke or transient ischemic attack, coronary and peripheral vascular disease were identified from the EMR, during follow up. For patients with more than one CVE only the first one was considered for global incidence. Aortic aneurism (AA) was considered separately. Incidence rate with 95% CI of CVE is reported. In PMR patients a Cox proportional hazards models was fitted to analyze variables associated with CVE including age, sex, smoking, hypertension, diabetes mellitus, obesity, total cholesterol level, time on steroids, and use of aspirin.

Results: 872 PMR and 105 GCA were included . Demographic characteristics are shown in table 1. Among the 872 PMR patients (3945 patient-years (pt-yrs) of follow up)76 CVE occurred: incidence rate (cases per 1000 pt-yrs) : 19.3 (95% CI: 15.4-24.1); Females (F): 18 (14-23) and males (M): 24 (15-37). 46 patients suffered AA: incidence rate: 11.3/per 1000 pt-yrs (95% CI: 8.5-15); M: 22.3 (14.2-35) and F: 8.3 (5.7-12.2). Among the 105 ACG patients, 15 CVE occurred (501 pt-yrs of follow up): incidence rate: 29.9/per 1000 pt-yrs (95% CI: 18 - 49.6); M: 31.3 (7.8-125.3) and F: 29.7 (17.2-51.2). Nine patients had AA: incidence rate per 1000 pt-yrs: 17.9 (95% CI: 9.3–34.4); M: 30.4 (7.6-121.6) and F: 16 (7.6-33.6). The incidence rate of different CVE by gender, are shown in table 2. In the multivariate Cox proportional hazards model, variables associated with CVE were: diabetes mellitus: HR 3.3 (95% CI: 1.8-6.1), age at diagnosis: HR: 1.05 (95% CI: 1.01-1.08) and time on steroids (months of use): HR: 1.01 (95% CI: 1-1.02).

Conclusion: There was a high incidence of CVE and AA, in both patients with PMR and ACG. Diabetes, older age at diagnosis and prolonged use of steroids were significantly associated with more CVE. Table 1. Patient characteristics

Variable	PMR (n=872)	ACG (n=105)
Females, n (%)	678 (78)	88 (84)
Mean age at diagnosis (SD)	75.2 (7.9)	76.5 (5.9)

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous retrospective studies have suggested that simultaneous bilateral temporal artery biopsy (TAB) may lead to increased detection rates of giant cell arteritis (GCA). The term discordance represents one unilateral positive biopsy combined with one contralateral negative biopsy. Cases of discordance, through identification of false negatives, support the rationale for obtaining bilateral TAB. Reported discordance rates vary, ranging from 3 to 15 percent. Given the serious outcomes of untreated disease, including permanent blindness, establishing a consensus approach that increases detection of GCA is necessary. We aimed to identify cases of discordant temporal artery biopsies and to examine the role of performing simultaneous bilateral TAB in increasing the diagnostic yield of GCA.

Methods: Procedure codes for TAB were used to identify patients who underwent simultaneous bilateral temporal artery biopsies at three hospitals between the years 2009 and 2013. The following data was collected: biopsy results and length, age, gender, ESR and CRP levels. Patient data and biopsy results were compared based on their respective group: bilateral positive biopsies, bilateral negative biopsies and discordant biopsies. A combined positive biopsy group (bilateral positive biopsies and discordant biopsies) was additionally compared to the bilateral negative biopsy group. A separate chart review was performed for discordant biopsies to identify cases in which bilateral TAB may have increased the diagnostic yield of GCA.

Results: 181 patients were identified that had undergone simultaneous bilateral TAB. The mean age of the positive bilateral biopsy group was 78.2 years compared to 70.3 years for the negative bilateral biopsy group ($p < 0.001$). The mean age of the combined positive biopsy group was 77.1 years compared to 70.3 years for the biopsy negative group ($p<0.001$). 38/181 (21%) of patients had biopsy proven GCA. The overall discordance rate was 3.8% (7/181), comprising 18.4% (7/38) of the biopsy positive group. Biopsy lengths did not differ between groups. Average CRP values for the combined positive biopsy group were 6.4 mg/dL when compared to the biopsy negative group of 5.5 mg/dL ($p=0.04$). When considering localizing symptoms of the discordant group, bilateral TAB would have increased the yield of diagnosis definitively in one case (1/181 (0.5%) or 1/38 (2.6%) combined positive biopsy category alone). This may have increased to 3.3% (6/181) overall or 15.8% (6/38) as part of the combined positive group when considering best possible outcomes.

Conclusion: Bilateral TAB in patients with suspected giant cell arteritis may increase the diagnostic yield in a small number of overall cases. This increase may be more significant when considering the low prevalence of GCA diagnosis. Our results are consistent with previously reported discordance rates. The potential increase in diagnostic yield by performing bilateral TAB may have clinical significance given the negative implications of untreated disease and the side effects of long-term glucocorticoid therapy. Increasing age and CRP values may be associated with an increased likelihood of temporal arteritis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Temporal artery biopsy (TAB) is the gold standard for the diagnosis of Giant Cell Arteritis (GCA), yet is limited by the presence of skip lesions and atypical pathological features. The entity of “healed arteritis” (HA) has been described in the literature as having focal to complete loss of internal elastic lamina, irregular intimal thickening, medial fibrosis or neovascularization, and usually scant, if any, inflammation.We analyzed the treatment patterns and outcomes in patients with a diagnosis of HA on TAB, compared with positive and negative biopsies in patients suspected of GCA.

Methods: We identified 18 patients with TAB pathology report indicating HA, and matched these to 27 with classically positive biopsies (POS), and 29 with negative biopsies (NEG). Statistical analysis compared corticosteroid (CS) management among these 3 cohorts.

Changes in CS dose immediately following TAB report were recorded. The 90 day CS requirements were expressed as area under the curve (AUC). Rheumatologists' pre-biopsy clinical suspicion for GCA, clinical and laboratory parameters, remission rates, and steroid-related adverse events were also analyzed.

Results: In the immediate post-biopsy follow-up period, HA and POS were both less likely to have dose decreases compared to NEG ($p<0.001$). However, the mean 90 day cumulative steroid dose AUC was significantly lower in HA versus POS (2663 mg vs 4206 mg; $p=0.01$), and were similar to NEG (2663 mg vs 2088mg; $p=0.34$). At long term follow up (mean 3.4 +/- 0.41 years), patients with HA tended to more often be in remission (defined as off steroids or tapering with quiescent disease). Both HA and NEG had fewer adverse effects from CS (29 and 14%, respectively) compared to POS (48%) ($p=0.02$). When patients with HA were compared to POS, they were significantly more likely to have a low-moderate (vs. high) pre-biopsy clinical index of suspicion for GCA ($p=0.0032$). Pre-biopsy duration and cumulative CS dose was similar among all groups, as was frequency of polymyalgia rheumatica (PMR). Mean erythrocyte sedimentation rate was significantly higher in the POS group compared to the HA and NEG groups (87 vs. 54 and 66 mm/hr, $p=0.023$ and 0.01 respectively), while not statistically different between the HA and NEG groups ($p=0.32$).

Conclusion: Although a report of HA on TAB did not result in immediate reductions in CS, our study shows that ultimately a lower 90 day cumulative dose of CS was utilized in HA. Our data suggests that patients with "healed arteritis" on pathology required less steroid and may be more aggressively tapered without adverse consequence.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate disease characteristics, treatment patterns and comorbidities in patients with polymyalgia rheumatica (PMR) to those with giant cell arteritis (GCA), or with both diseases (PMR+GCA).

Methods: Patients enrolled in the national database of the German Collaborative Arthritis Centres between 2007 and 2014 were stratified to PMR, GCA, PMR+GCA. They were compared with regard to patient characteristics, treatment and comorbidities, subdivided by disease duration. Logistic regression analyses were performed to evaluate the risk of having PMR+GCA and the association of this condition with malignant neoplasms. To put the prevalence of malignant neoplasms into perspective, patients of the three groups were matched with patients with rheumatoid arthritis (RA) by age, sex and disease duration.

Results: Data of 1,858 patients with PMR/ GCA/ PMR+GCA (n=1,420/ n=177/ n=261) were available for analysis. Mean age (73 years in each group) and disease duration (4.2/3.6/4.4 years) were comparable between these groups. Patients with PMR only were less often female (63/74/72%). PMR+GCA patients had the highest mean ESR value (21/23/26 mm/h), and more frequently hypertension (49/54/59%) and malignant neoplasms (7/7/12%). Osteoporosis was most prevalent in GCA (17/26/21%). PMR+GCA patients were most often current smokers, especially at disease onset (10/13/20%, $p<0.01$). They received the highest mean prednisone dose (5.9/6.1/9.6 mg/d) and had the highest analgesics use (14/24/39%). Multivariate analyses confirmed smoking to be associated with an increased risk of having PMR+GCA (OR=3.6, $p<0.001$), and identified patients with PMR+GCA to suffer from a higher malignancy risk (OR=2.0, $p=0.002$). When compared to RA patients, PMR and GCA patients showed a prevalence of malignancies similar to their matched RA counterparts (PMR 6.6% vs. RA 6.7%, 95% CI of the difference [-0.9; 1.2] , n=1,299 pairs, and GCA 6.5% vs. RA 7.6%, 95% CI [-2.0; 4.5], n=155 pairs), while patients with PMR+GCA had a significantly higher prevalence (PMR+GCA 12.3% vs. RA 6.7%, 95% CI [-7.6; -

3.4], n=235 pairs). Thereby the frequency of smoking did not differ significantly between the corresponding groups.

Conclusion: Patients with PMR+GCA had higher inflammatory activity, the highest need of glucocorticoids and a high comorbid burden. The observed associations of PMR+GCA with smoking on the one hand and with malignant neoplasms on the other should be further investigated, since both would significantly affect patient education and GCA management.

The Phenotype of Macrophages in the Inflamed Vascular Wall of Giant Cell Arteritis Resembles the Phenotype of Non-Classical Monocytes

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophages are critical tissue destructive cells in the immunopathology of patients with giant cell arteritis (GCA). Macrophage precursors, monocytes, can be subclassified in three subsets: classical ($CD14^{bright}CD16-$) monocytes and the more pro-inflammatory intermediate ($CD14^{bright}CD16+$) and non-classical ($CD14^{dim}CD16+$) monocytes. Tissue migration of different monocyte subsets is determined by differential expression of chemokine receptors. Our previous data showed an altered distribution of monocyte subsets in newly diagnosed GCA patients. We therefore assessed the phenotype of macrophages in temporal arteries of GCA patients. Furthermore, we investigated expression of defined chemokine receptors and their ligands in temporal arteries of GCA patients.

Methods: We studied 16 positive temporal artery biopsies (TABs), all obtained from GCA patients fulfilling the ACR 1990 criteria . Twelve patients were without any treatment at the time of biopsy , 4 patients started corticosteroid treatment 2-14 days before the biopsy was taken. The phenotype of macrophages in the different layers of the TAB was studied by immunohistochemistry and by double staining using immunofluorescence-labeled antibodies. Expression of chemokines in TABs was determined by digitally analyzing the diffuse positive staining. Cellular staining was assessed by semi-quantitative scoring methods.

Results: All GCA TABs studied showed transmural inflammation, as CD68 expressing macrophages were detected throughout the vessel wall. Non-classical monocyte markers CD16 and CX3CR1 were strongly expressed at macrophage rich areas and immunofluorescent double staining confirmed that these macrophages co-expressed CD16 and CX3CR1. CCR2, a marker of classical monocytes, was less abundantly expressed and immunofluorescent double staining confirmed that most CD16+ cells did not express CCR2. Both CCR2 ligand CCL2 and CX3CR1 ligand CX3CL1 were readily detected in the GCA TAB.

Conclusion: The phenotype of macrophages in the TAB of GCA patients resembled the phenotype of non-classical monocytes. CD16 and CX3CR1 were co-expressed on tissue macrophages therefore indicating that migration of CD16+ non-classical monocytes to the GCA lesion may be driven by the CX3CR1-CX3CL1 axis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: There is only retrospective and very limited data for the long term prognosis of Takayasu's Arteritis (TAK), a rare large-vessel vasculitis. In this study, we aimed to present the preliminary results of a Takayasu Inception Cohort settled for long term, prospective follow-up of only newly-diagnosed patients with TAK.

Methods: Patients fullfilling the ACR 1990 criteria for TAK and diagnosed in the last 12 months were included to the study. Patients' data were recorded in an electronic database of an international "Takayasu's Arteritis Registry" requiring baseline and at least annual visits. Data is compared with an historical Turkish cohort previously published by Turkish Takayasu Arteritis Study Group(*Bıçakçıgil, et al, 2009)*.

Results: The study included 128 patients (age: 38.9±13.1 years,F/M: 112/16) with TAK from 15 tertiary Rheumatology centers in Turkey and one center from Japan. The mean symptom duration was 5.2 years at diagnosis. According to the angiographic classification, 59.2% of the study group had type I and only 17.2% had type V disease. When we compared our results to our retrospective cohort, constitutional symptoms (72.2% vs 66%) and limb claudication (62.3% vs 48%) were observed to be more frequent, whereas pulselessness (35.6% vs 88%) was less in the inception cohort.(Table 1) Carotidynia was present only in the inception cohort. Similarly, mucocutaneous symptoms also seem to be a feature of newly-diagnosed disease (26.4% vs 8.8%).Regarding comorbidities at diagnosis, the rate of dyslipidemia was 22%, diabetes mellitus 6%, smoking 28.5% and obesity (BMI>30) 15.8% among TAK patients. All patients were givenoral corticosteroid (CS) therapy (0.5-1 mg/kg) at diagnosis, 10 patients (7.8%) also having CS pulses. In addition to CSs, 55 patients (43 %) were given methotrexate, 14 patients (11%) azathioprine and 5 (4%) cyclophosphomide at disease-onset.

Conclusion: Our results suggest that, in an inception cohort, signs and symptoms of 'systemic inflammation' is more prominent in newly-diagnosed TAK patients, whereas vascular extent and damage accumulates during the disease course. The long term follow-up of our inception cohort will better show the actual course and predictors of prognosis in TAK. Table 1: Clinical characteristics of Inception and Retrospective Cohorts from Turkey.

	Inception Cohort (n=128)	Retrospective Cohort (*Bıçakçıgil, et al*) (n=248)
Constitutional symptoms	91/126 (72.2%)	163/248/ (66%)
Limb claudication	66/106 (62.3%)	119/248 (48%)
Carotidynia	26/104 (25%)	-
Pulseless	37/104 (35.6%)	218/248 (88%)
Musculoskeletal manifestations	66/124 (53.2%)	104/248 (42%)
Mucocutaneous manifestations	32/121 (26.4)	22/248 (8.8%)
Respiratory manifestations	40/122 (32.8%)	22/184 (12%)
Neurologic manifestations	58/124 (46.8%)	156/248 (63%)
Cardiac involvement	23/106 (21.7 %)	141/248 (57%)
Ophthalmologic involvement	29/125 (23.2%)	57/248 (36%)

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We aimed to determine the prevalence of overweight, obesity and metabolic syndrome (MetS) and leptin levels in patients with Takayasu arteritis (TA) and their associations with disease activity.

Methods: This cross-sectional study included 32 patients with TA followed up at a Rheumatology clinic of a university hospital. 25 age- and gender-matched patients with systemic lupus erythematosus (SLE) were enrolled as controls. According to the TA follow-up protocol of the Rheumatology and Radiology Board of our hospital, the patients were followed using 3-6 monthly B-mode/Doppler USG examinations and 6-12 monhtly magnetic resonance angiography (MRA). Disease activity was assessed by using the Indian Takayasu Clinical Activity Score 2010-A (ITAS2010-A), radiological activity parameters, and acute-phase reactants (AFR). We used carotid intima media thickness (IMT) measurements and the presence of atheromatous plaques in carotid arteries as indicators of atherosclerosis. We also searched serum leptin and ghrelin levels and their relationship with obesity, overweight and MetS in Takayasu patients.

Results: 32 patients (28 females; mean age: 43 years) who fulfilled the American College of Rheumatology (ACR) criteria for TA were enrolled in this study. The prevalences of overweight (body mass index (BMI) between 25 and 30 kg/m^2), obesity (BMI ≥30 kg/m^2) and MetS (The National Cholesterol Education Program Adult Treatment Panel III criteria), were 26.5%, 17.6% and 23.5%, respectively. These prevalences were similar in TA and SLE patients. TA patients with obesity/overweight had higher ITAS2010-A scores compared with those without obesity/overweight and those with MetS had higher radiological activity scores compared with those without MetS although they had similar AFR levels. TA patients with obesity/overweight had also higher leptin levels. The frequency of atheromatous

plaque was found to be higher in patients with MetS than those without MetS although there was no difference in carotid IMTs between the groups (Table 1).

Conclusion: This study showed that TA patients had similar prevalences of obesity/overweight and MetS to those found in SLE patients. It also suggested that there was a relationship between disease activity and obesity/overweight and MetS in TA patients. TA patients with greater BMIs had also increased leptin levels.

Table 1. Clinical and laboratory features in Takayasu patients with overweight/obesity and MetS

		Metabolic syndrome		P value	Overweight and obesity		P value
		(+) (n=8)	(-) (n=24)		(+) (n=15)	(-) (n=17)	
ITAS2010-A	Active(n)	1	4	>0.05	5	0	0.015*
	Inactive(n)	7	20		10	17

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasonographic alterations such as the halo sign and the compression test are now accepted as surrogate markers of artery inflammation. No data have yet been published on the correlation between the ultrasonographic grading of arterial wall inflammation and the grading of cellular infiltrate. To compare a semiquantitative ultrasonographic grading (USG) of TA involvement (halo sign and media-intima thickness) with a semiquantitative grading of the inflammatory burden in patients with giant cell (temporal) arteritis (GCA).

Methods: fiftheen consecutive patients with new onset clinical symptoms and satisfiing ACR criteria for GCA, with positive halo sign in the frontal branch and positive temporal artery biopsy have been enrolled. For each patients we performed power Doppler ultrasonography of temporal artery with a 18-6 MHz linear probe (Esaote MyLab 70) and measured the maximum halo thickness of TA frontal branch in a quantitative and semiquantitave (0-3) grade of involvement (0= < 0.37 mm, 1= in between 0.38-0.44, 2 = 0.45- 0.6 mm, 3 = > 0.6). TA biopsy was done in the same frontal branch evalutaed with US. Then we compared the ultrasonographic data with a semiquantitative (0: absent, 1: mild, 2: moderate, 3: severe) grading of the trasmural cellular inflammatory infiltrate and with the intima-media thickness of the TA biopsy specimen. Moreover US results were correlated with the other patterns of histological alterations (giant cells, calcifications, laminar necrosis). Correlation between variables was done by Rho of Spearman method.

Results: 15 patients, 6 males and 9 females (mean age 71.6± 7 years - duration symptoms at onset 1.7 ± 1.3 months - mean ESR 60 mm/h ±29 - mean CRP 8 mg/dl ± 5.2) entered the study. US halo sign was bilateral in 10/15 (66,7%). The mean halo thickness was 0.53 mm ± 0.12. Five patients had USG =1, six patients =2 and four patients =3. The hystological inflammatory grade 1 was present in seven pts, grade 2 in four and grade 3 in four pts. No significant correlation were found between USG and histological inflammatory grade, nor with the presence of giant cells, calcifications, laminar necrosis and intima-media thickness.

Conclusion: No correlation has been found between the size of the halo sign and the hystological inflammatory grading.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the clinical features and long-term outcome of Chinese Takayasu arteritis (TAK) patients.

Methods: Medical records of 411 Chinese TAK in-patients (325 female, 86 male) who fulfilled 1990 ACR classification criteria during 1990 to 2014 were retrospectively reviewed. Clinical manifestations, angiographic presentations, and causes of death were collected and analyzed.

Results: The median age at disease-onset was 23(18, 30) years old, and the median disease duration was 21(6, 60) months. Aortic aneurysm, renal dysfunction, and heart failure were more likely to be found in patients with heart involvement, while weight loss and arthralgia were more likely occur in patients without. Pulse deficit were more likely to be found in patients with cerebral artery involvement, while pericarditis, ischemic heart disease, and fever were more likely occur in patients without. No difference were found in patients with and without renal, or pulmonary arteries involvement (See Table 1). Subclavian(79%), carotid(64%), abdominal aorta(38%), vertebral(29%), mesenteric(28%), thoracic aorta(21%), innominate(20%), iliacofemoral(11%), ascending aorta(10%), and aortic arch(8%) were most commonly involved. Stenosis (93%) and occlusion (59%) were much more common than dilation (20%) and aneurysm (6%) (Table 2). Analysis of 10 deceased patients found heart failure (42%), hemorrhage (17%), and pulmonary infection (17%) were the top 3 direct causes of death, and congestive heart failure, secondary hypertension, and long disease duration were risk factors for poor prognosis in TAK (Table 3).

Conclusion: The clinical manifestations, blood vessel involvement, and angiographic presentations in Chinese TAK patients are different from reports in the literature. Heart failure is the leading cause of death in these patients and are the risk factor of poor prognosis.

Table 1 Major characteristics of 411 Chinese TAK patients and comparisons between different groups Patient Number (%)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Giant Cell Arteritis (GCA) have an increased risk of devastating cranial ischaemic complications including vision loss and stroke. The BSR guidelines recommend platelet inhibition with aspirin to reduce the risk of ischaemic complications in GCA. Thrombosis occurs following platelet activation. The glycoprotein VI (GPVI) receptor is found exclusively on platelets and megakaryocytes. The proteolytic cleavage of GPVI occurs following platelet activation and is detectable in the plasma as soluble GPVI (sGPVI). Therefore elevated plasma sGPVI is a marker of platelet activation and a risk marker for adverse cardiovascular outcomes. Enhanced platelet activation is observed in inflammatory arthritis. We hypothesized that GCA would also be associated with platelet hyperreactivity which might support the rationale for aspirin use in GCA.

Methods: Following ethics approval and informed consent, blood samples were taken from patients with GCA. Healthy control samples were obtained from volunteers. Demographic and clinical data were collected for all participants. Blood samples were processed as double spun platelet poor plasma. sGPVI levels were measured using ELISA. sGPVI levels were compared between patients with GCA and healthy controls, between active and inactive GCA, and between those with and without cranial ischaemic compications. Mann-Whitney U test was used to compare groups. Spearman¡¯s Rank Correlation Coefficient was used to assess for associations between sGPVI levels and demographic and clinical markers. GraphPad Prism and SPSS were used for data analysis.

Results: 122 patients were included in the study, 70 with GCA and 53 healthy controls. Of the GCA patients, 19 had active disease and 19 had had cranial-ischaemic complications. There was no difference in sGPVI levels between GCA and healthy controls , median (IQR) 2.32 ng/ml (1.60, 4.21) vs 2.19 ng/ml (1.72, 3.31) (p=0.76). sGPVI levels were similar in GCA patients with active and inactive disease, median 2.31 ng/ml (1.86, 4.21) vs 2.33 ng/ml (1.57, 4.21) (p=0.93). sGPVI levels were similar in GCA patients with and without a history of cranial ischaemic complications, median 2.04 ng/ml (1.33, 4.21) vs 2.37 ng/ml (1.88, 4.21) (p=0.85). sGPVI levels taken from patients at initial presentation with and without cranial ischaemic complications were no different, median 2.31 ng/ml (1.33, 4.21) vs 2.27 ng/ml (1.72, 3.22) (p=0.91). Aspirin therapy did not significantly affect sGPVI levels, median 2.22 ng/ml (1.40, 4.20) vs 2.74 ng/ml (2.01, 4.64). There was no correlation between sGPVI levels and CRP (r=0.16), ESR (r=0.10), or prednisolone dose (r=-0.21).

Conclusion: We found no evidence of increased platelet activation in patients with GCA. There was no association between platelet activation and disease activity or cranial ischaemic complications in GCA. **Figure 1: sGPVI levels in GCA**

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several Clinical trials indicate that Methotrexate (MTX) could be considered as a feasible option in addition to corticosteroids for patients with GCA, but there is a need to corroborate these results in clinical practice. We want to assess the risk of relapses in GCA patients treated with MTX (since and after the diagnosis) and without MTX. Other factors associated were also investigated.

Methods: An inception cohort of GCA was assembled. We included patients from the date of diagnosis (January 1991 until September 2013) and followed-up in the out-patient clinic at Hospital Clinico San Carlos until September 2014. Main outcome: relapses defined as after an objective improvement (absence of symptoms of GCA and normalization of laboratory values) patient had again presence of symptoms or signs of GCA with high ESR and the need to increase corticosteroids at least 7.5mg. The independent variable was exposure to MTX (no exposure, exposure in the first month from the time of diagnosis, and exposure after). Covariables: 1) Sociodemographic, 2) Clinical symptoms and analytical data at diagnosis 3) Treatment: including concomitant corticoids, aspirin 4) Calendar time. Incidence rates of relapses (IR) per 100 patient-years with their respective 95% confidence interval [CI] were estimated using survival techniques. The time of exposure comprised the period from diagnosis until the occurrence of any of the following cut off points: lost of follow-up, main outcome, exposure to MTX or the end of the study. MTX influence on IR was analyzed by multivariable Cox models.

Results were expressed as hazard ratio (HR) and [CI]. Results: We included 168 patients (675 patient-years). Most of the patients were female (80%), with a mean age of 76±7 years. The mean dose of corticoids at starting was 55±15 mg/day. 65% of the patients were on MTX, and 45% of them started in the first month after the diagnosis. The mean dose was 10mg / week, being the maximum dose 20mg / week. 32.7% of patients (n=55) had 93 relapses during follow-up with an IR of 20.8[15.8-27.4]. The median [p25-75] number of relapses was 1[1-2], with a median lag time of 1.8 [0.6-5.8] years. In the multivariate analysis, after adjusting by age, gender, corticoids and calendar time, exposure to MTX in the first month had less risk of relapses compared to non exposed (HR: 0.44[0.2-0.9], p=0.02), whereas exposure to MTX after the first month of diagnosis (p=0.6) did not achieve statistical significance. Other variables in the model were: clinical debut with headache (HR: 4.6 [1.6-13.5], p=0.004), and visual alterations (HR: 2.3 [1.3-4.1], p=0.004). Taking aspirin during the follow- up (HR: 0.6 [0.3-1.1], p=0.1), and haemoglobin value (HR: 0.8 [0.7-1.0], p=0.1) did not achieve signification.

Conclusion: Early use of MTX seems to decrease the risk of recurrences. The treatment with aspirin involves a tendency to lower risk of relapses. We have also found other factors that can influence on the risk of recurrences.

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu arteritis (TAK) is a large vessel vasculitis involving the aorta and its major branches in patients younger than 40 years. Glucocorticoids (GCs) are the mainstay of treatment for TAK, but relapses and GC dependence are seen in more than two-thirds of patients. Increasing evidence supports a role for B cells in the pathogenesis of TAK. Circulating plasmablasts and memory B cells are increased, while naive B cells are decreased in patients with active TAK as compared with inactive and control patients [1]. These findings suggest a potential role for B cell depleting therapy in TAK. Our aim was to assess the efficacy of Rituximab (RTX) in a single center series of patients with TAK.

Methods: We conducted a prospective, single center, open-label study on 5 TAK patients treated with RTX. All patients satisfied the American college of Rheumatology classification criteria for TAK. Four of the 5 patients had a refractory disease and had received high dose GCs and synthetic and/or biological immunosuppressive (IS) agents before RTX. One new diagnosed, treatment naïve TAK patient refused GCs and received RTX in monotherapy. RTX was administered according to rheumatoid arthritis scheme (2 infusions of 1.000 mg, 15 days apart). Clinical evaluation, laboratory tests (full blood count, ESR, CRP) and imaging modalities (CTA or MRA, and PET/CT) were performed at first RTX administration and every 6 months thereafter. Disease activity was assessed using Kerr index. Radiographic disease progression was defined as new or worsening lesions at follow-up CTA or MRA. PET/CT was considered positive for active disease if two or more large vessels showed grade 2 FDG uptake or higher.

Results: Five patients (4 female) were included in the study. Mean (SD) age was 30.4 (17.4) years. At first RTX administration, all patientshad active disease according to Kerr index (≥2), and had evidence of active disease at PET/CT. Table 1 summarizes the main results of our study. Despite RTX treatment, 4 of the 5 patients had evidence of persistent disease activity and/or radiographic disease progression at follow-up CTA or MRA. Only one patient experienced long-term remission (30 months to date) after two courses of RTX.

Conclusion: Our data do not support a role for RTX in refractory TAK patients. **References:** [1] Hoyer BF et al. Takayasu arteritis is characterised by disturbances of B cell homeostasis and responds to B cell depletion therapy with rituximab. Ann Rheum Dis 2012;71:75–9. Table 1.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Giant Cell Arteritis (GCA) is considered an urgent condition in Rheumatology, due to high risk of permanent vision loss and cerebro-vascular insults. No diagnostic or prognostic markers are yet known for GCA. While erythrocyte sedimentation rate (ESR) is part of the ACR 1990 GCA classification criteria, other acute phase proteins could represent an added value for distinguishing between GCA/non-GCA and GCA remission/recurrence. The **aims**of our cross-sectional study were to a) measure serum levels of 40 selected biomarkers in 95 patients with GCA and 42 nonGCA patients, b) determine the associations of the biomarkers with GCA diagnosis, clinical complications and disease relaps.

Methods: Sera were collected from newly diagnosed (still steroid naive) GCA patients and nonGCA controls at time of first visit. GCA patients were followed carefully for the first year looking at signs and symptoms of relapsing disease. Sera proteins (Chitinase-3 Like-1, ICAM-1, VCAM-1, IL-1α, IL-1β, IL-1RI, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-17, IL-22, IL-23, IL-33, MMP-1,-2, -3, -9, -12, TNFα, Leptin, Resistin, IFN-γ, CD62L, TNFRI,IP-10, LIF, MIG, α-Fetoprotein, MCP-1) were measured by Luminex platform. SAA, CRP, haptoglobin, fibrinogen, ferritin, hemopexin, orosomucoid, albumin were measured by nephelometry.

Results: Acute phase proteins SAA, CRP, haptoglobin, ferritin, hemopexin, orosomucoid and albumin all showed significant association with GCA diagnosis, in addition to elevated ESR, leukocyte and thrombocyte counts (Table). The highest diagnostic value was observed for SAA and CRP (n=92/93 and n=94/95, both 98.9%), followed by ESR (n=93/95, 97.9%). Patients with afterward visual disturbances had significantly lower levels of acute phase proteins: SAA (median (IQR):143 (51-290) vs. 270 (95-680) g/l), CRP (51 (28-86) vs. 73 (41-139) g/l), haptoglobin (3.7 (3-5.8) vs. 5.1 (3.6-6.5) g/l), and ESR (70 (52-88) vs. 89 (61-111) mm/h), while showing significantly elevated levels of VCAM-1 (824 (629-965) vs 502 (326-677) ng/ml) as compared to patients without visual disturbances. Among all the markers tested VCAM-1 had the highest area under ROC curve (AUC) (0.818) for visual disturbances. VCAM-1 was also significantly associated with extracranial artery disease. GCA patients who relapsed during follow-up, had significantly higher levels of SAA (311 (177-765) vs. 154 (41-418) g/l), CRP (86 (48-141) vs. 55 (32-120) g/l), ESR (94 (70-108) vs. 70 (52-90) mm/h), leukocyte counts (10.3 (8.7-12.3) vs. 9.1 (7-10.4)*10^9/l) at the disease onset.

Conclusion: Testing multiple acute phase proteins with additional blood parameters and biomarkers can represent an added value to earlier diagnosis, as well as optimize prediction of relapses and complications, such as visual disturbances and extracranial artery involvement. Table: Association of biomarkers with diagnosis GCA

Name of biomarker Cut off	Median (IQR) GCA	Median (IQR) non GCA	p	Diagnostic sensitivity (% positives in patients)	OR (95% CI)	AUC under ROC for diagnosis

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Vasculitis - Poster I: Large Vessel Vasculitis and Polymyalgia Rheumatica

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is reported that 15-25% patients with GCA present with visual complications. Sight loss (SL) in the elderly is associated with considerable morbidity. There is evidence for reducing this by implementing a fast track pathway nationwide. However, data on the burden of SL due to GCA is lacking. The aim of this study is to estimate the incidence of visual complications in GCA and the factors that contribute to it.

Methods: This is an on-going observational study of new cases of SL attributable to GCA. In order to correctly estimate the incidence of SL, information is collected by participating ophthalmologists and rheumatologists on all patients with new or relapsing GCA with or without SL. Only patients that present with signs and symptoms fulfilling 1990 ACR criteria for classification of GCA or fulfilling 2/5 criteria along with positive imaging (PET-CT or vascular ultrasound) substituting for biopsy are recruited. SL is defined as symptomatic loss of acuity or field of vision, as diagnosed by an ophthalmologist. When a patient with definite visual complications of GCA is identified, an initial reporting “yellow card” will be completed electronically and either posted or emailed to the investigators. The primary statistical analysis is the estimation of the percentage incidence as well analysis risk factors using binary logistic multiple regression methods.

Results: Yellow cards and detailed reports have been sent regarding 105 patients so far from 13 centres. We plan to recruit 250 patients. Patients who developed SL had symptoms for 23.2 days preceding the diagnosis vs. 37.97 days in the non-sight loss group. 27 (25.71%) presented with visual disturbances. Mean age at presentation was 79.96 (57-93) sight loss vs. 72.86 (50-95) non-sight loss group. Interestingly, GCA patients with sight loss had a higher ESR value (60.04 vs. 50.78, p=0.025, 95 %CI 2.47-11.18) and a lower Haemoglobin level (99.98 vs. 118.91, p=0.03, 95% CI -36.087 to -1.767). There was no statistically significant difference between the two groups in terms of symptoms including headaches, jaw claudication or constitutional symptoms or risk factors (p>0.05). 70.47% of the recruited patients had temporal artery biopsy. There was no difference with regards to biopsy results (14 vs 32; OR 0.8750, CI 95%0.2903 to 2.6378, p=0.81) or USS (7 vs 26; OR 3.2308, CI 95% 0.3565 to 29.2791, P=0.29). 18.51% of the SL had a previous diagnosis of GCA or PMR compared to 8.97% (RR 0.66, CI 95% 0.1667 to 2.6657, p=0.56).

		Sight Loss n=27	No sight loss n=78	p-value

Table 1. Patient demographics, symptoms and risk factors; AF atrial fibrillation, CKD chronic kidney disease, MI myocardial infarction, AION (acute ischemic optic neuropathy; CRON central retinal occlusion

Conclusion: Our study shows a major delay associated with the diagnosis of GCA in the UK. This may be related to the high percentage of SL seen in all participating centres. The study confirms that patients with SL have higher inflammatory markers suggesting a more active disease. Our results highlight the need for implementing the fast track GCA pathway to improve outcome and reduce ischemic complication.

Survival Benefit of Statin Use in Ankylosing Spondylitis and Psoriatic Arthritis: A General Population-Based Cohort Study

Amar Oza[1], Na Lu[2] and Hyon K. Choi[3], [1]Allergy, Immunology, and Rheumatology, Massachusetts General Hospital, Boston, MA, [2]Clinical Epidemiology, Boston University School of Medicine, Boston, MA, [3]Rheumatology, Allergy and Immunology, Massachusetts General Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Plenary Session I: Discovery 2016

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Recent studies have shown an increase in cardiovascular and all-cause mortality in ankylosing spondylitis (AS) and psoriatic arthritis (PsA).[1] The hypothesized dual role of statins in both lowering lipids and reducing inflammation may thus lead to survival benefits in patients with these seronegative spondyloarthropathies. We examined the potential survival benefit of statin use in AS and PsA within a general population context.

Methods: We performed an incident user cohort study with time-stratified propensity score matching using a UK general population database. The population studied included patients with AS or PsA between January 1, 2000 and December 31, 2014. To account for potential confounders, we compared propensity score-matched cohorts of statin initiators and comparators (non-initiators) within 1-year cohort accrual blocks. 50 variables were used to create propensity scores, including but not limited to the disease duration, socio-economic status, BMI, lifestyle factors, and medication use.

Results: 2,904 patients with AS or PsA who initiated statins compared to 2,904 propensity matched-comparators with AS or PsA that were not started on statins. 271 died during the follow up (mean = 5.3 years), whereas among the propensity-matched non-initiators, 376 patients died during the follow up (mean = 5.15 years) (**Figure 1**). This corresponds to incidence rates of 17.62/1000 and 25.14/1000 person-years (PY), respectively. The baseline characteristics were well balanced in the two groups. Statin initiation was associated with a 33% reduction of all-cause mortality (HR=0.68, 95% CI 0.57-0.81). When we compared the unmatched cohorts to determine the effectiveness of our propensity score matching, the statin initiators (n=3,389) actually showed a 44% higher risk of mortality (HR=1.44, 95% CI 1.22-1.70) than non-initiators (n=3,389 randomly selected) due to confounding by indication (**Figure 2**).

Conclusion: This general population-based cohort study indicates that statin initiation is associated with a 33% lower risk of mortality for patients with AS or PsA. The magnitude of the inverse association appears to be larger than that observed in population-based cohort studies of patients with rheumatoid arthritis (21%)[2] and in meta analyses of randomized trials of the general population (9-14%)[3], potentially due to the dual benefits of statin use (i.e. lipid lowering and anti-inflammatory effects) in patients with seronegative spondyloarthropathies. SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Plenary Session I: Discovery 2016
Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose: The efficacy and safety of tocilizumab (TCZ), an IL-6 receptor-alpha inhibitor, was evaluated in patients with giant cell arteritis (GCA) in GiACTA, a randomized, double-blind, placebo-controlled trial with blinded glucocorticoid regimens of variable dose and duration (*Int J Rheumatol.* 2013:912562). Data up to week 52, the time of primary outcome measurement, are presented.

Methods: Patients aged ≥50 years had active GCA previously confirmed by temporal artery biopsy or cross-sectional imaging and documented acute-phase reactant elevation attributable to GCA. Randomization was stratified by baseline prednisone dose (≤30 or >30 mg/day). Patients were randomized 1:1:2:1 to 4 groups: A, short-course prednisone (26-week prednisone taper + weekly subcutaneous [SC] placebo); B, long-course prednisone (52-week prednisone taper + weekly SC placebo); C, weekly SC TCZ 162 mg + 26-week prednisone taper; D, every other week SC TCZ 162 mg + 26-week prednisone taper. The baseline prednisone dose (20-60 mg/day) was selected by the investigator. Prednisone doses <20 mg/day were blinded. Patients who flared or could not adhere to the protocol-defined tapering schedule received open-label prednisone escape therapy but continued on double-blind TCZ/placebo. Sustained remission was defined at week 52 as the absence of flare and normalization of C-reactive protein after week 12, combined with adherence to the protocol-defined prednisone taper. The primary and key secondary end point was the proportion of patients in sustained remission, comparing both TCZ groups (C, D) with the short-course prednisone group (A) and with the long-course prednisone group (B), respectively, at a significance level of 0.005. A dose hierarchy of statistical testing was implemented. Cumulative prednisone exposure was a secondary end point.

Results: Of 251 patients randomized, the mean ± SD age was 69 ± 8.2 years, and 75% were female. In the primary comparison, 56% of patients in the weekly TCZ group and 53.1% in the every other week TCZ group achieved sustained remission at 12 months compared to only 14% in the short-course prednisone group ($p < 0.0001$). In the key secondary efficacy comparison, the percentage of patients in sustained remission in each TCZ group was also superior to that of patients in the long-course prednisone group (17.6%) ($p \leq 0.0002$). The median cumulative steroid exposure in both TCZ groups was less than half that of those in the long-course prednisone group (Table). The incidence of adverse events was similar among the 4 treatment arms. No deaths and no new vision loss occurred over the period of observation.

Conclusion: TCZ plus a 26-week prednisone taper was superior to both short- and long-course prednisone tapers for the achievement of sustained remission at 52 weeks. The addition of TCZ to prednisone also led to a substantial reduction in the cumulative prednisone doses required to control GCA.

Table. Efficacy and Safety During GiACTA Part 1

	A) Short-course prednisone n = 50	B) Long-course prednisone n = 51	C) Weekly SC TCZ n = 100	D) Every other week SC TCZ n = 49
Patients in sustained remission at 52 weeks, n (%)	7 (14.0)	9 (17.6)	56 (56.0)	26 (53.1)
TCZ groups vs short-course prednisone Unadjusted difference in proportion of responders (99.5% CI)	—	—	42.0 (18.0, 66.0) $p < 0.0001$	39.1 (12.5, 65.7) $p < 0.0001$
TCZ groups vs long-course prednisone[a] Unadjusted difference in proportion of responders (99.5% CI)	—	—	38.4 (17.9, 58.8) $p < 0.0001$	35.4 (10.4, 60.4) $p = 0.0002$
Cumulative CS dose, median (min-max)	3296.00 932.0-9777.5	3817.50 822.5-10697.5	1862.00 630.0-6602.5	1862.00 295.0-9912.5
AEs Patients with event, n (%)	48 (96.0)	47 (92.2)	98 (98.8)	47 (95.9)
Withdrawals Patients withdrawn from study, n (%)	6 (12.0)	5 (9.8)	15 (15.0)	9 (18.4)
Withdrawals due to an AE, n (%)	2 (4.0)	0	7 (7.0)	3 (6.1)
SAEs Patients with event, n (%)	11 (22.0)	13 (25.5)	15 (15.0)	7 (14.3)
Infection SAEs Patients with event, n (%)	2 (4.0)	6 (11.8)	7 (7.0)	2 (4.1)

AE, adverse event; CI, confidence interval; SAE, serious adverse event.
Patients who receive escape therapy, withdraw, or do not achieve remission by week 12 are classified as nonresponders.
Patients who have 2 consecutive CRP elevations >1 mg/dL from week 12 or have >100 mg additional steroids from week 12 are classified as nonresponders.
p values for superiority of the primary and key secondary end points were compared to a significance level of 0.005 to account for multiplicity; all other secondary end points are compared to 0.01.
p values for superiority calculated using a Cochran-Mantel-Haenszel test adjusting for starting prednisone dose (≤30 mg/day, >30 mg/day).
[a]Noninferiority margin of −22.5 was used to compare TCZ groups with long-course prednisone group using 99.5% CIs.

Urate Lowering Therapy in Moderate to Severe Chronic Kidney Disease Levy G, Cheetham C, Shi J, Rashid N

Background/Purpose: To determine if urate lowering therapy (ULT) can improve Chronic Kidney Disease (CKD) function when patients achieve a serum uric acid (sUA) <6mg/dL (Goal). To determine if baseline CKD stage influences the benefits when attaining Goal with

ULT.

Methods: A retrospective cohort study was conducted from 1/1/2008 to 7/31/2014 within an integrated healthcare delivery system. A sUA > 7mg/dL was necessary for inclusion and the first occurrence sUA >7mg/dl was defined as the index date. In addition, patients were required to have an estimated Glomerular Filtration Rate (eGFR) in the 6 months preceding the index date, and at least one sUA and eGFR during follow-up, from 3 months to 12 months post index. Patients were required to be ULT naïve, ≥ 18 years of age, and have Chronic Kidney Disease Stages 2, 3 or 4 at index. Continuous health plan enrollment with a drug benefit during the entire study period was required. Exclusions included active treatment for cancer, dialysis or kidney transplant. Outcomes were defined as either a 30% decrease or a 30% improvement in eGFR from baseline to the last available value. Pairwise differences in proportion were compared using Chi-square test and 95% Confidence Interval (CI) were reported for the differences.

Results: Of the 12, 751 patients meeting inclusion criteria; 2, 690 received ULT during the study period and 10,061 did not. Goal sUA was achieved in 1,118 (42%) patients on ULT. A 30% improvement in eGFR was seen in 17.1% achieving Goal versus 10.4% of patients who did not reach sUA goal (Difference = 6.7% (95% CI = 4.0%, 9.4%), p<0.001). Pairwise comparison of CKD stages showed patients at or below Goal were more likely to have a 30% improvement in eGFR: in CKD 2: 7.1% v 3.3%, (Difference = 3.8% (95% CI = 0.7%, 7.0%), p=0.015) , in CKD3: 19.9% v 10.0%, (Difference = 9.9% (95% CI = 6.1%, 13.6%), p<0.001) and CKD 4: 30.0% v 22.2%, (Difference = 7.8% (95% CI = -1.1%, 16.8%), p=0.080).

Conclusion: This study suggests that patients who achieve ACR Goal of sUA of <6mg/dl on ULT have higher rates of eGFR improvement (≥ 30% improvement). This effect is seen across the CKD spectrum from Stage 2 through Stage 4 with the most pronounced effect in CKD 3 patients.

Session Date: Sunday, November 13, 2016

Session Title: Plenary Session I: Discovery 2016

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: A bacterial etiology of rheumatoid arthritis (RA) has been suspected since the beginnings of modern germ theory. Recent studies implicate mucosal surfaces as sites of disease initiation, particularly the gingiva, the gut and the lungs. The common occurrence of periodontal dysbiosis in RA suggests that oral pathogens may trigger the production of anti-citrullinated protein antibodies (ACPAs) and arthritis in susceptible individuals. Here, we studied the periodontal microenvironment in health and disease to define mechanisms underlying mucosal inflammation and autoimmunity in RA.

Methods: Gingival crevicular fluid (GCF) from patients with periodontitis and healthy subjects without periodontitis was analyzed by immunoblotting to detect citrullinated proteins (AMC). Mass spectrometry (MS) was employed to define the microbial composition and antigenic repertoire of GCF in periodontal disease and oral health. Isolated human neutrophils were analyzed by AMC immunoblotting and MS after incubation with periodontal pathogens (*Aggregatibacter actinomycetemcomitans* [*Aa*], *P gingivalis*, *T forsythia*, *T denticola*, *F nucleatum*, *P micra*, *P intermedia*, *S intermedius*) and purified *Aa* leukotoxin A (LtxA). Neutrophils incubated alone or with LtxA were stained with SYTOX Green, anti-citH3, and ACPA-positive RA serum. Antibodies against *Aa* and LtxA were quantified in patients with RA (n=196) and healthy controls without periodontitis (n=37) by ELISA.

Results: Periodontitis was characterized by the presence of citrullinated autoantigens that are primary immune targets in RA. The citrullinome in periodontitis mirrored patterns of cellular hypercitrullination observed in the rheumatoid joint, implicating this mucosal site in RA pathogenesis. Proteomic signatures of several microbial species were detected in hypercitrullinated periodontitis samples. Among these, *Aa*, but not other candidate pathogens or commensals, induced hypercitrullination in host neutrophils. We identified the pore-forming toxin LtxA as the molecular mechanism by which *Aa* triggers dysregulated activation of citrullinating enzymes in neutrophils, mimicking membranolytic pathways known to sustain autoantigen citrullination in the RA joint. Moreover, LtxA induced changes in neutrophil morphology suggestive of extracellular trap formation, thereby releasing the hypercitrullinated cargo. Exposure to *Aa* was confirmed in RA patients (43% vs 8% of controls without periodontitis; $p<0.0001$) and significantly associated with both ACPAs and rheumatoid factor (RF). The effect of RA susceptibility alleles (the HLA-DRB1 *shared epitope*) on ACPA and RF positivity was surprisingly conditioned on patient exposure to LtxA (Table 1), suggesting a two-hit model of RA pathogenesis.

Conclusion: These studies identify the periodontal pathogen *Aa* as a candidate bacterial trigger of autoimmunity in RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Plenary Session I: Discovery 2016

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: SLE is a systemic autoimmune disease that predominantly affects women in reproductive years. SLE pregnancies result in higher rates of adverse outcomes compared with healthy pregnancies.

Methods: To understand the molecular mechanisms underlying SLE pregnancy, we characterized the blood transcriptome of 135 pregnant (92 SLE and 43 healthy) subjects from the PROMISSE Study and 54 non-pregnant (NP) (20 SLE and 34 healthy controls) women by microarray. Blood was drawn at 4 time points during pregnancy (P1: <15 weeks gestation; P2: 16-23 wks; P3: 24-31 wks; P4: 32-40 wks) and 8-20 wks postpartum (PP). Poor pregnancy outcomes were classified as preeclampsia (SLE-PE) or other complications (SLE-OC) that included fetal or neonatal death, preterm delivery (<36 wks because of IUGR or placental insufficiency), and growth restriction (<5th %ile). SLE pregnancies included 24 SLE-PE, 22 SLE-OC, and 46 non-complicated (SLE-NC). Data were analyzed using a linear mixed model accounting for disease, complication groups and visit time point.

Results:

We first identified transcriptional signatures associated with healthy pregnancy. Using healthy NP controls as baseline, 9,687 transcripts were differentially expressed in healthy pregnancy; these included upregulation of neutrophil, myeloid inflammation and erythropoiesis signatures and downregulation of immune pathways linked to lupus pathogenesis, such as IFN and plasma cells **(Fig. 1A)**. We then assessed how the signature was affected in SLE-NC compared to healthy NP women. SLE-NC pregnancies displayed the dynamic features similar to healthy pregnancies **(Fig. 1B)**. However, while the plasma cell signature was decreased to levels lower than those of SLE-NP and healthy NP controls, the IFN signature remained patent through the course of pregnancy compared to healthy NP controls (green line). Finally, we identified complication-related transcriptional signatures by comparing SLE-PE and SLE-OC to SLE-NC **(Fig. 2)**. Both SLE groups with complications failed to downregulate IFN and plasma cell signatures to SLE-NC levels throughout the pregnancy. In addition, SLE-PE displayed early upregulation of neutrophil signatures. Network analysis at P1 identified neutrophil- (AZU1, CTSG, ELANE) related signaling pathways as early biomarkers of preeclampsia.

Conclusion: Blood transcriptomics reveals systemic changes during healthy and SLE pregnancies and highlights the neutrophil signature as a potential early biomarker of preeclampsia.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: B Cell Biology and Targets in Autoimmune Disease I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Autoantibodies which recognize integral membrane proteins are generally accepted as pathogenic. However, it had been technically difficult to identify plasma membrane proteins as autoantigens by conventional methods including proteomics. Anti-endothelial cell antibodies (AECAs) are autoantibodies against cell surface molecules on the endothelium, and play important roles on promoting vascular inflammation. Most of the reported autoantigens were intracellular molecules, and their target antigens on endothelium were poorly understood. In order to identify cell-surface autoantigens, we constructed a Serological identification system for Autoantigens using a Retroviral vector and Flow cytometry (SARF).

Methods: cDNA library of human umbilical vein endothelial cells (HUVECs) were generated and inserted into the retroviral vector. Retroviruses possessing the cDNA library were generated and infected into the rat myeloma cells. Rat myeloma cells which have different HUVEC cDNA were stained with serum IgG from patients with AECA-positive collagen diseases, and AECA-positive fraction was sorted by flow cytometry. After cloning of an AECA-positive cell, cDNA inserted into each clone was identified by DNA sequencing and microarray.

Results: The identified molecules included fibronectin leucine rich transmembrane protein 2 (FLRT2), ephrin type-B receptor 2 (EphB2), and Pk antigen for systemic lupus erythematosus, and intercellular adhesion molecule-1 (ICAM-1) for rheumatoid arthritis. Expressions of these molecules on ECs were confirmed by flow cytometry and AECA IgGs bound specifically to the cells which were transfected with each of the molecules. Importantly, anti-FLRT2 antibody induced complement-dependent cytotoxicity against FLRT2 expressing cells including HUVECs. Clinical manifestations of each autoantibody-positive patient were associated with the distribution of autoantigens in different cell types, indicating that AECAs can act not only on ECs but also on other target cells. We further identified autoantigens in Takayasu arteritis, in which no definite autoantigens were reported. The autoantigens in Takayasu arteritis play important roles for the coagulation and lipid metabolism, suggesting that AECAs can directly modify vascular inflammation in Takayasu arteritis.

Conclusion: We successfully identified membrane proteins as autoantigens against AECAs by using SARF and confirmed the usefulness of SARF. Moreover, identified molecules were associated with the clinical manifestations of patients, suggesting direct contributions of AECAs for promoting pathological conditions. Using this system, it is possible to achieve a comprehensive analysis of autoantibody-mediated injury in inflammatory diseases and develop more specific interventions.

Session Title: B Cell Biology and Targets in Autoimmune Disease I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Autoimmune rheumatic diseases, including rheumatoid arthritis (RA), have multifactorial pathogenesis associated with failure of immune tolerance. Advances in understanding the disease immunopathology have led to the development of biological drugs targeting components of the immune response that drive disease progression (including TNFα, IL-6, and B cells). However, these drugs are not effective in all individuals and many patients fail to respond for unknown reasons. The ability to predict patient responses to conventional and to biological treatment would provide a crucial step change improvement in the clinical management of patients with RA. We proposed a novel immunophenotyping approach to identify unique 'signatures' that could stratify patients for a more personalised approach to treatment of this complex disease.

Methods: We optimised a novel high through-put immunophenotyping platform, LEGENDScreen^{TM}, measuring the expression of 332 cell surface markers on B-cell and T-cell populations. We used this multi-dimensional approach to screen 50 RA patients, either treated with DMARDs or with anti-TNFα treatments, compared to patients with MS, SLE and healthy donors (HCs) as controls. The antigen-specific fluorescence intensity for each subset was examined. Differentially expressed markers (DEMs) between patient groups were determined using multiple unpaired *t*-test analysis ($p<0.05$). The results guided us to further stratify the data looking at B cell subsets, disease activity and immunogenicity (presence or absence ADA, measured by ELISA).

Results: We identified phenotypic markers specific for anti-TNFα-treatment-naïve RA patients, developing an "immune-signature" that differentiates these patients from HCs, RA patients treated with anti-TNFα-treatment, and from patients with MS or SLE. We observed that the majority of DEMs, with significantly different expression between patient groups, were on $CD19^+$ B-cells rather than $CD4^+$T-cells, confirming the contribution of B-cells in the pathogenesis of RA. Comparing HCs to anti-TNFα-treatment-naïve patients we identified 31 DEMs that were significantly differentially expressed on B-cells but only 2 DEMs on T-cells. Further stratification of B-cells, looking at immature, mature, and memory subsets, identified 40 and 41 DEMs on immature and mature B-cells respectively, and only 20 DEMs on memory B-cells. We identified a unique immune-phenotype associated with the lack of response to anti-TNFa and the development of ADA.

Conclusion: We have developed a new strategy, which clustered patients based on shared immune-phenotypes and distinguished between patients who developed anti-drug antibodies (ADA+) and those with active vs inactive disease. The predictive capacity of these immune-signatures is being validated in a prospective cohort of patients treated with anti-TNFα, which will also predict response to switching therapies (e.g. from anti-TNFα to rituximab). We proposed to use this novel immunophenotyping signature for a more personalised approach to treatment of this complex disease. Conducted as part of the ABIRISK consortium.

Session Title: B Cell Biology and Targets in Autoimmune Disease I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) is frequently associated with bone loss due to imbalanced bone resorption and formation. B cell depletion therapy (BCDT) attenuates bone erosion in a subset of RA patients. B cells promote osteoclast formation, but their role in osteoblasts (OB) in RA has not been well studied. Here, we used B cells from TNF-transgenic (TNF-Tg) mice and mice with Collagen-Induced Arthritis (CIA), mouse models of RA, and from RA patients to investigate if RA B cells inhibit OB differentiation and the mechanisms involved.

Methods: B cells were isolated using CD19 magnetic beads from bone marrow (BM) and subchondral BM (SB) of TNF-Tg and CIA mice, and from peripheral blood of RA patients with active disease, but not on biologics. Immunofluorescent (IF) staining, RNA sequencing, co-cultures of mesenchymal precursor cells (MPCs) and B cells, and BCDT were performed.

Results: To study the distribution of B cells and their relationship with OBs, we performed IF on frozen bone sections from TNF-Tg and CIA mice with anti-B220 Ab for B cells and anti-osteocalcin Ab for OBs. B cells were enriched in the SB and endosteal BM areas of RA mice and were adjacent to OBs. To investigate if RA B cells produce OB inhibitors, we performed RNA sequencing of BM and SB B cells from TNF-Tg mice. Compared to WT BM B cells, TNF-Tg BM B cells expressed about 2-fold higher levels of OB inhibitors, including CCL3, TNF, and Dkk3. SB B cells expressed much higher levels of these inhibitors compared to their BM counterparts, and this was confirmed by qPCR (fold increase in TNF-Tg SB/TNF-Tg BM: CCL3 x12, TNF x4, Dkk3 x12; in CIA SB/CIA BM: CCL3 x20, TNF x10, Dkk3 x38). To determine if RA B cells directly affect OBs, we co-cultured B cells with WT MPCs in OB-inducing medium. RA B cells significantly inhibited OB differentiation (ALP+ area: 7±1 in TNF-Tg vs. 16±2 mm^2 in WT; 7±2 in CIA vs. 20±2mm^2 in non-CIA). To investigate potential signal pathways responsible for OB inhibition, expression of NF-kB, ERK and b-catenin in MPCs after co-culture with B cells was examined. RA B cells increased expression of NF-kB and pERK in MPCs.The effect of RA B cells on OB inhibition and NF-kB/ERK activation in MPCs was partially blocked by a CCL3 or TNF neutralizing Ab. To examine the overall effect of BCDT on bone mass and OB function, we treated TNF-Tg mice with murine anti-CD20. BCDT increased SB bone volume (BV/TV: 40±2 vs. 31±1% in IgG) and OBs (#/mm bone surface: 26±5 vs. 16±3 in IgG). BM cells from BCDT-treated mice had increased OB differentiation (CFU-ALP#: 53±9 vs. 21±5 in IgG). To determine if B cells from RA patients have a similar OB inhibitory effect, we co-cultured peripheral blood B cells from RA patients with MPCs. RA B cells inhibited OB differentiation and this was partially blocked by CCL3 or TNF neutralization. Furthermore, IF of synovial specimens from RA patients showed expansion of CCL3 and TNF-producing B cells.

Conclusion: B cells are enriched in the SB area of RA joints and are adjacent to OBs. RA B cells produce multiple OB inhibitors, including CCL3 and TNF, which inhibit OB differentiation. BCDT reduces bone loss and stimulates OB function. Thus, B cells may directly target OBs, and thus contribute to bone loss and joint erosion in RA.

Session Title: B Cell Biology and Targets in Autoimmune Disease I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Anergic autoreactive B cells are thought to play a critical role in systemic lupus erythematosus (SLE), a chronic autoimmune disease where breach of tolerance to nuclear antigen leads to the production of pathogenic anti-nuclear autoantibodies (ANA). There is evidence that anergic B cells survive longer and are less tolerized in SLE patients and lupus-prone mice; however, their exact contribution to SLE pathogenesis remains unclear. Our laboratory has used congenic derivatives of the lupus-prone New Zealand Black mouse to parse the B and T cell defects involved in SLE, uncovering a B cell defect required for ANA production (in the 170.8-181 Mb interval on chromosome 1 [C1d]) as well as T cell defects (in the 124-181 Mb interval [C1b-d]) that exacerbate disease. Since these defects were sufficient to breach B cell anergy to the neo-self antigen hen egg lysozyme, we hypothesized that a similar breach would occur in the Vκ8/3H9 model of anergy, a better analogue for human SLE.

Methods: The 3H9 heavy chain and Vκ8 light chain were knocked into their correct loci in the C1d and C1b-d strains to generate mice with homogeneous, ssDNA-specific, anergic B cell repertoires. ANAs in female 8 month old non-autoimmune (B6), C1d and C1b-d wild type (WT) and double knock-in (dKI) mice were measured by ELISA, while splenic B and T cells were examined using flow cytometry. Adoptive transfer of B6 or C1d dKI B cells into B6 or C1d WT recipients was conducted to assess the effect of the anergic milieu on B cell activity; recipients were sacrificed after 7 days and splenocytes analyzed via flow cytometry.

Results: C1b-d WT mice had significantly increased anti-ssDNA IgG and IgM, and higher proportions of germinal centre (GC) B cells, $CD86^+$ B cells and T follicular helper (T_{FH}) cells than B6 WT mice, with C1d WT mice also trending to significance. Surprisingly, the autoimmune B cell phenotype was attenuated in both C1 dKI strains, such that C1 dKI mice were equivalent to B6 counterparts. While the levels of T_{FH} cells remained significantly higher in C1 dKI mice than in B6, they were significantly decreased compared to C1 WT mice, suggesting that the attenuated breach of B cell tolerance could result from insufficient T cell priming. This explanation was supported by the observation that anergic C1d dKI B cells adoptively transferred into C1d WT mice showed similar trends to increased GC and $CD86^+$ B cells as in C1d WT mice. Finally, while the proportion of T_{FH} cells was significantly decreased in C1b-d dKI mice compared to their WT counterparts, the proportion of T follicular regulatory (T_{FR}) cells remained similar to WT levels, suggesting that selective survival or induction of T_{FR} cells in the dKI congenic strains may play a role in their decreased autoimmune phenotype.

Conclusion: Our results demonstrate that while the B and T cell defects in New Zealand Black congenic mice generate autoimmunity in an unconstrained immune system, these defects are not sufficient to robustly breach tolerance to endogenous nuclear antigen when the B cell repertoire is predominantly anergic, possibly due to modulation of T cell activation or regulatory cell fate.

Session Date: Sunday, November 13, 2016

Session Title: B Cell Biology and Targets in Autoimmune Disease I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In autoimmune prone BXD2 mice, abnormally upregulated IL-17 acts through NF-κB p65 role to promote the spontaneous germinal center response and autoantibody production. Recently, a pre-germinal center defect in the early transitional B cell

development of autoimmune BXD2 mice was identified. This defect was characterized by accelerated B cell development, a feature which was normalized by IL-17RA deficiency on the BXD2 background. The hypothesis of this work is that IL-17 induced NF-κB regulates transitional B cell development

Methods: Using a B cell antigen tetramer, La_{13-27} autoreactive B cells from the spleens of B6, autoimmune wild-type (WT) BXD2, and BXD2-*Il17ra*$^{-/-}$ mice were analyzed by FACS for the development of CD93^{+} transitional B cell subsets. Intracellular phospho-flow was used to determine levels of phospho-p65 (p-p65) and total phospho-tyrosine following anti-IgM (5 µg/mL) stimulation at different time points. Super-resolution molecular imaging (STORM) was carried out to visualize p65 and p50 in BXD2-*Il17ra*$^{-/-}$ B cells. WT BXD2 and BXD2-*Il17ra*$^{-/-}$ were treated *in vivo* with AdIL-17 or AdIL-17RA:Fc to enhance or block endogenous IL-17RA signaling, respectively. Activation vs anergic responses were assessed by Dojindo cell survival assay following anti-IgM stimulation.

Results: There was an enhanced BXD2-*Il17ra*$^{-/-}$ transitional B cell anergy phenotype *in vivo*, which was characterized by a normalized La_{13-27}^{+} transitional B cell development compared with WT BXD2. BXD2-*Il17ra*$^{-/-}$ B cells further exhibited strong anergic responses to BCR or TLR7 stimulation *in vitro*. The strong anergic phenotype of BXD2-*Il17ra*$^{-/-}$ mouse B cells was associated with a dramatically enhanced nuclear expression of NF-κB1 (p50) and down-modulation of NF-κB p-p65. Super-resolution imaging supported increased p50 homodimer presence in the nucleus of BXD2-*Il17ra*$^{-/-}$ B cells relative to WT BXD2. *In vivo* injection of AdIL-17 in pre-disease BXD2 mice enhanced anti-IgM induced survival and anergy loss. Surprisingly, despite normal expression of BAFF-R on transitional and mature B cell subsets, BlyS cannot reverse the anergic response of BXD2-*Il17ra*$^{-/-}$ B cells to BCR stimulation. Analysis of the expression of IL-17RA in the B-cell subsets in BXD2 mice showed that IL17RA is strongly upregulated in transitional T2 (CD93^{+}IgM^{+}CD23^{+}) and germinal center (PNA^{+}Fas^{+}) B cells. Single cell analysis of T2 B cells revealed the co-expression of *Il17ra* with B-cell activation gene, *Bclxl*.

Conclusion: Our results suggest that, in BXD2-*Il17ra*$^{-/-}$ B cells, the anergy phenotype is established at the transitional stage. In these B cells, stimulus-specific transcription repressive p50/p50 homodimers may act as a master transcriptional regulator to counteract pro-activation/survival NF-κB signaling provided by other major B-cell stimulators. Reagents that can promote the NF-κB p50/p50 repressome complex may be a novel strategy to enhance B-cell tolerance for autoimmunity. *(Supported by NIH R01AI071110, R01AI083705, P30AR048311, T32 AI007051, VA Merit Review grant 1I01BX000600, Lupus Research Institute, Lupus Foundation of America. *Il17ra*$^{-/-}$ mice were a generous gift from Amgen).

Background/Purpose: Antiphospholipid syndrome (APS) is a serious autoimmune clotting disorder of unknown etiology but with a well-defined major autoantigen, β_2-glycoprotein I (β_2GPI). Infectious triggers have been implicated in transient autoantibody production, but the persistent stimuli for anti-β_2GPI antibodies remain unknown. Given the vast antigenic potential of the gut microbiota, we hypothesize that human gut commensal bacteria induce and sustain autoreactivity via cross-reactivity. To this end, we characterized APS β_2GPI-specific T cell and autoantibody reactivity to *in silico* candidates.

Methods: NCBI BLAST was used to identify microbial protein sequences with high homology to major β_2GPI epitopes. Sorting of IgA-coated fecal microbiota followed by 16S rDNA sequencing (IgA-Seq) was performed on APS and control microbiomes. Human-derived candidate and control strains were cultured anaerobically. Blood and stool samples were collected from APS patients and controls. A novel strain-specific real-time PCR strategy was developed and validated using isolated strains and defined fecal microbiomes. Memory $CD4^+$ T cells specific to β_2GPI were cloned using a T cell library assay and a monoclonal antibody specific to the RGGMR domain I epitope of β_2GPI was expressed for cross-reactivity studies.

Results: Systematic *in silico* searches revealed *Roseburia intestinalis* as a major candidate with high homology to the main B and T cell epitopes of β_2GPI. *R. intestinalis* colonization load was abundant and persistent throughout the study population. IgA-Seq showed IgA coating of the genus *Roseburia*. APS PBMC proliferated significantly more to protein extracts from *R. intestinalis* versus control subjects (p=0.0002), and also compared to the phylogenetically related, but mimic-deficient gut commensal *Eubacterium rectale* (p=0.02). APS memory CD4+ T cells specific for a T cell epitope in domain V cross-react with *R. intestinalis* mimic peptide. Further, an APS patient-derived anti-domain I β_2GPI monoclonal antibody bound significantly to *R. intestinalis* lysates whereas a control antibody against an unrelated β_2GPI epitope did not.

Conclusion: We have identified a common gut commensal, *R. intestinalis,* as a potential chronic cross-reactive trigger in APS. *Roseburia* is IgA-coated in APS microbiomes suggesting adaptive immune responses to the candidate *in vivo*. *In vitro* studies support cross-reactivity of β_2GPI-specific CD4 memory T cells and a pathogenic autoantibody with *R. intestinalis*. This study provides a concept for common human gut commensals as chronic cross-reactive triggers in genetically susceptible autoimmune hosts such as APS patients.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In order to better understand the IL-17A signaling pathway we have analyzed the effects of IL-17A in human primary synovial fibroblasts (SF), a major source of inflammatory mediators in rheumatoid arthritis (RA), as an example of stromal cells. We could show that IL-17A alone and in combination with TNF induces NFKBIZ encoding the NFκB pathway modulator IκBζ. In this study we assessed the role of NFKBIZ/IκBζ as a signaling node downstream of IL-17A by NFKBIZ siRNA knockdown. Since NFKBIZ has recently been identified as a psoriasis susceptibility locus, and shown to drive inflammation in psoriasis-like mouse models and in human keratinocytes, we analyzed the mRNA levels of NFKBIZ and of selected target genes in skin biopsies from psoriasis patients that have been treated with the anti-IL-17A antibody secukinumab (approved for the treatment of psoriasis and psoriatic arthritis).

Methods: Human primary RA-SF (Cell Application Inc.) were transfected with control or NFKBIZ siRNA (24h) before stimulation with IL-17A alone or in combination with TNF (18h). mRNA levels of inflammatory mediators (e.g. IL-6, CSF3/G-CSF, CXCL-1) were determined by qPCR, and released protein levels by AlphaLISA or homogeneous time resolved fluorescence. Secukinumab was added prior to TNF/IL-17A to determine its neutralizing activity. The mRNA levels of NFKBIZ and target genes in lesional and nonlesional skin biopsies from psoriasis patients at baseline and after 12 week treatment with secukinumab (n=19) or placebo (n=9) were determined by Nanostring.

Results: IL-17A stimulation induced marked levels of NFKBIZ and IκBζ in SF, which were further increased by TNF/IL-17A costimulation. We achieved a > 90% knockdown by NFKBIZ siRNA transfection, and could show that the expression of several inflammatory mediators induced synergistically by TNF/IL-17A, e.g. IL-6, CXCL-1, CSF3/G-CSF, were significantly reduced both on mRNA and protein level, suggesting that NFKBIZ represents an important node controlling several pro-inflammatory genes. Secukinumab potently inhibited the TNF/IL-17A induced release of these mediators at picomolar concentrations. We observed that NFKBIZ mRNA levels were upregulated in lesional versus nonlesional skin from psoriasis patients and that the increased expression of NFKBIZ was reduced after 12 week treatment with the anti-IL-17A antibody secukinumab. The expression of main biomarkers for the efficacy of secukinumab was also decreased, including CXCL-1 and the gene encoding β-defensin2 which is specifically expressed in keratinocytes and described to depend on NFKBIZ.

Conclusion: We show that NFKBIZ is induced in psoriatic lesional skin and by IL-17A alone and in combination with TNF in synovial fibroblasts. We demonstrate that NFKBIZ controls the expression of IL-17A-stimulated main inflammatory mediators. We also observe that mRNA levels of NFKBIZ, CXCL-1 and of the gene encoding β-defensin2 are reduced in lesional skin from psoriasis patients after secukinumab treatment. These data suggest that the therapeutic effect of secukinumab seen in psoriasis and potentially other indications may be mediated at least in part by the downregulation of the NFKBIZ signaling node.

Session Date: Sunday, November 13, 2016
Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: IL-17 cytokines have emerged as drivers of autoimmunity. Indeed, the IL-17A-targeting antibody secukinumab (Cosentyx) was recently approved for treatment of plaque psoriasis, and shows efficacy in psoriatic arthritis and ankylosing spondylitis. IL-17 family members signal through a dimeric receptor composed of a common subunit, IL-17RA, and a variant co-receptor. Both IL-17A and IL-17C have been implicated in psoriasis pathology, but while IL-17A signals through IL-17RA and IL-17RC, IL-17C is reported to act

through an IL-17RA/IL-17RE heterodimer. To date, little is known about the regulatory mechanisms that control the amplitude of inflammation mediated by IL-17 cytokines, particularly in the context of autoimmunity. Not surprisingly, numerous mechanisms have evolved to restrict IL-17 signaling to limit bystander tissue damage. The endoribonuclease Regnase-1 [also known as MCP1-Induced Protein 1 (MCPIP1), encoded by *Zc3h12a*] is a key regulator of inflammation. We previously showed that Regnase-1 downregulates IL-17A signaling, including expression of IL-6 and IkBz. Consequently, Regnase-1-deficient mice had exacerbated CNS inflammation in the experimental autoimmune encephalomyelitis model. Here, we assessed the impact of MCPIP1 in a murine model of psoriasis, and verified its presence in human psoriatic lesions.

Methods: Psoriatic inflammation was induced by application of imiquimod (IMQ). *Zc3h12a*$^{+/-}$, *Il17ra*$^{-/-}$, *Il17c*$^{-/-}$, *Il17re*$^{-/-}$and intercrossed mice or littermates were subjected to IMQ-induced psoriasis for 1-5 days. Disease was assessed by measurement of ear thickening, H&E staining of skin sections, immune cell infiltration by flow cytometry, and gene expression by qPCR. Bone marrow chimeras were made by adoptive transfer into irradiated recipients. De-identified skin biopsies were stained for Regnase-1 by IHC.

Results: During IMQ-induced inflammation, *Zc3h12a* mRNA was elevated in mouse skin. Consistently, *ZC3H12A* was more highly expressed in human lesional skin than in non-lesional or healthy skin biopsies. Consistent with its recognized role as a feedback inhibitor, mice deficient for Regnase-1 (*Zc3h12a*$^{+/-}$) showed more dermal inflammation following IMQ-induced psoriasis induction than littermate controls, whereas *Il17ra*$^{-/-}$ mice were fully resistant to disease. Genes associated with Regnase-1-induced inflammation included prototypical IL-17 target genes such as *Il6* and *Lcn2*. Bone marrow chimeras indicated that the inhibitory activity of Regnase-1 in IMQ-psoriasis was restricted to the non-hematopoietic compartment, which was also consistent with an IL-17-dependent pathogenesis. Further evidence to support this model was the finding that *Zc3h12a*$^{+/-}$*Il17ra*$^{-/-}$ mice were fully protected from disease. Surprisingly, neither *Zc3h12a*$^{+/-}$*Il17c*$^{-/-}$ nor *Zc3h12a*$^{+/-}$*Il17re*$^{-/-}$mice were protected, suggesting that Regnase-1 activity is restricted to IL-17A in this setting.

Conclusion: Regnase-1 negatively regulates IL-17A but not IL-17C or IL-17RE in the context of autoimmune skin inflammation. Regnase-1 is overexpressed in active dermal inflammation, but is nonetheless insufficient to control disease.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Vitamin A and its major metabolite, retinoic acid (ATRA), modulate T cell function and fitness to shape immune responses. Vitamin A deficiency causes increased susceptibility to infection, leading to the death of an estimated 250,000-600,000 children per year. Osteoarthritis has been linked to variants in the ALDH1A2 gene, which metabolizes Vitamin A to ATRA. Retinoic acid is an essential positive regulator of T effector cell responses, yet retinoids can also dampen immune responses through inhibition of effector cytokine production. Moreover, ATRA induces expression of the transcription factor Foxp3, which is necessary for immune tolerance. This multifaceted effect of ATRA complicates dissection of the molecular mechanisms that elicit negative immunoregulatory functions.

Methods: We aimed to evaluate the direct effects of retinoic acid induced immunomodulation that are not dependent on enhancing T regulatory cell function. We performed RNA-seq and compared the transcriptomes of ATRA-treated and untreated T helper cell subsets.

We used Chromatin Immunoprecipitation-sequencing (ChIP-seq) and Assay for Transposase-Accessible Chromatin-sequencing (ATAC-seq) to characterize ATRA-induced changes in chromatin architecture.

Results: We characterized an ATRA-regulated gene signature that was independent of CD4 T cell subset. We identified IL-9 as the cytokine whose gene expression is most strongly inhibited. Using Foxp3-mutant (Scurfy) mice, we demonstrated that ATRA's immunomodulatory effects, including IL-9 inhibition, are Foxp3-independent. We confirmed that retinoic acid potently inhibits IL-9 in T cells *in vitro*, and in T cells and Type 2 innate lymphoid cells (ILC2s) in an *in vivo* model of allergic lung disease. We mapped chromatin accessibility of the *Il9* locus by ATAC-seq and enhancer marks by ChIP-seq, which led us to identify several novel *Il9* enhancers. We observed that RAR-alpha binds directly to the *Il9* locus, reduces chromatin accessibility, and disrupts looping between the *Il9* promoter and associated enhancers.

Conclusion: Our observation suggests that ATRA-RAR-alpha directly suppresses IL-9 by modifying enhancer architecture, which may serve as a paradigm for the mechanism by which retinoic acid modulates cytokine expression.

Intestinal Dysbiosis Influences Gut-Joint Lymphocyte Trafficking

Kristine Kuhn[1,2], Hanna Schulz[2], Jason Hendrickson[2] and Neha Ohri[2], [1]Mucosal Inflammation Program, University of Colorado School of Medicine, Aurora, CO, [2]Division of Rheumatology, University of Colorado School of Medicine, Aurora, CO

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Intestinal microbiome studies in IBD and AS have shown significant bacterial dysbiosis (i.e., a substantial alteration of the individual species) in similar populations, as compared to healthy controls. However, *the mechanistic linkage between the microbiota, changes in mucosal immunology, and the subsequent pathogenic targeting of the spine has not been defined.* Intraepithelial lymphocytes (IELs) are a unique population of antigen-experienced T cells which are anatomically associated with intestinal epithelial cells and function to protect the host from microbial invasion and maintain epithelial homeostasis. Our ongoing studies have revealed that dysbiosis in patients with IBD and mouse models alters the function of IELs. We hypothesize that resident bacteria educate IELs, which in turn, traffic systemically and cause arthritis under dysbiotic conditions.

Methods: Dysbiosis is modeled by administration of broad-spectrum antibiotics (ampicillin, neomycin, metronidazole, and vancomycin) in the drinking water for one week; recolonization of mice is done by cohousing with unmanipulated littermates for one week. KikGR mice contain a transgene for a photoconvertible green-to-red fluorescent protein. Endoscopy-guided violet light allowed photoconversion of distal colonic IELs in vivo. $TNF^{\Delta ARE/+}$ mice contain a mutation in the AU-rich element of the TNF-α gene resulting in increased mRNA stability and systemically elevated TNF-α. As a result, these mice develop ileitis and arthritis beginning around 8 weeks of age. Microbial analysis was performed on fecal pellets via high-throughput 16S rRNA gene sequencing. Trafficking of photoconverted lymphocytes was determined by flow cytometry of tissues.

Results: One week following photoconversion of the distal colon lymphocytes in KikGR mice, labeled intestinal lymphocytes were detected systemically in tissues including the spleen, liver, lungs, and Achilles entheses; few lymphocytes remained in the colon. Treatment of mice with antibiotics following photoconversion resulted in substantially reduced trafficking to distal tissues as well as a depletion of the colonic population. After recolonization, labeled colonic lymphocytes substantially increased in the colon while few remained in distal tissues. Our analysis of $TNF^{\Delta ARE/+}$ mice demonstrates significant dysbiosis occurs as mice age and develop disease compared to $TNF^{+/+}$ littermates.

Conclusion: Manipulation of intestinal bacteria through antibiotic use alters intestinal lymphocyte trafficking to extra-intestinal tissues. We have generated $TNF^{\Delta ARE/+}$ X KikGR mice, and our future studies will link dysbiosis, lymphocyte trafficking, and disease. Our goal is to identify triggers for systemic IEL trafficking from the intestine during health and IBD-related SpA and define the role of trafficked IELs

in the target tissue. Through understanding these mechanisms we hope to identify biomarkers of gut-joint trafficking to diagnose patients earlier and/or treatment strategies to improve disease outcomes for SpA.

Complement C5a Receptor Is the Key Initiator of Neutrophil Adhesion and Inflammation in Immune Complex-Induced Arthritis

Yoshishige Miyabe[1], Chie Miyabe[1], Thomas Murooka[2], Edward Kim[3], Nancy Kim[3], Thorsten R. Mempel[4] and Andrew D. Luster[1], [1]Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]University of Manitoba, Winnipeg, MB, Canada, [3]Massachusetts General Hospital, Boston, MA, [4]Massachusetts General Hospital, Charlestown, MA

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Inflammatory arthritis, including rheumatoid arthritis, is characterized by neutrophil (PMN) recruitment into the joint in a highly regulated process controlled by chemoattractants (CAs). Four different chemoattractant receptors (CAR), BLT1, CCR1, CXCR2 and C5aR, are required and collaborate to mediate PMN recruitment into the joint in immune-complex (IC) induced arthritis. However, the precise role for each CA in the process of PMN recruitment into the joint *in vivo* remains unclear. This process begins with the capture of free-flowing leukocytes to the vessel wall, followed by *rolling* and then *arrest* on the vessel wall, release from adhesion and then *crawling* in all directions on the vessel to locate a receptive location for *transendothelial migration* (TEM) into the joint.

Methods: Multiphoton intravital imaging (MP-IVM) was performed to analyze the migratory behavior of wild-type (WT) and CAR-deficient (KO) PMNs in the joint of WT and CAR-KO-LysM-GFP mice, in which endogenous PMNs and macrophages express GFP, on day 7 after K/BxN serum transfer (KST). We analyzed the ability of WT and CAR-KO PMNs to enter the joint in short term adoptive transfer assays on day 7 after KST. We also analyzed joint tissue for the expression of C5a using immunohistochemistry and synovial fluid (SF) for the levels of CKs by ELISA. We analyzed the expression of CARs by flow cytometry on PMNs isolated from the bone marrow (BM), blood and SF. Lastly, we generated mixed bone marrow chimeric (BMC) mice with WT and CAR-KO BM cells transferred into lethally irradiated WT mice to analyze PMN recruitment into the joint through the entire course of arthritis development. Finally, the effect of CXCR2 ligands on SF PMN survival was evaluated.

Results: In the inflamed joint of WT- LysM-GFP mice, abundant PMN adhesion and TEM was observed. However, PMN adhesion and TEM were not observed in the joint of C5aR-KO-LysM-GFP mouse. PMN adhesion was observed in the joints of BLT1-KO-, CCR1-KO- and CXCR2-KO-LysM-GFP mice but PMN TEM was either not observed or was markedly diminished. Short term adoptive transfer assays demonstrated a decrease in the adhesion and TEM of C5aR-KO PMNs, whereas BLT1-KO, CCR1-KO and CXCR2-KO PMNs were able to adhere to the endothelium but had a decrease in TEM into the inflamed joint. 40% adoptively transferred C5aR-KO PMNs that arrested on the endothelium detached, while 20% of CCR1-KO PMNs that crawled on the endothelium detached. WT arrested and crawling PMNs were not observed to detach from the endothelium. C5a deposition was observed on the endothelium and cartilage in arthritic joints. C5a was detected in the joint on day 1, whereas the other CAs were detected at later time points. In mixed BMC mice with arthritis, CXCR2-KO PMNs were not observed in joint and CXCR2 ligands prevented SF neutrophils from undergoing apoptosis.

Conclusion: Our data demonstrate that C5a is the critical initiator of PMN adhesion on joint endothelium and is required to initiate joint inflammation in IC-induced arthritis. In addition, we have found that CCR1 contributes to the interaction of PMNs with the joint endothelium and that PMNs self-propagate their recruitment and survival via CXCR2 in the joint space.

Increased Concentration of Receptor Activator of Nuclear Factor Kappa-B Ligand (RANKL) Predate Onset of Rheumatoid Arthritis

Linda Johansson[1], Lisbeth Ärlestig[1], Heidi Kokkonen[2] and **Solbritt Rantapaa-Dahlqvist**[3], [1]Public Health and Clinical Medicine/Rheumatology, Umeå University, Umeå, Sweden, [2]Public Health and Clinical Medicine/ Rheumatology, Umeå University, Umeå, Sweden, [3]Umeå University, Department of Public Health and Clinical Medicine/ Rheumatology, Umeå, Sweden

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Receptor activator of nuclear factor κB ligand (RANKL) an important regulator of bone metabolism has a key role in local bone destruction and osteoporosis in rheumatoid arthritis (RA). The aim of this study was to investigate the relationships between RANKL and biomarkers (anti-citrullinated peptide antibodies (ACPA), anti-carbamylated (anti-CarP) antibodies and cytokines) in individuals before symptom onset of RA and their association to radiological findings at disease onset.

Methods: A case-control study with 470 (334 women/136 men) pre-symptomatic individuals (mean age±SD 52.3±9.4) who had donated blood samples before symptom onset and 96 (60 women/36 men) population based controls was performed within the Medical Biobank of Northern Sweden. The median (IQR) predating time before symptom onset was 5 (5.1) years. Radiographs of hands and feet performed when diagnosed with RA were grade using Larsen score. ELISAs were used for analysing RANKL (BioVendor, Karasek, Czech Republic), anti-CCP2 antibodies (Eurodiagnostics, Sweden), anti-CarP antibodies (in-house ELISA in collaboration with L Trouw, NL) and ACPA using multiplex ISAC platform (PhaDia AB, Sweden) in plasma. Cytokines were analysed using Meso Scale Discovery V-plex methods (Maryland, USA). The cut-off for RANKL was set at 95% according to the ROC curve.

Results: The concentration of RANKL was significantly higher in the pre-symptomatic individuals compared with controls, mean±SEM 0.50±0.03 nmol/L versus 0.22±0.02 nmol/L, ($p<0.001$). The RANKL concentration increased gradually over time the closer to onset of symptoms samples were collected. Anti-CCP2 positive pre-symptomatic individuals had higher levels of RANKL compared with sero-negative individuals, as for rheumatoid factor positive individuals ($p<0.001$). Concentrations of RANKL were significantly associated with several ACPA specificities, anti-CarP antibodies, interleukin (IL)6 and IL10 concentrations in pre-symptomatic individuals. RANKL concentrations were related to higher Larsen score at RA diagnosis in men ($p<0.05$). Combination of positivity of RANKL and anti-CarP antibodies yielded increased risk for higher Larsen score at RA diagnosis compared with being negative for both as a reference, ß= 6.23 (95%Cl 0.96, 11.50, $p<0.021$).

Conclusion: RANKL concentrations were increased several years before symptom onset of RA and associated with Larsen score when RA was diagnosed in men. Combination of positivity of both RANKL and anti-CarP antibodies yielded the highest Larsen score at disease onset. These findings provide new insight into some of the key mechanism of RANKL in bone destruction in individuals already years before onset of symptoms of RA.

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research I: Workforce and Quality of Care in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The 2015 ACR Workforce study updated the current and projected pediatric rheumatology workforce for the next 15 years.

Methods: The 2015 ACR/ARHP Workforce Study was completed using several primary and secondary data sources, including, ACR member data, state licensure registries, 2005 ACR workforce study, professional organizations, and other medical literature. These data were supplemented with a web-based survey to collect information about work settings, practice patterns, retirement planning, and demographics. Utilizing an integrated workforce modeling methodology, supply and demand projections were computed for pediatric rheumatologists from 2015-2030. The factors affecting supply included the current pediatric rheumatology workforce, demographic changes, completed fellowships, retirement trends, patient workload and practice settings. Multivariate regression modeling was used to determine significant factors affecting demand. These included healthcare utilization, provider practice trends, disease prevalence, population demographics, per capita income and access to care trends. Clinical FTE was defined as 1.0 FTE for private practice and 0.5 FTE for academic practice and compared to actual projections (Figure 1), assuming 95% of the pediatric rheumatology workforce was in academic practice vs. 5% in private practice.

Results: The 2015 ACR current pediatric workforce is estimated to be 300 providers (287 Clinical FTE). The majority (56%) of pediatric rheumatologists are in the Northeast, Mid-Atlantic and Great Lakes Regions. There are two states that have no board-certified practicing pediatric rheumatologists (Alaska, New Mexico) and many states where there is only 1-3 covering the entire state. A 20% reduction in supply coupled with a 21% increase in need results in a projected excess demand of about 100% pediatric rheumatologists by 2030 (461-231=230) (Figure 2). Projected need is much greater when compared to that projected in 2005.

Conclusion: This severe shortage of pediatric rheumatologists is likely due to several factors, including increases in projected patient population, coupled with the decrease in clinical FTE due to increases in females, part-time, and millennial workers. Additionally, the number of unfilled fellowship positions average 40% each year contributing to the shortage. As a result, patients in need have severely limited access to the care. Regional and innovative recruitment strategies will be necessary to help increase the supply, manage access to care and reduce barriers to care for pediatric rheumatology patients.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research I: Workforce and Quality of Care in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The 2015 ACR/ARHP Workforce Study assessed the current and projected rheumatology workforce and the regional distribution of rheumatologists. Over the next 10 years, a declining rheumatology workforce resulting from significant “baby boomer” retirements, millennial ascendency and a gender shift toward women will be met with an increasing patient demand. We analyzed regional workforce differences and retirement trends within the context of population expansion to better understand the impact of workforce changes in the decade of 2015-2025.

Methods: The 2015 ACR/ARHP Workforce Study was completed using several primary and secondary data sources, including the ACR member database, state licensure registries, 2005 ACR workforce study results, professional organization information and peer-reviewed literature. These data were supplemented with a web-based survey assessing work settings, practice patterns, retirement planning and demographics. A clinical FTE was defined as 1.0 FTE for private practice and 0.5 FTE for academic practice to determine rheumatologists actually treating patients vs. total number of physicians. Population growth estimates were obtained using U.S. Census Bureau data.

Results: The U.S. ranks 3rd in projected population growth in the world with an anticipated growth of 16.5% by 2030. Thirty-two percent of ACR members responded to the survey (1996/6342).The highest concentrations of rheumatologists are found in the Northeast and Mid-Atlantic regions (Table 1). Response rates ranged from 17% in the Northeast to 54% in the Southwest/South Central regions (Table 1). The estimated total number of rheumatologists in the U.S. workforce in 2015 by FTE is 4,933 with a projected decrease to 3,645 by 2025. Combining the projected growth rates by region coupled with the projected retirement rates, the three regions with the greatest increase of

adult to physician ratio would be the Northwest (148%), North Central (136%), and South Central (102%) (Figure 1). The overall adult-to-physician is projected to be 99,177 by 2025 (Table 1).

Conclusion: There is a regional maldistribution of rheumatologists in the United States, and disparities will increase with anticipated retirements and regional population growth estimates. The South Central, North Central and Northwest regions will experience the greatest change in population to provider ratios. The challenge of an increasing demand for rheumatology care requires novel solutions, processes and a multidisciplinary approach to ensure timely access to care for rheumatology patients.

Table 1. 2015-2025 Projected Regional Distribution of Rheumatologists with Population Growth

Retinal Examinations Among SLE Patients Newly-Initiating Hydroxychloroquine in a U.S. Medicaid SLE Population, 2000-10

Tzu-Chieh Lin[1], CH Feldman[2], Hongshu Guan[3], Sarah Chen[4], Medha Barbhaiya[1] and Karen H. Costenbader[1], [1]Rheumatology, Immunology and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Social and Behavioral Sciences, Harvard T. H. Chan School of Public Health, Boston, MA, [3]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [4]Beth Israel Deaconess Medical Center, Boston, MA
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Health Services Research I: Workforce and Quality of Care in Rheumatology
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: U.S. Medicaid provides medical benefits to low-income people. Although the Federal government establishes guidelines, each state sets vision benefits. The American Academy of Ophthalmology recommends a baseline retinal examination at hydroxychloroquine (HCQ) initiation and periodically thereafter, but there is lack of real-world practice information. We investigated the proportion of SLE Medicaid patients newly-initiating HCQ who receive indicated retinal exams and identified factors associated with receiving this care.

Methods: We conducted a retrospective cohort study of SLE patients 18-65 years old in Medicaid Analytic eXtract (MAX) from the 29 most populated U.S. states, 2000-2010. SLE patients were identified by ≥ 3 codes for ICD-9 710.0, each ≥ 30 days apart, in hospital discharge diagnoses and physician visit claims. HCQ new-users were identified by a new HCQ prescription fill (index date) after 1st SLE code, with no HCQ use in the prior 12 months. We restricted to those with ≥12 months of continuous enrollment before and after index date to assess both ophthalmologic and retinal exams, identified by CPT and HCPCS codes. Comorbidities and healthcare utilization were collected from the 12 months before index date. Examination rates were calculated across calendar years and by comorbidity and healthcare utilization subgroups. Differences between patients with and without exams were detected by the difference in means or proportions of a variable divided by a pooled estimate of the standard deviation of the variable.

Results: We identified 12,755 SLE patients newly starting HCQ. Proportions of patients undergoing exams 1 year before or after initial HCQ prescription ranged from 35.8 to 42.8% for ophthalmologic exams and 4.7 to 7.7% for retinal exams during year 2001-2009. Patients who received ophthalmologic exams, compared to those who had not, were older (40.8 ± 12.1 vs. 37.5 ± 11.5 years), more were White/Hispanic/Asian vs. Black. They also had more comorbid conditions and had received more SLE-related lab tests (ANA, anti-dsDNA, C3, C4) in the pre-index period. The proportions of lupus nephritis patients (35.2%) and pregnant patients (32.6%) who had *any* ophthalmologic exam were among the lowest. Overall, a high proportion of SLE patients newly starting HCQ did not have *any* Medicaid claims for retinal exams (92.7%) or even for *any* ophthalmologic exam (55.2%) in the 1 year before and 1 year after HCQ initiation. (**Table**)

Conclusion: The proportions of U.S. Medicaid SLE patients starting HCQ who received ophthalmologic and retinal exams were extremely low overall, possibly due to state-dependent vision coverage. SLE patients may not be getting these indicated exams or they may be paying out-of-pocket or through supplemental vision insurance. Future studies will examine state-to-state variation in retinal exam rates and Medicaid vision coverage.

Table. Proportions of 12,755 SLE Patients Newly-Initiating HCQ who Received Ophthalmologic and Retinal Exams in the Year prior to or following First HCQ Prescription Fill

	Ophthalmologic Exams	Retinal Exams
Any baseline exams[a], %	22.8	2.8
Baseline exams only, %	13.8	2.2
Exams both before and after HCQ initiation, %	9.0	0.6
After HCQ initiation only[b]	22.1	4.5
No exams both before and after HCQ initiation	55.2	92.7

Session Title: Health Services Research I: Workforce and Quality of Care in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The EULAR recommendations for cardiovascular disease (CVD) risk management in patients with inflammatory joint diseases (IJD) states that CVD risk assessment should be considered annually in this patient population, and emphasizes that such assessment can be easily incorporated into a routine rheumatology visit; but they are rarely implemented. The aim of the NOrwegian Collaboration on Atherosclerosis in patients with Rheumatic joint diseases (NOCAR) was to design a program of annual CVD risk assessment for IJD patients that could be implemented into routine visits in rheumatology outpatient clinics.

Methods: NOCAR was started in April 2014 for quality assurance purposes, and comprises 11 rheumatology centres across Norway. All IJD patients >30 years registered in the electronic patient journal program GoTreatIt® Rheuma (GTI) are eligible. The CVD risk factors recorded in NOCAR are imputed directly into the GTI journal and are collected in a multidisciplinary manner: 1) Patients self-report CVD risk factors, 2) non-fasting lipids are ordered by health secretaries in addition to routine laboratory tests and 3) rheumatology nurses perform blood pressure measurement. Based on the Systematic COronary Risk Evaluation (SCORE) algorithm, GTI automatically calculates the patient's 10-year risk of a fatal CVD event. If the SCORE estimate is ≥5%, the rheumatologist forwards a note to the patient's primary physician to inform that there is indication for initiation of CVD-preventive measures (e.g. medication and lifestyle changes). Additionally, the rheumatologists and rheumatology nurses are instructed in how to deliver brief advice regarding smoking cessation and healthy diet. We report the initial capture rate in 3 NOCAR centres from which visit data was extracted in October 2015. We evaluated how many of the eligible patients who had received a CVD risk evaluation during these first 1.5 years of the NOCAR project. A CVD risk assessment was defined as having recoded all of the CVD risk factors included in the SCORE algorithm (total cholesterol, systolic blood pressure, smoking status, age and sex).

Percent of eligible patients for whom all CVD risk factors included in the SCORE algorithm were recorded

	ALL	RA	AS	PsA	SpA
Eligible patients	6150	3504	1107	1108	431
Patients who received CVD risk assessment	2519	1569	418	350	122

Results: Of the 6150 IJD patients (Rheumatoid arthritis [RA]: 3504, ankylosing spondylitis [AS]: 1107, psoriatic arthritis [PsA]: 1108, and other spondyloarthritides [SpA]: 431) who were eligible for the NOCAR project, 2519 (41%) patients received a CVD risk assessment during this 1.5 year interval (RA: 1569 [45%]), AS: 418 [38%], PsA: 350 [32%], SpA: 122 [28%]). The major obstacles to successful implementation encountered in NOCAR were time scarcity; defining a date for annual CVD risk assessment and making sure that lipids were measured before seeing the rheumatologist.

Conclusion: To our knowledge, this is the first multi-centre clinical project to show that incorporation of CVD risk assessment into routine rheumatology visits is feasible.

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research I: Workforce and Quality of Care in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: We have recently found that rates of myocardial infarction (MI) are similar among individuals with SLE and those with diabetes mellitus (DM) in a nationwide cohort of Medicaid recipients. Given high cardiovascular disease (CVD) risks in both SLE and DM patients, lipid testing is widely advocated for both groups. We investigated rates of lipid testing and statin prescriptions among SLE and DM patients within Medicaid.

Methods: Within Medicaid Analytic eXtract (MAX), with billing claims from 2007-2010 for patients from the 29 most populous US states, we identified patients aged 18-65 years with prevalent SLE (>3 ICD-9 codes for SLE, >30 days apart), and a 1:2 age- and sex-matched DM cohort (>3 ICD-9 codes for DM, >30 days apart). We required 6 months of continuous Medicaid enrollment (baseline period) prior to the 3rd diagnosis code (index date). Subjects were followed from index date until death, Medicaid disenrollment or end of follow-up (12/31/2010). Within claims, we used CPT codes to identify lipid testing and NDC codes to identify statin prescriptions. We calculated rates per 100 person-years for lipid testing (>1 per person) and statin prescriptions (> 1 per person), and rate ratios (with 95% CIs) adjusted for baseline demographics and CVD using Poisson regression to compare rates (DM=referent).

Results: 32,089 SLE patients were matched to 64,178 DM patients; 92% were female and mean age was 41.3 (+ 12.1) years in both cohorts. Mean years of follow-up from index date was 1.68 (+1.03) for SLE, and 1.81 (+1.08) for DM. Baseline CVD covariates for SLE vs. DM cohorts were similar for MI (0.90 vs. 0.67%), angina (2.19 vs. 2.08%), old MI (0.89 vs. 0.67%), PCI (2.29 vs. 1.61%), CABG (0.18 vs. 0.12%), CVA (2.23 vs. 0.14%), and presence of any any CVD (4.62 vs. 3.57%). Rates (per 100 person years) of lipid testing increased from 22.2 to 44.1 for SLE and 38.2 to 59.1 for DM and statin prescription increased from 7.0 to 23.4 for SLE and 24.6 to 57.9 for DM between 2007 and 2010. Unadjusted rates (per 100 person years) for lipid testing were 25.8 (95% CI 25.3-26.3) for SLE and 41.6 (95% CI 41.1-42.0) for DM, and for statin prescription were 9.1 (95% CI 8.8-9.4) for SLE and 27.6 (95% CI 27.3-28.0) for DM. The highest rates of lipid testing and statin prescriptions were found among Asians and lowest rates were seen among Native Americans for both SLE and DM. After adjusting for age, race/ethnicity, sex, region, socioeconomic status, calendar year, and CVD at baseline, the rate ratios in SLE compared to DM patients were 0.61 (95% CI 0.60-0.63) for lipid testing and 0.32 (95% CI 0.31-0.34) for statin prescriptions.

Conclusion: Rates for lipid testing and statin prescriptions increased in both SLE and DM cohorts during the study period and were highest among older patients and those with baseline CVD. Although DM and SLE confer similar risk of CVD, in this cohort, lipid testing rates were 40% lower and statin prescription rates were 70% lower in patients with SLE compared to DM.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Health Services Research I: Workforce and Quality of Care in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with rheumatic diseases may have systemic complications from disease as well as therapy and often suffer symptoms towards the end-of-life comparable to patients with advanced cancer. Palliative care in this group of patients has not been well evaluated due to a lack of data in the current literature. The aims of this study were to: (i) describe the multidimensional symptom profile and prevalence and (ii) analyze the factors associated with symptom prevalence and referral to palliative care services in patients with systemic rheumatic diseases in the last 1 year of life.

Methods: The electronic records of patients with systemic rheumatic diseases who died at the National University Hospital, Singapore from 2012 to 2016 were reviewed. Patients with crystal arthritis, septic arthritis, osteoarthritis and fibromyalgia were excluded. Symptom prevalence was assessed by summation of the number of symptoms experienced by the patients in the last 1 year of life. Charlson Comorbidity Index (CCI) and its predicted 1-year survival were constructed from the medical records. Linear and logistic regressions were used to identify independent predictors for symptom prevalence and referral to palliative care services.

Results: In total, 70 deceased patients with systemic rheumatic diseases were identified. The mean age at death was 66.2 years (standard deviation 14.5), 52 (74.3%) were females. The majority of patients had rheumatoid arthritis (30.0%) and systemic lupus erythematosus (25.7%), 58.6% of the deceased patients had active disease. The most common cause of death was infection (45.7%). Table 1 summarizes the symptom profile and prevalence of the deceased patients. Only 5.7% had advance care planning and 15.7% were referred to palliative care services. Active rheumatic disease was associated with escalation of immunosuppression ($p < 0.001$) but not with recurrent infections or symptom prevalence ($p > 0.05$, respectively). Among the various symptoms examined, only depression was associated with referral to palliative care services ($p = 0.013$). Predicted 1-year survival ($\beta = -0.104$, SE = 0.027, $p < 0.001$) was independently associated with

symptom prevalence. When considering only patients with active rheumatic diseases, predicted 1-year survival (β = -0.089, SE = 0.030, p = 0.005) and recurrent infections (β = 1.866, SE = 0.749, p = 0.017) were independently related to symptom prevalence. Predicted 1-year survival (OR = 0.902, 95% CI 0.825-0.986, p = 0.023), but not symptom prevalence (p > 0.05), was independently associated with referral to palliative care services.

Conclusion: This is the first study to describe the symptom profile and prevalence in patients with systemic rheumatic diseases in their last 1 year of life. Predicted 1-year survival using the CCI may be used to identify patients in earlier need of palliative care.

Table 1: Cumulative Symptom Prevalence Over Last 1 Year of Life

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases I: Advanced Imaging in RA and Spondyloarthritides

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) can be differentiated according to rheumatoid factor (RF) and citrullinated peptide antibodies (ACPA). It is unclear whether seropositive RA (spRA) and seronegative RA (snRA) are different forms of the same disease or separate entities. Differing manifestation patterns between spRA and snRA on hand radiographs were first described by Burns/Calin in 1983[1]. To our knowledge, this observation has not been pursued further.

Methods: Hand and foot radiographs of 54 patients with RF negative, ACPA negative, erosive RA (snRA) were evaluated according to the Sharp-van-der-Heijde score (SHS) and compared with radiographs of 55 age-matched, RF-positive, ACPA-positive, erosive RA (spRA) patients. The average SHS for both cohorts was determined for the entire set of radiographs, for the carpal, MCP, PIP and foot compartments and for each single joint separately. We also evaluated the relative erosion score for each compartment (compartment SHS/total SHS). The results were transferred to a ‘heat map’ for visual representation. All data are given as mean± SD.

Results: Total SHS was significantly higher in spRA than in snRA (SHS 47.4± 53.5 vs. 20.6± 24.7, p=0.0012). The difference in SHS was significant in the MCP (8.5± 11.3 vs. 2.6± 4.7, p<0.001) and foot (20.9± 26.3 vs. 6.1± 14.8, p<0.001) but not in the PIP (4.9± 9.7 vs. 2.2± 5.4) or carpal (12.2± 14.4 vs. 8.8± 12.5, p=0.192) compartments (Fig.1). The greatest single-joint difference was found in MCP 2 (1.26± 1.60 vs. 0.27± 0.48) and proximal MTP 5 (2.11± 1.48 vs. 0.44± 0.89, p<0.0001 respectively). Significant differences in relative erosion score were found in the carpal (28± 23% vs. 42± 33%, p=0.017) and foot (44± 26% vs. 27± 34%, p=0.004) compartments.

Conclusion: Sharp-van-der-Heijde score (SHS) is higher in seropositive RA (spRA) than in seronegative RA (snRA). The difference in SHS is significant for the MCP and foot, but not for the carpal or PIP compartments. The single joint difference is greatest in MCP 2 and proximal MTP 5. Considering the relative erosion score (compartment SHS/total SHS), spRA shows a predilection for the foot and snRA for the carpal compartment. The different erosion patterns suggest that pathophysiological processes differ between the forms.

Fig. 1: Erosion distribution between different compartments (PIP, MCP, carpal and foot) for seropositive (spRA) and seronegative (snRA) Rheumatoid Arthritis

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Imaging of Rheumatic Diseases I: Advanced Imaging in RA and Spondyloarthritides

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Magnetic Resonance Imaging (MRI) osteitis and synovitis have been identified as predictors of structural damage progression in rheumatoid arthritis (RA)[1,2], but the predictive value of MRI joint space narrowing (JSN, a measure of cartilage damage) and tenosynovitis needs further investigation. The purpose was to investigate the predictive value of baseline MRI inflammatory and damage parameters on 2 year MRI and X-ray damage progression in an early RA (eRA) cohort following a non biologic treat-to-target strategy.

Methods: In 129 eRA (<6months) patients from the double-blind randomized CIMESTRA trial (randomized to receive methotrexate, intraarticular betamethasone and cyclosporine (CYA)/placebo CYA) contrast-enhanced MRIs of the non-dominant wrist and X-rays of hands and feet were performed at baseline and after 2 years. MRIs were evaluated according to the RAMRIS scoring system for osteitis, synovitis, erosion, JSN, and for tenosynovitis according to Haavardsholm et al[3]. X-rays were evaluated according to the Sharp/van der Heijde method. MRIs and X-rays were read with known chronology by two experienced radiologists. Potential predictive baseline variables (MRI osteitis, synovitis, tenosynovitis, erosion, JSN, X-ray erosion and JSN, DAS28, gender, age, anti-CCP, smoking status) were tested in univariate linear regression analyses with 2-year change in MRI total damage score, Total Sharp Score (TSS), and MRI and X-ray JSN and erosion scores as dependent variables. Significant variables ($p<0.05$) were included in multiple regression analyses with backward selection.

Results: Independent predictors of structural damage progression are presented in table 1. If MRI JSN was not included in the model, MRI osteitis score was statistically significant independent predictor of X-ray progression (coefficient 0.32, p=0.001, vs. TSS progression).

Table 1

Final Models

	Dependent variables					
	MRI variables			X-ray variables		
	MRI erosion	MRI JSN	MRI total damage score	X-ray erosion	X-ray JSN	TSS
Explanatory variables	Coefficient(CI)	Coefficient(CI)	Coefficient(CI)	Coefficient(CI)	Coefficient(CI)	Coefficient(CI)
MRI synovitis	0.23 (0.06-0.31) p=0.006		0.18 (0.03-0.36) p=0.023			
MRI JSN	0.39 (0.27-0.68) p<0.001	0.66 (0.35-0.54) p<0.001	0.54 (0.66-1.17) p<0.001	0.41 (0.89-2.15) p<0.001	0.24 (0.12-0.83) p<0.001	0.39 (1.10-2.82) p<0.001

MRI total damage score: sum score of MRI erosion and JSN; CI: Confidence Interval

Conclusion: This trial is the first to report that MRI JSN independently predicts both X-ray and MRI damage progression in early RA. Further studies are needed to confirm early MRI-determined cartilage damage as predictor of progressive joint destruction in RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases I: Advanced Imaging in RA and Spondyloarthritides
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Plasma cytokines include tumour necrosis factor (TNF)-ƒ¿, interleukin (IL)-1 and IL-6 play important roles in the pathogenesis of rheumatoid arthritis (RA) causing not only joint inflammation but also joint destruction. On the other hand, magnetic resonance imaging (MRI) can visualize fine distinction in the inflamed joint sensitively, and bone erosions on MRI are well relevant with prospective tangible erosions on X-ray. The aim of this study is to examine the relationship of pretreatment plasma inflammatory cytokines with MRI bone erosion progression in patients with RA patients.

Methods: We enrolled 89 newly diagnosed, untreated patients with RA. Contrast MRIs of the dominant hand and X-ray of hands and feet at baseline and 1 year later were performed. MR images were scored according to the latest OMERACT rheumatoid arthritis magnetic imaging score (RAMRIS) for synovitis, osteitis, bone erosions. Changes in MRI erosion scores (DRAMRIS erosion) from baseline to 1 year were calculated. X-ray were also assessed using the modified total Sharp score (mTSS). Plasma levels of ten cytokines were measured by electrochemiluminescence assay.

Results: The median age and symptom duration were 58 years and 3.2 months, respectively. The mean DAS28 decreased from 4.8 at baseline to 2.4 at 1 year. Progression in bone erosion were observed more frequently in MRI than in X-ray (54% in MRI vs 21% in X-ray, p = 0.005). Multiple linear regression model with baseline DAS28, seropositivity (positive for anti-CCP or RF), CRP and cytokines including IL-6, VEGF and IL-1ƒÀ as an independent variable revealed that baseline IL-6 levels and seropositivity were independent predictive factors for 1 year DRAMRIS erosion score. Receiver operating characteristic curve found the baseline IL-6 level of 7.6 pg/ml discriminated MRI erosion progression during 1 year with AUC of 0.82 with sensitivity of 69% and specificity of 95% (figure 1). We divided the patients into 4 groups (high, moderate-high, moderate-low and low) according to baseline IL-6 levels. The RAMRIS erosion progression was significantly dependent on baseline IL-6 concentration (p<0.001). While erosions in MRI significantly increased in high and moderate-high IL-6 groups (p < 0.05), mod-low and low IL-6 group showed slight improvement of MRI erosion at 1 year (figure 2)

Conclusion: In newly diagnosed, untreated RA patients, baseline plasma IL-6 levels predict 1-year MRI bone erosion progression in patients with RA. Figure 1

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases I: Advanced Imaging in RA and Spondyloarthritides
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Tenosynovitis in the hand occurs frequently and early in rheumatoid arthritis (RA) and sensitive outcome measures are important to assess and monitor the inflammatory activity. Magnetic resonance imaging (MRI) can visualize tenosynovitis and a semiquantitative scoring system for tenosynovitis in the hand has previously been suggested[1]. In a multi-reader exercise, we aimed to assess the intra- and inter-reader agreement and responsiveness of a proposed OMERACT MRI tenosynovitis scoring system in the wrist and metacarpophalangeal (MCP) flexor tendons in the hands of RA patients.

Methods: Axial T1-weighted pre- and post-contrast fat-sat MRIs (0.8mm slice thickness) of the hand of 43 patients initiating rituximab therapy were obtained at baseline and after 3 (n=5), 6 (n=8), 9 (n=15) or 12 (n=15) months. The MRIs were read and scored twice on separate days with intermediate re-anonymization by 4 readers blinded to patient data but not to chronology. The tendons of 6 extensor and

3 flexor tendon compartments of the wrist and 4 flexor tendon compartments of the 2nd to 5th MCP joints were assessed. Tenosynovitis was defined as peritendinous effusion (PE) or post-contrast tenosynovial enhancement (PTE) on 3 consecutive slices. Pathologies were measured perpendicularly to the tendon at the thickest point of the effused or enhanced tenosynovium. Tenosynovitis was scored as follows: 0: no, 1: >0 but <1.5mm, 2: ≥1.5 but <3mm, 3: ≥3mm PE or PTE. Change in score over time was assessed using descriptive statistics and the Wilcoxon signed-rank test. Intra- and inter-reader agreement was calculated using intra-class correlation coefficients (ICC), percentage of exact and close agreement (PEA and PCA) and the smallest detectable change (SDC). Responsiveness to change was assessed using standardized response mean (SRM).

Results: The mean (SD) change in score between baseline and follow-up was -1.38 (2.84) for wrist, -0.94 (1.85) for MCP flexor tendons and -2.31 (4.63) for total score (all p<0.01). Intra- and inter-reader ICC for status scores were very good in all readers, except baseline scores in the MCP region in 1 reader. Intra-reader ICC for change scores were good to very good in all readers, and inter-reader ICC for status and change scores were very good in all readers. Intra-reader PEA for status and change scores was above 57% and PCA above 95% for all parameters. Inter-reader PEA was above 40% and PCA above 81% for all parameters. Intra-reader SDC was equal or below 3.0 and inter-reader SDC was below 2.0 in all readers. SRM was small to moderate (table 1).

Conclusion: The proposed OMERACT tenosynovitis scoring system showed high intra- and inter-reader agreement and small to moderate responsiveness for the wrist and MCP tendons and is a reliable tool for MRI-assessment of tenosynovitis in the RA hand. [1]Haavardsholm et al. Ann Rheum Dis 2007;66(9):1216-20

Table 1 Intra- and inter-reader agreement and responsiveness to change for the wrist, metacarpophalangeal (MCP) flexor tendons and total score

INTRA-READER		Wrist			MCP flexor tendons			Total score

	SDC			2.9			1.8			2.9
	SRM			0.52			0.47			0.58
INTER-READER	AvmICC	0.94	0.90	0.91	0.96	0.97	0.94	0.96	0.94	0.94
	PEA	42.5	48.1	59.0	41.6	48.7	42.4	42.6	48.6	47.8
	PCA	81.1	83.2	84.0	86.9	89.8	87.2	82.9	86.5	85.0
	SDC			1.7			0.8			1.8
	SRM			0.44			0.47			0.50

Single measure intra-class correlation coefficients (SmICC) and average measure intra-class correlation coefficients (AvmICC) were calculated for intra-reader and inter-reader agreement respectively. An ICC ≥0.50 was considered good and an ICC ≥0.80 was considered very good. Percentage of exact agreement (PEA) was defined as the percentage of tendons given the same score within and between the readers (expressed as the average percentage for wrist, MCP tendons and total scores). Percentage of close agreement (PCA) was defined as the percentage of tendons given scores that differed ≤1 within and between the readers (expressed as the average percentage for wrist, MCP tendons and total scores). Smallest detectable change (SDC) was calculated for change scores and expresses the minimal amount of change that can be deemed as true change and not measurement error. Standardized response mean (SRM) was calculated by dividing the mean change score with the standard deviation of the change score.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases I: Advanced Imaging in RA and Spondyloarthritides
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: A third of cases of skin psoriasis are complicated by potentially incapacitating psoriatic arthritis (PsA). Nail psoriasis, especially onycholysis, is present in more than 70% of PsA and the risk of developing PsA is significantly higher in patients with nail involvement (OR = 2.24; 95% CI [1.26-3.98]) (*Wilson FC. Arthritis Rheumatism 2009*). In this study, we wanted to test the hypothesis that onycholysis, in patients without PsA, may be a potential clinical marker of subclinical distal pathogenic enthesopathy and thus may present early bone microstructural alterations of the distal interphalangeal joint.

Methods: We compared bone microstructural damages (erosions, osteophytes) of the distal interphalangeal joint using High Resolution Peripheral Quantitative Computed Tomography imaging HR-pQCT (XtremCT Scanco, Switzerland®) in patients with psoriatic onycholysis without PsA (ONY) and in patients with cutaneous psoriasis only without PsA or nail psoriasis (PsO). We used, as reference for bone features, patients with peripheral psoriatic arthritis (PsA) and healthy gender/age-matched controls. Ultrasonography of the target distal interphalangeal joint was used to assess enthesopathy (finger extensor tendon thickness), synovitis, and nail apparatus (nail plate and matrix).

Results: Between 2013 and 2016, 80 patients were recruited in the four following groups (20 per group): controls, ONY, PsO and PsA. Mean±SD age of the participants was 45.7±4.3 years. Nail plate thickness, matrix and finger extensor tendon thickness were increased in ONY versus PsO patients. Erosions and synovitis were observed in respectively 8.3% and 4.1% of ONY patients but never in PsO patients. By HR-pQCT, ONY patients were associated with a mean number of 3.6±0.77 erosions of the distal interphalangeal joint versus only 0.21±0.1 in PsO patients (p=0.035). PsA patients presented several V-shaped, Omega-shaped, U-shaped erosions and osteophytes.

Conclusion: We describe for the first time the existence of bone erosions in interphalangeal distal joints of patients with psoriatic onycholysis. These findings support the pathogenic role of enthesopathy in joint involvement of PsA. These data underly the potential severity of onycholysis compared to isolated cutaneous psoriasis only. Onycholysis may be considered as a clinical marker for patients with psoriasis who have an increased risk of joint destruction.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Imaging of Rheumatic Diseases I: Advanced Imaging in RA and Spondyloarthritides
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Sacroiliitis, as detected by plain radiographs of the sacroiliac joints (SIJ), has been reported in a third of the psoriatic arthritis (PsA) population. (1) Referred to as radiographic axial spondyloarthritis (r-axSpA), this finding represents a late axial disease. For detection of an *non –radiographic* (nr-axSpA) axial disease in the presence of normal pelvic XR (non-radiographic axSpA – nr-axSpA), MRI is commonly applied. Yet, there is limited data on the frequency of nr-axSpA in the PsA population. The purpose of our study was to establish the prevalence of nr-axSpA in a consecutively recruited observational cohort of PsA.

Methods: Adult PsA patients from the Tel Aviv Medical Center Rheumatology Clinic were consecutively recruited into the study. All patients underwent clinical evaluation, CRP and HLA-B27 tests, plain XR of the SIJs and MRI of the entire spine and SIJs. Spinal sagittal T1-W and STIR images of the spine and semi-coronal T1-W and T2-W with fat saturation of the SIJs were performed. Radiographs were independently read by two musculoskeletal radiologists (NY criteria)(2), and MRI examinations were interpreted by a third musculoskeletal radiologist using ASAS criteria and global (both structural and acute) SIJ scoring(3), all blinded to the clinical data. Data were analyzed by SPPS Version 20.0. Categorical descriptive data were presented as absolute values with percentages and continuous data as mean (standard deviation). Group comparisons of categorical data were performed by χ^2-tests and of continuous data by the Mann-Whitney U-test.

Results: Sixty-nine patients were recruited into the study. For 51 patients, all imaging set was available at the time of the interim analysis. Demographic and clinical data is presented in Table 1. All patients but two were HLA-B27 negative. Inter-reader agreement between the two XR readers was good (κ=0.73). Nr-axSpA was detected in 20% of the cohort, and r-axSpA was detected in 23%. 12% of patients demonstrated false positive sacroiliitis by XR not confirmed by MRI. MRI positive sacroiliitis (ASAS/Global) was detected in 29%/43%, respectively. Extensive psoriasis assessed by PASI was associated with global MRI sacroiliitis presence (*p 0.03*). Clinical indices of peripheral and spinal disease activity did not correlate with MRI sacroiliitis. There was no difference in the sacroiliitis prevalence among male and female sub-groups. Biologic naïve patients demonstrated similar rates of sacroiliitis as patients exposed to biologic therapies.

Conclusion: This is the first study to report the frequency of nr-axSpA (20%) in an observational PsA cohort. Our study also emphasizes the limitations of pelvic XR in diagnosing clinical sacroiliitis. **Table 1. Cohort demographics and clinical data.**

Circulating IgG4 Antibody Secreting Cells Are Better Biomarker of Disease Activity Compared to Serum IgG4 Levels in Patients with IgG4-Related Disease

Arezou Khosroshahi[1], Alessia Corrado[1], Takashi Muraki[2], Shuya Kyu[3], Xiaoqian Wang[4], Ignacio Sanz[5] and F. Eun-Hyung Lee[1], [1]Medicine, Emory University School of Medicine, Atlanta, GA, [2]Pathology, Emory University School of Medicine, Atlanta, GA,

Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a fibro-inflammatory condition with a consistent set of pathological features that affect multiple organ systems. Patients with IgG4-RD typically present with mass lesions in different organs. Clinical and radiologic findings usually resemble malignancy, infection, or other autoimmune diseases making the diagnosis challenging. Up to now, the best marker of the disease is elevated serum IgG4 concentrations; however, many different studies find that this analyte is not a reliable disease biomarker, measured by current immunoassays. We hypothesized that reliance on elevated serum IgG4 concentration fails to identify a significant fraction of patients, at least partly due to assay limitations. Here we describe the direct measurement of IgG4 production by circulating antibody secreting cells (ASCs) as a more reliable biomarker for diagnosis and disease activity monitoring in patients with IgG4-RD.

Methods: This study compared serum IgG4 levels measured by nephelometry assay with frequency of IgG4 ASC in blood measured with IgG4 ELISpot (Enzyme-linked immunospot) assay. We enrolled 30 IgG4-RD patients with various degrees of disease activity, 4 patients with diseases mimicking IgG4-RD, and 7 healthy controls. Using the IgG4-RD Responder Index (RI), where an RI $\geq$ 3 is regarded as active disease, we had 21 patients with active disease. We used multivariate analysis and Pearson correlation for statistical comparison.

Results: Serum IgG4 concentration was elevated in 10 IgG4-RD patients (33%) while increased IgG4/IgG percentages in ELISpots (>5% IgG4/IgG) occurred in 23 patients (76%). All IgG4-RD patients who had serum elevation showed IgG4/IgG >5 % in the ELISpot assay. Among patients who had normal serum IgG4 by nephelometry but elevated number of IgG4 on the ELISpot, 11 out of 13 had active IgG4-RD with IgG4-RD responder index score of $\geq$ 3. Of the patients with active IgG4-RD with RI $\geq$ 3, 16 of 21 (76%) had elevated IgG4/IgG ASC percentages > 5% compared with only 5 out of 21 (23%) with elevated serum IgG4 (r=0.23 P=0.18). Furthermore, among the control group, one subject had elevated serum IgG4 at 176 mg/dl (normal 0-89 mg/dl) but normal Elispot IgG4/IgG percentages 1.2 % (<5%) showing improved specificity.

Conclusion: Circulating IgG4/IgG ASC percentages > 5% is a more sensitive and reliable marker for disease activity in patients with IgG4-RD both for diagnosis and disease activity monitoring. This method overcomes spurious low serum IgG4 levels due to the prozone phenomenon, cell binding and other unknown phenomena. This preliminary study shows that IgG4 ASC ELISpots are sensitive markers for IgG4-RD.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: IgG4-related disease (IgG4-RD) is an immune-mediated condition responsible for fibro-inflammatory lesions that can lead to irreversible damage. No approved therapies for IgG4-RD exist. We report the use of a novel monoclonal antibody, XmAb5871, in IgG4-RD. XmAb5871 is a humanized anti-CD19 antibody with an Fc portion engineered for increased affinity (200- to 400-fold over native IgG) to FcgRIIb, the only Fc receptor on B cells. Co-ligation of CD19 and FcgRIIb leads to downregulation and inhibition of B lineage cells bearing these targets. Reversible inhibition of B cell function without B cell ablation is one potential advantage of this approach.

Methods: The trial is an open-label investigation of XmAb5871 in active IgG4-RD, defined as an IgG4-RD Responder Index of ≥3. XmAb5871 (5 mg/kg) is administered IV every 14 days for 12 doses. Positron emission tomography (PET) scans are performed at baseline and at three months. The primary outcome measure is the proportion of patients on day 169 with decrease in the IgG4-RD RI ≥2 compared to baseline. Glucocorticoids are permitted but not required at entry and must be discontinued by two months. Other immunosuppressive medications are not allowed. Mechanistic studies are performed at baseline and at selected intervals.

Results: The first patient was infused in March 2016. As of June 2016, 8 of the targeted 15 patients have been enrolled. The mean age among the 8 patients enrolled to date is 58 years (range: 47 to 77 years). Four patients are male, 4 female. All are Caucasian. Seven of the 8 patients had elevated serum IgG4 concentrations at screen, with a mean serum IgG4 of 526 mg/dL (range: 27 – 1877; normal < 86 mg/dL). The mean baseline IgG4-RD RI score was 12.4 (range: 3 – 22), with active inflammatory disease in at least one organ system (range: 1-8, mean 5). The organs most commonly affected were submandibular glands (7 patients), parotid glands (6), lymph nodes (6), lacrimal glands (5). Two patients had bile duct involvement and kidneys, lungs, pancreas were affected in 1 each. Six of the 8 patients are being treated with XmAb5871 alone. One patient was started on prednisone 40 mg/day concomitantly with enrollment because of serious IgG4-related kidney disease (tubulointerstitial nephritis; serum Cr 2.6 mg/dL). PET scans at baseline identified disease involvement of organs that had not been suspected by other diagnostic means in 5 of 8 patients. Six of 6 patients with major salivary or lacrimal gland enlargement on physical examination demonstrated improvement on follow-up, some as early as one week. One patient had been on glucocorticoid treatment for 2 years and was on prednisone 15 mg/day at baseline, but was able to discontinue prednisone by 2 months after baseline treatment. Three patients experienced minor, transient gastrointestinal side-effects during the 1st infusion. One patient had GI symptoms on the 5thinfusion. This patient also developed symptoms suggestive of serum sickness and has discontinued the study.

Conclusion: XmAb5871, which targets the B cell lineage through reversible co-ligation of CD19 and FcgRIIb, may be a promising treatment approach for IgG4-RD.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: IgG4-related disease (IgG4-RD) is an immune-mediated condition responsible for fibro-inflammatory lesions that can affect nearly any organ and lead to irreversible damage. To evaluate the efficacy of treatments, a tool understood and adopted by many types of specialists that can assess disease activity accurately and reliably across various organs is necessary. The IgG4-RD Responder Index (RI) was developed for this purpose. We sought to validate the RI among an international, multi-specialty group of IgG4-RD experts.

Methods: The RI requires participants to assess disease activity in 25 domains (24 disease sites and 1 domain for constitutional symptoms). Completing the instrument takes approximately three minutes per patient visit. Scoring incorporates higher weights for "urgent" manifestations and those that worsened despite treatment. After completing a training exercise, 25 participants were asked to review 12 written cases describing patients with diverse manifestations of IgG4-RD. The vignettes were supplemented by photographs, radiology images, and pictures of pathology findings. For each case, participants calculated the RI as well as a physician global assessment (PGA) of disease activity on a 100mm scale. We then assessed: 1) consistency (the inter-observer reliability) of the RI and PGA using intra-class correlation coefficients (ICCs); 2) precision (the inter-observer variation) by applying the signed rank test to the differences between the coefficients of variation for the RI and PGA of each case; 3) construct validity by determining the correlation between the RI and the PGA using the Spearman's rank correlation coefficient; 4) and sensitivity to change (discriminant validity) using a paired T-test comparing RI scores before and after treatment in six consecutive real-life cases as well as by assessing the Spearman's rank correlation coefficient when comparing the change in RI and PGA before and after treatment.

Results: Twenty five participants completed the study, including 11 rheumatologists, 5 gastroenterologists, 4 immunologists, 2 pulmonologists, 2 nephrologists, and 1 internist. Experts from the Canada, China, Italy, France, Japan, South Korea, Turkey, the UK, and the US participated. Correlations (construct validity) between the RI and PGA were high ($r=0.9$, $P<0.0001$). The consistency (interobserver reliability) was higher for the RI ($r=0.88$) than the PGA ($r=0.83$) as assessed using ICCs. The precision (interobserver variation) of the RI and PGA was similar ($P=1$). The RI was sensitive to change (discriminant validity). Following treatment (median 46.5 days, IQR 38-54 days), there was a significant improvement in the RI ($P=0.007$) and a high correlation between the change in RI and PGA ($r=0.8$, $P=0.04$).

Conclusion: In this international, multi-specialty study, we found that the RI is a valid and reliable disease activity assessment tool for IgG4-RD. The performance of the RI was assessed in patients with diverse manifestations of IgG4-RD in both cross-sectional and longitudinal phases. The RI can be used to determine the response to treatment and will be an important tool for international studies investigating the effectiveness of IgG4-RD treatment.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Familial Mediterranean fever (FMF) is the most common autoinflammatory disease and colchicine is the mainstay of treatment. Around 30-45% of FMF patients were reported to have attacks despite the colchicine treatment. Currently the data regarding the treatment of colchicine unresponsive or intolerant FMF patients is limited and the most promising alternatives seem to be anti-interleukin-1 (IL1) agents. Herein we report our experience in the off-label use of anti-IL1 agents in a large group of FMF patients.

Methods: This study was conducted by the means of Turkish Multi-centered Investigations Platform in Rheumatology (TULIP). Twenty-one centers from different geographical regions of Turkey were included in the study. Medical records of all FMF patients who used anti-IL1 treatment for at least 6 months were reviewed. Demographics, disease related clinical and laboratory data were collected by a web based structured questionnaire.

Results: In total 135 FMF patients (69 [51%] male, mean age 34.1 [range; 18-67] years) were included in the analysis. In our FMF patients the mean age at symptom onset was 12.3 (range; 1-45) and at diagnosis was 20.1 (3-60) years. 98 patients were carrying M694V mutation. The mean colchicine dose was 1.8 (1.0-4.0) mg/day and attack frequency was reported to be decreased from a mean of 26/years (3-96) to 13.9/years (0-96). 116 out of 135 patients were put on anakinra and 19 on canakinumab treatment due to colchicine resistance in 114 patients, amyloidosis in 15 and other reasons in 4 patients. During the median 14.5 (6-69) months of treatment period; yearly attack frequency was significantly reduced (P<0.001), and 74 (54%) patients reported no FMF attacks. Besides serum levels of C-reactive protein, erythrocyte sedimentation rate, and 24 hours urinary protein excretion were significantly reduced, as shown in table. Although serum creatinine levels were also improved with anti-IL1 treatment, it was not reached to statistical significance.

Conclusion: The results of this large study showed that anti-IL1 treatment is an effective alternative for not only controlling the attacks but also decreasing the proteinuria in quite challenging FMF patients.

	Before treatment	After treatment	*P*
Attacks/year, mean (range)	16.8 (0-96)	2.1 (0-24)	**<0.001**
CRP level (mg/L), mean (range)	34.5 (0.14-220)	6.6 (0-52)	**<0.001**
ESR (mm/h), mean (range)	45.2 (2-129)	15.6 (0-154)	**<0.001**
24 hour urinary protein (mg), mean (range)	2746.7 (20-19610)	1769.6 (0-18500)	**<0.001**
Serum creatinine (mg/dL), mean (range)	1.68 (0.3-10.2)	1.18 (0.4-7.7)	0.907

Session Date: Sunday, November 13, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disease characterized by self-limiting febrile attacks associated with serosal or synovial inflammation as well as increased risk for AA-amyloidosis. There are limited data about kidney transplantation (KT) in FMF patients with amyloidosis regarding the post-transplant course of FMF and amyloidosis. This study aims to investigate the efficacy, safety and long term outcome of IL-1 receptor antagonist (IL-1RA, anakinra) treatment in FMF patients with amyloidosis who underwent KT. **Methods:** We screened our database for FMF patients diagnosed with amyloidosis between 1978-2016, and reviewed charts of those who underwent kidney transplantation (KT). Seventeen FMF patients with KT and receiving anakinra constituted the study group. All patients were also receiving colchicine treatment. All patients were on maintenance immunosuppressive therapy. Partial response was defined as ≥50% decrease in proteinuria whereas complete response was defined as <0.3 gr/d proteinuria.

Results: Demographic features of the patients are shown in Table. The percentage of irregular/inadequate colchicine use in patients who developed amyloidosis was 41%. Mean age of transplant recipients at the time of transplantation was 32±7 (22-51). The reasons to start anakinra treatment in the post-transplant FMF group included inadequate response to colchicine treatment (n=13), persistently elevated CRP (n=8), and persistence of proteinuria (n=3). Recurrence of renal amyloidosis in transplant kidney was noted in four patients. Mean GFR at the last follow-up was 62±30(15-142) mL/min. Attack frequency was significantly decreased in patients after anakinra treatment Table2. After initiation of anakinra treatment, CRP decreased to normal values in 50% of the patients, and partial and complete response were achieved in only two patients with proteinuria. The proteinuria levels remained stable in three patients under colchicine and anakinra treatment. Serious infection required hospitalization was observed in two patients (pneumonia and pyelonephritis) treated with anakinra on

top of other immunosuppressives, and the patient with pneumonia died due to septic shock. Severe neutropenia (<500/mm^3) developed in one patient after three years of anakinra therapy without serious complications. **Table-1.** Demographic and Clinical Parameters of FMF Patients Who Underwent KT.

Male/Female ratio (n)	12/5
Age (mean±SD, range)	39±10 (24-59)
Age of onset (mean±SD, range)	10±7 (2-26)
Age of diagnosis (mean±SD, range)	21±11 (8-48)
Family history of FMF, n (%)	10 (58%)
Family history of amyloidosis, n (%)	1 (6%)
Disease follow-up duration (mo)	32±50 (3-216)
Time to diagnosis (mo)	140±137 (6-504)
Arthritis at presentation n(%)	9 (53%)
MEFV mutation, n (%)	M694V, 11 (100%)
Duration of IL-1RA (mo)	21±16 (4-51)
High CRP rate during attack free periods n (%)	9 (53%)
Mean colchicine doses after KT (mg)	1.1±0.4 (0.5-2)

Abbreviations: FMF, Familial Mediterranean Fever; mo, months; CRP, C-reactive protein; KT, kidney transplantation **Table-2. Attack frequency under anakinra treatment**

Patients	Anakinra Duration (months)	Before anakinra attack frequency /month	After anakinra attack frequency / /month
1	3	1	0
2	3	2	0
3	4	0	0
4	4	0,5	0
5	4	0	0
6	7	1	0
7	11	0	0
8	14	1	0
9	15	1	0
10	24	1	0
11	27	0	0
12	31	3	1
13	36	2	0
14	36	1	0
15	37	0,7	0
16	48	1	0
17	51	1,3	0

Conclusion: Anakinra treatment seems to be effective and safe in refractory FMF patients with amyloidosis who underwent KT

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Mutations in *NLRP3* cause 3 different dominantly inherited autoinflammatory syndromes: familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and neonatal-onset multisystem inflammatory disease (NOMID). All three manifest urticarial rash and episodic or in some cases continuous elevation of acute phase reactants. Here we describe a novel *NLRP3* mutation that has been identified in two separate families and presents with a predominantly neurological phenotype.

Methods: Two families presented to the NIH Otolaryngology Clinic with a history of sensorineural hearing loss. Patients from both families underwent genetic testing, a thorough rheumatologic evaluation, measurements of acute phase inflammatory markers, and cytokine profiling. Patients underwent evaluation by neuro-otology, MRI of the inner ear with the fluid-attenuation inversion recovery (MRI-FLAIR) protocol, and audiograms. Neurology evaluation and lumbar puncture was performed on patients with neurological symptoms. Peripheral blood leukocytes from patients and matched healthy controls were studied for constitutive NLRP3 inflammasome activation.

Results: Dideoxy sequence analysis of *NLRP3* identified a heterozygous transition c.2753G>A in exon 7, predicted to result in the missense substitution p.Arg918Gln (also known as p.Arg920Gln) in the leucine rich repeat domain of the NLRP3 protein, that co-segregated with hearing loss in both families. Patients from both families had either mildly elevated or normal inflammatory markers in the peripheral blood. Affected members of the first family had no dermatologic or rheumatologic manifestations while those in the second family exhibited urticariform maculopapular rash, oral ulcers, and lymphadenopathy. MRI of the inner ear showed active and chronic inflammation in the labyrinth and cochlea of all patients, and audiograms from the second family had worsened in the last year. A member of the first family with progressive lower extremity weakness showed a strong predominance of innate immune activation, but no evidence of intrathecal activation of adaptive immunity in the cerebrospinal fluid. Patients from both families exhibited evidence of constitutive NLRP3 inflammasome activation. Based on these findings, the father and two older siblings from the second family were started on treatment with anakinra. Follow up audiograms three months after treatment was started showed improvement in all three patients. The most severely affected member of the first family was started on anakinra and within three weeks started to normalize her deep tendon reflexes.

Conclusion: The R918Q *NLRP3* mutation is associated with a distinct phenotype, relative to other patients with CAPS. Nevertheless, initial data suggest a favorable response to IL-1 inhibition.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Juvenile Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Magnetic resonance imaging (MRI) is the most attractive imaging modality for the investigation of patients with juvenile arthritis (JIA). Musculoskeletal ultrasound (MSUS) has intuitive advantages over MRI including noninvasiveness, low cost, ability to scan multiple joints at once, repeatability and high patient acceptability. The aim of the study was to compare these imaging modalities and to evaluate whether MSUS might replace MRI in the management of JIA in a daily setting.

Methods: All consecutive JIA patients who performed a joint MRI at the study unit over the last 2 years were included. The main clinical indications for MRI were: 1) to quantify disease activity, 2) to confirm disease remission, 3) to evaluate structural damage. The joint assessed by MRI was scanned on the same day with MSUS; the sonographer was blind to MRI's results. MR and MSUS pathological findings were assessed based on the OMERACT RAMRIS and MSUS definitions and scores. Concordance between MR and MSUS was tested using Cohen's kappa coefficient and Bland and Altman.

Results:

A total of 101 JIA patients (median age 13.5 years, median disease duration 7.2 years) were included. Overall, 33 patients were imaged in the ankle, 26 in the wrist, 20 in the hip, 10 in the temporomandibular joints (TMJs), 10 in the knee and 2 in the shoulder. Fifty patients had clinically active arthritis; both imaging modalities confirmed active disease in 36/50 (72%) patients; 14/50 (28%) patients had no signs of active disease on MSUS, but only 9 of them showed inactivity on MRI. Concordance between MRI and MSUS for evaluating disease activity was substantial (k=0.72) for the joint recesses and almost perfect (k=0.81) for the tendons. The mean differences (95 %-limits of agreement) between MRI and MSUS were 0.56 (-7.1 to 8.21) for the wrist and 4.8 (-5.85 to 15.38) for the ankle, resulting in an acceptable agreement of these imaging techniques in quantifying disease activity. The concordance was moderate (k=0.56) for the hip. In 51 patients, the imaged joint was clinically inactive. MRI and MSUS confirmed remission in 23/51 (45%) patients, whereas both imaging modalities revealed active disease in 16/51 (31%) patients. In the remaining 12 (24%) patients, persistent synovitis was detected only on MRI. Concordance between MRI and MSUS for evaluating remission was moderate (k=0.53). Major discrepancies between MRI and MSUS were found for the TMJ and hip joints. MRI and MSUS agreed on the presence of structural damage in 11 out of 13 patients (85%) for which MRI was requested for evaluating joint damage.

Conclusion: In patients with clinically active disease, MSUS performs as well as MR not only in detecting but also in quantifying disease activity, especially in the wrist. In patients in remission the concordance between MSUS and MR was acceptable, suggesting the use of MSUS as a first-line imaging modality. In patients with long disease duration and established structural damage MSUS is as sensitive as MR in detecting bone damage. References Colebatch-Bourn AN et al. EULAR-PReS points to consider for the use of imaging in the diagnosis and management of juvenile idiopathic arthritis in clinical practice. Ann Rheum Dis. 2015;74:1946-57.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Juvenile Arthritis

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: First-line treatment for Lyme arthritis is fairly standardized, but second-line strategies are more variable. We compared the effectiveness of oral antibiotics, intra-articular glucocorticoid injections (IAGC), and intravenous (IV) antibiotics in second-line regimens for pediatric Lyme arthritis.

Methods: We performed a retrospective cohort study of children age ≤18 seen in 3 pediatric rheumatology clinics for Western blot-confirmed Lyme arthritis. We limited the cohort to children who began second-line therapy ≤4 months after starting antibiotics, a timeline consistent with usual practice at these sites. Second-line strategies were: 1) a second course of oral antibiotics alone, 2) IAGC with or without oral antibiotics, or 3) a course of IV antibiotics. The primary outcome was development of antibiotic-refractory Lyme arthritis (ARLA), defined as persistent arthritis ≥2 months after completing ≥56 days of oral antibiotics or ≥14 days of IV antibiotics, per IDSA/Red Book guidelines. The secondary outcome was rate of clinical resolution of arthritis. We compared second-line treatment strategies using logistic regression for ARLA and Cox regression for rate of resolution, adjusted for confounders.

Results: There were 129 children with second-line treatment for Lyme arthritis, of whom 42 (33%) developed ARLA: 29/83 (35%) on oral antibiotics alone; 3/18 (17%) with IAGC ± oral antibiotics; and 10/28 (36%) after IV antibiotics. Children who received second-line IAGC or IV antibiotics were more likely female (Table 1). Children whose arthritis markedly worsened after antibiotic initiation were more likely to receive second-line IV antibiotics (P<0.01). After adjusting for sex and worsening arthritis, children who received IAGC ± oral antibiotics appeared to have a decreased risk of developing ARLA compared with children receiving second-line oral antibiotics alone, but this did not meet traditional levels of significance (aOR 0.4, 95% CI 0.1, 1.4, P = 0.14) (Table 2). Similarly, second-line IAGC was associated with non-significantly increased rates of resolution of arthritis (aHR 1.6, 95% CI 0.9, 2.9, P = 0.11). There was no significant difference in the risk of developing ARLA (P=0.55) or rate of resolution (P=0.46) between groups receiving second-line IV or oral antibiotics (Table 2). Results were similar after excluding children whose disease worsened after antibiotic initiation.

Conclusion: Use of second-line intra-articular glucocorticoid injection may hasten the resolution of Lyme arthritis and prevent chronic Lyme arthritis in children. Further study of this strategy in larger cohorts is warranted.

Table 1. Clinical and treatment characteristics of children who received second-line treatment for Lyme arthritis					
Characteristic	**(1) Oral antibiotics alone (N=83)**	**(2) IAGC ± oral antibiotics (N=18)**	**P-value (2) vs. (1)**	**(3) IV antibiotics (N=28)**	**P-value (3) vs. (1)**
Age in years, median (IQR)	12.1 (9.4, 14.5)	11.2 (8.3, 13.7)	0.38	12.2 (10.2, 14.2)	0.77

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Juvenile Arthritis

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) often requires biologic medication to control polyarticular disease courses. This study assesses the pharmacokinetics (PK), efficacy and safety of certolizumab pegol (CZP)±MTX in children and adolescents with moderate to severe polyarticular-course JIA.

Methods: PASCAL (NCT01550003) is an ongoing, multi-center, open-label study for patients (pts) aged 2–<18 years (yrs), weight ≥10 kg, with signs and symptoms of JIA for ≥6 months and prior history of DMARD use. Pts were enrolled from 7 PRCSG-PRINTO countries in North/South America and Russia. Original CZP doses were weight-adjusted based on simulations from a population PK model (adult rheumatoid arthritis [RA] data): pts 10–<20kg received a loading dose (LD; Week [Wk] 0, 2, 4) of CZP 100 mg and maintenance dose (MD; Q2W) of CZP 50 mg; 20–<40 kg, LD CZP 200 mg and MD CZP 100 mg; ≥40 kg, LD CZP 400 mg and MD CZP 200 mg. Interim analyses revealed higher CZP plasma trough concentrations than the target range (C_{trough} geometric mean in adult RA pts: 15.7 µg/mL [95% CI: 14.0–17.7]). Thus, MD was reduced by 50% and additional pts were enrolled with 50% reduction in LD and MD. Non-responder imputation and last observation carried forward were used for binary and continuous efficacy endpoints, respectively.

Results: Of 163 pts: 78 enrolled on the Original Dose Regimen (ODR) with dose reduction as early as Wk 12; 85 pts enrolled on the Reduced Dose Regimen (RDR). Overall, 68.7% were female, median (min, max) age of 12.0 (3, 17) yrs, 2.0 (0.5, 14.7) yrs since diagnosis. At Wk 12, C_{trough} values were higher than target range for ODR pts but largely within range for RDR pts, with lower exposure in 10–<20 kg pts. 15.4% of ODR pts and 28.2% of RDR pts were anti-CZP antibody positive, with no apparent impact on efficacy or safety. At Wk 16, JIA ACR30 responses were achieved by 79.2% of ODR pts and 80.0% of RDR pts. JIA ACR 50/70/90 responses were similar across the two dosing regimens (Table A). Clinically inactive disease (CID) was seen in 2.6% of ODR pts and 9.4% of RDR pts. Improvements were also observed in JADAS-71 score for ODR and RDR pts. Efficacy improvements were maintained through Wk 24 (Table A). The incidence rate (IR) of AEs was similar for ODR and RDR pts, with no new safety signals (Table B). The most common class of AE was infection and infestation. There were 2 deaths among RDR pts (CZP 100 mg): 1 was a road traffic accident in a 16 yr old pt considered unrelated to CZP±MTX, the other occurred post Wk 24 in an 18 yr old Mexican pt and is described by the investigator as hepatic tuberculosis and septic shock, considered related to CZP±MTX treatment at the time of onset.

Conclusion: For JIA pts on RDR, distribution of CZP plasma concentrations fell largely within the range seen in adult RA pts. Clinically-relevant JIA improvement was observed across all weight groups by Wk 16 and maintained to Wk 24. The safety profile of CZP seemed in

Table A: Efficacy outcomes for PASCAL study patients at Week 16 and Week 24 (Full analysis set)

	Original Dose Regimen [a], N=78 [b]		Reduced Dose Regimen, N=85 [c]	
	Wk 16 (n=77)	Wk 24 (n=76)	Wk 16 (n=85)	Wk 24 (n=85)
JIA ACR30, % responders	79.2	72.4	80.0	81.2

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Juvenile Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: IV abatacept (ABA) 10 mg/kg every 4 weeks was well tolerated and effective in reducing the signs and symptoms of polyarticular-course juvenile idiopathic arthritis (pJIA) in patients aged 6–17 years (yrs).[1] SC ABA 125 mg weekly has equivalent therapeutic efficacy and comparable safety to IV ABA in adult patients with RA. Here we assessed SC ABA treatment in patients with active pJIA aged 2–17 yrs.

Methods: Two age cohorts (2–5 and 6–17 yrs) of patients with pJIA with an inadequate response/intolerance to ≥1 DMARD were enrolled in this single-arm, open-label (OL), Phase III pharmacokinetic study (NCT01844518) and received OL SC ABA weekly for 4 months (M) based on body weight tier (10–<25 kg [50 mg ABA]; 25–50 kg [87.5 mg ABA]; >50 kg [125 mg ABA]). JIA-ACR criteria 30 (JIA-ACR30; ACR Pediatric 30) responders at 4M could receive ABA for another 20M. Primary endpoint was ABA steady-state blood trough concentration (C_{minss}) at 4M in the 6–17-yr cohort.

Results: Patients were aged 2–5 yrs (n=32; interim analysis) or 6–17 yrs (n=173; complete 4M/interim 20M analysis; Table 1). Mean (SD) drug exposure duration was 9.8 (4.12) and 11.7 (4.33) M in the 2–5- and 6–17-yr cohorts, respectively (latter comparable to IV ABA exposure)[1]. The target therapeutic C_{minss} of 10 µg/mL at 4M was achieved in the 2–5-yr cohort (mean [SD] C_{minss}: 50.1 [14.2] µg/mL) and the 6–17-yr cohort[2] (42.1 [14.7] µg/mL; Figure). Robust JIA-ACR30/70 and inactive disease (no active joints, physician's global assessment of disease activity <10 mm, CRP <0.6 mg/dL) responses, respectively, were seen at 4M in the 2–5-yr cohort: 86.7, 70.0 and 51.7%, and in the 6–17-yr cohort:[2] 80.9, 52.6 and 29.5%. Safety data are presented in Table 2; no laboratory abnormalities or unexpected safety concerns were reported. Immunogenic responses (anti-drug antibodies) were seen in 3/31 (0 persistent [≥2 consecutive visits]) and in 3/171 (2 [1.2%] persistent) patients in the 2–5- and 6–17-yr cohorts, respectively.

Conclusion: The target therapeutic exposure for SC abatacept of C_{minss} of 10 µg/mL was achieved, and exceeded, in patients with pJIA aged 2–17 yrs (observed>predicted values), with marked improvements in JIA-ACR responses and no new safety concerns compared with that observed in adults or with IV abatacept in pJIA. 1. SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Juvenile Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Treatment response, remission rates and compliance in polyarticular JIA patients treated with adalimumab(ADA), etanercept(ETA), or tocilizumab(TCZ) were analyzed in clinical practice.

Methods: Data from the German BIKER registry were analyzed in all patients with polyarticular JIA who started treatment with ETA, ADA or TCZ from 2011-2015. Baseline patient characteristics, treatment response, safety and drug survival were compared.

Results: : In total 236 patients started ADA, 419 ETA and 74 TCZ, with several differences in baseline patient characteristics (table 1). The baseline JADAS10 scores (mean +/-SD) in the ADA/ETA/TCZ cohorts were 12.1+/-7.6, 13.8+/-7.1 and 15.1+/-7.4, respectively (ADA vs ETA $p<0.004$), and the CHAQ-disability index scores were 0.43 +/-0.58, 0.59 +/- 0.6 and 0.63+/-0.55 (ADA vs ETA $p<0.001$). Uveitis history was more frequent in the ADA cohort (OR 5.73; $p<0.0001$). PedACR30/50/70/90 criterion improvement after 3 months of treatment was achieved by 69%/60%/42%/24% in the ETA cohort, 68%/61%/44%/27% in the ADA cohort and 61%/51%/33%/ 25% in the TCZ cohort. At 12 months, JADAS minimal disease activity was achieved in 57.2%/68.6%/60.5% and JADAS remission in 30.3%/44.4%/21.1% patients in the ADA/ETA/TCZ cohorts, respectively. ETA was used as a first biologic for 374 patients, ADA for 122 patients and TCZ for 13 patients. There were no important differences in efficacy between first and second-line use of the biologics. A total of 60.4%/49.4%/31.1% patients discontinued ADA/ETA/TCZ, respectively (OR for ADA 1.73; $p= 0.006$; OR for TCZ 0.46; $p=0.004$). The drug survival rates did not differ significantly for patients on biologic monotherapy compared with combination therapy with methotrexate. Over 4 years of observation in the ETA/ADA/TCZ cohorts 996/386/103 adverse events, and 148/119/26 serious adverse events, were reported.

Conclusion: In clinical practice, ETA is most frequently used as first-line biologic. ADA/ETA/TCZ showed comparable efficacies toward polyarticular JIA. Remission was achieved more frequently with ETA and TOC than with ADA. Overall, tolerance was acceptable. Interestingly, compliance was highest with TCZ and lowest with ADA. Because the patient cohorts differed at baseline, these results are preliminary and demonstrate the need for well-controlled head-to-head studies for confirmation. **Table 1 Patient characteristics and response**

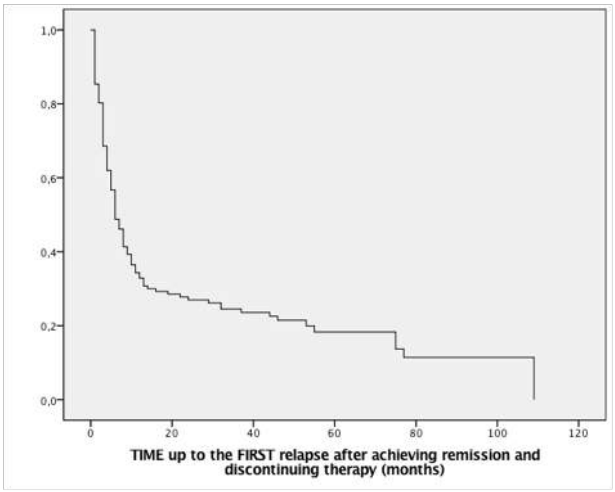
SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Juvenile Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Information regarding the history of patients with JIA after systemic treatment withdrawal would be helpful in driving the choice of duration therapy. While some informations in this regard exist for second-line drugs (eg methotrexate), studies on biologics are lacking. Aim of our study was to assess the time on remission after discontinuing biologic therapy in a retrospective, comparative, multicenter, cohort study of patients with JIA,

Methods: Among 349 JIA patients followed in three tertiary care centres and treated with biologics (started before age 18 y), 135 (103 F, 32 M; median age 15 years) achieved remission and could discontinue such treatment. Only first cycle of biologics was considered for this study: 87 received Etanercept, 27 Adalimumab, 12 Infliximab, 7 Anakinra, 1 Rituximab, and 1 Abatacept. Primary outcome was to assess, once remission was achieved, the time on remission up to the first flare after discontinuing treatment. Time to achieve remission once biologic drug was started, corticosteroid usage, and time on remission on therapy before discontinuing all treatments were also considered, along with demographic, clinical, and laboratory data. Mann–Whitney U-test, Wilcoxon signed-rank test for paired samples, chi-square, and FisherÕs exact test, when appropriate, were used to compare data. Pearson and Spearman correlation tests were used to determine correlation coefficients for different variables. In order to identify predictors of outcome Cox regression model and Kaplan–Meier curves were constructed, each one at mean of entered covariates.

Results: The vast majority of enrolled patients flared after stopping treatment with biologics (102/135, 75.6%) with a median follow-up time on remission of 6 months (range 1–109) [Figure1]. Considering the time point one year after treatment discontinuation 43/135 (31.9%) patients were still in remission. For this group, remission lasted for a median period of 53 months (range 12-109): 30/48 with polyarticular onset, 7/27 oligoarticular extended, 6/35 oligoarticular persistent, 2/6 enthesitis-related arthritis (ERA), 2/7 psoriatic arthritis, and 8/12 systemic onset JIA. A higher probability of maintaining remission after discontinuing treatment was present in systemic onset disease and in ERA compared to the rest of JIA patients (Mantel-Cox χ^2 14.58, $p<0.012$) [Figure 2]. ANA positivity was associated with a higher probability of flare (Mantel-Cox χ^2 4.17, $p<0.04$). Patients who received biologics > 2 years after achieving remission had a higher probability of maintaining such remission off therapy (median 21.74 ±3.4 months vs 13.4 ±2.3; Mantel-Cox χ^2 6.86, $p<0.009$). No other clinical variable, including total length of treatment and type of treatment, resulted significantly associated with a long-lasting remission.

Conclusion: Even if in a retrospective study, we showed that patients with ANA positivity and those who stop treatment before two years of remission have a higher chance of relapsing after biologic withdrawal, and that patients with systemic onset disease and ERA are less



likely to flare.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Treatment Strategies
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: According to national guidelines issued in May 2015, a non-medical switch from originator infliximab (IFX) (Remicade) to biosimilar Remsima was conducted in all Danish patients with inflammatory rheumatic diseases treated in routine care. We aimed to investigate the clinical outcomes in Remicade-treated patients (pts) with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthrits (AxSpA) who were switched to Remsima and monitored prospectively in the Danish nationwide quality registry, DANBIO.

Methods: Patients who switched from Remicade to Remisma before Feb 1st 2016 and who had available data on treatment outcomes in DANBIO were included. In each patient, disease activity at 3 mths before switch (pre-switch) (defined as between minus 180 and minus 30 days before switch), at the time of switch (-30 days before to 6 days after), after 3 mths (70 to 120 days after switch) (post-switch) and changes over time (Dpre-switch and Dpost-switch) were calculated. Disease flare was defined as DDAS28≥0.6, DDAS28≥1.2 (in RA and PsA) or DASDAS≥1.3 (AxSpA). Reasons for withdrawal (adverse events (AE), lack of effect (LOE) or other) were registered. Multivariable Cox regression analyses stratified according to diagnosis (RA, PsA or AxSpA) were used to identify baseline characteristics (gender, age, use of methotrexate (yes-no), Remsima dosing interval, Remsima dose (mg/kg), patient's global score (Visual analogue scale from 0-100mm, VAS)) associated with Remsima treatment adherence. Numbers are medians (interquartile ranges) unless otherwise stated.

Results: 768 of 792 switching pts (97%) had available data regarding disease activity after switching. 52% were women, age (56 (46-66)yrs) (Table). Prior Remicade treatment duration was 6.6 (3.9-9.4) yrs, and in 75% of patients it was the first biological treatment. Median follow-up time after switching was 336 (297-357) days. Disease activity and disease flare rates remained largely unchanged 3 months prior to versus after the switch (Table 1). At the latest visit after switch, disease activity was for RA: DAS28 2.2 (1.7-3.0) and for axSpA: ASDAS 2.0 (1.2-2.9). Proportion of patients with disease flare pre-/post switch was 25%/21% (DDAS28≥0.6, RA+PsA)(p=0.4), 10%/10% (DDAS28≥1.2,RA+PsA) (p=0.8) and 2%/2% (AxSpA)(p=1.0) (related samples McNemar test). Overall, 117 patients (15%) stopped Remsima treatment between switch and end of follow-up (AE 34, LOE 51, remission 1, death 2, cancer 1, pregnancy 1, other 27). Prior Remicade treatment duration in those who withdrew was 6.0 (2.6-8.9) years and disease activity in those who stopped due to LOE was for RA: DAS28 4.3 (3.1-4.9) and for AxSpA: ASDAS 3 (2.6-3.8). Treatment adherences were similar in RA, PsA and AxSpA (Figure). In multivariable Cox regression analysis, lower baseline VAS patient's global and use of methotrexate was associated with better treatment adherence in RA (Table 2) whereas in AxSpA it was lower baseline VAS global and lower IFX doses (Table 2). No significant baseline predictors were found in PsA.

Conclusion: In 768 patients with inflammatory rheumatic diseases treated with Remicade for >4 years, disease activity was largely unaffected in the majority of patients after non-medical switch to biosimilar Remsima, and the fluctuations 3 months after the switch were comparable to the fluctuations observed in the 3 months prior to the switch. However, several patients (15%) stopped treatment. This warrants further investigation before such a non-medical switch can be recommended.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Treatment Strategies
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: There is interest in tapering or stopping biologic DMARD therapy in RA patients (pts) who have achieved sustained disease control.[1] We report the results from C-EARLY Period 2 (P2), in which pts continuing on certolizumab pegol (CZP; standard and reduced dose-frequency) were compared with pts stopping CZP.

Methods: Pts from C-EARLY Period 1 (P1; NCT01519791)[2] treated with dose-optimized MTX and CZP (200 mg Q2W) or placebo (PBO) who achieved sustained low disease activity (sLDA; DAS28[ESR] ≤3.2 at both Weeks [wks] 40 and 52) entered P2 (NCT01521923),[1] a randomized, double-blind dose withdrawal study. CZP-treated pts were randomized 2:3:2 to CZP standard dose (200 mg Q2W+MTX), reduced dose-frequency (200mg Q4W+MTX) or CZP stopped (PBO+MTX). The primary endpoint was the percentage of pts in maintained (Wks 52–104 without flares) LDA. The hierarchical testing scheme compared CZP standard dose vs CZP stopped; if $p<0.05$ was achieved, then CZP reduced dose-frequency vs CZP stopped was compared. Data presented use imputation: NRI for primary endpoint; LOCF for continuous variables; linear extrapolation for mTSS.

Results: The study was powered assuming 455 CZP-treated pts would achieve sLDA in P1 and enter P2; however, only 293 pts (64%) were eligible and entered P2. 49% CZP standard and 53% reduced dose-frequency pts in sLDA were able to maintain LDA to Wk 104 vs 39% CZP stopped pts ($p=0.112$ and $p<0.05$, respectively; the study did not achieve its primary endpoint). 44% CZP standard and 43% reduced dose-frequency pts were able to maintain remission (DAS28[ESR] <2.6) to Wk 104 vs 33% CZP stopped pts. Overall, a higher proportion of CZP-treated pts (standard and reduced dose-frequency) achieved LDA at Wk 104 vs CZP stopped pts (Figure A). At Wk 104, more pts continuing CZP (standard and reduced dose-frequency) had radiographic non-progression (change from baseline mTSS ≤0.5) vs CZP stopped and MTX alone pts (Figure B). The safety profiles of all 4 groups were similar, with no new safety signals for pts continuing CZP treatment up to 2 years.

Conclusion: The study did not achieve its primary endpoint of maintained LDA at all visits in CZP-treated pts (standard and reduced dose-frequency) vs those who stopped CZP; however, there was a numerical difference between these groups. One possible reason may have been that 36% fewer pts were eligible for P2 than planned, based on the entry criteria. A higher proportion of CZP-treated pts (standard and reduced dose-frequency) achieved LDA and radiographic stabilization compared with those who stopped CZP. Additionally, despite clinical improvement, more pts treated with MTX alone experienced radiographic progression than pts treated with CZP over 2 years.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Treatment Strategies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Low disease activity and remission in rheumatoid arthritis (RA) patients is achieved earlier and in higher frequency when the initial treatment includes a combination of methotrexate (MTX) with corticosteroids or a biologic disease modifying anti-rheumatic drug than MTX alone. However, it is unknown whether persistently good responders to MTX monotherapy have similarly good long-term outcomes than persistently good responders to initial combination therapy. The aim was to compare 10 years disease outcomes of RA patients with persistent low disease activity on MTX monotherapy with patients on initial combination therapy with infliximab or prednisone and sulfasalazine.

Methods: RA patients with 10 years follow-up from the BeSt study were analyzed. RA patients fulfilling the American College of Rheumatology 1987 criteria with <2 years symptom duration were 'treated to target' aiming at disease activity score (DAS) ≤2.4, assessed with 3-monthly intervals. Patients in arms 1 and 2 started MTX monotherapy, patients in arm 3 started MTX, sulfasalazine and prednisone and patients in arm 4 started MTX and infliximab. All had DAS ≤2.4 from t=6 months until t=10 years and therefore stayed on initial treatment, with patients in arms 3 and 4 tapering to monotherapy within 10 months. Patients in arms 1 and 2 were compared with patients in arms 3 and 4. Between-group differences over time were compared using (generalized) linear mixed model analyses, for the outcomes DAS, Health Assessment Questionnaire (HAQ), erythrocyte sedimentation rate (ESR), visual analogue scale (VAS) patient global health (range 0-100), % patients in remission and drug free remission and % patients with Sharp/van der Heijde score progression ≥1.

Results: At t=10 years 28/247 (11%) patients in arms 1 and 2 had continued DAS≤2.4 compared to 68/261 (26%) patients in arms 3 and 4. Patients in arms 1 and 2 were less often ACPA positive (46% versus 54%), had shorter symptom duration at baseline [median (range) 14 (1-191) versus 18(4-263) weeks] and less radiologic damage progression after 10 years [0 (0-16) versus 2.5 (0-26)] than patients in arms 3 and 4. No between-group differences were found over time. Significant group-time interactions were found for DAS, ESR, VAS patient's global health, percentage remission, but not HAQ and percentage drug free remission, with slightly worse results over time for arms 3 and 4 compared to arms 1 and 2 (table 1).

Conclusion: More patients achieved persistent low disease activity on initial combination therapy with prednisone or infliximab than on MTX monotherapy, but additional benefits of combination treatment strategies for patients who have continued DAS ≤2.4 could not be found. These results strongly suggest that rapid achievement of remission/LDA itself, rather than how you achieve it, is crucial for determining long-term outcome in RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Treatment Strategies
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Use of biologicals such as Rituximab (RTX) in Rheumatoid Arthritis (RA) is effective and often only licensed in combination with Methotrexate (MTX). In cases of contraindications to or intolerances of MTX, other cDMARDs are frequently used in routine care without data from RCTs. In addition, in daily practice different strategies for retreatment with RTX are used. The objective of this study was to demonstrate safety and efficacy of RTX in combination with Leflunomide (LEF) and compare effectiveness of therapy for different dosages of RTX as retreatment at week 24 in a multicenter randomized placebo (PLA) controlled clinical trial in Germany.

Methods: A total of 189 patients with active RA (DAS28 > 3.2 and at least 3 SJC and 3 TJC) despite stable LEF treatment were screened for a 52-weeks randomized double-blind placebo controlled multicenter clinical trial, separated into two parts: in part I, patients were randomized to receive either two times 1000mg RTX i.v. followed by two times 1000 (RTX-RTXhigh) or 500 mg (RTX-RTXlow) at week 24 or PLA, followed by a second course of RTX of either two times 1000 (PLA-RTXhigh) or 500 mg(PLA-RTXlow) at week 24 in part II. The primary endpoint of part II of the study for the retreatment was change in DAS28 at week 52. Adult patients who had inadequate response to more than one antiTNF or failed more than three cDMARDs were excluded. Disease activity as well as patient reported outcomes were measured at each visit until week 52. For safety evaluation, frequency and severity of adverse events were documented.

Results: Of 189 screened patients 148 were randomized. The mean age was 56 years; the mean body weight 76 kg and 74% were female. The disease activity (DAS28) at baseline was 5.57 for RTX and 5.54 in the PLA group. All baseline-characteristics were well balanced between the treatment groups. A superior response for ACR 20 and 50 of RTX vs PLA was seen at week 16 in Part I with 51.6% vs 23.4% ($p<0.05$) and 31.2% vs 14.9% ($p<0.05$). For retreatment in part II in patients treated with RTX (2x1000mg) (n=60) at baseline no differences were seen for both groups (RTX-RTXhigh and RTX-RTXlow) with a change in DAS 28 to week 52 of -2.46 and -2.42 respectively. In patients who initially responded to placebo and therefore entered Part II (n=24) a clear difference for two times 1000 mg (PLA-RTXhigh) vs two times 500 mg (PLA-RTX low) could be detected with changes in DAS28 to week 52 of -2.68 and -2.32 respectively. A total of 372 adverse events (AE) were observed during the one-year study period, only 14 were classified as severe (10 in RTX and 4 in PLA). 43 serious adverse events were reported, 28 of them in the RTX treatment group during the placebo controlled period.

Conclusion: Here we report for the first time data of a RCT of combination of RTX with LEF. The treatment with RTX in combination with LEF demonstrated significant efficacy compared to PLA in part I. Retreatment with two times 500mg RTX after standard first course of RTX (two times 1000mg) is comparable to two times 1000mg while clear differences were seen after PLA-treatment. This illustrates the importance of two times 1000mg as initial therapy while retreatment with the lower dose seems equally effective after regular induction therapy. The combination of RTX and LEF demonstrated a reasonable safety profile.

Tocilizumab Infusion Intervals Can be Extended to 5 or 6 Weeks in RA Patients Who Sustained Low Disease Activity By 4 Weeks Interval of Tocilizumab Infusion

Hiroshi Uda and Osamu Saiki, Rheumatology, Higashiosaka City General Hospital, Higashiosaka, Japan
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Treatment Strategies
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: A period of 4 weeks (w) has been recommended as the interval between tocilizumab (TCZ) infusions. The cost of TCZ is very high, which makes it difficult for all patients to receive TCZ because of the associated expenses. Treating the patients with TCZ, we experienced that longer intervals than 4w were also effective. We examined whether the intervals between TCZ infusions could extend from 4w to 6w or 5w.

Methods: The RA patients who had shown good response and sustained low disease activity (LDA) with 8mg/kg of TCZ infusions at 4w intervals were enrolled in the study. To the eligible patients, the intervals between TCZ infusions were extended to 5w at the same TCZ dose (8mg/kg). For the patients who could maintain LDA for 6 months and more at 5w interval of TCZ infusion, the intervals between TCZ infusions were extended to 6w. We followed the patients up for 2 years and more. Good response and LDA was defined as DAS-28CRP EULAR criteria.

Results: One hundred patients were enrolled in the present study, and 96 patients completed the study. 93 patients maintained LDA with 8mg/kg of TCZ infusion every 5w for 6 months and more and the rest of 7 patients could not keep LDA and the intervals between TCZ infusions were shortened to 4w. The 93 patients who maintained LDA with 8mg/kg of TCZ infusion every 5w were received 8mg/kg of TCZ infusion every 6 weeks, and 62 patients maintained LDA with 6w-interval. After 2 years follow-up, 96 patients could maintain LDA and 4 patients were dropped from the study. Among 96 patients who could maintain LDA, the intervals between TCZ intervals were 6w in 62 patients, 5w in 28 patients, and 4w in 6 patients, indicating that 90% of patients who had shown good response and sustained LDA with 4w intervals could extend the intervals between TCZ infusions from 4w to 5w or 6w. The mean baseline DAS28-CRP score in patients who could maintain LDA with TCZ infusions at 6w intervals were 2.2 and was significantly lower than that at 4 weeks interval (2.6). The frequency of adverse events with TCZ infusions at 6 weeks intervals was lower than that at 4 weeks intervals.

Conclusion: The present study provides evidence that most of RA patients who showed good response to TCZ infusions at 4w and sustained LDA could extend the intervals to 6w or 5w. This finding should be of great interest for both financial and labor reasons.

The Effect of Treatment Adjustments Aimed at DAS Remission on Physical Functioning in Undifferentiated and Rheumatoid Arthritis Patients in Low Disease Activity

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Treatment Strategies
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Should we aim at remission if patients are in low disease activity (LDA)? We assessed if rheumatoid or undifferentiated arthritis (RA, UA) patients who achieved LDA benefit with better functional ability from treatment intensification aimed at DAS remission.

Methods: In the IMPROVED study 610 patients with early RA (ACR 2010) or UA were 'treated to target' aimed at DAS remission, assessed every 4 months. Initial treatment was methotrexate (MTX) + tapered high dose prednisone. Patients with DAS≤1.6 tapered treatment. Patients with DAS>1.6 were randomized to MTX + hydroxychloroquine + sulphasalazine + prednisone or to MTX + adalimumab. Over 5 years, patients with DAS>1.6 were required to increase, change or restart medication. HAQ was measured 4-monthly. A linear mixed model analysis with random intercept and independent covariance matrix was performed to test the relationship between changes in therapy and HAQ over time. Patients in LDA with DAS>1.6 with and without (i.e. protocol violation) treatment change were compared. ΔHAQ and ΔDAS at each visit compared to the previous visit were calculated. We tested the interaction effect between change in treatment and follow-up time adjusted for possible confounders.

Results: Over 5 years DAS and HAQ showed a statistically significant and clinically relevant decrease [Baseline HAQ mean (SD) 1.2 (0.7), ΔHAQ -0.59, 95% CI -0.61, -0.57; Baseline DAS mean (SD) 3.2 (1.7), ΔDAS -1.77, 95% CI -1.79; -1.75]. The number of patients in LDA per visit ranged from 88 to 146, of which 26% to 73% had no treatment change, with an increase in such protocol violations towards the end of study. We found a statistically significant but not clinically relevant effect of treatment change on ΔHAQ, corrected for baseline HAQ, age, gender and treatment arm (model 1, β -0.085, 95% CI -0.13, -0.044). When ΔDAS was added (model 2), treatment change was partly explained by ΔDAS and the effect of treatment change was no longer statistically significant (β -0.022, 95% CI -0.060; 0.015). When the interaction between treatment change and time in follow-up was added (model 3), a statistically significant interaction was found (β 0.0098, 95% CI 0.0010; 0.019), indicating a lower improvement in HAQ after treatment change if follow-up time increased (table 1).

Conclusion: During 5 years of DAS remission steered treatment in early RA or UA patients, treatment intensification or change for patients already in LDA resulted in a statistically significant but not clinically relevant improvement in HAQ, which was partly explained by ΔDAS. The effect decreased with increasing follow-up time. This supports the call for rapid treatment start to suppress disease activity in order to restore physical functioning. Remission may be the optimal goal, but when patients are in longer follow-up and HAQ is acceptably low, it might be sufficient to accept LDA rather than continue treatment changes aiming at remission.

Table 1. Linear Mixed Model analysis to assess the effect of treatment change on change in HAQ (n visits = 1532, n patients = 482)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I: Psoriatic Arthritis – Treatment
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: A psoriatic arthritis (PsA) core domain set to be measured in randomized controlled trials (RCT) was developed by Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) and endorsed by Outcome Measures in Rheumatology (OMERACT) in 2006. Over the past 2 years, the GRAPPA-OMERACT PsA working group conducted research projects with the objective to update the PsA core domains set to reflect patients' and physicians' priorities and evolving PsA research.

Methods: We conducted: 1) a systematic literature review (SLR) of domains assessed in PsA RCTs and longitudinal observational studies (LOS); 2) international qualitative focus groups on five continents to identify domains important to patients with PsA; 3) international surveys with patients with PsA and physicians to prioritize domains; and 4) an international face-to-face consensus meeting among patient research partners (PRPs) and physicians using the nominal group technique (NGT) method to draft a PsA core domain set. Patient research partners (PRPs) were involved in each phase and one co-chaired the working group.

Results: Thirty-nine unique PsA domains were identified through the SLR (24 domains) and focus groups (34 domains). Patients (n=50) and physicians (n=75) completed electronic surveys rating the importance of the 39 domains for inclusion in the core set (Figure 1). At the consensus meeting, 12 patients and 12 physicians used these data to agree upon 10 domains for inclusion in PsA clinical trials, one strongly recommended to be measured at least once during the development of a new medication (middle circle) and four domains for the research agenda. These domains were rated in a second international survey with patients (n=49) and physicians (n=71) (Figure 1). The results were presented at the OMERACT conference in May 2016 and voted upon for endorsement. The updated PsA Core Domain set endorsed at OMERACT 2016 with 90% vote includes: musculoskeletal disease activity (peripheral arthritis, enthesitis, dactylitis, and spine symptoms), skin disease activity (skin and nail disease), pain, patient global, physical function, health-related quality of life, fatigue, and systemic inflammation (Figure 2).

Conclusion: The updated PsA Core Domain Set incorporates patients' and physicians' priorities and evolving PsA research. Next steps include identifying outcome measurement instruments that adequately assess these domains. **Figure 1: Survey results from patients and**

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I: Psoriatic Arthritis – Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Since inhibition of either Tumor Necrosis Factor (TNF) or interleukin 17 (IL-17) alone has demonstrated efficacy in psoriatic arthritis (PsA) on both joint and skin features, dual inhibition of TNF and IL-17 holds the promise for a superior therapeutic profile. ABT-122 is a dual variable domain immunoglobulin (DVD-Ig™) inhibitor of TNF and IL-17A that has shown an enabling safety profile from phase 1 studies. The purpose of this study was to investigate the safety and efficacy of ABT-122 in PsA patients (pts) with inadequate response to methotrexate (MTX).

Methods: Pts with active PsA (N=240) on background MTX were randomized in a 3:3:3:1 ratio to receive ABT-122 (120 mg every week [ew], or 240 mg ew), adalimumab (ADA) 40 mg every other week (eow), or matching placebo (PBO) subcutaneously in a 12-week (wk) double-blind, parallel group study. The primary efficacy endpoint was the ACR20 responses versus PBO at week (wk) 12. Additional efficacy endpoints included ACR50/70, low disease activity (LDA) and clinical remission (CR) based on DAS28 (hsCRP), and PASI 75/90 responses in pts who had psoriasis ≥3% body surface area at baseline.

Results: ACR20 responses for both ABT-122 dose groups were statistically superior to PBO and comparable to ADA (**Table 1**). ACR50 and ACR70 responses were superior to PBO for all active dose arms, with numerical superiority for ABT-122 240 mg dose versus ADA. LDA or CR rates based on DAS28 (hsCRP) were superior to PBO across all active dose arms, but did not differ between ABT-122 and ADA. All active dose arms showed higher PASI 75 and PASI 90 response rates than PBO. PASI 75 responses for both ABT-122 doses were numerically greater than ADA; but PASI 90 responses were similar. Treatment-emergent adverse events (TEAEs) were similar across active treatment groups (**Table 2**), with no differences in serious AEs (SAEs) or discontinuations; infection rates were higher in active treatment groups than PBO, however no serious infections were reported in any treatment group. There were no reports of drug-related SAEs, systemic hypersensitivity reactions, severe injection site reactions, or dose-limiting or clinically-concerning laboratory abnormalities in any dose arms.

Conclusion: Efficacy of ABT-122 over 12 wks was superior to PBO on all clinical outcomes. ACR20 and PASI 90 responses for both ABT-122 doses were similar to ADA, but ACR50/70 and PASI 75 responses for 240 mg ABT-122 were numerically superior versus ADA. ABT-122 had an acceptable safety profile in PsA pts on background MTX. Dual neutralization of TNF and IL-17 with a DVD-Ig offers similar infection rates to ADA, but does not have differentiated efficacy over 12 wks in PsA pts.

Table 1. Efficacy results (NRI) at week 12 from ABT-122 Phase 2 study (M14-197)‡

Efficacy Endpoint	n (%) Responders (NRI)‖			
		Adalimumab	ABT-122§	
	Placebo (N = 24)	40 mg eow (N = 72)	120 mg ew (N = 71)	240 mg ew (N = 73)

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I: Psoriatic Arthritis – Treatment
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Ixekizumab (IXE) is an IgG4 monoclonal antibody that binds with high affinity and specificity to the proinflammatory cytokine IL-17A. In this phase 3 study (SPIRIT P1), IXE was superior to placebo (PBO) in achieving ACR20 response at Week 24 in biologic DMARD-naive (bDMARD-naive) patients with active PsA1.The objective of this analysis was to evaluate efficacy and safety of IXE over 52 weeks in patients with active PsA.

Methods: A total of 417 bDMARD-naive patients with active PsA were randomized 1:1:1:1 to IXE 80 mg once every 4 weeks (Q4W) or once every 2 weeks (Q2W) including a 160 mg starting dose, to 40 mg adalimumab (ADA), or to PBO (all subcutaneous dosing) during the Double-Blind Treatment Period (DBTP: Weeks 0 to 24). Of these, 381 patients completed the DBTP and entered the Extension Period (EP: Weeks 24 to 52) where they were assigned to 80 mg IXE Q4W or Q2W. Patients randomized to IXE at Week 0 continued the same dose regimen in the EP. Patients randomized to PBO or ADA at Week 0 were re-randomized (1:1) to 80 mg IXE Q4W or Q2W at Week 16 (inadequate responders) or 24. Those patients who initially received PBO started IXE at Week 16 or 24; patients who initially received ADA started IXE at Week 24 or 32 after an 8 week wash out period. Efficacy measures included ACR20/50/70 response, HAQ-Disability Index (HAQ-DI) Score, Disease Activity Score 28 diarthrodial joint count based on C-reactive protein (DAS 28-CRP), Psoriasis Area and Severity Index 75, 90, 100 (PASI 75/90/100), Leeds Enthesitis Index (LEI), and Leeds Dactylitis Index-Basic (LDI-B). Efficacy and safety were analyzed using the EP population defined as all patients who received at least 1 dose of study drug in the EP. Missing values were imputed by nonresponder imputation for categorical data and modified baseline observation carried forward for continuous data.

Results: A total of 304 patients completed the EP. Efficacy and safety results in the EP population are summarized in Table 1.

Improvements from baseline in ACR20/50/70, HAQ-DI, DAS 28-CRP, PASI 75/90/100, LEI and LDI-B were observed at Week 52. The frequency of treatment-emergent adverse events (AEs) in the EP was similar to that observed in the DBTP; the majority were mild or moderate in severity. Serious AEs occurred in 12 patients and no deaths occurred in the EP population.

Conclusion: IXE demonstrated clinically significant improvement in signs and symptoms of PsA including arthritis, dactylitis and enthesitis as well as skin manifestations across treatment groups in the EP. The safety profile of IXE observed in the EP was similar to that observed in the DBTP and other phase 3 studies of IXE in patients with plaque psoriasis (UNCOVER studies). 1Philip J. Mease et al. *2015 ACR/ARHP Annual Meeting*, 6-11 November, San Francisco, CA 2015; [abstract 977]

Abbreviations: ACR20/50/70=American College of Rheumatology 20/50/70 index; ADA=adalimumab 40 mg; AE=adverse event; CFB=change from baseline; DAS 28-CRP=Disease Activity Score 28 diarthrodial joint count based on C-reactive protein; HAQ-DI=Health Assessment Questionnaire-Disability Index; IXE=ixekizumab; IXEQ2W=ixekizumab 80 mg once every 2 weeks; IXEQ4W=ixekizumab 80 mg once every 4 weeks; LDI-B=Leeds Dactylitis Index-Basic; LEI=Leeds Enthesitis Index; N=number of patients in the analysis population; n=number of responders; PASI 75/90/100= Psoriasis Area and Severity Index 75/90/100; PBO=placebo; SAE=serious adverse event; SD=standard deviation; TEAE=treatment-emergent adverse event.

[a]For efficacy analyses, baseline was defined as the last non-missing assessment recorded on or prior to the date of first injection of study treatment at Week 0. For analyses of TEAEs, baseline was defined as AEs which started prior to the study drug injection at Week 24 with an exception of patients who were randomized to ADA during the entire Double-Blind Treatment Period and started IXE at Week 32 where baseline was defined as AEs which started prior to the study drug injection at Week 32.

[b]Only patients with psoriatic lesions ≥3% of BSA at baseline were included in the analysis.

[c]Only patients with enthesitis at baseline were included in the analysis.

[d]Only patients with enthesitis and LEI ≥0 at baseline were included in the analysis.

[e]Only patients with dactylitis at baseline were included in the analysis.

[f]Only patients with dactylitis and LDI-B ≥0 at baseline were included in the analysis.

Ultrasonographic Improvement of Peripheral Subclinical Enthesopathy in Therapy-Naive Patients Treated with Ustekinumab for Chronic Plaque Psoriasis: A 52-Week, Prospective, Open Label, Controlled Cohort Study

Laura Savage[1], Mark Goodfield[2], Elizabeth M.A. Hensor[3], Paul Emery[3] and Dennis McGonagle[4], [1]NIHR Musculoskeletal Biomedical Research Unit, University of Leeds, Leeds, United Kingdom, [2]Department of Dermatology, Leeds Centre for Dermatology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]NIHR-Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I: Psoriatic Arthritis – Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Subclinical enthesopathy is recognised in up to 50% of psoriasis patients and is thought to precede inflammatory

PsA. It is not known if effective treatment in the asymptomatic phase can reduce inflammation and damage. Studies have assessed enthesitis only as a secondary endpoint in established PsA. This study used ultrasound to investigate the effect of ustekinumab on subclinical enthesopathy in asymptomatic treatment-naive patients with psoriasis.

Methods: 73 new patients with severe psoriasis (PASI>10) and no PsA (absence of inflammatory arthritis to satisfy the CASPAR criteria) were screened using ultrasound. Exclusion criteria included rheumatological disease, RF or ACPA positivity and prior treatment with DMARDs. Patients were eligible if they exhibited inflammatory sonographic changes that fulfilled the OMERACT definition of enthesopathy in at least one peripheral enthesis and met the screening requirements for biologic therapy. 23 psoriasis patients received ustekinumab at week 0, 4, 16, 28 and 40 and underwent further sonography of 26 entheses at week 0, 12, 24 and 52. The same protocol was used once only in 23 healthy controls for comparison. The primary endpoint was the change in sonographic enthesopathy inflammation score (extrapolated from the GUESS score) at 24 weeks. This was a prospective proof-of-concept study (no power calculation). Analysis was primarily descriptive with effect size (Cohens d) and paired t-tests provided for enthesopathy scores.

Results: 24% of 598 entheses in patients at week 0 (median (IQR) 6 (4,9) out of 26 per patient) had at least one inflammatory entheseal abnormality (thickening, hypoechogenicity, PD signal) compared to 5% in controls, reducing to 14% and 10% after 24 and 52 weeks of treatment respectively (fig. 1). Mean inflammation scores reduced by 42% to week 24 (mean (95% C.I.) reduction -4.2(-6.3,-2.1) d=1.2 p<0.001) and by 47.5% (-4.7 (-7.1,-2.3) d=1.3 p=0.001) to week 52. Of 187 inflammatory abnormalities found at week 0, 116 (62%) resolved, 4 (7%) improved, 55 (29%) remained unchanged and 2 (1.1%) worsened by week 24. 38 new abnormalities developed on treatment. There were no differences in scores between those achieving PASI90 (n=17) and those not at week 24 (difference -0.3 95% C.I.-4.5,3.8). Chronic damage abnormalities (calcification, enthesophytes, erosions, bone cortex irregularities) did not improve with therapy. 16% entheses at week 0 had at least one abnormality compared to 6% in controls, increasing to 19% and 20% after 24 and 52 weeks of therapy respectively (fig. 1). Mean chronicity scores increased by 17% to week 24 (1.3 (-0.2,2.7) d=0.5 p<0.082), and by 10% (0.8 (-1.6,3.1) d=0.2 p=0.512) to week 52.

Conclusion: This study suggests that ustekinumab therapy for psoriasis suppresses the inflammatory features of subclinical enthesopathy supporting the concept that early intervention may prevent arthritis evolution.

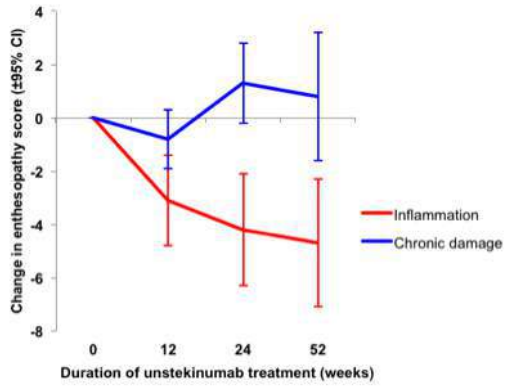

Figure 1: Change over time in total enthesopathy scores for inflammatory and chornic damage abnormalities in patients treated with ustekinumab

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I: Psoriatic Arthritis – Treatment
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Secukinumab, an anti–interleukin-17A monoclonal antibody, provided rapid and significant improvements in the key clinical domains of psoriatic arthritis (PsA) in the FUTURE 1 study (NCT01392326) with improvements sustained through 2 years.[1] Here, we present efficacy and safety results through 3 years in the extension of the FUTURE 1 study.

Methods: A total of 606 adults with active PsA were randomized to receive secukinumab or placebo (PBO). Secukinumab patients (pts) received a 10 mg/kg i.v. loading dose at baseline (BL), Weeks (Wks) 2 and 4, and then either 150 mg s.c. (IV→150 mg) or 75 mg s.c. (IV→75 mg) every 4 wks. PBO was given on the same dosing schedule. At Wk 16 or Wk 24, based on Wk 16 clinical response, PBO-treated pts were re-randomized to receive secukinumab 150 or 75 mg s.c. At Wk 104, pts could enter the extension phase of the study. Efficacy results at Wk 156 are presented for pts that were originally randomized to secukinumab (n = 308). Clinical assessments at Wk 156 included: ACR20/50/70, PASI 75, DAS28-CRP, SF-36 PCS, HAQ-DI, dactylitis, and enthesitis. Multiple imputation was applied to missing binary variables. Summary statistics are based on relative frequencies for binary variables and mean (±SD) for continuous variables. Analyses stratified by anti-TNFα status (anti–TNFα-naïve and anti-TNFα inadequate response [IR]) were pre-specified and reported as observed. Safety analysis is based on exposure adjusted incidence rate (EAIR). All pts (n = 587) who received ≥1 dose of study treatment through 156 wks were included in the safety analysis.

Results: Overall, 457 of the original 606 pts entered the extension study (including 308 originally randomized to secukinumab) of which 435 pts completed 156 wks (151 pts in IV→150 mg group; 142 in IV→75 mg group; 142 in PBO → secukinumab groups). At Wk 156, ACR 20/50/70 response rates were 76.8/54.9/32.9% with IV→150 mg and 65.2/39.0/26.0% with IV→75 mg, respectively. Sustained clinical improvements through Wk 156 were observed across other clinically important domains of PsA. Improvements were sustained in both anti–TNFα-naïve and anti–TNFα-IR pts (Table). Over the entire study period (mean [± SD] exposure to secukinumab of 1025.1 ± 372.7 days) the type, incidence and severity of adverse events (AEs) were consistent with those reported previously.[1] EAIRs for serious infections/infestations, candida infections, Crohn's disease, malignant/unspecified tumors, and major adverse cardiac events with secukinumab were 1.7, 1.2, 0.1, 0.9, and 0.7 per 100 pt-years, respectively.

Conclusion: Secukinumab provided sustained improvements in signs and symptoms and multiple clinical domains of active PsA in pts who completed 3 years of therapy. Secukinumab was well tolerated with a safety profile consistent with that previously reported. References: 1. Mease PJ, et al. *Arthritis Rheumatol*. 2015; 67 (suppl 10).

Table. Summary of Efficacy Results at Week 156				
Variables	**Secukinumab IV→150 mg (n = 161)**		**Secukinumab IV→75 mg (n = 147)**	
ACR 20/50/70[a] (% responders)	76.8/54.9/32.9		65.2/39.0/26.0

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I: Psoriatic Arthritis – Treatment
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Secukinumab, a fully human anti–interleukin-17A monoclonal antibody, has been evaluated and approved for the treatment of moderate to severe psoriasis, active psoriatic arthritis (PsA) and active ankylosing spondylitis (AS). Inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), is commonly associated with psoriasis, PsA and AS.[1,2] The risk of CD in moderate to severe psoriasis patients (pts) is ~2–4-fold higher than that in the general population,[1,3,4] occurring at a rate of up to 0.25 cases per 100 pt-years.[4] CD has been reported at a rate of 0.06 cases per 100 pt-years among pts with PsA,[3] and 0.7 cases per 100 pt-years among placebo-treated pts in AS trials.[5] Endoscopic subclinical inflammation occurs in up to 50% of AS pts.[2] Here, we report the incidence of CD and UC among secukinumab-treated pts in the psoriasis, PsA, and AS clinical trial programs.

Methods: This analysis included data from 10 Phase II and Phase III studies in moderate to severe psoriasis, 2 Phase III studies in active PsA, and 2 Phase III studies in active AS, pooled per indication. Most studies included short-term, placebo treatment arms; 1 psoriasis study included an etanercept active comparator arm. Pts with prior history of, but not active, IBD could be enrolled. Study durations varied; data from all pts receiving ≥1 secukinumab dose up to Week 52 (psoriasis studies) or Week 112 visit (PsA/AS studies) were included. Data are reported as crude frequency rates (%) in the short-term (Week 12 in the psoriasis studies and Week 16 in the PsA/AS studies) and exposure adjusted incidence rates (EAIR; per 100 pt-years) over the entire treatment period.

Results: Overall, 3430, 974, and 571 pts received ≥1 secukinumab dose in the psoriasis, PsA, and AS studies, respectively. Adverse events of CD or UC were reported infrequently amongst secukinumab-treated pts in both the short- and long-term treatment periods (Table). Rates of CD and UC were similar across the psoriasis and PsA cohorts, and rates with secukinumab were similar to those seen with etanercept in psoriasis pts. Across all indications, there was no dose dependency with respect to the incidence of CD or UC with secukinumab, and no pattern in time-to-onset (data not shown).

Conclusion: Events of CD and UC in the 14 clinical studies were reported infrequently in secukinumab-treated pts with psoriasis, PsA, or AS; rates were similar across the psoriasis and PsA cohorts. EAIR rates of CD and UC observed in secukinumab-treated pts are consistent with those reported in the literature in psoriasis, PsA, and AS populations. **References:** 1. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Nephritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Homocysteine is a proven prospective risk factor for stroke and arterial thrombosis in SLE. However, checking for

homocysteine and treating high levels is actually discouraged, because randomized clinical trials in the general population did not show a reduction in coronary events.

Methods: 1623 SLE patients (92% female; 52% Caucasian and 40% African-American) were studied. For the first homocysteine measurement, 85.6% were below 15 umol/L. High levels were treated with folic acid or Folbic. We used GEE to estimate the association between homocysteine and the urine protein/cr ratio using serial tests of homocysteine.

Results: The same day homocysteine > 15 was associated with the same day urine protein/cr ratio (p=0.0008). Homocysteine was associated with serum creatinine (p>0.0001). Among 829 patients, 604 had at least two homocysteine measurements, 272 had three or more. A 10 umol/L decrease in homocysteine within a person corresponds to an average 0.011 (95% CI: 0.006 to 0.015) unit decrease in urine protein/creatinine ratio (P < 0.0001), after adjusting for sex and ethnicity. The association remained significant (0.004 (95% CI 0.002 to 0.007), P = 0.0005) when we only included patients with a first homocysteine greater or equal to 15 umol/L and a same day urine protein/creatinine ratio greater or equal to 0.2. In addition, the association was not changed if we adjusted for the serum creatinine. Table 1. Association of a 10 umol/L Decrease in Homocysteine with Lower Urine Protein/Cr

All patient analysis	0.011 decrease (95% CI 0.006 – 0.015	P<0.0001
Homocysteine > 15 and urine p/c > 0.200	0.004 decrease (95% CI 0.002 – 0.007)	P< 0.007

Conclusion: High homocysteine levels, when treated, resulted in significant lowering of the urine protein/cr ratio, that was independent of serum creatinine.

Tubulointerstitial Damage Is an Independent Predictor of End Stage Renal Disease in Lupus Nephritis Patients with Mild to Moderate Renal Impairment

Bojana Jovanovic[1], Hina N. Khan[1], Wenzhu Mowrey[1], Peter M. Izmirly[2], Daniel Schwartz[1], Jill P. Buyon[3], Chaim Putterman[1], Beatrice Goilav[1] and Anna R. Broder[1], [1]Albert Einstein College of Medicine/Montefiore Medical Center, New York, NY, [2]New York University School of Medicine, New York, NY, [3]Medicine, New York University School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Nephritis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Tubulointerstitial damage (TID) is considered to be a later sequela of lupus nephritis (LN). The clinical significance of TID in patients with only mild to moderate renal impairment at the time of biopsy has not been studied. The objective of this study was to determine if TID predicts progression to end-stage renal disease (ESRD) in LN patients with mild to moderate renal impairment.

Methods: We identified all adult and pediatric SLE patients (by ACR and/or SLICC criteria) with who had an index biopsy consistent with LN (>6 glomerulai examined) between January 2005 and July 2015. Renal impairment was defined as mild (estimated glomerular filtration rate [eGFR] ≥ 60 mL/min/1.73m^2) or moderate (eGFR≥30 and <60 mL/min/1.73m^2) at index biopsy. Demographic data, comorbidities, medications, laboratory data, ESRD onset, and deaths through December 2015 were ascertained from medical chart reviews, the United States Renal Data Systemic Report, and National Death Index. TID was defined as the presence of moderate to severe tubular atrophy and/or interstitial fibrosis as reported on the renal biopsies in accordance with the 2003 ISN/RPS criteria. Time to ESRD onset was defined as time from the index biopsy date to incident ESRD date; non-ESRD patients were censored at time of death or the last visit. Kaplan-Meier survival curves and Cox proportional hazards models were used to evaluate whether TID was predictive of ESRD progression adjusting for eGFR (as a continuous variable) and LN class.

Results: Of the 155 patients with renal biopsies, 131 (85%) had baseline eGFR>30 mL/min/1.73m^2: 8(6%) Class II, 58(44%) Class

III/IV, 38(29%) Class V, and 27(21%) mixed; 16 (12%) progressed to ESRD. Eighty six percent of ESRD progressors had proliferative or mixed LN vs. 51% of non-ESRD, p=0.02. ESRD and non-ESRD groups were similar with respect to age, sex, race, comorbidity scores, complement levels, anti-dsDNA, and protein to creatinine ratio at index biopsy. Median (IQR) baseline eGFR was 65 (51, 75) mL/min/1.73m^2 in the ESRD group and 97 (69, 127) mL/min/1.73m^2 in the non-ESRD group, p=0.001. TID was present in 12% of biopsies with eGFR≥60 mL/min/1.73m^2 and in 35% of biopsies with GFR between 30 and 60 mL/min/1.73m^2. Moderate to severe TID was associated with a high risk of ESRD progression (Figure 1, log-rank p-value<0.001), HR=8.3, 95% CI: (2.6, 27), p-value<0.001, adjusted for eGFR and proliferative or mixed LN. Similarly, TID remained a significant predictor in the subgroup with eGFR>60 mL/min/1.73m^2, HR= 5.6, 95% CI: (1.3, 22.9), p=0.02.

Conclusion: TID was highly prevalent among LN patients with mild to moderate renal impairment. TID was a strong predictor of ESRD progression in these patients independent of eGFR or biopsy class. Identifying factors associated with the presence of TID early in the disease may lead to the development of effective prevention strategies to decrease the risk of ESRD.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Nephritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Lupus nephritis (LN) is associated with high treatment failure rates and the development of new therapies for LN is limited by the lack of validated predictors of clinical response. Recent analyses have identified early predictors of renal outcome in LN.[1,2] The combined placebo control arms of two multi-center, double blinded placebo controlled trials in LN patients (LUNAR and BELONG), where standard of care immunosuppression was given, provide the opportunity to explore the association of clinical variables with renal response.[3,4]

Methods: The analysis population included 146 patients given standard of care immunosuppression plus placebo infusions. Response was assessed in the following 3 mutually exclusive categories at one year: complete renal response (CRR), defined as urine protein/creatinine

ratio (UPCR) <0.5 on 24-hour urine collection and serum creatinine ²25% above baseline; partial renal response (PRR), defined as ³50% reduction in UPCR, reduction of UPCR to <3 if screening value >3, and serum creatinine ²25% above baseline; and nonresponse (NR), no CRR or PRR. Multivariate logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI) for the associations between independent variables and renal response. These associations were examined in univariate and multivariate models to identify variables independently associated with response.

Results: All patients had biopsy-proven ISN/RPS 2003 class III or IV LN with 38 (26%) having concomitant class V. Mean UPCR was 4.1 ± 2.9 and mean estimated glomerular filtration rate (eGFR) was 87 ± 38 mL/min/1.73 m^2 at baseline. 85% were treated with mycophenolate mofetil and 15% with the Euro-Lupus cyclophosphamide regimen. In multivariate analysis (Table 1), baseline UPCR (OR 1.18 for each 1 unit decrease, 95% CI 1.01 to 1.37) and the presence of concomitant class V nephritis (OR 2.8, 95% CI 1.17 to 6.7) were associated with achievement of CRR. ³25% reduction in UPCR at week 8 was associated with CRR in univariate but not multivariate models. ³25% reduction in UPCR at week 8 (OR 0.33, 95% CI 0.15 to 0.76) and the presence of concomitant class V nephritis (OR 0.32, 95% CI 0.13 to 0.79) were associated with a decreased likelihood of NR.

Conclusion: In this pooled population from two phase III randomized trials of LN treated with standard of care immunosuppression, baseline UPCR, concomitant class V LN, and achievement of 25% reduction in UPCR at week 8 were independently associated with renal response. These findings build upon an emerging literature of early predictors of clinical response in LN with the ultimate goals of individualizing treatment decisions based on patient risk and accelerating the development of new therapeutics for LN. Renal Activity In Lupus (RAIL) Urinary Biomarkers Predict Treatment Response

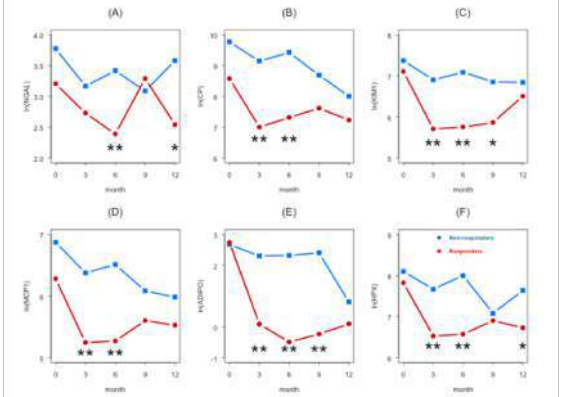
Background/Purpose: We have previously demonstrated the strong predictive value of the Renal Activity In Lupus (RAIL) algorithm, using 6 urinary biomarkers (UBMs), in children (RAIL) and adult (A-RAIL) populations. The purpose of the present study was to prospectively study these six UBMs in relation to the response to therapy for lupus nephritis.

Methods: Patients with a diagnosis of Systemic Lupus Erythematosus (SLE) with new biopsy proven class III/IV lupus nephritis were enrolled. In addition to routine lab work, including anti-dsDNA antibody levels, complement levels, and urinalysis, the patientsÕ serial urine samples were collected during the 12 months of treatment with immunosuppressive medications. The six RAIL biomarkers, namely neutrophil gelatinase associated lipocalin (NGAL), ceruloplasmin (CP), kidney injury molecule 1 (KIM 1), monocyte chemotactic protein 1 (MCP 1), adiponectin (ADIPO) and hemopexin (HPX), were measured longitudinally using standardized ELISA-based assays during the patientsÕ course. Patients were treated with standard induction regimen using cyclophosphamide versus mycophenolate mofetil, and categorized as responders or non-responders, based on the American College of Rheumatology (ACR) lupus nephritis response criteria. Longitudinal patterns of RAIL biomarkers were assessed and compared between visits (0, 3, 6, 9 and 12 months) and groups (Responders versus Non-responders) using mixed effect models.

Results: A total of seventy-two patients were enrolled in this longitudinal prospective study, with 32 responders and 40 non-responders. About 80 percent in each group were females, and non-Caucasian race was predominant (13 out of 32 responders; 19 out of 40 non-responders, respectively). At 6 month follow up since induction therapy, all 6 UBMs showed significantly lower levels among responders when compared to non-responders (Figure 1). The differences were also significant for all except NGAL at 3 month follow up. At 12 months of treatment, the responders and non-responders did not continue this trend and differences in biomarkers became largely non significant, except NGAL and HPX, which showed significant differences.

Conclusion: The RAIL UBMs demonstrate strong value in predicting response to therapy, can be used as a reliable surrogate in predicting treatment response, and will be highly valuable in making therapeutic changes and clinical decisions.

FIGURE 1: RAIL UBMs: Changes after response to Induction Therapy



LEGEND: The symbol "*" and "**" denotes a *p value* of 0.05 and 0.01 respectively for difference between the two groups for the given time point. The RAIL biomarkers ((A) NGAL, (B) Ceruloplasmin, (C) KIM-1, (D) MCP-1, (E) Adiponectin, and (F) Hemopexin) are represented as standardized log transformed concentration values. Non-responder values are marked with blue, and responders with red.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Nephritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Variability in response criteria for lupus nephritis (LN) clinical trials (CTs) has compromised the legitimacy and generalizability of CT results, primarily because short term response, however defined, does not necessarily equate to good long term kidney function. The aim of this study was to examine associations between short term renal parameters and long term renal outcomes to establish novel endpoints for LN CTs that predict long term kidney health.

Methods: A database of 944 patients with LN flare (baseline) and extended follow-up was established from 12 multinational clinical centers and 3 CTs. Performance of clinical variables at 12 months was assessed for predicting development of new or progressive chronic kidney disease (CKD), defined as a sustained decrease in eGFR ≥30%. Treatment was standard of care or as dictated by CT protocol. Statistical analyses included Kaplan-Meier curves for comparison of survival times using the log-rank test between categorical grouping variables and univariate Cox proportional hazards regression for continuous variables; Bonferroni correction was used for multiple comparisons. Factors significantly associated with CKD on univariate analysis ($p<0.10$) were included in a multivariable Cox regression analysis to build a prognostic model for time to CKD.

Results: Accounting for inclusion criteria and missing data, final analyses included 558 subjects (**Table** 1). 75 events of CKD occurred in 558 subjects; follow-up time ranged 22-317 months. Urine RBCs at baseline and 12 months, age, race (binary variable Black/non-Black), ISN Class, SCr at baseline and 12 months, proteinuria at 12 months and % change (%Δ) in SCr and proteinuria from baseline to 12 months were significantly associated with CKD by univariate analysis. The final multivariate model for significant predicators of CKD included the log (%Δ in proteinuria, $p<0.0001$), log (SCr at 12 months, $p<0.0001$) and race ($p=0.04$). The hazard ratios (HR) for CKD were 1.86 (95% CI: 1.52, 2.65) for log (%Δ proteinuria), 5.11 (3.04, 8.58) for log SCr and 1.65 (1.003, 2.70) for race. These predictors were combined into a "Hazard Index Tool" formula for developing CKD: $\text{Hazard Index}_i = 0.61859*X_1 + 1.63100*X_2 + 0.49870*X_3 + 13$, where X_1= log (%Δ proteinuria), X_2=log (SCr 12 months), X_3=1 if Black; 0 if non-Black.

Conclusion: Evaluation of a longitudinal cohort of patients with LN flare demonstrates that race and 12 month measures of proteinuria and SCr predict risk for development of CKD, whereas urine RBCs do not. HRs derived from multivariable analysis of these clinical variables were used to develop a Hazard Index Tool that predicts hazard of developing CKD. This tool can be used in CTs to evaluate superiority of new LN drugs in preventing future development of CKD (i.e., comparison of mean Hazard Index scores between treatment and placebo groups). Tool validation studies are planned. **Table 1.**Subject characteristics and predictor variables at baseline and 12 months stratified by development of CKD defined as a sustained decrease in eGFR≥30% after month 12.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Nephritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Alternatively activated (M2) macrophages are the major macrophage subtype infiltrating the glomeruli in lupus nephritis (LN). CD163 is a marker of M2 macrophages. In urine, soluble CD163 (sCD163), which is the shed form of CD163, may reflect the activation of M2 macrophages in kidney. Thus, it may serve as a biomarker for identification and assessment of treatment response in patients with LN.

Methods: Patients with SLE with active nephritis (AN), active disease without nephritis (active non-renal; ANR) and inactive disease (ID) were enrolled. Disease activity was assessed using SLEDAI and renal SLEDAI (rSLEDAI). Patients in AN group were treated according to the ACR guidelines and followed up every 3 months for 1 year. Urine and plasma samples were collected at baseline for all and every 3 months in AN group. Urine samples from 25 healthy subjects (HC) and 20 patients of rheumatoid arthritis (RA) served as controls. Plasma sCD163 (pCD163) and urinary sCD163 were measured using ELISA and urinary values were normalized for creatinine excretion.

Variables are expressed as median (range) and non-parametric tests were used for analysis.

Results: A total of 122 SLE patients (females 114) were enrolled. At baseline, normalized urinary sCD163 (uCD163) was significantly higher in AN group as compared to ANR, ID, HC and RA (p-value <0.001 for all). uCD163 showed good correlation with protein:creatinine ratio (r=0.55; p-value <0.001), rSLEDAI (r=0.47, p-value <0.001) and SLEDAI (r=0.3, p-value <0.001) but not with pCD163 levels (r=0.23). uCD163 but not pCD163 could differentiate between AN and ANR groups (Table 1) and on ROC analysis, uCD163 (AUC=0.76) performed better than pCD163, C3, C4 and anti-ds DNA antibodies. In the longitudinal study, with reduction in disease activity, uCD163 also decreased significantly at all follow-up visits as compared to baseline (p-value <0.001) (Table 2). pCD163 also decreased significantly but had an erratic and irregular trend. uCD163 and not pCD163 showed a rise before conventional markers in 4 patients who relapsed within 1 year of follow-up.

Conclusion: uCD163 is a potential biomarker of LN disease activity. Among patients with active SLE, it helps differentiate between patients with and without LN. It shows modest correlation with renal disease activity and has a potential to predict relapse of LN.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic sclerosis (SSc) is a debilitating disease with few treatment options. Interleukin-6 (IL-6) appears to play a

role in SSc pathogenesis (*J Rheumatol* 1998;25:308; *Pathobiology* 1993;61:239). Data from the 48-week, double-blind (DB), placebo (PBO)-controlled period of the faSScinate trial of subcutaneous (SC) tocilizumab (TCZ) in patients with SSc have been published (*Lancet* 2016: doi: 10.1016/S0140-6736(16)00232-4). Herein we present data on the safety and efficacy of TCZ in SSc patients during 48 weeks of open-label (OL) TCZ treatment.

Methods: Patients ≥18 years of age with active SSc (≤5-year duration, modified Rodnan skin score [mRSS] 15-40, and elevated acute-phase reactants) diagnosed according to 1980 ACR criteria received OL TCZ 162 mg SC weekly from week 48 to week 96. Change from baseline in mRSS, patient-reported outcomes (PROs), and forced vital capacity (FVC) at week 96 were exploratory measures. Observed means used all available data.

Results: In total, 27 of 43 (63%) TCZ and 24 of 44 (55%) PBO patients completed week 96. Baseline (BL) characteristics were similar at BL and at entry into the OL period. Patients who switched from PBO→OL TCZ showed improvement in observed mean change from BL in mRSS at week 96 (–9.4) compared with the end of the 48-week DB period (–3.1). In patients initially randomly assigned to TCZ (TCZ→OL TCZ), mean change in mRSS was –5.6 at week 48 and –9.1 at week 96. In the OL period, improvements in PROs were noted at week 96 compared with week 48 in the PBO→OL TCZ group (mean [SD] change from BL at week 96 vs week 48 in HAQ-DI: –0.3 [0.4] vs 0.2 [0.4]; Patient Global VAS: –23.8 [36.0] vs –4.0 [24.0]; FACIT-Fatigue: 11.3 [12.8] vs 1.4 [7.6]). Of patients who completed the study, none experienced a >10% decline in % predicted FVC during the OL period on TCZ therapy. Rates (95% CI) of serious adverse events/100 patient-years (PY) in the DB period were 76.1 (50.6, 110.0) in PBO patients and 66.7 (42.3, 100.1) in TCZ patients and were 36.0 (18.0, 64.4) in PBO→OL TCZ patients and 16.5 (5.4, 38.5) in TCZ→OL TCZ patients in the OL period. Rates (95% CI)/100PY of serious infections in the DB period were 10.9 (3.0, 27.9) in PBO patients and 34.8 (18.0, 60.8) in TCZ patients. In the OL period they were 19.6 (7.2, 42.7) in PBO→OL TCZ patients and 0.0 (0.0, 12.2) in TCZ→OL TCZ patients. No deaths occurred in the OL period (deaths in DB period: 3 TCZ, 1 PBO).

Conclusion: Although OL data have to be interpreted with caution, efficacy and safety in PBO-treated patients who switched to OL TCZ were generally similar to those observed in patients randomly assigned to TCZ in the DB period. Results over 96 weeks of TCZ treatment suggest maintenance of the clinical response for mRSS in SSc patients. Rates of serious infection increased in PBO patients after they switched to OL TCZ. Long-term safety was consistent with the natural history of SSc and the safety profile of TCZ.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Circumstantial evidence from preclinical studies indicates a key role of serotonin (5-HT) signaling via the 5-HT-2B receptor in the development of fibrosis. Terguride is an orally available 5-HT-2 receptor inhibitor that has shown beneficial effects in different animal models of systemic sclerosis (SSc). **Objectives:** To evaluate the efficacy of Terguride for the treatment of fibrosis in patients with SSc in an investigator initiated phase 2 proof of concept study.

Methods: Main inclusion criteria were fulfillment of ACR classification criteria and diffuse cutaneous SSc (dcSSc). Patients with end-stage organ involvement and treatment with potentially disease modifying agents including immunosuppressives were excluded. Patients were treated with Terguride at up to 3 mg/d p.o. or standard of care (post hoc control) for three months. Primary efficacy endpoints were changes of pre-defined skin biopsy biomarkers over the three months treatment period. Secondary efficacy endpoints included change of mRSS and lung function parameters. Serious adverse events (SAEs) and AEs were coded using MedDRA. The study was externally monitored.

Results: Twelve patients were recruited into the Terguride group and 6 patients into the control group. The primary endpoints, skin biopsy biomarkers, showed a consistent and statistically significant down-regulation compared to the control group (Figure) for dermal thickness, myofibroblast counts and mRNA levels of col1a1, col1a2 as well as for the Lafyatis 4-gene biomarker set (COMP, THSP-1, SIGLEC-1, IFI-44). This was accompanied by a reduction in mRSS of - 32.3% versus baseline in the Terguride group versus stable values in the control group ($p < 0.05$). Lung function parameters did not change significantly. Overall, 33 AEs (n=27 mild and n=6 moderate) and one SAE (pyelonephritis, not related) occurred in the Terguride group, most often consisting of nausea and vomiting (9% and 13% of patients respectively).

Conclusion: Terguride was well tolerated in patients with dcSSc. Strong and consistent effects on fibrosis related skin biopsy biomarkers could be observed in this open-label controlled phase 2 proof of concept study, which was further supported by a significant improvement of the mRSS over the control group. These data justify further investigation in an upcoming randomized placebo controlled phase 3 study.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Forced vital capacity (FVC) is used as a primary outcome measure in clinical trials of systemic sclerosis-related interstitial lung disease (SSc-ILD). Minimally Clinically Important Difference (MCID) can help interpret whether changes in outcomes are meaningful and can potentially lead to management changes. Our objective was to define inter-rater reliability and MCID of FVC using SLS-I and II data.

Methods: SLS-I and II patients (pts) were adults with SSc with disease duration of ≤7 years, FVC between 45-85 %-predicted and symptomatic ILD. In SLS-1, pts were randomized to daily oral cyclophosphamide (CYC) or matching placebo for 1 year. SLS-II pts were randomized to either mycophenolate mofetil (MMF) for 2 years or daily oral CYC for 1 year followed by 1 yr of placebo. Spirometry was assessed at 3-month intervals. We evaluated the test-retest reliability for FVC between the screening and baseline visits using intra-class correlation (ICC). An ICC of ≥0.90 was considered acceptable. MCID estimates were calculated in the pooled SLS I and II data using SF-36 health transition question: "Compared to one year ago, how would you rate your health in general now?" Pts answering "a *little better" or "a little worse*)" were defined as the MCID changed subgroup. We also assessed the association of MCID for improvement and worsening of FVC (absolute change in % predicted from baseline) with the patient reported outcomes (PROs): HAQ-DI, Mahler's Transition Dyspnea Index (TDI), Saint George's Respiratory Questionnaire (SLS II only), computer-assisted quantitation of extent of fibrosis (QLF) and of total ILD (QILD) on HRCT (12-0 month in SLS-1 and 24-0 month in SLSII). Student's t-test compared the mean difference in outcomes between the MCID improvement/ worsening and "no change" group. P-values < 0.05 were considered statistically significant.

Results: FVC reliability was 0.90 for SLS I, 0.97 for SLS II pts and 0.93 for the combined database. The MCID estimate for improvement in FVC% predicted, after adjusting for "no change" group, was a mean change of 2.97% and -3.32% ($p<0.05$) for worsening. For easy interpretation, FVC% change of >3% was used as the MCID estimate for improvement and >3.3% for worsening. When FVC improved by ≥3%, trends toward significant improvement were noted for SGRQ, SF-36 MCS and QLF, while statistically significant improvement was noted for SF-36 PCS, TDI, HAQ-DI and QILD (Table 1). For negative FVC changes ≥3.3%, worsening was noted in all PROs with statistically significant worsening in SGRQ, TDI, QILD and QLF scores.

Conclusion: Reliability of FVC measurement was acceptable. Our analysis supports an absolute change of +3% for improvement and -3.3% for worsening in FVC% predicted as the MCID estimates for improvement and worsening in SSc-ILD. Estimates correspond to changes in the PROs as well as HRCT quantification of ILD. This needs to be validated in future SSc-ILD trials. **Table 1. Change in PROs, HRCT-QILD and QLF based on MCID estimates of FVC %**

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

ABSTRACT:

Background/Purpose: We investigated predictors of outcome, including mortality and cardiopulmonary hospitalizations in the Òat riskÓ group for pulmonary hypertension in PHAROS, a prospective longitudinal cohort study to understand the natural history of pulmonary hypertension (PH) in systemic sclerosis (SSc).

Methods: The **Ò**at riskÓ population for PH was defined by the following entry criteria: echocardiogram (echo) systolic pulmonary arterial pressure (sPAP) >40mmHg, or diffusion lung capacity of carbon monoxide (DLco) <55% predicted or ratio of % forced vital capacity (FVC) /%DLco >1.6 measured by pulmonary function testing (PFT) (1), were followed annually between 2005 and 2015. The population was stratified into 2 groups: those who developed PH, confirmed by right heart catheterization (RHC), and those who remained Òat riskÓ. Associations of baseline predictors with all-cause mortality and cardio-pulmonary hospitalizations were assessed using Kaplan Meier plots and Cox proportional hazards models adjusted for age, gender, race and disease duration.

Results: In total, 266 Òat riskÓ SSc patients were followed for a median of 4 years (range 0.4-8.5 years). The median overall survival was 84.6% at 5 years and nearly 80% at 8.5 years. Thirty four patients Òat riskÓ developed PH and 232 remained Òat riskÓ. Though median survival was similar in both groups, 45% deaths in the Òat riskÓ group were due to cardio-pulmonary complications versus 70% in the PH group. In the Òat riskÓ group (Table 1), lower risk of mortality was significantly associated with female sex, higher %DLCO, and no exercise oxygen desaturation, whereas higher mortality risk was significantly associated with anemia, higher UCSD scores, and presence of pericardial effusion. Moreover, higher UCSD scores and presence of pericardial effusion were associated with elevated risk of cardiopulmonary hospitalizations. Stratified analysis showed that PH patients with DLCO<50% had higher risk of cardiopulmonary hospitalizations as compared to other groups (figure 1). No other significant differences were observed in the associations of predictors with cardiopulmonary hospitalization risk comparing PH and Òat-riskÓ groups.Ó .

Conclusion: This is one of the largest prospective study of SSc patients Òat riskÓ for PH. Though survival was better than those with incident PH (2, 3), male sex, low %DLCO, exercise oxygen desaturation and pericardial effusion, were similarly associated with worse outcomes.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Pulmonary hypertension (PH) is a leading cause of death in patients (pts) with Systemic Sclerosis (SSc). The World Health Organization (WHO) classifies PH into groups: pulmonary arterial hypertension (PAH, WHO1); PH secondary to left heart dysfunction or isolated post-capillary PH (WHO2); and PH secondary to pulmonary disease (WHO3). The purpose of this study was to describe the clinical characteristics and outcomes of those pts in the PHAROS cohort categorized as WHO2.

Methods: Pts were enrolled in PHAROS within 6 months of the diagnosis of PH. PH was defined by a mean pulmonary artery pressure (mPAP)≥25 mmHg on right heart catheterization (RHC.) Pts were categorized as WHO2 if they had a pulmonary capillary wedge pressure (PCWP)>15 mmHg. Pts with Interstitial Lung Disease (ILD) as defined by a forced vital capacity (FVC) <65% predicted and/or significant fibrosis on chest CT with a normal PCWP were included in WHO3. Clinical expertise from the treating centers was also used to categorize pts best, as individuals may have features of more than one group. Statistical analysis was carried out using Shapiro-Wilk, Kruskal-Wallis, Kaplan-Meier and stratified log-rank tests.

Results: There are 335 pts with PH in the PHAROS database: WHO1 - 215, WHO2 – 57, and WHO3 –63. As shown in table 1, WHO2 pts are different from WHO1 but similar to WHO3 pts in that they are more likely to be African American, to have diffuse SSc and to be scl70 positive. WHO2 pts had lower FVC and FVC%/DLCO% ratio than WHO1 pts. They had normal ejection fractions but significantly larger left atrial measurements. WHO2 patients by definition have higher PCWP, which is associated with a lower pulmonary vascular resistance on RHC. Stratified log-rank tests did not show a significant difference in time to death between the groups, p=0.28. Survivals for 1, 3, and 5 years are shown below in table 2. WHO2 patients had a significantly higher proportion of deaths related to scleroderma than WHO1 (95% v. 70%, p=0.02). The most common cause of death among WHO2 pts was PH (37%) followed by multifactorial causes (26%.) WHO I pts died most commonly from PAH (50%), while the most common cause among WHO III patients was pulmonary fibrosis (46%, p<0.001).

Conclusion: Patients with WHO2 PH have different features that help to separate them from WHO1 pts. Overall survival in the PH pts enrolled in PHAROS has improved over historical values. WHO group classification did not affect survival in these incident patients. However, pts with WHO2 PH were more likely to die from scleroderma-related causes.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Despite the fact that up to 90% of scleroderma (SSc) patients are affected by gastrointestinal (GI) dysmotility, features associated with severe GI disease are not well-defined. We sought to identify such features by studying a large cohort of SSc patients requiring parenteral nutrition (TPN) for severe GI dysmotility and SSc controls with mild or no GI symptoms.

Methods: Patients were selected from the Johns Hopkins Scleroderma Center cohort database (clinic visits from 1991-2015) and met either 1980 American College of Rheumatology criteria or at least three of five features of the CREST (calcinosis, Raynaud's phenomenon, esophageal dysmotility, sclerodactyly, telangiectasia) syndrome for SSc. All patients with SSc who required TPN for SSc GI dysmotility, and all patients with SSc and mild or no GI symptoms (modified GI Medsger score of 0 or 1) were included in this study. Demographic and clinical data were obtained on each patient at the time of the clinical visit when they were first assigned their maximum GI score. Myopathy was defined by the presence of abnormal muscle enzymes (CK, aldolase), an irritable myopathy on EMG, and/or muscle biopsy findings associated with SSc. In the cross-sectional analysis, associations between dichotomous variables were assessed using Chi-square or

Fischer's exact tests. T-tests were applied to parametric data to evaluate for significant differences in the means of continuous variables between two groups. Univariate logistic regression analyses further explored associations between disease characteristics and severe GI dysmotility. Significant findings from the univariate analyses and potential confounders were then included in a multivariable model to determine whether associations remained significant after adjusting for relevant covariates.

Results: There were 59 TPN dependent SSc patients, and 1,744 SSc patients with mild or no GI symptoms. 1,456 (81%) of patients were female and 347 (19%) of patients were male. In the univariate analysis, we identified male sex (OR 2.2, CI 1.28, 3.86; p = 0.005), diffuse cutaneous disease (OR 2.62, CI 1.53, 4.45; p = <0.001), and black race (OR 2.5, CI 1.42, 4.39; p = 0.001), as features associated with severe GI dysmotility in SSc. Myopathy was also found to associate with severe SSc GI dysmotility (OR 4.5, CI 2.61, 7.79; p = <0.001). After adjusting for potential confounders (age, disease duration, and history of diabetes), male gender (OR 2.6, CI 1.17, 5.90; p=0.02), diffuse disease (OR 2.79, CI 1.20, 6.47; p = 0.017), and myopathy (OR 3.6, CI 1.54, 8.33; p = 0.003), all remained significantly associated with severe GI dysmotility.

Conclusion: We utilized the largest reported cohort to date of TPN-dependent SSc patients to define phenotypic features associated with severe GI dysmotility. Our results demonstrate that male sex, diffuse cutaneous disease, and myopathy are significantly associated with severe SSc GI dysmotility. As myopathy is a complication associated with severe SSc GI dysmotility, defining autoantigens common among smooth and skeletal muscle may provide insight into disease pathogenesis.

Session Title: Vasculitis I: Novel Approaches to Therapy

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: To evaluate the effect of maintenance therapy on the outcomes of adult patients with primary angiitis of the central nervous system (PACNS).

Methods: We analyzed long-term outcomes (relapse, survival and functional status) of adult patients enrolled in the French multicenter cohort of PACNS who achieved remission under induction treatment and with at least 12 months of follow-up (or who died earlier after having achieved remission), according to whether or not they received maintenance therapy. Good functional outcome was defined as a modified Rankin scale (MRS) inferior or equal to 2 at last news.

Results: Ninety-seven patients [46 (47%) female, median age: 46 [18-78] years-old at diagnosis] were included and followed for a median of 55 [5-198] months. Induction treatment consisted of glucocorticoids (GC) in 95 (98%) patients, combined with an immunosuppressant in 80 (83%), mostly cyclophosphamide (CYC, median of 6 [2-12] pulses for 6 [2-10] months). Maintenance therapy

was prescribed in 48 (49%) patients, including 42 with previous CYC treatment. Azathioprine (AZA), mycophenolate mofetil (MMF) and methotrexate (MTX) were chosen in 38, 4 and 6 patients, respectively. Maintenance therapy was started 4 [2-18] months after GC initiation and was prescribed for a median duration of 24 [6-72] months. Thirty-two (33%) patients relapsed, 4 of whom died. At last follow-up, patients who had received maintenance therapy, compared to those who did not, had better median MRS (1 [0-6] vs. 3 [0-6], p<0.0001) and had less disease relapse (10 (22%) vs. 22 (45%), p=0.01; Figure 1). At the time of relapse, 6/10 of the former patients had stopped maintenance therapy (3-6 months before). In multivariate analysis, maintenance therapy was the strongest predictor of good functional outcomes (OR = 8.17 [3.03—24.91], p<0.0001), and had a protective effect against relapse (OR=0.23 [0.07—0.67], p=0.01).

Conclusion : The results of this long-term follow-up study suggest that maintenance therapy in patients with PACNS improves functional outcomes and lowers relapse rate. It should thus be prescribed after induction treatment. **Figure 1**. **Kaplan-Meier curves of relapse-free survival in patients with primary angiitis of the central nervous system, according to whether or not they received maintenance therapy.**

Session Title: Vasculitis I: Novel Approaches to Therapy

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Glucocorticoids (GC) are the mainstay of treatment options for patients (pts) with Takayasu arteritis (TAK); however, long-term GC therapy is associated with adverse events (AEs). TAK pts have elevated IL-6 levels, which correlates with TAK disease activity (*Rheumatology*. 2006;45:545-48). Tocilizumab (TCZ), a humanized anti–IL-6 receptor antibody, was investigated for the treatment of relapsing TAK.

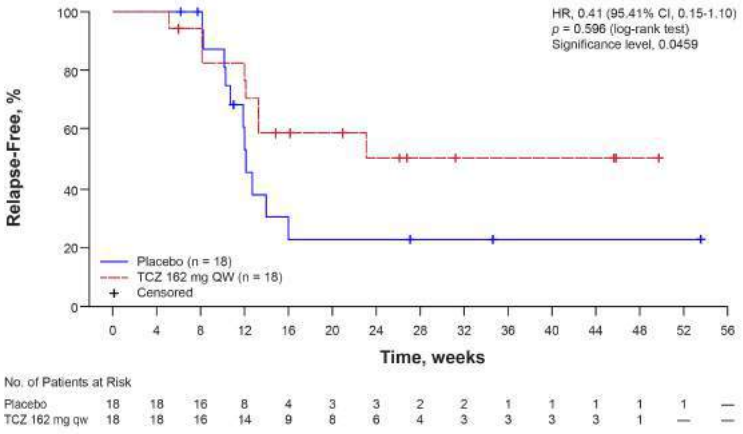
Methods: Pts ≥12 y with TAK (*Circ J*. 2011;75:474-503) receiving GC (≥0.2 mg/kg/d prednisolone equivalent) who had relapsed ≤12

weeks (wks) before enrollment were randomly assigned 1:1 to subcutaneous (SC) TCZ 162 mg or placebo (PBO) every wk (QW). Pts had to be receiving a stable GC dose at ≥2× dose at relapse and to be in remission for 1 wk before randomization. During the double-blind (DB) period, which lasted until relapse occurred in 19 pts, background GC were tapered by 10%/wk from wk 4, which is more rapid than in a general clinical setting. The primary end point was time to first relapse of TAK per protocol-defined criteria in the intent-to-treat (ITT) population estimated with the Kaplan-Meier analysis method and analyzed with the log-rank test stratified by age (<18 y, 18–64 y, ≥65 y). Time to relapse by Kerr's definition (*Ann Intern Med.* 1994;120:919-29) was a secondary end point.

Results: The ITT and safety populations included 18 TCZ pts and 18 PBO pts; median disease duration was 3.33 y and 2.89 y, respectively; mean ± SD GC dose at randomization was 0.57 ± 0.19 (TCZ) and 0.52 ± 0.16 (PBO) mg/kg/d; 38.9% of TCZ and 72.2% of PBO pts were HLA-B52 positive; 86.1% of pts were female. The per-protocol (PP) population included 16 TCZ and 17 PBO pts. No pts withdrew during the DB period. In the ITT population, 8 (44.4%) TCZ and 11 (61.1%) PBO pts relapsed. Estimated relapse-free rates at wk 24 were 50.6% and 22.9%, respectively, no statistical difference of time to first relapse between groups was seen (Figure; hazard ratio [HR], 0.41 [95.41% CI, 0.15-1.10]; $p = 0.0596$). Results were the same with Kerr's definition. In the PP population, for relapse according to protocol-defined criteria, HR was 0.34 and $p = 0.0345$ (95.41% CI, 0.11-1.00), favoring TCZ. In addition, TCZ showed favorable trends in each sign of relapse, including objective systemic symptoms, subjective systemic symptoms, elevated inflammation markers, vascular lesions, and ischemic symptoms accompanied by organ lesions (ITT population). AEs were reported in 14 (77.8%) TCZ and 11 (61.1%) PBO pts, and serious AEs were reported in 1 pt and 2 pts. Infections were the most frequent AEs. No pts died.

Conclusion: There was a trend toward relapse suppression favoring TCZ, though the primary end point was not met. The safety of TCZ was consistent with the current safety profile for TCZ in RA/JIA. TCZ may be a promising treatment option for rapidly tapering GC in TAK pts.

Figure. Time to first relapse[a] (Kaplan-Meier analysis; ITT population)



[a]Defined as ≥2 of 5 signs of relapse present, including objective systemic symptoms, subjective systemic symptoms, elevated inflammation markers, vascular lesions, ischemic symptoms accompanied by organ lesions. Relapse was also considered to have occurred if there was severe aortic valve incompetence accompanied by symptoms of cardiac failure or if there were ischemic symptoms accompanied by organ lesions ≥grade 2 or ≥grade 3 for myocardial infarction. TAK had to be medically confirmed as the cause of relapse by eliminating causes other than TAK on ≥2 consecutive assessments.

Session Title: Vasculitis I: Novel Approaches to Therapy
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Giant cell arteritis (GCA) is a large-vessel vasculitis usually treated with glucocorticoids (GC). GC are effective but responsible for substantial morbidity and mortality. Tocilizumab (TCZ) is a humanized monoclonal antibody against interleukin-6 receptor (IL-6R) that has recently been shown to be effective for the induction and maintenance of remission in GCA when used monthly for 1 year (1). However, data concerning the course of GCA after TCZ discontinuation are lacking and the optimal duration of this expensive immunosuppressive therapy in GCA is unknown. Our study therefore aimed to evaluate TCZ as an add-on therapy to GC during the first 3 months of GCA treatment (2).

Methods: Patients affected by GCA, as defined by the 1990 ACR criteria and a positive temporal artery biopsy (TAB) or CT-scan or PET-scan-proven aortitis were included in this French multicenter prospective open-label study. GC were started at 0.7 mg/Kg/day and then tapered according to a standardized protocol (2) with the aim to reach 0.1 mg/Kg/day at week 24 (W24). All patients received 4 infusions of TCZ (8 mg/Kg/4 weeks) after inclusion (W0, W4, W8 and W12). The primary endpoint was the percentage of patients in remission with a dose of prednisone ≤0.1 mg/Kg/day at W26. Patients were followed for 26 weeks and data about relapses and adverse events were prospectively recorded. Quantitative data are presented as mean±SD. This trial was registered with ClinicalTrials.gov, number NCT01910038.

Results: Twenty patients (15 women, 19 new-onset GCA) were included in this study between March 2014 and June 2015. Age at diagnosis was 72.6±7.6 years. TAB was positive in 17/19 (90%) patients and 7/16 (44%) had aortitis. Remission was obtained in all the cases, at W4 for 18/20 (90%) patients and at W8 and W12 for the two others. At W26 (14 weeks after last TCZ infusion), 5 patients (25%) had relapsed, 24.5±2.3 weeks after inclusion and at a mean dose of prednisone of 6.4±2.1 mg/day. One of these relapses was limited to a slight increase in the CRP (10 mg/L) and fibrinogen (4.6 g/L) level at W24; GC were briefly increased but the primary endpoint was reached at W26 without subsequent relapse. One patient died suddenly at W26 and was not considered to have reached the primary endpoint in the final analysis. Finally, 15 (75%) patients met the primary endpoint at W26, which is higher than previously reported with the same GC tapering i.e. 50% in the placebo group from the HECTHOR trial (2). Prednisone cumulative dose at W26 was 3,524±811 mg. After 26 weeks, 60 adverse events were reported in 19 patients and 20 were considered directly related to the study, the most common being hypercholesterolemia (n=8), infections (n=7 [3 before week 16]), and hepatic cytolysis (n=1).

Conclusion: Four TCZ infusions as an add-on therapy to GC for GCA treatment allowed rapid GC tapering and persistent remission with a low dose of GC (0.1 mg/Kg/day) after 6 months of follow-up. However, relapses can occur after TCZ discontinuation and further studies are needed to identify predictive factor of relapse after TCZ discontinuation. **REFERENCES** 1. Villiger PM et al. Session Title: Vasculitis I: Novel Approaches to Therapy
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Complement 5a (C5a) is involved in the pathogenesis of anti-neutrophil cytoplasm antibody (ANCA)-associated vasculitis (AAV). CCX168 is an orally administered, small molecule selective inhibitor of the C5a receptor (C5aR). It was shown to be effective and safe in a randomized clinical trial (CLEAR) in patients with AAV, and safely substituted for treatment with prednisone without a loss of efficacy. In the current trial (named CLASSIC), conducted in the USA and Canada, CCX168 was added to full-dose glucocorticoids plus either rituximab (RTX) or cyclophosphamide (CYC) to investigate the safety profile of CCX168 in addition to standard of care (SOC) treatment.

Methods: Patients with new or relapsing AAV and PR3 or MPO ANCA were eligible. Patients were randomized into one of three groups: i. SOC+placebo (N=13), ii. SOC+10 mg CCX168 twice daily (N=13), or iii. SOC+30 mg CCX168 twice daily (N=16) and were treated for 12 weeks with CCX168/placebo. Two patients, one in each of the CCX168 groups, were excluded from the intention to treat analysis but included in the safety analysis: one did not receive any study drug and one received only 2 weeks of study drug and thus did not have any on-treatment disease activity assessment. All patients received either RTX (375 mg/m^2 IV weekly for 4 weeks) or CYC (15 mg/kg IV up to 1.2 g, on Days 1, 15, 29, 57, and 85) at investigators' discretion. The starting dose of prednisone for all patients was 60 mg/day, tapered to 10 mg/day by week 12. Since CCX168 was added to full-dose glucocorticoid SOC treatment, the primary endpoint was safety measured by comparison of the incidence of adverse events (AEs) among the groups. Efficacy was mainly assessed based on clinical response, defined as a decrease of Birmingham Vasculitis Activity Score (BVAS) from baseline to week 12 of at least 50%, and no worsening in any body system; however, the study was not powered to detect differences among groups.

Results: Forty-two patients with AAV were enrolled. Presenting features were typical of AAV and well balanced across groups. Mean ±SD age: 58±13 years; female/male: 55%/45%; newly-diagnosed/relapsing AAV: 64%/36%; PR3/MPO-ANCA: 50%/50%; BVAS: 15.3±6.6, eGFR: 59±27 mL/min/1.73 m^2; RTX/CYC use: 93%/7%. A total of 7 patients had serious adverse events, 2 of 13 patients in the SOC+placebo group, 2 of 13 in the SOC+10 mg CCX168 group, and 3 of 16 in the SOC+30 mg CCX168 group. These included 4 infection-related SAEs: toe gangrene (1), cellulitis and skin abscesses (1), and sepsis and urinary tract infection (1 each) in the three groups, respectively. Total AEs occurred in 13, 11, and 15 patients in the three groups, respectively. Response at week 12, based on BVAS, was achieved in 10, 11, and 12 patients, respectively, in each group. Early remission (BVAS = 0 at week 4) was achieved in 2, 1, and 5 patients, respectively. eGFR mean change from baseline to week 12 was 0.8, -0.8, and 3.1 mL/min/1.73 m^2, respectively, in each group.

Conclusion: CCX168 was found to be safe when added to SOC high-dose glucocorticoids and either RTX or CYC. Based on these results and the prior CLEAR trial, 30 mg CCX168 twice daily appears to be an appropriate and safe dose for further study in patients with AAV.

Session Title: Vasculitis I: Novel Approaches to Therapy
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Takayasu's arteritis (TAK) is a large-vessel primary systemic vasculitis that affects the aorta, its branches, and the pulmonary arteries. Despite treatment with glucocorticoids, relapse with treatment- and disease-related morbidity occurs in a high percentage of patients. Several other immunosuppressive agents have been used to treat TAK, but their use is based solely on open-label experience. T-cell activation has been implicated in the pathophysiology of TAK. A multi-center, randomized, double-blind, placebo-controlled, withdrawal design trial was conducted to examine the efficacy and safety of treatment with abatacept (CTLA4-Ig) combined with prednisone in patients with TAK.

Methods: Patients with newly-diagnosed or relapsing TAK were eligible for the trial. All patients were treated with abatacept 10 mg/kg IV on days 1, 15, 29, and week 8, together with prednisone. At week 12 patients in remission underwent a double-blinded randomization to continue monthly abatacept or be switched to placebo together with a standardized prednisone taper reaching discontinuation at week 28. Patients remained on their randomized assignment until meeting criteria for early termination or until the common closeout date, 12 months after enrollment of the last patient. The primary endpoint was duration of remission (relapse-free survival, RFS). A planned sample size of 30 patients was based on detecting a 30% improvement in RFS utilizing a one-sided alpha = 0.1. Kaplan-Meier curves were constructed and differences in treatment arms compared using the log-rank test in an intent-to-treat analysis.

Results: 34 eligible patients received study drug with 26 reaching the week 12 randomization. Disease characteristics of the 26 randomized patients are outlined in Table 1. The RFS at 12 months was estimated to be 22% for those receiving abatacept and 40% for those receiving placebo (p= 0.853), Figure 1. Treatment with abatacept in patients with TAK enrolled in this study was not associated with a longer median duration of remission (abatacept 5.5 months, placebo 5.7 months). 114 adverse events occurred in 28 patients including 23 serious adverse events in 15 patients. There was no difference in the frequency or severity of adverse events between treatment arms, including the rate of infection.

Conclusion: In this study, which was the first randomized, double-blind trial conducted in TAK, the addition of abatacept to prednisone did not reduce the risk of relapse in patients with TAK. Concurrent abatacept was not associated with a higher rate of toxicity compared to prednisone alone.

Short-Course Glucocorticoids in ANCA-Associated Vasculitis: A Proof of Concept Study

Eli Miloslavsky[1], John Niles[2], Karen Laliberte[2], Katherine Cosgrove[2] and John H. Stone[3], [1]Division of Rheumatology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]Department of Medicine, Division of Nephrology, Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Vasculitis I: Novel Approaches to Therapy
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Despite therapeutic advances in ANCA-associated vasculitis (AAV), patients continue to be exposed to considerable treatment morbidity from long-term glucocorticoid (GC) use. The optimal duration of GC treatment has not been studied in AAV. We conducted an open-label, proof of concept study investigating whether an 8-week GC taper, in combination with rituximab (RTX), would be sufficient to control AAV in a subset of patients who have a more favorable prognosis. Such an approach would reduce the cumulative GC dose by at least 45%, thereby diminishing the potential for GC toxicity.

Methods: Patients with granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) who had newly diagnosed or relapsing disease with a BVAS/WG of 3 or more were eligible to participate. Patients with diffuse alveolar hemorrhage requiring intubation, MPO-ANCA-positive patients with severe renal involvement (GFR < 30 ml/min/1.73m^2) and PR3-ANCA-positive patients with glomerulonephritis were excluded. Subjects were treated with RTX 375mg/m^2 weekly for four weeks and an 8 week GC taper (60mg x 2 weeks, 40mg x 2 weeks, 30mg x 1 week, 20mg x 1 week, 10mg x 1 week and 5mg x 1 week then off). Patients on chronic GCs prior to trial entry were permitted to taper to their pre-relapse dose. The primary outcome was no disease activity (BVAS/WG = 0) and being off prednisone (or at baseline dose for those on chronic GCs prior to trial entry) at 6 months.

Results: Eighteen patients have enrolled and 14 have completed the study to date (Table 1). The mean age was 59.7 and 66% were female. Sixty-seven percent had GPA, 39% were PR3-ANCA-positive and 44% had relapsing disease. Mean BVAS/WG at study entry was 5.6. Nine of fourteen patients (64%) successfully reached the primary endpoint. Of the 5 patients who failed the primary endpoint, 2 had flares of glomerulonephritis, one had relapse of diffuse alveolar hemorrhage, one of mononeuritis multiplex and one had recurrent meningitis. All of these patients reached remission after treatment according to best medical judgment. There were no relapses of clinical features associated with granulomatous inflammation. Vasculitis damage index at study entry was 0.9 and 1.5 at the completion of the study.

Conclusion : A 2-month course of prednisone in combination with rituximab resulted in 64% of patients reaching and maintaining complete remission at 6 months, similar to rates reported in the Rituximab in ANCA-associated Vasculitis (RAVE) trial. Relapses were primarily due to manifestations associated with vasculitis rather than granulomatous inflammation. Further study of this protocol in larger numbers of patients should be considered.

Table – Demographic characteristics and organ involvement at baseline

Characteristic	N (%)
Age (years)	59.7
Sex (female)	12 (67%)
GPA	12 (67%)
MPA	6 (33%)
PR3-ANCA	7 (39)
MPO-ANCA	9 (50%)
ANCA negative	2 (11%)
Relapsing disease	8 (44%)
BVAS/WG at baseline	5.7
Organs involved	
General	9 (50%)
Cutaneous	7 (39%)
Mucous membranes/eyes	2 (11%)
Ear, nose, throat	10 (56%)
Pulmonary	11 (61%)

Effectiveness of a Six-Week Hand Osteoarthritis Program in a Primary Care Setting

Nina Brodin[1,2], Linda Bjurehed[3] and Mathilda Björk[4,5], [1]Department of Neurobiology, Care Sciences and Society, Division of Physiotherapy, Karolinska Institutet, Huddinge, Sweden, [2]Department of Orthopaedics, Division of Physiotherapy, Dandeyd Hospital, Stockholm, Sweden, [3]Department of Activity and Health, Linköping, Linköping University Hospital, Linköping, Sweden, [4]Department of Rheumatology and Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden, [5]Department of Rheumatology and Department of Social and Welfare Studies, Linköping University, Linköping, Sweden

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Hand Osteoarthritis (hand OA) is highly prevalent among women and men aged 55 and older. It often causes pain, reduced range of motion and grip strength which, in turn, reduce hand function and cause activity limitations in daily life. Effects of structured hand OA programs in primary care settings, including both patient education and exercise, are sparsely reported. The aim of the study is to evaluate the effectiveness of a six-week hand OA primary care program on hand function and activity limitation in individuals with hand OA.

Methods: Individuals with diagnosed hand OA that began a hand OA program at a primary care unit in southeastern Sweden were enrolled consecutively between 2008 and 2011. In total 64 individuals agreed to participate, of which 15 did not fulfill the program. The remaining 49 (92% female, mean age 69, range 47-89 years) performed the hand OA program starting with a theoretical part with two lectures of 1.5 hours each. The program continued with group based hand exercises including paraffin treatment twice weekly during the six-week period. Outcome measures were the Grip Ability Test (GAT), the Signal of Functional Impairment (SOFI) and the JAMAR (grip strength). To assess activity limitation the Patient Specific Functional Scale (PSFS) and the Quick Disabilities of the Arm, Shoulders and Hand (Quick-DASH) were used. The evaluations were performed at baseline, after three months and after one year by occupational therapists trained in

using the study specific outcome measures. The study was conducted in accordance with the ethical principles of the Helsinki declaration.

Results: The participants and the drop-outs were comparable with the exception that patients in the drop-out group were working to a higher extent (p=0.005). The comparisons based on non-parametric analyses showed that the participants' hand function, concerning grip strength (JAMAR), range of motion (SOFI - hand) and grip ability (GAT) improved significantly from baseline to the three-month follow-up (p<0.001- 0.011), as well as when comparing baseline with the one year follow-up (p<0.001-0.004). Activity limitations (PSFS and Quick-DASH) also decreased during the same periods (0.001- 0.008 and 0.001- 0.013 respectively).

Conclusion: The result indicates that a structured hand OA program, including both patient education and hand exercises, is a useful non-pharmacological group treatment in primary care as it improves hand function and activity limitation with a retentive effect up to one year after completion of the intervention.

High Financial Strain, but Not Poverty or Lower Education, Increases the Risk of Incident Depression in Systemic Lupus Erythematosus (SLE)

Natalie McCormick[1], Laura Trupin[2], Edward H. Yelin[2] and Patricia P. Katz[2], [1]Faculty of Pharmaceutical Sciences, University of British Columbia/Arthritis Research Canada, Vancouver, BC, Canada, [2]Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Depression is common in women with SLE. Low socioeconomic status (SES) has been associated with prevalent depression, but the longitudinal relationship between SES and onset of depression has not been examined. We assessed poverty, income, education, and subjective financial strain (FS) as predictors of incident depression in the UCSF Lupus Outcomes Study (LOS).

Methods: Data were from the 2010-2015 cycles of the LOS, obtained through annual structured phone interviews of individuals with confirmed SLE. Depression was assessed with the Center for Epidemiological Studies Depression Scale (CESD), using a validated cutoff value (≥ 23) for major depressive disorder. Women interviewed in ≥ two consecutive cycles, with scores < 23 in the first cycle (T1), were included. Participants' level of FS was classified as High, Moderate, or None based on responses to 3 questions on current and anticipated FS (Table 1). Generalized estimating equations were used to assess the impact of educational attainment, poverty (≤ or > 125% of federal poverty level), income, and FS at T1 on the risk of incident depression the next year (T2), while adjusting for age, race, marital status, current smoking, obesity, physical functioning, disease duration, and T1 CESD score, self-reported disease activity (Systemic Lupus Activity Questionnaire; SLAQ) and damage (Brief Index of Lupus Damage; BILD).

Results:

682 women (mean age 51±13.6, SLE duration 18 ±8.9 years) contributed 2,097 observations. 45% were college graduates; 13% were living in poverty. 19% had High FS, 47% Moderate FS, and 34% No FS. High FS was reported by 61% of those in poverty, but also 13% of those not in poverty (Table 1).

166 women had 184 episodes of incident depression (rate=8.8/100 person-years). Depression occurred in 40% of those with High FS at T1, 24% with Moderate FS, and 16% with No FS. In univariate analysis, poverty, lower income and education, higher T1 SLAQ, BILD, and CESD scores, and high FS were each associated with onset of depression (Table 2); race/ethnicity was not. Neither poverty, income, nor education remained significant in multivariate analyses, but FS did. In the final model, odds of developing major depression were nearly two times higher for those with High FS compared with None (OR=1.89, 1.09-3.28).

Conclusion:

In this community-based cohort of SLE, the annual incidence of depression was 9%, and high financial strain (FS) was a significant predictor, even after controlling for disease factors and other measures of SES. Determining specific, modifiable sources of FS in SLE patients may help identify those with elevated risk of depression.

Table 1: Levels of Financial Strain by Poverty Status and Educational Attainment

	High Financial Strain[a]	Moderate Financial Strain[b]	No Financial Strain[c]
All Participants	130 (19%)	320 (47%)	232 (34%)
Poverty Status[1]			
Poverty	54 (61%)	28 (32%)	6 (7%)
Not in poverty	74 (13%)	287 (50%)	218 (38%)
Educational Attainment			
No college degree	92 (25%)	190 (51%)	93 (25%)
College degree	38 (12%)	130 (42%)	139 (45%)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: ARHP I: Exemplary Abstracts
Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid Arthritis (RA) can result in functional disability and is associated with an increased risk of cardiovascular disease (CVD). In healthy adults and patient populations, light physical activity (LPA) engagement is reported to confer benefits to cardiovascular health and physical function, with time spent sedentary (i.e., activities ≤ 1.5 METS whilst sitting/lying) demonstrated to be adversely related to these health outcomes. Studies also indicate the manner in which sedentary time is accumulated (i.e., sedentary time, bouts, breaks) to hold implications for CVD profile and physical function. However, it is not known whether sedentary behaviour patterns and LPA are relevant to CVD risk and functional ability in RA. The aims of this study were therefore to investigate relationships between objectively assessed sedentary behaviour patterns and LPA with (1) 10-year risk of CVD, and (2) individual CVD risk factors and functional disability in RA. A secondary aim was to determine if associations were independent of moderate-to-vigorous physical activity (MVPA) engagement**.**

Methods: Patients with RA (N = 61) provided a fasted blood sample and underwent physical assessments to evaluate factors associated with their cardiovascular health. Ten-year CVD risk was computed via the Q-risk-score. Individual CVD risk factors were determined from fasted blood samples (Table 1), and functional disability assessed via the Stanford Health Assessment Questionnaire (HAQ). Sedentary behaviour patterns, LPA and MVPA were measured via 7-days of accelerometry. Sedentary time, LPA and MVPA (min/day) were defined as <100, 100 – 2019, and ≥2020 counts per minute, respectively. Sedentary breaks (number/day) were calculated as interruptions in sedentary time for ≥1 minute. Sedentary bout variables (number/day, average length) were derived by determining the number and length of consecutive zeros recorded above a ≥20 zero-count threshold.

Results: Regressions analyses were conducted to answer study aims. Models were adjusted as appropriate for age, gender and accelerometer-wear time (Model 1). Where significant associations were observed, models were further adjusted for daily MVPA engagement (Model 2). Results revealed significant positive associations between sedentary time and the number of sedentary bouts per day ≥20 minutes with 10-year CVD risk, with the reverse true for LPA participation (model 1; sedentary time, $\beta = .38$, $p < .01$, sedentary bouts, $\beta = .37$, $p < .01$, LPA, $\beta = -.45$, $p < .01$). Associations were independent of MVPA engagement (model 2; β change = .01 to .03). Sedentary behaviour patterns and LPA were not related to individual CVD risk factors or functional disability.

Conclusion: Promoting LPA participation and restricting sedentary time to bouts <20 minutes may attenuate long-term CVD risk in RA, independent of MVPA engagement.

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: To describe the clinical presentation and associations of patients with IM associated with cancer in a large group of inflamatory myopathy (IM) from the multicentric REMICAM registry

Methods: A multicenter retrospective study from the REMICAM registry was performed. Patients older than 40 years at diagnosis were selected. All patients were diagnosed with IM according to Bohan and Peter criteria, followed between Jan 1980 and Dec 2014 and classified into 7 different clinical subgroups: primary dermatomyositis (DM), primary polymyositis (PM), cancer associated myositis (CAM), overlap myositis (OM), inclusion body myositis (IBM) and necrotizing myositis (NM). Only cancers diagnosed within 3 years of IM diagnosis were considered as CAM. Descriptive statistics, univariate and multivariate analysis were performed. Kaplan Meyer curves with long-rank analysis were used for survival.

Results: From 283 patients (72% w, 60±11 y at diagnosis, 9±7 y of follow-up, 39% DM, 61% PM), 64 (23%) presented any type of cancer: 11 lung, 8 hematological, 8 skin, 7 breast, 4 colon, 4 stomach, 4 ovary, 4 bladder, 3 endometrium, 3 prostate and 8 others. Median time between IM and cancer was 5 months. In multivariate analysis, patients with cancer were more frequently men (p<.0001), with DM (p=.005) and presented more ischemic lesions (p<.0001). No other clinical findings were different between patients with or without cancer. Mortality was higher in patients with cancer, with a median survival of 10±3 years, compared to 22±3 years for patients without cancer (p<.0001). From the CAM group, 41 (64%) patients died, mainly as a consequence of cancer.

Conclusion: In our registry, over 20% of patients older than 40 years presented IM associated with cancer. This type of IM is more common in men and present as dermatomyositis with ischemic lesions. As expected, mortality is highly increased in IM patients with cancer.

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Much progress has been made in identifying risk factors for RA, but it is unclear whether individuals at risk for RA have knowledge of these factors. Potential educational interventions include reading materials, interactive web-based tools, and sessions with health educators. We assessed the effect of these educational interventions on RA risk factor knowledge among first-degree relatives (FDRs) of patients with RA using a randomized controlled trial.

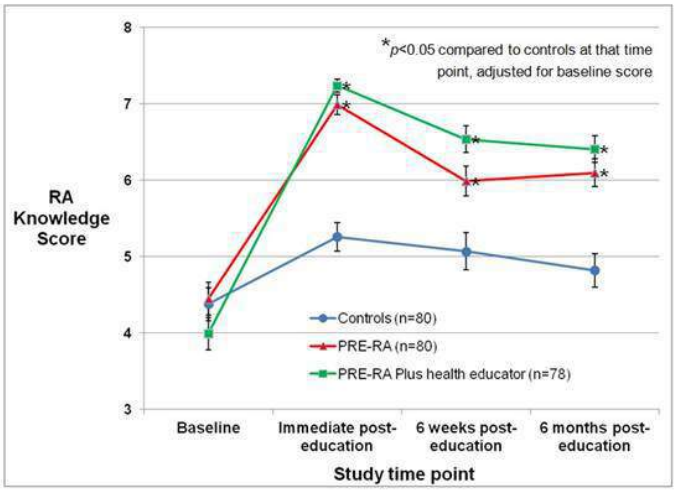
Methods: We developed a web-based tool, the Personalized Risk Estimator for Rheumatoid Arthritis (PRE-RA), which collects data on an individual's age, sex, family history, and risk-related behaviors; presents genetic and autoantibody results; displays relative risk and

absolute risk of RA; and provides personalized education about RA risk. We randomly assigned FDRs without RA to 1 of 3 educational interventions: 1) Control group that received standard education about RA (n=80), 2) PRE-RA group that received personalized education via the web-based PRE-RA tool (n=80), and 3) PRE-RA Plus group that received PRE-RA and a one-on-one session with a health educator (n=78). We assessed RA knowledge at baseline and immediately, 6 weeks, and 6 months after education using the validated Illness Perception Questionnaire modified for RA. We calculated an RA knowledge score by summing the number of 8 RA risk factors that a subject agreed were related to RA. We used linear regression to compare RA knowledge scores from PRE-RA and PRE-RA Plus vs. controls at each time point adjusted for baseline score. We additionally evaluated the impact of the health educator in PRE-RA Plus vs. PRE-RA alone at each post-intervention time point as well as change in RA knowledge compared to baseline.

Results: Among 238 randomized FDRs at baseline, mean age was 45.6 years (SD 14.4), 76% were female, 88% were college educated, and mean RA knowledge score (possible range 0-8) was 4.3 (SD 1.9). At baseline, only 31% agreed smoking was a risk factor for RA, but this increased to 77% at 6 months after PRE-RA (p<0.001). Those who received PRE-RA or PRE-RA Plus had higher mean RA knowledge scores immediately (7.1 [SD 1.0]) and 6 months (6.3 [SD 1.6]) after personalized education compared to controls (immediate 5.3 [SD 1.7] and 6 months 4.8 [SD 2.0]; p<0.001, **Figure**). Compared to only the PRE-RA tool, those who also met with a health educator had similar RA knowledge 6 months after education (improvement of 1.7 [SD 1.8] for PRE-RA; 2.4 [SD 1.9] for PRE-RA Plus, p=0.16).

Conclusion: Despite being both familiar with and at increased risk for RA, FDRs had low baseline knowledge about RA risk factors. We created an interactive, web-based personalized tool that educated FDRs about RA, and this increased knowledge persisted for 6 months. While there may be some additional benefit by also using a health educator, the PRE-RA tool alone is an effective method to educate individuals about RA risk factors to encourage positive health behaviors.

Figure. Mean RA knowledge scores for subjects by randomized group at baseline and immediately, 6 weeks, and 6 months after educational intervention (n=238).



The RA knowledge score was calculated by summing the number of 8 established risk factors for RA that a subject agreed was related to RA (range 0-8, higher scores with more knowledge): smoking, diet, being overweight/obese, poor dental health, personal behavior, heredity/genetics, aging, and altered immunity.

PRE-RA (Personalized Risk Estimator for Rheumatoid Arthritis) is a web-based risk assessment tool that uses an individual's genetics (shared epitope), autoantibodies (CCP and RF), age, sex, family history, and RA risk-related behaviors to provide personalized education on their RA risk.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: There are sex disparities in both utilization and outcomes of total hip arthroplasty (THA).[1] Identification of sex-specific biomechanical factors related to outcomes could lead to new perioperative rehabilitation strategies to ultimately reduce disparities. We have previously shown that gait mechanics are associated with self-reported function and pain.[2] The purpose of this secondary analysis was to test the hypothesis that these associations differ by sex. We also hypothesized that associations between abductor strength and pain or function differ by sex.

Methods: 124 subjects (age 61 ± 10; 64 Female; BMI 29 ± 5) from an IRB approved repository, were assessed before and ~1 year after THA. Dynamic sagittal plane hip range of motion (ROM) and peak 3D hip external moments, averaged from trials at subjects' self-selected normal walking speeds, were analyzed. Hip abductor strength was assessed using manual muscle testing. Function and pain were assessed using Harris Hip Score (HHS) subscores. To test our hypotheses, we used first-order partial correlations to identify relationships between changes in HHS and changes in gait variables, controlling for speed. Next we used Pearson correlations to identify relationships between changes in HHS and muscle strength. Men and women were analyzed separately. We compared the associations by sex.

Results: We found several sex-specific associations (Table 1). There were no associations between improved function and either gait or strength in men. By contrast, improved function was significantly correlated with increased hip ROM, peak adduction and external rotation moments, and abductor strength, in women. Improved pain was associated with increased ROM and decreased peak adduction moment, in men. Improved pain was associated with increased external rotation moment in women. There were no other associations ($p > 0.112$).

Conclusion: Sex-specific associations among improvement in self-reported pain and function, and improvement in gait mechanics and strength, suggest that sex-specific rehabilitation may be helpful. Although these findings are preliminary, they may indicate that women could benefit from interventions to improve dynamic sagittal plane ROM, and frontal and transverse plane hip mechanics, as well as hip abductor strength. Further research should investigate the feasibility and effectiveness of sex-specific rehabilitation protocols.

Session Title: Epidemiology and Public Health I: Inflammatory Arthritis – Risk and Impact

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Studies suggest an association between farming and risk of rheumatoid arthritis (RA), but knowledge on the role of pesticides is sparse. Two prior studies have reported use of insecticides may increase risk of RA in women, but associations of RA with specific pesticides in men and in farmers are not known.

Methods: We investigated associations between specific pesticides and RA in a cohort of licensed male pesticide applicators/farmers in the Agricultural Health Study (AHS). Of 30,316 participants enrolled in 1993-97 who completed at least one follow-up questionnaire through 2014, 358 (138 prevalent; 220 incident) cases of RA were confirmed by medical records or self-reported use of disease modifying anti-rheumatic drugs. We evaluated associations between RA and ever-use and intensity-weighted lifetime days of use for 46 pesticides with at least 5 exposed cases, comparing confirmed cases and non-cases (n=27,744) who did not self-report RA using logistic regression to estimate odds ratios (OR) and 95% confidence intervals (CI), adjusted for age at enrollment, state, smoking pack-years, and education.

Results: Incident RA was associated with ever using the insecticides fonofos (OR: 1.70; 95%CI: 1.22-2.37) and carbaryl (OR: 1.51; 95%CI: 1.03-2.23), and use of the herbicide chlorimuron ethyl (OR: 1.45; 95%CI: 1.01-2.07), while overall (prevalent + incident) RA was associated with having used the insecticides terbufos (OR: 1.27; 95%CI: 1.01-1.60) and DDT (OR: 1.38; 95%CI: 1.01-1.89) and the overall insecticide class of organophosphates (OR: 1.51; 95%CI: 1.02-2.23). Statistically significant exposure-response trends were observed for incident RA, confirming the association with fonofos (trend p=0.005), and also showing associations with the insecticide toxaphene (trend p=0.02) and the herbicide atrazine (trend p=0.01). For RA cases overall, exposure-response relationships were confirmed for terbufos (trend p=0.02) and DDT (trend p=0.04), and were also observed for the herbicides alachlor (trend p=0.03) and glyphosate (trend p=0.02).

Conclusion: Our results provide evidence of associations between use of specific pesticides and risk of RA in men, including organophosphate insecticides. Our findings also replicate an association of RA risk with the organochlorine insecticide DDT, recently described in female spouses of farmer/applicators in the AHS cohort. The immunotoxic effects of pesticides are complex, and the potential role of specific pesticides in the development of RA warrants further investigation in other samples and mechanistic studies.

Session Title: Epidemiology and Public Health I: Inflammatory Arthritis – Risk and Impact

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Rheumatoid Arthritis (RA) is a disease that can have a long sub-clinical phase. During this phase the person with pre-RA could have factors in the peripheral blood, that could confer a risk of developing RA to a blood recipient. One factor could be anti-citrullinated peptide/protein antibodies (ACPA), which has a high specificity for RA and has been found in blood donors to precede the clinical RA by several years (1). In experimental murine models it has been shown that ACPA can not only induce but also enhance arthritis (2). Previous studies on risk of RA and blood transfusion have been few and inconclusive, and none of them described the blood donor population. Based on these findings we speculated whether blood products from a donor with subclinical RA at the time of donation, could be a risk factor of RA development in the recipient.

Methods: We used the Scandinavian Donations and Transfusions database (SCANDAT2) linked with Danish and Swedish nationwide health outcomes registers to attain complete follow-up for up to 47 years regarding hospital care, cancer, and death. In 2015 the database contains 25.523.334 donation records, 21.318.794 transfusion records, and 3.692.653 unique persons with valid identification, presently followed over 40 million person-years(3). Incident RA was defined as having two registered RA diagnoses in the national health registers within a two-year period. Taking a look-back approach, we first identified all donors in SCANDAT2 diagnosed with RA subsequent to their earliest registered donation. We then followed all recipients in SCANDAT2 for the occurrence of RA, starting follow-up one year after first registered transfusion. In analyses, we then assessed the occurrence of RA in recipients according to blood donor characteristics, e.g. whether exposed to donors with subsequent RA or not. Rate ratios adjusted for patient age, sex, ABO blood group, birth cohort, geographic region, and number of transfusions were calculated.

Results: We identified 55 recipients who developed RA during 72017 person-years of follow-up after receiving blood from donors who developed RA (55 events/72017 person-years). For comparison, we identified 9370 recipients who developed RA during 11,733,459 person-years of follow-up after receiving blood from donors who remained free of RA. These figures corresponded to a rate ratio of 1.01 (95% confidence interval 0.73-1.39). Detailed data on recipient RA occurrence by time since transfusion and according to donor rheumatoid factor status, age and sex will be presented.

Conclusion: We found no evidence that a pre-RA condition in the blood donor contributes significantly to a higher risk of developing RA in the transfusion recipients. References:

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health I: Inflammatory Arthritis – Risk and Impact
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

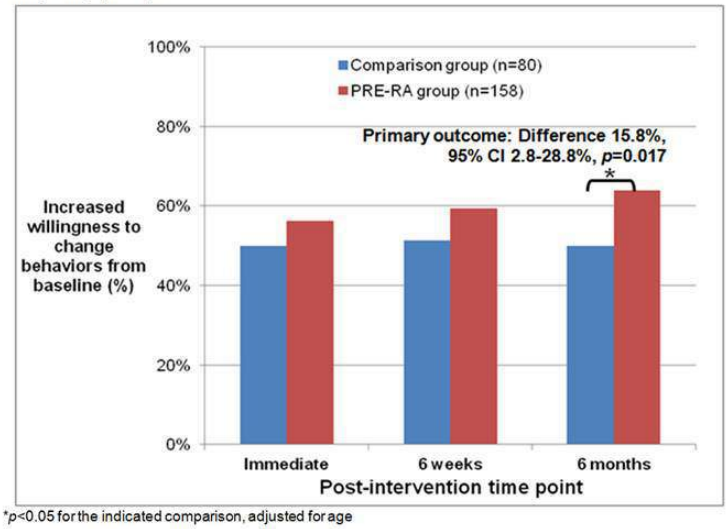
Background/Purpose : Disclosure of genetic risk information alone has had limited impact on changing health behaviors in research trials. Prior studies have not evaluated whether disclosure of risk personalized to genetics, biomarkers, and lifestyle factors may motivate changes in health behaviors. We performed a randomized controlled trial to test the effect of personalized RA risk disclosure, including genetics and autoantibodies, on willingness to change RA behavioral risk factors among a high-risk population of first-degree relatives (FDRs).

Methods : We developed the Personalized Risk Estimator for RA (PRE-RA) tool as a web-based intervention for use in the PRE-RA Family Study. PRE-RA provides summary estimates of absolute and relative RA risks and educates individuals about their RA risk factors —including *HLA-DRB1* genotype results, CCP and RF autoantibody results, lifestyle risk factors (smoking, overweight/obesity, low fish intake, periodontitis), and demographics. We recruited asymptomatic FDRs without RA at a single center and randomized them to receive PRE-RA education alone (n=80) or PRE-RA education with health educator guidance (n=78; total n=158, PRE-RA group), or to receive standard education about RA (n=80, comparison group). We measured willingness to change behaviors based on Prochaska's Stages of Readiness for Change using validated ladder scales (range 0-10, higher score indicating more willingness to change) at 4 time points: baseline and immediately, 6 weeks, and 6 months after intervention. The primary outcome for willingness to change behaviors was defined as an increase in any ladder scale for 4 modifiable RA risk factors (exercise, diet, dental care, and smoking among current smokers) 6 months after intervention compared to baseline using intention-to-treat (ITT) analysis. Secondary analyses investigated differences among the three study arms.

Results : Among the 238 randomized subjects, 87% were White and 77% were female. The PRE-RA intervention group was older (mean 46.7 years [SD 14.4]) than the comparison group (mean 43.4 years [SD 14.7]). In the primary ITT analysis, 63.9% of the PRE-RA group met the primary outcome, compared to 50.0% in the comparison group (age-adjusted difference 15.8%, 95%CI 2.8-28.8%, p=0.017, **Figure**). Within the PRE-RA group, the addition of a health educator resulted in no additional effect on willingness to change behaviors beyond the web-based PRE-RA education tool alone (p=0.54 at 6 months after intervention).

Conclusion : Disclosure of RA risk to FDRs personalized to genotype, autoantibody results, and lifestyle risks resulted in increased willingness to change behaviors related to RA. Personalized risk education incorporating factors beyond genetics may motivate health behavior changes in those at risk for chronic disease and could be widely disseminated using a web-based tool.

Figure. Proportion of unaffected first-degree relatives who had increased willingness to change RA-related behaviors according to those randomized to receive RA risk disclosure personalized to genetics autoantibodies, and lifestyle (PRE-RA group) or standard RA education (comparison group) in the PRE-RA Family Study (n=238).



*$p<0.05$ for the indicated comparison, adjusted for age

The primary outcome for increased willingness to change behaviors was defined as an increase after intervention compared to baseline in any ladder scale for 4 modifiable RA behavioral risk factors (exercise, diet, dental care, or smoking).

PRE-RA (Personalized Risk Estimator for Rheumatoid Arthritis) is a web-based risk assessment tool that uses an individual's genetics (*HLA-DRB1* shared epitope), autoantibodies (CCP and RF), age, sex, family history, and RA risk-related behaviors to provide personalized education on their RA risk.

Session Title: Epidemiology and Public Health I: Inflammatory Arthritis – Risk and Impact

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Certain autoantibodies (aabs) are highly disease specific, can be detected prior to the onset of clinically apparent disease and oftentimes increase in number and titer up to disease classification. Whether preclinical autoreactivities are already specific for the eventual clinical disease, or if they initially cross specificity boundaries but become more disease-specific closer to diagnosis, is unknown. First-degree relatives (FDRs) provide an ideal group to examine aabs prior to disease classification. We tested samples from nearly 1,700 patients, unaffected FDRs , and unaffected controls from SLE, RA and Type 1 Diabetes (T1D) cohorts to categorize both non-specific and disease-specific autoreactivities.

Methods: Previously collected cohorts of disease-specific autoantibody (aAb) positive patients with SLE (n=187), RA (n=200), and T1D (n=188), disease-specific aab positive (aAb+) and negative (aAb-) FDRs of SLE (n=136 aAb+, n=186 aAb-) and RA (n=198 aAb+ and n=194 aAb-) patients, and unaffected controls from the SLE (n=198) and T1D sites (n=200) were used. All individuals were tested for 8 SLE (dsDNA, Chromatin, Ro, La, Sm, SmRNP, RNP, and aRibo P by Bioplex2200; IF ANA), six RA (CCP2, CCP3.1, RF IgA, RF IgM, RF IgG, RF-neph), and three T1D (GADA, IA2 and mIAA) aabs. 38 Anti-citrullinated protein/peptide antibodies (ACPA) were measured using a bead-based array.

Results: Higher rates of SLE aabs, Ro/La and Sm/SmRNP/RNP, were seen in RA patients (8.0% and 4.0%), RA aAb+ FDRs (5.0% and 4.0%), and RA aAb- FDRs (5.1% and 5.7%) than T1D patients (1.1% and 1.6%) and T1D controls (1.5% and 2.0%). Overall positivity rates for any SLE aab in the RA groups (patients: 16.1%, aAb+ FDRs: 14.7%, aAb- FDRs: 15.5%) were twice as high as those of the T1D cohort (7%). All SLE groups were more likely to be positive for any of the RA aabs than the T1D groups, but a higher percent of SLE aAb+ FDRs were positive for RA aabs than SLE patients (CCP3.1: 9.6% vs 2.7%; RF Neph: 16.9% vs 11.8%; RF IgM: 20.6% vs 12.8%). ACPA were highly RA patient specific, although a higher percent of SLE patients (43.0%) and SLE aAb+ FDRs (31.1%) were positive for any citrullinated antigen, more than RA aAb+ FDRs (20.2%). Using logistic regression, we estimated the probability of an individual testing positive for an alternate autoantibody. Compared to RA FDRs, SLE FDRs are more likely to test positive for other aabs (OR= 3.4). In patients and FDRs who tested positive for aabs associated with the familial autoimmune diseases, males are less likely to have aabs associated with other autoimmune disease than females (OR = 0.63).

Conclusion: Limited but detectable evidence of autoimmunity expanding beyond the familial disease specificity was found in FDRs. RA and SLE patients and FDRs exhibit more autoantibody specificities than T1D patients. Male FDRs are more likely to only have antibodies associated with the familial disease, whereas female FDRs more often have antibodies across autoimmune diseases. Understanding the clinical relevance of detecting other aabs in unaffected FDRs will require additional prospective study.

Familial Aggregation of Rheumatoid Arthritis in Sarcoidosis: A Register-Based Case-Control Study in Sweden

Elizabeth V. Arkema, Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health I: Inflammatory Arthritis – Risk and Impact
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Sarcoidosis is an inflammatory disease with unknown etiology that primarily affects the lungs and lymph glands. Sarcoidosis shares some features with rheumatoid arthritis (RA), such as joint involvement and genetic susceptibility related to HLA class II alleles. The aim of this study was to estimate the familial co-aggregation of sarcoidosis with RA.

Methods: A case-control study using Swedish national registers was performed. Adults with sarcoidosis (cases) were identified from the National Patient Register (NPR) and required to have at least two visits listing a sarcoidosis ICD code 2001-2013. Population controls matched 10:1 on age, sex and county who were living in Sweden with no history of sarcoidosis at the time the case was diagnosed (index date) were identified from the Total Population Register. The Multigeneration Register was used to identify parents, siblings and children. Family members with at least two visits listing an ICD code for RA were identified from the NPR (2001-2013). A subset was identified who had any listing of seropositive RA (M05, M08.0). Mean number of first degree relatives (FDR) was calculated for cases and controls

to assure that family structures did not differ by case status. Familial relative risks for sarcoidosis associated with having a family history of RA were estimated using odds ratios and 95% confidence intervals (OR 95%CI) from conditional logistic regression models. Models were stratified by sex of the proband. In a sensitivity analysis, cases and controls with comorbid RA were excluded.

Results: 11,669 sarcoidosis cases and 115,581 controls were identified. The average age at diagnosis was 50 and 55% were male. Cases and controls had a similar mean number of FDRs (4.8 and 4.7, respectively). A higher proportion of cases had a family history of RA compared to controls (4.4% vs. 3.3%). The OR for sarcoidosis comparing any family history of RA to no family history was 1.4 (95%CI 1.2, 1.5). The OR associated with a family history of seropositive RA was similar (OR 1.3; 95%CI 1.1, 1.6). The OR was higher for male probands (OR 1.5; 95%CI 1.3, 1.7) compared to females (OR 1.2; 95%CI 1.0, 1.4). When excluding cases and controls with comorbid RA (2% and 1%, respectively), the OR was 1.3 (95%CI 1.2, 1.5).

Conclusion: There exists a 40% increased risk for sarcoidosis associated with a family history of RA. This indicates that, to some extent, the two diseases share a common etiology and an overlap in genetic risk.

The Impact of Inflammatory Arthritis (rheumatoid arthritis, spondyloarthritis, psoriatic arthritis, reactive arthritis) on Maternal and Neonatal Outcomes: A Population-Level Analysis

Stephanie Keeling[1], Anamaria Savu[2] and Padmaja Kaul[3], [1]Department of Medicine, Division of Rheumatology, Edmonton, AB, Canada, [2]Canadian Vigour Center, Edmonton, AB, Canada, [3]Cardiology, University of Alberta, Edmonton, AB, Canada
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Epidemiology and Public Health I: Inflammatory Arthritis – Risk and Impact
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The impact of inflammatory arthritis (IA) including rheumatoid (RA), psoriatic (PsA), and spondyloarthritis (SpA) on maternal, obstetrical and neonatal outcomes is not well described at the population level. Accordingly, we compared maternal and neonatal outcomes of women with and without IA in a contemporary pregnancy-birth cohort in a defined geographic area (province of Alberta, Canada) with universal health care.

Methods: The patient population consisted of 316,458 women who delivered singleton, live babies between 01/01/05 and 12/31/2014. Only the first birth for each woman during the study time period was included in the analysis. Previously established International Classification of Disease (ICD) version 9 or 10 was used to identify women with IA. A woman was considered to have IA if the diagnosis was present in a hospitalization, or in two outpatient records within 2 years that were at least 2 months apart. Women with IA were further categorized as RA and other IA . Other IA included psoriatic arthritis, spondyloarthritis, and reactive arthritis. Psoriasis patients were included in “other IA” due to the overlapping ICD 9/10 codes between PsO and PsA.

Results: There were 577 women with RA; 2281 with other IA; and 313600 with neither. Although statistically significantly different, maternal age did not differ substantially across groups (Table 1). Babies of women with RA were more likely to be small for gestational age (SGA). Maternal and neonatal outcomes in the other IA group were similar to those in women with neither disease (no IA). Rates of caesarean section and preterm delivery were significantly higher among women with RA (Table 1).

Conclusion: Our study provides novel data on the prevalence of RA and other IA in a contemporary cohort of pregnant women. We find that RA is associated with a higher likelihood of undergoing a caesarean section, preterm delivery and of having an SGA infant; however, other IA had no impact on maternal and neonatal outcomes. Our study highlights the need for peripartum counselling of women with RA.

Neonatal Outcome	No Inflammatory Arthritis	Rheumatoid Arthritis	Other Inflammatory Arthritis	P-value
Mean Maternal Age (years) (SD)	28.6 (5.6)	29.9 (5.7)	29.4 (5.4)	<0.0001
Mean Birthweight (grams) (SD)	3335.7 (565.6)	3203.1 (592.8)	3348.5 (563.0)	<0.0001
Small for gestational age (SGA) (n (%))	37826 (12.1%)	93 (16.1%)	261 (11.5%)	0.0074
Preterm Delivery (< 37 weeks) (n (%))	22779 (7.3%)	85 (14.7%)	170 (7.5%)	<0.0001
Caesarean section (n (%))	87956 (28.0)	196 (34.0)	665 (29.2)	<0.001

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: A small number of studies have examined the long-term consequences of having chronic widespread pain (CWP). Most report premature mortality, but the magnitude and type of excess mortality has varied considerably between studies. We report the largest study to examine mortality, and possible lifestyle mediators of premature mortality, amongst person with CWP.

Methods: UK Biobank involves 502,627 persons aged 40-69 years recruited in 2006-10. At recruitment, participants completed touch-screen questionnaires about health and lifestyle, including questions on pain. Those who reported "pain all over the body" that had lasted >3 months were defined as having CWP. Body mass index (BMI) was determined by measuring height and weight. Lifestyle factors measured included days of moderate/vigorous physical activity in a typical week; frequency of alcohol consumption; amount of fruit and vegetables consumed; smoking status. Vital status was determined through record linkage to national registers up to 2015. The relationship between CWP and mortality was analysed by Poisson regression and expressed as Mortality Rate Ratio (MRR) with 95% Confidence Intervals.

Results: The prevalence of CWP was 1.4% (female v. male 1.7%, 1.1%; peak prevalence 50-59 years 1.7%) and at the time of current follow-up 12,799 persons had died after a mean of 46.5 months. Mortality was higher amongst those with CWP compared to those without chronic pain (5.7% v 2.5%; $MRR_{adj\ age/sex}$ 2.4 95% CI 2.1,2.6). The difference was attenuated after adjustment for markers of lifestyle ($1.6_{adj\ full}$ 1.4,1.8) but did not further change excluding deaths occurring in the first two years of follow-up. Specific causes which were in excess included death from cardiovascular disease ($2.9_{age/sex\ adj}$, $1.9_{full\ adj}$ 95% CI (1.5,2.4)), respiratory disease ($5.0_{age/sex\ adj}$, $2.4_{full\ adj}$ 95% CI (1.7, 3.5)) and cancer ($1.7_{age/sex\ adj}$, $1.2_{full\ adj}$ 95% CI (1.01,1.4)).

Conclusion: This study provides the strongest evidence to date that persons with CWP experience long-term excess mortality. An important part of this excess risk is explained by lifestyle factors which should be targets for intervention, alongside current best care.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The provisional criteria of the American College of Rheumatology (ACR) 2010 and the 2011 self-report modification for survey and clinical research are widely used for fibromyalgia diagnosis. To determine the validity, usefulness, potential problems and modifications required for the criteria, we assessed multiple research reports published in 2010-2015 in order to provide a 2016 update to the criteria.

Methods: We reviewed 14 validation studies that compared 2010/2011 criteria with ACR 1990 gold standard classification and clinical criteria, as well as epidemiology, clinical and databank studies that addressed important criteria-level variables, including the polysymptomatic distress (PSD) scale - also known as the fibromyalgia severity (FS) scale. Based on definitional differences between 1990 and 2010/2011 criteria, we interpreted 85% sensitivity and 90% specificity as excellent agreement.

Results: Against 1990 and clinical criteria, the median sensitivity and specificity of the 2010/2011 criteria was 86% and 90% (Figure 1). There was a strong association between ACR 1990 tender point levels in cases and controls, and among 2010/2011 PSD/FS scale results (Figure 2). Data from the ACR 2010 study indicated the correlation between tender points and PSD/FS scale was 0.781. Plotting the levels of PSD in FM (+) and FM (-) cases (Figure 3) provided further insight into the effect of symptom severity on diagnosis. Fibromyalgia is milder in population studies. Studies of fibromyalgia criteria are sensitive to selection issues and severity, and to characteristics of control subjects. Various study authors were uncertain as to how to interpret criteria in the presence of other medical disorders. 2010/2011 criteria led to misclassification when applied to regional pain syndromes, but when a test modified widespread pain criterion was added misclassification was eliminated.

Conclusion: The fibromyalgia criteria have good sensitivity and specificity, and were perceived as useful and easy to use. Results of these analyses will be incorporated into revised criteria to eliminate observed problems.

Abstract Number: 995

Use of Opiate Diminished the Treatment Benefits of Motivational Interviewing for Fibromyalgia

Dennis Ang[1] and James Slaven[2], [1]Wake Forest University, Winston-Salem, NC, [2]Biostatistics, Indiana University, Indianapolis, IN
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Opiate is not indicated in the treatment of fibromyalgia (FM). In fact, chronic use of opiate may even worsen the symptoms of fibromyalgia. There are reports in other pain conditions that long term use of opiate may even contribute to pain chronicity or the persistence of pain. Given the known medical complications from opiate (e.g., cognitive dysfunction) we hypothesized that the use of opiate may modify (or diminish) the effects of motivational interviewing (MI) treatment intervention on FM-relevant clinical outcomes.

Methods: This is a secondary data analysis of a 36-week randomized clinical trial to assess the efficacy of MI to promote physical activity among patients with FM. Participants were randomized to 1 of 2 treatment arms: 6 phone-based MI sessions (n=107) or an equal number of FM self-management instructions (attention control/AC, n=109). Subjects were evaluated at 4 time points: baseline, week 12 (post-intervention), week 24 and week 36. In the previous main outcome analyses†, MI was marginally superior (p=0.06) to AC in improving global FM symptom severity (as measured by Fibromyalgia Impact Questionnaire/FIQ total) from baseline to week 36. For the current analyses, the clinical outcomes were changes in FIQ total and SF36 physical function scores, from baseline to each follow-up visit. At study entry, subjects were categorized as opiate users vs. non-users. Repeated measures ANOVA were used to assess treatment effects within each category.

Results: Approximately 5 subjects in MI and 8 subjects in the AC group had missing data; and therefore, were not included in the analyses.

	MI	AC	p-value
Improvement in global FM severity (FIQ total)			
Opiate **users**	-9.90 (1.78), n=35	-9.21 (1.73), n=35	0.781
Opiate **non-users**	-15.42 (1.23), n=66	-11.90 (1.20), n=66	0.042*
Improvement in SF36 physical function			
Opiate **users**	9.84 (2.00), n=35	7.38 (1.93), n=35	0.375
Opiate **non-users**	14.04 (1.35), n=67	10.08 (1.33), n=66	0.037*

Values are means (standard errors) Stratifying the data based on the use of anticonvulsant (i.e., pregabalin or gabapentin) at study entry, we found the reverse (data not shown). Specifically, treatment benefits from MI were observed among anticonvulsant users, but not among non-users.

Conclusion: In contrast to opiate users, opiate non-users reported greater treatment benefits from MI. Based on our findings, a hypothesis can be made that opiate interferes with the (biological and/or psychological) mechanisms of psychoeducational treatment intervention for FM. If replicated in future studies, opiate status may guide clinician on when best to offer MI for patients with FM. †Ang DC et al. Research to Encourage Exercise for Fibromyalgia. Use of a Shared Medical Appointment for Patients with Fibromyalgia in a Rural, Academic Medical Center: A Process Improvement Initiative for the Development of a New Care Model

Nicole M. Orzechowski[1], Debra Lloyd[2], Katherine Tuthill[1], Julie Puttgen[3] and Rachael Bergeron[1], [1]Rheumatology, Dartmouth Hitchcock Medical Center, Lebanon, NH, [2]Rheumatology, Dartmouth-Hitchcock Med Ctr, Lebanon, NH, [3]Dartmouth Hitchcock Medical Center, Lebanon, NH

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Fibromyalgia is a complex chronic pain condition with patients often presenting with multiple somatic complaints that are difficult to address in standard new patient visit. Primary care providers have considerable discomfort in diagnosing fibromyalgia due to the lack of specific diagnostic modalities prompting a referral for verifying the diagnosis. The increased demand in rheumatologic consultation, compounded by the constraints in staffing, necessitated the creation of a new care model for patients with fibromyalgia. We describe a fibromyalgia shared medical appointment (SMA) that evaluates, educates, enhances timely access, and improves patient satisfaction.

Methods: We assembled an interdisciplinary team of a rheumatologist, 2 nurse practitioners, a chaplain and a secretary. All referrals, notes, and ancillary studies, with an indication of myalgia or fibromyalgia were reviewed by a staff rheumatologist (NMO). Eligible patients were called using a standardized script by the secretaries explaining the visit details. A patient history questionnaire was mailed prior to the appointment. Primary care providers were notified by letter about the SMA and its format, and asked to perform specific labs if not performed already. Patients arrive simultaneously to our clinic on the visit day with nursing staff measuring vital signs and reconciling medications. Each patient is examined individually for confirmation of the diagnosis. A facilitated discussion by a trained chaplain followed by a short presentation by the clinician permits ensuing time for discussion and questions among the group. The session concludes with a demonstration of mindfulness techniques by the chaplain for managing chronic pain.

Results: The SMA format was designed between January and April 2015 and implemented in June 2015. Between June 1st, 2015 and June 30, 2016, 67 patients have been evaluated. The visit length was 2.5 hours. Using Plan-Do-Study-Act methodology, we made incremental changes to the session including location, length, flow, content of the presentation and different mindfulness techniques. Post-session surveys identified uniform themes. First, all patients strongly agreed/agreed that the SMA would assist in managing their condition. Most patients (95%) found that interacting with others in a peer-to-peer support environment with the same condition was extremely helpful. Longer appointment times were welcomed by patients to allow for additional question/answer time than would be offered during routine new patient visits. Clinical efficiency in assessing multiple new patients in a defined period of time was observed. The SMA improved wait times for fibromyalgia patients from 3 months to 1 month. The SMA also freed up new patient consultation slots for other conditions. Estimated additional work Relative Value Units (wRVUs) generated as a result of the SMA since its inception is 113.

Conclusion: Considerable benefits were observed in the use of a SMA in an academic, rural consultative rheumatology practice. Future work will enhance and optimize the visit, expand its use, address referring provider satisfaction and examine post-visit resource utilization.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The provisional criteria of the ACR 2010 and the 2011 self-report modification for survey and clinical research are valid, reliable and widely used for fibromyalgia diagnosis. In this 2016 fibromyalgia criteria update, we address identify problems and provide further guidelines for use.

Methods: Based on analysis of criteria studies and clinician and researchers comments, we identified problematic areas, including a) misclassification in asymmetric pain disorders, b) inconsistent and unclear instructions in the presence of other medical conditions, c) different clinician (2010) and self-report criteria (2011), d) unclearly defined pain assessment regions.

Results: Based on the above data and clinic usage data, we developed a (2016) revision of the 2010/2011 fibromyalgia criteria. Fibromyalgia may now be diagnosed in adults when all of the following criteria are met:

1) Widespread pain index (WPI) ≥7 and symptom severity scale (SSS) score ≥5 OR WPI 4–6 and SSS score ≥9.

2) Generalized pain, defined as pain in at least 4 of 5 regions, is present.

3) Symptoms have been present at a similar level for at least 3 months.

4) A diagnosis of fibromyalgia is valid irrespective of other diagnoses. A diagnosis of fibromyalgia does not exclude the presence of other clinically important illnesses.

The revision makes the following changes:

1) Changes criterion 1 to "Widespread pain index (WPI) ≥7 and Symptom Severity Scale (SSS) score ≥5 OR WPI 4–6 and SSS score ≥9." (WPI minimum must be ≥4 instead of previous ≥3)

2) Adds a generalized pain criterion (Criterion 2) that is defined as pain in at least 4 of 5 regions (Left upper, right upper, left lower, right lower, axial). In this definition, jaw, chest and abdominal pain are not evaluated as part of the generalized pain definition.

3. Standardizes and makes 2010 and 2011 criterion (criterion 3) wording the same: "Symptoms have been generally present for at least 3 months."

4) Removes the exclusion regarding disorders that could (sufficiently) explain the pain (criterion 4) and adds the following text: "A diagnosis of fibromyalgia is valid irrespective of other diagnoses. A diagnosis of fibromyalgia does not exclude the presence of other clinically important illnesses."

5) Adds the Fibromyalgia Symptom (FS) [or polysymptomatic distress (PSD)] scale as a full component of the fibromyalgia criteria.

6) Creates one set of criteria (2016) instead of having separate physician (2010) and patient (2011) criteria by replacing the physician estimate of somatic symptom burden with ascertainment of the presence of headaches, pain or cramps in lower abdomen, and depression during the previous 6 months.

Conclusion: This revision combines physician and questionnaire criteria, minimizes misclassification of regional pain disorders, and eliminates the previously confusing recommendation regarding diagnostic exclusions. The physician-based criteria are valid for individual patient diagnosis. The self report version of the criteria are not valid for clinical diagnosis in individual patients, but are valid for research studies. The changes to the criteria allow them to function as diagnostic criteria, while still being useful for classification.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Fibromyalgia Syndrome (FMS) is a disorder characterized by the presence of widespread pain and tenderness, which is now believed to be, at least in part, a disorder of central pain processing producing hyperalgesia and allodynia. These phenomena might be caused by defective top-down sensorimotor regulation. In order to test this notion, we activated the pain matrix in a top-down manner by presenting pictures of painful situations while recording brain activity using Magnetoencephalography (MEG). We hypothesized that FMS patients will show different responses to pain pictures and will not show normal alpha desynchronization.

Methods: 19 FMS patients (ACR 1990 criteria) and 14 age-matched healthy controls (age 20-60) were recruited from the community as well as from a specialized fibromyalgia clinic. Participants were shown photographs of right hands and feet in situations depicting pain and in control situations with no depiction of pain and were instructed to judge the painfulness of each situation (painful vs. not-painful). A total of 160 pictures (80 each) were presented in random order, displayed for 200ms followed by a "?" that remained on screen until the response was made. A whole-head, 248-channel magnetometer array (4-D Neuroimaging, Magnes 3600 WH) was used in a magnetically shielded room. The data were digitized with a sample rate of 1017Hz and an online 1-400Hz band-pass filter. Data were filtered offline (1-40Hz), segmented into 2s epochs with a 800ms pre-stimulus baseline. Segments containing excessive artifacts were removed. Sources were localized with beamforming (SAM) using alpha-band filtered data from all segments to derive the covariance matrix and weights. Normalized alpha (10-11Hz) power was then estimated separately for each condition and group. Functional images were co-registered with a template MRI adapted to individual head shapes. Statistical analyses were performed using AFNI (3dMVM).

Results: In healthy controls exposure to pictures depicting painful situations induced a decrease in alpha activity (10-12Hz) which was significantly more pronounced than the one induced by non-painful content. However, FMS patients did not show decreased alpha for pain relative to no-pain pictures, indicating abnormal regulation of sensorimotor cortex. Reduction in alpha power at 100-500ms was significant at right Precentral and Postcentral regions, only in the healthy control group [$p<0.05$, cluster size=37]. Overall, FMS patients showed more alpha activity in bilateral visual areas , left Fusiform, right Precentral and right Inferior Frontal, left Middle Frontal and Anterior Cingulate Gyri [$p<0.05$, clusters size>20].

Conclusion: Consistent with previous findings, healthy participants displayed stronger alpha desynchronization for pain pictures, indicating automatic disinhibition of the sensorimotor cortices in response to the observation of pain in others. We found evidence for a deficient modulation of sensorimotor cortex in FMS patients. The lack of differential response suggests that they perceived relatively neutral pictures as potentially painful, at least in this setting. Our findings suggest that defective top-down regulation may play a role in the pathogenesis of FMS.

Session Date: Sunday, November 13, 2016

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Fever is a common presenting manifestation of systemic lupus erythematosus (SLE) and ANCA associated vasculitis (AAV). Treating physician is challenged to differentiate between disease activity *vs.* infection as to the cause of fever. Presently, there is no clinical or serological biomarker that may reliably differentiate between these two. We aimed to determine the usefulness of CD64 (FcγR1) glycoprotein expression on the surface of neutrophils and sTREM-1 (soluble triggering receptor expressed on myeloid cells) levels in serum in distinguishing bacterial infection from disease flare in SLE and AAV patients

Methods: In this descriptive, cross sectional, observational study 20 healthy control and adult patients of SLE and AAV admitted to our unit either with disease flare or bacterial infection were recruited over a period of 1 year. Neutrophil CD64 expression was measured by flowcytometry and sTREM by ELISA from blood samples collected on the day of admission. Other parameters such as Total Leukocyte Count (TLC), erythrocyte sedimentation rate (ESR), C-Reactive Protein (CRP), C3, and C4 were noted.

Results: Among the 45 patients included in the study 29 (SLE-18 and AAV-11) had disease flare while 16 (SLE-12 and AAV-4) had infection**.** 62% had fever at presentation. Percentage of neutrophil with CD64 expression and their mean fluorescence intensity in patients with infection were significantly ($p<0.05$) higher as compared to those without infection and healthy controls (Table-1). CD64 expression as a marker for differentiation between disease flare and infection had a sensitivity of 94% and specificity of 88% at cut off of 30% (percentage of neutrophil expressing CD64). In contrast to CD64 expression on neutrophils, serum sTREM-1 level was not significantly different in patients with disease flare when compared to patients with infection. Though, CRP was significantly higher in patients with infection compared to those with disease flare ($p<0.05$), however, sensitivity and specificity of CRP to differentiate disease flare with infection was 53% and 79% respectively. TLC, ESR, C3, C4 levels were not significantly different between disease flare and infection group. On subgroup (Table-2) analysis patients of SLE with infection had a higher CRP and TLC compared those with disease flare ($p<0.5$). Sensitivity and specificity of TLC to differentiate SLE disease flare with infection was 54% and 77% respectively.

Conclusion: CD64 expression on neutrophils is helpful in differentiating bacterial infection from disease flare in patients with SLE and AAV.

Table 1 Comparison of various parameters between healthy controls, patients with disease flare and infection

Variable	Disease flare (n=29)	Infection (n=16)	Healthy controls (n=20)
CD64 expression on neutrophils (%)	3.01(1.2-16)	76.24(59.9-93.9)*	7.05(1.4-9.5)
Mean fluorescence intensity of CD64	198.5(82.5-287)	1610(955.7-2563.75)*	99.5(54.7-140.7)
sTREM-1 (pg/ml)	1131.59(666.54-1645.45)**	1041(546-1618.25)**	255.1(95.1-634.8)
CRP (mg/dl)	1.49(0.6-6.6)	9.2(1.7-20.4)***	-
TLC (cells/mm^3)	10000(4825-12475)	11650(6200-17125)	-
ESR (mm/hr)	75(28-107)	70(28-107)	-
C3 (mg/dl)	58(36.8-114.3)	46.6(23.2-63)	-
C4 (mg/dl)	9.3(6.2-16.7)	9.8(6.4-28.3)	-

*$p<0.05$ vs. disease flare group & healthy controls
**$p<0.05$ vs. healthy controls
***$p<0.05$ vs. infection group
All values have been expressed as median (25^{th}-75^{th} Interquartile range)
Abbreviation used- CRP- C-reactive protein, ESR- Erythrocyte sedimentation rate, TLC- Total leucocyte count, sTREM- Soluble triggering receptor expressed on myeloid cells.

Table 2 Subgroup analysis of patients with SLE and ANCA associated vasculitis

Variable	SLE disease flare (n= 18)	SLE with Infection (n=12)	AAV with disease flare (n=11)	AAV with infection (n=4)
CRP (mg/dl)	0.8(0.33-1.52)	9.2(1.24-16.7)*	6.6(2.05-8.72)	11.7 (2.08-20.85)
TLC (cells/mm^3)	5500(2800-9400)	12300(4750-18200)*	11000(10500-16000)	12000(10,300-20100)

*p<0.05 vs. SLE with disease flare
All values have been expressed as median (25th-75th Interquartile range)

Subclinical Cytomegalovirus Viremia Is Associated with Increased Nosocomial Infections and Prolonged Hospitalization in Patients with Systemic Autoimmune Diseases

John McKinnon[1], Junying Zhou[2], Jenna Hudy[1], Sara Hegab[1] and Kathleen Maksimowicz-McKinnon[3], [1]Henry Ford Hospital, Detroit, MI, [2]Infectious Diseases, Henry Ford Hospital, Detroit, MI, [3]Rheumatology, Henry Ford Hospital, Detroit, MI

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Infection-related Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Both subclinical cytomegalovirus (CMV) viremia and CMV disease have been associated with adverse outcomes in select immunosuppressed populations, including an increased incidence of other infections, prolonged hospitalization, and mortality. We examined the incidence and impact of subclinical CMV viremia in hospitalized patients with systemic autoimmune diseases (AD) [systemic lupus erythematosus (SLE) or anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV)] using the Investigation Use Only (IUO) Abbott RealTi*me*CMV assay (RT assay).

Methods: Prospectively collected blood samples were obtained from AD hospitalized patients at study entry with a second sample collected 1 week later or at discharge from the hospital, whichever occurred first. Controls included age- and gender- matched inpatients without AD and rheumatology clinic outpatients with vasculitis or SLE without active infection. All plasma samples were tested in batch using the IUO RT assay with a LLOD (LLOQ) at 21 IU/mL (32 IU/mL).

Results:

Twenty-three inpatients (10 SLE, 8 AAV, 5 controls), and 31 outpatient controls were recruited. Detectable CMV viremia by the RT assay was found in 61% (11/18) of inpatient AD subjects, 3% (1/31) of outpatient AD subjects, and in none of the five inpatient controls (p<0.001). Average CMV viremia for AD patients at entry was 51.8 IU/mL (33.1 copies/mL) and at 7 days was 175.3 IU/mL (112.4 copies/mL). CMV IgG titers were similar between controls, AD patients, and AD patients with CMV viremia (2.90 vs. 3.01 vs. 3.75, p=0.54). CMV viremia was associated with increased length of ICU stay (25 vs. 5 days, p=0.033), length of hospital stay (35 vs. 10 days,

p=0.014), increased nosocomial infections (7 vs. 1, p=0.007) and trends towards increased frequency of disease flare (3 vs. 0) and renal failure requiring hemodialysis at hospital discharge (4 vs. 1). Two AD patients developed overt CMV disease, neither of which was receiving immunosuppressive therapy at the time of hospitalization. CMV viremia was not associated with the overall severity of illness at study entry (as measured by SOFA and APACHE II scores) nor with disease-specific activity (as measured by SLEDAI or BVAS scores).

Conclusion: More than half of hospitalized AD patients in our cohort had subclinical CMV viremia, which was associated with increased length of hospital stay and nosocomial infections, with trends suggesting a possible impact on disease activity and severity. This low level CMV viremia would be missed by most currently used clinical CMV assays, and occurred even in patients with detectable anti-CMV antibodies. These data suggest that subclinical CMV viremia may wield significant adverse effects in hospitalized patients with SLE and AAV, and that further study of the Immunomodulatory effects of CMV in AD is warranted.

Session Date: Sunday, November 13, 2016
Session Title: Infection-related Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Intensive immunosuppressive treatment for remission induction in connective tissue diseases (CTDs) sometimes causes serious infection. Cytomegalovirus (CMV) is a herpesvirus remaining latent after primary mild or asymptomatic infection, and the reactivation of CMV is one of the problematic opportunistic infections in immunocompromised patients. This study was to investigate the relationship between CMV reactivation and other infections.

Methods: All hospitalized patients with CTD who started immunosuppressive agents as induction therapy from January 2012 until March 2016 were retrospectively reviewed. Clinical information including history of all infection until June 2016 were collected from their medical charts. CMV reactivation was defined by the detection of CMV PP65 antigen in polymorphonuclear leukocytes from peripheral blood. We defined severe infection as infections which required hospitalization. The relationship between CMV reactivation and other infections were statistically analyzed.

Results: A total of 179 CTD cases with CMV PP65 measured during the remission induction therapy were enrolled in the analysis. Mean age was 57.1±17.0 years old and the female ratio was 68.7%. The CTDs were 48 systemic lupus erythematosus (26.8%), 35 antineutrophil cytoplasmic antibody-associated vasculitis (19.6%), 23 polymyositis/dermatomyositis (12.8%), 21 rheumatoid arthritis (11.7%), 10 adult-onset Still's disease (5.6%), and others 42 (23.4%). 118 cases (65.9%) were new-onset. All cases were treated with moderate to high dose of glucocorticoid (mean prednisolone (PSL) dose, 50.0±11.0 mg/day). Methylprednisolone (mPSL) pulse therapy was conducted in 55 (30.7%), and concomitant immunosuppressants were used in 129 (72.1%). CMV was reactivated in 71 (39.7%) including 18 CMV infection (bone marrow suppression 14, pericarditis 2, liver injury 1, retinitis 1) following the initiation of remission induction therapy. During the immunosuppressive treatment, severe infection occurred in 28 cases (15.6%), and it was more frequent in the CMV-positive cases than the CMV-negative cases with statistical significance (31.0% vs. 5.6%. p<0.001). The incidence of severe lung infection (18.3% vs. 3.7%. p=0.002) and sepsis (8.5% vs. 0.0%. p=0.003) were significantly higher in the CMV-positive cases than the CMV-negative cases. The mortality rate were 14.1% in the CMV-positive cases compared with 1.9% in the CMV-negative cases (p=0.002). The relapse-free survival rate for CTD was significantly lower in the CMV-positive cases by log-rank test (p=0.001).

Conclusion: CMV reactivation in connective tissue disease by immunosuppressive therapy predicts severe infection and high mortality. The cases with CMV reactivation require particular attention to other severe infection.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Pneumocystis jiroveci (PJP) is an opportunistic infection associated with high mortality in patients with rheumatologic conditions. Given the paucity of data, clinical guidelines to initiate PJP prophylaxis are based on expert opinion and identify patients on >20 mg daily prednisone for >4 weeks duration for treatment. Herein we describe the PJP experience over a 20-year period at a single academic center.

Methods: We conducted a retrospective review of all patients admitted to a tertiary academic institution who received an ICD-9 code for Pneumocystis jiroveci (PJP) or Pneumocystis carinii (PCP) (136.3) from 1/1/1996-9/30/2015. Records were abstracted for clinical information including underlying disease, immunosuppressive regimen, lymphocyte count on admission, and outcome. Patients with underlying oncologic diagnoses or organ transplant history were excluded. Summary statistics were performed using Stata v.14.

Results: A total of 21 cases with confirmed PJP were reviewed, averaging to a rate of approximately one case per year. The most common underlying rheumatologic conditions with PJP infection were inflammatory myopathy, systemic lupus erythematosus (SLE), and granulomatosis with polyangiitis (GPA). None of these 21 patients was receiving PJP prophylaxis upon admission. The average time from rheumatologic disease diagnosis to PJP diagnosis was 50 ± 50 months. Data on duration of therapy prior to diagnosis were unavailable. All but three patients were lymphopenic upon presentation (absolute lymphocyte count 558 ± 449, range 40-1580, normal 1100-4800/mm^3). Seventeen patients (81%) were receiving >20 mg prednisone at the time of diagnosis. Of the 4 who were receiving <20 mg prednisone, all received concomitant immunosuppressive medications, including 3 with cyclophosphamide (Table 1). For those patients with available lung function data (pulmonary function testing and/or high-resolution CT imaging, n=12), half had a history of ILD. There was a 43% (9/21) mortality rate overall.

Conclusion: PJP is a largely preventable complication of rheumatic disease treatment with a high mortality, and often occurs years after the initial rheumatologic disease is diagnosed. No patient developed PJP while on less than 20 mg prednisone monotherapy; however, lower doses were noted in those who developed PJP while on concomitant cyclophosphamide. While expert guidelines recommend PJP prophylaxis with patients on >20 mg prednisone for >4 weeks, consideration should be made for patients receiving any dose of prednisone who are also receiving cyclophosphamide, regardless of the underlying rheumatic disease. Table 1. Patients who developed PJP on less than 20 mg of prednisone

Patient	Disease	Prednisone (mg/day)	Other Immunosuppressant
1	SLE	10	CYC
2	Sarcoidosis	10	CYC
3	SSc	5	CYC, MTX
4	RA	1	MTX, TNFi

SLE = systemic lupus erythematosus, SSc = systemic sclerosis, RA = rheumatoid arthritis, CYC = cyclophosphamide, current or in past 12 months, MTX = methotrexate, TNFi = tumor-necrosis factor inhibitor, NR = not reported

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Infection-related Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Ultrasonography (US) is useful to study the joints and the synovial tissue. It allows the evaluation of the synovial membrane thickness and inflammation. It can depict effusions and help to assess the surrounding soft tissues. Therefore, US could be of interest in the monitoring of septic arthritis. The main goal of this study was to describe the US changes observed during the course of septic arthritis and their association with clinical and functional outcomes.

Methods: We included all patients seen for a native joint infection in 3 different hospitals between January 2014 and July 2015. We collected baseline demographic, clinical, biological and microbiological characteristics. Patients were followed up prospectively with clinical and US evaluation at Day 0, 4, 15 and at 3 months (M3). US exam included the study of synovial membrane thickness, Power Doppler and involvement of the periarticular tissue. Evolution of the synovial thickness was compared to baseline (% of change). X-Ray of the joint was made at baseline and M3. Functional outcome was assessed at M3 (range of motion; SF-36 score).

Results: Thirty four patients were included, mean age 63.7 (range 22-90) with 24 men (70.6%). Most of the time, septic arthritis occurred in patients with pre-existing joint disease (n=24; 70.6%) and the knee was mostly affected (n=19; 55.9%). Predominant causative organism was Staphylococcus Aureus (n=15; 44.1%). Twelve patients (35.3%) underwent joint lavage mean time 4.2 days (range 0-13) after the diagnosis with synovectomy in 2 cases (5.9%). US synovitis was present in 96.4% of the cases at D0, 100% at D15 but was less frequent at M3 (77.8%; p=0.051). The synovial thickness increased at D4 and D15 compared to baseline (respectively median +17.3%, +20%, p = 0.015) and significantly decreased at M3 (median -31.5%; p = 0.015). Doppler signal was frequent (64.3% (D0); 66.7% (D4); 61.3% (D15)) and decreased significantly at M3 (25.9%; p = 0.04). The effusion was present at D0 (92.8%), D4 (88.9%), D15 (80.6%) and significantly less frequent at M3 (55.6%, p =0.001). Periarticular abscess or cellulitis was rare (10.7% and 3.7% at D0 respectively). At M3, one patient died (2.9%) and 5 (14.7%) patients were lost to follow-up. Twenty (58.8%) patients had a decreased joint range of motion. A high total Sharp score and a high joint space narrowing score at M3 was associated with a late start antibiotic treatment (respectively p=0.048, p=0.03). We found no correlation between US characteristics and any of the baseline clinical or biological parameters. In contrast, joint limitation at M3 was associated with an increase of the synovial thickness between D0 and M3 (p=0.024) and with the persistence of Doppler at D15 and at M3 ((p=0.033; p=0.002).

Conclusion: Septic arthritis have a poor functional outcome in more than half of the cases. US synovitis remains present at 3 months in most patients but with a significant decrease in synovial thickness compared to baseline. Doppler signal persists in a quarter of the cases at M3. Persistence of Doppler signal and a thickened synovial tissue at 3 months are associated with a poor clinical outcome.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Infection-related Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Biologic therapies (bDMARDs) have improved the treatment of rheumatic diseases; however, the risk of herpes zoster (HZ) virus infection or reactivation in patients treated with these drugs remains a concern. Objectives: We investigated the clinical characteristics and prognostic factors of HZ in an Argentine registry of rheumatic diseases patients treated with bDMARDs.

Methods: Database included demographics of patients, type and duration of treatments and clinical information of adverse events. A control group was included for comparison consisting of patients not treated with bDMARDs but similar demographics. Values are expressed as mean±standard deviation, median (ranges), and frequencies (percentages), as appropriate. Multivariate logistic and regression analysis were used to identify variables associated with the occurrence of HZ; OR and 95% CI were calculated by exponentiation of regression coefficients.

Results: As of January 2016, 3483 patients, 4762 treatments and 2580 adverse events were studied. 2748 (78.9%) patients were women, mean age was 56.1±15.7 years. Patients were treated with non-bDMARDs in 2011 (57.7%) and 1472 (42.3%) with bDMARDs. BIOBADASAR included 2706 (77.7%) patients with rheumatoid arthritis (RA), 293 (8.4%) with psoriatic arthritis (PsA), juvenile idiopathic arthritis (JIA) and SLE with 117 (3.36%) each. Most frequent biological drugs were etanercept 1193 (41.4%), adalimumab 626 (21.7%), and abatacept with 282 (9.8%). Of 3483 patients, 25 (0.72%) developed HZ infection as an adverse event, their mean age was 59.44±19.31 years. The mean time between treatment and HZ infection was 10.5 (range 1.6 - 251.5) months. Twenty two (88%) patients with HZ received bDMARDs (5 patients developed HZ after more than one biological treatment) and 3 (12%) patients received only non-bDMARD treatments. Ten (40%) patients developed HZ infection during treatment with etanercept. Severities of HZ infections were: non-serious in 21 (84%) and serious in 4 (16%) cases. In comparison with patients treated with non-bDMARDs, patients with bDMARDs showed a high risk of development of HZ infection; incidence rate ratio (IRR) of HZ in the bDMARDs group was 9.084 (95% CI 2.72-47.40; $p<0.001$). The risk was higher for those who used concomitant corticoids (HR 2.97, CI95% 1.55–8.66) and bDMARDs (HR 2.48, CI95% 1.37–15.5) than for those who used methotrexate (HR -3.42, CI95% 0.10–0.53); statistical differences were found in the univariate analysis, and confirmed by the multivariate models. The outcomes of HZ infection were: recovered without sequelae in 21 (84%), not recovered at time of report in 3 (12%) and recovered with sequelae in 1 (4%) case.

Conclusion:

A higher frequency of HZ was seen in patients treated with bDMARDs and concomitant corticoids whereas use of methotrexate has a protective effect. However, results should be interpreted cautiously because of registries inherent limitations.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Innate Immunity and Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Autoinflammatory diseases are caused by mutations in genes regulating innate immune responses. More than 20 genes have been associated with various monogenic autoinflammatory disorders.

Methods: We performed whole-exome and candidate gene sequencing in the patients and their unaffected family members. We used an NF-κB luciferase assay and overexpression experiments in 293 cells to confirm the causality of mutations. Patient samples were analyzed using immunoprecipitation, immunoblotting, gene expression and cytokine profiling.

Results: We studied 3 unrelated families, one of Pakistani and two of Turkish ancestry, with neonatal-onset systemic inflammation, neutrophilic dermatitis/rash, and lipodystrophy. We identified three novel homozygous mutations in the *FAM105B*gene, which encodes OTULIN, the only deubiquitinase that specifically hydrolyzes Met-1 linked ubiquitin chains. The p.Leu272Pro and p.Tyr244Cys mutations are located near the linear ubiquitination binding region, and they reduce OTULIN protein stability, while the p.Gly174Aspfs*2 mutation truncates the protein. The three mutations do not disrupt OTULIN interaction with LUBAC. Over-expressed mutant OTULIN plasmid p. Leu272Pro and p.Gly174Aspfs*2 failed to restrain NF-κB activity compared to WT OTULIN. Patient-derived PBMCs and fibroblasts sustained higher levels of phosphorylated IKKα/IKKβ and IκBα, and showed increased phosphorylation of P38 and JNK MAP-kinases compared to healthy controls. These results demonstrate enhanced signaling of the NF-κB and MAPK pathways in OTULIN deficient patients. Transfected OTULIN mutant plasmids showed decreased enzyme activity and a substantial defect in deubiquitination of target molecules NEMO, RIPK1, TNFR1 and ASC. This defect could be partially rescued by cotransfecting the mutation proteins with wild type OTULIN. Stimulated patients' fibroblasts and PBMCs showed a higher linear-ubiquitinaton level of NEMO, RIPK1, TNFR1, and ASC. These results indicate that inefficient deubiquitination of OTULIN target proteins might explain increased NF-κB activity in mutant cells. OTULIN-deficient patients' cells showed a strong inflammatory signature. We observed an excessive production of IL-1β, IL-6, IL-12, IL-18, and IFN-γ in stimulated patient whole blood and patients' serum. Purified patient's monocytes had significantly higher secretion of IL-1β, IL-6, IL-16, IL-18, and TNF in response to LPS, TNF, or IL-1β stimulation relative to controls. Intracellular staining for TNF and IL-6 from Patient 1 and 3 was higher at basal levels in monocytes, dendritic cells and T cells than in controls.

Conclusion: A new disorder caused by loss-of-function mutations in OTULIN expands the spectrum of autoinflammatory diseases caused by defects in deubiquitination and proteasomal degradation.

Immune Complex-Mediated TLR8 Activation Shifts Neutrophils from Phagocytosis to Netosis through Furin-Dependent Shedding of Fcgriia

Christian Lood[1], Sabine Arve[2], Laura Durcan[2], Jeffrey Ledbetter[2] and Keith B. Elkon[1], [1]Department of Medicine, Division of Rheumatology, University of Washington, Seattle, WA, [2]University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Innate Immunity and Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Neutrophils participate in host defense through mechanisms including phagocytosis and formation of neutrophil extracellular traps (NETs), a neutrophil cell death process in which DNA is extruded together with cytoplasmic and granular content to trap and kill pathogens. Immune complex (IC)-mediated NET formation has emerged as a mechanism that may increase the autoantigenic burden as well as promote type I interferon production in patients with the autoimmune disease, systemic lupus erythematosus (SLE). Although TLR agonists, such as nucleic acids, have been shown to enhance phagocytosis by macrophages and dendritic cells, the role of TLR signaling in neutrophil phagocytosis of RNA-containing ICs has not been extensively studied. The aim of the current study was to explore the cross-talk between TLRs and FcgRs in the regulation of IC-mediated phagocytosis and NETosis.

Methods: Neutrophils, isolated from healthy individuals, were incubated with RNA-ICs and analyzed for phagocytosis and NETosis by flow cytometry and fluorimetry, respectively, in the presence of FcgR blocking antibodies or TLR8 inhibitors (oligonucleotides, RNase). FcgRIIA cleavage on neutrophils was assessed on ex vivo isolated neutrophils from healthy controls (n=7) and SLE patients (n=19) as well upon serum incubation, using two antibody clones recognizing full length or cleaved FcgRIIA, and the results related to clinical data.

Results: Both FcgRIIA- and TLR8-engagement were required for induction of NETosis by RNA-ICs, as demonstrated by FcgR blocking antibodies as well as RNase treatment. While degradation of RNA inhibited NETosis as expected, surprisingly, removal of the TLR ligand by RNase markedly increased the phagocytosis of RNA-ICs by neutrophils ($p<0.0001$), suggesting that TLR activation suppressed phagocytosis. Consistent with this hypothesis, addition of TLR8 agonist (R848) inhibited phagocytosis of ICs ($p<0.0001$), but not of latex beads, by neutrophils. Mechanistically, TLR8 activation mediated furin-dependent proteolytic cleavage of the most N-terminal part of FcgRIIA, reducing the phagocytic capacity, while promoting progression into NETosis. Interestingly, the opposite was also true, namely that phagocytic stimuli (beads) could suppress IC-mediated NETosis ($p<0.01$) while promoting phagocytosis ($p<0.05$), suggesting plasticity of the neutrophils in adapting into specific effector cell functions. Importantly, ex vivo isolated neutrophils from SLE patients demonstrated increased shedding of FcgRIIA ($p<0.0001$), which correlated with neutrophil activation ($r=-0.73$, $p=0.003$) and the presence of anti-Sm/RNP antibodies ($p<0.001$), consistent with the in vitro data.

Conclusion: Neutrophils are not terminally differentiated cells but can mature into phagocytic or NETosing cells, partly regulated by a cross-talk between TLR8 and FcgRIIA. SLE patients have ongoing shedding of neutrophil FcgRIIA, demonstrating the in vivo relevance of our observation. Therapeutic approaches aimed at degrading the TLR8 ligand would be predicted to increase the uptake of circulating ICs, while disarming their inflammatory potential and ability to induce NETs.

Interferon Regulatory Factor 1 Is the Key Driver of Inflammasome Activity in Systemic Lupus Erythematosus

Jianhua Liu[1] and **J. Michelle Kahlenberg**[2], [1]Internal Medicine, Division of Rheumatology, University of Michigan, Ann Arbor, MI, [2]Internal Medicine, Division of Rheumatology, Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Innate Immunity and Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: *The inflammasome complex has recently emerged as a driver of organ damage in systemic lupus erythematosus (SLE). This complex, via its enzymatic subunit caspase-1, is responsible for the cleavage and activation of the inflammatory cytokines* IL-1β *and IL-18. While type I interferons (IFNs) are well established as mediators of SLE pathogenesis, their role in inflammasome activation has not been assessed in this disease. In this study, we examine type I IFNs as regulators of inflammasome activation, and identify interferon regulatory factor-1 (IRF-1) as the critical intersection between the two pathways.*

Methods *:* All patients and controls gave written, informed consent and were treated according to the declaration of Helsinki. SLE patients fulfilled >4 ACR criteria and were recruited from the University of Michigan Lupus Cohort. Primary monocytes were isolated from SLE patients or healthy controls by negative selection. To study inflammasome activation, monocyte cultures were treated with or without lipopolysaccharide (LPS) and adenosine tri-phosphate (ATP). The effects of IFNα on inflammasome activation were measured by pre-treating with IFNα overnight before or concurrently with inflammasome activators. IL-1β secretion was measured by ELISA. Expression levels of caspase-1, STAT1, STAT2, and IRF-1 were assessed by Western blotting. IRF-1 expression was specifically downregulated by siRNA transfection.

Results: Expression of inflammasome (caspase-1, NLRP3, ASC, IL-1β) and interferon-regulated genes (IFI44, MX1, IRF-1) was tightly and significantly correlated in lupus, but not control, monocytes. Indeed, lupus monocytes exhibited increased expression and enhanced activation of the inflammasome by ATP when compared to control monocytes. Importantly, inflammasome activity was increased in control and SLE monocytes with prolonged, but not brief, exposure to IFNα. IFNα treatment resulted in robust upregulation of caspase-1 and IRF-1, a known transcription factor of caspase-1. Reduction of IRF-1 expression via siRNA blocked caspase-1 upregulation after treatment with IFNα. Importantly, hyperactivity of the inflammasome in lupus monocytes was significantly reduced after knock-down of IRF-1.

Conclusion: Prolonged type I IFN exposure, as seen in SLE patients, primes monocytes for robust inflammasome activation in an IRF-1-dependent manner. IRF-1 inhibition may serve as a novel target for treatment of SLE-associated inflammation and organ damage.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Innate Immunity and Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Human Endogenous Retroviruses (HERVs) are remnants of retroviral infections in the human germline. Most, but not all, HERV genes have become inactive by accumulation of mutations. The presence of open reading frames (ORFs) in a few select HERV genes, suggest an evolutionary advantage for the host in maintaining the protein coding capacity. We investigated whether differences could be detected between upregulation of a panel of ENV-proteins in patients with Systemic Lupus Erythematosus (SLE) compared to healthy controls. Further, we examined a peptide form of the highest upregulated ENV-protein for an anti-inflammatory potential *in vitro*, *ex vivo* and *in vivo*

Methods: 45 patients fulfilling the ACR criteria for SLE and 50 age and gender matched blood donors, were included consecutively. By real time PCR, we analyzed the transcriptome of 11 genes with coding capacity for complete envelope protein. Subsequently, we cloned the *Env59* gene to examine if it retained its retroviral fusion protein activity. Sequence analysis of the protein identified an immune suppressive domain (ISD). A corresponding peptide was synthesized and examined *in vitro* for immune suppressive activity on stimulated experimental cell lines and *ex vivo* on human PBMCs from patients with SLE and Rheumatoid Arthritis. Next, in two separate treatment experiments, we tested the anti-inflammatory potential of the peptide *in vivo* in an experimental model of arthritis, the Sakaguchi mouse (first experiment n=15, second n=40). Mice were treated daily for 4 weeks. Arthritis scoring was performed blinded. At termination, hind paws were fixated in ethanol for histology and stained with Masson-Golden trichrome.

Results: We found that the HERV-H derived *Env* gene (Env59) was highly expressed in SLE patients. Further, that expression of Env59 showed negative correlation with the central inflammatory protein IL-6 (P=0.0065). The peptide version of the Env59 ISD had anti-inflammatory activity and ability to lower IL-6 levels *in vitro* and *ex vivo*. Lastly, in two independent *in vivo* experiments of experimental arthritis, we illustrated the peptide significantly lowered arthritis score ($p<0.05$) in treated versus untreated mice. The reduction in arthritis was confirmed measuring serum amyloid A3 as a biomarker for inflammation and by histology in mice treated with saline compared to peptide-treated mice.

Conclusion: We demonstrated an upregulation of *Env59* in SLE patients compared to healthy controls, and that ENV59 expression was negatively correlated to IL-6 expression in SLE patients. With a synthetic peptide derived from the ISD domain of the retroviral gene we illustrated an anti-inflammatory potential of the peptide *in vitro, ex vivo and in vivo*. We propose the peptide represents a possible new treatment strategy for inflammatory diseases.

Plasmacytoid Dendritic Cells Are Activated in Systemic Sclerosis and Contribute to the Disease By Inducing Ifnα and CXCL4

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Innate Immunity and Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Plasmacytoid Dendritic Cells (PDCs) are key immune cells involved with anti-viral responses due to their ability to produce large amount of type I IFN in response to Toll-like receptor (TLR)7 and TLR9 signaling. Several studies have reported that PDCs play a role in autoimmune diseases, including lupus, and inflammatory skin diseases such as psoriasis or dermatomyositis. Although the role of PDCs in Systemic Sclerosis (SSc) is less clear, several parallels studies suggest that mechanisms of innate immune dysfunction

operating in SLE may also be important in SSc. Both diseases are associated with presence of autoantibodies to nucleic acid-binding proteins, e.g topoisomerase I and centromere and with increased expression of interferon-responsive genes by peripheral blood mononuclear cells, suggesting the participation of PDC in SSc. Recently, CXCL4 (Chemokine CXC motif ligand 4) was identified as a major protein secreted by PDC and as a biomarker of SSc as its level correlated with the presence of lung and skin fibrosis. The aim of this study is to investigate the role of PDC and the mechanisms by which these cells participate to the pathogenesis of SSc.

Methods: Blood was obtained from 55 SSc patients or 14 healthy volunteers (HV) and PBMC isolated by density gradient. PDC were then isolated from PBMC by positive selection with BDCA4 magnetic beads or by cell sorting. PBMC was analyzed by flow cytometry. In addition, PDC were cultivated for 24h and IFNα and CXCL4 secretion were analyzed by ELISA.

Results: We observed a decrease in the percentage of PDC in SSc PBMC as compared to HV PBMC (0.25±0.02 vs 0.51±0.09; p=0.003). SSc PDC spontaneously secreted excessive IFNa as opposed to HV (10-fold, p=0.03). On the other hand, no difference was observed in the expression of co-stimulatory molecules, CD86, CD83 and CD80 (46.5±10.5, 108.8±16.7 and 9.3±1.5 vs 54.9±5.9, 101±7.6, 18.4±4.9) as well as in the secretion of IL-6 in HV and SSc PDC (1.1±07 vs 8.3±3.1 pg/ml, p=0.2). We also confirmed an increased secretion of CXCL4 in SSc PDC (6903±662 in HV vs 17111±1855 pg/ml; p=0.001), which we showed is dependent on PI3Kδ. We also demonstrated that the increase of CXCL4 in patients is solely due to the secretion of this chemokine by PDC, and not by other cells in PBMCs. Moreover, we show that the CXCL4 and IFN pathways are intertwined in SSc as CXCL4 synergized with TLR9 signaling in PDC to induce enormous levels of type I IFN.

Conclusion: Taken together our data provide evidence of a role of PDC in the pathogenesis of SSc. Decrease in number of PDC in SSc blood suggest an activation of PDC and their migration to the site of disease, probably the skin. We also show that SSc PDC exhibit a non-mature state, with high production of IFNα and low expression of maturation molecules. CXCL4 secretion is dependent on PI3Kδ pathway and contribute to increased IFNa secretion through TLR9 activation.

Session Title: Innate Immunity and Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Genome-wide gene expression studies implicate macrophages (MØs) as mediators of fibrosis in systemic sclerosis (SSc) and our data indicate that MØs constitute the dominant inflammatory signature in SSc tissue. Because MØs are plastic and subject to modulation by local micro-environmental factors, *in vivo*MØ polarization spans a broad spectrum of activation states. Therefore, SSc MØ activation is likely shaped by the interplay of many factors, resulting in the development of an immuno-phenotype that supports disease development and progression. In this study, we define the activation profile of human SSc MØs as pro-fibrotic, and provide direct evidence that SSc MØs elicit activation of NFkappaB signaling pathways and proliferation in fibroblasts.

Methods: Plasma and PBMCs were obtained from whole blood of 14 SSc patients (disease duration <5 years) and from 5 healthy age and gender-matched control subjects following informed written consent. $CD14^{+}$monocytes were isolated from PBMCs using magnetic bead selection, and were cultured with either autologous or allogeneic plasma for 7 days to differentiate the cells into MØs. Immune activation studies were performed using 10 ng/ml LPS. For reciprocal activation studies, SSc MØs were co-cultured with fibroblasts using Transwells. RNA expression in MØs and fibroblasts was analyzed using genome-wide analysis and RT-PCR, and protein expression and secretion were monitored using flow cytometry and by ELISA.

Results: Genome-wide expression profiling of human SSc MØs shows up-regulation of signaling pathways involved in antigen presentation and extracellular matrix organization. SSc MØs show an alternatively activated phenotype based on expression of cell surface markers, and express higher levels of TGF-beta and IL-6 under both basal and LPS-stimulated conditions. Differentiation of healthy MØs with SSc plasma results in enhanced TGF-beta and IL-6/JAK/STAT3 signaling pathway activation, and SSc-differentiated MØs co-cultured with dermal fibroblasts show enrichment of inflammatory and proliferation expression signatures. Dermal fibroblasts co-cultured with SSc-differentiated MØs show an activated phenotype.

Conclusion: The activation profile of SSc-differentiated MØs is pro-fibrotic. We demonstrate that SSc MØs are activated under basal conditions, and that these cells release mediators associated with both alternative and inflammatory MØ activation. For the first time, we show that co-culture of SSc MØs with fibroblasts induces fibroblast activation and proliferation. Intriguingly, these data suggest that activation of SSc MØs arises from soluble factors in local microenvironments. Collectively, these studies implicate MØs as likely drivers of fibrosis in SSc and suggest therapeutic targeting of these cells may be beneficial in ameliorating disease in SSc patients.

Session Time: 4:30PM-6:00PM

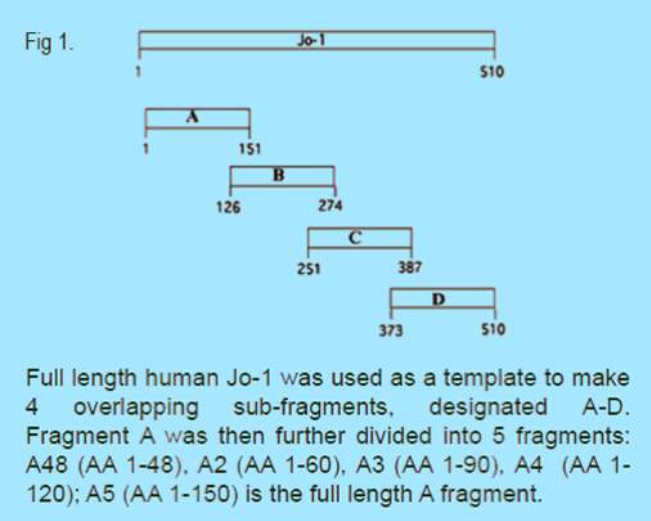
Correlations Between B Cell Epitope Specificity and Clinical Features in Patients with Jo-1 Antibodies and the Anti-Synthetase Syndrome

Background/Purpose: Idiopathic inflammatory myopathy (IIM) is an autoimmune disorder characterized by muscular as well as extra-muscular organ pathology. The anti-synthetase syndrome is specifically associated with auto-antibodies directed against amino-acyl-tRNA synthetases and encompasses a clinical spectrum comprised of myositis, interstitial lung disease, Raynauds's phenomenon, symmetric non-erosive arthritis, mechanic's hands, and fever. The most common autoantibody is anti-Jo-1 which targets histidyl-tRNA synthetase (HRS). Previous work assessing the reactivity of serum anti-Jo-1 antibodies with full length recombinant HRS demonstrated cross-sectional as well as longitudinal correlations with serum creatinine kinase levels, myositis visual analogue scale (VAS), arthritis VAS, and different components of the Myositis Intention to Treat Activity Index (MITAX). In the current study, we aimed to refine these correlations through more detailed assessment of the relationship between HRS epitope specificity and clinical features of the anti-synthetase syndrome.

Methods: We assessed serum reactivity (via ELISA) against overlapping sub-fragments of HRS/Jo-1 protein (Fig 1) in 139 patients with anti-Jo-1 antibodies and different patterns of organ involvement. Use of Mann U Whitney and Kruskal Wallace testing permitted statistical correlations of epitope specificity with various clinical features encompassed by the Myositis Disease Activity Assessment Tool (MDAAT).

Results: Our results indicate that defined clinical features such as joint swelling and Raynaud's are associated with enhanced antibody binding of amino-terminal HRS sub-fragments—with a trend toward preferential antibody affinity for sub-fragments containing amino acids 90-150 (A3-A5). While reactivity to A3-A5 generally overlapped in different patient subsets, reactivity to A2 (aa 1-60) was frequently lower than that of larger subfragments encompassed by A3-A5. Patients with joint swelling had significantly increased reactivity to fragments A2 ($p = 0.0036$), A3 ($p = 0.0015$), A4 ($p = 0.0014$) and A5 ($p = 0.0016$) relative to patients without joint swelling. Patients with Raynaud's also had significantly increased reactivity to fragments A2 ($p = 0.0147$), A3 ($p = 0.0497$), A4 ($p = 0.0209$) and A5 ($p = 0.0225$) compared to patients without Raynaud's.

Conclusion: This work not only confirms that the amino terminal portion of HRS/Jo-1 contains an immunodominant B cell epitope, but also suggests that fine specificity mapping may provide useful biomarkers for different patterns and/or severity of organ involvement. More broadly, these results support the possibility that tissue-specific alterations in antigen presentation are linked to disease pathogenesis.



Full length human Jo-1 was used as a template to make 4 overlapping sub-fragments, designated A-D. Fragment A was then further divided into 5 fragments: A48 (AA 1-48), A2 (AA 1-60), A3 (AA 1-90), A4 (AA 1-120); A5 (AA 1-150) is the full length A fragment.

Session Date: Sunday, November 13, 2016

Session Title: Muscle Biology, Myositis and Myopathies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: To investigate the risk of concomitant use of statin on the development of myopathy in gout patients who received colchicine.

Methods: We included patients with gout at a tertiary medical center in Korea from January 2000 to March 2016, who received colchicine with or without statin. Clinical characteristics including comorbidities such as hypertension, diabetes mellitus, chronic kidney disease, and

liver cirrhosis were collected. Myopathy was defined as the presence of muscle symptoms with elevation of creatinine phosphokinase (CPK) and/or myoglobin. Multivariate Cox analysis was performed to identify risk factors of developing myopathy. And by combining inverse probability of treatment weighting (IPTW) to Cox analysis, we evaluated whether concomitant statin use was associated with increased myopathy.

Results: Of the total 674 patients with gout, 486 received colchicine alone and 188 received colchicine with statin. The rate of myopathy was not higher in patients who received colchicine with statin than in those who received colchicine alone (2.7% vs 1.4%, p=0.330). In multivariate Cox analysis, following factors were associated with increased risk of myopathy: chronic kidney disease (hazard ratio [HR] 29.056, 95% confidence interval [CI] 4.387-192.450, p<0.001), liver cirrhosis (HR 10.676, 95% CI 1.279-89.126, p=0.029), colchicine dose increment (HR 20.960, 95% CI 1.835-239.481, p=0.014) and concomitant CYP 3A4 inhibitor use (HR 12.027, 95% CI 2.743-52.725, p=0.001). Concomitant use of statin, however, was not associated with increased risk of developing myopathy even after adjusting for confounders using IPTW (Multivariate-adjusted HR 1.123 [95% CI 0.262-4.814, p=0.875] and IPTW adjusted HR 0.321 [95% CI 0.077-1.345, p=0.120]).

Conclusion: In patients with gout, concomitant use of colchicine with statin was not associated with increased risk of myopathy compared to use of colchicine alone. The increased risk of myopathy was significantly associated with the following variables: chronic kidney disease, liver cirrhosis, colchicine dose increment and CYP 3A4 inhibitor use. Thus, concomitant use of statin with colchicine seems to be safe from myotoxicity in patients with gout.

Session Title: Muscle Biology, Myositis and Myopathies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Few studies describe the natural course and long term outcomes of myositis in childhood in large, prospectively-followed patient cohorts, treated in the modern era. We aimed to describe long term patient-reported outcomes in adolescents and young adults (≥ 16 y) who had myositis in childhood and to find outcome predictors from data in the Juvenile Dermatomyositis Cohort and Biomarker Study, UK and Ireland (JDCBS)

Methods: Participants in the JDCBS, previously diagnosed with idiopathic inflammatory myopathy and now aged 16 years or over, completed the SF36 v2, HAQ and a newly developed questionnaire to collect information on current disease features and damage, medication use and side effects, and education and employment opportunities.

Results: Of 205 sets of questionnaires sent, 84 (41%) were returned. Average age of respondents was 21.5 years (maximum 30.8y). Average disease duration was 11.8 y (SD 5.1), age at onset 9.2y (SD 4.3) and female to male ratio 4.25:1. Most patients were white (82.1%) and had a diagnosis of Definite Juvenile Dermatomyositis (69%). Of the 68 who had Myositis-Specific Autoantibody testing, eight (11.8%) had TIF1γ and eight had NXP2. Six (8.8%) were positive for Mi2. Nine (13.2%) had unknown bands and 14 (20.6%) were negative. Of note, 49 (59%) reported persistently active disease and 54 (65%) were still taking immunosuppressive medication for myositis. Among respondents at school or in higher education, 13 out of 29 (44.8%) reported that their academic results were adversely affected by myositis, and that time missed, muscle weakness and fatigue were all significant contributors. Around two-thirds of respondents found that myositis had made it difficult to study. Fourteen of 50 (28%) reported career compromise caused by myositis; of these, 10/37 (27%) were employed and 4/13 (30.8%) were unemployed. Among 47 patients aged 18 to 24 there were 21 (44.7%) who were employed; patients in this study were twice as likely to be unemployed compared to the corresponding age group in the UK population (p=0.001, OR 0.456, 95% CI 0.24, 0.84). SF36 Physical Composite Scores (PCS) were significantly better in those who did not report current myositis (p=0.0003) arthritis (p=0.002) or muscle weakness (p=0.0001). Mental Composite Scores (MCS) were also better in those who did not report current arthritis (p=0.03) or muscle weakness (p=0.013). Intensity indices were calculated for skin DAS, CMAS and MMT by dividing area under the curve (AUC) of score trajectories by the duration (y) of study follow-up. There was significant correlation between MCS and MMT index scores (p=0.007, *rho* 0.328). This association remained significant after fitting a quantile regression model to predict changes in the median MMT intensity score as a function of MCS after adjusting for education/employment status.

Conclusion: We found high patient-reported rates of persistently active disease and medication use in long term follow-up of juvenile myositis, although response bias exists. The young people had reduced rates of employment compared to the UK general population. Persistent muscle disease affected quality of life outcomes in this cohort.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Muscle Biology, Myositis and Myopathies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of rare, heterogeneous autoimmune diseases of unknown etiology. Different physiopathogenic mechanisms have been proposed, including the production of autoantibodies and pathogenic cytokines. Ro52/TRIM21 is a ubiquitin ligase, and antibodies against this molecule have been described in different autoimmune diseases, including IIM. The aim of this study was to assess if there is a differential production of cytokines, associated with Ro52/TRIM 21 levels, in patients with recent-onset IIM.

Methods: We included patients within the first month of IIM diagnosis according to Bohan and Peter's criteria. They all had active disease, had no treatment, and were seen at a tertiary care center between 2013 and 2015. Patients with diagnosis of dermatomyositis (DM), polymyositis and antisynthetase syndrome, as well as age and gender-matched healthy donors were recruited. PBMCs were isolated by Ficoll-Hypaque. $CD4^+$ T cells and monocytes ($CD14^+$) were purified by magnetic selection. Effector T cells were stimulated with PMA plus ionomycin and monocytes with LPS. Supernatants were collected and cytokine levels were measured. Levels of IFN-α were determined by ELISA, and the other cytokines were assessed by cytometric bead array. The expression of TRIM21 in different PBMC subsets was evaluated by Western Blot.

Results: We included 15 patients with IIM and 15 healthy controls. DM was the most prevalent IIM (73.3%). Most patients were female (66%), with a mean age of 43 ± 15 years. After stimulation, T cells from IIM patients had a higher production of IL-17 (80.22 ± 28.57 *vs* 14.7 ± 5.47, p=0.017) and TNF-α (2325.1 ± 405.14 *vs* 1055.62 ± 235.21, p=0.005) than healthy controls. After being stimulated with LPS, monocytes from IIM patients produced more IL-6 (8441.2 ± 1801.03 *vs* 1996.6 ± 650.58, p=0.003) and IFN-α (85.27 ± 13.78 vs 13.3 ± 0.87, p=0.002) than control monocytes. Also, patients with IIM showed a decreased protein expression of TRIM21 in comparison to healthy controls in different PBMC subsets: total PBMC (0.971 ± 0.603 *vs* 1.849 ± 0.927 p=0.016), $CD4^+$ lymphocytes (0.797 ± 0.54 *vs* 2.413 ±0.786, p=0.017), and monocytes (0.875 ± 0.358 *vs*1.89 ±0.209, p<0.001).

Conclusion: Our findings suggest that patients with IIM are characterized by a higher production of proinflammatory cytokines, associated with decreased levels of TRIM21. The deficiency in TRIM21 could potentially lead to decreased IRF ubiquitination and degradation, enhancing type-1 IFN signaling. Along with the higher IFN-α production, this could contribute to the IFN signature found in IIM patients. Also, the specific cytokine profile could represent a potential biomarker for IIM, particularly DM patients.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Muscle Biology, Myositis and Myopathies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Antisynthetase syndrome (ARS) is an inflammatory myopathy (IM) commonly associated to interstitial lung disease (ILD) and different anti-tRNA-synthetase autoantibodies. The immune mechanisms leading to ARS are yet poorly understood. Recently, we have shown an infiltration of NK cells inside target tissues associated to a specific decrease of peripheral NK cells expressing the natural cytotoxicity receptor-3 (NKp30). These events resulted in a down-modulation of NK cell functions in active ARS patients, suggesting a contribution of NK cells to ARS pathogenesis. In patients with certain tumor subtypes, down-modulation of NKp30 has also been reported and correlated with an abnormal expression of NKp30 ligands, namely B7-H6 and BAT3. These two stress molecules are also expressed or secreted by monocytes/macrophages. In the present study we evaluated the possible impact of the soluble forms of B7-H6 and BAT3 in ARS.

Methods: From 2013-16, 53 treated or untreated patients with ARS were included (15 men = 28%; median age 48, range 18-77; 40 with Jo-1 auto-antibody = 75%) and grouped according to the disease activity (27 active and 26 inactive patients). Patients were compared to 17 healthy donors (2 men = 12%, median age 29, range 22-44) and to 20 patients with non-ARS active IM (8 men = 40%; median age 48, range 25-78; with 12 dermatomyositis = 60%, 7 auto-immune necrotizing myopathy = 35% and 1 overlaping myopathy = 5%). Serum IL-2 & IL-15 were quantified using Quantikine-ELISA-kits (R&D systems), as were soluble forms of NKp30 ligands sB7-H6 and sBAT3 (EIAab & Cusabio, respectively). Statistical analyses were performed using appropriate tests.

Results: Whereas sB7-H6 median concentration was similar in ARS patients and healthy donors, sBAT3 titers were significantly increased in patients with ARS (250 *vs.* 134 and pg/mL, p=0.0002, Figure 1). Importantly, sBAT3 strongly correlated with ARS activity: median sBAT3 concentration reached 340 pg/mL in active patients *vs.* 160 pg/mL in inactive patients (p<0.0001). Furthermore, in patients with increased sBAT3 who were tested twice longitudinally, sBAT3 decreased under treatment in 5/6 (83%) cases (from 472 to 259 pg/mL, p=0.06). sBAT3 increase was highly specific for ARS, as only 1/20 (5%) patients with non-ARS active IM showed a sBAT3 titer above 2 times the healthy donors range (median concentration in patients with non-ARS active IM = 178 pg/mL, p<0.0001). The mechanism of sBAT3 increase remains unknown and sBAT3 level did not correlate with inflammatory cytokine IL2 and IL15 serum concentrations.

Conclusion: The significant and specific increase of sBAT3 in patients with active ARS and its decrease under treatment suggested that this stress molecule may be involved in ARS pathogenesis and could also be considered as a new biomarker for ARS patients.

Statistical Simulation Using Data from the Foundation for the National Institute of Health/Osteoarthritis Initiative Biomarkers Consortium to Evaluate the Clinical Utility of Prognostic Knee Osteoarthritis Biomarkers in Designing a Knee Osteoarthritis Clinical Trial

Sheng Feng[1], Zheng (Roger) Liu[2], Feng Hong[1], Jeroen Medema[1], Rajesh Kamath[1] and Marc C. Levesque[1], [1]AbbVie Bioresearch Center, Worcester, MA, [2]AbbVie Inc, AbbVie Bioresearch Center, Worcester, MA

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects I: Epidemiology and Progression
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Development of disease-modifying osteoarthritis drugs (DMOADs) for knee osteoarthritis (OA) has been challenging, partially owing to lack of prognostic biomarkers. Our objective was to identify baseline (BL) biomarkers of rapid OA progression and estimate the potential value and cost of using biomarkers in a knee OA trial.

Methods: The Foundation for the National Institute of Health/Osteoarthritis Initiative (fNIH/OAI) Biomarker Consortium included 600 patients (pts) with knee OA. Pts with nonprogression (n=200), pain progression (n=100), x-ray progression (n=100), and pain/x-ray progression combined (n=200) had knee x-rays, MRIs, and blood and urine biomarkers of bone and cartilage damage. BL biomarkers associated with progression were identified using receiver operator characteristics and multivariate models (Random Forest, Neuro-Network, and Monte Carlo empowered LASSO). To identify subgroups, Patient Rule Induction Method and the Adaptive Index Model were used. To evaluate the value of implementing biomarkers in a trial, we simulated biomarker data based on the OAI population, from which fNIH samples were selected. We estimated potential benefit (reduction in sample size) and cost (screen failure rate) of the biomarker strategy for conducting a knee OA trial.

Results: BL urine CTX-II was the best soluble biomarker predicting OA progression in 12 of 25 multivariate models tested, although predictive power was low (AUROC <60%; **Table 1**). Use of urine CTX-II during the screening phase of a DMOAD trial enriched the number of pts with OA progression by 13% and reduced sample size by 45%; screen failure rate was 83% **(Fig; Table 2)**. The number of medial tibiofemoral subregions affected by MRI bone marrow lesion (BML) was one of the best imaging predictors of OA progression. BL MRI BMLs enriched the number of pts with OA progression by 20% and reduced sample size by 62%; screen failure rate was 78% **(Fig; Table 2)**.

Conclusion: A novel approach combining statistical analysis of fNIH/OAI data with clinical simulations indicated that stratification using urine CTX-II and MRI BML would reduce the sample size needed for a DMOAD clinical trial. However, use of CTX-II and MRI BML could increase the screen failure rate and preclude their implementation as stratification biomarkers in clinical trials.

Table 1. Multivariate Analyses Exploring a BL Prognostic Biomarker Signature to Predict Rapid Progression of OA

Observed Statistics	Random Forest	Neuro-Network	MC-LASSO
Number of predictors most likely to be selected by final multivariate model in 10 runs (frequency)	1 (7/10)	3 (4/10)	1 (5/5)
Most common top predictor likely to be selected by final multivariate model in 10 runs (frequency)	CTX-II (4/10)	CTX-II (3/10)	CTX-II (5/5)
Other notable predictors (selected as the top predictors more than once)	BTI Coll 2-1 NO_2	None	None
Best AUROC of multivariate models in all runs	56.6%	56.4%	56.8%

AUROC, area under the receiver operating characteristic; BL, baseline; BTI, bone trabecular integrity; Coll 2-1 NO_2, nitrated fragment from α-helical region of type 2 collagen; CTX-II, C-telopeptide of type 2 collagen; MC-LASSO, Monte Carlo empowered LASSO; OA, osteoarthritis.

Table 2. The Incremental Value and Cost of Implementing a Test of BL Urine CTX-II and MRI/BML in a Future Clinical Study*

Assumptions and Design Parameters	Without Biomarker	With Biomarker	
		CTX-II	MRI (BML)
Screen-failure rate in general OA population, %	0	83	78
Enrichment: pts with rapid OA progression in the subgroup, %	38	51	58
Sample size calculation per arm	1535	850	585

BL, baseline; BML, bone marrow lesion; CTX-II, C-telopeptide of type 2 collagen; MRI, magnetic resonance imaging; OA, osteoarthritis; pts, patients.
*The efficacy was defined as the difference of relative changes from BL between treatment and placebo. A 25% minimum efficacy was assumed for pts with rapid OA progression. The SD of the efficacy is set to 75% of mean. For the sample size estimation, 5% type 1 error and 80% power are assumed.

Figure. Potential benefit* and cost† of using urine CTX-II, MRI/BML, or no biomarker (reference) in a future knee OA trial. Session Title: Osteoarthritis – Clinical Aspects I: Epidemiology and Progression
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Dietary fiber reduced risks of metabolic diseases in part by reducing systemic inflammation and body weight. These factors are both likely to contribute to causing osteoarthritis (OA) and both are more strongly associated with painful OA than with radiographic disease. In this study, we assessed the relationship between dietary fiber and risk of knee OA.

Methods: We used data from the Osteoarthritis Initiative, a prospective, multicenter cohort of 4,796 U.S. men (41.5%) and women [mean (SD) age: 61.2 (9.2) years and BMI: 28.6 (4.8) kg/m^2] with or at risk of knee OA. Dietary fiber was estimated using a validated food frequency questionnaire at baseline and sex-specific quartiles of dietary fiber were created. Total dietary fiber was the sum of fibers from grains, fruits and vegetables, and nuts and legumes. Incident radiographic OA (ROA), symptomatic OA (SxOA), and knee pain worsening were followed annually until 48 months. Incident ROA was defined as a knee newly developing Kellgren and Lawrence grade ≥2. Incident SxOA was defined as a new onset of both ROA and a painful knee on most days in past month. Knee pain was estimated used the WOMAC pain subscale ranging from 0 (no pain) to 20 (most pain) points, and pain worsening was defined if the score difference between the baseline and each annual exam ≥ 14% of the base score according to the published estimates for the minimal clinical important difference in WOMAC. We used Generalized Estimating Equations to account for the correlation between two knees individually and for analysis of pain worsening for each exam. We further assessed to what extent the association between fiber and OA was mediated by BMI using a marginal structural model.

Results: At 48 months, we identified 869 knees with incident SxOA, 152 knees with incident ROA, and 1,964 knees with pain worsening among 5,752 / 3,350 / 7,951 eligible knees, respectively (**Table**). Dietary total fiber was inversely associated with SxOA and pain worsening (p- trend <0.01); grain fiber was similarly associated with pain worsening (p-trend<0.02). Approximately 34% of the association between total fiber and SxOA and 22% between total fiber and pain worsening was through the mediation by BMI. As a secondary analysis, adjustment for baseline BMI yielded similarly significant results. No associations were found for dietary fiber with ROA or for other fiber with OA phenotypes.

Conclusion: This is the first study demonstrating that dietary fiber is associated with lower risks of symptomatic OA and pain worsening in the knee that may be partially mediated through reduced BMI. The strongest association was found at the highest quartile of fiber intake, which is in line with the recommended daily fiber of 25 grams for Americans.

Table. Relative risk (95% CI) to estimate total effect of dietary fiber on knee incident symptomatic (Sx) OA (n=2,876 persons), incident radiographic (R) OA (n=1,675 persons), and knee pain worsening (n=3,976 persons) for all eligible participants

The Impact of Hip and Knee Osteoarthritis on the Subsequent Risk of Incident Diabetes: A Population-Based Cohort Study

Tetyana Kendzerska[1,2,3], Lauren King[1], Ruth Croxford[2], Ian Stanaitis[3], Angela Wall[3] and Gillian Hawker[1,2,3], [1]University of Toronto, Toronto, ON, Canada, [2]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada, [3]Women's College Research Institute/Women's College Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoarthritis – Clinical Aspects I: Epidemiology and Progression

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Osteoarthritis (OA) and diabetes commonly co-occur. Potential explanations include common risk factors (aging, obesity) and the effects of OA-related functional limitations on diabetes risk factors (e.g., sedentary behavior exacerbates metabolic syndrome). However, whether or not there is a causal relationship between OA and diabetes is unclear. In a large population-based cohort free of diabetes at baseline, we examined the relationship between self-reported hip and knee OA and incident diabetes.

Methods: A population cohort aged ≥55 years was recruited from 1996-98 and followed through provincial health administrative data to 2014. Subjects with baseline diabetes, rheumatic diseases, and medical conditions associated with functional disability were excluded.

Age, sex, height, weight, joint complaints and functional limitations were collected. Hip and knee OA were defined as swelling, pain, or stiffness in any joint lasting 6 weeks in the past 3 months and indication on a joint homunculus that a hip or knee was "troublesome". Comorbidities were defined using validated algorithms for health administrative data. Using Cox-regressions, we examined the relationship of baseline hip/knee OA (0-2 hips; 0-2 knees) with subsequent incident diabetes as defined from health administrative data (sensitivity - 86%, specificity - 97%), incrementally controlling for age, sex, BMI, preexisting hypertension and cardiovascular disease (CVD), income and prior primary care exposure, and finally walking limitation.

Results: 16,362 participants without baseline diabetes were included: median age 68 years, 61% female and median BMI 25.3 kg/m^2. 1,637 (10%) individuals met criteria for hip OA, 2,431 (15%) for knee OA, and 3,908 (24%) for walking limitation. Over a median follow-up of 13 years, 3,539 individuals (22%) developed diabetes. Controlling for baseline age, sex, income, BMI, preexisting hypertension and CVD, and prior primary care exposure, a significant dose-response relationship was observed between number of hip/knee joints with OA and incident diabetes: HR for two vs. no OA hips 1.25, 95% CI: 1.08-1.44 (p=0.003); HR for two vs. no OA knees 1.16, 95%CI: 1.04 -1.29 (p=0.008). Further adjustment for walking limitation resulted in attenuation of these relationships, which became non-significant.

Conclusion: In a large population cohort aged ≥55 years free of diabetes at baseline and after controlling for multiple confounders, the presence and burden of hip and knee OA was a significant independent predictor of incident diabetes. This association was explained largely by OA-related walking limitation. Increased attention to management of hip and knee OA with a view to improving mobility has potential to reduce risk of incident diabetes.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects I: Epidemiology and Progression
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Accelerated knee osteoarthritis (KOA) is a painful disorder and associated with several risk factors: greater age, greater body mass index (BMI), static knee alignment, and coronal tibial slope. While no single risk factor can accurately predict who is at risk for accelerated KOA, it would be beneficial to recognize the combinations of risk factors that identify people at risk for accelerated KOA. Hence, we assessed which combinations of risk factors can classify adults who develop accelerated KOA or not and which risk factors are most important.

Methods: We conducted a case-control study using data from baseline and the first 4 annual visits of the Osteoarthritis Initiative. Eligible participants had no radiographic KOA at baseline (Kellgren-Lawrence [KL] < 2). We classified 3 groups: 1) accelerated KOA: ≥ 1 knee progressed to advance-stage KOA (KL 3 or 4) within 48 months, 2) typical onset of KOA: ≥ 1 knee increased in radiographic scoring within 48 months (excluding those defined as accelerated KOA), and 3) No KOA: no change in KL grade by 48-months. We did 1:1:1 matching for the 3 groups based on sex. A laboratory blinded to group assignment conducted serum assays in duplicate for CRP, GSP, and glucose concentrations. Staff recorded age, sex, and BMI based on standardized protocols. Weight-bearing, fixed flexion posterior-anterior knee radiographs were obtained at baseline and follow-up visits. One reader manually measured baseline coronal tibial slope (ICC = 0.87). Baseline femorotibial alignment angle was measured on the radiographs using a semi-automated program software tool. We performed classification and regression tree (CART) analysis to determine rules for classifying individuals as accelerated KOA or not (no KOA and gradual onset) based on baseline age, BMI, coronal tibial slope, static alignment, serum measures, and sex.

Results: Based on the CART analysis, the most important baseline variables for classifying individuals with incident accelerated KOA (in order of importance) were BMI, glucose concentrations, and age (Figure 1). Individuals < 63.5 years of age were likely not to develop accelerated KOA, except when they were overweight. Individuals ≥ 63.5 years of age were more likely to develop accelerated KOA unless their glucose levels were > 81.98 mg/dL, had varus malalignment, and had GSP concentrations < 225.6 nMol/mL. The relative error (unexplained variance) of the CART = 63%.

Conclusion: Age, BMI, and serum assays may enable the classification of individuals who will develop accelerated KOA in the subsequent 4 years. Future studies should explore other novel risk factors that may help classify individuals at risk for accelerated KOA and recognize the complex inter-play between risk factors. **Figure 1. Classification and Regression Tree for Accelerated Knee Osteoarthritis (AKOA) versus those without AKOA**

Maintaining Sufficient Serum Vitamin D Levels over 2 Years Is Associated with Reduced Knee Structural and Symptomatic Changes in Patients with Knee Osteoarthritis

Shuang Zheng[1], Xingzhong Jin[1], Flavia M Cicuttini[2], Xia Wang[1], Zhaohua Zhu[1], Anita E Wluka[3], Weiyu Han[1], Tania Winzenberg[1], Leigh Blizzard[1], Graeme Jones[4] and Changhai Ding[4], [1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia, [3]Australia, Armadale, Australia, [4]Musculoskeletal Unit, Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Osteoarthritis – Clinical Aspects I: Epidemiology and Progression
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: To examine whether those maintaining sufficient serum vitamin D levels have reduced knee structural changes and

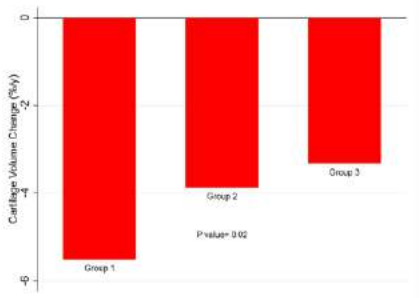
symptomatic improvement compared with those not maintaining sufficient serum vitamin D levels over 2 years in patients with knee osteoarthritis (OA).

Methods: Participants (n= 413, age 63.2; 50% females) with symptomatic knee OA and vitamin D insufficiency were enrolled in a multicentre, parallel randomized, placebo-controlled and double-blind clinical trial. 340 participants (82.3%) completed the study as well as 25-hydroxyvitamin D [25(OH)D] measurements at month 3 and month 24. In the post-hoc analyses, participants were classified as maintaining insufficient vitamin D group (Group 1, serum 25(OH)D≤50nmol/l at month 3 and month 24, n=45), fluctuating vitamin D group (Group 2, 25(OH)D>50nmol/l only at one point, n=68) and maintaining sufficient vitamin D group (Group 3, 25(OH)D>50nmol/l at month 3 and month 24, n=226). Serum 25(OH)D were measured at baseline, month 3 and month 24 using direct competitive chemiluminescent immunoassays. Knee structural changes including cartilage volume, cartilage defects, bone marrow lesions (BML) and effusion-synovitis volume were assessed using magnetic response imaging (MRI) at baseline and month 24. Knee pain was assessed at baseline, month 3, 6 12 and 24 using Western Ontario and McMaster Universities Arthritis Index (WOMAC) and visual analogue scale.

Results: Patients in Group 3 had significantly less tibial cartilage volume loss per year (β: 2.2, 95% CI: 0.4, 4.0) and change in effusion-synovitis volume per year (β: -69.5, 95% CI: -133.4, -5.6) than participants in Group 1 (*Figure 1 and Figure 2*). The differences remained significantly after further adjustment for age, sex, BMI and season of blood sampling (β: 2.1, 95 CI%: 0.3, 3.9 and β: -61.8, 95 CI%: -121.9, -1.7, respectively). There were no significant differences in changes of tibiofemoral cartilage defects and BML between Group 3 and other two groups. Patients in Group 3 had significantly less loss of WOMAC physical function (β: -94.8, 95% CI: -183.1, -6.6) than others two groups in the mixed-effect models.

Conclusion: Patients maintaining sufficient serum vitamin D at month 3 and 24 had less cartilage volume loss, less increase in effusion-synovitis volume and more improvement in physical function compared with those not maintaining sufficient serum vitamin D over 2 years in symptomatic knee OA patients with vitamin D insufficiency. These findings suggesting that maintaining sufficient 25(OH)D is beneficial for structural change and functional improvement in knee osteoarthritis.

Figure 1. Tibial Cartilage Volume Change (%/y) in knee OA patients with or without sufficient serum vitamin D levels over 24 months.

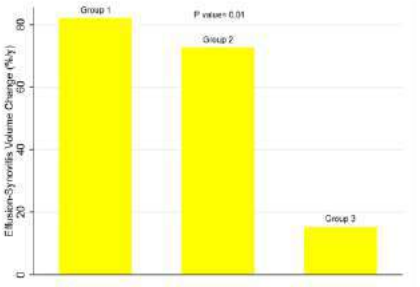


Group 1: maintaining insufficient vitamin D (serum 25-OHD≤ 50nmol/l at both month 3 and 24);

Group 2: fluctuating vitamin D group (serum 25-OHD> 50nmol/l only at one time point);

Group 3: maintaining sufficient vitamin D (serum 25-OHD> 50nmol/l at both month 3 and 24);

Figure 2 Effusion-Synovitis Volume Change (%/y) in knee OA patients with or without sufficient serum vitamin D levels over 24 months.



Group 1: maintaining insufficient vitamin D (serum 25-OHD≤ 50nmol/l at both month 3 and 24);

Group 2: fluctuating vitamin D group (serum 25-OHD> 50nmol/l only at one time point);

Group 3: maintaining sufficient vitamin D (serum 25-OHD> 50nmol/l at both month 3 and 24);

Session Title: Osteoarthritis – Clinical Aspects I: Epidemiology and Progression

Session Type: ACR Concurrent Abstract Session

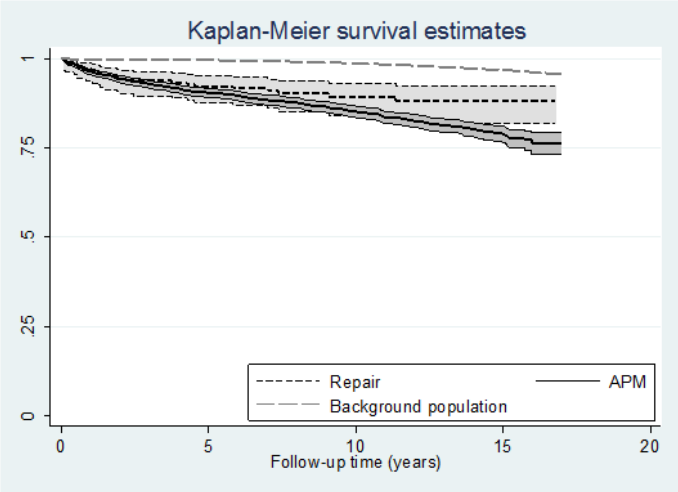
Session Time: 4:30PM-6:00PM

Background/Purpose: Traumatic meniscus injury is associated with increased risk of developing knee osteoarthritis (OA). The purpose of meniscus repair, beyond short time symptom relief and restoration of knee biomechanics, is to reduce the risk of later knee OA. However, the long-term consequences of meniscus repair have not been sufficiently investigated. Thus, our objective was to compare the consultation rate for symptomatic knee OA in patients after meniscus repair, arthroscopic partial meniscectomy (APM), and in the general population.

Methods: We identified patients aged 16-45 years having had meniscus surgery due to acute meniscus tear in 1998-2009 in southern Sweden by a healthcare register. All patients were followed from the time of first meniscus surgery until a diagnosis of knee OA, relocation outside the Skåne region, death, or December 31st, 2014. We studied the consultation rate for knee OA compared to the general population as well as calculated the age- and sex-adjusted hazard ratio (HR) for knee OA consultation after meniscus repair vs. APM.

Results: We identified 2409 patients with an acute meniscus tear (mean [SD] age 30.5 [8.6] years); 211 (8.8%) of them had had meniscus repair. The absolute risk of having consulted for knee OA during the study period was 16.4% after APM, 10.0% after meniscus repair, and 2.1% in the general population (Figure). The age- and sex-standardized incidence of knee OA was 110/10 000 person-years after meniscus repair, 165/10 000 person-years after APM, and 19/10 000 person-years in the general population. The HR for knee OA after repair vs APM was: 0.79 (95% confidence interval [CI] 0.51, 1.24). A sensitivity analysis, excluding cases with OA within the first 2 years post-surgery, yielded the HR of 0.53 (95% CI 0.27, 1.04).

Figure. The survival estimates for doctor-diagnosed knee osteoarthritis among persons aged 16 to 45 years in patients having had arthroscopic partial meniscectomy (APM), meniscal repair or in the general population.



Conclusion: The point estimates suggests about 20-50% lower risk of knee OA in patients after meniscus repair as compared to patients with APM. However, the consultation rate for OA after repair was still at least 2.5 times higher as compared to the general population.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Romosozumab (Romo) is an investigational bone-forming monoclonal antibody that binds sclerostin and has a dual effect, increasing bone formation and decreasing bone resorption. Here, we report results of the FRActure study in postmenopausal woMen with ostEoporosis (FRAME) (NCT01575834).

Methods: This multicenter, randomized, double-blind, placebo-controlled study enrolled postmenopausal women aged 55 to 90 years with osteoporosis (BMD T-score ≤ –2.5 at the total hip or femoral neck). Subjects were randomized 1:1 to subcutaneous placebo (Pbo) or 210 mg Romo monthly for 12 months, followed by subcutaneous denosumab (DMAb) every 6 months for 12 months in both groups. The co-primary endpoints were subject incidence of new vertebral fracture through month (M) 12 and M24. Secondary endpoints included clinical (nonvertebral plus symptomatic vertebral) and nonvertebral fracture, and BMD.

Results: A total of 7180 women (mean age 71 years, mean total hip T-score –2.5) were enrolled. At M12, Romo reduced new vertebral fracture, with a relative risk reduction (RRR) of 73% (subject incidence of fracture: 1.8% Pbo vs 0.5% Romo; $P < 0.001$). In subjects who

received Romo in year 1, vertebral fracture risk reduction persisted through M24 after both groups transitioned to DMAb (2.5% Pbo/DMAb vs 0.6% Romo/DMAb; RRR 75%; $P < 0.001$). Romo reduced clinical fracture risk at M12 (2.5% Pbo vs 1.6% Romo; RRR 36%; $P = 0.008$). Nonvertebral fracture incidence through M12 was 2.1% for Pbo (lower than expected) vs 1.6% for Romo (RRR 25%; $P = 0.096$), with a similar risk reduction through M24 (Pbo/DMAb vs Romo/DMAb RRR 25%; nominal $P = 0.029$, adjusted $P = 0.057$). A preplanned analysis revealed a significant interaction between treatment and geographic region for nonvertebral fracture at M12 ($P = 0.042$). Nonvertebral fracture incidence in Central/Latin America was 1.2% for Pbo vs 1.5% for Romo, whereas a 42% RRR in nonvertebral fracture was observed in rest-of-world ($P = 0.012$). Compared to Pbo, Romo increased BMD by 12.7% and 5.8% at the lumbar spine and total hip, respectively, at M12 ($P < 0.001$). Adverse events were generally balanced between groups, with injection-site reactions in 2.9% of Pbo subjects and 5.2% of Romo subjects during year 1. One atypical femoral fracture and 2 osteonecrosis of the jaw events were positively adjudicated in the Romo group through M24.

Conclusion: In postmenopausal women with osteoporosis, Romo 210 mg monthly was well tolerated and reduced vertebral and clinical fracture risk vs Pbo at M12; vertebral fracture risk reduction persisted in Romo subjects through M24 after both groups transitioned to DMAb. The sequence of Romo followed by DMAb may be a highly effective treatment for postmenopausal women with osteoporosis.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: STRUCTURE was a phase 3, open-label study evaluating the effect of romosozumab or teriparatide for 12 months in women with postmenopausal osteoporosis transitioning from bisphosphonate therapy (NCT01796301).

Methods: This multicenter, active-controlled study enrolled women with postmenopausal osteoporosis who had taken an oral bisphosphonate for ≥ 3 years prior to screening and alendronate (70 mg weekly or equivalent) in the year prior to screening; had a bone

mineral density (BMD) T-score ≤ –2.5 at the total hip, lumbar spine, or femoral neck; and had a history of nonvertebral fracture after age 50 or vertebral fracture. Subjects received daily calcium and vitamin D and were randomized to receive subcutaneous romosozumab 210 mg once monthly or teriparatide 20 µg once daily. The primary endpoint was percent change from baseline in BMD by DXA at the total hip through month 12 (the average at months 6 and 12). Secondary endpoints included percent change from baseline at months 6 and 12 in BMD by DXA at the total hip, lumbar spine, and femoral neck; hip integral and cortical BMD by quantitative computed tomography (QCT); and estimated hip strength by finite element analysis. Imaging assessments were done blinded to treatment.

Results: A total of 436 women, with a mean age of 72 years, were randomized to receive romosozumab (N = 218) or teriparatide (N = 218). Baseline mean total hip, lumbar spine, and femoral neck T-scores were –2.2, –2.9, and –2.5, respectively. Through 12 months, the mean (95% CI) percent change from baseline in total hip BMD by DXA was 2.6% (2.2, 3.0) with romosozumab and –0.6% (–1.0, –0.2) with teriparatide ($p < 0.0001$ between groups). Total hip BMD changes at months 6 and 12 were significantly larger with romosozumab than with teriparatide ($p < 0.0001$): month 6, 2.3% (1.9, 2.7) vs –0.8% (–1.2, –0.4); month 12, 2.9% (2.5, 3.4) vs –0.5% (–0.9, 0), respectively. Romosozumab also resulted in significantly larger BMD gains at the lumbar spine at months 6 and 12 vs teriparatide ($p < 0.0001$): month 6, 7.2% (6.6, 7.8) vs 3.5% (2.9, 4.0); month 12, 9.8% (9.0, 10.5) vs 5.4% (4.7, 6.1), respectively. QCT assessments of the hip demonstrated significantly greater gains in integral and cortical BMD with romosozumab vs teriparatide at months 6 and 12 ($p < 0.0001$). Estimated hip strength gains were also significantly larger with romosozumab at both time points ($p < 0.0001$) and declined from baseline in teriparatide-treated subjects at month 6. The subject incidences of treatment emergent adverse events and adverse events of interest were generally balanced between treatment groups.

Conclusion: In subjects transitioning from bisphosphonate therapy, romosozumab was well-tolerated and was associated with significant BMD gains at both the hip and spine compared with teriparatide. BMD gains in the cortical compartment contributed to the greater treatment effect of romosozumab at the hip. Estimated hip strength improved with romosozumab over 12 months but decreased early with teriparatide. A global phase 3 program evaluating romosozumab for the treatment of postmenopausal osteoporosis is ongoing.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The efficacies of switching bisphosphonate (BP) to denosumab (DMAb), an anti-RANKL antibody which strongly inhibits bone resorption, or daily teriparatide (TPTD), a bone anabolic agent which induce bone formation, has been reported in primary osteoporosis. However, its adaptation and efficacies in patients with rheumatoid arthritis (RA) still lack reliable evidence and also no

previous reports directly compared the results of these two switching treatments.

Methods: 194 patients with RA treated by BP [177 female, 65.9 years old, disease duration 17.8 years, RF positivity 77.8%, DAS28-CRP 2.3, 75.8% with oral prednisolone (PSL) 3.6mg/day, 23.2% with biologics, prior BP duration 40.0 months, prior vertebral fracture rate 41.8%, T-scores: lumbar spine (LS) -1.8, femoral neck (FN) -2.3, total hip (TH) -2.0] were allocated to either the (1) BP-continued group (BP; n=80), (2) switched-to-DMAb group (DMAb; n=74), or (3) switched-to-TPTD group (TPTD; n=40) based on each physicians' decision and followed up for 12 months by monitoring bone mineral density (BMD), trabecular bone score (TBS), bone turnover markers, and fracture incidence.

Results: At baseline, TPTD group showed significantly lower T-scores than BP group in all resions ($P<0.05$), while no significant differences were observed between DMAb and BP group, and DMAb and TPTD group. Changes of BMD from baseline→6→12 months were as follows. (1) BP group: LS; 0→1.1→2.5%, TH; 0→0.3→0.2%, FN; 0→0.5→0.8%, (2) DMAb group: LS; 0→2.8→4.9%, TH; 0→1.5→3.0%, FN; 0→2.0→3.9%, (3) TPTD group: LS; 0→4.2→6.0%, TH; 0→-1.4→1.4%, FN; 0→-1.1→2.1%. TBS changed from baseline to 12 months as follows. (1) BP group: -1.4%, (2) DMAb group: 0.4%, (3) TPTD group: 2.7%. DMAb group showed significant increase in LS, TH, and FN BMD ($P<0.01$) and maintained TBS ($P<0.01$) compared to BP group at 12 months, and TPTD group showed significant increase in LS BMD ($P<0.01$) and TBS ($P<0.001$) compared to BP group at 12 months. TPTD group showed similar increase in LS, TH, and FN BMD, while significantly increased TBS ($P<0.05$) compared to DMAb group at 12 months. Changes of bone turnover markers were as follows. (1) BP group: bone resorption marker, TRACP-5b; 0→-3.5→1.4%, bone formation marker, PINP; 0→-9.6→-13.4%, (2) DMAb group: TRACP-5b; 0→-28.5→-27.9%, PINP; 0→-14.5→-17.6%, (3) TPTD group: TRACP-5b; 0→77.1→77.6%, PINP; 0→296.5→227.7%. DMAb group showed significant decrease in TRACP-5b ($P<0.001$), and TPTD group showed significant increase in TRACP-5b and PINP ($P<0.001$) compared to BP and DMAb group at 12 months. The fracture incidence during this period was (1) BP group: 3.8% (1 vertebra, 1 forearm, and 1 humerus), (2) DMAb group: 1.4% (1 rib), (3) TPTD group: 2.5% (1 toe). DMAb and TPTD group showed no major fractures during this period.

Conclusion: Switching oral BP to DMAb significantly increased LS, TH, and FN BMD, and decreased TRACP-5b, while switching to TPTD increased LS BMD, TBS, and total bone turnover at most compared to continuing BP at 12 months. Our results indicate that switching BP to DMAb or TPTD by determining treatment target may provide useful treatment option in RA associated osteoporosis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Odanacatib (ODN) is a selective oral inhibitor of cathepsin K (CatK) in development for the treatment of osteoporosis. Because of reports with the CatK inhibitor balicatib, morphea-like skin lesions were deemed Events of Clinical Interest in the Phase 3 Long-Term Odanacatib Fracture Trial (LOFT; NCT00529373).

Methods: LOFT was a double-blind, placebo-controlled trial. Women ≥65 years with total hip (TH) or femoral neck (FN) bone mineral density (BMD) T-score ≤-2.5, or with a radiographic vertebral fracture and T-score ≤-1.5 at TH or FN, were randomized (1:1) to ODN 50 mg/week or placebo. In a preplanned double-blind extension, 51% of patients continued on their originally assigned treatment up to 5 years. As part of the safety evaluation, external adjudication committees evaluated specific adverse event (AE) categories, including AEs with skin changes suggestive of morphea or systemic sclerosis.

Results: Of 16,713 participants randomized at 388 centers in 40 countries, 16,071 were included in the safety analysis; of these, 12,290 completed the base study, 8,257 continued into and 6,047 completed the extension. Adjudication confirmed morphea-like skin lesions occurred in 13 patients (0.16%) treated with ODN versus 3 patients (0.04%) treated with placebo. The time of onset varied from Study Day 115 to 1315, with 3 cases occurring in the first year of the study and 10 cases occurring within the first two years. Lesions were characterized most consistently as indurated (often termed “hardened” or “thickened”), with pallor, pruritus, and erythema reported less frequently. Although histopathology was generally consistent with that of spontaneous (idiopathic) morphea, atypical features included pandermal involvement and occasionally dense eosinophilic infiltrates. Most lesions affected the trunk or lower extremities. There were no reports of accompanying constitutional symptoms or systemic involvement. All ODN-treated patients were negative for autoantibodies. Study medication was discontinued in all but one patient (ODN). As of the last follow-up, 12/16 cases (10 ODN, 2 placebo) were reported as fully recovered (including the patient who continued on ODN), 3/16 (3 ODN) as improved or recovering, and the remaining patient (placebo) declined further contact.

Conclusion: Confirmed morphea-like skin lesions were uncommon but occurred more often with ODN than placebo. Although the gross features and histopathology of these lesions were generally consistent with those of spontaneous morphea, in all patients in whom follow-up was obtained improvement or full recovery was reported.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Odanacatib (ODN) is a selective oral inhibitor of cathepsin K in development for the treatment of osteoporosis. The randomized, double-blind, placebo (PBO) controlled, event-driven, Phase 3 Fracture Trial (Long-Term Odanacatib Fracture Trial [LOFT]; NCT00529373) evaluated efficacy and safety of ODN in postmenopausal women with osteoporosis. In a planned double-blind

extension to LOFT, eligible patients continued on their originally assigned treatment for up to 5 years. We present efficacy and safety data for the entire 5-year double-blind period.

Methods: Women ≥65 years of age with BMD T-score ≤–2.5 at total hip (TH) or femoral neck (FN), or with radiographic vertebral fracture (VFx) and T-score ≤–1.5 at TH or FN, were randomized (1:1) to ODN 50 mg/week or PBO. All received vitamin D_3 (5600 IU/week) and calcium as required. Endpoints included morphometric VFx, hip fracture, non-VFx, clinical VFx, and safety and tolerability. Specific adverse events (AEs) were adjudicated.

Results: Of 16,071 patients (8043 ODN, 8028 PBO) in LOFT, 12,290 (6092 ODN, 6198 PBO) completed the study. Among these, 8,257 (4297 ODN, 3960 PBO) who were eligible and consented entered the extension and 6,047 (3432 ODN, 2615 PBO) completed it. Mean (SD) age at randomization was 72.8 (5.3) years, 46.5% had prior VFx, and mean BMD T-scores were lumbar spine (LS) –2.7, TH –2.4, and FN –2.7. Mean (SD) follow-up was approximately 44 (18) months. Compared with PBO, ODN treatment over 5 years resulted in relative risk reductions of 52% for morphometric VFx, 48% for hip fracture, 26% for non-VFx, and 67% for clinical VFx (all p<0.001). Compared with PBO, ODN treatment led to progressive mean percent increases (95% CI) in BMD of 10.9% (10.5, 11.2) at LS and 10.3% (10.0, 10.6) at TH (both p<0.001) at 5 years. Incidences of AEs and serious AEs overall were balanced for ODN vs PBO (88.3 vs 88.2% and 30.3 vs 30.4%, respectively). Deaths reported in patients being followed on study were 378 (4.7%) vs 327 (4.1%), ODN vs PBO, respectively (HR 1.12 [95% CI: 0.97, 1.30]); more complete ITT analysis of deaths among all patients, including those who discontinued from study, showed 682 (8.5%) vs 660 (8.2%), respectively (HR 1.04 [95% CI: 0.93, 1.16]). Delayed fracture union occurred in 18 patients in each group. Femoral shaft fractures occurred more often with ODN (26 patients [0.3%] vs 7 [0.1%]), of which 10 (0.1%) on ODN and none on PBO met criteria for atypical femoral shaft fractures (AFFs). No cases of osteonecrosis of the jaw (ONJ) were confirmed. Morphea-like skin lesions occurred more often with ODN (13 [0.2%] vs 3 [<0.1%]), most with onset within 2 years and 15 of 16 improved or fully recovered. Systemic sclerosis occurred in 2 (<0.1%) with ODN vs 1 (<0.1%) with PBO. Independent adjudication of CV events is ongoing and will be presented separately.

Conclusion: Consistent with the results of LOFT, treatment with ODN for up to 5 years reduced the risk of hip, vertebral and non-vertebral fractures. Overall incidence of AEs, including serious AEs, was generally balanced between ODN and PBO. Femoral shaft fractures, including AFFs, and morphea-like skin lesions were uncommon but more frequent with ODN.

Session Title: Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Denosumab (DMAb) treatment has been shown to decrease fracture (Fx) risk. Unlike bisphosphonates, DMAb is a

monoclonal antibody against RANKL. Discontinuation is characterized by reversal of effect, including transient increases in bone turnover markers to above-baseline (BL) levels returning to BL within 2 yr and loss of bone mineral density (BMD) to BL levels. An analysis from FREEDOM showed similar subject incidence of Fx in DMAb and placebo (PBO) groups upon discontinuation. Recent reports describe isolated cases of multiple (≥2) vertebral Fx (VFx) after DMAb cessation (Aubrey-Rozier *OI* 2015; Anastasilakis *OI* 2015; Popp *OI* 2016). To better understand VFx incidence—particularly multiple VFx—upon DMAb cessation, we describe VFx risk and possible determinants in subjects who discontinued DMAb during the 3-yr FREEDOM or 7-yr Extension.

Methods: Subjects who received ≥2 doses of investigational product (IP; DMAb 60 mg Q6M or PBO) and discontinued IP but stayed in study ≥7 M after the last dose were included in the analysis. Subjects who discontinued DMAb from FREEDOM or Extension were analyzed as one group. A logistic regression model explored covariates related to off-treatment new VFx or multiple new VFx.

Results: Of 1001 subjects who discontinued DMAb during FREEDOM or Extension, 56 (5.6%) sustained new VFx. Upon DMAb discontinuation, new VFx incidence increased relative to the on-treatment period but stayed within the range of those who discontinued PBO, ie, had never been treated (Table). The same pattern was seen in subjects with prior VFx, who had higher on- and off-treatment VFx rates than the overall population. Among subjects with off-treatment new VFx, a greater percentage of those who discontinued DMAb (34/56 [60.7%]) than PBO (10/29 [34.5%]) sustained multiple new VFx. Logistic regression models found prior VFx before or during treatment to be the strongest predictor of off-treatment new VFx, including multiple VFx (odds ratio 2.1-3.4). Off-treatment femoral neck BMD loss was a weak covariate.

Conclusion: Discontinuation of DMAb is associated with an increase in VFx rate to levels comparable to PBO. Among subjects who sustained new VFx after DMAb cessation, there was a greater incidence of multiple new VFx than in PBO. Subjects with prior VFx are at high risk for off-treatment new VFx and should continue osteoporosis therapy. Consequently those who discontinue DMAb should transition to another therapy after the 6-M dosing interval. **Table. Off-treatment vertebral fracture incidence in subjects who discontinued IP in FREEDOM or its Extension**

	FREEDOM	FREEDOM + Extension
	Placebo	Denosumab
All subjects	N = 470	N = 1,001
Off-treatment new VFx, n (%)	29 (6.2%)	56 (5.6%)
Off-treatment multiple new VFX, n (%) [among all subjects]	10 (2.1%)	34 (3.4%)
Off-treatment multiple new VFX, n (%) [among all subjects with new VFx]	10 (34.5%)	34 (60.7%)
On-treatment new VFx (per 100 subject-years)	7.0	1.2
Off-treatment new VFx (per 100 subject-years)	8.0	7.1
Subjects with prior VFx before treatment	N = 122 (26%)	N = 255 (25%)
Off-treatment new VFx, n (%)	12 (9.8%)	19 (7.5%)
Off-treatment multiple new VFx, n (%) [among subjects with prior VFx]	5 (4.1%)	15 (5.9%)
Off-treatment multiple new VFx, n (%) [among subjects with prior VFx and new VFx]	5 (41.7%)	15 (78.9%)
On-treatment new VFx (per 100 subject-years)	11.6	1.9
Off-treatment new VFx (per 100 subject-years)	14.4	12.1

Session Title: Rheumatoid Arthritis – Animal Models I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Genome-wide association studies have linked polymorphisms in the *PTPN2* locus to rheumatoid arthritis (RA). *PTPN2* encodes the tyrosine phosphatase TC-PTP, an important regulator of cytokine signaling. Disease-associated variants of *PTPN2* result in a partial loss of expression. To model the functional genetics of *PTPN2* in mice, we studied the effect of *PTPN2* haploinsufficiency in the SKG mouse, a spontaneous $CD4^+$ T-cell-driven model of autoimmune arthritis.

Methods: Development of spontaneous and/or mannan-induced arthritis was evaluated in SKG mice. $CD4^+$ T-cells isolated from SKG mice were transferred to $RAG2^{-/-}$ mice. Clinical scoring of arthritis was followed by histological and micro-CT analysis. Flow cytometry was used to assess T-cell development and T-cell effector populations. Gene expression was analyzed using qPCR. Statistical differences were calculated using the Mann-Whitney or un-paired T tests.

Results: Haploinsufficiency of *PTPN2* caused increased severity of spontaneous *(P=0.003)* and mannan-induced (*P=0.007*) arthritis in SKG mice, with high expression of *TNF (P=0.056)*, *IL-1b* (*P=0.020*), *IL-6 (P=0.026)* and *RANKL (P=0.007)* in arthritic joints. $PTPN2^{+/-}$ mice showed an increased presence of ectopic lymphoid-like structures within arthritic joints, correlating with an increased expression of *Cxcl13 (P=0.035)*. Increased susceptibility to arthritis could be transferred to $RAG2^{-/-}$ mice by $PTPN2^{+/-}$ $CD4^+$ T-cells (*P=0.011 vs* $PTPN2^{+/+}$ $CD4^+$ T-cells). Next we generated a novel C57BL/6 mouse carrying the SKG mutation and the $H2^d$ haplotype (B6.$H2^d$.SKG), which showed similar arthritis development as BALB/c SKG mice. B6.$H2^d$.SKG carrying T-cell specific haploinsufficiency of *PTPN2* (Lck-Cre^+.$PTPN2^{floxed/wild\ type}$) developed increased severity of arthritis (*P=0.002*) when compared to WT mice. Further investigation into the effect of *PTPN2* haploinsufficiency in T-cell function revealed no alterations in thymocyte development or selection; however, $PTPN2^{+/-}$ SKG mice had an increased accumulation of Th17 cells (*P=0.027*) in arthritic joints which correlated to an increased sensitivity to IL-6 stimulation in $PTPN2^{+/-}$ CD4+ T-cells.

Conclusion: Haploinsufficiency of human RA-associated *PTPN2* mediates autoimmune arthritis in mice by rendering $CD4^+$ T-cells more susceptible to IL-6 stimulation and promoting expansion of pathogenic Th17 cells in arthritic joints. We validate our newly generated B6.$H2^d$.SKG model as a novel powerful tool for mechanistic studies of RA pathogenesis.

Synovial Tissue Resident Macrophages Play the protective role in the Development of Inflammatory Arthritis in CD11c-Flip-KO Mice

Qi-Quan Huang[1], Renee Doyle[1], Robert Birkett[1] and Richard M. Pope[1]

Background/Purpose: We have generated a CD11c-Flip-KO (HUPO) mouse line that spontaneously develops erosive arthritis resembling rheumatoid arthritis. Arthritis spontaneously developed beginning at 5weeks of age in ~10% of HUPO, progressing to ~80% incidence at ≥20 weeks. HUPO mice crossed with Rag-/- mice developed a mild non-progressive arthritis due to macrophage infiltration, supporting an important role for macrophages in disease pathogenesis. This study examined the phenotype of macrophages in the joints of littermate control mice and of ≥ 20 week old HUPO mice with and without arthritis.

Methods: Ankle joint cells were dissected and digested with collagenase. Cells were analyzed by flow cytometry employing multicolor fluorochrome-antibodies. Arthritis were evaluated by clinical score for the inflammation, joint deformity and grip strength, ranging from 0-28.

Results: Under homeostatic conditions in control mice synovial macrophages are defined as $CD11b^+CD64^+F4/80^+$, about 90% co-express $CD11c^+$. Further, macrophages may be defined as $F4/80^{hi}$ or $F4/80^{mid}$ (Figure). The $F4/80^{mid}$ $Ly6C^+$ $MHCII^-$ are macrophages recently differentiated from peripheral blood monocytes. Increase of MHCII and loss of Ly6C represents progressive stages of macrophage differentiation. The percent $F4/80^{mid}$ $Ly6C^+$ $MHCII^-$ macrophages were increased ($p < 0.001$) in ankles of HUPO mice with arthritis, compared with littermate controls. The $F4/80^{hi}$ macrophages are $Ly6C^-$, and either $MHCII^+$ or $MHCII^-$. During homeostasis, the $F4/80^{hi}$ $MHCII^-$ macrophages are considered as tissue resident macrophages. $F4/80^{hi}$ $MHCII^-$ tissue resident macrophages are greatly reduced and $F4/80^{hi}$ $MHCII^+$ macrophages increased ($p < 0.01$-0.001) in HUPO mice with arthritis, compared with littermate controls or HUPO mice without arthritis. $F4/80^{hi}$ $MHCII^-$ macrophages were also decreased in the joints of HUPO mice at 4 weeks, before arthritis onset. In HUPO mice the $F4/80^{hi}$ $MHCII^-$ macrophages were inversely correlated ($p = 0.023$) with arthritis severity, while the $F4/80^{hi}$ $MHCII^+$ macrophages were positively correlated ($p = 0.024$). Further supporting the role of $F4/80^{hi}$ $MHCII^-$ macrophages in suppressing inflammation, the percent $F4/80^{hi}$ $MHCII^-$ macrophages was strongly, inversely correlated ($r = -0.874$, $p<0.001$) with the percent granulocytes in the synovial tissue.

Conclusion: In HUPO mice the reduction of synovial tissue resident macrophages, which are also $CD11c^+$, was highly associated with inflammation and the onset and severity of arthritis. The influx of peripheral blood monocytes and their differentiation into macrophages was observed in HUPO arthritis. Approaches to preserve tissue resident macrophages or to decrease influx of peripheral blood monocytes may be effective therapeutically in HUPO, and potentially other forms of inflammatory arthritis.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Rheumatoid arthritis is commonly treated with potent anti-inflammatory glucocorticoids (GC), despite severe side effects such as osteoporosis and insulin resistance associated with chronic dosing of GCs. The prevailing view is that GCs solely rely on repression of cytokines and elimination of immune cells for their anti-inflammatory effects. However, we now show that these direct effects on immune cells are insufficient. GCs modulate transcription by activating the glucocorticoid receptor (GR), a ligand activated transcription factor that binds DNA either as a monomer or dimer. Whereas previously the anti-inflammatory actions of the monomeric GR were considered to be sufficient for immune suppression, we demonstrate for a variety of disease models including arthritis, that GR dimerization is essential to reduce inflammation.

Methods: We induced serum transfer-induces arthritis (STIA) in wild type (wt) mice and in mice with impaired GR dimerization (GR^{dim}) and treated them with Dexamethasone (Dex) or PBS after the onset of STIA. To test the importance of immune cells, we generated bone marrow chimeric GR^{dim} mice, reconstituted with wt hematopoietic cells (wt/GR^{dim}) and wt/wt littermates, induced STIA and treated with Dex or PBS as a control. Disease severity was assessed clinically and histologically and inflamed ankles were analysed by flow cytometry, iTRAQ proteomics and qPCR. Co-culture of wt and GR^{dim} fibroblast-like synoviocytes (FLS) and bone marrow derived macrophages (BMDM) were used to analyse the interplay of FLS and BMDM *in vitro*.

Results: GR^{dim} mice are not able to resolve the infiltration of immune cells in STIA after Dex treatment in contrast to wt control mice. Unexpectedly, we show that wt/GR^{dim}-chimeras, with impaired GR dimerization in non-immune, radio-resistant cells are resistant to Dex treatment in STIA, too. Flow cytometry analysis of inflamed ankles of wt/wt- and wt/GR^{dim}-chimeras with STIA reveals a reduction of leukocytes (70%) in wt/wt but not in wt/GR^{dim}-chimeras treated with Dex. Moreover, Dex induced non-classical, non-activated M2-like macrophages (F4/80+, Ly6C-, MHCII-) are only evident in wt/wt- (+70% compared to wt/wt-chimeras treated with PBS) but not wt/GR^{dim}-chimeras. Proteomics and gene expression analysis of inflamed ankles confirmed the induction of known M2 polarization markers of macrophages, such as CD163, CD36 and MerTK after Dex treatment of STIA in wt/wt-chimeras, which was absent in wt/GR^{dim}-chimeras. We corroborated our findings in an in vitro co-culture system of GR^{dim} FLS with wt primary BMDMs. Concomitant TNF/Dex treatment induced CD163 in wt co-cultures, but not in GR^{dim}FLS co-cultured BMDMs.

Conclusion: Taken together, we discovered a novel anti-inflammatory mechanism of corticosteroids that involves GR dimerization dependent gene regulation in non-immune cells to control M2 polarization of macrophages for resolution of arthritis.

Session Title: Rheumatoid Arthritis – Animal Models I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Type I interferons (IFN-I) can be both anti- and pro-inflammatory. Among them, IFN-α inhibits normal Th17 differentiation, whereas it is pathogenic in lupus. The role of IFN-I is also controversial in rheumatoid arthritis (RA) and experimental models. An IFN-I signature has been reported in RA patients, the signification of which is unclear. In mice, IFN-I enhance or inhibit arthritis development according to the IFN subtype, arthritis model and the kinetics. Because of the reported IFN-I/TNF cross-regulation, and TNF being a key pathogenic cytokine in RA, we have evaluated the therapeutic effect of early IFN-α production in collagen-induced arthritis (CIA).

Methods: CIA was induced by 2 immunizations with collagen/CFA. Disease development was studied in conditional transgenic mice over-expressing mouse IFN-α1 after cessation of doxycyclin (Dox) administration (Tet-off system). IFN-α1-negative littermates were used as controls. All mice express endogenous IFN-α. All mice were treated with Dox. Arthritis was followed by clinical evaluation. Inflammation/bone destruction were estimated by histology. Plasma cytokines and anti-collagen antibodies were measured by Luminex/ELISA. Leukocytes sub-populations and Th1/Th2/Th17 polarization were analyzed by flow cytometry. Bone marrow cells were cultured with M-CSF/RANKL to evaluate osteoclast differentiation and activity. $CD4^+CD25^+$ regulatory T cells (Treg) and $CD4^+CD25^-$ effector T cells (Teff) were purified by magnetic sorting. Treg ATPase activity was determined in vitro by a luminescent assay. Treg inhibition of Teff proliferation/activation was measured by flow cytometry/ELISA in co-cultures. The in vivo therapeutic capacity of purified Treg was estimated by adoptive transfer.

Results: Induction of mouse IFN-α1 production before the first or even before the second immunization resulted in CIA protection. Both immunized IFN-$\alpha1^-$ and IFN-$\alpha1^+$ mice produced anti-collagen antibodies, however the latter produced less. Likewise, IFN-$\alpha1^+$ mice produced less IL-6 but more IL-5. Protection was associated with decreased polarization to Th17 and increased polarization to Th1 and Th2 lymphocytes. Moreover, IFN-$\alpha1^+$ mice showed increased levels of IFN-γ-positive NK cells. On the contrary, osteoclastogenesis and osteoclast activity were decreased in IFN-$\alpha1^+$ mice. Particularly, CIA protection in IFN-α1-overexpressing mice was associated with an expansion of Treg with a higher CD39 expression, higher ATPase activity and a higher capacity to inhibit Teff. Most importantly, adoptive transfer of those highly suppressive Treg purified from CIA IFN-$\alpha1^+$ mice impaired CIA development in recipients in comparison to adoptive transfer of Treg purified from CIA IFN-$\alpha1^-$ mice.

Conclusion: This is the first study analyzing the impact of IFN-α on CIA development. Induction of IFN-α1 production before immunization or even after the first immunization nearly completely protects against arthritis. Protection is associated with an expansion of more suppressive Treg able to confer protection upon adoptive transfer. This work better defines the role of IFN-α and shows its potent modulatory effect in inflammatory arthritis.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Increased expression of Notch signaling molecules has been reported in synovial samples of patients with rheumatoid arthritis (RA). However, the identity of the cell type(s) in RA joints with Notch activation or how they might contribute to RA pathogenesis is unknown. Here, we used GFP+ cells from *Hes1*-GFP/TNF transgenic (TNF-Tg) mice (a model of RA) to identify Notch-activated cells, i.e., those with high Hes1 expression, in the joints of these mice and to study the source and effect of the deletion of GFP+ cells on joint tissue damage.

Methods: *Hes1*-GFP/TNF-Tg mice were generated by crossing *Hes1*-GFP reporter mice and TNF-Tg mice. Immunofluorescent (IF) staining, flow cytometry and bone marrow (BM) transplantation assays were used. BM macrophages (BMM) were generated by culturing BM cells with M-CSF. M1 inflammatory macrophages (M1s) and M2 anti-inflammatory cells (M2s) were induced from BMM by TNF and IL-4, respectively. Thapsigargin (Thap), a recently recognized Notch inhibitor, was used.

Results: To determine the cell type(s) with high Hes1 expression in RA joints, we performed flow cytometry of BM and synovial cells from 6-m-old *Hes1*-GFP/TNF-Tg mice when they had developed severe RA joint damage. Compared to *Hes1*-GFP control (Ctl) mice, *Hes1*-GFP/TNF-Tg mice had significantly more GFP+ cells, especially in the synovial tissue (Ctl BM 2±0.6% vs. *Hes1*-GFP/TNF-Tg BM 5±0.7% vs. synovium 12±4%). Synovial GFP+ cells comprised 60% F4/80+, 2% B220+, 5% CD3+, 0.7% CD31+, and 3% CD45-Sca1+ cells. Significantly more of the F4/80+/GFP+ cells expressed the M1 marker, iNOS than the M2 marker CD206 (75+6% M1s vs. 25+6% M2s). IF staining showed that M1s were located mainly in the inflamed synovial tissue. To study if synovial M1s came from BM, we transferred *Hes1*-GFP/TNF-Tg BM cells into irradiated TNF-Tg and WT recipient mice. Chimeric mice were sacrificed 8 wks post-BM transfer. IF staining indicated numerous GFP+ cells in the synovium of TNF-Tg mice, but there were few GFP+ cells in the BM of the same mice. No GFP+ cells were detected in the synovium of WT recipient mice. To determine if Notch inhibition could reduce M1s and attenuate joint tissue damage in RA, we demonstrated that TNF treatment of *Hes1*-GFP BMMs promoted GFP+/iNOS+ M1s, while IL-4 promoted GFP-/CD206+ M2s. Thap reduced Hes1 expression and switched TNF-induced M1s to M2s (M1s: 32±18% vs. 79±11%; M2s: 63±14% vs. 23±11% in PBS). More importantly, the inhibitory effect of Thap on TNF-induced M1s was abolished in BMMs from mice carrying a constitutively active Notch intracellular domain. In vivo, Thap treatment of *Hes1*-GFP/TNF-Tg mice significantly reduced bone resorption (subchondral BV/TV: 30±3 vs. 20±4% in Ctl), inflammation area (0.7±0.3 vs. 1.3±0.2mm^{2}in Ctl), synovial M1s and GFP+ cells (M1s: 35±28 vs. 78±16 % in Ctl; GFP+: 6±1 vs. 11±2% in Ctl).

Conclusion: M1s derived from BM are the main cells with activated Notch signaling in the inflamed synovial tissues of TNF-Tg mice. Switching Notch-activated M1s to M2s by Thapsigargin attenuated joint inflammation and erosion; thus targeting Notch-activated M1s may represent a new therapeutic approach for patients with inflammatory arthritis.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: MicroRNA (MiR-) 146a plays an important role in the regulation of the innate immune response and has also been shown to suppress cancer development in myeloid cells. Although in late stages of arthritis elevated expression of miR-146a in synovial tissue of rheumatoid arthritis patients was detected, the level of this miRNA was found to be down regulated in early disease, but its role in the development of inflammatory arthritis is still elusive.

Methods: To induce arthritis we used the chronic inflammatory hTNFtg disease model, therefore we crossed miR-146a deficient into hTNFtg mice. Disease severity was assessed clinically and histologically. Serum cytokine levels were measured by Elisa. Synovial fibroblasts were isolated from metatarsal bones. Proliferation of fibroblasts was analysed histologically and by ^{3}[H]thymidine incorporation. RNA expression levels were measured by qPCR

Results: When we crossed miR-146a$^{-/-}$ into hTNFtg mice, histological examination revealed a significant increase in synovial inflammation and even more striking a more than twofold increase in local bone destruction, due to increased generation of osteoclasts in the tarsal joints in miR-146a$^{-/-}$/hTNFtg mice compared to hTNFtg mice. Interestingly, systemic bone loss was comparable in hTNFtg compared to miR-146a$^{-/-}$/hTNFtg mice, suggesting an important local role of miR-146a. Indeed, we detected increased levels of IL-1β, TRAF6, a major target of miR-146a and RANKL, in addition the expression level of OPG was decreased locally in the paws of miR-146a$^{-/-}$/hTNFtg compared to hTNFtg mice. By performing bone marrow transplants we could indeed show a pivotal role for miR-146a in mesenchymal cells in controlling local osteoclast generation and bone destruction. Analysis of important mesenchymal cells in arthritis, the synovial fibroblasts exhibited enhanced proliferation if miR-146a is missing, *in vitro* and *in vivo*. Moreover stimulation of these cells with IL-1β, a prominent cytokine in arthritis which was also shown to be negatively regulated by miR-146a, led to increased expression of RANKL and TRAF6 in miR-146a deficient synovial fibroblasts.

Conclusion: These data demonstrate an important mitigating role of the miR-146a in inflammatory arthritis, most importantly in local bone destruction, by controlling mesenchymal expression of osteoclastogenic factors. This shows an important anti-inflammatory role of miR-146a, which might possibly be exploited for therapeutic purposes.

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects I: Pre-RA and Progression to Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

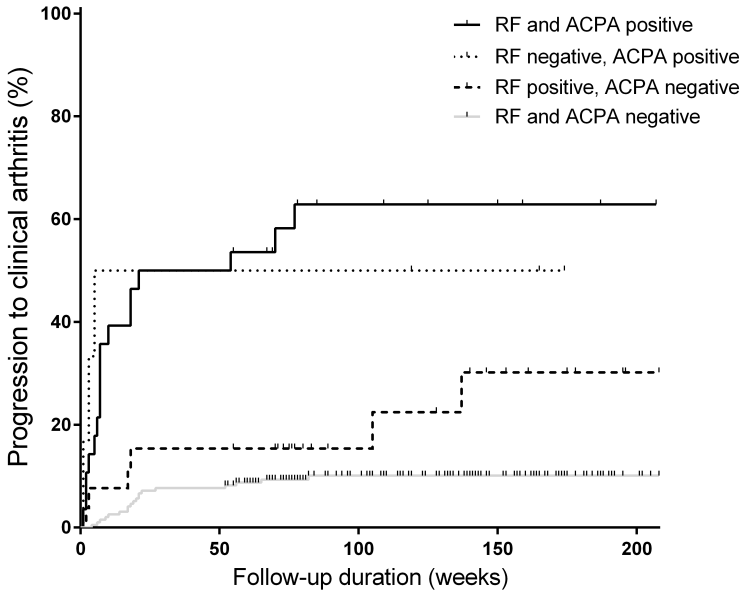
Background/Purpose: Previous longitudinal studies in arthralgia patients studied Rheumatoid Factor (IgM-RF) and Anti-Citrullinated Protein Antibodies (ACPA) in relation to arthritis development. Participants in these studies were often selected on the presence of at least one autoantibody and consequently the predictive values of different autoantibodies were evaluated relative to each other. This study evaluated the association of RF, ACPA and anti-carbamylated protein antibodies and arthritis development in arthralgia patients that were selected based on the clinical suspicion to progress to RA (Clinically Suspect Arthralgia).

Methods: 255 Clinically Suspect Arthralgia patients were included in our cohort. Patients had arthralgia for <1 year, without clinical arthritis and were considered at risk for RA based on clinical presentation by their rheumatologists. RF, ACPA and anti-carbamylated protein status determined at baseline were studied in relation to the development of clinical arthritis during a median follow-up of 96 week using univariable and multivariable Cox regression analyses.

Results: 45 patients developed clinical arthritis. In univariable Cox regression analyses, presence of RF (HR=4.8, 95%CI=2.7-8.7), ACPA (HR=7.9, 95%CI=4.4-14.3) and anti-carbamylated protein (HR=3.7, 95%CI=1.9-7.3) antibodies were all shown to have a significant association with arthritis development. In multivariable Cox regression including RF, ACPA and anti-carbamylated protein, only ACPA-seropositivity was significantly associated with arthritis development (HR=5.0, 95%CI=1.9-12.9). When stratifying the patients in groups with different combinations of RF and ACPA (see Figure 1), Cox regression revealed the highest hazard ratio for RF-positive ACPA-positive patients (HR=9.5, 95%CI=4.9-18.3, compared to RF-negative ACPA-negative patients). No significant differences were observed for RF-negative ACPA-positive compared to RF-positive ACPA-positive patients. Although nearly 70% of ACPA-positive RF-positive patients progressed to clinical arthritis, 30% did not develop clinical arthritis during a median follow-up duration of 96 weeks.

Conclusion: Within Clinically Suspect Arthralgia patients, presence of ACPA alone or in combination with RF, is associated with an increased hazard on progression to clinical arthritis. However, although still 30% of patients that have both antibodies did not develop arthritis within 96 weeks follow-up and patients without antibodies also developed arthritis suggest that information on autoantibodies alone is not sufficient for optimal risk stratification.

Figure 1. Kaplan-Meier One Minus Survival plots for combinations of Rheumatoid Factor and Anti-Citrullinated Protein antibodies and progression to clinical arthritis.



Glossary: Kaplan-Meier one minus survival plot showing cumulative progression to clinical arthritis for Clinically Suspect Arthralgia patients, according to being positive for either positive for anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) positive (N=28), single ACPA-positive (N=6), single RF-positive (N=26) and double negative patients (N=195). Cox regression of combinations of RF- and ACPA-positivity revealed that the presence of both ACPA and RF yielded the highest HR of 9.5 (95%CI=4.9–18.3) for arthritis development compared to the group negative for both autoantibodies, as shown in figure 1. The hazard ratio of single ACPA-positivity was 8.1 (95%CI=2.4–27.4), compared to the group that was negative for both RF and ACPA. The hazard ratio for single RF-positivity was 2.5

(95%CI=1.0–6.3) compared to the group that was negative for both RF and ACPA.

Session Title: Rheumatoid Arthritis – Clinical Aspects I: Pre-RA and Progression to Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The onset of seropositive rheumatoid arthritis (RA) is preceded by the presence of specific autoantibodies in the absence of synovial inflammation. Only a subset of these *at-risk* individuals will develop clinical disease. This impedes efforts to implement early interventions that may prevent onset of clinical disease. Here we analyze whether clonal changes in the B-cell receptor (BCR) repertoire can reliably predict onset of clinical disease.

Methods: In a prospective cohort study in 21 individuals *at-risk* for RA, the BCR repertoire of paired peripheral blood and synovial tissue samples was analyzed using RNA-based next-generation BCR sequencing. BCR clones that were expanded beyond 0.5% of the total repertoire were labeled dominant. The relative risk for onset of arthritis was assessed, using a cut-off of presence of 5 or more dominant BCR clones. Findings in peripheral blood were validated in an independent prospective cohort of 50 *at-risk* individuals. Based on the test cohort, individuals in the validation cohort were considered BCR positive if peripheral blood at study entry showed 5 or more dominant BCR clones.

Results: Both in the test and validation cohort, the presence of 5 or more dominant BCR clones in peripheral blood was significantly associated with arthritis development (validation cohort relative risk (RR) 6.3, 95% confidence interval (CI) 2.7 - 15, $p < 1*10^{-4}$). Figure A and B show the arthritis-free survival curves of BCR negatives (black) and BCR positives (red) for the test and validation cohort respectively. After adjustment for the recently described clinical prediction rule the association remained intact (relative risk 5.0, 95% CI 1.2 - 20, $p = 0.024$). When individuals developed arthritis, dominant BCR clones disappeared from peripheral blood and appeared in synovial tissue, suggesting a direct role of these clones in disease pathogenesis.

Conclusion: Dominant BCR clones in peripheral blood predict onset of clinical symptoms of RA in *at-risk* individuals with high accuracy.

Our data suggest that during onset of RA these clones shift from peripheral blood to target tissue.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects I: Pre-RA and Progression to Rheumatoid Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Early diagnosis of rheumatoid arthritis (RA) coupled with an effective treatment strategy is a key imperative in the effective management of disease. Anti-citrullinated peptide antibodies (ACPA) and antibodies against rheumatoid factor (RF) are two serological markers cited in the 2010 RA classification criteria that are commonly used in routine clinical practice. 14-3-3η protein is a mechanistic marker which seems to have a biologic role in the joint erosive process, that assists with the diagnosis of RA. The aim of this study, was to assess the clinical utility of 14-3-3η in the European EIRA (Epidemiological Investigation of Rheumatoid Arthritis) cohort.

Methods: 14-3-3η levels were measured in a total of 505 patient samples, 305 early RA patients samples and 200 control samples from the EIRA cohort using the 14-3-3η ELISA test (Augurex). Control samples included patients with various autoimmune conditions, infections, malignancies, osteoarthritis and healthy subjects. The specificity and sensitivity of 14-3-3η was assessed using the manufacturer's suggested positivity cut-off of ≥ 0.19 ng/ml and at 2 and 4x of the diagnostic cut-off. The added value of 14-3-3η to CCP2 (Eurodiagnostica) in the diagnosis of RA was determined by examining the additional patients captured by 14-3-3η.

Results: As shown in the Table below, CCP2 had a sensitivity of 66.2% and a specificity of 96.5%. For 14-3-3η with a serum cutoff of ≥ 0.8 ng/ml the sensitivity was calculated to 47.2% and the specificity to 94.5%. Adding 14-3-3η resulted in a sensitivity of 74.1% compared to 66,2% for CCP2 alone. Depending upon the selected cut-off, up to 50.5% of the CCP-negative patients within the EIRA cohort could be identified by 14-3-3η.

	CCP2 IgG (E/ml)	14-3-3η (ng/ml)		
Cut off	≥ 25 E/ml	≥ 0.19	≥ 0.40	≥ 0.80
Sensitivity %	66.2	68.2	59.3	47.2
Additional No of Positives to CCP2		52	37	24
Added Cohort Sensitivity %		17.0	12.1	7.9
Added sensitivity of CCP -ve patients %		50.5	35.9	23.3
Specificity	96.5	83.0	90.5	94.5
Loss of cohort specificity %		16.0	9.5	4.5

Conclusion: Based on past publications the 14-3-3η protein is more frequently increased in established RA patients than in early RA patients. Nevertheless, even in our early RA cohort we could identify a considerable added value of increased sensitivity compared to CCP2. The 14-3-3η protein used in conjunction with CCP2 improves diagnostic sensitivity in the early diagnosis of RA.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects I: Pre-RA and Progression to Rheumatoid Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

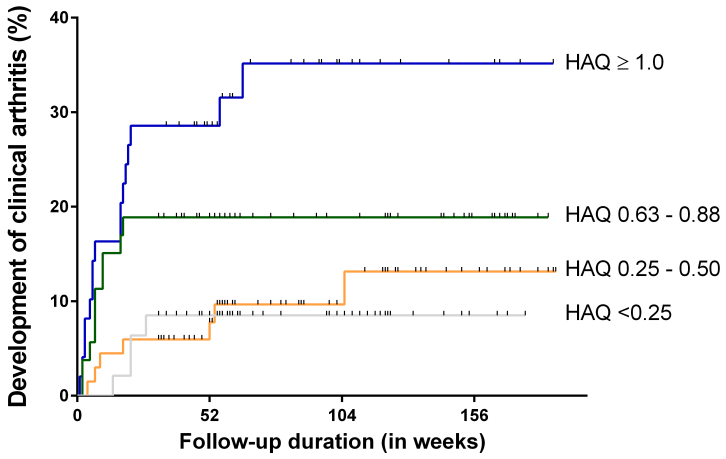
Background/Purpose: A phase of arthralgia precedes the emergence of rheumatoid arthritis (RA). It is unknown if patients have functional limitations in this phase. We assessed functional disability in patients with Clinically Suspect Arthralgia, its association with MRI-detected subclinical inflammation and with progression to clinical arthritis.

Methods: From April 2012 to April 2015, 255 CSA-patients had arthralgia for <1 year and were, based on clinical presentation, considered at risk for RA by their rheumatologists. At baseline, functional disability was assessed using HAQ-scores. Subclinical inflammation was assessed using unilateral 1.5Tesla MRI of MCP, wrist and MTP-joints. Synovitis, tenosynovitis and bone marrow edema scores were summed in the total MRI-inflammation score. Patients were followed on arthritis development.

Results: Median HAQ-score at presentation was 0.50. Higher total MRI-inflammation scores were associated with higher HAQ-scores (β=0.017, 95%CI=0.004-0.030). During median 61 weeks follow-up, 41 patients progressed to clinical arthritis. HAQ-scores ≥1.0 were associated with arthritis development (HR=4.60, 95%CI=1.54-13.75). Within converters, median HAQ-scores did not increase from

presentation with Clinically Suspect Arthralgia to arthritis development (0.88 and 0.75, p-value=0.59).

Conclusion: Functional limitations already exist during the symptomatic pre-arthritis phase, with a similar severity as in the early clinical arthritis-phase. HAQ-scores ≥1.0 were associated with progression to clinical arthritis. **Figure 1**. Kaplan-Meier One Minus Survival plot showing cumulative progression to clinical arthritis for CSA-patients divided in four groups based on their baseline HAQ-score.



Glossary: Patients were appointed into quartiles according to their total HAQ-score to create four subgroups with equal numbers, see supplementary file 2. Each line represents one HAQ-score quartile and cumulative progression to clinical arthritis. The lowest quartile contains patients with HAQ-scores <0.25 with N=49. The second quartile contains HAQ-scores 0.25–0.50 (N=67), with a HR for progression to clinical arthritis of 1.2 (95%CI=0.37–4.3). Patients in the third quartile had HAQ-scores 0.63–0.88 (N=53) with a HR for progression to clinical arthritis of 2.4 (95%CI 0.77–7.8). Finally, the quartile with the highest HAQ-scores contains HAQ-scores ≥ 1.0. (N=49).The hazard ratio for this quartile (HR=4.60, 95%CI=1.54–13.75) was significantly elevated, compared to the lowest quartile.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects I: Pre-RA and Progression to Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Identifying individuals at risk for rheumatoid arthritis (RA) development is a prerequisite to understand preclinical events and to develop prevention. Based on a systematic review of the literature, our goals were to determine the risk of RA in first degree relatives (FDR) of RA patients (Q1), to study the serological status of FDR (Q2), to determine risk of developing RA among asymptomatic subjects seropositive either for RF or anti-CCP (Q3) and to determine whether being seropositive for RF or anti-CCP increases RA risk among subjects complaining of arthralgia (Q4).

Methods: 3185 articles were screened using various databases until june 2016 and data was extracted independently by two authors. Meta-analysis were performed to assess odds-ratios (OR) for each studied group using the inverse variance approach to estimate pooled OR with their 95% confidence interval. Heterogeneity was assessed according to Cochran Q-test and I^2 values. Calculations were made with

the Cochrane RevMan 5.3 software. P-values less than 0,05 were considered as significant.

Results: For Q1 : FDR of RA patients have a two to fourfold risk of RA, compared to controls. For Q2 : IgM-RF were positive among 14,4% of FDR and 5,7% of unrelated controls, resulting in an OR 3,19 (1,27-8,01 ; I^2=66%). Anti-CCP were found among 4,4% of FDR and 2,1% of unrelated controls, resulting in an OR 2,42 (IC95% 1,22-4,79 ; I^2=0%) (figure 1). For Q3 : the risk of developing RA among asymptomatic seropositive subjects was OR 7,89 (IC95% 4,54-13,72; I^2=54%) when positive for IgM-RF, and OR 21,60 (IC95% 5,8-80,37 ; I^2=92%) when positive for anti-CCP, compared to seronegative subjects (figure 2). For Q4 : arthralgia subjects showed an increased risk for arthritis with an OR 3,53 (IC95% 1,49-8,39; I^2=88%) if these subjects were positive for IgM-RF and OR 12,67 (IC95% 5,37-29,90; I^2=61%) when positive for anti-CCP, compared to seronegative arthralgia subjects (figure 3).

Conclusion: Our study allows to quantify the increased risk conferred by a family history of RA, and a seropositivity for IgM-RF or anti-CCP among asymptomatic and arthralgia subjects. These results should help the physician to answer questions often asked by RA patients, and should help him to better define and to monitor closely at risk subjects with the aim of early screening and earlier treatment

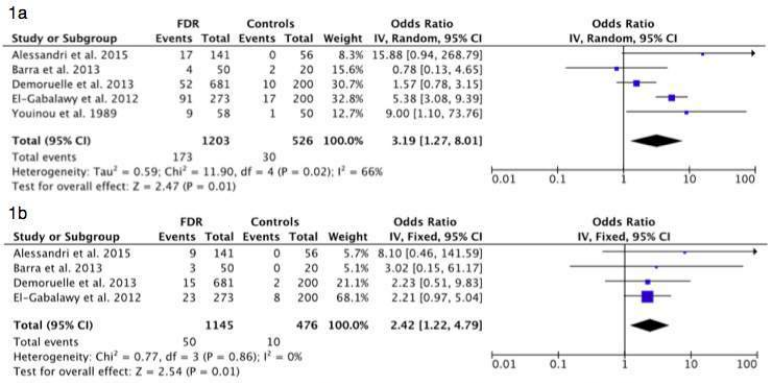

Figure 1. Risk of seropositivity among FDR for IgM-RF (1a) and anti-CCP (1b) compared to unrelated controls

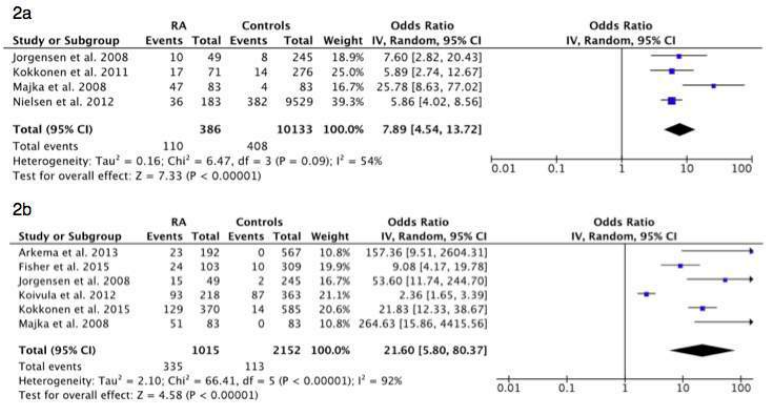

Figure 2. RA risk among asymptomatic subjects when positive for IgM-RF (2a) and anti-CCP (2b) compared to seronegative subjects

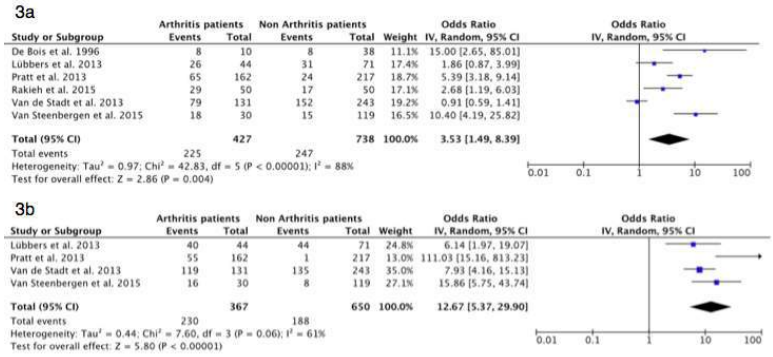

Figure 3. Risk of arthritis among arthralgia subjects when positive for IgM-RF (3a) or anti-CCP (3b) compared to seronegative subjects

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects I: Pre-RA and Progression to Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: To assess the association between recent stressful life events and rheumatoid arthritis (RA) onset.

Methods: We conducted a monocentric case-control study of in and out patients. Cases were RA patients fulfilling ACR EULAR criteria and controls were osteoarthritis (OA) patients. With face-to-face interviews, we assessed stressful life events occurring during the year before rheumatoid arthritis onset according to the Social Readjustment Rating Scale (SRRS), which provided a life change unit (LCU) score representing the level of stress experienced. Patients were classified in 3 subgroups by life change unit score: 0-40, 41-100 and 101-300.

Results: Overall, 69 RA and 65 OA patients were included (71% were women). Cases and controls did not differ in characteristics except age, with younger age for RA than OA patients. RA onset within a year was increased with SRRS ≥100 (OR=15.31 [95% CI 6.00-39.09], p<0.0001) and 41 to 100 (OR=4.99 [1.87-13.32], p=0.001) as compared with 0-40. High LCU score remained associated with RA onset within a year on multivariable analysis adjusted for age, sex, disease duration and current depression: > 100 (OR=16.05 [5.44-47.32], p<0.001) and 41–100 (OR=5.46 [1.82-16.37], p=0.002).

Conclusion: We found a strong association between stressful life events and RA onset within a year. The more the patient experienced stress, the greater was the risk of RA developing. Clinicians should look for stressful life events in the history-taking of patients with early arthritis.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II: Axial Spondyloarthritis – Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Abatacept (ABA), a selective T-cell co-stimulation modulator, showed promise for the treatment of PsA in a Phase II trial.[1] This prompted the conduct of the Phase III Active pSoriaTic aRthritis rAndomizEd triAl (ASTRAEA; NCT01860976); key results are presented here.

Methods: In this international, double-blind, multicenter study, patients (pts) with PsA were randomized (1:1) to SC ABA 125 mg wkly or placebo for 24 wks, and then treated with open-label SC ABA up to 24 mths. Pts had active disease (≥3 tender and ≥3 swollen joints), ≥2 cm target lesion of plaque psoriasis and inadequate response or intolerance to ≥1 non-biologic DMARD. Randomization was stratified by MTX use, prior TNFi use and skin involvement ≥3% of body surface area (BSA). Pts not achieving ≥20% improvement in SJC and TJC at Day 113 were switched to open-label ABA (early escape). Primary endpoint: ACR20 response at Wk 24. Key secondary endpoints at Wk 24: HAQ response (change from baseline ≥0.35); ACR20 response in the TNFi-naïve and -exposed subgroups; radiographic non-progression (PsA-modified total Sharp/van der Heijde score; change from baseline ≤0). Other secondary/exploratory endpoints included: ≥50% improvement in Psoriasis Area and Severity Index score (PASI50) in pts with ≥3% BSA; change in HAQ score; safety. Comparisons were performed using a 2-sided Cochran–Mantel–Haenszel chi-square test, adjusted for stratification criteria. Pts designated as early escape or with missing data were imputed as non-responders/radiographic progressors. Change in HAQ score was analyzed using a longitudinal repeated measures model (early escape pts set to missing at Days 141 and 169). Primary and key secondary endpoints were tested using a hierarchical approach.

Results: Of 424 pts enrolled, 213 received ABA and 211 placebo; 76 were early escape pts in ABA and 89 in placebo; 12 pts discontinued in ABA and 24 in placebo. Table 1 shows baseline characteristics. Most (>60%) pts had prior exposure to TNFis. ABA significantly improved the proportion of pts achieving an ACR20 response at Wk 24 ($p<0.001$) (Table 2). The proportion of HAQ responses was numerically higher with ABA vs placebo ($p=0.097$). Higher proportions of pts receiving ABA vs placebo had an ACR20 response in the TNFi-naïve and -exposed subgroups, and radiographic non-progression (nominal $p<0.05$), with modest numerical improvement in PASI50. Efficacy was maintained at 1 year. The safety profile of ABA was similar to placebo, with no new safety signals.

Conclusion: Abatacept improved disease and was well tolerated in pts with active PsA, regardless of prior exposure to TNFis.

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II: Axial Spondyloarthritis – Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: RAPID-axSpA (NCT01087762) was a long-term study in patients (pts) with axial spondyloarthritis (axSpA) treated with certolizumab pegol (CZP). This is the first report of 4-year imaging results in CZP-treated axSpA pts, including ankylosing spondylitis (AS) and non-radiographic (nr-)axSpA.

Methods: RAPID-axSpA[1] was double-blind, placebo (PBO)-controlled to Wk 24, dose-blind to Wk 48 and open-label to Wk 204. Pts fulfilling ASAS axSpA criteria were stratified according to presence/absence of radiographic sacroiliitis (AS/nr-axSpA) at randomization, and had active disease. Wk 0 CZP-randomized pts (200 mg Q2W/400 mg Q4W) continued assigned dose; PBO pts received CZP after Wk 16 or 24. Lateral X-rays of cervical/lumbar spine at BL, Wk 96 and 204 were assessed using mSASSS (average of 2 independent central readers blind to timepoint). SI joint X-rays were scored for sacroiliitis by 2 independent central readers (3rd reader adjudicated grade scoring differences) at BL and Wk 204. MRI scans using STIR sequences were performed at BL, Wk 12, 48, 96 and 204, and were assessed using SPARCC for SI joints and Berlin score for spine. Data are shown for CZP-treated pts (including those starting on PBO). mSASSS data were estimated for all pts by MMRM analysis covering all available observations. MRI data at each timepoint are shown as observed for pts with a valid assessment at that timepoint. SI joint X-ray data were assessed in pts with valid assessments at both BL and Wk 204.

Results: Of 315 CZP-treated pts, 196 had available spinal X-rays and were included in MMRM analysis (BL mean mSASSS: 9.47). 158 pts had MRI assessments and were included in this reading campaign (BL mean SPARCC: 8.17 [n=151]; Berlin: 6.10 [n=153]) and 137 pts had SI Joint X-rays at BL and Wk 204 (BL: 67.9% radiographic sacroiliitis). In AS pts, mean mSASSS change between BL and Wk 204 was 0.98 (95% CI: 0.34–1.63); 0.67 (0.21–1.13) from BL to Wk 96 and 0.31 (0.02–0.60) from Wk 96 to Wk 204. These numbers were 0.06 (-0.17–0.28), -0.01 (-0.19–0.17), and 0.07 (-0.07–0.20) respectively for nr-axSpA (**Table**). MMRM estimates were similar to observed values (axSpA Wk 204 mean change: 0.62 and 0.70 respectively). Limited changes in SI joint X-ray grading were observed to Wk 204: only 2/44 pts (4.5%) progressed to AS, while 4/93 (4.3%) shifted from an AS classification to nr-axSpA. MRI assessments showed maintained improvements in SPARCC and Berlin scores from Wk 12 to Wk 204 (**Table**).

Conclusion: This is the first report of imaging data from a clinical trial including both AS and nr-axSpA pts over 4 years. Limited spinal radiographic progression was observed in CZP-treated pts with lower progression between Wk 96 and Wk 204, compared to the first 96 wks. Limited change in radiographic sacroiliitis was observed and scores were even similar in both directions. Early reductions in MRI inflammation were maintained to Wk 204. References: 1. Landewé R. Ann Rheum Dis 2014;73:39

Table A: Mixed-effects model repeated measures (MMRM) estimates of mSASSS to Week 204 of the RAPID-axSpA study for all patients treated with CZP

	Baseline	Week 96		Week 204	
	LS mean score (95% CI)	LS mean score (95% CI)	LS mean change from BL (95% CI)	LS mean score (95% CI)	LS mean change from BL (95% CI)
axSpA (n=196)	9.47 (7.20 – 11.73)	9.86 (7.52 – 12.21)	0.40 (0.11 – 0.69)	10.08 (7.71 – 12.46)	0.62 (0.22 – 1.01)
AS (n=113)	13.17 (9.79 – 16.56)	13.84 (10.35 – 17.34)	0.67 (0.21 – 1.13)	14.16 (10.61 – 17.71)	0.98 (0.34 – 1.63)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II: Axial Spondyloarthritis – Treatment
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Subcutaneous (SC) golimumab (GLM) is currently approved for adult patients (pts) with RA, PsA, and AS. The GO-ALIVE study was designed to evaluate the safety and efficacy of IV GLM in adult pts with active AS.

Methods: GO-ALIVE is a Phase 3, multicenter, randomized, double-blind, placebo (PBO)-controlled trial. Pts (aged ≥18 yrs) had a diagnosis of definite AS (per modified New York criteria) and BASDAI ≥4, total back pain visual analogue scale ≥4, and CRP ≥0.3mg/dL. Pts were randomized (1:1) to IV GLM 2mg/kg at weeks (wks) 0, 4, and every 8 wks or PBO at wks 0, 4, and 12, with crossover to GLM at wk16. Up to 20% of pts could have had a prior anti-TNF agent (other than GLM), and up to 10% of pts could have complete ankylosis of the spine. The primary endpoint was ASAS20 at wk16. Major secondary endpoints were ASAS40, BASDAI50, and change in BASFI score at wk16. Other statistically-controlled assessments were BASMI, ASAS partial remission, SF-36 PCS/MCS, and ASQoL. Pts were monitored for adverse events (AEs). Data through wk28 are reported here. All investigators and some sponsor personnel will remain blinded to the treatment group assignments through the end of the study (wk60); thus treatment group assignments for individual pts are not reported here.

Results: 208 pts were randomized and received study agent (PBO: 103; GLM: 105). Baseline demographic and disease characteristics were similar between treatment groups. 78% of pts were male, mean age was 39 yrs; mean disease duration was 5.5 yrs, 89.9% were HLA-B27 positive, 5.8% had complete ankylosis of the spine, 14.4% used a prior anti-TNF. At wk16, significantly greater proportions of GLM pts vs PBO had ASAS20 (73.3% vs. 26.2%), ASAS40 (47.6% vs. 8.7%), and BASDAI 50 (41.0% vs. 14.6%) responses (all $p<0.001$; Table). Reductions in BASFI were also significantly greater with GLM. Improvements in SF-36 PCS/MCS and ASQoL were significantly greater in the GLM group vs PBO at wk16. ASAS20 was significantly higher with GLM than PBO as early as wk2 (37.1% vs 19.4%; $p=0.005$). Responses in the GLM group were maintained through wk28. PBO pts who crossed over to GLM at wk16 had improvements in clinical response at wk20 that were maintained through wk28. Through wk16, 23.3% of PBO pts and 32.4% of GLM pts had ≥1 AE. Infections were the most common AE (PBO, 7.8%; GLM, 11.4%). Through wk28, 34.8% of all GLM-treated pts had ≥1 AE; nasopharyngitis (5.4%) was the most common. Two pts (1.0%) had SAEs (pancreatitis, n=1; pneumonia, n=1).There were no opportunistic infections, malignancies, or deaths through wk28. The rate of infusion reactions was low (1.4%). 3 pts had 4 reactions; none were serious or severe.

Conclusion: IV GLM 2mg/kg was efficacious in reducing the signs and symptoms of AS compared with PBO. GLM was well-tolerated

through wk28; the safety profile was consistent with other anti-TNFs, including SC GLM.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II: Axial Spondyloarthritis – Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor. Minimum clinically important differences (MCID) for SPondyloArthritis Research Consortium of Canada (SPARCC) MRI SI joint and spine scores (SIJ, spine) are ≥2.5 and ≥5, respectively.[1] We assessed whether MCID in SIJ and spine can discriminate between tofacitinib and placebo (PBO) in patients (pts) with AS and whether this is concordant with clinical responses.

Methods: In this 16-week (wk), Phase 2, double-blind, dose-ranging study (NCT01786668),[2] 207 adult pts meeting modified New York AS criteria were randomized 1:1:1:1 to PBO or tofacitinib 2, 5, or 10 mg twice daily (BID) for 12 wks. Clinical response endpoints included in this post-hoc analysis were: Assessment of AS 20% improvement (ASAS20) and ASAS40 response rates, AS disease activity score major improvement (ASDAS MI), ASDAS <1.3, Bath AS disease activity index (BASDAI), Bath AS functional index (BASFI). Pts (%) achieving MCID in SIJ, spine, both SIJ and spine, in tofacitinib and PBO groups were summarized based on observed data and pooled tofacitinib vs PBO were compared using Fisher's exact test. Concordance between achieving MCID and Wk 12 clinical responses was assessed. Wk 12 clinical responses were compared between pts achieving/not achieving MCID.

Results: MRI data for 164 pts were evaluated. Baseline demographics were generally balanced between treatment groups and typical of AS populations. All tofacitinib doses improved SIJ and spine scores vs PBO; proportion of pts achieving MCID in SIJ or spine was ~3 times higher in pooled tofacitinib group vs PBO (Table 1; $p<0.05$ for SIJ, $p<0.01$ for spine). Achieving MCID in SIJ and spine correlated with clinical response. In pts on tofacitinib, ASAS20, ASAS40, ASDAS MI, and ASDAS <1.3 responses were more likely in pts achieving MCID in SIJ, spine (Table 2), or both SIJ and spine vs not achieving MCID. Compared with not achieving MCID, pts on tofacitinib achieving MCID in SIJ had larger improvements in BASDAI, BASFI, and back pain.

Conclusion: Tofacitinib-treated pts with AS experienced clinically meaningful reductions in axial MRI inflammation. Pts achieving MCID for MRI inflammation had increased clinical response rates. **References** 1. Maksymowych WP et al. J Rheumatol 2012; 39: 1666-1674. 2. van der Heijde D et al. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II: Axial Spondyloarthritis – Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: In 2010 the latest ASAS-EULAR recommendations for AS and the ASAS recommendations for the use of TNF-inhibitors (TNFi) have been published. Since then new treatments for axSpA have become available. We aimed to update and integrate the two sets of recommendations into one set applicable to patients with axSpA.

Methods: The EULAR Standardised Operating Procedures have been followed. First, two Systematic Literature Reviews have been performed to update the evidence on all treatment options (pharmacological and non-pharmacological) since 2009. The results have been presented during a one-day meeting of the task force. Thereafter, overarching principles and recommendations were updated by a process of achieving consensus and voting.

Results: A total of 5 overarching principles and 13 recommendations have been formulated (Table). The first 3 recommendations deal with personalised medicine including treatment target and monitoring. Recommendation 4 deals with non-pharmacological management. Recommendation 5 describes the central role of NSAIDs as first pharmacological treatment. Recommendations 6 to 8 define the limited place of analgesics, glucocorticoids and conventional synthetic DMARDs. Biological DMARDs (bDMARDs) include TNF- and IL17-inhibitors and are indicated in patients diagnosed with axSpa by a rheumatologist, who have radiographic sacroiliitis and/or inflammation on MRI and/or an elevated CRP-level. Patients should also have high disease activity despite the use of -or intolerance for- at least 2 NSAIDs. High disease activity is defined as an ASDAS ≥2.1 or BASDAI ≥4 and an indication to start a bDMARD by a rheumatologist (Figure). The continuation of a bDMARD should be considered if an improvement of ASDAS ≥1.1 or BASDAI ≥2 has been achieved after at least 12 weeks. Current practice is to start with a TNFi. Switching to another TNFi or an IL-17i is recommended in case of failure of TNFi treatment. Tapering -but not stopping- of a bDMARD can be considered in patients with sustained remission. The final two recommendations deal with surgery and fractures.

Conclusion: The 2016 ASAS-EULAR recommendations provide up-to-date guidance on management of patients with axSpA.

Table: 2016 update of the ASAS-EULAR management recommendations
Overarching principles of the management of axSpA
Axial Spondyloarthritis (axSpA) is a potentially severe disease with diverse manifestations, usually requiring multidisciplinary management coordinated by the rheumatologist
The primary goal of treating the patient with axSpA is to maximize health related quality of life through control of symptoms and inflammation, prevention of progressive structural damage, preservation/normalisation of function and social participation.
The optimal management of patients with axSpA requires a combination of non-pharmacological and pharmacological treatment modalities.
Treatment of axSpA should aim at the best care and must be based on a shared decision between the patient and the rheumatologist.
axSpA incurs high individual, medical and societal costs, all of which should be considered in its management by the treating rheumatologist
Recommendation 1
The treatment of patients with axSpA should be individualised according to the current signs and symptoms of the disease (axial, peripheral, extra-articular manifestations) and the patient characteristics including comorbidities and psychosocial factors
Recommendation 2
Disease monitoring of patients with axSpA should include patient reported outcomes, clinical findings, laboratory tests and imaging, all with the appropriate instruments and relevant to the clinical presentation. The frequency of monitoring should be decided on an individual basis depending on symptoms, severity, and treatment.
Recommendation 3
Treatment should be guided according to a predefined treatment target.
Recommendation 4
Patients should be educated about axSpA and encouraged to exercise on a regular basis and stop smoking; physical therapy should be considered.
Recommendation 5
Patients suffering from pain and stiffness should use an NSAID as first line drug treatment up to the maximum dose, taking risks and benefits into account. For patients who respond well to NSAIDs continuous use is preferred if symptomatic otherwise.
Recommendation 6
Analgesics, such as paracetamol and opioid-(like) drugs, might be considered for residual pain after previously recommended treatments have failed, are contraindicated, and/or poorly tolerated.
Recommendation 7
Glucocorticoid injections directed to the local site of musculoskeletal inflammation may be considered. Patients with axial disease should not receive long-term treatment with systemic glucocorticoids.
Recommendation 8
Patients with purely axial disease should normally not be treated with csDMARDs; Sulfasalazine may be considered in patients with peripheral arthritis.
Recommendation 9
bDMARDs should be considered in patients with persistently high disease activity despite conventional treatments (box1); current practice is to start with TNFi therapy
Recommendation 10
If TNFi therapy fails, switching to another TNFi or IL17i therapy should be considered.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II: Axial Spondyloarthritis – Treatment

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The introduction of anti-TNF therapy has proven effective to reduce inflammation and clinical symptoms in several chronic inflammatory diseases. However, TNF-blockers are effective only in a subpopulation of patients and can be associated with serious side effects. Despite intense efforts, it is currently not possible to predict responsiveness of patients to anti-TNF treatment. To address this issue, we have asked whether the analysis of the immune functions of patients will allow us to define biomarkers that can predict therapeutic responses to TNF blockers. The goals of this project were to define (i) the impact of anti-TNF therapy on immune responses to microbial challenges and stimuli targeting specific immune pathways in axial spondyloarthritis (axSpA) patients and (ii) to identify immunological correlates associated with therapeutic responses to TNF blockers before the initiation of therapy.

Methods: We have recently developed a set of whole-blood, syringe-based assays to assess innate or adaptive immune responses to stimuli targeting different signaling pathways (e.g. cytokines and TLR/NLR agonists), or mimicking infections in patients (1). This “TruCulture” system is designed to capture immune cell activity in response to specific stimuli without introducing sample collection and manipulation variables. Using this assay system, we have investigated immune responses to 20 different stimuli in a pilot study involving 12 axSpA patients before and 3 months after initiation of anti-TNF therapy. We are currently validating our findings in a replication cohort.

Results: We noted a highly significant reduction of the secretion of IL-1ra, IL-1β, and MIP-1β in response to selected stimuli after treatment with TNF-blockers. In contrast, TNF blockers had only minor effects on cytokine/chemokine production in unstimulated cultures, indicating that the effects of anti-TNF therapy can be measured when immune cells are challenged, but not at steady state. We also tested whether there is a correlation between the responses of immune cells to specific stimuli and the clinical response to TNF-blockers. For this, we calculated the “Ankylosing Spondylitis Disease Activity Score” (ASDAS) before treatment and 3 months after initiation of anti-TNF therapy and determined the “Improvement Score”. We found that axSpA patients who secreted the highest levels of inflammatory cytokines and chemokines in response to specific immune stimuli before initiation of anti-TNF therapy had the best therapeutic responses (highest improvement score).

Conclusion: Our results show that TruCulture assays are an efficient and robust tool to monitor immune functions in patients and that anti-TNF therapy induces specific changes in immune responses to selected stimuli. Our data also indicate that analyzing immune responses in patients before therapy is a promising strategy to develop biomarkers predicting therapeutic efficacy of TNF-blockers. Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: SLE clinical trials typically require that patients have either a positive ANA serology at a central laboratory during screening or have prior positive results. The definition of positive serology has varied among trials but, in all cases, a pre-specified titer of ANA has been sufficient to meet entry criteria. Studies that have allowed patients to enter with historically positive ANA serologies have been criticized because of concerns that these patients may not truly have lupus. Inconsistencies in the performance of ANAs and lack of standardization among the assays used in these trials may, however, contribute to the variability in ANA assay results.[1] To further evaluate this issue, we have analyzed different ANA assays using samples collected in a Phase 2 randomized clinical trial which evaluated the efficacy and safety of an IL-6 mAb for the treatment of SLE.[2] All potentially eligible subjects underwent a careful review of serology and clinical laboratory findings (ANA, anti-dsDNA, anti-Sm, anti-RNP, anti-SSA, anti-SSB, C3, and C4), medical history, and current lupus symptoms at screening. Those without a current positive ANA (Kallestad HEp-2 Cell Line Substrate) or anti-dsDNA by the central laboratory were also reviewed by an independent panel of lupus experts to confirm that the subject had both a positive historical ANA and clinically active lupus prior to randomization. Of the 183 patients enrolled, there were 43 (23.8%) who had <1:80 ANA titer at screening from the central laboratory.

Methods: 181 samples collected at baseline in the clinical trial were evaluated using 5 commercially available HEp-2 ANA indirect fluorescent antibody (IFA) assays. All assays were performed according to the manufacturers' protocols. Samples at 1:40 and 1:80 dilutions were run with each manufacturers' positive and negative controls, and visualized using an EVOS FL Cell Imaging System.

Results: Overall, the EuroImmun assay resulted in the greatest percentage of positive results at a 1:80 dilution (99.4%). The Kallestad and Immunoconcepts assays had the lowest number of positive results of 86% and 72%, respectively. When combined, the EuroImmun and Nova Lite or Zeus assays yielded the maximum number of positive responses (100%). All 43 subjects with a <1:80 ANA titer during screening were ≥1:80 in 1 or more assays during this analysis.

Table 1. HEp-2 ANA Assay Results from Five Commercial Assays

	EuroImmun	Nova Lite	Zeus	Kallestad	Immunoconcepts
Positive Samples at 1:80, n (%)	180 (99.4)	175 (96.7)	171 (94.5)	156 (86.2)	131 (72.4)
Negative Samples at 1:80, n (%)	1 (0.6)	6 (3.3)	10 (5.5)	25 (13.8)	50 (27.6)

Assays: ANA IFA: HEp-20-10 Test (Euroimmun, Boonton Township, NJ), Nova Lite Hep-2 ANA (INOVA Diagnostics, San Diego, CA), the ANA/HEp-2 Cell Culture IFA test System (Zeus Laboratories, Raritan, NJ), the Kallestad HEp-2 Cell Line Substrate (Bio-Rad Laboratories, Hercules, CA), and the HEp-2000 Fluorescent ANA-Ro Test System (ImmunoConcepts, Sacramento, CA)

Conclusion: In a well characterized lupus population, there was a large variation in the frequencies of positive samples depending on the ANA assay. These results suggest that careful consideration should be applied in the selection of an ANA assay for the purpose of establishing clinical trial eligibility. Preference may be given to assays that exhibit high sensitivity in patients with established SLE and using 2 sensitive assays may provide additional evidence for patient enrollment in SLE trials. 1. Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The CLSP is a population-based registry of individuals with SLE residing in San Francisco County, California from 2007 – 2009. The registry has a special focus on improving our understanding of SLE in Asian/Pacific Islander (PI) and Hispanic individuals, two groups previously understudied in population-based epidemiologic investigations. We used CLSP data to analyze differences in 1) lupus manifestations by sex and race/ethnicity and 2) time to development of these manifestations after disease onset.

Methods: Relative risks (RR) of SLE manifestations were calculated using Poisson regression models adjusted for race/ethnicity, sex, age at SLE diagnosis, and duration of SLE disease. Kaplan-Meier and Cox proportional hazards methods were used to analyze time to development of severe manifestations of SLE, with higher hazard ratios (HR) indicating a shorter time to development of specific manifestations.

Results: 724 prevalent cases of SLE were identified with the following distribution by race/ethnicity: white (26.2%), Black (18.8%), Asian/PI (36.9%), Hispanic (15.5%), missing (2.6%). For lupus manifestations, Blacks, Asians/PIs, and Hispanics had increased prevalence of lupus nephritis relative to whites (RR 1.78, RR 1.74, and RR 1.46, respectively). Furthermore, Blacks had increased neurological manifestations (RR 1.50), Asians/PIs had increased mucocutaneous manifestations (RR 1.16), and both Blacks and Asians/PIs had increased hematologic manifestations (RR 1.08 and RR 1.07, respectively). For time to development of manifestations, statistically significant differences in lupus nephritis ($p < 0.001$), thrombocytopenia ($p = 0.006$), and neuropsychiatric abnormalities ($p = 0.042$) were observed by race/ethnicity, though this was not the case in the analysis of antiphospholipid (APS) ($P = 0.092$). Blacks, Asians/PIs, and Hispanics had earlier development (higher hazards) of lupus nephritis, thrombocytopenia, and APS relative to whites. Men had earlier development of lupus nephritis and thrombocytopenia relative to women (Table).

Table. Factors associated with earlier occurrence (higher hazards) of manifestations of SLE in multivariate cox proportional models, among prevalent SLE cases in San Francisco County, 2007 – 2009.

SLE = systemic lupus erythematosus; APS = antiphospholipid antibody syndrome; Combined outcome = any of lupus nephritis, thrombocytopenia, neuropsychiatric, or APS
**Any of the following surrogate labs were used to define lupus nephritis: 24 hour urine for protein > 300mg, 24 hour urine protein/creatinine ratio > 0.5, or spot protein/creatinine ratio > 0.5.*
***Neuropsychiatric manifestations studied include: seizures, psychosis, and acute confusional state.*

Conclusion: This analysis represents the first epidemiologic study comparing lupus manifestations among four major racial/ethnic groups and includes large numbers of Asians/PIs and Hispanics. We found 1) dramatic differences in the prevalence of several clinical SLE manifestations among race/ethnicities and 2) that Blacks, Asians/PIs, and Hispanics are at increased risk of developing many manifestations earlier than whites following initial SLE diagnosis. Men also developed lupus nephritis and thrombocytopenia earlier than women with SLE.

High Titer ANA Not Necessarily a Valid Criterion for Lupus – Proposal of a Modification to the Criteria for Classification of SLE

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: A positive ANA test is one of ACR Revised Criteria for Classification of SLE, as well as the SLICC classification. The ANA test provides a direct initial assessment of autoantibody response in candidate patients of systemic autoimmune rheumatic diseases (SARD). As a follow-up to the International Consensus on ANA Patterns (ICAP) initiative (ANApatterns.org), which aims to promote harmonization of ANA pattern nomenclature and provides guidelines for ANA interpretation, thereby optimizing usage in patient care, the relevance of each ANA pattern is being re-evaluated. An important observation is that, while the Homogeneous (AC-1) and Coarse Speckled nuclear (AC-5) patterns are linked to autoantibodies strongly associated with SARD, the Dense Fine Speckled (DFS) nuclear pattern (AC-2) virtually rules out a SARD diagnosis. A clear-cut DFS pattern is usually present when anti-DFS70 is the only predominant autoantibody. DFS is the most common pattern in high titer ANA+, apparently healthy, individuals. Although DFS has been reported in a wide variety of chronic inflammatory diseases, it is not associated with SARD even when present at very high titer.

Methods: ANA test at 1/80 screening dilution was performed in 269 sequentially selected patients with SLE diagnosis, 918 healthy individuals, and 558 patients with non-SARD conditions (arterial hypertension, diabetes mellitus, dyslipidemia, various cancers, psychiatric diseases, and HCV/HIV infection). ANA interpretation was the consensus of 3 independent readers using 2 HEp-2 cell slide brands at 400x mag. Conversely, sequentially selected individuals presenting >1/640 titer DFS ANA pattern in a large clinical laboratory within a 2-year period had the diagnosis assessed by interview with the respective physician.

Results: Among 269 consecutive SLE patients, 96.3% had a positive ANA with the following principal nuclear patterns: homogeneous (29.3%), coarse speckled (14.7%), fine speckled (40.1%). One patient (0.3%) had the DFS pattern and the reactivity to DFS70 confirmed by ELISA. Conversely, among 118 ANA+ healthy individuals and 102 ANA+ patients with miscellaneous non-SARD conditions, 33.1 and 16.7% presented the DFS pattern, respectively. In addition, the 327 consecutive high-titer DFS individuals presented mostly non-SARD conditions or non-specific clinical presentation. Only 7 had possibly SARD-related presentations: 1 anti-phospholipid syndrome, 1 “possible” SLE (polyarthritis, arthritis, chronic urticaria), 1 WG, 1 DLE, 1 primary biliary cirrhosis, and 1 RA.

Conclusion: Well-defined anti-DFS ANA, confirmed by antigen-specific reflex testing, should not be considered a criterion for SLE - either in the ACR or SLICC classification criteria.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Remission is a desirable but not a common enough outcome in systemic lupus erythematosus (SLE) and therefore additional measures are needed to evaluate new therapies. Our aims were: 1. to define and identify a group of SLE patients with low disease activity (LDA) in a prospective cohort; 2. To examine whether the LDA group was similar to a remission group and whether these 2 groups were different from a high disease activity group (HDA) in short term outcomes.

Methods: The study population included patients with SLE who were followed according to a standard protocol from 1970 to 2015 and who had visits no more than 18 months apart. The LDA group was defined as Systemic Lupus Erythematosus Disease Activity Index (SLEDAI-2K) of 2 or less (with or without positive serology) based on the presence of only 1 clinical manifestation of: rash, alopecia, mucosal ulcers, pleurisy, pericarditis, fever, thrombocytopenia or leukopenia. The patients could be taking antimalarial, but not corticosteroids or immunosuppressives. The remission group was defined as inactive clinical manifestations while only antimalarials were allowed and the HDA group was defined as SLEDAI-2K>6. The minimal time for inclusion in each group was 1 year.

Results: Of 620 patients with active disease who were seen during this period 80 (12.9%) patients fulfilled the criteria for LDA, 191 (30.8%) for remission and 349 (56.3%) for HDA. The LDA patients with positive serology (30 patients) were similar to the LDA patients without serology (50 patients) in baseline and prior disease manifestations, co-morbidities, treatments and in the distribution of the defined SLEDAI-2K items at baseline. After 2 years of follow-up, the LDA and remission groups were similar in their adjusted mean SLEDAI score (AMS), organ involvement (including central nervous system, vasculitis, renal and musculoskeletal), SLICC score, mortality and different treatments (Table 1). After 2 and 4 years of follow up, the HDA group had higher AMS, more major organ involvement, higher SLICC score, more mortality and was given more treatments compared to the LDA and remission groups. Further comparison according to these categories between the HDA group and a combined group of LDA and remission groups, showed the same trend of worse outcome and prognosis for the HDA group (Table 2).

Conclusion: SLE patients with LDA were defined and identified in a large SLE cohort. The LDA and remission groups had similar short term outcomes and both had better outcomes and prognosis than the HDA group. LDA may be used as an outcome measure in therapeutic trials or in treat to target regimens.

Table 1: Disease activity and prognosis of the LDA and the remission groups at 2 years from the definition year

Determining the Minimal Clinically Important Difference for Improvement for Systemic Lupus Erythematosus Disease Activity Index-2000 Responder Index-50 (S2K RI-50)

Zahi Touma[1], Dafna D Gladman[2], Dorcas Beaton[3], Jiandong Su[4] and Murray Urowitz[1], [1]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Mobility Program Clinical Research Unit, St Michael's Hospital, Toronto, ON, Canada, [4]Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic Lupus Erythematosus Disease Activity Index-2000 Responder Index-50 (S2K RI-50) is a reliable and valid index able to measure ≥ 50% improvement in disease activity. We aimed to determine the Minimal Clinically Important Difference (MCID) for improvement for S2K RI-50.

Methods: Analysis was conducted on patients seen during 2010-2012 at a single lupus centre. The S2K RI-50 data retrieval form was completed at each visit. Physician global assessment was determined at baseline visit on a visual analogue scale (0-10) and at follow up visits on a 7-point Likert scale (LS) (1-3 reflects worsening, 4 unchanged, 5 slightly improved, 6 moderate improved (≥ 50%) and 7 much

improved). This analysis is focused on the first follow up visit. LS was collapsed into 2groups; LS 6-7 and LS 1-5. The change of SLEDAI-2K scores was calculated between baseline and follow up. The change of S2K RI-50 was calculated between baseline SLEDAI-2K and follow up S2K RI-50 scores. MCID was determined with the anchor-based and the distribution-based approaches. *Anchor-based approach using the whole cohort*: we modeled the 1st follow up LS ≥ 6 as the outcome variable, and continuous S2K RI-50 change as the predictor in Logistic Regression model. Area Under the Curve (AUC) was obtained to determine the predictive power of S2K RI-50. We also derived the best S2K RI-50 cutoff based on optimal sensitivity/specificity in receiver operating characteristic (ROC) determined by the Youden index. *Distribution-based approach*: Standardized Response Mean (SRM) was used to confirm the effect size. The Standard Error of Measurement (SEM) was derived based on the following equation: SEM = $Pooled\ SD_{Baseline} \times \sqrt{(1 - test - retest\ reliability\ coefficient}$

[S2K RI-50 test-retest reliability = 0.98 based on a previous publication from the same centre]

Results: 509 patients were studied (age and lupus duration at baseline visit were 44.3 ± 14.7 and 15.2 ± 11.0 years respectively). 48 patients had an improvement (LS 6 or 7). The characteristics of the patients with LS 6-7 and LS ≤5 are represented in table 1. **Anchor-based approach**: MCID of improvement is equal to 1 based on the ROC analysis [AUC 0.82 (95% CI: 75-89), sensitivity 81% and specificity 72%] (Figure 1). **Distribution-based approach**: SRM of S2K RI-50 for LS 6-7 was -0.97 (95% CI: -1.3, -0.6) which is considered a large effect size. SEM was equal to 0.96 from the previous equation.

Conclusion: The estimated MCID of S2K RI-50 derived from both ROC analysis and SEM confirmed that it is close to 1. Thus a reduction of S2K RI-50 of 1 represents a relevant change in disease activity.

Table 1. Characteristics of the patients with LS 6-7 and LS ≤5

VARIABLE		LS≤5 N=461	LS 6-7 N=48	p
Sex	F	411 (89.2%)	44 (91.7%)	0.59
	M	50 (10.8%)	4 (8.3%)	
Age at baseline	Mean ± SD	44.11 ± 14.90	45.60 ± 14.22	0.50
SLE duration at baseline	Mean ± SD	15.27 ± 11.21	13.32 ± 8.70	0.24
SLEDAI-2K baseline	Mean ± SD	2.93 ± 3.54	7.33 ± 4.85	<.001
SLEDAI-2K at 1st follow up	Mean ± SD	3.26 ± 4.06	4.71 ± 4.08	0.01
SLEDAI-2K change	Mean ± SD	0.32 ± 2.74	-2.63 ± 4.15	<.001
S2K RI-50 at 1st follow up	Mean ± SD	2.90 ± 3.88	3.19 ± 2.53	0.61
S2K RI-50 change	Mean ± SD	-0.04 ± 3.15	-4.15 ± 4.24	<.001

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Most clinical trials of new treatments for systemic lupus erythematosus (SLE) have shown weak discrimination between investigational agents and placebo when added to standard of care (SOC). Given that targeted biologics are unlikely to be effective in all patients, it is challenging for these experimental therapies to exceed the high response rates observed with SOC alone in placebo arms. The design of future SLE trials may be improved by considering strategies for reducing placebo response rates and obtaining a better understanding of the within-patient variability in disease activity during follow up. The goal of this study was to evaluate longitudinal patterns of response in SLE patients who received placebo plus SOC in two completed 52-week clinical trials. Baseline characteristics discriminating early and persistent responders from non-responders to SOC were also examined to identify patient populations who may benefit most from experimental therapies and could be targeted for enrollment in future trials.

Methods: Data was obtained from the Collective Data Analysis Initiative (CDAI) of the Lupus Foundation of America and included 147 patients from the placebo plus SOC arms of two randomized Phase II/III trials in moderately-to-severely active lupus patients without acute nephritis. A BILAG-based response was evaluated at weeks 12, 24, 36, 48, and 52. Both cross-sectional and longitudinal analyses of response patterns were performed. Clinical variables, including background medications and baseline factors associated with disease severity, that discriminated persistent responders from non-responders were identified using logistic regression.

Results: The cross-sectional response rates ranged from 37% - 46% between 12 - 52 weeks for patients treated with placebo plus SOC, similar to the placebo response rates estimated in most non-nephritis lupus trials. The response rate decreased to 14.3% (95% CI: 8.6% - 19.9%) when the criterion was complete response, i.e., response at all visits between 12 - 52 weeks. Agreement between response status at 12 weeks and 36-52 weeks was low (kappa = 0.15 - 0.25); furthermore only 31% of initial 12 week responders maintained response at all subsequent visits. Factors contributing to non-response to SOC at all visits included more severe disease, as suggested by more organ systems active at baseline, and low C3 levels at baseline. Less aggressive immunosuppression was also associated with non-response.

Conclusion: An endpoint based on a sustained rather than cross-sectional response may reduce high placebo response rates in SLE trials that continue aggressive SOC and may improve discrimination between effective experimental treatments and SOC. Although there is increasing interest in conducting efficient 12 or 24 week early phase trials, the observed lack of stability in response to SOC over time highlights a potential weakness with shorter studies that use an endpoint of improvement. Our data also confirm earlier reports that the likelihood of response in the placebo group depends on the severity of disease and the aggressiveness of background treatments.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: ARHP II: Healthcare Disparities and and Psychosocial Impact on Rheumatic Disease

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Research shows that chronic illnesses such as SLE have multi-level impact on the family; it can be challenging for both patients & caregivers to cope with & manage the illness. An analysis of session evaluations was conducted for a monthly psychoeducation group, ongoing since 2001, for teens & young adults with SLE & their loved ones with a focus on Hispanic/Latino communities. The bilingual groups provide support & education strategies to manage & cope with SLE. Each 2-hour evening program occurs at a hospital site where many patients receive care & includes a professionally-led presentation, workshop or open discussion on a SLE-related topic.

Methods: A 16-item evaluation with Likert scale, multiple choice & open-ended questions was distributed after each of the 7 groups (2015-2016) focused on a SLE-related topic, such as Medications, Nutrition, Research & Doctor-Patient Communication. Items included demographics, overall satisfaction, knowledge, coping & disease management. There were 148 surveys distributed. Separate analyses were conducted for teens/young adults (T/YAs) < age 30 & parents/caregivers (Ps). Responses were also stratified by Hispanic (H) ethnicity. Fisher's exact tests were used to examine differences.

Results: There were 141 surveys (95%) submitted. Respondents were 50% T/YAs & 73% female. Over half (68%) were Hispanic, 29% African American, 28% some other race, 23% White & 13% Asian. Hispanic ethnicities included 32% Puerto Rican & 13% Dominican. Most (99%) respondents were satisfied overall with the program; 94% agreed that the program increased their understanding of SLE-related issues; 88% agreed that the program helped them cope with SLE; 90% agreed that they could apply what they learned to manage lupus; 95% agreed that the program met their expectations; 98% agreed that the presenter was clear & informative; 96% agreed that they would recommend this program. Ps reported ↑ agreement than T/YAs across 6 relevant Likert questions, with a significant difference in applying what they have learned to manage SLE (95% vs. 84% respectively, p=0.044). Differences in agreement for Hispanics (Hs) vs. Non-Hispanics (NHs) were significant across 6 Likert questions using Fisher's exact tests. Hs reported ↑ agreement (99%) than NH (82%) that the program increased knowledge of SLE, p=.001. This was similarly found in coping (95% vs. 73%, p=.005), disease management (94% vs. 79%, p=.024), meeting expectations (99% vs. 85%, p=.004), presenter clarity (100% vs. 93%, p=.032) & recommending the

program (99% vs. 90%, p=.042). Responses to open-ended questions, such as learning “how to manage my portions,” “how to explain lupus to others” & “how to communicate with doctors,” underscored substantial increases in knowledge and coping strategies.

Conclusion: Despite a limited sample size, our results demonstrate the value of the groups & our success in engaging patients. The significant differences found when stratified by Hispanic ethnicity speak to the positive impact the program has on the target community & indicate a need to further monitor this trend. This evaluation underscores the relevance of the family model of support when serving chronically ill diverse T/YAs with SLE & their caregivers.

Session Date: Sunday, November 13, 2016

Session Title: ARHP II: Healthcare Disparities and and Psychosocial Impact on Rheumatic Disease

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Current RA research reflects the preponderance of women with the condition (30% male). Research in other conditions suggests men need their own health strategy. Our previous Q-methodology study (qualitative and quantitative approach to grouping people according to subjective opinion) found a sample of men with RA (n=30) formed two groups (termed ‘Factors’ in Q-methodology): Factor 1 ("accept and adapt") take control of other areas of their lives to enable them to accept and adapt to their RA. However, Factor 2 ("struggling to match up") try to continue masculine activities without accepting physical help or emotional support. The aim is to investigate the existence, distribution, coping strategies and psychological impact of these two groups in the wider male RA population.

Methods: Q-survey methods investigated the distribution of the Q-methodology factors from our previous study in the wider male RA population. Men with RA completed numerical rating scales (NRS) of the statements that define each factor and were assigned to a factor based on a weighted averaging of their scores[2]. Validated scales were used to measure disease severity (Patient-based DAS: PDAS), coping strategies; acceptance of illness; perceived stress; anxiety; depression and emotional well-being. The survey was sent to a random sample of 620 men with RA. Chi[2], ANOVA and t-tests were used to compare responses between the factors (groups) of men.

Results: 293/620 male patients (47%): mean age 66yrs (SD 10.9), dis dur 14yrs (SD 11.3), HAQ 0.56 (SD 0.57), PDAS 4.13 (SD 1.10) Of the 293 men, 12 had missing data, thus 281 were included in the analysis. Of these 61 (22%) were assigned to Factor 1 ("accept and adapt") and 120 (43%) were assigned to Factor 2 ("struggling to match up") and 99 (35%) were unassigned due to insufficient difference (<1SD) between the weighted averaged NRS scores The two factors differed significantly on measures of disease status, coping strategies and psychological status. Factor 2 reported higher scores on PDAS, confrontation, avoidance and resignation coping strategies; and perceived stress. Factor 2 had significantly more cases or borderline cases of anxiety and depression than Factor 1. Factor 1 reported higher scores on acceptance of illness and mental well-being (Table 1).

Conclusion: Some men seem able to accept and adapt to their RA, but others (43%) report severe disease, poor coping and poor psychological status. Future research needs to identify effective and appealing support for men with RA, particularly for those who seem to be struggling (Factor 2). References: [1]Flurey et al. Session Date: Sunday, November 13, 2016

Session Title: ARHP II: Healthcare Disparities and and Psychosocial Impact on Rheumatic Disease
Session Type: ARHP Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: While physical activity (PA) has been recommended as a part of the non-pharmacological management of inflammatory arthritis (IA), previous research within this area has strong predominance of women and thus knowledge of the men's PA behavior is lacking. Accordingly, the aim was to examine PA behavior in men with IA, and the association between selected clinical and demographic variables and engagement in regular physical activity. Also men's motivation, barriers and preferences for PA was explored.

Methods: A cross-sectional study based on the Danish nationwide DANBIO registry covering patient with IA treated in routine care. Men, ≥18 years and rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS) recruited consecutively from one hospital. PA level was determined using the patient-reported Saltin-Grimby PA Level Scale, categorized into groups of low PA (level 1 and 2 on the scale: mainly sedentary or only light physical activity) or regular PA (moderate-vigorous PA min. 2 h/w; level 3 and 4). Other measures included VAS for global, pain and fatigue, C-reactive protein (CRP) level, Clinical Disease Activity and Health Assessment Questionnaire (HAQ). Logistic regression analyses were performed to identify factors associated with engagement in regular physical activity.

Results: In total, 325 were included in the analyses (47% RA, 29% AS and 25% PsA); median age 55 y, 10 y median disease duration. Totally, 129 (40%) reported regularly physically active (i.e. recommended level), 196 (60%) reported mainly sedentary or engage in only light PA. Those regularly physically active were significantly younger, smoked less ($p<0.05$), reported less pain, fatigue and global ($p<0.01$) compared to the group who reported PA at a suboptimal level. Also a better score on physician's global, lower disease activity and a better functional status than the less active ($p<0.01$). Only VAS fatigue remained independently associated with engagement in regular PA (OR=0.814, 95%CI=0.741-0.895); $p<0.001$) (multivariable logistic regression analysis). The most frequently reported motivators for PA were to maintain/improve health (62%), be in shape (50%) and maintain/reduce weight (42%), whereas the most frequently reported barriers were being too tired (29%), lacking energy (27%) and prioritizing work/studies (23%). In total, 42% stated they would be motivated for participating in an intervention or other initiative aiming at promoting PA in men with IA. Most preferred interventions including strength training (43%), swimming (34%) or road cycling (20%). 41% would like the training to be individual and 30% to exercise in groups.

Conclusion: A majority of men with IA are not meeting the recommendations of regular engagement in PA. This group seems to perform worse than their more active counterparts on clinical, subjective and objective parameters. Fatigue seems to play a crucial role in explaining motivation and barriers for PA. However, a causal relationship cannot be established. Taking into account preventive and general health promoting effects of physical activity, further focus on strategies to increase the engagement in PA in men with IA is needed.

Session Title: ARHP II: Healthcare Disparities and and Psychosocial Impact on Rheumatic Disease
Session Type: ARHP Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Although depressive symptoms are prevalent in persons with SLE, no studies to date have evaluated psychotherapy approaches in persons with SLE who also have comorbid depression.

Methods: Ninety persons with SLE with comorbid depression were randomly assigned to receive 8 weekly individual sessions and 3

monthly booster sessions of Mind-Body Skills Training (MBST, n=45) or Supportive Counseling/Symptom Monitoring (SCSM, n=45). SLE was defined by 1997 ACR criteria and depression was defined by Quick Inventory of Depressive Symptomatology – clinician interview version (QIDS-C) diagnostic criteria and Center for Epidemiology Studies Depression (CESD) scale score of >/=16. The MBST protocol included elements of cognitive-behavioral therapy and mindfulness meditation methods and principles. The SCSM protocol resembled traditional supportive, non-directive counseling but with a focus on topics of particular interest to persons with SLE, such as living with chronic illness, and communication with family and heathcare providers. Both interventions included information on SLE and depression as well as goal setting, and were delivered by trained, experienced psychotherapists. Participants completed study evaluations at baseline, mid-treatment, end of intervention, and 6 and 12 month follow-up. Mental health outcomes (CESD, QIDS) are reported here. Data were analyzed using generalized mixed effects models.

Results: The average age of participants was 49 years (+/- 12), 92% were females, and 23% were African American or other non-white race. Of the 90 persons enrolled, 73 (81%) completed the study. Levels of depressive symptoms in the two groups did not differ at baseline, and were in the range of moderate to severe (MBST CESD=29.7 +/- 6.4, SCSM CESD=30 +/- 6; MBST QIDS=12 +/- 3.4, SCSM QIDS=11.6 +/- 3). Both MBST and SCSM resulted in improvement in self-reported depressive symptoms (CESD) [time effect $F(4,286)=44$, $p<.001$] with a marginally significant group x time effect in favor of SCSM [$F(4,286)=2$, $p=.07$]. Likewise, both groups improved on QIDS [time effect $F(4,284) = 78$, $p<.001$], and there was not a significant group x time effect. At the 12 month follow-up evaluation, CESD scores averaged 21.3 (SD=8) for MBST and 20.2 (SD=6.5) for SCSM, indicating that, despite improvement, participants continued to report some symptoms consistent with depression and/or chronic illness. QIDS scores at 12 month follow up averaged 5.5 (SD=4.6) for MBST and 3.6 (SD=2.6) for SCSM, which is consistent with ‘no’ to ‘mild’ depression.

Conclusion: We found that both MBST and SCSM resulted in improvement in depressive symptoms in persons with SLE. Skills training was not superior to supportive counseling. Clinical diagnostic interviews indicated ‘no depression’ to ‘mild’ levels of depression at follow-up, whereas participants continued to self-report symptoms at follow-up, perhaps due to overlap between SLE and depressive symptoms such as lack of energy and difficulty concentrating. Psychotherapy approaches tailored to SLE may benefit many SLE patients who experience comorbid depression.

Session Title: ARHP II: Healthcare Disparities and and Psychosocial Impact on Rheumatic Disease

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The Food and Drug Administration (FDA) requires that patients prescribed a bisphosphonate to treat osteoporosis receive an FDA-approved Medication Guide that warns of the risk of unusual thigh fracture. These Medication Guides state: "Some people have developed unusual fractures in their thigh bone. Symptoms of a fracture may include new or unusual pain in your hip, groin, or thigh". However, no information is given concerning the probability of experiencing an unusual thigh fracture. We hypothesized that providing quantitative information concerning the probability of fracture would: (1) increase willingness to use the medication, (2) increase perceptions of medication safety, and (3) decrease perceptions of the likelihood of experiencing an unusual thigh fracture.

Methods: Participants (N=258) were recruited using Amazon Mechanical Turk. Using an internet-based survey design, each participant was randomly assigned to 1 of 3 groups that viewed a medication fact sheet with general information about a fictional bisphosphonate called, Bonemax. The fact sheet included information about medication benefits and the risk of atypical femoral fractures. For atypical femoral fractures, one format presented only non-numeric risk information, modeled after Medication Guides, while the other 2 formats presented numeric risk information for differing durations of therapy (0-2 years and 2+ years). The risk of atypical femur fracture was reported as 2 in 10,000 in the 0-2 year duration group and 8 in 10,000 in the 2+ year duration group. All 3 formats presented the same benefit information. The primary outcome variables were: 1) Likelihood of taking the medication if recommended by one's physician; 2) Medication safety; and 3) Likelihood of causing an atypical femoral fracture. All responses were recorded on 7-point rating scales and

statistical significance was set at alpha=0.05. Statistical analyses were performed using SAS®9.4.

Results: All three hypotheses were supported. Participants in the non-numeric group reported being less likely to use the medication (Mean=3.15) compared to those in either of the other two groups (Means=4.14 and 3.96 in the 0-2 year and 2+ year duration groups respectively, both p's < 0.01). Participants in the non-numeric group rated the medication as less safe (M=2.79) compared to those in either of the other two groups (Means=3.89 and 3.74 in the 0-2 year and 2+ year duration groups, both p's < 0.001). Participants in the non-numeric group believed that the medication was more likely to cause an atypical femur fracture (Mean=3.20) compared to those in either of the other two groups (Means=1.71 and 1.56, respectively, both p's < 0.001). None of the variables significantly differed between the numeric risk information groups.

Conclusion: Study findings suggest that the addition of numeric risk information to Medication Guides may facilitate patient decision making.

Session Title: ARHP II: Healthcare Disparities and and Psychosocial Impact on Rheumatic Disease

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Only one-third of FM patients obtain benefits after receiving one of the available therapy modalities. Insights into the heterogeneous picture of FM might improve therapy effectiveness. The present study aimed to examine 1) whether it is possible to differentiate between clinically meaningful profiles (subgroups) and 2) whether these profiles differ in terms of FM severity.

Methods: The al-Ándalus project allowed us to perform a comprehensive cross-sectional approach including assessments of physical, psychological, and cognitive adjustment in a total of 510 FM patients, who met either the 1990 or the modified 2010 ACR FM criteria. Measurements included objective (e.g., neuropsychological tests) and subjective data (i.e., questionnaires). Analyses of these assessments involved a two-step approach of exploratory factor analysis and cluster analysis.

Results: The first (factor analyses) step yielded 8 factors; 3 including objective measures (*declarative memory, performed physical fitness, and active lifestyle*) and 5 including subjective measures (*fatigue, psychological distress, catastrophizing, resilience, and subjective physical fitness*). In cluster analyses, the combination of these 8 factor scores yielded 5 profiles. An *Adapted* profile (*n*=88, 17%) showing low *psychological distress*, *catastrophizing*, and *physical fatigue* as well as high *resilience* and (both *objective* and *subjective*) *physical fitness*. A *Fit* profile (*n*=96, 19%) characterized by an *active lifestyle* and enhanced *objective physical fitness*. A *Positive* profile (*n*=116, 23%) in which *catastrophizing* was low. An *Unfit* profile (*n*=91, 18%) characterized by poor *subjective physical fitness*. A *Maladapted* profile (*n*=119, 23%) characterized by poor *resilience* and (*objective* and *subjective*) *physical fitness* as well as increased levels of *psychological distress*, *catastrophizing*, and *physical fatigue*. One-way analyses of variance showed that the mean score (standard deviation) of FM severity at the Revised FM Impact Questionnaire was 47 (13), 60 (15), 65 (13), 66 (14), and 79 (11) for *Adapted, Fit, Positive, Unfit*, and *Maladapted* profiles, respectively. After Student-Newman-Keuls posthoc tests, significant differences emerged between all the profiles; the only one exception was between *Positive* and *Unfit* groups.

Conclusion: Our study suggested the existence of 5 adjustment profiles that were differentially associated with FM severity. Future research using longitudinal designs should examine whether these profiles are associated with the prognosis of FM and the effectiveness of interventions, which would enhance the development of interventions customized to the adjustment profiles of FM patients. **Funding**: The Spanish Ministry of Economy and Competitiveness (I+D+i DEP2010-15639, I+D+i DEP2013-40908-R, BES-2014-067612, and BES-

Session Title: Antiphospholipid Syndrome - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Few studies have reported impaired health related quality of life (HRQoL) in patients with primary antiphospholipid syndrome (APS); however the causes of this outcome have been scarcely explored. Our aim was to evaluate HRQoL in patients with primary APS and to correlate it with a crude estimate of accrual organ damage, comorbidity and treatment.

Methods: We registered demographics, criteria and non-criteria APS features, comorbidities (diabetes mellitus, hypertension, dyslipidemia) and use of oral anticoagulation, immunosuppressors and prednisone. We assessed HRQoL with the SF-36 as a generic instrument and in the absence of a specific HRQoL questionnaire for APS, we used the Spanish version LupusQoL. We also evaluated the disease burden with a modified SLICC/ACR SDI including four additional items (livedo racemosa, adrenal infarcts requiring chronic treatment, permanent Greenfield filter replacement and multiple sclerosis-like disease). As controls we used SF-36 data from Mexican general population within the same age range.

Results: We included 50 patients (86% women), mean age 47.6 ± 14.5 years, median disease duration 9.4 years, median SLICC/ACR score of 1 point. Eighty percent had thrombotic events, 28% pregnancy morbidity and 72% non-criteria APS features (non-exclusive groups). APS patients had lower HRQoL than controls (SF-36= 66.1 ± 22.4 vs. 96.3 ± 29.8, p=0.0001). The results of each domain of SF-36 and LupusQoL are shown at Table 1. We found a positive correlation between SF-36 and LupusQoL (r=0.85, p<0.0001). The SLICC/ACR DI correlated negatively with both LupusQol and SF-36, specifically the peripheral vascular domain (r=-0.29, p=0.03, for both instruments). Patients on anticoagulant therapy (n=37) had lower LupusQoL physical functioning, intimate relationships, burden to the others and pain scores than patients without them. They also had a lower SF-36 physical functioning score. We did not find differences in HRQoL regarding comorbidities, prednisone and immunosuppressors use. **Table 1.**

	SF-36		LupusQoL
Total score	66 ± 22.4		69 ± 29.36
Comparable domains			
Physical functioning	71.9 ± 27.5	Physical health	77.6 ± 19.7
Mental health	64.6 ± 19.4	Emotional health	78.1 ± 18.1
Bodily pain	68.8 ± 25.5	Pain	81.3 ± 23.7
Vitality	54.8 ± 21.5	Fatigue	74.1 ± 19.5
Non Comparable domains			
Role physical	71.5 ± 40.7	Planning	82.3 ± 23.8
General health	56.9 ± 22.5	Intimate relationships	77.9 ± 35.5
Social functioning	78.8 ± 22	Burden to others	67.1 ± 30.8
Role emotional	60.6 ± 44.6	Body image	79.1 ± 24.2
Physical component summary score	64.6 ± 22.6	Not applicable	Not applicable
Emotional component summary score	67.6 ± 26	Not applicable	Not applicable

Conclusion: HRQoL in APS is related to burden of the disease specifically at the vascular peripheral area and use of anticoagulation treatment.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Antiphospholipid Syndrome - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A systematic review of case reports to summarize existing evidence in the literature regarding the association of APS and infection during childhood. Our aims were to identify all possible presumed infections that may predispose to elevation of aPL antibodies, and related clinical events.

Methods: Medline, EMBASE, Web of Science, PubMed ePubs, and the Cochrane Central Register of Controlled Trials (CENTRAL) were searched with no restriction through June 2016. References cited in the included articles were searched manually. We included case reports describing children who developed elevated aPL antibodies after a prior infection. One positive laboratory test for anticardiolipin, lupus anticoagulant, or anti-β2-GPI antibodies after a previous diagnosis of infection was required for inclusion. We extracted data on the infectious agent identified, pre-existing conditions, aPL antibody profile, clinical manifestations, treatment required, and reported outcome. Patients with systemic lupus were excluded.

Results: A total of 2,740 unique citations were identified through the databases and hand-searched bibliographies. Of these, 72 publications met inclusion criteria, reporting on 87 cases. The age of the cases ranged from 6 months to 18 years; 48 children (55.2%) were female. Cases were classified into four groups according to the clinical presentation reported following infection: 1) patients fulfilling criteria for diagnosis of APS (13.8%) including three cases with catastrophic antiphospholipid syndrome (CAPS), 2) patients with transient

thromboembolic events, not fulfilling APS criteria (31.0%), 3) patients developing hemorrhage rather than thrombosis (31.0%), and 4) patients with elevated aPL antibodies but no clinical manifestations (24.2%). Viral infection was the most frequent preceding infections across all groups (56.3%), followed by bacterial infection (26.0%). Ten different viral and bacterial agents were reported in group 1, with *Escherichia coli*, *Pseudomonas aeruginosa*, and *Parvovirus B19* recognized in the three cases who developed CAPS. *Varicella Zoster* and *Mycoplasma Pneumonia* were mainly identified in group 2, *Adenovirus* in group 3, and both *Adenovirus* and *Parvovirus B19* were equally reported in group 4. Infection was the sole precipitating factor in 85.1% of the reported cases; 8.1% had pre-existing autoimmune diseases such as juvenile idiopathic arthritis, or celiac disease, where *Parvovirus B19* was the predominant infection. Thirty nine (44.8%) cases developed thromboembolic events, predominantly hematologic, followed by skin manifestations, peripheral thrombosis, and stroke. Splenic infarction and other non-typical presentations were also reported. Positive lupus anticoagulant was most frequently reported in (81.7%). Anticoagulation or antiplatelet therapy were required for the majority of cases in groups 1 and 2. While complete recovery was achieved in the majority of cases, 37.5% of patients in group 1 reported persistent APS, and 25.0% died.

Conclusion: Development of aPL antibodies, APS and CAPS can occur in children after an infection. Further studies are needed to determine the risk and long-term outcomes of aPL-related events following infection.

Session Title: Antiphospholipid Syndrome - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It is well known that anti-phospholipid antibodies (aPL) are associated with an increased risk of arterial and venous thrombosis and pregnancy loss/morbidity. However, assessment of the risk associated with various antibody profiles, risks associated with aPL in the setting of other risk factors, and the evaluation of risk in individual patients are challenging issues. Our study aims to investigate the clinical and epidemiological characteristics of patients in a large APS cohort and to identify potential predictors of thrombosis and pregnancy morbidities.

Methods: This study included 180 consecutive patients who attended the rheumatology clinic at People's Hospital of Beijing University Health Science Center. All patients fulfilled the 2006 revised APS criteria. The criteria aPL profiles [anticardiolipin (aCL), anti-β2glycoprotein-I (anti-β2GPI) and lupus anticoagulant (LA)] were assessed with an in-house assay. Complement (C3/C4) and platelet levels were assessed in a University laboratory. Hypertension (HTN) was classified based on 8th Joint National Committee (JNC-8) guidelines. Hyperlipidemia (HLD) was defined as fasting total cholesterol >200 mg/dl. Diabetes (DM) is defined as Hemoglobin A1c >7. Pearson Chi-squared or Fisher's exact test univariate analysis with two tailed P value was used to evaluate correlation between different cardiovascular and epidemiological risk factors and clinical manifestations.

Results: 180 patients who met 2006 revised APS criteria were analyzed. There were 135 females and 45 males with a mean age of 42.85 (+/- 15.72). 66 (36.7%) patients had primary APS and 114 (63.3%) had secondary APS. Among those patients 141(78%) had thromboembolic events and 60 (33.3%) patients had recurrent thrombosis. 54 (30%) patients had pregnancy related morbidities. 59 (32.8%) patients had HTN and 28 (15.6%) were smokers. 102 (56.7%) patients exhibit hypocomplementemia and 81 (45%) exhibit thrombocytopenia. 24 (13.3%) had Raynaud's phenomenon. Age >50 (OR=9.548, 95%CI 2.206- 41.3, P<0.00002), HTN (OR=4.221, 95%CI 1.6 – 11.4, P<0.003), and smoking (OR=19.84, 95%CI 1.182 – 332.8, P<0.0038) were significantly associated with thromboembolic events (Fig 1). HLD, DM, hypocomplementemia, and thrombocytopenia did not demonstrate significant correlation with thrombosis. Only double positive antiphospholipid antibodies (defined as patients have at least two positive criteria aPLs) were significantly associated with pregnancy morbidity. None of the other analyzed clinical characteristics showed significant correlation with obstetric manifestations.

Conclusion: A high frequency of thrombocytopenia and hypocomplementemia were observed in APS patients. Age >50, HTN, and smoking are predictors of thromboembolic events while double positive aPLs is a predictor for pregnancy morbidities in Chinese APS patients.

Session Title: Antiphospholipid Syndrome - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the prevalence of non-conventional APL in patients with obstetrical APS pregnancy adverse outcome without conventional APL and the impact of treatment on pregnancy outcome.

Methods: The inclusion criteria were: (1) ≥3 early miscarriages less than 10 weeks of gestation; (2) intrauterine fetal death ≥10 weeks of gestation; (3) preeclampsia, prematurity <34 weeks of gestation related to placental insufficiency; (4) absence of inherited thrombophilia (V Leiden and II homozygous mutations, proteins C, S, ATIII deficiencies) and of conventional APL (LA, ACL IgG/M, anti- β_2GPI IgG/M). 96 patients with clinical obstetrical APS criteria were tested for anti-phosphatidylethanolamine (aPE) IgG/M, anti-prothrombin/phosphatidylserine (anti-PS/PT) IgG/M and anti-annexin V IgG. Pregnancies losses rates were compared between APS, non-conventional APS and non-APL and in untreated pregnancies to treated ones for each group. A control group of 47 healthy pregnant patients without any pregnancy complication have been selected from Bichat Hospital, without any age difference with clinical APS and without conventional APL (31±6 versus 33±4 years; p>0.05). A control group of patients with confirmed APS (Sydney criteria) (n=83) was also

selected.

Results: Using the cut-offs (ROC), 65/96 (68%) patients have been considered as non-conventional APS and compared to 83 APS and 31 patients without APL. Among these 65 non-conventional APS, recurrent miscarriage was noted in 44 (46%) cases, intrauterine fetal deaths in 38 (40%) cases, premature term<34 weeks of gestation in 25 (27%) cases, preeclampsia and/or HELLP syndrome in 25 (26%) cases and thrombosis in 14 (15%) cases. The obstetrical history in non-conventional APS did not differ in comparison to confirmed APS. The frequencies of anti-annexin V IgG antibodies tended to be more frequent in non-conventional APS (88% versus 73%; p=0.06), and those of anti-PE IgG and M were similar. The anti-PS/PT IgG and M antibodies were more frequent in confirmed APS than in non-conventional APS (63% and 37% versus 4% and 5%, p<0.0001). Overall 261 pregnancies in patients with non-conventional APS were compared to 81 pregnancies of confirmed APS and 132 pregnancies from non-APL group. 136/474 (29%) patients have been treated during pregnancies and treatment significantly increased the rate of live birth (26% in untreated versus 72% in treated pregnancies, p<0.0001). In univariate analyses, treatment effect on pregnancies losses was similar in patients with APS and non-conventional APS, with odds ratio at 3.3 [95% CI; 1.8 to 6.1] and 6.9 [95% CI; 3.9 to 12.3] (p=0.49) and significantly more important for the 2 APS groups pooled versus non-APL group (OR at 1.9 [95% CI; 1.1 to 3.5] for non-APL group versus 5.3 [95% CI; 3.5 to 8.1] for APS groups, p=0.0025).

Conclusion: In this study 68% of patients with clinical criteria for obstetrical APS seronegative for conventional APL have non-conventional APL. These patients have a significant decrement of pregnancy losses if they receive treatment for APS during their pregnancy.

A Systematic Review of Direct Oral Anticoagulant Use in Antiphospholipid Syndrome

Ayten Yazici[1,2], OZAN UNLU[3] and Doruk Erkan[4], [1]Hospital for Special Surgery, Cornell Weill Cornell Medicine, NEW YORK CITY, NY, Turkey, [2]Rheumatology, Kocaeli University School of Medicine, Kocaeli, Turkey, [3]Rheumatology Department, Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [4]Rheumatology, Hospital for Special Surgery- Weill Cornell Medicine, New York, NY
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Antiphospholipid Syndrome - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Oral direct oral anticoagulants (DOACs) are approved for the treatment of venous thrombosis and the prevention of venous/arterial thrombosis. There is growing information from case reports and series where DOACs have been used in antiphospholipid syndrome (APS) patients with controversial results. Thus, our objective was to systematically review the literature for DOAC use in APS.

Methods: We reviewed the literature (Pubmed, Cochrane Library, congress abstracts books, and the reference lists of studies) without language restrictions. Medical subject heading terms were: “antiphospholipid syndrome”, “direct oral anticoagulants”, “oral direct inhibitors of thrombin”, “oral direct inhibitors of factor Xa”, “rivaroxaban”, “dabigatran”, “apixaban”, and “edoxaban”. In a systematic fashion, we recorded the type of the study, DOACs used, indication for DOAC use, follow-up time, and outcomes.

Results: As of April 2016, we identified seven case reports and four case series, which included 99 APS patients (primary APS: 38; APS associated with lupus: 23; and unspecified: 38) treated with DOACs (rivaroxaban: 84; dabigatran: 14; and apixaban: 1) (Table). Direct oral anticoagulants were used due to: international normalized ratio (INR) lability in 69 patients; recurrent thrombosis on warfarin in 12; first line therapy in 12; and life-threatening bleeding on warfarin in 5. The follow up time varied between 1- 39 months (mean ± SD: 12.9 ± 8.6 months) (not specified in two studies). Recurrent vascular events (including two superficial venous thrombosis and one transient ischemic attack) were reported in 17 (17%) patients; and minor bleeding in 4 (4%) patients. The frequency of recurrence was not different between the patients who used rivaroxaban (18%) or dabigatran (14%) (p: 0.85), or between the patients with (30%) or without (16%) a previous history of recurrence (p: 0.43).

Conclusion: Based on our systematic literature review of DOAC-receiving APS patients, approximately 20% of patients develop thrombosis during a mean follow-up of 12 months. Given the publication bias and also the low evidence level study designs, e.g., case reports and series, it is difficult to have strong clinical recommendations based on the current literature. Ongoing randomized controlled

clinical trials evaluating DOACs in APS will determine if these agents can be incorporated into the management of APS patients. **Table:** Direct Oral Anticoagulated (DOAC)-treated APS Patients

Reference (1st Author/Year)	N (PAPS/SAPS)	DOAC (Dose)	Mean F/U time (range)	Recurrence

Session Date: Monday, November 14, 2016

Session Title: Antiphospholipid Syndrome - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Direct oral anticoagulants (DOACs) are approved for the treatment of venous, and prevention of venous/arterial thrombosis. There have been case reports/ series where DOACs have been used in antiphospholipid syndrome (APS) with controversial results. Our objective was to describe the clinical characteristics of and thrombosis risk in APS patients treated with DOACs.

Methods: A web-based data capture system stores patientsÕ clinical and laboratory characteristics in the context of the Antiphospholipid Syndrome Alliance for Clinical Trials and International Networking (APS ACTION) Clinical Database and Repository (ÔRegistryÕ), which has been created to study the natural course of persistently aPL-positive patients with/without autoimmune diseases (AIDx) over 10 years. The inclusion criteria are aPL positivity according to the Updated Sapporo Classification Criteria. For this descriptive study, we analyzed the demographics, clinical characteristics, and outcomes of aPL-positive patients who have been treated with DOACs.

Results: As of 4/2016, 627 aPL-positive patients were recruited (aPL/APS without any other AIDx: 410 [thrombotic APS with/without obstetric APS: 286]; and aPL/APS associated with another AIDx: 217 [thrombotic APS with/without obstetric APS: 142]). Of 428 thrombotic APS patients, 19 (4.4%) were current or past DOAC users (rivaroxaban: 17; dabigatran: 2).Of 19 patients, 17 (90%) had history of thrombosis; however only seven [37%] had single venous thrombosis. The indications for DOAC use were: INR lability (n:3); recurrent thrombosis or adverse events on warfarin (n: 4); first line therapy for thrombosis treatment (n:2) and prevention (n:2); clinical trial (n:5); and patientsÕ request (n: 3). The follow up time on DOACs was 1- 84m (mean ± SD: 23.3 ± 22.3m). Recurrent vascular events were reported in six patients (32%) (including 1 microthrombosis; 4 retrospective; and 2 prospective) (Table). One of two patients with prospective follow-up had cardiovascular disease risk factors at the time of the event. The annual incident thrombosis risk was 16.2% (for comparison, the risk was 2.1% for warfarin-users).

Conclusion: Based on a descriptive analysis of a large-scale international aPL/APS registry, less than five percent of patients receive a DOAC, mostly rivaroxaban. One-third of these patients developed recurrent events during the two-year follow-up; however, in approximately 60% of these patients the DOAC use was not as per licensed indications aside from the APS diagnosis. Although the small number of patients and the retrospective/prospective nature of the data collection might have resulted in a relatively high recurrence rate, DOAC use in APS should be guided by the results of appropriate randomized clinical trials. Currently no recommendations can be made against or for the use of DOACs in APS.

Table : Clinical Data on DOAC-treated APS Patients

#	Age*/Sex/Race	Thrombosis History	aPL Profile	Warfarin History**	DOAC Indication	DOAC Duration	Outcome
1	48/M/W	AT, VT#	aCL+ aB2GPI	No	DVT	R x 17m	Stroke

Session Title: Antiphospholipid Syndrome - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The clinical scoring systems to quantify the probability for the diagnosis of antiphospholipid syndrome (APS) or future thrombosis, have been proposed as to reflect the diverseness of antiphospholipid antibodies (aPL) profiles into the clinical judgments: They are the Antiphospholipid Score (APLS) and the Global Antiphoshpholipid Syndrome Score (GAPSS). However, the clinical applications of these scores have been obstructed mainly of its burdensome procedure of performing more than 10 aPL tests routinely. The aim of this study is to confirm the function of modified APLS (mAPLS) with reduced number of needed aPL tests.

Methods: This study comprised 261 consecutive patients with autoimmune diseases including APS who visited Hokkaido University Hospital Rheumatology Clinic between 2002 and 2003 and has been followed more than five years afterwards. Five lupus anticoagulant assays (three mixing studies and two confirmatory tests) and six ELISAs (IgG/M of anticardiolipin antibodies, anti-b2-glycoprotein I antibodies and phosphatidylserine dependent antiprothrombin antibodies) were performed in all subjects. All of the aPL were calculated of their hazard ratio for developing thrombosis on definition of the APLS. Using those original data, mAPLS was constituted of the aPL tests that had high odds ratio over 5.0 for thrombotic events. The functions of mAPLS were compared with those of APLS and GAPSS. To evaluate the diagnostic powers, area under the curve (AUC) of receiver operating characteristic (ROC) curves were calculated. Cox proportional hazard regression analyses were performed separately to evaluate the powers of thrombosis prediction. To evaluate and compare the predictive powers of the two scores, Somer's d coefficient was calculated.

Results: The diagnostic values of the three scores were similar(AUC of the ROC curve: APLS vs mAPLS vs GAPSS : 0.853 vs 0.810 vs 0.831). The Cox multivariate proportional hazard regression analyses revealed that three scores have functions of predicting future thrombotic events. However, Somer's d coefficient revealed that the APLS and mAPLS have similar power of predicting thrombosis while GAPSS showed lower predictive value(0.50 vs 0.48 vs 0.40, $p<0.01$). Moreover, when these scores were evaluated in patients with SLE, exactness of accuracy for diagnosis fell rapidly in every scores (APLS(0.91 for non-SLE, 0.80 for SLE), mAPLS(0.90 for non-SLE, 0.85 for SLE), GAPSS(0.85 for non-SLE, 0.80 for SLE)) and predictive value of future thrombosis was only confirmed by mAPLS; these phenomenon possibly reflecting the pseudo-positive aPL occasionally found in SLE patients.

Conclusion: Modified APLS with its high performances on APS diagnosis and thrombosis prediction, along with its simplified calculation, may be an available option in general practice.

History of Lupus Nephritis Is an Independent Risk Factor for Thrombosis in Systemic Lupus Erythematosus Patients with Antiphospholipid Antibodies

Vinicius Domingues[1], Janet Nwaukoni[2], Jill P. Buyon[3] and H. Michael Belmont[4], [1]Rheumatology, NYU Langone Medical Center, New York, NY, [2]Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, [3]Medicine, New York University School of Medicine, New York, NY, [4]New York University School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Antiphospholipid Syndrome - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Few studies have analyzed the risk factors for thrombosis in Systemic Lupus Erythematosus (SLE) patients with antiphospholipid

antibodies (aPL) and most had small sample sizes and homogenous patient populations. We examined whether a history of nephritis is an additional risk factor for thrombosis on a large multi-ethnic SLE cohort database.

Methods:

The NYU SLE SAMPLE biorepository and registry was initiated in September 2013 and includes 612 patients fulfilling ACR and/or SLICC criteria for SLE. Within SAMPLE, we identified patients with a positive aPL test (lupus anticoagulant, IgG or IgM anti-β_2-glycoprotein-I antibodies and/or IgG or IgM anticardiolipin antibodies) and determined if these patients had also ever fulfilled nephritis criteria. We reviewed each patient's medical record for presence/absence of venous and arterial thrombosis, and obstetric events as well as the non-criteria manifestations such as thrombocytopenia or valvulitis. We compared the prevalence of antiphospholipid syndrome (APS) manifestations in SLE patients with and without a history of lupus nephritis.

Results:

Of the initial 612 SLE patients (90% female; mean age 43.0±0.9 years), 54% were Caucasian, 31% African American, 15% Asian; 30% Hispanic white, and 5% Hispanic Black. Of the 612 patients, 105 had aPL, including 93 females and 12 males (mean age 43.0±0.2 years), 56% Caucasian, 33% African American, 11% Asian, 24% Hispanic white and 4% Hispanic Black. The total number of patients with thrombotic events was 45/105 (43%), including 26/43 (60%) in the nephritis subset and 19/62 (30%) (p=0.04) among patients without prior renal involvement. The most common thrombotic event was deep vein thrombosis (DVT) followed by stroke.

Conclusion:

The prevalence of APS criteria in the NYU SLE SAMPLE was 17%. Within this group, adverse events were more common among the patients with, versus without, a prior history of renal involvement (60% vs 30%). It remains uncertain if this association can be explained by, for example, by the presence of other accompanying findings that distinguish nephritis from non-nephritis SLE (e.g. anti-dsDNA, complement consumption) or drug treatment. This observation provides further support for the universal use of hydroxychloroquine in SLE, especially in those with current or previous nephritis and suggests that event-free aPL positive patients with a prior history of nephritis may be at increased risk for future thrombosis. Further studies are needed to determine whether such patients could benefit from prophylaxis with low-dose aspirin, statins or even other mild anti-thrombotic agents.

History of Thrombocytopenia Is Associated with Lower Prevalence of Thrombotic Events in Systemic Lupus Erythematosus Patients with Antiphospholipid Antibodies

Vinicius Domingues[1], Janet Nwaukoni[2], Jill P. Buyon[3] and H. Michael Belmont[4], [1]Rheumatology, NYU Langone Medical Center, New York, NY, [2]Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, [3]Medicine, New York University School of Medicine, New York, NY, [4]New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Antiphospholipid Syndrome - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Thrombocytopenia is a common feature of both systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) and in the former most frequently results from antiplatelet antibodies (i.e., AITP) or aPL antibodies. Patients with AITP paradoxically have an increased risk of thrombosis and it has been speculated that this can result from co-presence of aPL. Primary APS is associated with both thrombosis and thrombocytopenia. We assessed whether there was an association between a history of thrombocytopenia and the prevalence of a thrombotic event in a large, multiethnic cohort of SLE patients.

Methods: We analyzed the NYU SLE SAMPLE registry, consisting of patients fulfilling ACR and/or SLICC criteria for SLE. We identified 105 patients whose SLE criteria included the presence of one or more of the following aPL antibodies: lupus anticoagulant, IgG or IgM anti-β_2-glycoprotein-I, and/or IgG or IgM anticardiolipin antibodies; and determined whether these patients had thrombocytopenia

(<100,000/μL) recorded among their SLE classification criteria. We reviewed each patient's medical record to identify the prevalence of arterial or venous thrombosis (defined as DVT, PE, stroke, arterial occlusion with gangrene or amputation), and/or obstetric events. We compared the prevalence of thrombotic events in SLE patients with and without history of thrombocytopenia.

Results:

The NYU SLE SAMPLE currently includes 612 patients (90% female, mean age 43.0±0.9 years, and mean age of 41.0±0.3 years in the males); 54% of the subjects were Caucasian, 31% African American, 15% Asian, 30% Hispanic White, and 5% Hispanic Black: 17% had aPL antibodies, of whom 89% were female and 11% male (mean age 43.0±0.2 years, 56% Caucasian, 33% African American, and 11% Asian, 24% Hispanic white and 4% Hispanic Black). The total numbers of patients with thrombotic events were 45 (43%), with 5/21 (23%) in the SLE patients with aPL and prior history of thrombocytopenia and 40/84 (47%; p=0.042) in the patients without thrombocytopenia. The most common thrombotic event was DVT followed by stroke.

Conclusion:

The prevalence of aPL in the NYU SLE registry was 17%, and adverse thrombotic events were less common in the patients with prior history of thrombocytopenia (5/21, 23%) as compared to those without (40/84, 47%). This unexpected finding could be explained by protective benefit of anti-platelet antibodies when co-occur with aPL in SLE, or less thrombogenic aPL in SLE when there is concomitant thrombocytopenia. Additionally, our data suggest that there might be different consequences of aPL between primary APS patients and SLE patients with aPL.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Antiphospholipid Syndrome - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In some antiphospholipid syndrome (APS) patients, the antiphospholipid antibodies (aPL) becomes persistently negative. Discontinuation of anticoagulation has been proposed, however the long term follow-up after negativization is uncertain**.**The purpose of this study is to evaluate the clinical outcome after aPL negativization in primary APS patients.

Methods: From a cohort of 70 patients diagnosed with primary APS, we selected patients with positive aPL determinations at onset and ≥2 subsequent negative aPL determinations during the last 5 years. In order to corroborate the immunologic profile, a cross-sectional analysis was made. We determined IgG/IgM aCL antibodies, IgG/IgM antiβ2GPI, anti-annexin A5 antibodies (Enzyme Linked Immunosorbent Assay,ELISA) and lupus anticoagulant (LA) (Russell viper venom). All patients continued treatment with oral anticoagulants. We reviewed clinical charts to obtain clinical data and aPL determinations at onset and after negativization. Statistical analysis: descriptive statistics and Kaplan-Meier analysis.

Results: We found 24 patients with persistently negative aPL, including the last immunologic profile, 17 females, 7 males, mean age 51.7, disease evolution 16.3 years, mean of 4 aPL previous positive determinations. aCL was found positive at onset in 87.5% and 21% had double aPL positivity at onset (aCL/LA). Deep venous thrombosis (DVT) was the most frequent manifestation at onset in 33%,ischemic stroke in 29% and pulmonary embolism in 12%. INR range: 2-3.The most frequent concomitant cardiovascular risk factors

were dyslipidemia (29%), overweight (20.8%) obesity (16.7%). Mean time with aPL positive 109.4± 80.7 months. The median of thrombotic events was 2 (range 2-19). After 60 months of follow-up since negativization of aPL, Kaplan-Meier analysis: 40% of patients presented thrombosis recurrence, of these, DVT was observed in 29.2%, and ischemic stroke in 4,2%, despite optimal anticoagulant treatment. Other non-thrombotic APS manifestations were chronic ulcers in lower extremities in16.7%, and severe thrombocytopenia in 8%

Conclusion: This study suggest, that in primary APS, persistent negativization of aPL, is not an indication to interrupt oral anticoagulant therapy. Additional risk factors and other aPL can contribute to the recurrence of thrombosis.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Antiphospholipid Syndrome - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Acute deep vein thrombosis (DVT) is generally treated with anticoagulants for 3 to 6 months. Antiphospholipid syndrome (APS) is an important cause of DVT. However, APS can be diagnosed only 24 weeks after DVT according to the current APS classification criteria.[1] Thus, undiagnosed APS patients, who cease anticoagulant therapy after 3 months, might be exposed to a greater risk for recurrent thromboembolic event. Studies evaluating the significance of positive antiphospholipid antibody (aPL) test immediately after acute DVT are lacking. Our aim was to evaluate whether positive aPL test at the time of acute DVT diagnosis is predictive of APS.

Methods: Patients with acute DVT, confirmed by compression ultrasound, were included into a 24-month prospective study. All patients were given anticoagulants according to the current DVT treatment guidelines. Anticardiolipin antibodies (aCL) and *anti-beta2-glycoprotein* I antibodies (anti- β2GPI) were determined first at inclusion and then every 4 weeks for the first 24 weeks. The last aPL measurement was performed 24 months after inclusion into the study. APS was confirmed if a patient tested positive (medium or high positive aCL and/or presence of anti-β2GPI) 12 and 24 weeks after DVT. Lupus anticoagulants (LA) were tested 4 weeks after anticoagulation therapy had been stopped. aCL IgG/IgM and anti-β2GPI IgG/IgM/IgA antibodies were determined by our in-house ELISA.[2]

Results: 157 patients (91 male, 66 female, age 52.6 ±15.8) who were included in the study had aPL titer assessed at least 5 times. 20 patients ultimately fulfilled APS classification criteria. Among these, 15/20 (75%) patients had medium or high titer aPL, 4 of whom had multiple positive aPL, already at the time of acute DVT, 2/20 (10%) had low positive aCL IgG and 1/20 (5%) had low titer aCL IgM. 2/20 (10%) were negative for aPL, but had later fulfilled APS criteria due to positive LA. APS was not established in 137/157 (87.3%) patients. Among these, 114/137 (83.2%) patients were negative for aPL at inclusion, while 2/137 (1.5%) had low titer aCL IgM and 21/137 (15.3%) had low titer aCL IgG. Altogether, diagnostically important aCL IgG/IgM and/or anti- β2GPI titer at the time of acute DVT had 93.7% specificity and 75% sensitivity for APS. Isolated low titer aCL IgG were not more frequent in patients with APS than in patients without APS (P=0.059, χ^2). Completely negative aCL IgG/IgM aCL and anti-β2GPI at the time of acute DVT had a negative predictive value of 98.3%.

Conclusion: Here we show that in patients with acute DVT positive medium or high titer aCL IgG/IgM or anti-β2GPI is suggestive of APS. These patients should therefore continue with anticoagulant therapy beyond the initial 3 to 6 months required for DVT. Our results also indicate that patients with negative aPL at the time of acute DVT do not need further aPL testing; however, LA should be determined. Low

aPL titer at the time of acute DVT deems further testing imperative. References: 1. Miyakis S et al.Thromb Haemost 2006; 4: 295–306.2. 2. Cucnik S, et al. Clin Chem Lab Med 2000; 38: 777-783.

Session Title: Antiphospholipid Syndrome - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In APS, irreversible organ damage may result of disease activity, medications, or comorbid illnesses. To assess it, different methods have been used including the SLICC index which tends to underestimate APS-related damage (Arthritis Rheum. 2011;3:Abstract). Recently, a new instrument to evaluate organ damage in APS, the Damage Index in Antiphospholipid Syndrome(DIAPS), was constructed and internally validated by adding items specific of APS that are not included in the SLICC (Lupus.2015;9:927).

Our aim was to externally validate the DIAPS in a large cohort of primary APS patients and compare its performance against the SLICC index.

Methods: A total of 77 patients with an established APS diagnosis (either primary or secondary to SLE) were recruited in our Rheumatology clinic from March to June 2016. Main demographic, clinical and laboratory data were collected and both DIAPS and SLICC indexes were simultaneously scored. In addition, anxiety (GAD-7) and depression (PHQ-9) scales were measured as surrogate of quality of life. Data were expressed as frequencies and medians (interquartile range) or means (± standard deviation) as corresponded. Differences were assessed by either Fisher's exact or Mann-Whitney tests, while linear regressions were performed to assess linearity between DIAPS and SLICC scores. The GraphPad Prism 4.02 software was used for calculations.

Results: Out of the 77 patients included, 50 had primary APS and 27 had SLE-associated APS. Basal characteristics were similar in both groups, except for an older age (46.8±12.4 years *vs* 39.1±9.7 years; p=0.007) and a longer disease duration (9.6±6.4 years *vs* 6.0±4.8 years, p=0.01) in primary APS. Similar median DIAPS scores were found in primary APS patients as compared to secondary APS patients (2, 1 to 2.75 *vs* 2, 1 to 3; p=0.3); similar results were observed for the SLICC index (2, 1 to 2 *vs* 2, 1 to 3; p=0.3). No differences were observed for the GAD-7 (5, 2 to 6 *vs* 4, 1 to 5; p=0.4) and PHQ-9 (4.5, 2 to 6.25 VS 5, 2 to 6; P=0.9) indexes. No correlation was observed between the DIAPS index and either GAD-7 or PHQ-9 scores.

Finally, a linear association (see the Figure) between the DIAPS and the SLICC indexes was found both in primary APS patients (r^2=0.64; p=0.0001) and in patients with SLE-associated APS (r^2=0.57;p=0.0001).

Conclusion: Our cross-sectional study externally validates the DIAPS index as a useful instrument to evaluate cumulative organ damage in primary APS. However, it also suggests that the advantage of this current version of DIAPS over the SLICC index to assess organ damage in APS patients is marginal at best.

Background/Purpose: Thrombocytopenia and hemolytic anemia (HA) are considered non-criteria clinical manifestations by the Sydney revised criteria for APS. These features can precede, follow a thrombotic event or remain as such. We aimed to evaluate the serological phenotype of patients with both conditions

Methods: We included 77 consecutive patients with primary APS according the Sydney classification criteria and/or patients with hematological features (thrombocytopenia and HA). Patients from both groups fulfilled the Sydney laboratory criteria for APS. We registered demographics, disease duration and type of manifestation. aCL (IgG and IgM), antibodies to purified human anti-β2GP-I (IgG and IgM) and IgG and IgM anti-phosphatidylserine/prothrombin (aPS/PT) antibodies were assessed by ELISA. Lupus anticoagulant (LA) was determined by LA/1 screening reactant and a confirmatory test LA/2 according to published guidelines. The reactivity of IgG antibodies to domains 1-5 of β2GP-1 genetically engineered in our laboratory were determined by immunoblotting.

Results: Most patients were females (75.3%), mean age 45.3 ± 15 and mean disease duration 9.6 ± 6.5.The most prevalent antibody was aCL-IgM (87%) followed by anti-β2GP-l IgG (81.8%), anti-β2GP-I IgM (80%), aCL-IgG (79.2%) and LA (70%); 33% of patients were triple-positive. The prevalence of aPS/PT antibodies was 61.3% (both isotypes). Of the 62 IgG anti-β2GP-I-positive patients 31 (50%) had only thrombotic features, 14 (22.5%) hematological manifestations and 17 (27.4%) had both. They were not different in gender, age, disease duration, nor in the prevalence of aCL (both isotypes), LA, anti-β2GP-I IgM, aPS/PT–IgM or anti-D 1, 2, 4 and 5. In contrast, we found a significant difference in the prevalence of aPS/PT-IgG (70% thrombotic vs. 35.7% hematological and 87.5% both, p=0.01) and anti-domain 3 antibodies (64.5% thrombotic vs. 78.6% hematological and 33.3%, p=0.01). The logistic regression analysis of patients with both manifestations (n=17) vs. those with only one (n=45) showed that anti-D3 (OR 0.16 95% CI 0.35-0.76, p=0.02) and aPS/PT-IgG antibody (OR 11.7 95% CI 1.02-133.6, p=0.04) remained associated.

Conclusion: We identified a serological phenotype that discriminates APS patients with both thrombotic and hematological features. This finding further supports our contention that thrombocytopenia and hemolytic anemia are part of the APS. Future studies in other cohorts are

needed to validate this finding.

Session Date: Monday, November 14, 2016

Session Title: Antiphospholipid Syndrome - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Traditional cardiovascular disease (CVD) risk factors increase the risk of thrombotic clinical manifestations in antiphospholipid antibody (aPL)-positive patients. The prevalence of CVD risk factors has not previously examined in a large cohort of aPL-positive patients. Our objective was to examine the prevalence of CVD risk factors among aPL-positive patients with or without lupus.

Methods: A secure web-based data capture system is used to store patientsÕ clinical and laboratory characteristics in the context of the APS ACTION International Clinical Database and Repository (ÒRegistryÓ), created to study the natural course of persistently aPL-positive patients (according to the Updated Sapporo Classification Criteria) with or without autoimmune disorders over 10 years. Patients with systemic lupus erythematosus (SLE) fulfilled the American College of Rheumatology SLE Classification Criteria. Based on the enrolment data, CVD risk factors included in the analysis were hypertension, diabetes, and hyperlipidemia requiring medications, smoking (ever/current), estrogen use, obesity (BMI>30), family history, and sedentary lifestyle.

Results: As of April 2016, 627 persistently aPL-positive patients were recruited from 24 centers. Fifty-two patients were excluded due to the diagnosis of other systemic autoimmune diseases and 4 patients due to missing data. Of the remaining 571, 124 (21.7%) were asymptomatic carriers. The prevalence of CVD risk factors was not different between aPL-positive patients with or without SLE, except current smoking (15.9% vs 9.2%, p: 0.01) and hypertension (35.5% vs 27.3%, p: 0.05) that were more frequent in SLE patients. In a subgroup analysis of aPL-positive patients with thrombosis, hypertension (44.7% vs 31.5%, p: 0.01), and obesity (26.8% vs 36.8 %, p: 0.05) were significantly higher in those with SLE compared to those without SLE. Among all patients, thrombotic APS patients had significantly higher frequencies of hypertension, hyperlipidemia, obesity, and sedentary lifestyle compared to those with only obstetric APS and asymptomatic aPL carriers (Table).

Conclusion: The prevalence of CVD risk factors was similar between aPL-positive patients with or without SLE except current hypertension and smoking, supporting the need for awareness for these risk factors in both SLE and non SLE patients. Cardiovascular disease risk factors were more frequent among patients with thrombotic APS than those with only obstetric APS or asymptomatic aPL carriers. This suggests that the physicians should also be vigilant about the CVD risk factors and manage them well in order to decrease the risk of thrombosis in aPL-positive patients.

Table: Cardiovascular Risk Factors in aPL- positive patients with or without SLE, and among the groups of Thrombotic APS, Obstetric APS, and Asymptomatic aPL-positive carriers

Variables	aPL (with/without APS) without SLE (n=402)	aPL (with/without APS) with SLE (n=169)	p	Thrombotic APS (n=393)	Obstetric APS only (n=54)	Asymptomatic aPL carriers (n=124)	p
Hypertension	110 (27.3%)	60 (35.5%)	0.05	139 (35.3%)	9 (16.6%)	22 (17.7%)	< 0.001
Diabetes	20 (4.9%)	7 (4.1%)	0.66	22 (5.5%)	1 (1.8%)	4 (3.2%)	0.32
Hyperlipidemia	95 (23.6%)	34 (20.1%)	0.35	108 (27.4%)	3 (5.5%)	18 (14.5%)	< 0.001
Smoking ever	148 (36.8%)	73 (43.1%)	0.15	155 (39.4%)	13 (24%)	53 (42.7%)	0.054
Smoking current	37 (9.2%)	27 (15.9%)	0.01	40 (10.1%)	6 (11.1%)	18 (14.5%)	0.41
Estrogen use	3 (0.7%)	2 (1.1%)	0.6	3 (0.7%)	1 (1.8%)	1 (0.8%)	0.72
Obesity	101 (25.1%)	54 (31.9%)	0.09	117(29.7%)	8 (14.8%)	30 (24.1%)	0.048
Family history	62 (15.4%)	17 (10%)	0.09	58 (14.7%)	9 (16.6%)	12 (9.6%)	0.29
Sedentary lifestyle	188 (46.7%)	79 (46.7%)	0.99	202 (51.3%)	20 (37%)	45 (36.2%)	0.004

Session Title: Antiphospholipid Syndrome - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The APS ACTION International Clinical Database and Repository ("Registry") was created to study the natural course of disease over 10 years in persistently aPL-positive patients with/without other systemic autoimmune diseases. The network consists of five international core laboratories created to confirm aPL-positivity and for mechanistic studies. In this study we aimed to assess the agreement between inclusion and core laboratory anticardiolipin (aCL) and anti-β2glycoprotein I antibodies (aβ2GPI) ELISA

Methods: A secure web-based data capture system is used to store patient information including demographics, aPL/APS history, and aPL data. The inclusion criteria are positive lupus anticoagulant (LA) test based on the ISTH recommendations and medium-to-high titer aCL and/or aβ2GPI tested at least twice within one year prior to enrollment. The baseline samples of registry patients were re-tested for aCL and aβ2GPI (IgG, IgM and IgA with the QUANTA Lite® ELISA kits, Inova Diagnostics) at five different core laboratories. As part of this validation exercise, two different cut off values assays for aPL ELISA were arbitrarily used (20 and 40 GPL/MPL/APL for IgG, IgM and

IgA, respectively). Data was analysed using SPSS (IBM Software, NY).

Results: Four hundred and ninety-seven patients were included. Categorical agreement between the baseline values at inclusion vs. core laboratory results is summarized in Table 1. Cohen's kappa coefficients ranged between 0.61 and 0.80 (as substantial agreement). Overall, the correlation between quantitative results in the aCL and aβ2GPI was better for IgM and IgA compared to IgG (Spearman rho 0.789 and 0.666 vs. 0.600 for aCL and rho 0.892 and 0.744 vs. 0.432 for aβ2GPI).

Conclusion: aCL and aβ2GPI results showed very good categorical agreement between aPL testing at inclusion and core laboratories results. This agreement increases when considering high titer samples (>40 units). Based on the evaluations performed by the APS ACTION core laboratories, different ELISA tests used for inclusion displayed substantially equivalent performance for the detection of aCL and aβ2GPI. However, some non-substantial misclassification in terms of titers can be observed, especially for IgG isotype. **Table 1: Categorical agreement between the baseline values (BV) at inclusion vs. core laboratory (CR) results**

		cut off 40 %(BV/CR)	cut off 20 %(BV/CR)
aCL	**IgG**	81.7% (368/450)	81.6% (367/450)
	IgM	85.2% (381/447)	79.2% (354/447)
	IgA	90.8% (99/109)	83.5% (91/109)
aβ2GPI	**IgG**	82.2% (287/349)	79.7% (278/349)
	IgM	88.9% (346/389)	86.1% (335/389)
	IgA	88.5% (108/122)	82.2% (100/122)

Session Date: Monday, November 14, 2016

Session Title: Antiphospholipid Syndrome - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The association of low titer anti-phospholipid antibodies (aPL) with obstetric anti-phospholipid syndrome (APS) is increasingly acknowledged, even though some studies have showed conflicting results. To raise further evidence on the relevance of low titer aPL in pregnancy morbidity (PM), we retrospectively reviewed the clinical records of pregnant women attending a joint obstetric/rheumatology clinic over the years 2009-2016.

Methods: Patients were included when positive in at least one criteria aPL assay, at any titer, in two occasions minimum 12 weeks apart. Statistical analysis was performed using R package.

Results: 111 women (338 pregnancies) were identified. 51 women displayed low-titer aPL, with 160 pregnancies. 60 patients carried aPL at medium-high titers, with 178 pregnancies. 4 patients (4%) had thrombotic APS, 27 (24%) obstetric APS, 7 (6%) thrombotic and

obstetric APS, 15 (14%) medium-high titer aPL and non criteria PM, 7 (6%) medium-high titer aPL and no PM, 18 (16%) low titer aPL and non criteria PM and 15 (14%) low titer aPL and no PM. Low-titer aPL were significantly associated with pregnancy complications (c^2=8.82, p=0.003). Considering 245 untreated pregnancies, a significant difference in PM distribution was noted for low titer and medium-high titer aPL (p=0.003, **Table 1**). Among patients with low titer aPL, treatment with low molecular weight heparin [LMWH] + low-dose aspirin [LDASA] significantly improved pregnancy outcomes (p<<0.001, odds ratio [OR]=0.07, 95% CI=0.007–0.300), leading to a 14.3-fold reduction of obstetric complications. Hydroxychloroquine [HCQ] was not associated with a significant improvement in live birth rate (p=0.079). Among women with medium-high titer aPL, the standard therapeutic approach with LMWH+LDASA resulted in a significant improvement of obstetric outcome (p<<0.001, OR=0.20, 95% CI=0.100–0.400). HCQ treatment significantly improved obstetric outcome, carrying a 3-fold increase in the live birth rate (p=0.025, OR=0.34, 95% CI=0.117–0.894).

Conclusion: According to our data, low titer aPL are significantly associated with aPL-associated obstetric complications, with a lower prevalence of premature birth compared to medium-high titer aPL. Treatment with LDASA+LMWH led to a higher increase of live birth rate in women with low titer aPL compared to those with medium-high titer aPL. Additional treatment such as HCQ were effective in women with medium-high titer aPL but not those with low titer aPL. **Table 1. Obstetric outcomes (defined according to Miyakis et al, 2006) in 245 untreated pregnancies in women with low titer and medium-high titer anti-phospholipid antibodies.**

	Live birth	Early loss	Late loss	Premature birth	Total
Low titer aPL	57 (42%)	60 (45%)	16 (12%)	1 (1%)	134
Medium-high titer aPL	31 (28%)	59 (53%)	13 (12%)	8 (7%)	111

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: T cell-dependent activation of B lymphocytes is a key effector arm of the adaptive immune system, resulting in protective antibody responses and long-lived humoral immunity. Such B cell responses often occur in germinal centers (GCs); specialized anatomical locations within secondary lymphoid organs. Similar GC-like structures can also be found in involved tissue in various autoimmune diseases, including the salivary glands of primary Sjögren's syndrome (pSS) patients. Previous work has implicated CD40-CD154 pathway-dependent processes in regulating B cell survival and function in GCs, and we wanted to investigate whether this costimulatory pathway might be linked to ELS formation and function in pSS

Methods: Histological analysis of minor salivary gland biopsies from pSS patients revealed evidence of CD40 and CD154 expression on ELS-resident B and T cells respectively, co-locating receptor and ligand positive cells in affected tissue. These results suggested that there might be ongoing T-B cell collaboration in these ELS and we therefore wanted to examine whether there was evidence of CD40 pathway activation *in situ*. To do this we first generated a CD40-pathway gene signature in primary human B cells following recombinant CD154 stimulation *in vitro*

Results: Using a published microarray dataset generated using parotid gland biopsies we could demonstrate upregulation of a portion of the B cell CD40 gene signature in biopsies from pSS patients but not from healthy donors or individuals with Sicca symptoms, suggesting that CD40 pathway activation was occurring within disease-relevant tissue in lymphocytes implicated in disease pathology. To better understand the role of CD40-CD154 interactions in ELS, we examined salivary glands in CD40 knockout NOD mice. Wild-type NOD mice

develop sialadenitis, anti-SSA/SSB autoantibodies, and display evidence of ELS in salivary glands. In contrast, there was no evidence of ELS, sialadenitis or autoantibodies in CD40 deficient NOD mice up to one year of age. Further, anti-CD154 treatment resulted in disaggregation in splenic GCs as well as established ELS in NOD mice and resulted in decreased levels of IgG secreting cells in salivary glands

Conclusion: Collectively our data indicate that CD40 pathway signalling is essential for formation and maintenance of salivary gland ELS and suggest that CD40 pathway signalling is active in established ELS from pSS patients, supporting the notion that blockade of CD40-CD154 interactions may provide therapeutic benefit in patients suffering from this autoimmune exocrinopathy

Session Date: Monday, November 14, 2016

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We have reported that soluble BAFF (sBAFF) robustly increases IL-6 production in vitro by peripheral monocytes of patients with primary Sjögren's syndrome (pSS) as compared to healthy controls. In an attempt to elucidate the underlying mechanism, we have found that the expression level of BAFF receptor (BR3) is elevated in pSS monocytes and that the level is significantly and positively correlated with serum IgG level of pSS patients. These data collectively suggest that the elevated expression of BR3 on monocytes is involved in the pathogenesis of pSS which is often accompanied with hypergammaglobulinemia, and that BR3 is a possible therapeutic target to treat pSS. We have also successfully discovered two low-molecular weight compounds, pyrrolopyrimidine derivatives, BIK-12 and BIK-13, as BAFF receptor antagonists. The compounds inhibit BAFF-binding to BR3 and suppress both IL-6 production by BAFF-stimulated peripheral pSS monocytes and IgG production by peripheral pSS B cells co-cultured with BAFF-stimulated monocytes. In this study, we investigate the mechanisms of action of these compounds.

Methods: Peripheral monocytes were stimulated with sBAFF and cultured in vitro in the presence of BIK-12 or BIK-13. PBMC were stimulated with a mixture of sBAFF, recombinant human IL-21 (rhIL-21), and anti-IgM and anti-CD40 antibodies (multiple B cell activation) in the presence of BIK-12 or BIK-13. The expression levels of CD80/CD19/CD38/IgD and NF-kB/AID (Activation-induced cytidine deaminase) in the cells were analyzed by FACS and quantitative PCR, respectively. The amounts of IL-6 and IgG produced in the culture supernatants were measured by ELISA.

Results: sBAFF-induced IL-6 production by peripheral monocytes was significantly suppressed by BIK12 and BIK13 in a dose dependent manner. The elevated expression of CD80 and NF-kB, the markers of activated monocytes, in sBAFF-stimulated monocytes was also suppressed by the compounds. Interestingly, increased IgG production by activated PBMC was suppressed by BIK12 and BIK13. FACS analysis of PBMC indicated that differentiation of B cells into plasma blasts and/or plasma cells was inhibited by these compounds in a dose dependent manner. In addition, the expression level of AID was also suppressed by these compounds, suggesting that an IgG class switching was impaired.

Conclusion: Our results suggest that BAFF receptor antagonists suppress not only activation of monocytes but also IgG production by B

cells possibly by impairing differentiation and an IgG class switching of B cells. Our findings strongly suggest that BIK-12 and BIK-13 are drug candidates for hyper-activated B cell-related autoimmune diseases, such as pSS.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Recent research indicates that lipid rafts play an important role during B-cell activation and could be defective in patients with primary Sjögren's syndrome (pSS). No previous comparisons between the lipid raft profile in patients with lupus (SLE), SLE and secondary Sjögren's syndrome (SLE/SS) and pSS are available. Our study aimed to: 1. identify peripheral B and T cell abnormalities in patients with pSS compared to SLE and SS/SLE patients and correlate them with immune phenotype with clinical features and serological abnormalities. 2. investigate lipid raft expression in different B cell populations and their correlations with disease activity scores (ESSDAI and BILAG).

Methods: Blood samples and clinical and laboratory parameters from 34 patients with pSS, SLE and SS/SLE and 13 age/sex matched healthy controls (HC) were obtained. We used flow-cytometry to perform B-cell immunophenotyping and analysis of lipid-raft expression (marker of B-cell activation). In vitro cultures assessed lipid-raft expression in response to BAFF. We used ImageStream cytometry to characterise the interaction between lipid rafts and IgD and BAFF receptor (BAFF-R).

Results: Figure 1 presents the heatmaps assessing the expression of T and B cell populations in HC compared to patients with SS, SLE and SS/SLE. Lipid rafts were significantly elevated in B cells from patients with SS and SLE but not SLE/SS. Figure 2 shows the correlation between different immune cell populations and clinical and laboratory parameters. Figure 3 shows altered colocalisation of BAFF-R, Ig D and lipid rafts in patients with pSS, SLE and SS/SLE compared to HC.

Conclusion: This is the first comprehensive immunophenotype analysis performed in patients with pSS and SS/SLE, which identified that the SS/SLE patient group is immunologically distinct from pSS and SLE patients. The SS/SLE group had the most striking B cell phenotype abnormalities compared to patients with pSS or SLE (increased Bm2 cells and decreased early and late Bm5 cells). These abnormalities suggest a disturbance of B cell trafficking in the patient groups, and a possible bias towards plasma cell differentiation (as all disease groups had low memory B cells). The significant correlation between lipid raft expression and disease activity (ESSDAI score) in patients with pSS suggests abnormal B cell signalling. This could be relevant for the variability of patients' response to biologic treatments in SLE compared to pSS, as B cell targeted monoclonal antibodies are internalised within the lipid rafts.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is well recognized as an autoimmune disease accompanied by hypergammaglobulinemia and production of autoantibodies such as anti-Ro/SSA and anti-La/SSB antibodies. Although these serological aberrations suggest that abnormally activated B cells play a key role in the pathogenesis of pSS, the possible involvement of hyperactivated

B cells in the development of pSS has not been fully understood. In this study, we tried to identify B cell subsets in peripheral blood which may be responsible for disease activities of pSS.

Methods: Peripheral blood was collected from pSS patients (n = 34) and gender- matched healthy controls (HC, n = 20), and the proportion of B cell subsets characterized by anti-CD19, anti-IgD and anti-CD38 antibodies was analyzed by flow cytometry. $CD19^{+}$B cells prepared from pSS patients and HC by using CD19-microbeads were stimulated in vitro with a mixture of an anti-IgM antibody, recombinant human CD40 ligand, recombinant human IL-4 and recombinant human soluble BAFF (B cell stimulation). IgG production by the cells was measured by ELISA. Disease activities of the pSS patients were quantified based on the European League against Rheumatism (EULAR) Primary Sjögren's syndrome disease activity index (ESSDAI). The serological data of the patients were collected by clinical records.

Results: The proportion of $CD19^{+}$ B cells was significantly increased in pSS patients as compared with HC. In addition, IgG production by $CD19^{+}$ B cells in vitro upon B cell stimulation was also significantly increased in pSS patients. Moreover, the IgG production was positively and significantly correlated with serum IgG levels of the patients. Interestingly, FACS analysis of whole blood samples revealed that both $CD38^{high}IgD^{+}$ and $CD38^{high}IgD^{-}$ B cells were significantly increased in pSS patients compared with HC. Moreover, the number of $CD38^{high}IgD^{+}$ B cells was significantly higher than that of $CD38^{high}IgD^{-}$ B cells in the patients. In addition, the proportion of $CD38^{high}IgD^{+}$ B cells to $CD19^{+}$B cells was positively and significantly correlated with ESSDAI, serum levels of IgG, anti-Ro/SSA and anti-La/SSB antibodies.

Conclusion: Our results suggest that $CD38^{high}IgD^{+}$ B cells, which are known as activated B cells, are involved in overproduction of IgG and associated with disease activity of pSS. Our findings may shed light on the mechanism of pathogenesis of pSS.

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a common autoimmune disease with exocrine gland dysfunction and multi-organ involvement. With the growing interest in conducting clinical trials in pSS, there is a need for new biomarkers that can be used to diagnose pSS, identify clinical subsets of pSS, predict treatment outcome and assessment of disease activity. Activation of B-cells and dysregulation of the cytokine network plays a critical role in the pathophysiology of pSS. In the exocrine glands, elevated levels of cytokines, such as type I interferon (IFN), tumor necrosis factor alpha (TNF), interleukin 12 (IL-12) and B cell activating factor (BAFF) can be found. Dysregulated pathways of the innate and adaptive immune system lead to loss of tolerance and the production of organ-specific and non-specific autoantibodies. Current diagnostic criteria for pSS utilize autoantibodies directed to nuclear antigens (ANA), especially to SS-A/Ro (TRIM21, TROVE2) and La (SSB), but those are not specific, and can be identified as well in SLE and even in healthy volunteers. Several studies have shown that not all patients with pSS are tested positive for Ro and La autoantibodies, but suggested the existence of additional autoantibodies in pSS. This autoantibody burden is not well understood for the importance of disease progression, for its role in patient segmentation, or for response to treatments. The discovery of autoantigens may provide a deeper understanding of mechanisms of actions for pSS drugs, and may be useful to stratify patients.

Methods: The autoantibody reactivity pattern of pSS serum patients was analyzed using a Luminex bead-based antigen array (SeroTag) and 1,600 selected human protein antigens from our hPEX protein library of 8,000 recombinant proteins. We screened over 2,000 serum samples from patients with autoimmune diseases as active controls targeting Sjögren's Syndrome (n= 70), SLE (n= >500), SSc (n= >250), RA (n= >500), and over 1,000 healthy individuals to confirm known and to discover novel autoantibodies.

Results: Apart from clear confirmation the known benchmark autoantigens known for many years we have discovered a small set of additional, novel autoantibodies, which were detected in frequencies of 8 to >20% in pSS. Accumulation of autoantibody reactivities allows for a first subgroup definition of Sjögren's, and for clear segregation of SjS/SLE overlap syndrome patients.

Conclusion: A set of novel autoantigens for diagnosis and subgroup definition in Sjögren's syndrome was discovered by high content screening using a Luminex bead-based array platform. Validation in additional, large patient cohorts is ongoing.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by chronic inflammation of salivary and lacrimal glands. Patients with pSS have increased clonal expansions of B-cells in glandular tissue. The driving force for this expansion is unknown. Previous Ig heavy chain (IGHV) analysis studies of both parotid and labial glands revealed that there are no indications for an antigen driven expansion. However, our sequence analysis of RNA transcripts encoding for IGHV3 (IGHV3) genes derived from parotid pSS B-cell clones revealed significantly higher incidence of acquired N-glycosylation sites due to somatic hypermutation, suggesting a role for N-glycosylation motifs (N-glycs) in the selection of Ig producing cells. The aim of this study was to assess clonal expansions with Next Generation Sequencing (NGS) technology for all IGHV family genes in parotid gland tissue derived from pSS and non-pSS sicca patients.

Methods: mRNA was isolated from biopsies of parotid glands of 5 pSS patients diagnosed according to the AECG criteria and 5 non-pSS sicca patients. IGHV sequences of all IGHV families were amplified and sequenced using NGS. The Ig sequences were analyzed for IGHV gene usage, somatic hypermutation, CDR3 length and rearrangement by alignment with germline gene sequences of the IMGT reference directory. Sequences with the same CDR3 region (amino acids) and shared mutations within the Ig variable region were referred to as clonally related. Clones composed of more than ≥0.3% of the total amount of productive sequences were referred to as dominant clones. These clones were analyzed for expansion patterns, signs of antigen selection and acquired N-glycs.

Results: From each patient 1800-4000 unique sequences were recovered. We observed no difference in IGHV gene usage or CDR3 length between the pSS and non-pSS IGHV sequences. A total of 70 dominant clones (mean 14.0±5.6 clones) was found in pSS biopsies, whereas in non-pSS biopsies a significantly lower (p=0.0079) number of 15 dominant clones was detected (mean 3.0±1.6 clones). No difference in

percentage of mutations was seen between dominant clones from pSS and non-pSS patients. Analysis of dominant clones showed that in 4 of the 5 pSS patients, and in none of the clones of the non-pSS patients, the germline sequence was present in some of the clones. There was no evidence for antigen driven selection in the dominant clones. We observed that the IGHV sequences of dominant clones in pSS patients had acquired significantly more N-glycs compared to non-pSS sicca patients. These N-glycs were not restricted to IGHV3 genes. Remarkably, the majority of N-glycs was seen in the framework 3 region of IGHV3.

Conclusion: The presence of germline and heavily mutated IGHV sequences in dominant clones in parotid gland tissue of Sjögren patients is direct evidence that naïve B-cells entering the parotid gland expand and differentiate locally into plasma cells. Lack of evidence for antigen-driven clonal expansion in conjunction with significantly higher incidence of N-glycs, outside the antigen-binding site, in these clones suggests an alternative selection of Ig producing B-cells in pSS. We postulate that there might be a possible role for lectins in this process.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Changes in the ratio of circulating memory, naive, and double negative $CD27^{-}IgD^{-}$ B cell subsets are associated with a higher disease activity index in systemic lupus erythematosus (SLE) patients. Little is known about the soluble factors that may induce plasmablast differentiation from B-cell subtypes infiltrating inflamed tissue environments where they have proximity to, but often spatially separated from T-cells. We investigated the potential for SLE-associated soluble BAFF, IL-2 and IL-21 to drive plasmablast differentiation from B-cell subsets in a T-cell contact independent manner and whether CC-220, a Cullin Ring Ligase 4 Cereblon ($CRL4^{CRBN}$) E3 Ubiquitin Ligase Modulator, has an impact on generating potential autoantibody producing cells. The objective of the study was to determine the potential of BAFF, IL-2 and IL-21 to induce plasmablast differentiation from memory, naive, and lupus-associated double negative B-cell subsets and to determine the impact of CC-220 on differentiation and proliferation within these B-cell populations.

Methods: We investigated the effects of CC-220 on plasmablast differentiation from purified B-cell subsets in *in vitro* models mimicking germinal center T cell contact dependent (CD40L, IL-2, IL-21) and extra-germinal center T-cell contact independent (BAFF, IL-2, IL-21) systems. Plasmablast differentiation and antibody secretion was measured 5 days post treatment of $CD27^{+}$ memory B-cells and $CD27^{-}$ naive B-cells. Sorted B-cell subsets based on the CD27 memory and the IgD class switch markers were also tested: $CD27^{-}IgD^{+}$ naïve; $CD27^{+}IgD^{-}$ switched memory (SMe); $CD27^{+}IgD^{+}$ non switched memory (NSM); and $CD27^{-}IgD^{-}$ double negative (DN) B cells. Plasmablast differentiation and antibody production in the absence or presence of CC-220 were analyzed by flow cytometry and ELISA, respectively.

Results: BAFF, IL-2, and IL-21 in combination induced proliferation and plasmablast differentiation in SMe and DN B-cells, but not NSM or naive B-cells. Induced IgG secretion by BAFF, IL-2, and IL-21 was observed only from SMe and DN B-cells. Induced IgM secretion by BAFF, IL-2, and IL-21 was observed from SMe, to a lesser degree DN, but not from NSM or naive B-cells. CD40L, IL-2, and IL-21 induced B-cell proliferation and differentiation from all four subpopulations, with SMe producing the largest amount of IgG secretion followed by DN and DP and little from naive B-cells. Similar to IgG, IgM secretion was induced most from SMe, followed by NSM and DN in the CD40L, IL-2, IL-21 system. CC-220 inhibited plasmablast differentiation and antibody production in all cases, with different

efficacy depending on the B-cell subpopulations and stimuli.

Conclusion: In the presence of IL-2 and IL-21, BAFF induced proliferative and plasmablast differentiation effects are only observed on class switched $CD27^{+}IgD^{-}$ memory and DN $CD27^{-}IgD^{-}$ B-cells. This is in contrast to CD40L, IL-2, and IL-21,which drives B-cell proliferation and differentiation in all four subpopulations tested. In all conditions used to induce B-cell proliferation and plasmablast differentiation, CC-220 inhibited these processes at clinically relevant concentrations (1-10 nM).

Session Date: Monday, November 14, 2016

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by an expanded population of peripheral memory B cells. However, little is known about the qualitative abnormality of B cells associated with the pathogenesis of SLE. We assessed the subset of B cells by expression of chemokine receptors in patients with SLE and performed in vitro analysis to assess the differentiation mechanisms of those subsets.

Methods: PBMCs obtained from subjects with 56 patients with SLE, 31 patients with rheumatoid arthritis (RA) and 20 healthy donors (HD) were analyzed. Circulating B cell subsets were categorized by expression of chemokine receptors such as CXCR3 and CXCR5. Additionally, pan B cells obtained from HDs were cultured 4 days under stimulation with B cell receptor, co-stimulatory molecules and cytokines such as IL-21 and type I/II interferons (IFNs), and we assessed the expression of chemokine receptors such as CXCR3 and CXCR5 and transcription factors such as T-bet and Bcl-6 by multi-color flow cytometry.

Results: 1) The proportion of effector memory B cells (EM B cells; $CD19^{+}CD20^{+}IgD^{-}CD27^{-}$) has significantly increased in SLE compared to HD and RA ($p<0.01$). 2) The proportion of $CD19^{+}CD20^{+}CXCR5^{-}CXCR3^{-}$ B cells and $CD19^{+}CD20^{+}$ $CXCR5^{-}CXCR3^{+}$ B cells has significantly increased in SLE, compared to HD and RA, which were remarkably noted in $CD19^{+}CD20^{+}IgD^{-}CD27^{+/-}$ memory B cells ($p<0.01$). 3) CXCR5 expression was decreased in cultured B cells stimulated by BCR, CD40 ligands and IFN-β ($p<0.05$). By contrast, CXCR3 expression was increased in cultured B cells stimulated by BCR, CD40 ligands and IFN-γ ($p<0.05$). 4) T-bet expression was increased in cultured B cells stimulated by BCR, CD40 ligands and IFN-γ ($p<0.05$).

Conclusion: The results indicated that abnormality of B cell in SLE is characterized by not only quantitative increase in peripheral memory B cells but also unique expression pattern of chemokine receptors with down-regulation of CXCR5 and up-regulation of CXCR3 in EM B cells, indicating a potential of preferential migration into peripheral organs. Furthermore, in vitro experiments revealed that type I/II IFNs are a potent inducer of EM B cells involving abnormal chemokine receptor expression, suggesting an importance of these cytokines for the pathogenesis of SLE.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In systemic lupus erythematosus (SLE), early diagnosis and prognostic stratification are still great challenges. The broad characterization of the autoantibody repertoire in SLE is an emerging tool to supporting a personalized disease management approach. We have recently conducted autoantibody profiling studies of SLE, systemic autoimmune diseases (AID), and healthy controls to identify biomarkers for improving lupus diagnosis and patient stratification. Here we describe the identification of autoantibodies against the major vault protein (MVP) in SLE and its subsequent development into an ELISA based assay.

Methods: A large-scale Luminex bead-based autoantibody screen was conducted by combining diagnostic with putative antigens. In the discovery phase the autoantibody reactivity of serum samples from 130 SLE patients, 794 AID patients (systemic sclerosis, rheumatoid arthritis/RA, early RA, ankylosing spondylitis) and 343 healthy controls were tested against 6,912 recombinant human proteins. Following validation in independent SLE samples (n=101), consistent autoantibody reactivity against 46 antigens was found (p-value <0.05). The newly discovered autoantigen was developed into a prototypical ELISA format and analyzed for diagnostic performance using a medium sized control cohort consisting of n=93 serum samples (24 healthy controls, 42 SLE, 14 SSc, and 13 Sjögren syndrome (SjS) serum samples).

Results: A data base search of 46 known and novel SLE-associated antigens revealed that the expression of ten proteins is upregulated by type I interferon (INF) (http://www.interferome.org). Beyond known antigens (TRIM21/Ro52, SSB), we identified a novel autoantibody target MVP with a frequency of 20 % in SLE. Initial findings of the Luminex based screening results were verified by the results of the ELISA test; the newly discovered MVP autoantigen revealed sensitivity and specificity of 26% and 98% respectively. Anti-MVP antibodies were also found in SLE patients tested negative for dsDNA, Sm, and Ribosomal P. Interestingly, MVP is the major constituent of the vault particle, which is a cytoplasmic organelle and the largest known ribonuclear protein complex. Although the exact biological function of MVP is not well understood, literature data suggest that MVP is a virus-induced host factor, which up-regulates type I INF production [1].

Conclusion: Anti-MVP autoantibodies represent a useful marker in SLE and, in combination with anti-dsDNA, anti-Sm and anti-ribosomal P, optimizes the strategy for autoantibody testing. Furthermore, although more studies are needed, our findings suggest a previously undescribed linkage of type I INF and autoantibody targets in SLE. Liu S et al. (2012). Hepatology. 56(1):57-66.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Severe lupus tubulointerstitial nephritis (TIN) is prognostic of renal failure and characterized by tertiary lymphoid organogenesis. We have previously demonstrated that the dominant target of monoclonal antibodies (mAbs) cloned from B cells isolated from TIN biopsies was vimentin and not nuclear antigens. Probing bovine lens vimentin coated arrays confirmed anti-vimentin antibody (AVA) reactivity and serum IgG AVA titers correlated with TIN severity. Vimentin is an abundant secreted antigen in inflamed tissue. Citrullinated vimentin comprises a low proportion of the antigen, yet high titers of anti-citrullinated protein antibodies (ACPAs) are specific features of rheumatoid arthritis. However, it is not known if in situ selected AVAs in TIN target citrullinated vimentin. Furthermore, the origin of AVAs, and how they are selected in situ, is not clear.

Methods: Recombinant human vimentin was made in E.coli and used as substrate by ELISA. Eight TIN mAbs (with high vimentin reactivity) from six different TIN biopsies were probed for reactivity with unmodified and in vitro citrullinated vimentin. Predicted germ-line reversions of the respective TIN mAbs, 23 mAbs from healthy naïve and 20 mAbs from anergic B-cells, were also assayed for vimentin reactivity. Lupus serum samples from 101 subjects were screened for IgM, IgG, IgA and IgE AVAs. Other routinely assayed autoantibodies were titrated using commercially available ELISAs.

Results: In vitro citrullination of human vimentin, confirmed by mass spectrometry, inhibited TIN mAb binding. Germline reversion of seven of eight somatically hypermutated TIN mAbs diminished but did not ablate AVA activity. Vimentin immunoreactivity was, surprisingly, a common feature of the naïve and anergic repertoires. Furthermore, the range of relative affinities between reverted AVAs and anergic antibodies with AVA activity was similar. IgM and IgA AVAs could be readily detected in the serum of some patients with SLE. High titers of one AVA isotype did not categorically determine high titers of another isotype.

Conclusion: These studies demonstrated that the AVAs associated with SLE and the ACPAs associated with RA are different. It also appeared that AVAs are selected in situ from preexisting repertoires of AVA and are common through the spectrum of antibody isotypes associated with SLE. These data suggest that loss of tolerance to vimentin, and selection of high affinity and potentially pathogenic AVAs, is a common feature of SLE.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by expanded antibody secreting cells (ASCs) and the production of a variety of autoantibodies. Depletion of B cells by the anti-CD20 monoclonal antibody, Rituximab, has been widely used in autoimmune disease therapy. However, ASCs express low levels of CD20 and are poorly targeted. In this study, we examined the ability of TAK-079, a monoclonal against CD38 which is expressed at high levels by ASCs, to inhibit antibody production.

Methods: TAK-079 was provided by Takeda California, in collaboration with XOMA Corporation. Mononuclear cells were isolated from bone marrow aspirates or blood from healthy control (HC) and SLE patients. B cell subset frequencies were measured by flow cytometry following *ex vivo* depletion with TAK-079. To determine the frequency of ASCs, ELISpot was used to enumerate total IgG-producing and autoantigen specific cells. In some cultures NK cells were added to purified B cells to effect target cell killing.

Results: The addition of TAK-079 *in vitro* depleted 80% of plasma cell populations, which were characterized by the expression of CD27, CD38, and CD138 using flow cytometry. More importantly, with intracellular staining, cells positive for plasma cell markers BLIMP1 and IRF4, were also significantly reduced. Furthermore, TAK-079 depleted both short-lived plasma cells (CD19+ plasma cells), and long-lived plasma cells (CD19- plasma cells) from bone marrow. ASCs measured directly by ELISpot were also reduced in both HC and SLE patient samples. In HC samples, with TAK-079 treatment there was 70% reduction in the number of IgG producing cells from both blood samples and bone marrow samples. Similar depletion was seen in SLE patient samples. Additionally, the number of cells producing autoantigen specific antibodies was also dramatically reduced, including: VH4-34 9G4+ antibodies (70% reduction), anti-Ro antibody (70% reduction), and anti-dsDNA antibody (80% reduction). We elucidated the mechanism of plasma cell depletion and found that antibody-dependent cell-mediated cytotoxicity (ADCC) is an essential mechanism of plasma cell lysis *in vitro* by TAK-079. Purified B cells alone were unaffected by TAK-079 mAb, whereas addition of NK cells elicited TAK-079 dependent depletion of ASCs.

Conclusion: Our results highlight the potential of TAK-079 monoclonal antibody for treating SLE via plasma cell depletion. By targeting CD38, a molecule highly expressed on all plasma cells, TAK-079 effectively depleted both short lived and long-lived ASCs. Furthermore SLE ASCs producing antibodies against self-antigens were also efficiently depleted through NK cell and TAK-079 mediated ADCC *in vitro*.

Session Date: Monday, November 14, 2016
Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: BAFF is a TNF-like cytokine that supports the survival and differentiation of B cells. The anti-BAFF antibody belimumab is the only new drug that has been approved by the FDA for the treatment of lupus in the last 50 years. While it is clear that BAFF inhibition depletes B cells and can alter selection of the naïve B cell repertoire in mice, especially in the absence of competition from non-autoreactive B cells, some autoreactive VH genes are unaffected by belimumab and can subsequently enter and expand in the germinal center. A single study in humans did not show exaggerated loss of autoreactivity between the transitional and naïve compartments in belimumab treated patients. Furthermore, it is still not certain that altered selection is the mechanism by which BAFF inhibition achieves its therapeutic effect either in mice or humans. The purpose of this study was to determine how belimumab treatment alters the VH

repertoire of the naïve B cell repertoire in SLE patients.

Methods: Blood was collected from 14 SLE patients who had received and responded to belimumab for > 3years and from 10 SLE patients matched for age, ethnicity, disease duration, disease activity and other medications. Blood was also collected from 5 patients before and 6 months after starting belimumab therapy. PBMCs were analyzed by flow cytometry for B cell phenotype and naïve B cells ($CD3^-/CD11b^-/CD56^-/CD19^+/CD27^-/CD10^-$) were sorted as pellets. RNA was generated from the isolated cells and libraries were made for next generation sequencing using iRepertoire primers. Multiplexed libraries were sequenced using miSeq.

Results: Naïve B cells were depleted in all chronic belimumab treated patients with up to 90% depletion in treated patients 6 months after treatment initiation. 60-100 x 10^3 cells were sorted from belimumab treated patients and 350-700 x 10^3 cells were sorted from control SLE patients. 120-600 x 10^3reads were obtained from each sample. The number of distinct CDR3 regions was two to three-fold less in belimumab treated patients compared with either SLE or pre-treatment controls. The D50, calculated as a percent of dominant B cell clones that cumulatively account for 50% of the total CDR3s per sample was lower in the chronic belimumab patients compared with the SLE controls ($p<0.02$) but was not different in the pre-treatment vs. 6 month post-treatment belimumab samples. Each patient had a unique distribution of VH genes. Little difference was observed in the overall distribution of VH genes in patients examined before and 6 months after belimumab treatment. Since VH3-23 and VH4-34 are autoreactive genes it might be expected that naïve B cells expressing these genes would be preferentially deleted by belimumab therapy. However no difference was observed in the frequency of either of these two VH genes in pre vs. 6 month post belimumab treated samples or in chronic belimumab vs. SLE controls. Furthermore, belimumab did not preferentially delete the “naïve activated” B cell population that preferentially expresses VH4-34.

Conclusion: Treatment with belimumab depletes approximately 90% of naive B cells with a modest decrease in diversity over a long time period. However at 6 months after treatment initiation, when B cell depletion has already occurred, belimumab treatment does not result in significant skewing of the overall VH repertoire. Belimumab does not induce preferential deletion of naïve B cells expressing the autoreactive VH3-23 or VH4-34 genes even after three years of treatment. These data suggest that loss of autoreactivity in the naïve B cell compartment is not a sufficient explanation for the therapeutic efficacy of belimumab.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Insight into B cell subset dynamics and homeostasis can provide a biological rationale for use of B cell targeted therapies in SLE patients. Using our B cell signature (BCS) approach we wanted to assess whether treatment with Belimumab would result in a unique BCS that reflects a reduction in B cell subsets that are most sensitive to B cell activating factor (BAFF) depletion. Our BCS used the CD21/CD24 model that delineates analogous mouse and human nonmemory B cell subsets. Mouse studies have used CD21 and CD24 co-expression to identify which subsets are susceptible to BAFF depletion.

Methods: PBMCs were isolated from healthy donors, and SLE patients on Belimumab or standard of care therapy (SCT). Cells were stained for flow cytometry to identify nonmemory and memory subsets. BCS were determined based on the frequency of each B cell subsets within the nonmemory and memory pools and compared across treatment groups. One-way ANOVA test and Tukey’s post-hoc test were used for statistical analysis.

Results: Our evaluation of BCS showed that Belimumab (n=13) patients had significantly higher proportions of nonmemory transitional 1 cells ($p = 0.0062$) compared to SCT (n=24) patients and healthy controls (n=14). Alternately, Belimumab patients had significantly lower

proportions of nonmemory transitional 2 subset (p=0.0014) compared to healthy controls. FM (naïve) cells displayed no significant differences between the three groups. When we assessed the ratio of T1 to T2, Belimumab B cells had a larger ratio compared to both healthy and SCT (p=0.0033), but healthy and SCT were not significantly different. We also evaluated total transitional B cells to FM cells and noted no significant differences.

Conclusion: Our results show that B cell subsets must be stringently assessed as indicated by the transitional B cell subset data. BCS from Belimumab patients display unique profiles compared to both SCT and healthy donors. Our future studies will consist of a longitudinal evaluation of BCS in pre-Belimumab treatment and at subsequent time points in order to correlate BCS alterations with specific patient clinical characteristics.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: B cell hyperactivation and autoantibody (auto-Ab) production are hallmarks of SLE. Auto-Abs, reactive to RNA-containing antigens are found in a fraction of SLE patients, particularly those with severe disease activity. Toll-like receptor 7 (TLR7), an intracellular TLR that recognizes ssRNA, has been highly implicated in the generation of pathogenic anti-RNA autoantibodies in SLE, however the cellular origin of anti-RNA Ab–secreting cells is not well defined. Human transitional (TR) B cells have been previously shown to be enriched in polyreactive specificities and increase of TR B cells have been described in SLE patients. This study was undertaken to determine a possible link between the transitional B cell expansion and increase in *TLR7* expression in SLE.

Methods: Human peripheral blood mononuclear cells (PBMCs) were collected from both SLE patients and healthy donors (HDs) and analyzed by multicolor flow cytometry. Frequencies of TR B cells within the $CD19^+$ cell population were determined based on the relative expression of IgD, CD10, CD24, CD27, and CD38 surface markers. Expression levels of *TLR7* and *TLR9* were measured by real-time PCR. Additionally, $CD19^+$ $CD38^{++}CD24^{++}$ TR B cells from human cord blood were isolated by cell sorting. These cells were stimulated with IFNα, followed by stimulation with anti-IgM and/or TLR7 agonist R848. Changes in mRNA levels of *TLR7* were analyzed 3-6 hours post-stimulation. Plasma cell differentiation was assessed by flow cytometry after 5 days of *in vitro* cell culture; antibody production was analyzed by ELISA, and the expression of cytokines was measured by bead-based immunoassay.

Results: Analysis of the B cell compartment revealed a significant increase in the frequencies of circulating $CD19^+CD27^-IgD^+CD10^+CD38^{++}CD24^{++}$ TR B cells in SLE patients, compared to HDs. We found a significant positive correlation between the levels of *TLR7,* but not *TLR9* expression, and the frequencies of circulating TR B cells. SLE patients who carry a risk G allele (TLR7 polymorphism rs3853839, associated with increased *TLR7* expression) show a trend toward increased TR cell frequencies compared to non-risk allele carriers. SLE patients with high frequencies of TR B cells were also more likely to been found positive for pathogenic Sm/RNP auto-Abs in the clinic. IFNα treatment induced a nearly 10-fold increase in the expression of *TLR7* and *IRF7* in TR B cells isolated from umbilical cord blood. IFNα-primed TR B cells become highly responsive to *in vitro* stimulation with R848 and differentiated into $CD27^{++}CD38^{++}CD24^-$plasmablast in the absence of any other stimuli. Stimulation of TR B cells with R848 promoted IgM production, whereas stimulation with anti-IgM plus R848 induced IFN-γ, IL-6 and IL-10 cytokines.

Conclusion: Our findings show a direct correlation between *TLR7* expression levels and the expansion of TR B cells in SLE patients. Upon IFNα exposure, human TR B cells become hyper-responsive to stimulation through TLR7. Our study suggest that human TR B cells might be

an important source of auto-Abs and provide a new link between innate IFN and TLR7 signaling and B cell activation in SLE.

Decreased B Cell Activation-Induced Apoptosis in Cells Overexpressing Interferon Regulatory Factor 5 (IRF5), a Gene Associated with Risk for Systemic Lupus Erythematosus and Other Autoimmune Diseases

Brian Poole[1], Caleb Cornaby[2], Kalare Eberting[2], Wesley Cheney[2], Grant Walker[2], Craig Smith[2], Tosh Dowling[2] and Emily Mello[2], [1]Brigham Young University, Provo, UT, [2]Microbiology and Molecular Biology, Brigham Young University, Provo, UT

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The transcription factor Interferon Regulatory Factor 5 (IRF5) plays a crucial role in the functioning of several cell types such as macrophages, dendritic, and B cells. In Systemic Lupus Erythematosus (SLE), the IRF5 gene locus has been identified as a risk factor with various single nucleotide polymorphisms (SNPs) that demonstrate a strong correlation with disease development. It has been demonstrated that these polymorphisms cause increased production of IRF5 protein. In this study we investigate the effects of IRF5 overexpression in B cells on apoptosis. We hypothesized that overexpression of IRF5 would decrease activation-induced apoptosis. This would reduce tolerance and likely contribute to the development of lupus or other autoimmune diseases.

Methods: A lentivirus transduction system was engineered by cloning the human IRF5 gene into the bicistronic lentivirus pUltra-Chili, which expresses the reporter dTomato along with IRF5. Naïve B cells were isolated from healthy donors and transduced with our lentivirus construct with and without IRF5. The cells were then stimulated with IgG anti-Igm to induce activation. As an added control, a population of un-transduced naïve B cells was also stimulated. Forty-two hours post stimulation, apoptosis was measured by Annexin V staining and flow cytometry, with naïve B cell populations being gated on dTomato expression. Statistical analysis was done using the Wilcoxon signed-rank and p values with an alpha less than 0.05 were considered significant.

Results: Anti-IgM treated naïve B cells showed increased apoptosis compared to non-stimulated samples as expected. Comparing naïve B cells overexpressing IRF5 with naïve B cells treated with the empty vector, the IRF5 overexpressing cells demonstrated, on average, 46.5 % less apoptosis ($p < 0.05$).

Conclusion: These results support our hypothesis that overexpression of IRF5, which is a result of lupus-associated IRF5 SNPs, decreases apoptosis in activated B cells after B cell receptor engagement. This could provide a greater risk of breaking self-tolerance in individuals with the IRF5 risk haplotype.

CpG-Stimulated B Cells Require Glutaminolysis for Glycolysis, Mitochondrial Respiration, and Cytokine Production

Matthew Cheung[1], Dongyue Huang[1], Doujiao Wu[2], Edward Pearce[3] and **Alfred Kim**[1], [1]Rheumatology, Washington University School of Medicine, Saint Louis, MO, [2]Pathology & Immunology, Washington University School of Medicine, Saint Louis, MO, [3]Immunometabolism, Max Planck Institute of Immunobiology and Epigenetics, Freiburg im Breisgau, Germany

Session Date: Monday, November 14, 2016
Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: B cells contribute to disease pathophysiology through several mechanisms, including cytokine secretion. A wide variety of stimuli can activate B cells to produce cytokines including B cell receptor and Toll-like receptor engagement. Recently, numerous observations have established the role of metabolic pathways in the diverse array of immune cell functions. It is unknown though how these metabolic pathways influence B cell cytokine production. We sought to elucidate the metabolic programs required for B cell cytokine production.

Methods: B cells were isolated from the spleens of C57Bl/6J mice and activated overnight individually by the following agents: anti-μ antibody, anti-CD40 agonist antibody, poly(I:C), LPS, loxoribine, and CpG. Supernatants were collected and analyzed for the quantification of cytokines using the Milliplex cytokine kit (EMD Millipore). Real-time analysis of extracellular acidification rates and oxygen consumption rates of activated B cells were performed using the XF-96 Extracellular Flux Analyzer (Seahorse Bioscience). Three or more consecutive measurements were obtained under basal conditions and after the sequential addition of 1 μM oligomycin, to inhibit mitochondrial ATP synthase; 1.5 μM FCCP (fluoro-carbonyl cyanide phenylhydrazone), a protonophore that uncouples ATP synthesis from oxygen consumption by the electron-transport chain; and 100 nM rotenone plus 1 μM antimycin A, which inhibit the electron transport chain. To assess 3-carbon sources for oxidative phosphorylation, inhibitors to fatty acid oxidation (etomoxir, which irreversibly inhibits carnitine palmitoyltransferase-1), pyruvate transfer to mitochondria (UK-5099), and glutamine usage (BPTES, which inhibits mitochondrial glutaminases) were used.

Results: CpG stimulation of mouse splenic B cells increased both glycolysis and mitochondrial respiration to a larger extent that by other stimuli such as LPS or B cell receptor alone. These processes are highly dependent on glutamine, as inhibition of glutaminolysis with BPTES significantly reduced both processes. Importantly, production of TNF-α, IL-6, and IL-10 by CpG-stimulated B cells also heavily relied on glutaminolysis.

Conclusion: B cells undergo metabolic reprogramming when stimulated with CpG, requiring glutaminolysis. Cytokine production is intrinsically linked with this reprogramming. These data are the among first to demonstrate a relationship between B cell effector function and metabolic reprogramming, and suggest that B cell cytokine secretion can be manipulated by altering the local metabolic environment. Manipulating metabolic pathways may represent an interesting therapeutic approach for modulating B cells in autoimmune diseases.

Synergistic Immunoregulatory Effects of IL-10 and TGF-β on Humoral Immunity

Session Date: Monday, November 14, 2016
Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously identified $CD4^{+}CD25^{-}Foxp3^{-}$ regulatory T cells (Treg) that characteristically express lymphocyte-activation gene 3 (LAG3) produce IL-10. Recently we reported that these Treg regulate humoral immunity and ameliorate lupus pathologies in MRL/*lpr*mice with producing large amounts of TGF-β3. However, the immunological significance of the co-existence of IL-10 and TGF-β3 has not been elucidated. Here we examined the synergistic role of IL-10 and TGF-β3 in the control of lupus pathogenesis.

Methods: *In vivo*, 4-hydroxy-3-nitrophenylacetyl (NP)- keyhole limpet hemocyanin (KLH) immunized C57BL/6 mice were intravenously injected with plasmid pCAGGS-Mock, pCAGGS-Il10, pCAGGS-Tgfb1, or pCAGGS-Tgfb3 vectors. NP-specific antibody titers were quantified by ELISA. Lupus-prone MRL/*lpr* mice were also injected with each pCAGGS-Mock, pCAGGS-Tgfb1, or pCAGGS-Tgfb3 vectors and comparative analyses of splenomegaly, autoantibody production, and renal pathology were conducted. *In vitro*, B cells stimulated with lipopolysaccharides (LPS) were cultured in the presence or absence of IL-10 and TGF-β3, and the proliferation and antibody production were assessed. Further, the comprehensive gene expression analyses by next generation sequencing (NGS) analysis and immunoblotting in each condition were conducted.

Results: NP-specific IgG antibody titer was significantly suppressed in NP-KLH immunized mice only in cases with simultaneous administration of pCAGGS-Il10 and pCAGGS-Tgfb3. In MRL/*lpr* mice whose serum IL-10 levels were quite higher than MRL/+ mice, not pCAGGS-Tgfb1, but pCAGGS-Tgfb3 ameliorated lupus-like phenotypes, such as splenomegaly, glomerulonephritis, and anti-dsDNA antibody production. In *in vitro*experiments, although LPS stimulated B cells either with IL-10 or TGF-β3 enhanced the proliferation and antibody production, conversely, the simultaneous addition of IL-10 and TGF-β3 suppressed them. Hierarchical clustering of NGS data revealed that the genes of "stimulated B cells with IL-10 and TGF-β3" and "no stimulated B cells", but not "stimulated B cells either with IL-10 or TGF-β3", located within the same cluster. Immunoblot analyses confirmed the specific down-regulation of mammalian target of rapamycin (mTOR) target molecules in "stimulated B cells with IL-10 and TGF-β3".

Conclusion: We revealed that IL-10 and TGF-β3 synergistically suppressed humoral immune responses through suppressing mTOR signaling. Also, in lupus pathology, TGF-β3 exhibited the superior therapeutic effects compared to TGF-β1. The combination of IL-10 and TGF-β, especially TGF-β3, could be a novel therapeutic approach to systemic autoimmune diseases including lupus.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster I: SLE and Sjögren's

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Age-associated B cells (ABCs) are a novel B cell subset, which expresses CD11c and preferentially accumulates with age in female mice. Increased expansion of ABCs has also been observed in some autoimmune-prone mice. ABC differentiation is promoted by T cell help and TLR7 stimulation. Although the generation of ABCs is known to rely on the transcription factor T-bet, the molecular mechanisms regulating this novel B cell subset are poorly understood. Our laboratory previously identified a protein termed

DEF6, which shows significant homology to only one other protein, SWAP-70. Notably, the human DEF6 locus has recently been identified as a new SLE risk variant and mice deficient in both DEF6 and SWAP-70 (DKO mice) spontaneously develop a lupus-like disease on a C57BL/6 background. Similarly to human SLE, the lupus-like disorder in DKO mice preferentially affects the female sex. Autoimmunity in DKO mice is characterized by a number of T cell abnormalities including accumulation of T_{FH} cells and increased IL-21 production. Here we have investigated whether DEF6 and SWAP-70 regulate the ABC subset.

Methods: Presence of $CD11c^+CD11b^+B220^+CD19^+$ B cells (ABCs) was evaluated by FACS in WT and DKO mice as well as in DKO mice concomitantly lacking either IL-21 or SAP. ABCs were FACS-sorted from spleens and stimulated *in vitro* with TLR7 ligands or generated *in vitro* by culturing $CD23^+$ follicular B cells with aIgM, aCD40, and IL-21±TLR7 ligands. ABC markers and gene expression were analyzed by FACS, qPCR and western blot.

Results: We have found that DKO mice exhibit a marked accumulation of ABCs in the spleen but not in the draining lymph nodes or bone marrow. ABC expansion was higher in DKO female mice as compared to DKO male mice. ABC expansion in DKO mice was dependent on both DEF6 and SWAP-70 since mice lacking only DEF6 or only SWAP-70 did not show accumulation of ABCs. Expansion of ABCs in DKO mice was dependent on both IL-21 and T-B cell interactions as demonstrated by a significant reduction of ABCs in DKO mice concomitantly lacking either IL-21 or SAP. *In vitro* stimulation of $CD23^+$ B cells with aBCR, aCD40, +/- IL-21, furthermore, demonstrated increased frequencies of $CD11c^+CD11b^+Tbet^+$ ABCs from DKO B cells stimulated with IL-21. FACS-sorted ABCs from DKO mice stimulated *in vitro* with TLR7 ligands produced high levels of IgG2a/c anti-dsDNA autoantibodies compared to follicular B cells, confirming that ABCs are capable of producing autoantibodies.

Conclusion: Our study demonstrate that the absence of DEF6, a genetic risk factor for lupus, leads to the aberrant expansion of ABCs, a novel B cell subset previously associated with the development of autoimmunity. We also show that accumulation of ABCs in murine lupus is dependent on T-B cell interactions and IL-21. Finally, we demonstrate that ABCs may contribute to SLE pathogenesis by producing high levels of anti-dsDNA IgG2a/c antibodies.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies revealed epigenetic changes in DNA methylation associated with rheumatoid arthritis (RA) synovial fibroblasts (SF). In addition, we have shown that SF exhibit large anatomic differences in their epigenome, transcriptome and function. Here, we investigated the role of DNA methylation in the regulation of joint specific gene expression.

Methods: RNA and DNA were isolated from cultured SF obtained from hands (n= 1 OA/4 RA), shoulders (n = 3 OA/4 RA) and knees (n = 1 OA/4 RA) of RA and OA patients. RNA sequencing (Illumina HiSeq2000) of SF was used to identify differentially expressed genes (n=3 for each joint and condition). DNA from the same samples was subjected to the Illumina HumanMethylation 450 array. After quality control, we calculated differentially methylated CpG sites and islands using the COHCAP Bioconductor package (version 3.3) in R statistical program.

Results: We compared the methylation profile of the following joints shoulder-hand, knee-hand and knee-shoulder. The analysis identified 66, 32 and 64 differentially methylated CpG sites, respectively (methylated beta > 0.7 and unmethylated beta <0.3, $p<0.05$, FDR <0.05). Principal component analysis showed clustering of samples in relation to the joint localization. In detail, we found 40 CpG sites to be

hypomethylated and 26 hypermethylated in hand compared to shoulder SF. Of these, 13 and 6 CpG sites were hypomethylated on the CpG island of lncRNAs HOXA11AS and LOC145845. 8 hypermethylated CpG sites were found on the CpG island of MEIS1 in hand. In hand versus knee SF 28 CpG sites were hypomethylated and 4 hypermethylated. Of these, 5 CpG sites were hypomethylated on the gene body of the lncRNA HOTAIR and 4 CpG sites along the region of HOXC6, C5, C4 genes in hand. Last, we compared SF of shoulders versus knees and identified 51 hypomethylated and 13 hypermethylated CpG sites. Of these, 4 CpG sites were hypomethylated on the CpG island of HAND2 and 5 hypomethylated CpG sites were spread along the MEIS1 gene body in shoulders. Functional annotation analysis revealed that the majority of differential methylated genes are associated with limb development. The grade of DNA methylation matched the expression of most but not all differentially methylated genes, pointing to other regulating mechanisms of joint specific transcription. HOXA11-AS was higher (log2 ratio 2.89, $p=1.18x10^{-23}$) and MEIS1 lower expressed in hand than in shoulder SF (log2 ratio -1.63, $p=2.77x10^{-21}$). Expression of LOC145845 was not detectable. HOTAIR and HOXC6, C5, C4 were however overexpressed in knee compared to hand SF (log2 ratios 5.85, 3.04, 3.23, 3.08, $p<5.6x10^{-21}$). Expression of HAND2 (log2 ratio 3.13, $p=3.53x10^{-8}$) and also MEIS1 (log2 ratio 0.94, $p=1.52x10^{-5}$) was increased in shoulder compared to knee SF.

Conclusion: We show that DNA methylation regulates the expression of genes in a joint specific manner. These results point towards a fundamental role of epigenetics in maintaining location specific identities in joint stromal cells. We suggest that these joint specific differences in gene expression mediate the occurrence of distinct patterns of joint involvement in the development of arthritides.

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Bromodomain proteins (BRD) contain conserved acetyl-lysine binding domains that specifically recognize ε-N-lysine acetylation motifs, a key event in the reading process of epigenetic marks. We have identified a single nucleotide polymorphism in the BRD1 locus that is associated with the progression of joint destruction in rheumatoid arthritis (RA) in stage-I of a genome-wide association study (Knevel et al., Ann Rheum Dis. 2014). In the current study we investigated the role of BRD1 in the regulation of gene expression levels and functional properties in rheumatoid arthritis synovial fibroblasts (RASF).

Methods: RASF (n=8-10) were transfected with siRNAs targeting BRD1, or scrambled siRNAs as a control. 24 hours later cells were stimulated with TNFα (10 ng/ml), IL1β (1 ng/ml), or the Toll-like receptor (TLR) 2 agonist Pam3 (100 ng/ml), the TLR3 agonist pIC (10 µg/ml) or the TLR4 agonist LPS (100 ng/ml). Knockdown of BRD1 was verified by quantitative RT-PCR and Western blotting. Expression levels and secretion rates into cell culture supernatants of MMP1, MMP3, IL6 and IL8 were evaluated by RT-PCR and ELISA, respectively. The enrichment of histone 3 (H3) lysine 14 acetylation (H3K14ac) levels, a histone mark associated with BRD1 function (Mishima et al., Blood, 2011), in promoter regions of MMPs, IL6 and IL8 were determined by Chromatin Immunoprecipitation (ChIP, n=4) and analyzed relative to input DNA. Proliferation (n=6) properties of RASF after silencing of BRD1 were analyzed using an impedance-based system for real-time cell-based proliferation and adhesion (xCELLigence System) in presence and absence of TNFα.

Results: Silencing of BRD1 increased the TNFα and LPS-induced secretion rates of MMP3 (TNFα $p<0.01$, LPS $p=0.056$), IL8 (TNFα $p<0.01$, LPS $p<0.01$) as well as LPS-induced levels of IL6 ($p<0.01$). In contrast, basal MMP1 ($p<0.05$) secretion levels were decreased by BRD1 silencing. Similar results were obtained on mRNA levels. After stimulation of RASF with other inflammatory stimuli silencing of BRD1 had no effect on secretion rates of MMP1, MMP3, IL6 and IL8. ChIP analysis showed no differences in H3K14ac levels in TNFα treated compared to untreated RASF in promoter regions of MMP1, MMP3, IL6 and IL8. However, we detected strongly reduced levels of total histone 3 (H3) levels in IL6 and IL8 ($p<0.05$) but not MMP promoter regions after TNFα stimulation, indicating that histone eviction is

involved in the cytokine response induced by TNFα. Furthermore, silencing of BRD1 reduced proliferation rates ($p<0.05$) and increased the doubling time ($p<0.05$) of RASF both in presence and absence of TNFα without changing the adhesion properties of RASF towards plastic.

Conclusion: Our results demonstrate that BRD1 has a dual role in RASF by inducing proliferation rates but limiting expression levels of matrix degrading enzymes and cytokines specifically in TNFα and LPS-induced pathways. The anti-inflammatory role of BRD1 should be kept in mind in the drug development of bromodomain inhibitors. **Acknowledgements:** IMI-BT Cure (Pfizer), IAR Epalinges, euroTEAM, EMDO Stiftung, Novartis Stiftung, Jubiläumsstiftung

Periarticular Bone Loss in Arthritis Is Induced By Autoantibodies Against Citrullinated Vimentin

Cecilia Engdahl[1], Holger Bang[2], Katharina Dietel[1], Stefanie C Lang[1], Ulrike Harre[1] and **Georg Schett**[3], [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, Friedrich-Alexander-University Erlangen-Nuremberg (FAU), Erlangen, Germany, [2]Orgentec Diagnostics, Mainz, Germany, [3]Department of Internal Medicine III, Institute for Clinical Immunology,, Friedrich-Alexander-University Erlangen-Nuremberg (FAU), Erlangen, Germany

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Periarticular bone loss is a long known and early but yet insufficiently understood phenomenon in patients with rheumatoid arthritis. This study investigated whether autoimmunity against citrullinated proteins is causally involved in triggering focal trabecular bone loss by modifying a standard experimental model of periarticular bone loss in the context of arthritis.

Methods: Antigen induced arthritis (AIA) was induced by methylated bovine serum albumin (mBSA) and modified by mutated citrullinated vimentin (MCV). Periarticular bone loss, subchondral osteoclastogenesis as well as expression of PAD enzyme, bone associated genes and cytokines, were assessed after arthritis induction. Immune cell and osteoclast precursor infiltration were detected in the periarticular bone marrow and the local lymph nodes. In addition, periarticular bone loss was assessed upon challenge of mice with anti-MCV antibodies.

Results: Despite inducing a milder form of arthritis than mBSA, MCV triggered significant periarticular bone loss associated with an increased infiltration of osteoclast precursors and mature osteoclasts in the periarticular bone marrow. MCV enhanced the expression of the osteoclast inducers RANKL and MCSF, the cytokines IL-8, IL-1, IL-6 and TNF-α as well as PAD2 and PAD4 enzymes in the focal bone marrow. In addition, also anti-MCV antibody challenge induced significant periarticular bone loss and osteoclastogenesis in the bone marrow of mice.

Conclusion: Autoimmunity against citrullinated vimentin triggers periarticular bone loss by osteoclast activation in the bone marrow. These findings may explain why periarticular bone loss is already found very early in the disease course of rheumatoid arthritis patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Wnt family proteins canonically stabilize β-catenin to activate T-cell factor (TCF) for the transcription of several genes, including *Runx2*, which is important for osteoblastogenesis. *Wnt* transcripts are highly expressed in RA synovia (Am J Pathol. 2005; 167: 97–105), suggesting the role of Wnt signaling in bone metabolism during articular disease development. Interestingly, fibroblast-like synoviocytes (FLS) also produce remarkable amount of Dickkopf1 (DKK1), a soluble protein that blocks Wnt pathway. Therefore, FLS have both positive and negative effects on Wnt signal activation. It is plausible that a change in WNT and DKK1 expression can affect the strength of Wnt signaling and regulate bone metabolism and joint destruction in articular diseases. In this study, we aimed to determine the cytokines that regulate Wnt signaling in FLS.

Methods: The mRNA expression levels of *Wnt1*, *2*, *3*, *3a*, *4*, *5a*, *5b*, *7b*, *8b*, *10A*, *10B*, *11*, *DKK1*, and *Runx2* in FLS were quantified by SYBR green real-time PCR after treatment with cytokines (TNFα, IL-1β, IL-6, IL-17, and IFNγ). Activity of Wnt pathway was assessed by luciferase assay using TCF reporter plasmid, which was transfected to U2OS, an osteosarcoma cell line that lacks DKK1 expression. The concentration of DKK1 in the culture media was measured by ELISA. Anti-DKK1 antibodies were used to neutralize DKK1 in FLS culture medium.

Results: FLS expresses mRNA of *Wnt2*, *3*, *4*, *5A*, *5B*, *7B*, *8B 10A*, *10B*, *11*, and *DKK1*. DKK1 secreted by FLS was functional, as it blocked the activation of TCF luciferase activity induced by recombinant Wnt3a, and was effectively blocked by anti-DKK1 antibody. TNFα and IL-6 induced *Wnt2*, *4,* and *Wnt4* mRNA levels in FLS, respectively, whereas, IL-1β increased *Wnt2*, *5A*, *7B*, *10A*, *10B*, and *11* mRNA levels. Importantly, IL-1β dampened *DKK1* mRNA expression in FLS, but TNFα and IL-6 did not alter its expression. Consistent with these results, luciferase activity was induced by the supernatant of FLS treated with IL-1β, but not with other cytokines. In addition, *Runx2* mRNA expression in FLS was induced by only IL-1β.

Conclusion: Our data indicates that IL-1β has the highest potential to enhance Wnt signaling, among the tested cytokines. It is already known that IL-1β induces phosphorylation of glycogen synthase kinase-3β for the activation of transcriptional factor TCF. Our findings demonstrate that IL-1β also activates the canonical Wnt signaling pathway by changing the expression pattern of Wnt family proteins and DKK1 in FLS. It is suggested that IL-1β, but not the other cytokines, changes the gene expression pattern of Wnt family and DKK1 in FLS to up-regulate Wnt signaling in the joint during aberrant bone formation.

Tankyrase Regulates Osteoclastogenesis Via SH3BP2

Shunichi Fujita, Tomoyuki Mukai, Takafumi Mito, Shoko Kodama, Akiko Nagasu, Hiroyasu Hirano and Yoshitaka Morita, Department of Rheumatology, Kawasaki Medical School, Kurashiki, Okayama, Japan

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tankyrase is a poly (ADP-ribose) polymerase that leads to ubiquitination and degradation of target proteins. Axin, a regulatory protein of Wnt/β-catenin signaling, is one of the target proteins of tankyrase, therefore tankyrase inhibitors function as a Wnt/β-

catenin inhibitor. Tankyrase has recently been reported to degrade an adaptor protein SH3BP2 (SH3 domain-binding protein 2). We have previously reported that SH3BP2 gain-of-function mutation in murine bone marrow-derived macrophages enhances RANKL-induced osteoclastogenesis. Though the interaction between tankyrase and SH3BP2 has been reported, it is not fully elucidated whether tankyrase is involved in osteoclastogenesis. In this study, we investigated the role of tankyrase in bone metabolism.

Methods: Primary murine bone marrow-derived macrophages and murine preosteoclastic RAW264.7 cells were treated with RANKL in the presence of tankyrase inhibitors (IWR1 or XAV-939) and Wnt inhibitors (ICG001 or IWP2). Osteoclasts were visualized by a tartrate-resistant acid phosphatase (TRAP) staining, and TRAP-positive multinucleated cells (TRAP+ MNCs) were counted as osteoclasts. Expression levels of osteoclast-associated genes (*Cathepsine K, Oscar, Acp5 and Dc-stamp*) were measured by quantitative PCR analysis. Osteoclastic function was assessed by resorption assay. To determine the intracellular mechanisms, protein expression patterns of SH3BP2, NFATc1, and Syk were examined by western blotting.

Results: Both IWR1 and XAV-939 enhanced RANKL-induced TRAP+ MNCs formation, osteoclast-associated genes expression, and mineral resorbing activity. SH3BP2 protein levels were elevated in cells treated with tankyrase inhibitors but not with Wnt inhibitors. Tankyrase inhibitors significantly augmented nuclear localization of NFATc1 and phosphorylation of Syk in response to RANKL. Finally, FK506, an NFATc1 inhibitor, fully abolished the promoting effect of tankyrase inhibitors on osteoclast formation.

Conclusion: These findings suggest that the inhibition of tankyrase enhances osteoclastogenesis through activating Syk and NFATc1 via elevated SH3BP2 expression. Our findings highlight the undetermined effect of tankyrase inhibition in addition to its suppressive effect on Wnt/β-catenin signaling. Modulating tankyrase activity could be a novel therapeutic option of bone destructive diseases including osteoporosis and rheumatoid arthritis.

Session Date: Monday, November 14, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mechanisms associated with intrinsic mRNA regulation are important players in development and disease processes. The terminal uridylyl transferases (TUT) are a family of enzymes involved in the regulation of mRNA turnover and apoptosis-mediated global mRNA decay. However, their role in skeletal homeostasis has not been explored. In this study, we investigated the role of ZCCHC6/ TUT7 in osteogenesis and bone homeostasis in mice.

Methods: RNA and protein expression were analyzed using SYBR green-based qPCR and Western blotting respectively. Osteoblasts (OB) and osteoclasts (OC) were generated following our published protocols. TUT7KO mice were generated by gene targeting and their skeletal phenotype was characterized using DXA, mCT, histology and histochemistry. Osteocalcin (OCN), OPG and RANKL were quantified by ELISA. Promoter activity was assessed by Luciferase assays.

Results: TUT7 showed an age-dependent differential pattern of expression in osseous tissues with expression being high in calvaria and

long bones of newborn mice which declined with aging. Next, we generated TUT7KO mice and characterized their skeletal phenotype. Deletion of TUT7 was not lethal and neonatal TUT7KO mice developed normal similiar to wildtype (WT) littermates. However, at 8 weeks of age TUT7KO mice showed significantly increased bone mass compared to WT as determined by DEXA, mCT, and histomorphometric analyses. Serum analyses revealed an increase in OCN and OPG levels as well as a decrease in RANKL suggesting an overall increase in bone mass. *Ex vivo* analysis of bone marrow derived osteoprogenitor cells and primary calvarial OBs from TUT7KO mice demonstrated increased matrix mineralization as shown by von Kossa staining. These data suggest that TUT7 plays an important role in OB function. Interestingly, osteoclasts derived from TUT7KO mice showed no significant difference in differentiation and function as determined by TRAP staining and osteoclast activity assay. Co-culture of osteoblast and osteoclast precursors from WT and TUT7KO mice revealed that TUT7KO osteoblasts inhibited the generation of TRAP positive osteoclasts. This suggests that the role of TUT7 in bone homeostasis is predominantly mediated by the osteoblasts. Expression analyses of genes known to be important in osteogenesis showed that constitutive expression of master transcription factor osterix (Osx) was significantly upregulated in OB derived from TUT7KO mice compared to OB derived from WT littermates. Importantly genes known to be regulated by Osx were also expressed at significantly higher levels in OB derived from TUT7 KO mice. Regulation of Osx activity by TUT7 was demonstrated using an Osx reporter activity assay and inhibition of the promoter activity by overexpression of TUT7 in OB derived from TUT7 KO mice.

Conclusion: Overall, our data demonstrate that TUT7 is a negative regulator of bone formation through suppression of Osx activity in OB and influencing osteoblast-mediated regulation of osteoclastogenesis. This study is the first to demonstrate the role of TUT7 in bone formation and identifies a potential target for therapeutic interventions.

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Exosomes are small membrane vesicles (40-150 nm) of endocytic origin secreted by many types of cells and engage in cell-to-cell communication by transferring proteins, microRNAs, mRNA, and lipid to recipient cells. Exosomes are also identified in various biological fluids including blood, urine, amniotic fluid, saliva, malignant ascites, and synovial fluid. We investigated the effect of synovial exosomes on osteoclast differentiation in inflammatory arthritis.

Methods: Synovial exosomes were isolated from SF of rheumatoid arthritis (RA, n=16), ankylosing spondylitis (AS, n=7), gout (n=9), and osteoarthritis (OA, n=8) patients. The size and morphology of synovial exosomes was evaluated by transmission electron microscopy. The number of synovial exosomes was assessed by acetylcholinesterase activity and CD81-ELISA. Monocytes isolated from healthy peripheral blood mononuclear cells (PBMCs) were differentiated into macrophages by treatment of macrophage colony-stimulating factor (M-CSF). Then, macrophages were incubated with synovial exosomes without M-CSF and receptor activator of nuclear factor kappa-B ligand (RANKL). Cell proliferation was determined using cell counting kit-8 assay. Osteoclast differentiation was evaluated by tartrate resistant acid phosphatase (TRAP) stain. Cellular uptake of CFSE-labeled exosomes was analyzed by confocal microscopy.

Results: The size of synovial exosomes ranged from 20 to 150 nm. The number of exosomes in the same volume of synovial fluid was higher in SF of RA ($p=0.0235$), AS ($p=0.0135$), and gout ($p=0.2245$) patients compared to OA patients. Exosomes from RA ($p=0.8639$), AS ($p=0.0823$), or gout ($p=0.2571$) SF induced higher macrophage proliferation compared to those from OA SF but the difference was not significant. Exosomes from RA or AS SF induced osteoclastogenesis in the absence of M-CSF and RANKL. Osteoclast formation was

significantly increased in the presence of RA (p=0.01) exosomes compared to OA exosomes, but not in AS or gout. Synovial exosomes labeled with CFSE were internalized by macrophage and enriched in perinuclear space.

Conclusion: The number of exosomes was increased in SF of RA and AS compared to OA. Exosomes from SF of RA induced osteoclast differentiation.

Tenofovir, a Nucleoside Analog Reverse Transcriptase Inhibitor for Treatment of HIV, Promotes Osteoclast Differentiation and Decreases Osteoblast Formation By a Mechanism Depending on ATP Release and Adenosine

Session Date: Monday, November 14, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Human Immunodeficiency Virus (HIV) infection devastates the immune system but also affects tissues and organs such as kidney, liver, central nervous system, heart and bone. Bone alterations have been observed in HIV disease for nearly two decades, in particular a higher risk of low bone mineral density (BMD) and fragility fractures. Treatment of patients with tenofovir alone or in combination (as part of HAART), leads to changes in bone catabolism markers and significant reductions in BMD in children and young adults. Tenofovir is taken up by cells and phosphorylated; tenofovir-phosphate inhibits HIV-reverse transcriptase by mimicking AMP. We have recently found that tenofovir inhibits Pannexin-1/Connexin-43-mediated ATP release from cells and decreases extracellular adenosine levels and fibrosis in murine models. As adenosine and ATP are key regulators of bone homeostasis, we determined whether tenofovir directly affects bone by an adenosine- or ATP-dependent mechanism.

Methods: M-CSF/RANKL-induced osteoclast (OC) and stimulated osteoblast (OB) differentiation were studied in primary murine bone marrow culture as the number of TRAP-positive or Alizarin Red-positive cells, respectively, after challenge with tenofovir (1nM-100mM) alone or in combination with dipyridamole (1nM-100mM), an agent that increases extracellular adenosine by blocking cellular adenosine uptake. Pannexin-1 and Connexin-43 expression were permanently knocked down by lentiviral infection with appropriate shRNA or scrambled shRNA and these cells were induced to differentiate into OC by RANKL. Male C57Bl/6 (WT), A2AKO and A2BKO mice received tenofovir 75mg/Kg/day for 4 weeks. Double labelling of bone with calcein (15mg/Kg)/Alizarin Red (30mg/Kg) was performed and long bones prepared for mCT and histology.

Results: There was a dose-dependent increase in OC differentiation after treatment with Tenofovir (EC50=44.5nM), that was reversed by dipyridamole (IC50=0.3μM). Moreover, tenofovir inhibited OB differentiation (IC50=0.4μM) which was also reversed by dipyridamole (EC50=10nM). When both Pannexin-1 and Connexin-43 were absent, tenofovir did not increase OC number. Tenofovir treatment reduced bone formation in WT-mice (49±8μm vs 110±7μm untreated $p<0.0005$) but not in A2AKO (72±6μm vs 71±5μm untreated, p=ns) and A2BKO mice (64±8μm vs 86±9μm untreated, p=ns). mCT revealed decreased BMD and both cortical and trabecular bones were affected. TRAP-staining showed increased OCs *in vivo* in tenofovir-treated WT mice (21±1 vs 16±1 OC/hpf in untreated, $p<0.005$). There are increased osteoclasts in A2AKO mice and this was unaffected by tenofovir treatment (24±1 OC/hpf, vs 22±1 OC/hpf in untreated p=ns) and osteoclast number in A2BKO mice was unchanged (19±1 OC/hpf, vs 18±1 OC/hpf in untreated, p=ns). Similar results were obtained for Cathepsin K.

Conclusion: These results indicate that tenofovir enhances osteoclast differentiation and inhibits osteoblast differentiation by an

adenosine-dependent mechanism and suggests that treatment with agents that increase local adenosine concentrations, like dipyridamole, might prevent bone loss following tenofovir treatment.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF has been shown to contribute to osteoclastogenesis independently and in conjunction with M-CSF or RANKL, two key cytokines involved in osteoclast (OC) development. We have previously demonstrated that TNF enhances the kinetics of RANKL-induced human osteoclastogenesis and that its effects are mitigated more effectively by the anti-TNF biologic adalimumab (ADA) as compared to etanercept (ETN). To determine the mechanism responsible for the difference in effectiveness between the two biologics, a label-free quantitative proteomics study was conducted on TNF-activated human OC upon biologic treatment using an EASY Nano LC1000/ QExactive Plus LC/MS system.

Methods: Human OC precursors (OCP) were exposed for up to 5 days to M-CSF, M-CSF+RANKL (RANKL) alone or in combination with 100 ng/mL TNF +/- 5 ug/mL ADA, ETN or human IgG1 (IGG) as a pre-formed complex. OC differentiation was confirmed by measuring tartrate-resistant acid phosphatase 5b (TRAP 5b) activity. Peptides from cell lysates were generated using modified Filter Aid Sample Preparation. Sample pooling (sham) was used to minimize false discovery by applying a cut off value (ratio >150% or <66.7%) based on reproducibility between sham samples. Data was analyzed with a 3 database search algorithm through Proteome Discoverer (PD) 2.0 and a 4th algorithm using MaxQuant. Protein IDs were aggregated in Scaffold software. Relative quantification was achieved using precursor ion area extraction function within PD. Data is expressed as percentage based on ratio of ion counts of each condition to that of RANKL with differences considered significant if >150% only for proteins whose percentage between TNF and IGG conditions are similar. Flow cytometry analysis for monocyte-related markers was performed on day 4 OCP cultures.

Results: Ten OC-related proteins were identified (e.g. OSTF1, NFATC1, ACP5, CTSK, MMP9, TCIRG1, ATP6V0D2), 5 of which (underlined) were induced by TNF (>161%), decreased by ADA (<77%), but unaffected by ETN. Overall, TNF upregulated the levels of 110 proteins as compared to RANKL. A greater proportion of these proteins had levels reduced following ADA treatment as compared to ETN (69% and 20%, respectively) concordant with a greater reduction in OC maturation with ADA as to that of ETN (TRAP 5b levels of 11 and 40U/L, respectively). In addition to lowering TNF-induced protein levels concordant with neutralization by ADA, we observed indications for OCP development toward an alternative myeloid lineage based on its >1.5-fold induction of 25 proteins that are typically expressed in monocytic cells (e.g. PSMB9, DPP7 & IFI30) including 2 proteins reportedly shown to negatively regulate OC development (LGMN & ZFAND5). Moreover, several monocyte-related markers (CD14, CD163 & CD206) were increased by the ADA:TNF complex as compared to RANKL based on flow cytometry.

Conclusion: Our *in vitro* findings demonstrate that ADA treatment, unlike exposure to ETN, dramatically reduces the TNF-induced protein levels in human OC and moreover, that the ADA:TNF complex may potentially alter their proteome to a profile resembling that of a monocytic cell through an increase in negative regulators of OC development.

Session Date: Monday, November 14, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis is characterized by bone loss, increased fracture risk and reduced regeneration ability. Age-related bone loss leading to osteoporosis correlates with increased bone marrow fat infiltration and is characterized by an inverse relationship between bone mass and bone marrow adiposity. Bone marrow adipose tissue releases immunmodulatory (e.g. adipokines) and matrix-degrading proteins (e.g. matrix metalloproteinases, MMP) which promote bone loss observed in osteoporosis and osteoarthritis. Bone marrow adipocytes share mesenchymal stem cell (MSC) as precursors with osteoblasts. Therefore, adipocyte-derived factors might influence differentiation of bone marrow-derived MSC and be involved in the shift of differentiation from osteoblasts to adipocytes observed in osteoporosis. The aim was to analyze the presence of adipokines in the bone marrow cavity and their effects on MSC differentiation.

Methods: Spongiosa from femoral heads containing bone marrow were collected (hip replacement of osteoarthritis patients or after osteoporotic femoral neck fracture). Primary spongiosa-derived mesenchymal stromal cells (hMSC) and commercially obtained 'normal' MSC were cultured in adipogenic and osteogenic media 3 weeks with/without adipokines. Adipogenic differentiation was confirmed using Oil Red O staining. Realtime PCR for adipokines, bone marker genes, TIMP, MMP as well as of bone samples was performed. Matrix produced was stained and quantified using Alizarin S. Proinflammatory factors were measured by ELISA.

Results: Visfatin and leptin level were increased in osteoporotic bone (n=14) vs. non-osteoporotic bone (n=13). Visfatin induced the secretion of proinflammatory factors during both, osteogenic and adipogenic differentiation but not leptin or resistin (IL-6, IL-8, MCP-1). While MMP2 was reduced by stimulation of all adipokines during osteogenesis (n=3), visfatin reduced MMP13 expression during osteogenic differentiation (e.g. day 21: -55-fold) as well as TIMP1, -2 and RunX2 (e.g. day 21: -2.86-fold) / -3.17-fold / -5.85-fold, respectively) while leptin and resistin did not affect these parameters. Visfatin significantly increased matrix production during osteogenic differentiation. During adipogenesis, visfatin but not leptin or resistin stimulation of hMSC significantly increased MMP13 (e.g. day 21: 72-fold).

Conclusion: Visfatin and leptin were increased and resistin reduced in osteoporotic bone. MMP production was specifically reduced by visfatin during adipogenesis. Therefore, visfatin might promote bone destruction during increased adipogenic differentiation in osteoporosis. Of note, the shift towards osteogenic differentiation may be beneficial as visfatin appears to reduce MMP production during osteogenesis. Leptin had no direct effects on MSC differentiation *in vitro,* but could indirectly modulate bone degradation by affecting inflammatory cells.

Session Title: Biology and Pathology of Bone and Joint - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by chronic inflammatory synovitis leading to joint destruction and systemic bone loss. Osteoclasts are responsible for bone destruction in rheumatoid arthritis (RA). GMSCs have been demonstrated to suppress T cell responses and suppress the progress of experimental collagen induced arthritis model. This study aims to determine whether GMSCs also directly suppress osteoclastogenesis and bone erosion in collagen induced arthritis (CIA).

Methods: Osteoclasts were induced from bone-marrow cells with RANKL and M-CSF stimulation, and assessed with tartrate-resistant acid phosphatase (TRAP) staining. For human cells, osteoclasts were induced from human $CD14^+$cells. GMSCs were isolated from the volunteer donors and were generated understand a standard protocol. GMSCs were added to cultures with different ratios with BM cells. Transwell, antibody or inhibitors blockade experiments were performed to define the mechanisms of action. NF-κB activation as well as RANKL expression was determined by western blot and qRT-PCR. 2×10^6 GMSCs or fibroblast cells were adoptively transferred to DBA1/J mice on day 14 after immunization with CII/CFA. CIA onset and severity were monitored, osteoclast expression and distribution in CIA model was analyzed by TRAP stain, and bone erosion was examined by micro CT scan.

Results: GMSCs but not fibroblast cells markedly suppressed osteoclastogenesis *in vitro* for human and mice. GMSCs injected after immunization and before of onset of CIA significantly suppressed disease development. Treatment with GMSCs dramatically decreased the levels of NF-κB p65/p50 in osteoclasts *in vitro* and P65/50 and RANKL expression by synovial tissues *in vivo*. Blockade of CD73 signal significantly revised the effect of GMSCs on osteoclast formation and bone erosion.

Conclusion: We demonstrate that GMSCs dramatically and directly inhibited NF-kB- and RANKL-mediated osteoclast formation, as well as bone erosion in CIA. Manipulation of GMSCs may have therapeutic effects on rheumatoid arthritis and other bone erosion related diseases.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic tendinopathy is an inflammatory and degenerative condition caused by injuries or overuse. Current therapeutic options focus on alleviating the symptoms and pain rather than treatment of the underlying causes. The Wnt pathway plays an important role in tenocyte differentiation, and is upregulated in chronic tendinopathy. SM04755, a novel, topical, small-molecule Wnt pathway inhibitor, was evaluated in preclinical studies to determine its potential to inhibit inflammation, reduce fibrosis and increase tenocyte differentiation, thereby promoting tendon healing.

Methods: Wnt pathway inhibition was measured via cell-based reporter assay. Anti-inflammatory activity was evaluated by measuring TNFα and IL-6 secretion using ELISA in lipopolysaccharides (LPS)-stimulated THP-1 monocytes and anti-CD3/anti-CD28-stimulated peripheral blood mononuclear cells (PBMCs). Histological expression of scleraxis A (SCXA), tenomodulin and tenascin C were measured using high-content imaging to evaluate differentiation of human mesenchymal stem cells (hMSCs) to tenocytes. Pharmacokinetics were evaluated by topical application in rats, dogs and mini-pigs, followed by analysis of compound concentrations in tendon and plasma. *In vivo* efficacy of topical SM04755 was evaluated in an intra-tendon collagenase-induced rodent tendinopathy model by scoring (range 5-20) several histological indicators of tendon health. Inflammation in the rodent model was measured by chemokine ligand 1 (CXCL1) levels in plasma by ELISA and other inflammatory markers in the tendon by qPCR. Tendon regeneration was evaluated by qPCR based gene expression of tenocyte differentiation markers- SCXA and tenascin C.

Results: SM04755 demonstrated potent (EC_{50}=152nM) and selective inhibition of Wnt signaling. SM04755 inhibited both LPS and anti-CD3/anti-CD28 induced TNFα and IL6 secretion (EC_{50}=500nM) in THP-1 cells and PBMCs. SM04755 induced differentiation of hMSCs into SCXA, tenomodulin, and tenascin C expressing tenocytes (EC_{50}=200nM). A single topical application of SM04755 resulted in tendon concentrations >EC50 for up to 24hrs, with minimal systemic drug exposure or toxicity. In the collagenase-induced model, SM04755 treatment significantly increased the mean tendon health score ($p<0.01$, n=6), decreased the plasma levels of CXCL1 ($p<0.05$), reduced gene expression of pro-inflammatory markers (IL-6, TNF-a, IL-1b, INF-g, IL-8) ($p<0.05$), and increased expression of SCXA and tenascin C in tendon compared to vehicle.

Conclusion: Topical SM04755 reduced tendon inflammation and an inflammatory marker in plasma, showed evidence of tendon regeneration, and increased tendon health scores compared to vehicle in a rodent tendinopathy model. Plasma exposure and systemic toxicity were minimal. SM04755 demonstrates potential to promote tendon healing in chronic tendinopathy.

Figure. SM04755 inhibited inflammation and promoted tendon healing in a rat collagenase-induced tendinopathy model

Session Date: Monday, November 14, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity is associated with an increased risk of osteoarthritis also in non-weight bearing joints and increased amounts of visceral fat are associated with lower bone density. This observation and the association of chronically elevated free fatty acid (FFA) serum levels with a number of inflammatory cardiovascular and metabolic diseases suggest that FFA may also play a role in inflammation-related bone loss. We therefore analyzed the effect of FFA on the central cells of bone metabolism, i.e. osteoblasts and osteoclasts, in the context of rheumatic diseases.

Methods: Primary osteoblasts (OB) were isolated from cancellous bone of OA and RA patients undergoing knee joint surgery. Osteoclasts (OC) were differentiated from peripheral blood mononuclear cells (PBMC). OB and OC were stimulated with the saturated FFA palmitic acid (PA) and the unsaturated FFA linoleic acid (LA). Immunoassays were used to quantify protein secretion. mRNA expression levels were quantified by real-time PCR. Mineralization activity was quantified using Alizarin Red S staining, differentiated OC were quantified by counting TRAP-positive multinuclear cells. Toll-like receptor (TLR) 4 and TLR2 were blocked by neutralizing antibodies.

Results: OB secreted increased amounts of the proinflammatory cytokine IL-6 (up to 9-fold) as well as the chemokines IL-8 (up to 221-fold), GRO-a (from below detection level to detectable levels) and MCP 1 (up to 16-fold) upon stimulation with PA or LA. The degree of response was highly dependent on the patient. RANKL as well as OPG, important regulators of osteoclastogenesis and OC activity, remained unaffected by FFA on protein and mRNA level. OB activity appeared unaffected because alkaline phosphatase (ALP) and collagen type I mRNA expression as well as production of inorganic matrix was not altered. Differentiation markers of OB (e.g. osteocalcin) also remained unchanged after FFA stimulation. PA-induced IL-8 secretion by OB could be significantly reduced by TLR4 blockade (by 93%), while blocking TLR2 had no effect. Secretion of IL-8 by RA OC was increased by FFA, while MMP-9 was reduced. The number of TRAP positive multinuclear cells decreased (by around 50%). However, markers of osteoclast activity (CLCN7, CTSK, TCIRG) remained unchanged at the mRNA level.

Conclusion: Our results clearly suggest a pro-inflammatory effect of certain FFA on osteoblasts and osteoclasts. While this can indirectly contribute to bone loss, the reduced number of mature OC after FFA stimulation suggests an inhibitory effect on bone resorption. The effect of FFA on cells of bone metabolism therefore appears to be divergent. The effects on osteoblasts are at least in part mediated by TLR4, while TLR2 is not involved.

Test of the Spleen Tyrosine Kinase Inhibitor Fostamatinib in a Translational Joint Tissue Model Show Significant Effect on Bone, but Not on Synovial Tissue

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Spleen tyrosine kinase (Syk) inhibitor fostamatinib was not approved as treatment for rheumatoid arthritis (RA) due to insufficient effect on joint structure in the phase III OSKIRA-1 study. Here we use a translational model system to investigate the direct effect of Fostamatinib on the extracellular matrix (ECM) of the target tissues (cartilage, bone, and synovium) for a better understanding of the insufficient effect in joint structure found in OSIKRA-1.

Methods: Human mature osteoclasts (HOC) seeded on bone, bovine cartilage explants (BEX) and human synovial explants (SME) were treated with the active metabolite of Fostamatinib, R406, at 5μM-0.05μM. Osteoclasts were co-stimulated with 25 ng/ml M-CSF and RANKL, while BEX and SME were co-stimulated with TNFα 2 ng/mL and OSM 10 ng/mL (O+T) or TNFα 10 ng/mL, respectively. CTX-1 and Calcium (Ca^{2+}) were measured in conditioned medium (CM) from HOC. Metabolic activity of HOC was assessed with Alamar Blue®. C2M and AGNx1 were measured in CM from BEX, while acMMP3, C1M, and C3M were measured in CM from SME. The biomarkers in BEX and SME CM were measured at 4 time points and the total release were quantified by area under the curve (AUC). CTX-1, C2M, AGNx1, acMMP3, C1M, C2M and C3M were measured with ELISA. $Ca^{2+}$was measured with ADVIA Chemistry system. Statistical differences of metabolic activity was calculated with One-way ANOVA with Dunnett's multiple comparison test. Statistical differences between biomarkers levels or AUC were calculated with Kruskall Wallis test with Dunn's multiple comparision test.

Results: R406 decreased the release of CTX-1 (Fig 1A) and Ca^{2+} in a dose-dependent manner, with a significant decrease at 1μM ($P<0.01$). This might be due to a toxic effect of R406 on HOC (Fig 1B) ($P<0.05$). In cartilage, R406 decreased the total release of C2M and AGNx1 in a dose-dependent manner. C2M was inhibited a concentrations down to 1.25μM ($P=0.034$), and AGNx1 down to 5μM ($P=0.012$). In synovial explants, R406 tended to decrease release of C3M (Fig 1e), C1M and acMMP3 (Fig 1f) at 5μM, but this was not significant.

Conclusion: Serum-based biomarkers of the joint ECM turnover were measured in CM from HOC, cartilage and synovial explant cultures. R406 decreased bone resorption and HOC metabolic activity in a dose-dependent manner, together with the MMP-mediated degradation of type II (C2M) collagen and aggrecanse degradation of aggrecan (AGNx1) in cartilage. However, R406 had limited effect on the inflammation driven MMP-mediated degradation of type I (C1M) and III (C3M) collagen and activation of MMP-3. From these data it is expected that Fostamatinib would have some effect on bone and cartilage, but not on inflammation driven degradation of the synovium.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Cartilage destruction is accompanied by a tremendous loss of life quality due to deprivation of agility, flexibility and pain. Additionally, increased catabolic mediators such as inflammatory cytokines, matrix-degrading enzymes or bioenergetic-relevant proteins play a crucial role in the pathogenesis of rheumatic disorders such as OA and RA. However, therapeutic approaches including the cartilage restoration or replacement combined with anti-inflammatory properties are still elusive. Therefore, promising approaches link tissue engineering to gene therapy. To overcome critical challenges such as transient therapeutic effects as well as undesirable long-lasting overexpression of transgenes, several approaches focus on the expression control and optimization of viral vectors applied either directly or by a cell therapeutic approach.

Therefore, we aimed at engineering scaffold-free cartilage transplants (SFCTs) using the transgenic expression of the chondroprotective IL-4 under the control of the cyclooxygenase-2 promoter (pCox-2) being activated by the presence of and inactivated in the absence of inflammatory mediators and co-expressing the green fluorescence protein (GFP).

Methods:

First, the gene therapeutic approach (pCox-2 and IL-4) was tested by transient transfection of primary equine chondrocytes, subsequent activation with IL-1β and TNF-α and detection of inflammatory marker and matrix degrading enzyme gene expression (*IL1B, TNFA, IL6, IL8, COX2* and *MMP1, MMP3*). Secondly, the equine and human sequences of pCox-2 and IL-4 were subcloned into a lentiviral-based GFP-co-expressing vector backbone. Thirdly, to assess the durability of GFP-expression SFCTs were generated from primary chondrocytes, transduced and monitored for up to 4 months. Finally, to simulate OA, SFCTs were stimulated with IL-1β and TNF-α for 3 weeks and cultivated afterwards under non-stimulating conditions to determine the regenerative potential. Subsequently SFCTs were analyzed with regard to the inflammatory marker / matrix degrading enzyme gene expression and histological changes (Collagen I/II).

Results:

Feasibility and functionality of the gene therapeutic approach including the genetic switch was demonstrated by IL-4 mediated inactivation of inflammatory marker gene expression and matrix degrading enzyme gene expression. Generated SFCTs achieved diameters up to 1 cm. GFP-expression within transduced SFCTs was stable for up to 4 months. After stimulation of SFCTs with IL-1β and TNF-α, the inflammatory marker gene expression and matrix degrading enzyme gene expression was increased as compared to the untreated controls. The histological findings showed increased softening and wateriness of the tissue. A histological redistribution of Collagen I and II production could be demonstrated. The observed effects were reversible after 3 weeks of regeneration.

Conclusion:

First results show the feasibility and functionality of the gene therapeutic approach, promising features (stability and integrity) of our new generation cartilage transplants combined with gene therapy where the therapeutic gene will be expressed in a disease responsive way. Further investigations are needed to test and optimize the system.

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Immature dendritic cells (DCs) can develop into osteoclasts (OCs), however, the mechanisms regulating this differentiation switch are not yet understood. We have shown that protein citrullination can play important roles in OC differentiation, both at steady state and in rheumatoid arthritis (RA) when anti-citrulline protein antibodies (ACPAs) induce bone erosion through an IL-8 mediated induction of OC development. In the present study we analyzed how protein citrullination and ACPAs regulate differentiation plasticity towards the OC lineage in DCs.

Methods: We have previously shown that the endogenously produced lactic acid (LA), a glycolysis side product, can increase the ability of developing DCs to differentiate into osteoclasts in dense cell cultures, whereas sparse cultures, associated with low LA levels, promoted the development of immunostimulatory DCs with little ability to form OCs. By exploiting this mechanism we generated different monocyte-derived DC types in parallel with macrophages and cultured these cells in presence of M-CSF and RANKL to induce OC development. Mass spectrometry was applied to analyze protein expression and citrullination at different stages of OC differentiation. Activity of peptidylarginine deiminases, the enzymes responsible for protein citrullination, was measured by ELISA, cytokine levels were analyzed using CBA technology. We studied in detail the autocrine effects of IL-8 in OC cultures.

Results: Citrullinated-actin peptides were identified in all stages DC-OC transdifferentiation and citrullinated-vimentin peptides were identified in mature OCs. Expression of PAD2 and PAD4 increased during DC differentiation and PAD activity was detected in both DCs and OCs. Interestingly, the efficiency of DC-OC transdifferentiation correlated with the level of PAD activity and with higher detection of citrullinated peptides in DCs. The PAD inhibitor Cl-Amidine efficiently interfered with OC development form DC precursors. Polyclonal and certain monoclonal ACPAs increased osteoclastogenesis from DCs and the intensity bone resorption. DC-derived OC differentiation was inhibited by Cl-Amidine in the presence of ACPAs. The IL-8 receptors CXCR1 and CXCR2 were present on immature DCs and the increased osteoclastogenesis was associated with elevated IL-8 levels in ACPA-treated cultures. IL-8 neutralization blocked the ACPA-mediated increase of OC development.

Conclusion: Our results indicated that DCs are heterogenic in their ability to form OCs and the differentiation plasticity towards the OC lineage might be influenced by protein citrullination. The increase of LA at sites of immune activation might play an important role in the reprogramming DCs and increasing OC development. Antibodies that target citrullinated proteins and have been suggested to play an improtant pathogenic role in RA-associated bone destruction ACPAs can further increase osteoclastogenesis from DCs through an IL-8 dependent mechanism, which further support OC development in an autocrine manner. Blocking IL-8 and PAD activities represent important therapeutic possibilities that might interfere with DC transdifferentiation into OC and ACPA-induced bone damage.

Background/Purpose: Increased circulating levels of Interleukin-8 (IL-8) have been linked to the bone loss associated with breast cancer metastasis. Recently, we have shown that anti-citrullinated protein antibodies (ACPAs) can induce bone loss and pain-like behavior in mice through an IL-8 dependent mechanism. We aimed to further investigate the role of IL-8 and the IL-8 receptor molecules CXCR1 and

CXCR2 in osteoclasts (OC) development in the presence or absence of ACPAs.

Methods: ELISA was used to measure IL-8 in the serum of ACPA-positive patients with arthralgia and seronegative healthy controls and in the synovial fluid of RA and spondylarthropaty patients. Peripheral blood CD14-positive monocytes were used to generate OCs in the presence of M-CSF and RANKL. Expression levels of IL-8 and CXCR1/2 were measured during OCs maturation using ELISA, RT-PCR, flow cytometry and immunostaining. Inhibition of IL-8 and its receptors were performed in OC cultures using IL-8 neutralizing antibodies and small molecule CXCR1 and CXCR2 antagonists (Reparixin, SCH-527123, SB-332235), in the presence or absence of ACPAs. OC numbers were counted using light microscope after TRAP staining. Cytotoxicity was monitored with Cell counting kit 8 (CCK8).

Results: Serum IL-8 levels were significantly higher in the serum of ACPA-positive patients with arthralgia, as compared to ACPA-negative healthy individuals. Synovial fluid of ACPA-positive RA patients contained significantly higher levels of IL-8 as compared to spondyloarthritis patients. Endogenous IL-8 increased gradually in the maturing OC supernatants and exogenous IL-8 dose dependently increased RANKL-mediated OC development. IL-8 neutralizing antibodies inhibited OC differentiation with or without ACPAs. Reparixin and SCH-527123 significantly inhibited the RANKL-mediated osteoclastogenesis at doses as high as 80µM concentration, without inducing detectable toxicity. SB-332235, an inhibitor characterized by higher selectivity towards CXCR2, inhibited OC development at a concentration of 10µM. CXCR1 and CXCR2 expressions were detectable on the cell membrane of macrophages and decreased during OC differentiation. Expression of the CXCR1 and CXCR2 genes in developing OCs was weak and variable. Immunohistochemistry stainings confirmed the cell surface expression of CXCR1, and to a lesser extent of CXCR2, with high amounts of both of these receptors being present intracellularly during OC maturation.

Conclusion: Serum IL-8 is a potential biomarker for ACPA-positive arthralgia and possibly for the bone loss described in these patients. Small molecule CXCR2 antagonists might provide novel therapeutic tools for targeting OCs in RA.

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A major manifestation of Hemophilia A, an X-linked bleeding disorder, is hemophilic arthropathy (HA), a debilitating degenerative joint disease that is caused by intraarticular bleeding. HA typically begins with haemophilic synovitis (HS), hypertrophy of synoviocytes with inflammation of the synovium and a neovascular response, followed by joint erosion and, ultimately, arthropathy with cartilage destruction and erosion of the underlying bone. HS has features in common with inflammatory arthritides such as rheumatoid arthritis (RA). The pro-inflammatory TNFα is a major target for treatment of RA. TNFα is synthesized as a membrane-anchored precursor that is released by the TNFα convertase (TACE, also referred to as ADAM17). We have recently uncovered a crucial role for TACE and its regulator, inactive Rhomboid family member 2 (iRhom2), in the pathogenesis of inflammatory arthritis in mice. Since RA is caused, at least in part, by inappropriate release of TNFα, we hypothesize that iRhom2/TACE/TNFα also have pivotal roles in promoting HA.

Methods: To determine whether blood cells induce TNFα shedding, we exposed macrophages from WT and iRhom2-/- mice to intact and lysed red blood cells (RBC) and measured TNFα in supernatants. We used a joint puncture model in *Fviii-/-*, *Fviii-/-Tnfa-/-*, *Fviii-/-iRhom2-/-* and *Fviii-/-* etanercept-treated mice to simulate intra-articular bleeding. TNFα in the joint was measured on day 2 after puncture, and histological analyses and microCT were performed at 2 weeks.

Results: Treatment of WT macrophages with intact and lysed RBC *in vitro* activated TNFα shedding, but not in macrophages lacking iRhom2. *In vivo* studies of *Fviii-/-* mice subjected to knee joint puncture showed severe hemarthrosis and high elevated levels of TNFα on day 2 and synovial invasion with enhanced neovascularization in the joint space and cortical thickening of bone on day 14 compared to WT. MicroCT analysis showed a significant decrease in trabecular bone volume (-75%±12, n=8 mice), number of trabeculae (-40%% ±10), and a significant increase in trabecular separation (+71%%±35) in the punctured knee compared to the contralateral non-puncture knee. Inactivation of TNFa in *Fviii-/-* mice using TNFα-/-, iRhom2-/- and etanercept-treatment dramatically and significantly ($p<0.01$, n=7-9 per group) reduced the osteopenia in the HA/HS model and improved bone trabecular parameters compared in *Fviii-/-* mice. TRAP staining demonstrated that the bone loss in *Fviii-/-* mice was mainly caused by a local increase in osteoclast number (+132%±63) and osteoclast surface per bone surface which was abrogated in *Fviii-/-Tnfα-/-, Fviii-/-iRhom2-/-* and *Fviii-/-* etanercept-treated mice. Immunohistochemistry studies showed that although all of mice developed synovitis, the number of macrophages in the synovial membrane was markedly reduced in *Fviii-/-Tnfα-/-* and *Fviii-/-iRhom2-/-* compared *to Fviii-/-*.

Conclusion: Our results support the hypothesis that the iRhom2/ADAM17/TNFα signaling pathway contributes to the pathogenesis of HA/HS and the associated osteopenia observed in HA/HS patients and suggest that this pathway as a target for treatment.

Huntingtin Interactin Protein 1 (HIP1) Regulates Receptor Tyrosine Kinases Mediated Activity and Cell Invasiness in Fibroblast-like Synoviocytes

Teresina Laragione, Nasim Azizgolshani, Carolyn Harris, Erjing Gao and Percio Gulko, Medicine/Rheumatology, Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Huntingtin-interacting protein 1 (Hip1) is a new arthritis severity gene recently identified in the Pristane and Collagen-induced arthritis (PIA, CIA) quantitative trait locus Cia25/Pia42 on rat chromosome 12. This study aimed to characterize the mechanism of action of Hip1 in arthritis.

Methods: Synovial tissues and fibroblast-like synoviocytes (FLS) were obtained from DA and DA.ACI(Cia25/Pia42) subcongenic R6 (R6) rats (day 21 after the onset of PIA). FLS from DA and the DA.ACI(Cia25/Pia42) subcongenic R6 (R6) were treated with PDGF, EGF, 10% FBS or 0.1% FBS and studied for a) *in vitro* invasion in a two-chamber assay through Matrigel, b) proliferation, c) gene expression (qPCR) analysis. DA and rheumatoid arthritis (RA) FLS were also studied following siRNA knockdown of Hip1. Tissues from Hip1 knockout mice were used for qPCR.

Results: Synovial tissues from DA rats expressed higher levels of Hip1 compared with DA.ACI(Cia25/Pia42) (1.78-fold). FLS from DA were five-fold more invasive than FLS from protected DA.ACI(Cia25/Pia42)-R6 subcongenics. Hip1 siRNA knockdown reduced the invasiveness of DA FLS and RA FLS by 60% and 50%, respectively demonstrating a critical role for Hip1 in cell invasion. Hip1 is known to interact with receptor tyrosine kinases (RTKs). Therefore, we examined 84 PDGF pathway genes in FLS and detected 16 up and 12 down in DA, compared with R6 subcongenics, including PDGFR, IGFR and EGFR. siRNA knock down of Hip1 in DA FLS reduced the levels of these RTKs to nearly zero, with similar reductions in expression levels detected in tissues from Hip1 knock-out mice. We examined cell invasion in response to PDGFb and detected a more pronounced increase on mean DA FLS invasiveness (12-fold) compared with R6 FLS (7-fold). In the presence of low serum conditions (0.1% FBS) DA FLS also had increased growth rate compared with R6 subcongenic FLS, a characteristic previously reported in Hip1 transfected cells.

Conclusion: We describe new evidence suggesting increased expression and activity of Hip1 in arthritis-derived FLS. Our results suggest that Hip1 regulates different aspect of FLS behavior favoring survival and proliferation, as well as invasivess in FLS from arthritic rats and from patients with RA. Hip1 also regulates the expression levels and activity of RTKs and their response to ligands such as PDGFb. These new discoveries provide new understanding about event regulating FLS behavior in arthritis and have the potential to generate a new prognostic biomarkers and a new intra-cellular target for therapy.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Dysregulation of neutrophil activation is important in the pathogenesis of various inflammatory and autoimmune rheumatic diseases (ARDs), including RA, SLE and APS. Neutrophils are exquisitely sensitive to their environment and neutrophil function can be modulated by numerous factors including cytokines, circulating IgG and localised tissue hypoxia (0.5-2.7% O_2). One mechanism of neutrophil activation results in the release of a meshwork of chromatin fibres decorated with antimicrobial proteins, called neutrophil extracellular traps (NETs). Aberrant NETosis has been described in various ARDs. We have previously shown that purified IgG and hypoxia promotes NETosis, however the underlying mechanism is unknown. Integrin engagement modulates several aspects of neutrophil function including: adhesion, cytokine production, NETosis and reactive oxygen species (ROS) generation. Therefore, we investigated the effects of hypoxia upon neutrophil integrin expression, adhesion to immobilised ligands and endothelial cells and trans-endothelial migration (TEM) to better understand the effects of hypoxia upon the stages preceding NETosis.

Methods: Neutrophils were isolated from whole blood donated by healthy controls (HC) and cultured under normoxia (21% O_2) or hypoxia (1% O_2). NETosis was visualised by immunofluorescence (IF) staining for histone H3. Levels of surface integrin expression of α_1 (CD49a), α_4 (CD49d), α_5 (CD49e), α_L (CD11a), α_M (CD11b), α_X (CD11c), β_1 (CD29) and β_2(CD18) were measured by flow cytometry. Assessment of 2',7'-bis-(2-carboxyethyl)-5-(and-6)-carboxyfluorescein, acetoxymethyl ester (BCECF-AM)-labelled neutrophil adhesion to immobilised fibrinogen, fibronectin and intercellular adhesion molecule (ICAM)-1 and human umbilical cord endothelial cells (HUVEC) was measured using a fluorescent plate reader. Neutrophil TEM across HUVEC monolayers was measured by flow cytometry.

Results: IF studies found that NETosis was inhibited by EDTA treatment, indicating cation-dependent integrin involvement. Moreover, NETosis could be induced by integrin activation with either Mn^{2+} or macrophage-1 antigen (Mac-1, $\alpha_M\beta_2$)-specific activation with leukadherin-1. Hypoxia significantly increased expression of α_M ($p<0.001$) and α_X($p=0.038$) in HC neutrophils compared to normoxia ($n=7$). Adhesion to immobilised fibrinogen, fibronectin and ICAM-1 were all significantly reduced under hypoxia ($p<0.01$, $p<0.01$ and $p<0.01$ respectively). In contrast, hypoxia enhanced both unstimulated ($p<0.01$) and LPS-stimulated ($p<0.001$) adhesion to and TEM across HUVEC monolayers ($p<0.05$) compared to normoxic controls.

Conclusion: Hypoxia significantly increased neutrophil: expression of α_M and α_X integrin subunits; adhesion to HUVEC but not immobilised integrin ligands; and TEM across HUVEC monolayers. Further work is currently underway to dissect the molecular and signalling mechanisms that regulate neutrophil function under hypoxia and whether ARD-IgG further modulate these responses.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mast cells (MCs) are immune cells that produce and secrete a variety of mediators and cytokines, which influence various inflammatory and immune processes. It has become clear that MCs were not only related to allergic reactions, but also involved in several autoimmune diseases. However, the role and precise mechanism of MCs on the pathogenesis of primary Sjogren¡¯s syndrome (pSS) is not completely understood. Leptin is a protein secreted by adipose tissue, which has an important role in metabolism and immunity. MCs were found to express leptin receptors. It is therefore plausible that leptin, through its effects on MCs, may play an important role in the development of pSS. The present study aimed to investigate the distribution of MCs in labial salivary glands in an attempt to elucidate a possible role of MCs in the pSS pathogenesis. Furthermore, this work explored the correlation between MCs and leptin in the pSS.

Methods: All recruited patients fulfilled the American-European Consensus Group criteria for primary SS. The labial salivary glands were obtained from patients with pSS. Mast cell count in labial salivary glands was studied by toluidine blue stain and immunohistochemical staining using monoclonal antibody against tryptase. Serum leptin and tryptase were measured by enzyme-linked immunosorbent assay.

Results: Serum leptin and trypase in pSS patients were significantly higher than that of healthy control. The leptin concentrations were positively correlated with trypase levels in pSS patients (Fig 1). Both the toluidine blue and immunohistochemical stain showed that distribution of MCs was absent from lymphocyte foci, and was preference for location in the connective tissue. MCs were more common in salivary glands in pSS patients than in healthy controls. The MCs were more frequent in labial salivary glands with severely lymphocytic infiltration than those with slightly lymphocytic infiltration, which indicated the number of MCs positively correlated with the disease activity (Fig 2).

Conclusion: Our findings suggested that the proinflammatory role of MCs in the pathogenesis of SS was related to leptin. Treatment with leptin antagonists might be a potential target to control inflammatory activities of MCs in SS. **Figure 1**

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a progressive and degenerative joint disease with chronic synovial inflammation in multiple joints. Interestingly, the symmetry and spreading of the disease to multiple joints are clinically significant signs of RA, but not fully understood. Our hypothesis is that circulating extracellular vesicles (cEVs) obtained from blood of RA patients contribute to the polyarticular and systemic involvement of this disease. In this study we measured cytokines in platelet free plasma (PFP) and plasma EVs from RA patients and healthy controls (HC). Furthermore, we analyzed the biological activity of cEVs using functional studies in human monocytes (THP-1).

Methods: cEVs were obtained sterile from PFP of 21 RA patients or 15 HC (age matched) by size exclusion chromatography (SEC). Protein content of cEVs was measured by micro-BCA and characterized by Nanoparticle Tracking Analysis and electron microscopy. Level of TNFα, IL-1β, IL-6, IL-8, IL-10 and MCP-1 in PFP and cEVs were measured by Luminex. To study the functionality, 50.000 THP-1 cells were incubated for 24h with RA- or HC-cEVs and cytokine production was measured in supernatant by Luminex.

Results: The particle size and concentration of RA-cEVs (105 nm, 4.74 $x10^{10}$ particles/ml) were not different from HC-cEVs (106 nm, $4.40x10^{10}$ particles/ml). Protein content was also not significant different (RA;211 µg/ml, HC;176 µg/ml). In RA-cEVs the levels of TNFα, IL-1β, IL-6, IL-10 and MCP-1 were significant enhanced (RA-cEVs: 71,8,30,22 and 26 pg/ml ; HC-cEVs: 1,0,3,0 and 9 pg/ml resp.) while in PFP only levels of IL-1β and IL-6 were significant increased (RA-cEVs: 15 and 112 pg/ml, HC-cEVs: 1 and 5 pg/ml resp.). THP-1 cells exposed to cEVs were activated shown by enhanced production of IL-8. Cells incubated with RA-cEVs showed significant higher protein production of MCP-1 (45%) while TNFα, IL-1β and IL-6 were undetectable.

Conclusion: This study showed that cEVs obtained from platelet free plasma of RA patients contains cytokines and were able to stimulate THP-1 cells to release pro-inflammatory proteins. For that, it is plausible that cEVs contribute to the systemic nature of this disease.

Non-Esterified Fatty Acids Are Associated with Clinical Features and an Enhanced Th1 Response in Rheumatoid Arthritis: Towards Disease Profiling

Javier Rodríguez-Carrio[1], Mercedes Alperi-López[2], Patricia López[1], Francisco Javier Ballina-García[2] and Ana Suárez[1], [1]Area of Immunology, Department of Functional Biology, University of Oviedo, Oviedo, Spain, [2]Department of Rheumatology, Hospital Universitario Central de Asturias, Asturias, Spain

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Non-Esterified Fatty Acids (NEFA) are important lipid mediators which can play a role in a number of biological functions other than energy supply. NEFA are known to regulate gene expression in monocytes and macrophages, as well as to modulate of $CD4^+$ T-cell function. Thus, we hypothesized that altered NEFA levels may underlie rheumatoid arthritis (RA) pathogenesis.

Methods: NEFA serum levels (palmitic, stearic, palmitoleic, oleic, linoleic, g-linoleic, arachidonic –AA–, linolenic, eicosapentaenoic –EPA– and docosahexaenoic –DHA–) were quantified by LC-MS/MS after methyl-*tert*-butylether (MTBE)-extraction in 124 RA patients (all fulfilling 2010 ACR/EULAR RA criteria, 61.2% RF+, 59.6% ACPA+) and 56 healthy controls (HC). Moreover, 13 prospectively-followed RA patients undergoing TNFa-blockade were recruited. $CD4^+$ T-cell phenotype was studied by flow cytometry. TNFa, IL-8, VEGF, GM-CSF, IFNg, IL-17, MCP-1, IP-10, leptin and resistin serum levels were quantified by immunoassays. The effect of NEFA on IFNg production by PBMC was evaluated in vitro.

Results: Lower levels of palmitic ($p<0.0001$), palmitoleic ($p=0.002$), oleic ($p=0.010$), arachidonic ($p=0.027$), EPA ($p<0.0001$) and DHA ($p<0.0001$) were found in RA, some NEFA being altered at onset. No differences in total NEFA level were observed ($p=0.157$), thus pointing to an altered NEFA profile in RA. Cluster analysis identified a FFA profile ($NEFA^{low}$) characterized by increased stearic and decreased EPA and DHA levels to be overrepresented in RA patients compared to HC ($p=0.002$) (Figure 1). $NEFA^{low}$ profile was associated with clinical features (RF, shared epitope and erosions), increased IFNg expression in $CD4^+$ T-cells ($p=0.002$) and a Th1-enhanced serum milieu (IFNg, MCP-1 and IP-10, all $p<0.005$). In vitro assays demonstrated that imbalanced NEFA could underlie IFNg production by $CD4^+$ T-cells. Finally, changes on NEFA levels were associated with clinical response upon TNFa-blockade, decreasing EPA and DHA being related to a poor clinical outcome.

Conclusion: An altered NEFA profile can be found in RA patients associated with clinical characteristics of aggressive disease and Th1-enhanced response. Impaired NEFA levels may underlie a poor clinical outcome upon TNFa-blockade. A complex NEFA profile was observed, specific NEFA being altered independently of their chemical properties. These results support the relevance of lipidomic studies in RA and provide a rationale for new therapeutic targets.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Synovial fibroblasts (SFs) contribute to rheumatoid arthritis (RA) pathogenesis by growing into the synovial space and by producing pro-angiogenic and tissue remodelling factors, chemokines and inflammatory cytokines that recruit and stimulate various immune cells. We have recently demonstrated that anti-citrullinated proteins antibodies (ACPAs) promote osteoclastogenesis through an interleukin-8 (IL-8) dependent autocrine mechanism. In the present work we investigated alterations of synovial fibroblast morphology and behaviour in response to ACPAs, including signalling transduction, cytokine production and mobility.

Methods: SFs were isolated from synovial tissue of RA patients by enzymatic digestion. Polyclonal ACPA and others non-ACPA IgGs were separated from peripheral blood of RA patients by affinity purification on cyclic citrullinated peptide (CCP)-2 column. SF migration capacity were tested by scratch-assays in presence of various stimuli, including ACPAs, non-ACPA IgGs, TNF and IL-8 using starved

cells. The results were evaluated by NIH ImageJ software. SF adhesion was analyzed by xCELLigence System Real-Time Cell Analyzer (ACEA bioscience). Cytokine production was detected in supernatant by cytometric bead array. Signaling cascades were targeted using inhibitors of phosphoinositide 3-kinase (PI3K), phosphatase and tensin homolog (PTEN), G-protein coupled receptors (GPCRs), focal adhesion kinase (FAK) and peptidylarginine deiminases (PAD) in scratching assays. Protein phosphorylations were monitored by western blot.

Results: Polyclonal ACPAs but not non-ACPA IgGs induced migration (a fold increase of 2.6±0.5, mean±SD, $p<0,05$) and adhesion (a fold increase of 1.3±0.1 at 6 hours, $p<0.05$) after starvation. The cytokines TNF and IL-8 synergistically increased SF migration in presence of ACPAs. By inhibiting PADs, the enzymes responsible for protein citrullination, we showed that PAD activity is needed for the ACPA effects but not for baseline SF mobility. GPCR and PI3K blocking inhibited the effects of ACPAs whereas PTEN blocking enhanced migration, indicating important roles for GPCR and PI3K in the ACPA-mediated SF modulation. Immunoblot analysis revealed an increased AKT phosphorylation in ACPA-treated cells, further suggesting the involvement of PI3K in the ACPA-mediated signals.

Conclusion: ACPAs promote SFs migration and adhesion acting synergistically with IL-8 through a PAD-dependent pathway. Our findings suggest that SFs might have an active role in the ACPA-dependent disease propagation from the bone marrow to synovial tissue during RA.

Session Time: 9:00AM-11:00AM

Background/Purpose: Myeloid cell leukemia (Mcl-1) phosphorylation at Ser64 position (p-Mcl-1^{Ser64}) has been shown to enhance Mcl-1's stability and resistance to proteasomal degradation. However, the role of p-Mcl-1^{Ser64} in rheumatoid arthritis synovial fibroblasts (RASFs) resistance to TNF-α-induced apoptosis and the influence of ubiquitin and de-ubiquitin ligases in regulating Mcl-1 resistance is not yet studied in RA. This study was undertaken to understand the posttranslational mechanism of Mcl-1 regulation by epigallocatechin-3-gallate (EGCG), a potent anti-inflammatory molecule found in green tea, in human RASFs.

Methods: The expression of p-Mcl-1^{Ser64} and of the Mcl-1-specific ubiquitin ligases (Mule/Huwe1 and β-TrCP), and de-ubiquitin ligase (USP9X) was determined in SFs from RA, osteoarthritis (OA), and non-diseased (NL) SFs. Efficacy of an acute EGCG concentration (50 μM) or physiologically-achievable chronic concentrations (0.1-1 μM) were tested in regulating these posttranslational modifications in RASFs using Western blotting and immunoprecipitation methods. $P<0.05$ was considered significant.

Results: The levels of p-Mcl-1^{Ser64}, which enhances its anti-apoptotic property, was markedly upregulated in human RASFs compared to OASFs or NLSFs ($p<0.05$). Pretreatment of RASFs with EGCG (50 μM) for 24 h markedly inhibited p-Mcl-1^{Ser64}and total Mcl-1 expression and enhanced the expression of pro-apoptotic proteins (Bak and Bax) in TNF-α stimulated RASFs. Western blotting evaluation of the posttranslational processes showed a significant decrease in the expression of Mcl-1-specific ubiquitin ligases Mule/Huwe1 (~82%) and β-TrCP (~75%) in RASFs compared to NLSFs ($p<0.05$). However, the expression of Mcl-1-specific de-ubiquitin ligase, USP9X, was not significantly different between RASFs and NLSFs. Interestingly, Western blot analysis of samples immunoprecipitated with Mcl-1 antibody showed a reduced association with β-TrCP and an increased association with USP9X in RASFs compared to NLSFs. EGCG treatment significantly induced the expression of Mule/Huwe1 and β-TrCP in TNF-α-stimulated RASFs. In addition, Mcl-1

immunoprecipitation in the EGCG treated RASFs showed a marked decrease in Mcl-1-associated USP9X and an increase in Mcl-1-associated β-TrCP in TNF-α-stimulated RASFs compared to TNF-α alone group. The majority of beneficial effects of a single-dose EGCG (50 μM) were mimicked by the repeated RASF treatment for 7 days with EGCG (1 μM) to attain physiological concentrations of EGCG, if consumed in the form of green tea supplement.

Conclusion: This study provides a novel evidence that EGCG induces Mule/Huwe1 and β-TrCP ubiquitin ligases and inhibits USP9X de-ubiquitin ligase that are Mcl-1-specific, thereby, facilitating Mcl-1 degradation in RASFs and possibly regulating tissue invasion and destruction in RA.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is an autoimmune disease with various subsets and wide-ranging clinical manifestations. T lymphocytes are the predominant cell type found in lesions, but plasmacytoid dendritic cells (pDCs) and myeloid dendritic cells (mDCs) also play a pivotal role in the pathogenesis. Although antimalarials are the primary treatment for CLE, the exact mode of action is still not completely understood. To figure out the determining factor of treatment response to antimalarials in CLE patients, inflammatory cell infiltrates and cytokine profiles in lesional skin of CLE patients were evaluated.

Methods: Thirty-two skin biopsies of CLE patients (SCLE; n=13, DLE; n=19) were immunohistochemically investigated for the presence of pDCs, mDCs, neutrophils, and macrophages by employing antibodies against CD123, CD11c, MPO, and MAC387 respectively. Skin sections were examined by light microscopy and positive stained cells were quantified at x400 magnification in five non-overlapping adjacent microscopic fields in the dermis. The results were expressed as mean number of cells. RNA extracted from formalin-fixed paraffin-embedded (FFPE) skin samples from 21 CLE patients were analyzed by qRT-PCR for gene expression of type I IFN signature genes (LY6E, OAS1, OASL, ISG15, and MX1) and inflammatory cytokines TNFα. The patients were grouped according to their response to antimalarial treatment; 1) Hydroxychloroquine (HCQ) group, who were responsive to HCQ; and 2) HCQ + Quinacrine (QC) group, who were refractory to HCQ and responded to additional QC. The Mann-Whitney test was used to compare the number of each cell type and gene expression between HCQ and QC responsive groups.

Results: The number of mDCs was significantly higher (p=0.0106) in HCQ+QC group patients (19 cases) compared to those in HCQ group (13 cases) (Figure). The mean number (standard error) of pDCs, mDCs, neutrophils, and macrophages in each group of patients is summarized in the table. Gene expression of type I IFN signatures were significantly upregulated in the HCQ group compared to the HCQ+QC group (LYE p=0.0037; OAS1 p=0.0002; OASL p=0.0067; ISG15 p=0.01; and MX1 p=0.0083), while TNFα levels were significantly higher in the HCQ+QC group (p=0.003).

Conclusion: Increased numbers of mDCs together with higher TNFα expression might be responsible for refractoriness to HCQ and better response to QC. Our data suggest that the increased number of mDCs in CLE patients may be used as a predictive factor of refractoriness to HCQ and responsiveness to QC.

Table

CLE	CD123 Mean (SE)	CD11c Mean (SE)	MPO Mean (SE)	MAC387 Mean (SE)
HCQ (n=13)	29.4 (5.8)	16.6 (3.6)	16 (3.7)	25.3 (4.9)
HCQ+QC (n=19)	27.9 (5.1)	34.7 (4.9)	13.4 (1.8)	24.6 (3.1)

The Enhanced Expression of mRNA for Calgranulins, S100A8, S100A9 and S100A12, in CD34+ Cells of the Bone Marrow in Rheumatoid Arthritis

Tatsuo Nagai[1], Yu Matsueda[2], Tetsuya Tomita[3], Hideki Yoshikawa[3] and Shunsei Hirohata[2], [1]Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Sagamihara, Japan, [2]Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Kanagawa, Japan, [3]Department of Orthopedics, Osaka University Graduate School of Medicine, Suita Osaka, Japan

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory arthritis of unknown etiology. A subset of S100 proteins known as calgranulins (S100A8, S100A9 and S100A12) are constitutively expressed at high levels in neutrophils and monocytes and play a critical role in inflammation as they can activate the innate immunity pathway sensed by Toll-like receptors. Notably, recent studies have revealed that the expression of calgranulins was about 10-fold higher in RA synovial fluid (SF) versus osteoarthritis (OA) SF. However, the mechanisms for such upregulation of the expression of calgranulins in RA SF remain unclear. We have previously demonstrated that the expression of mRNAs for various genes in BM CD34+ cells, including nuclear factor kappa B1, is higher in RA patients than in OA patients. It is thus possible that the expression of mRNAs for calgranulins might be also upregulated in RA BM CD34+ cells. The current study therefore examined the mRNA expression of S100A8, S100A9 and S100A12 in BM CD34+ cells from RA patients versus OA patients.

Methods: BM samples were obtained from 45 patients with RA (5 males and 40 females: mean age 59.0 years) and 28 patients with OA (3 males and 25 females: mean age 70.8 years), who gave informed consent, during joint operations via aspiration from iliac crest. CD34+ cells were purified from the BM mononuclear cells by positive selection with magnetic beads. The expression of mRNAs for S100A8,

S100A9 and S100A12 was examined by quantitative reverse transcription PCR and is shown as the ratio of the copy numbers to those of b-actin mRNA.

Results: The expression of mRNAs for S100A9 and S100A12 was significantly higher in RA BM CD34+ cells than OA BM CD34+ cells. The expression of mRNA for S100A8 in RA BM CD34+ cells appeared to be increased compared to OA BM CD34+ cells, although it did not reach the statistical significance. (Fig. A). The mRNA expression levels of S100A8, S100A9 and S100A12 were not correlated with serum C-reactive protein or with the administration of methotrexate or oral steroid. Finally, the level of S100A8 mRNA as well as that of S100A9 mRNA was significantly correlated with the level of S100A12 mRNA in RA BM CD34+ cells (Fig. B).

Conclusion: These results indicate that the mRNA expression of S100A8, S100A9 and S100A12 is upregulated in RA BM CD34+ cells independently of the systemic inflammation or treatment regimen. Thus, the data account for the upregulation of the enhanced expression of calgranulins in RF SF compared with that in OA SF.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Changes in gene expression are closely related to inflammation and joint destruction in RA. Recently, it has been recognized that post-transcriptional regulation of the gene expression of various cytokines is important to the immunological process. In this study, we attempted to identify cytokines that regulate the metabolism of RA-related mRNA through unique AU rich elements (ARE), which are characterized by AUUUA repeats in their 3′ untranslated regions (3′UTR).

Methods: We generated dual luciferase reporter plasmids to study the influence of cytokines on the stability of transcripts associated with RA. The 3′-UTR sequences of RA-related genes (*CXCL2*, *PIM1*, *CSF2*, *IL12B*, *IL1B*, *TNF*, *TNFRSF10B*, *HIF1A*, *ARHGEF2*) with ARE were inserted into the 3′ end of the firefly luciferase gene in the pmirGLO Dual-Luciferase miRNA Target Expression Vector. *Renilla* luciferase in the plasmid was used as a control reporter for normalization. U2OS cells were transfected with these plasmids 2 hours before cytokine treatment. The transfected cells were stimulated with cytokines for 12 hours and were lysed using a passive lysis buffer for luciferase activity analyses with the Dual-Glo Luciferase Assay System and Infinite 200 PRO. TIA1, TIAR, TTP, or HuR were co-

transfected with the reporter. The expression of *CXCL2* mRNA in fibroblast-like synoviocytes (FLS) was examined by RT-PCR. In mRNA decay experiments, actinomycin D was used to stop RNA polymerase II dependent transcription in FLS.

Results: Various cytokine treatments affected the reporter luciferase activities. In particular, IL-1β and IL-17A increased the luciferase activities of the reporters harboring the 3′-UTR of *CXCL2* mRNA in a dose-dependent manner. Addition of IL-1β remarkably upregulated the *CXCL2* mRNA expression in FLS. The half-life of *CXCL2* mRNA was significantly longer in IL-1β treated FLS (21.7 hours) than that in untreated FLS (3.3 hours). ARE-harboring mRNA is potentially regulated by RNA binding proteins including TIA1, TIAR, TTP, and HuR. Among these, co-transfection of TTP with the reporter plasmid suppressed the luciferase activity with the 3′UTR of *CXCL2* mRNA.

Conclusion: Our data suggest that the metabolism of *CXCL2* mRNA is stabilized by IL-1β, leading to a remarkable increase in *CXCL2* mRNA in FLS. CXCL2 is a chemokine that is secreted from various cells for chemotactic attraction of polymorphonuclear leukocytes and is involved in the pathogenesis of infections and autoimmune diseases. Therefore, it is possible that IL-1β signaling stabilizes *CXCL2* mRNA by regulating RNA binding proteins like TTP, for the recruitment of neutrophils at the inflamed joint.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies of human genetics and mouse models have shown that interferon regulatory factor-5 (IRF5) is associated with the development of autoimmune disease. However, the role of IRF5 in their pathogenesis is not fully understood.

Methods: We generated dendritic cells (DCs) with Fms-related tyrosine kinase 3 ligand (Flt-3L) using bone marrow cells from wild type mice or IRF5-/- mice. We stimulated the DCs with toll-like receptor (TLR) ligands and cultured them with CD4+ T cells. We measured T cell cytokines (IFN-gamma, IL-17, IL-4 and IL-2) in the culture supernatant. In separate experiments, we stimulated B cells from wild type mice and IRF5-/- mice with TLR ligands in the presence of IFN-gamma, IFN-beta, IL-4 and IL-17.

Results: TLR7-IRF5 signaling in DCs stimulated CD4+ T cells to release large amounts of type II IFN (IFN-gamma). Concomitantly, IL-2 production from CD4+ T cells was suppressed. This balance of cytokine production was controlled by modulating IL-12 and type I IFN expression through IRF5. By neutralizing IL-12p40 and blocking IFN receptors, production of IFN-gamma was suppressed while that of IL-2 was increased. IFN-gamma enhances IgG2a/c and IgG2b production from B cells stimulated with TLR7 and TLR9 through IRF5-dependent pathways. In addition, dual activation of BCR and TLR7 induces IRF5-dependent enhancement of T-bet, which is responsible for IgG2a production in B cells.

Conclusion: IRF5 promotes Th1-type T cell responses and the production of pathogenic IgG isotypes. In adidition, our results provide a mechanism to explain the low level of T cell IL-2 expression that has previously been linked to lupus pathogenesis.

Session Date: Monday, November 14, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophages in rheumatoid arthritis (RA) synovium produce high levels of inflammatory cytokines/chemokines and play the pivotal role in promoting inflammation and joint destruction. Treatment of patients with RA with infliximab results in a rapid reduction of synovial tissue macrophages, which is a reliable biomarker of clinical response. Since the mechanism for reduction of macrophages has not been clearly defined, studies were performed with human TNF transgenic (hTNF-tg) mice to determine if the initial reduction of macrophages was due to increased cell death, increased efflux of macrophages or decreased influx of monocytes.

Methods: hTNF-tg mice and littermate controls at 5-6 week old were employed. Administration of infliximab was performed intraperitoneally (10mg/kg), 2 doses over 3 days. The clinical severity of the arthritis was defined as the sum score of inflammation, deformity and grip strength, ranging 0-28. Inflammation and bone destruction were assessed by ankle histology. The immune cell phenotypes and apoptosis were determined by flow cytometry. Monocyte migration into ankles was documented following intravenous administration of $CD115^+$ monocytes from $CD45.1^+$donors into the synovial tissue of hTNF-tg mice with or without the infliximab treatment. Ankle joint homogenizes were analyzed for cytokines/chemokines by quantitative ELISA.

Results: Arthritis in 5 week old CD45.2 hTNF-tg mice was significantly improved after 2 dosages of infliximab evaluated clinically and histologically, which demonstrated reduction of inflammation and bone erosion. In addition, the $Ly6C^+$ synovial tissue monocyte-derived macrophages ($CD64^+CD11b^+$ $F4/80^{mid}$ $Ly6C^+$) were sighnificantly reduced by infliximab ($p<0.001$), determined by flow cytometric analysis. No increase of macrophage apoptosis was identified following treatment, although there was a modest reduction neutrophil apoptosis. There was no increase of any subset of macrophages in the draining peritoneal lymph nodes (pLNs) of the treated mice. In fact the $Ly6C^+$ macrophages were actually reduced in the pLNs following treatment. The adoptive transfer CD45.1 monocytes was employed to track the influx of monocytes. The influx of $CD115^+$circulating monocytes into the synovial tissue of hTNF-tg mice was significantly ($p < 0.001$) reduced in the mice that received 2 doses of infliximab, one 24h before and another at the time of monocyte transfer, or just one dose simultaneously with monocyte administration ($p<0.001$). Ankle joint homogenizes demonstrated greatly reduced the CCL2 ($p<0.001$), but not Cx3CL1 ($p>0.05$), following treatment.

Conclusion: The initial effect of infliximab on macrophages in the joints of hTNF-tg mice was the reduction of Ly6C+ macrophages. The decrease was not due to increased efflux from the joint or increased apoptosis but due to decreased influx of circulating Ly6C+ monocytes, which are also CCR2+. These observations provide a potential explanation for the rapid reduction of synovial tissue macrophages observed in patients with RA treated with infliximab.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids (GC) have been used to treat inflammatory disease for more than six decades, but the broad spectrum of therapeutic effects is accompanied by significant metabolic adverse effects. Recent studies suggest that glucocorticoid-induced leucine zipper (GILZ) mimics the anti-inflammatory effects of GC, including inhibiting the activation of macrophage, B cells, Th1 and Th17 cells, but lacks GC adverse effects. However, little is known about molecular mechanisms of GILZ action that could empower drug discovery.

Methods:

Expression of GILZ and acetylated GILZ was measured by Western blotting in murine bone marrow-derived macrophages. WT and mutated GILZ plasmids were co-transfected with an NF-κB luciferase reporter into human microvascular endothelial cells (HMECs). IL-6 and MCP-1 were measured by ELISA. NF-κB activity was measured using a NF-κB luciferase reporter assay. Interactions between GILZ and p65/NF-κB were detected by Fluorescence lifetime imaging (FLIM)/ Fluorescence Resonance Energy Transfer (FRET).

Results: GILZ acetylation was detected in macrophages, and TSA, a deacetylase inhibitor, increased GILZ acetylation in a time-dependent manner. WT GILZ was constructed in the pcDNA3.1 expression plasmid and overexpression of GILZ significantly inhibited NF-κB activity and IL-6 and MCP-1 expression. Using an acetylation substrate-binding site alignment approach, we predicted three potential GILZ acetylation sites at K37, K77 and K108. Acetylation of GILZ was lost when K77, but not K37 or K108, was mutated to arginine (K77R). Mutation at K77 aborgated GILZ inhibition of NF-κB activity, and IL-6 and MCP-1 expression. Co-IP and FLIM/FRET demonstrated that GILZ mutation at K77 prevented interaction with p65/NF-κB.

Conclusion: Acetylation of GILZ at K77 is required for its interaction with NF-κB and anti-inflammatory effects. This suggests a potential target for enhancing the anti-inflammatory effects of GILZ as a GC mimic via inducing K77 acetylation.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In healthy cartilage, there is a balance between anabolic and catabolic activities of chondrocytes that maintains the functional integrity of the extracellular matrix. However, during osteoarthritis (OA), chondrocytes become more catabolically active and express matrix degrading enzymes, such MMPs and ADAMTSs. This process results in a net loss of the extracellular matrix and therefore leads to cartilage damage. Previously we found, that the anti-inflammatory cytokine Interleukin 37 (IL37) is able to counter-regulate the catabolic status of chondrocytes by reducing the IL1β-driven expression of pro-inflammatory cytokines and catabolic enzymes. The goal of this study was to investigate the effect of IL37 on content and synthesis of extracellular matrix molecules in human OA cartilage explants.

Methods: Human cartilage was obtained from sixteen OA patients undergoing total knee or hip arthroplasty. Biopsy punches of 4 mm in diameter were made to equalize explant size. After culturing overnight, explants were incubated for 48 h with three doses (1-10 ng/ml) of

recombinant-IL37 (rec-IL37). Sulfated glycosaminoglyans (GAG) were measured in the supernatant with the DMB assay and RNA was extracted from explants to analyze gene expression of extracellular matrix molecules and cartilage degrading enzymes. In addition, nitric oxide (NO) was measured in the supernatant using Griess reagens, because NO is an important effector molecule that may suppress cartilage matrix synthesis.

Results: Adding rec-IL37 (100ng/ml) to OA cartilage explants caused a significant reduction in GAG release in the supernatant of, on average, 32% in sixteen donors. Gene expression of the extracellular matrix molecules aggrecan and collagen type II was not different between rec-IL37 treated groups and controls in the five patients analyzed so far. This indicates that rec-IL37 does not inhibit GAG release by inhibiting the synthesis of the proteoglycan aggrecan. We did observe a reduction in the gene expression of the matrix degrading enzyme MMP3 after stimulation with 1 ng/ml rec-IL37. However, high doses of rec-IL37 did not significantly reduce MMP3 expression. Furthermore, we did not observe an effect of rec-IL37 on gene expression of MMP13 and ADAMTS5, which suggests that rec-IL37 does not inhibit GAG release by inhibiting expression of these enzymes. Another mechanism to prevent GAG release is via inhibition of NO synthesis, but NO levels in the supernatant were comparable between rec-IL37 treated groups and the control group. However, we did observe a trend towards increased gene expression of the metalloproteinase inhibitor TIMP3 in rec-IL37 treated groups, as a possible mechanism for reduced GAG release.

Conclusion: Our data show that rec-IL37 reduces GAG release out of OA cartilage explants. The mechanism behind this process is most likely positioned downstream of catabolic gene expression, and possibly runs via modulation of matrix degrading enzyme activity. Our results indicate that IL37 can maintain cartilage matrix integrity under OA conditions.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Persistent inflammation is a characteristic of several joint diseases, including OA. It is nowadays appreciated that this could be a result of a failure to (optimally) activate inflammation resolution pathways. Therefore, we investigated the presence of specialized pro-resolving lipid mediators (SPM) and their precursors as pathway markers of the resolution process in the joint of OA patients and controls.

Methods: SF was obtained from knee OA (2 populations) and rheumatoid arthritis (RA) patients fulfilling the ACR criteria for OA and RA, respectively, and healthy controls. Lipid mediators (LMs) were determined by targeted lipidomics using liquid-chromatography mass spectrometry. Sixty different lipids including pro-inflammatory (e.g. prostaglandins, leukotrienes) and anti-inflammatory/pro-resolving LM (e.g. SPM), as well as their precursors can be detected with our technique.

Results: SF from 24 OA and 12 RA patients were first studied. Thirty-seven lipids were detected in the soluble fraction of SF, including

polyunsaturated fatty acids (PUFA) and their lipoxygenase (LOX) and cyclooxygenase (COX) pathway markers in both OA and RA patients. Among these, pro-inflammatory LM such as PGE_2 and thromboxane B2, as well as the pathway markers of resolution and precursors of SPM, 17-HDHA and 18-HEPE, were detected. Except for the LOX products of arachidonic acid: 15-HETE, 6-trans-LTB_4 and 20-OH- LTB_4, which were lower in OA than in RA SF, all other lipid mediators and PUFA were comparable between OA and RA samples. Ratios of metabolites to their precursors indicated that both pro- (e.g. LTB_4) and anti-inflammatory LOX products (e.g. 17-HDHA) are more efficiently generated in RA than in OA patients, while no differences were observed in COX products. Interestingly, the SPM resolvin D2 (RvD2) could also be detected, but only in the insoluble fraction (cells and undigested matrix), indicating that the resolution pathways are activated in OA. This expands our previous publication showing activation of resolution in RA patients. To assess the efficiency of activation of resolution in OA, we have performed targeted lipidomics on total SF in an additional study with 32 OA patients and 10 healthy controls. Confirming earlier data, most LMs were also detected in this study, including the pro-inflammatory PGE_2, the SPM precursors 17-HDHA and 18-HEPE, and the SPM RvD2. Additionally, we detected 18S-resolvin E3 (18S-RvE3). Remarkably, both the absolute concentrations of the SPM RvD2 and 18S-RvE3, and the ratio to their precursors, 17-HDHA and 18-HEPE, were lower in OA compared to healthy SF, indicating less efficient generation of SPM in OA compared to healthy joints. In contrast, the pro-inflammatory lipid $PGE_2$was higher in OA than in healthy SF, indicating that the lower activation of resolution is paired by a higher inflammatory load in OA compared with healthy individuals.

Conclusion: By using a state-of-the-art technique, we show for the first time that resolution pathways are activated in OA patients. Importantly, resolution seems to be less efficiently activated than in healthy individuals, which could account for the persistent inflammation observed in OA and RA patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is characterized by severe cartilage destruction, with a putative role for synovial macrophages. Up to 50% of the patients also show low grade joint inflammation reflected by a thickened synovial lining and elevated release of macrophage-derived mediators like interleukin-1 (IL-1) and S100A8/A9. The deteriorating role of S100A8/A9 in OA has been studied extensively, but the contribution of IL-1 to OA pathology is still unclear. IL-1 mediates cartilage destruction by degrading existing proteoglycans through stimulating degradative enzyme production, and by inhibiting new formation of proteoglycans. However, treatment of OA patients with IL-1 inhibitors has so far been disappointing. Here we investigated the role of IL-1α and IL-1βin synovitis and cartilage destruction during collagenase-induced OA (CiOA).

Methods: CiOA was induced by intra-articular injection of collagenase in WT and IL-1$\alpha\beta^{-/-}$mice. In addition, IL-1 signaling was inhibited in WT mice with CiOA using osmotic pumps containing IL-1RA. Histology of total knee joints was used to assess synovitis and cartilage destruction with a modified Pritzker score. Activity of cartilage-degrading enzymes was determined using antibodies against aggrecan neo-epitopes VDIPEN and NITEGE. Synovial gene expression was analyzed using qRT-PCR. Serum protein levels were measured with Luminex. S100A8/A9 protein levels were determined with a sandwich ELISA.

Results: At early stage (day 7) of CiOA, gene expression of IL-1β within inflamed synovium was significantly elevated when compared to synovium of naïve control knees. In later stages (day 21 and 42), IL-1β expression levels showed a steep decline. This is in contrast to pro-

inflammatory mediators like S100A8 and S100A9 which remained elevated on day 21. Remarkably, synovial inflammation on day 7 in IL-1αβ$^{-/-}$ mice was not different from WT controls (2.9±0.2 vs. 2.7±0.4), suggesting that IL-1 does not aggravate synovitis. Absence of IL-1α and IL-1β had no effect on the synovial gene expression levels of pro-inflammatory factors KC, S100A8 and S100A9. IL-6 mRNA levels, however, were significantly decreased in the synovium of IL-1αβ$^{-/-}$ mice. The lack of IL-1α and IL-1β also did not affect gene expression of anti-inflammatory cytokines IL-10 and iNOS. Moreover, serum protein levels of KC, IL-6, IL-10 and S100A8/A9 on day 7 of CiOA in IL-1αβ$^{-/-}$ mice were not different when compared to WT mice. No difference was found in MMP and ADAMTS activity on day 7 between WT and IL-1αβ$^{-/-}$ mice. In line, cartilage destruction on day 42 was not significantly different between both strains (mean OA score of 59.2±25.4 and 74.8±27.0, respectively), which was supported by our finding that IL-1RA treatment in WT mice with CiOA did not alter joint destruction (mean OA score of 44.7±33.3 in treated mice vs. 56.2±20.5in untreated mice).

Conclusion: IL-1α and IL-1β are not involved in synovial inflammation and cartilage destruction during collagenase-induced osteoarthritis, implicating that other mediators are responsible for the joint damage.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Angiogenesis is a hallmark of the pathogenesis of rheumatoid arthritis (RA) but also of other inflammatory processes, tissue regeneration and progressing tumors. In RA, the neovascular network is dysfunctional and fails to restore tissue oxygen homeostasis, so that the inflamed joint remains markedly hypoxic. The hypoxia-induced multifunctional and pro-inflammatory protein macrophage migration inhibitory factor (MIF) participates in the regulation of hypoxia-induced angiogenesis. At cellular level, hypoxia is detected by a mechanism that regulates the amount of the oxygen-sensitive α-subunits of the transcription factors, hypoxia-inducible factor (HIF)-1 and -2, which activate a gene program associated with angiogenesis and glycolysis. Here, we focus on the role of MIF and its mechanism of action in the process of hypoxia-induced angiogenesis and in the regulation of HIFs.

Methods: Therefore, we developed a specific knockdown of MIF and its receptor CD74 in Human Microvascular Endothelial Cell (HMEC) using lentiviral-based shRNA technology allowing us to analyse the role of MIF in hypoxia-induced angiogenesis. We investigated the adaption of these cells towards pathophysiologic hypoxic conditions (1% O_2) analysing protein-levels of HIF-1α and HIF-2α, HIF-target gene expression, angiogenesis and VEGFA release. To further identify the underlying mechanisms angiogenesis assay was performed with HMECs treated with anti-CD74-IgG, rhMIF and 4-IPP, a small molecule inhibitor of MIF.

Results: Lentiviral-mediated reduction of MIF in HMEC led to significantly decreased angiogenesis ($p<0.01$) which could be restored by adding extracellular rhMIF. Interestingly, reduction of MIF did not influence hypoxia-induced (i) protein-levels of HIF-1α and HIF-2α, respectively, and (ii) HIF-target gene expression of *PGK1*, *GAPDH* and *VEGFA* but (iii) induced secretion of pro-angiogenic VEGFA and IL8. Moreover, addition of 4-IPP also decreased angiogenic response of non-transduced HMECs but enhanced the hypoxia-induced HIF-target gene expression of *PGK1* and *VEGFA*. Inhibiting MIF-signalling by the addition of extracellular anti-CD74-IgG also reduced angiogenic potential of HMEC ($p<0.001$), which was not restorable by the addition of extracellular rhMIF. Furthermore, lentiviral-mediated reduction of CD74 in HMEC also decreased angiogenesis ($p<0.01$) again without influencing HIF-target gene expression of *PGK1*, *GAPDH* and *VEGFA*.

Conclusion:

Our findings reveal an essential regulatory function of MIF upon the angiogenic potential of HMECs. Hypoxia-induced MIF-dependent induction of angiogenesis is independent of HIF-mediated activation of a gene program associated with angiogenesis and glycolysis including VEGFA secretion. These findings open new possibilities for therapeutic approaches in RA and other inflammatory disorders by targeting specific MIF-mediated signalling events.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease leading to joint destruction. In the previous Phase 1/2 clinical study, E6011, a novel humanized anti-fractalkine (FKN) monoclonal antibody (mAb) demonstrated a promising efficacy in active RA patients who were inadequately controlled by MTX and/or TNF-a inhibitors. However, the effect of anti-FKN mAb on joint destruction remains to be elucidated. In RA, synovium-infiltrated monocytes/macrophages cause synovitis and cartilage damage by the induction of matrix metalloproteases and inflammatory cytokines. Osteoclasts are generated from osteoclast precursor cells (OCPs) and cause bone erosion. FKN is expressed on endothelial cells and fibroblast-like synoviocytes in synovium in both experimental arthritis model and RA patient. Moreover, it is reported that FKN expressed by osteoblasts in neonatal mouse calvariae. CX3CR1, the receptor for FKN, is expressed on monocytes/macrophages and OCPs. Therefore, the interaction of FKN and CX3CR1 might play important roles in migration, differentiation and activation of these cells, leading to cartilage damage and bone erosion. In this study, we examine the efficacy of anti-FKN mAb on collagen-induced arthritis (CIA) in mice, especially on joint destruction.

Methods: For the induction of CIA, DBA/1J mice were immunized with intradermal injections of bovine type II collagen on days 0 and 21. Four hundred micrograms of anti-FKN mAb or control IgG intraperitoneally injected twice a week from the day of the 1stimmunization (for the prophylactic treatment) or after the onset of CIA (for the therapeutic treatment). The clinical arthritis score was defined as the sum of the scores of four paws. Plasma concentration of Tartrate-Resistant Acid Phosphatase type 5b (TRAP-5b), Cartilage Oligomeric Matrix Protein (COMP), Matrix Metalloproteinase 3 (MMP-3) were measured using ELISA. Radiological score was measured by the soft x-ray for limb bones. For histopathological analysis, Alcian blue/Alizarin red and Tartrate-Resistant Acid Phosphatase (TRAP) staining were performed using frozen sections of ankle joints.

Results: The prophylactic treatment of anti-FKN mAb significantly reduced the clinical arthritis score, soft x-ray score and plasma levels of TRAP-5b, COMP and MMP-3, compared with the treatment of control IgG. Histopathological analysis demonstrated almost complete suppression of synovitis, pannus formation, cartilage degradation and bone erosion by the treatment of anti-FKN mAb. The number of TRAP-positive cells was also dramatically decreased in anti-FKN mAb–treated mice. Importantly, therapeutic treatment of anti-FKN mAb significantly ameliorated clinical arthritis score and soft x-ray score compared with the treatment of control IgG.

Conclusion: Anti-FKN mAb demonstrated a remarkable efficacy in established mouse CIA and completely inhibited the cartilage damage and bone erosion with the reduction of osteoclasts. These results indicate that inhibition of FKN/CX3CR1 axis by a humanized anti-FKN mAb, E6011, is an attractive therapeutic strategy for the treatment of both inflammatory synovitis and joint destruction of RA.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: $CD4^+FoxP3^+$ regulatory T cells (Tregs) are essential for maintaining immune homeostasis, and are functionally defective in rheumatoid arthritis (RA) and other chronic inflammatory diseases. In RA, effective anti-TNF treatment was found to modify Tregs phenotype and restore their suppressive function. Tregs express the two TNF receptors (TNFR): TNFR1 and TNFR2. Nevertheless, the respective roles of TNFR1 and TNFR2 in mediating the effect TNF on Tregs are still unclear. Likewise, whether TNF blockade may affect Tregs via the TNF receptors, is not clearly established. To dissect the role of the TNF-TNFR2 system on Tregs in chronic inflammatory diseases by **:** 1) determining the effect of the interaction between TNF and TNFR2 on cultured mouse Tregs 2) studying the effect of TNFR2 deficiency in a model of chronic inflammation 3) analyzing the influence of anti-TNF therapy on TNFR2 expression on Tregs in RA patients

Methods: Tregs were purified by magnetic separation from mice spleen and their frequencies and phenotype were analyzed by flow cytometry. TNFR2 deficient mice were used. Psoriasis-like skin inflammation was induced by imiquimod skin application. Tregs from blood of RA patients were studied by flow cytometry.

Results: TNF induces Foxp3 maintenance in cultures of purified mouse Tregs. With two models of TNFR2 inactivation (a TNFR2-blocking antibody and a TNFR2 knock-out mouse) we showed that this effect was mediated by TNF-TNFR2 -and not TNFR1- interaction. Moreover, compared to Tregs from wild type (WT) mice, TNFR2-deficient Treg showed reduced suppression of effector T cells (Teff) proliferation and Teff interferon-g production. TNF decreased CD39 expression and ATP hydrolysis activity in cultured Tregs. Additionally, TNFR2-deficient Tregs were less effective in hydrolyzing ATP than Tregs from WT mice. In parallel, we evaluated the consequences of TNFR2 deficiency in a model of skin inflammation, namely imiquimod-induced psoriasis. In TNFR2- deficient mice, Tregs frequencies were lower and the clinical signs of psoriasis were aggravated, compared to WT mice. Moreover, in the peripheral blood of RA patients treated with anti-TNF agents there was both an increase in total Tregs frequencies, and in the frequency of Tregs expressing TNFR2 at 3 months of treatment vs. the baseline.

Conclusion: The integrity of the TNF-TNFR2 system is critical for Treg survival and suppressive activity *in vitro*. TNFR2 deficiency aggravates a model of chronic skin inflammation. Three-month anti-TNF treatment is associated with an increase of TNFR2-expressing Tregs in the peripheral blood of RA patients. These data suggest that the effect of TNF blockade on Tregs may rely on the activation of the TNF-TNFR2 system.

Session Date: Monday, November 14, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Aminopeptidase N/CD13 is a metalloproteinase expressed on the surface of fibroblast like synoviocytes (FLS). It is found in soluble form in serum and rheumatoid arthritis (RA) synovial fluid (SF). We have shown that CD13 induces T cell migration and FLS proliferation. In this study, we determine the role of CD13 in monocyte (MN) migration, signaling mechanisms involved and its role in acute inflammatory arthritis.

Methods: To examine the functional significance of CD13, we performed an *in vitro* migration assay using normal human MNs and U937 cells. We examined the signaling mechanisms involved in CD13-induced MN migration using signaling inhibitors and pertussis toxin (PT). To assess whether its enzymatic activity contributes to CD13-induced phosphorylation of signaling molecules and MN migration, we generated enzymatically inactive (mutant CD13) and active (WT CD13). MN chemotaxis was performed with CD13-depleted RA SF supplemented with mutant or WT CD13. To examine the role of CD13 in RA, MN migration was performed with CD13- and sham-depleted RA SF. To determine the crosstalk between CD13-induced signaling intermediates, RA FLS, MN, and U937 cells were treated with or without signaling inhibitors or PT before CD13 stimulation. To test the arthritogenicity of CD13 *in vivo*, CD13 or PBS was injected into mouse knees. Joint circumference was measured at 0 and 24h. Pro-inflammatory mediators in knee joint homogenates were measured by ELISA.

Results: We found that CD13 is a potent chemoattractant for MNs and U937 cells. Chemotaxis was significantly decreased by inhibitors of Erk1/2, Src, NFκB, and Jnk, and was strongly inhibited by PT, a G-protein coupled receptor (GPCR) inhibitor, indicating the role of these molecules in CD13-mediated MN migration. CD13-depleted RA SF induced significantly less MN migration than sham-depleted, while addition of mutant or WT CD13 to CD13-depleted RA SF restored MN migration similar to the sham-depleted. CD13 and WT and mutant CD13 had similar effects in activating signaling molecule phosphorylation, indicating that enzymatic activity had no effect on these CD13 functions. CD13 induced Erk1/2, Src, NFkB and Jnk phosphorylation in MNs and U937 cells. In RA FLS, phosphorylation of Erk1/2, Src, and NFκB showed similar results, but there was no phosphorylation of Jnk. We found that the GPCR inhibitor, PT, decreased CD13-stimulated phospho-Erk1/2 in MNs, U937, and RA FLS, suggesting that GPCRs are upstream in CD13-mediated signaling pathways. In an acute model of inflammation, there was a significant increase in the knee circumference in mice injected with CD13 compared to PBS, indicating that CD13 contributes to acute inflammatory arthritis. MCP-1/CCL2 and IL-1β were significantly higher in CD13-injected knee joint homogenates, while TNFα and IL-6 were not.

Conclusion: CD13 is strongly chemotactic for MNs and U937 cells. CD13 contributes to MN migration independent of its chemotactic activity. CD13 induces MN migration through Erk1/2, Src, NFkB, Jnk, and GPCR. CD13 plays an important role in RA SF mediated MN migration. CD13 contributes to acute inflammatory arthritis by increasing MCP-1/CCL2 and IL-1β. CD13 may be a potential therapeutic target in RA.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Inhibitor of DNA binding-1 (Id1) is a nuclear protein actively transcribed in endothelial progenitor cells (EPCs) and synovial fibroblasts. We previously identified Id1 as a soluble inflammatory protein that displays elevated expression in rheumatoid arthritis (RA) synovial tissues (STs) and effusions, contributing to angiogenesis, vasculogenesis and cellular migration. We and others have shown that RA fibroblasts display unchecked growth and are a major source of cytokine production. In this study, we investigated the mechanisms of Id1 regulation of synovial fibroblast cytokine production, trans-cellular activity and cellular growth in the RA joint.

Methods: RA STs and K/BxN mouse ankles were analyzed histologically for correlation of Id1 expression and disease severity. Exosomes from fibroblast supernatants and synovial fluids (SFs) were purified via differential centrifugation. Exosome fractions were then subjected to 0.5% Triton X-100 for lysis and measured for Id1 by ELISA. RA fibroblasts were transfected with a clustered regularly interspaced short palindromic repeats (CRISPR)/Cas9 plasmid, containing a GFP insert, via electroporation to induce error-prone non-homologous end joining repair (NHEJ), causing a nonsense mutation and removal of the targeted Id1 gene. To validate transfection efficiency, Tracking of Indels by Decomposition (TIDE) analysis was performed to verify CRISPR/Cas9 activity in the transfected fibroblasts. GFP-positive cells deleted of Id1 were then sorted by FACS, cultured for 24 hours, and measured for cytokine release and cell proliferation.

Results: Histologic analysis revealed positive correlations of Id1 expression and disease severity by Pearson's Correlation Coefficient in RA STs ($r=0.74$, $p<0.05$, $n=12$) and K/BxN mouse ankles ($r=0.87$, $p<0.05$, $n=10$). RA compared to osteoarthritis (OA) fibroblast culture supernatants contained greater amounts of exosomes, and >80% of the Id1 released by RA fibroblasts was encapsulated within exosomes. Correspondingly, exosomes isolated from SFs have abundant levels of Id1 with a two-fold higher amount of Id1 in RA compared to OA SFs. We targeted Id1 to determine the function of Id1 on RA fibroblast growth and cytokine production. TIDE analysis confirmed CRISPR/Cas9-mediated NHEJ at the Id1 gene, resulting in Id1 deleted cells. Id1 deleted RA fibroblasts showed a 40% decrease in cell proliferation, and four and 100 fold increases in IL-6 and IL-8 production respectively, compared to transfected control plasmids and sham transfected (no plasmid) cells. Epithelial-derived neutrophil-activating peptide 78 (ENA-78)/CXCL5 did not show an increase in the Id1 deleted RA fibroblasts. The attenuated fibroblast growth in the RA fibroblasts can be explained, in part, by a significant increase in IL-6, a known inhibitor of fibroblast growth.

Conclusion: We show that Id1 is upregulated and packaged within RA fibroblast exosomes for trans-cellular distribution. Id1 deletion by CRISPR/Cas9 transfection significantly slows RA fibroblast growth and induces elevated production of IL-6 and IL-8. Our data indicate that Id1 is an active regulator of both fibroblast growth and proinflammatory cytokine production in the RA joint.

The Musculoskeletal Master Educator Training Program: A New Resource and Professional Development Opportunity for Leaders in Medical Education

Andrea M. Barker[1], Yasuharu Okuda[2], Patricio Bruno[2], Brian Peplinski[2], Anthony Artino[3], Jeffry La-Rochelle[3], Grant W. Cannon[4] and Michael J. Battistone[1], [1]Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, [2]VHA SimLEARN National Center, Orlando, FL, [3]Uniformed Services University of the Health Sciences, Bethesda, MD, [4]Salt Lake City VA Medical Center and University of Utah Division of Rheumatology, Salt Lake City, UT
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In response to the Veterans Access, Choice, and Accountability Act of 2014, the Veterans Health Affairs (VHA) Simulation Learning, Education and Research Network (SimLEARN) National Simulation Center launched the Musculoskeletal (MSK) Master Educator program. This initiative aims to improve veteransÕ access to appropriate care by strengthening training in the evaluation and management of common MSK conditions. This report describes the first year of the SimLEARN MSK Master Educator program.

Methods: The 2-day course was held at the SimLEARN facility in Orlando, and focused on evaluation and management of shoulder and knee pain in primary care. Opportunity to attend was communicated through national, regional, and local VHA organizational networks. Curriculum was introduced through didactics, reinforced in small-group hands-on sessions enhanced by peer-teaching and simulation via standardized patients and joint injection task-trainers. Pre- and post-course self-assessments were collected, using a 5-point response scale. Competence was assessed using a previously validated objective structured clinical examination (OSCE). Finally, participants rotated through an observed structured teaching experience (OSTE), where they practiced roles of simulated patients, evaluators and learners. Data were analyzed using SPSS.

Results: Twenty-five participants completed the program in 2016 (15 physicians, 7 nurse practitioners (APRN), 2 physician assistants (PA), 1 nurse). Participants consistently gave high ratings to the importance of competence in the evaluation and management of MSK conditions, and self-reported competence ratings were significantly higher after the course (Table 1). Mean OSCE score was 83% (SEM = 3); statistical description of OSCE scores is reported in Table 2. There were no significant differences in OSCE score across disciplines or years of experience.

Conclusion: The SimLEARN MSK Master Educator course is a new professional development workshop for clinical educators, providing content instruction, external assessment of competence, a portable curriculum, and structured practice teaching and evaluating peer learners in an OSTE. Participants from a broad range of disciplines and experience levels reported significant increases in confidence and competence in evaluating and managing MSK problems. Next steps will involve dissemination of this opportunity to leaders in medical and health professions education, and implementation of adaptations of the training program at educatorsÕ local institutions.

Table 1. Self-Reported Survey Results

	Pre-course Mean	Post-course Mean	Mean Paired Difference (p)
How *confident* are you in your ability to:			
Evaluate shoulder pain	3.2	4.4	1.2 (<0.0001)

Can Patient Videos in Lectures Increase Interest and Improve Learning in Rheumatology Among Second Year Medical Students?

Shuwei Wang[1] and Michele Meltzer[2], [1]Internal Medicine, Thomas Jefferson University Hospital, Philadelphia, PA, [2]Rheumatology, Jefferson Universtiy, Philadelphia, PA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Given the expanding aging population and burden of rheumatic diseases, along with an anticipated shortage of rheumatologists, there is increasing urgency to develop curriculums that properly train and attract new fellows. A recent study showed a low level of self assessed confidence in rheumatology knowledge and skills among internal medicine residents despite increasing years of training1. Increased patient exposure can potentially increase students' interest in becoming rheumatologists. It remains to be tested whether videos featuring patients can be an effective teaching tool. The aim of this study is to assess whether videos featuring real patients can increase interest and improve learning in rheumatology among second year medical students.

Methods:

A rheumatologist gave a PowerPoint lecture on rheumatoid arthritis (RA) followed by short video segments featuring real patients talking about their experiences with RA. The rheumatologist explained and demonstrated physical findings characteristic of RA. Prior to filming, the patients completed informed consents stating that the videos will only be used for educational purposes. Immediately after lecture, students rated their confidence in taking a history from patients with joint pain, forming differential diagnoses for patients with joint pain and identifying physical exam findings associated with RA. The survey included a comments section to gather students' perception of the videos.

Results:

TABLE 1. Demographic Characteristics of Second Year Medical Students and their Interest in Rheumatology (n=61)

Gender	
Male	30 (49%)
Female	31 (51%)
Age	24 (median)
Career Plan	
Internal Medicine	0 (0%)
Internal Medicine Subspecialty	15 (24.6%)
Surgical Specialty	15 (24.6%)
Other	25 (41%)
Undecided	5 (8.2%)
Have you had a medical school lecture in rheumatology?	
Yes	53 (86.9%)
No	8 (13.1%)
Did this lecture increase your interest in taking a rheumatology elective?	
Yes	31 (51%)
No	15 (24.5%)
Undecided	15 (24.5%)
Do you have an interest in rheumatology as a career?	
Yes	1 (1.6%)
No	35 (57.4%)
Undecided	25 (41%)
Did this lecture increase your interest in pursuing rheumatology as a career?	
Yes	10 (16.4%)
No	31 (50.8%)
Undecided	20 (32.8%)
Do you have adequate exposure to rheumatology in two years of medical school?	
Not at all	6 (9.8%)
A little bit	12 (19.7%)
Somewhat	20 (32.8%)
Adequate	23 (37.7%)
Very Adequate	0 (0%)

TABLE2. Comparison of confidence rating based on self-reported impact from video exposure

Video Impact	N (%)	Average Rating┼ (+/- S.D.)	P value*
Patient History Gathering			
Increased confidence	31 (51%)	3.5 +/- 0.6	**<0.01**
No change in confidence	30 (49%)	2.5 +/- 0.7	
Forming Differential Diagnosis			
Increased confidence	23 (38%)	3.3 +/- 0.6	**<0.01**
No change in confidence	38 (62%)	2.5 +/- 0.8	
Identifying RA Physical Exam Findings			
Increased confidence	46 (75%)	3.8 +/- 0.7	**<0.01**
No change in confidence	15 (25%)	2.9 +/- 0.5	
Board Exam Preparation			
Helpful	27 (45%)	3.2 +/- 0.8	**<0.01**
Did not help	33 (55%)	2.5 +/- 0.9	

┼Rating on a (1) to (5) scale: (1) not at all (2) a little bit (3) somewhat (4) moderately (5) extremely

*p-values were obtained using the Mann-Whitney-Wilcoxon test

Among students who reported that watching the videos increased their confidence in history gathering, forming differential diagnoses, identifying RA physical findings in patients with joint pain, they also reported higher level of confidence in those areas compared to

students who did not report increase in confidence from watching the videos. In the comments section, students reported the videos were 'helpful', 'personable', 'memorable', and useful in recalling 'landmark manifestations more easily' and in realizing the drastic changes of RA on patients' lives.

Conclusion:

This study suggests that including patient videos in lectures may generate interest in rheumatology and increase self perceived confidence in taking a history and physical from patients with joint pain. More rigorous studies are needed to evaluate the role of patient videos in medical school curriculum.

Confidence and Competence of Medicine Trainees' Musculoskeletal Skills: A Report of the Relationship from a Large Multi-Year, Multidisciplinary Cohort

Andrea M. Barker[1], Grant W. Cannon[2] and Michael J. Battistone[1], [1]Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, [2]Internal Medicine, Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Musculoskeletal (MSK) Education Week for medical students, residents, fellows, and trainees of other health professions has been sustained since 2011. The objective of this study was to examine the relationship between self-reported measures of confidence and observed measures of competence in this multi-year, multidisciplinary cohort of trainees.

Methods: The MSK Education Week emphasized the evaluation and management of shoulder and knee pain. Self-reported confidence was captured utilizing a 5-point Likert scale at the start and conclusion of the program. Competence was measured at the end of the program by a validated 2-station objective structured clinical examination (OSCE) with a rater unaware of the self-reported confidence. Self-report ratings of 3 (neutral) or lower were categorized as ÒlessconfidentÓ; performance on the OSCE was categorized as ÒlowÓ for those lower than 2 standard deviations from the mean. Chi-square was calculated for dichotomized self-assessment ratings and OSCE scores, and PearsonÕs correlation was performed on all data.

Results: Since 2013, 233 trainees have participated in the MSK education week. Response rates producing complete data sets were 86% for shoulder and 80% for knee. Confidence ratings by participants across all disciplines increased after the course (Table 1). Mean OSCE score was 92% for the shoulder and 86% for the knee. Table 2 shows the relationship of dichotomized confidence ratings and OSCE scores; there was no significant difference between the groups (shoulder $X^2 = 1.22$, $p = .269$; knee $X^2 = 0.18$, $p = .672$). PearsonÕs coefficient indicated no correlation between confidence and competence for the shoulder (r = 0.02) or the knee (r = 0.1).

Total	71	82	80	233 (100)	2.9 / 3.2	4.4 / 4.4	4.6 / 4.3

Abbreviations: PGY, postgraduate year; PM&R, physical medicine and rehabilitation; MS 4, fourth year medical student.

Table 2 – Relationship of Dichotomized Confidence Rating and OSCE Score

		OSCE Performance		
		Low	High	Total
Shoulder	Less Confident	0 (0%)	17 (9%)	17 (9%)
	Highly Confident	11 (6%)	172 (86%)	183 (92%)
	Total	11 (6%)	189 (95%)	200 (100%)
				$X^2 = 1.22$, $p = .269$
Knee	Less Confident	1 (1%)	13 (7%)	14 (7%)
	Highly Confident	8 (4%)	165 (88%)	173 (93%)
	Total	9 (5%)	178 (95%)	187 (100%)
				$X^2 = 0.18$, $p = .672$

Conclusion: The MSK Education Week is a sustainable program that has demonstrated effectiveness across a range of disciplines and learner levels for over 3 years. Following the program, the majority of participants were both highly confident and highly competent. A small number of participants whose observed competence was low were nonetheless highly confident. The lack of correlation between self-report and objective measures supports the continued development and use of meaningful external measures of competence for trainees in medical education and health professions programs.

Long-Term Impact of an Enhanced Rheumatology Curriculum for Internal Medicine Residents

Susan F. Kroop[1], Cecilia P. Chung[2], Mario A. Davidson[3], Laura A. Skaug[4], D. Alan Johnstone[4] and Charlene M. Dewey[5], [1]Department of Rheumatology and Immunology, Vanderbilt University Medical Center, Nashville, TN, [2]Medicine, Vanderbilt University Medical Center, Nashville, TN, [3]Department of Biostatistics, Vanderbilt University School of Medicine, Nashville, TN, [4]Center for Experiential Learning and Assessment, Vanderbilt University School of Medicine, Nashville, TN, [5]Internal Medicine, Vanderbilt University School of Medicine, Nashville, TN

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Internal medicine (IM) residents need to be trained in the diagnosis and care of patients with rheumatologic disease. Our prior data show that a multimodal simulation training session (MSTS) enhanced curriculum improves post graduate year (PGY) 1 IM residents' self-confidence in rheumatologic history taking, physical exam, ordering and interpreting laboratory test results, procedures and patient care. To assess if this enhanced curriculum has a long-term impact on trainees' self-confidence, we compared self-assessment surveys of PGY3 IM residents who received this MSTS curriculum while PGY1 residents to those who had not.

Methods: Since 2014, all PGY1 IM residents participate in a MSTS enhanced curriculum during the ambulatory rheumatology block which includes direct observation , discussion and feedback of their evaluation of a standardized patient with knee pain as well as knee aspiration training using a mannequin model. All PGY3 residents are invited to complete a web-based survey assessing confidence (0=not confident, 100=extremely confident) in performing a rheumatologic history, exam and common rheumatologic procedures (injection and aspiration of the knee and shoulder and trochanteric bursa injection), in ordering and interpreting rheumatologic lab tests (ESR, CRP, RF, CCP, ANA) and in caring for patients with OA, SLE, RA, gout, and fibromyalgia. The survey also includes demographics and participation in additional rheumatology electives. We compared the PGY3 survey results between those who had participated in the MSTS enhanced curriculum 2 years prior during their PGY1 year (Group 1) with an historical control group who did not have the enhanced curriculum (Group 2)using the Wilcoxon Signed Rank test. The Institutional Review Board approved the study.

Results: 33/42 (79%) PGY3 IM residents from the MSTS enhanced group (Group 1) and 67/85 (79%) from the control group completed the survey. 48% of respondents were female in Group 1 and 55% were female in Group 2. 14/33 (42%) in group 1 and 30/67 (45%) in group 2 took an additional rheumatology elective during training. There was a significantly higher self-assessed confidence in ordering and interpreting ANA and RF in those residents that had participated in the MSTS enhanced curriculum (Group 1) compared to controls (Group 2). There was no significant difference in self-assessed confidence in all other metrics (Table).

Conclusion: Our MSTS enhanced curriculum during the PGY1 ambulatory rheumatology block was associated with higher self-assessed confidence two years later at the PGY3 level in ordering and interpreting ANA and RF, but not in the other metrics measured. This suggests that repeat or additional rheumatology specific training may be necessary during the later years of residency to improve IM residents' confidence in all aspects of the diagnosis and care of patients with rheumatologic disease.

Clinician Training in Motivational Communication Skills: The Impact of the Language

of Change Program Among Rheumatologists from Across Canada

Kim L. Lavoie[1,2], **Mary Bell**[3,4], Trudy Taylor[5], Regan Arendse[6], Michele Saum[7], Denis Faucher[7], May Shawi[7] and Monique Camerlain[8], [1]Université de Quebec á Montréal, Montreal, QC, Canada, [2]Montreal Behavioral Medicine Center, Hôpital du Sacre Coeur de Montréal, Montreal, QC, Canada, [3]University of Toronto, Toronto, ON, Canada, [4]Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [5]Dalhousie University, Halifax, NS, Canada, [6]University of Saskatchewan, Saskatoon, SK, Canada, [7]Janssen Inc., Canada, Toronto, ON, Canada, [8]Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, Canada
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Motivational communication (MC) is an evidenced-based communication style designed to enhance patients' intrinsic motivation to engage in a healthy lifestyle and adhere to treatment. Due to its efficacy and popularity, the demand for physician training has risen markedly over the past decade. Despite the widespread dissemination of these programs, there is little empirical data on the extent to which they impact physician knowledge and attitudes. This study assessed the impact of 2 1.5 hour MC workshops (phase 1 and 2 of the Language of Change Program) on MC attitudes among rheumatologists.

Methods: This was a single group pre-post intervention trial. The MC training program, called The Language of Change, was developed by rheumatologists and a behavior change expert. The program being assessed consisted of 2 live workshops (1.5 hour sessions, held roughly 6 months apart) delivered by an MC expert alongside a rheumatologist, to 67 rheumatologists from across Canada. Participants completed a battery of validated questionnaires measuring MC motivation, self-efficacy, outcome expectancies, and short term (30 day) intention to change, at baseline and after each of the Module 1 and 2 sessions. T-tests were conducted to assess the effects of the introductory workshop on each questionnaire.

Results: Analyses revealed significant post-introductory workshop effects on motivation to use MC (+.86, p<.0001), MC self-efficacy (+1.26, p<.0001), outcome expectancies (including perceived program usefulness [+.59, p<.0005], pertinence [+.48, p<.003], effectiveness [+.81, p<.00001], potential to benefit physicians [+.54, p<.0001], potential to benefit patients [+.65, p<.0002], and short term (30 day) intention to change (pre=43%, post=66%).

Conclusion: This study indicates that two 1.5 hour workshops on MC significantly increased motivation to use MC and MC self-efficacy, and had a uniformly positive impact on outcome expectancies and intention to use MC in practice. Results suggest that even a small amount of MC training may impact healthcare professional attitudes and intention to change.

Enhancing Pediatric Rheumatology Education through Computer-Assisted Fellow-Taught Case Modules

Rosemary Peterson[1], Rebecca Blankenburg[1], Michal Cidon[2] and Joyce Hsu[3], [1]Pediatrics, Stanford University, Palo Alto, CA, [2]Stanford University, Palo Alto, CA, [3]Pediatric Rheumatology, Stanford University, Palo Alto, CA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - Poster

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Teaching is an ACGME milestone for pediatric subspecialty fellows. Despite this expectation, there is little literature regarding how to empower fellows to teach residents. In a recent survey, 100% of Stanford Pediatric Rheumatology fellows were either extremely or very dissatisfied with the teaching they provide. Corroborating fellows' perceptions, Stanford pediatric residents rated the rheumatology rotation the lowest overall in 2014-2015, with teaching identified as a primary weakness. The objective of this study was to evaluate the effect of a novel resident curriculum on resident education and fellow teaching of core pediatric rheumatology topics.

Methods: This is an IRB-exempt, single site, prospective interventional study. Four existing pediatric rheumatology didactic lectures were converted into interactive, computer-assisted, case-based learning modules using e-learning software. Modules were designed to encourage fellow and resident interaction at each clinical decision point. Fellows led didactic sessions on four consecutive Thursdays during the rotation. Study participants included 27 residents and 5 pediatric rheumatology fellows during academic year 2015-2016. 15 residents in the pre-intervention group received 4 existing lectures. So far, 9 of 12 residents in the intervention group have received interactive, computer-assisted, case-based teaching modules. All residents received a pre- and post-rotation knowledge assessment and survey. The primary outcome was resident evaluation of fellow teaching. Secondary outcomes included fellow self-evaluation of teaching, resident knowledge of rheumatologic conditions, and resident evaluation of the Rheumatology rotation.

Results: 10/15 residents (66.6%) in the pre-intervention group and 7/9 residents (77.8%) in the post-intervention group completed the post-rotation survey. Pre-intervention feedback included desire for case-based instruction, a structured approach to rheumatologic diagnoses, and increased teacher-learner interaction. After the intervention, resident rating of fellow lectures improved from 2.75 to 3.60 on 4-point Likert scale ($p<0.05$) and amount of interaction/discussion improved from 2.63 to 3.60 ($p<0.05$). Pre and post-rotation knowledge assessment analysis was limited by suboptimal completion rates. Data collection regarding fellow self-evaluation of teaching and resident rotation evaluation will be completed by July 1, 2016.

Conclusion: Residents on the pediatric rheumatology rotation value case-based, interactive modules, which improve satisfaction and guide teacher-learner discussions about the complex clinical reasoning process in rheumatology. Additionally, this study suggests that computer-assisted case-based modules may be an effective, standardized and easily accessible modality to enhance fellows' teaching of residents.

Rheumapalooza Update: Applying a Flipped Classroom Instructional Model to an Intensive Rheumatology Curriculum for Second Year Medical Students

Kristen Hayward[1,2], Gregory Gardner[3] and Helen M. Emery[4], [1]Pediatric Rheumatology, University of Washington & Seattle Children's Hospital, Seattle, WA, [2]Pediatric Rheumatology, Seattle Children's Hospital, Seattle, WA, [3]Rheumatology, University of Washington, Seattle, WA, [4]Pediatric Rheumatology, Seattle Childrens Hospital, Seattle, WA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumapalooza was implemented in 2008 as a 2 half-day elective course with support from an ACR/REF Clinical Scholar Educator Award. Course evaluation demonstrated significant increases in studentÕs knowledge of rheumatologic disorders and high student satisfaction ratings.[1] Rheumapalooza was incorporated into the required UW Medical School 2nd year curriculum in 2010 and expanded to 3 half days. In 2015 a flipped classroom instructional model was applied to 1 half day of content. We describe lessons learned from ongoing curriculum review with emphasis on increasing opportunities for learner engagement.

Methods: The course now consists of 3 consecutive half-day sessions. Day 1 is structured as a series of foundational didactic lectures.[1] Day 2 was initially delivered in large-group lecture format. Revisions in 2015 put more emphasis on basic rheumatologic disorders and opportunities for active learning. Students were given required reading and 4 case studies to prepare prior to class. Cases reinforce key

aspects of RA, gout, JIA, and SLE. Faculty facilitate student discussion of cases in a small-group format. On day 3, students rotate through 14 stations, including adult and pediatric rheumatology patients, demonstrations of physical therapy, pathology specimens and imaging modalities. Multiple choice exams assess mastery of course material. Students complete annual course evaluations including overall rating, achievement of learning objectives, ratings of specific lectures and days. Numerical and qualitative responses were recorded.

Results: The patient panel day has received consistently high student ratings (Figure 1). Feedback on the lecture days revealed opportunities for improvement. Students reported the lectures felt overloaded and requested more opportunities for cementing knowledge. Modification of the 2nd day to a small-group flipped classroom model was associated with improvement in studentÕs rating of active learning opportunities and overall satisfaction (Figure 1). However, student comments indicated concern about less coverage of rare rheumatologic disorders and inconsistencies between small group instructors.

Conclusion: Integration of a case-based flipped classroom model into the Rheumapalooza curriculum was associated with improved student satisfaction, however, the breadth of information covered decreased. These findings have important ramifications for future medical school curricula development given increasing emphasis on active learning delivery models and shorter duration of pre-clinical teaching hours. Future work will focus on partnership with clinical year course directors to envision adequate coverage of essential rheumatologic concepts across the medical school curriculum. The Virtual Rheumatology Clinic: Virtual Patients for Resident Education in Rheumatology

Bethany A. Marston[1], David Siegel[2], Allen P. Anandarajah[3] and Valerie Lang[4], [1]Allergy, Immunology and Rheumatology, University of Rochester Medical Center, Rochester, NY, [2]Pediatrics, University of Rochester/Rochester General Hospital, Rochester, NY, [3]Dept of Rheumatology, Univ of Rochester Medical Ctr, Rochester, NY, [4]Medicine, University of Rochester, Rochester, NY
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatology topics can be challenging for residents to master during training. In our program, a survey of residents completing a 2- or 4-week rheumatology elective in 2014-15 demonstrated that many still felt unprepared to provide primary care (67%) or inpatient care (46%) for patients with rheumatologic disease, and for board exams (56%). Residents were confident in their ability to diagnose rheumatologic conditions (71%) but less confident in management of these conditions (47%). We aimed to assess the role of the Virtual Rheumatology Clinic, an online self-study tool developed to supplement resident education in rheumatology through virtual exposure to several common rheumatologic diagnoses, in enhancing the education of the resident.

Methods: Four virtual patient cases were developed to introduce evaluation and management options for patients presenting with

symptoms commonly seen in primary care: 1) monoarticular swelling in an adult, 2) joint swelling in a child, 3) fatigue and unexplained fever, and 4) back pain. Each case begins with the complaint and proceeds through several stages. Learners' decisions shaped the virtual patient's course, allowing the trainee to practice longitudinal decision making and experimentation in a safe environment. Activities included drag-and-drop quizzes, script concordance testing, procedure simulation, and matching exercises, and offer immediate feedback to enhance learning. Links to images, videos, review articles, and primary literature were embedded as well. Modules were available to residents on the web via any computer or tablet. Rotating residents were given time to complete these modules during their elective. Participating residents were asked to complete a pre-test, a post-test associated with each module, and a final survey.

Results: Ten residents rotating in 2015-16 completed the pretest and survey, 7 completed at least one module post-test, and 16 completed the final survey. On post-tests, residents scored higher on knowledge-based multiple choice questions than on key features questions, (76% vs 64% average score). On a 0-10 scale, residents who completed at least one module rated these as helpful (8.8), easy to use (8.7), and realistic (8.1). They were rated as more useful in learning to care for patients in a primary care setting (8.7) or in the hospital (8.3) than for board study (7.4). Residents who completed modules were more confident in their ability to manage rheumatologic conditions and expressed greater interest in caring for patients with these conditions than those who did not complete any modules.

Conclusion: The Virtual Rheumatology Clinic is a an online self-study tool developed to provide virtual exposure to common rheumatologic diagnoses likely to present in primary care. Participants in the pilot cohort found it helpful, easy to use, and realistic, and useful for a variety of settings. It is unclear whether participation increased interest in rheumatology or whether participants are self-selecting. Future work may be able to better assess knowledge acquisition and clinical reasoning skills by random selection of questions to be completed either before or after completion of each module.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Caring for children and adults with rheumatic diseases in the future requires training an adequate number of rheumatologists today. As part of the 2015 Workforce Study, rheumatology fellows-in-training (FITs) were surveyed to obtain insight into factors affecting the selection of rheumatology as a specialty and their expected career tracks.

Methods:

FITs completed an electronic survey assessing demographics, fellowship information, student debt, and career decisions. Missing responses were excluded from analysis and percentages were calculated based on the number of respondents answering each question.

Results:

Of 497 pediatric and adult FITs in the US, 415 completed the survey (83.5% response rate). FIT demographics are shown in Table 1. Most FITs were women; almost half (48.9%) were international medical graduates (IMGs). 70% of US graduates had student loan debt.

The most common reasons to choose rheumatology were intellectual interest, lifestyle/work hours, and clinical rotations; the least common

reason was income potential. Rheumatologists commonly inspired trainees to pursue rheumatology training, usually during residency.

FITs' career interests are shown in Figure 1. Although private practice was the most commonly preferred career path overall, it was significantly more common for men than women (51.1% vs 38.2%, p=0.0154). Women were more interested than men in the clinician educator track (37.8% vs 22.0%, p=0.0012).

Upon fellowship completion, 11.3% (n=47) of FITs were planning to work part-time, more commonly by women than men (15.9% vs. 2.8%, p=0.0001). 17.5% (n=72) of FITs plan to practice outside the US, the majority being IMGs, as compared to FITs from US medical schools (33% vs. 2.8%, p<0.0001).

Conclusion:

The current study sheds light on challenges facing the future of rheumatology in the US. Rheumatology fellowships are failing to attract graduates from US medical schools, these graduates also have significant student loan debt. Eleven percent of FITs plan to work part time, and 33% of IMGs plan to work abroad, contributing to a potential shortage of rheumatologists.

This study also highlights opportunities to increase the number of future rheumatologists. These include recruiting underrepresented minorities, increasing rheumatology exposure in medical school and residency, encouraging practicing rheumatologists to mentor trainees, providing incentives with loan repayment programs, and encouraging IMGs to stay in the US after fellowship.

Mentoring the Pediatric Rheumatology Community through the American College of Rheumatology/Childhood Arthritis and Rheumatology Research Alliance Mentoring Interest Group Network: A Five-Year Status Update

Kristen Hayward[1], Alexei Grom[2], Eyal Muscal[3], Peter Nigrovic[4], Kelly Rouster-Stevens[5], Lakshmi N. Moorthy[6] and the ACR/CARRA Mentoring Interest Group, [1]Pediatric Rheumatology, University of Washington & Seattle Children's Hospital, Seattle, WA, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Immunology, allergy and Rheumatology, Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [4]Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, [5]Pediatric Rheumatology, Emory University School of Medicine, Atlanta, GA, [6]Pediatric Rheumatology, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The American College of Rheumatology (ACR)/Childhood Arthritis and Rheumatology Research Alliance (CARRA) Mentoring Interest Group (AMIGO) is a subspecialty-wide inter-institutional mentorship program launched in 2011 to target mentorship gaps within pediatric rheumatology. AMIGO provides an annual opportunity for fellows and junior faculty to be paired with a more senior faculty based on career interests. These ongoing mentorship dyads last for a 3-year cycle. Initial survey of the pediatric rheumatology community after the first 3-year cycle revealed measurable increases in reported access to mentorship beyond the home institution and perceived benefit from AMIGO in specific domains, including career development, scholarship, work-life balance, and connectedness to the pediatric rheumatology community. We describe the sustainability and spread of the AMIGO mentoring network over the past five years (2011-2016).

Methods: A quality improvement framework was used to report on outcomes associated with annual cycles. ACR database and surveys were used to obtain data.

Results:

1) Process outcomes: Figure 1 demonstrates the number of new dyads entering the AMIGO network each year and the cumulative number of active dyads which reached 141 in 2015. 2011 and 2012 cohorts are now retired, for 75 dyads that have completed the program.
2) Participant experiences and perceptions: Participants have responded favorably to faculty development sessions held annually at the ACR and CARRA scientific conferences. Highlights from programmatic evaluations are shown in Table 1.

3) Outcomes for organizational effect: As of spring 2016, 252 unique individuals have participated in AMIGO as mentees, mentors or

both. The 2015 American Board of Pediatrics Workforce Survey identifies 325 pediatric rheumatologists with active board certification and 96 pediatric or medicine-pediatrics rheumatology fellows. Thus, participation in AMIGO has reached almost 60% (252/421) of the U.S. pediatric rheumatology community.

Conclusion: AMIGO continues to provide much needed access to mentorship for pediatric rheumatologists. Over the span of 5 years, more than half of the U.S. pediatric rheumatology community has been involved in this program. Exit survey of retired dyads and repeat survey of the pediatric rheumatology community are planned to identify factors contributing to mentorship success and areas for improvement.

Session Time: 9:00AM-11:00AM

Impact of a Student Led Rheumatology Interest Group on Medical Student Interest in Rheumatology

Background/Purpose: Based on data from the 2005 Rheumatology Workforce Study the demand for rheumatologists will continue to increase in the coming decades. Demand for rheumatologists outstrips the current supply of trained rheumatologists. The American College of Rheumatology has implemented several strategies to try to increase medical student interest in Rheumatology including programs such as Choose Rheumatology! The purpose of this observational study was to investigate impact of development of a student led Rheumatology Interest Group and the Choose Rheumatology! program on medical student interest in Rheumatology at a single institution.

Methods: In April 2015 a student led Rheumatology Interest Group was established at our institution. As part of the inaugural meeting the "Choose Rheumatology!" team presented on careers in rheumatology, several faculty gave testimonials on why they had chosen Rheumatology, and patients spoke on the impact their rheumatologist had on their lives. Follow up meetings included a meeting on finding research projects and two joint injection workshops. To assess medical student interest in rheumatology we retrospectively collected data from the two years before initiation of the interest group (2012-2014) and the year following initiation of the interest group (2015-16) based on four parameters: the number of medical student abstract submissions to the GW Research Day, the number of medical students enrolling in the rheumatology elective, and the number of manuscripts published by faculty with medical students. In order to account for the variable time periods in the pre and post intervention groups, the mean number of student-rheumatology interactions per 6 months in the pre and post intervention periods was assessed for each parameter. Data analysis was performed using GraphPad Prism version 5.00 for Windows (GraphPad Software, San Diego, CA).

Results: Student interest in the rheumatology elective significantly increased following the Interest Group intervention with a mean number of students per 6 months of 2.0±0.36 in the pre intervention period and 7.5±3.5 in the post intervention period (p=0.021). The number of abstract submissions also significantly increased with 0.5±0.34 in the pre-intervention period compared to 7.0±4.0 in the post-intervention period (p=0.017). The number of manuscripts submitted by student-faculty dyads has also increased from 0.16±0.16 to 1.5±0.5 (p=0.013).

Conclusion: A simple and low cost intervention of development of a student led interest group coupled with a Choose Rheumatology! Campus visit has dramatically impacted student interest in Rheumatology at a single institution.

Adressing Medical Students' Concerns in the Patient/Physician Interaction with People with Rheumatic and Musculoskeletal Diseases Leading to Handicap – a Pilot Experience Including Student Focus Groups and Interactions with Patient Associations

Stéphane Mitrovic[1,2], Christine Poitou-Bernert[1], Rebecca Haddad[1], Maeva Ferrari[1], Marie-Christine Renaud[1], Alexandre Duguet[1] and Laure Gossec[1,2], [1]Sorbonne Universités, UPMC University Paris 06, Paris, France, Paris, France, [2]Rheumatology, Pitié Salpêtrière Hospital, Paris, France
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Physicians may have difficulties dealing with patients with chronic rheumatic and musculoskeletal diseases, in particular due to bias against handicap. There may be preconceived ideas about these diseases associated with disabilities, leading to altered patient-physician interactions. In other specialties, the technique of focus groups (FG) including medical students who can discuss their preconceived ideas, followed by interactions with patients, has been used [1]. The objective of this study was to explore the usefulness of FG and interactions with patient associations during undergraduate training for medical students.

Methods: This was a pilot experience in one French University. Five FG were organized during spring 2016. Students in the fourth year of medical studies volunteered in one 3-hours FG, about one of the following themes: handicap (2 sessions), obesity (2 sessions) or mental health. The discussion groups were moderated by a neutral coordinator (Assistant Professor), attended by an observer and a transcriber. In the 2 handicap FG, the students first discussed together about 3 pre-defined questions: 1) which perception do you have about handicap and disabled people? 2) Do you have difficulties when you are faced with clinical examination of disabled people? 3) According to you, what do the handicapped people expect from medical doctors? After one-hour discussion, the students met the representatives of patient associations and shared the main elements resulting from the FG. Satisfaction was assessed through anonymous likert-scale questionnaires comprising 10 questions (final score 0-100%).

Results: Of the 375 students initially contacted by the University, 70 volunteered, and 5 FG of 14 students were organized: 2 FG (28 students) were centered on handicap. Preconceptions of undergraduates included difficulties to examine handicapped patients and to take care of them, with an uncomfortable feeling about how to look at them and how to behave, and the fear to harm them. The interaction with the patient associations allowed the students to compare their bias to the truth of living with a handicap. Satisfaction ratings among students were very high (mean value 93%). All the students (100%) reported that discussing about preconceived ideas was useful, and 92% declared that the FG helped them to observe the importance of social representations in the care of disabled patients. Interestingly, 54 % of the students estimated that medical training on handicap was not sufficient before attending the FG. The satisfaction rating of the patient association was 100%.

Conclusion: FG followed by a moment for dialogue and exchange with patients allow medical undergraduate students to express their bias against handicap, and to compare them with the truth of living with a handicap. This method, leading to high levels of satisfaction in our pilot study, may help in future teaching of patient-physician relationships and interactions around handicap. Long-term impact on care relationship remains to be studied. **References:** 1. Stalmeijer RE, Mcnaughton N, Van Mook WN. Using focus groups in medical education research: AMEE Guide No. 91. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A preference for shared decision-making among patients with chronic conditions has been associated with better health outcomes. We compared the impact of a multimedia patient education tool (MM-PtET) compared to a written booklet with the same information in patients with passive vs active decision-making role preference.

Methods: Patients were recruited from 5 centers and through advertisement. Inclusion criteria were: (i) age ≥18 years (ii) diagnosis of rheumatoid arthritis (RA), knee osteoarthritis, or osteoporosis/osteopenia (OP) (iii) adequate cognitive status and, (iv) ability to communicate in English or Spanish language. Participants with RA had a disease duration ≤10 years and all patients with OP were women. Our primary outcome was disease knowledge and secondary measures included decisional conflict, self-efficacy and disease management. Assessments were conducted before and after viewing MM-PtET, at 3 and 6 months. The Control Preference Scale (CPS) was used to characterize participants according to their preferred role in decision making (passive/uninformed vs active/informed role).

Results: 665 participants were randomized (331=MM-PtET, 334=written booklet). Mean age was 59.8±12.1 years, 87% were female, 65% non-White, 20% had inadequate health literacy levels and 26% answered the questionnaire in Spanish. Thirty-three percent had a diagnosis of OA, 34% OP, and 33% RA; 472 (232=MM-PtET, 240=booklet) and 522 (257=MM-PtET, 265=booklet) participants returned their questionnaires at 3 and 6 months, respectively. Most patients reported an active decision-making role preference in the intervention (48% active, 36% shared, and 15% passive) and control (47% active, 36% shared, 17% passive) groups. Greater knowledge scores were observed after viewing the MM-PtET compared reading the booklet in patients with a shared role preference (p=0.04). Compared to patients in the control group, patients in the intervention group with a passive role preference had less decisional (p=0.04) and better decision management (p=0.02) at 3 months. However, at 6 months improvements from baseline were only significant for patients with an active (decisional conflict, p=0.04) and shared role preference (disease management, p=0.03). Univariate analysis showed that greater improvements in knowledge (regardless of assignment) were associated with passive role preference compared to active (p=0.001, pre&post; p=0.03, pre&6-month) and shared role (p=0.01) preference.

Conclusion: Our MM-PtET improved outcomes after intervention, 3 and 6 months. However, the benefits varied according to the decision-making role preference. Given the observed differences, it is important that educational interventions are tailored to the patients' preferences about their involvement in the decision-making processes.

#Rheumjc: Impact of Invited Authors on a Twitter Based Rheumatology Journal Club

Isabelle Amigues[1], Paul Sufka[2], Suleman Bhana[3], Jose Campos[4] and Christopher Collins[5], [1]Division of Rheumatology, Columbia University, College of Physicians & Surgeons, New York, NY, [2]Rheumatology, HealthPartners, Saint Paul, MN, [3]Crystal Run Healthcare, Middletown, NY, [4]Rheumatology, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, [5]Medicine, MedStar Washington Hospital Center/ Georgetown University Medical Center, Washington, DC

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Twitter is an increasingly popular platform for discussion and engagement among healthcare professionals. #RheumJC is a Twitter-based international rheumatology journal club which occurs approximately once a month. One novel aspect of #RheumJC has been to include principal authors of the discussed manuscripts, whenever possible. Here we describe participant analysis and survey results from the past 18 months of this initiative with a focus on how the presence of authors has impacted the journal club and

participants.

Methods: A #RheumJC development team was created to help define the structure and moderate the online discussions. Prior to each journal club, principal authors of the selected manuscripts were invited to participate. A total of 10 different online journal clubs were conducted between January 29th, 2015 and June 2nd, 2016, each consisting of two "live" one hour chats, as well as a full 24 hrs to allow for asynchronous participation. In 4 of the 10 journal clubs, principal authors of the chosen manuscripts participated in the online discussion. An analysis of all the sessions was performed to assess participant demographics and participation rates. A follow up survey was conducted after the 10th journal club to both #RheumJC participants as well as the invited authors to assess metrics of satisfaction and identify additional strengths or barriers.

Results: In total, 433 individuals from 36 different countries participated in at least one #RheumJC session. For the 4 journal clubs during which principal authors were present, compared to sessions without an author present, there were a significantly greater number of participants (46 ± 11.5 vs 26 ± 13.3 respectively, p=0.039) and tweets (462 ± 103.5 vs 306 ± 111.0, p=0.048) suggesting the presence of principal authors was a popular feature. 35 individuals from 11 different countries responded to a survey and indicated they had participated or followed along in at least one journal club session. The majority (88%) indicated they were either satisfied or very satisfied with the #RheumJC initiative. Additionally, 37.5% of respondents indicated that their participation in #RheumJC had influenced practice decision making. When asked which sessions resulted in practice changes, 71% of the responses highlighted sessions where authors were available as discussants. Of interest, 7% of respondents indicated they had joined Twitter solely because of #RheumJC, and another 37% stated that #RheumJC had increased their use of Twitter as a tool for medical education. A survey of the invited authors revealed that they found their experience very rewarding and all of them indicated that they would be highly likely to participate again.

Conclusion: #RheumJC is a novel and popular approach to the traditional medical journal club. The involvement of manuscript authors has proven to be a particularly well received aspect of this initiative. The inclusion of authors in the discussion increases user engagement and possibly can influence practice decision making by journal club participants. We encourage authors to participate in this novel educational activity to potentially broaden the impact of their research.

Reducing Imaging Tests for Low Back Pain: Can Patients Choose Wisely?

Nick Bansback[1], Judy Chiu[2], Sheila Kerr[3], Rita McCracken[2,4] and Bruce Forster[5], [1]School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada, [2]Centre for Health Evaluation and Outcome Sciences, Vancouver, BC, Canada, [3]Arthritis Patient Advisory Board, Richmond, BC, Canada, [4]Family Practice, University of British Columbia, Vancouver, BC, Canada, [5]Professor and Head, Department of Radiology, University of British Columbia, Vancouver, BC, Canada

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

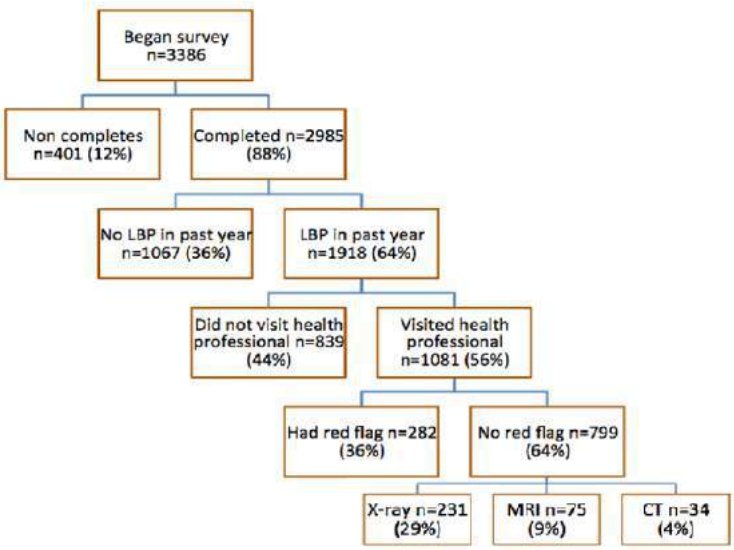
Session Time: 9:00AM-11:00AM

Background/Purpose: Management of nonspecific acute low back pain (LBP) is complicated by many patients' belief that imaging tests will be useful. Choosing Wisely is a campaign that represents a physician-driven effort to create conversations between physicians and patients around overuse and waste. The objective of this study was to determine the potential impact of the Choosing Wisely educational pamphlet on patients' behavioural intentions for future imaging tests.

Methods: We recruited a cohort representative of the Canadian adult general population to a web survey in English and French to consider the impact of the Choosing Wisely campaign for LBP. We first ascertained respondents' experiences of LBP, and baseline behavioural intentions for a future LBP episode, including attitudes, beliefs and knowledge on LBP and imaging tests. We next asked respondents to read the Choosing Wisely pamphlet before asking follow-up questions to understand the pamphlet's potential impact.

Results: Of the 3386 respondents that began the survey, 2985 completed all questions and were included in the analysis. Respondents broadly matched the age and gender of the Canadian population, with 7% completing the survey in French. 1918 (64%) of respondents reported an episode of LBP in the past year, of which 1081 (56%) visited a health professional. Of the 799 who reported they had no red

flag, 336 (42%) received an imaging test for their LBP, predominantly X-ray. Overall, 37% and 39% of respondents stated that they would want or expect an imaging test for future LBP. After reading the Choosing Wisely educational pamphlet, this reduced from 39% to 24% ($p<0.001$) for wanting, and 37% to 22% ($p<0.001$) for expecting an imaging test. Similar improvement was seen in knowledge questions about the need and potential risks of imaging tests, and for alternative management strategies.



Conclusion: The Choosing Wisely pamphlet for LBP was effective in changing some individuals' behavioural intentions around imaging tests. Simple extrapolation implies in Canada each year there are over 2 million inappropriate x-rays and 700,000 inappropriate MRIs for LBP. This costs between $300-$600 million per year. Conservative estimates suggest implementing the Choosing Wisely campaign could save $30 million per year. Future analysis will explore subgroups where the influence of the Choosing Wisely pamphlet is most and least. Follow-up studies are planned to assess whether respondents stated changes in behavioural intentions.

Abstract Number: 1147

A Novel Survey Tool to Assess Inpatient Consult Service Performance

Eli Miloslavsky[1] and Yuchiao Chang[2], [1]Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, MA, [2]General Internal Medicine, Massachusetts General Hospital, Boston, MA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The role of subspecialty consultation in inpatient medicine is increasing. Effective consultation services have an important impact on the quality and efficiency of patient care as well as care transitions. Within academic medical centers, successful resident-fellow interactions during consultation positively affect resident and student education and may influence their career choice. Therefore, enhancing the performance of subspecialty inpatient consultation services may have a broad reaching impact. To our knowledge, an instrument designed to measure consult service performance has not been described. We developed a consult service evaluation tool and evaluated its psychometric properties at a large academic center.

Methods: The instrument was developed by the investigators and Internal Medicine (IM) subspecialty fellowship program directors at a single academic center. It asked IM residents to evaluate ten IM subspecialty consult services (rheumatology, cardiology, etc.) on the following items (5-point scale): overall satisfaction, communication, professionalism, teaching and pushback (reluctance or resistance to perform the consult). The instrument was administered in May 2015 and May 2016 to all IM residents. Pearson correlation coefficients

were used to summarize the relationship between measured items and overall satisfaction. To take into account the repeated measures data structure, linear regression models with Generalized Estimating Equations were used to compare across post graduate year (PGY), year of survey administration or consult service.

Results: One hundred and thirteen residents responded (47 in 2015 and 66 in 2016 [45 PGY-I, 35 PGY-II and 33 PGY-III or IV], combined response rate 35%). Each of the four items measured (communication, professionalism, teaching, pushback) significantly correlated to the overall satisfaction rating in univariate analyses (all with $p<0.01$), suggesting internal validity. Multivariate analyses demonstrated that each item independently contributed to the overall satisfaction score (communication [r=0.68], professionalism [r=0.64], teaching [r=0.42] and pushback [r=0.47], all with $p<0.01$). There were no differences in ratings across PGY year or year of survey administration demonstrating reliability of the instrument (Table). There was considerable variation in ratings among the 10 services evaluated (all with $p<0.01$, Table) signifying that consult services are perceived differently, even within a single academic center.

Conclusion: We describe the development and evaluation of an instrument designed to evaluate subspecialty consult service performance. Our results suggest that perception of consult services varies considerably among residents. This tool can be utilized to assess consult services and measure the effect of interventions designed to improve consult service performance. **Table – Ratings of Internal Medicine Subspecialty Consult Services and Comparisons by PGY Year and Year of Survey Administration**

Implementation of a Gout Knowledge Based Assessment Tool in an Inter-Professional, Multi-Disciplinary Musculoskeletal Training Program

Erica Jaffe[1], Andrea M. Barker[2], Grant W. Cannon[2] and Michael J. Battistone[2], [1]Internal Medicine, Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, [2]Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Musculoskeletal (MSK) Education Week is an interprofessional, multidisciplinary, multilevel training initiative launched in 2012. In 2015, this program was expanded to include a written assessment of participants' knowledge regarding the evaluation and treatment of patients with gout. Our objective was to examine the initial experience in implementation and compare the self-assement versus standardized questions scores.

Methods: The week-long course is held monthly at a VA Medical Center affiliated with a university training program. The curriculum includes didactics, technology-enhanced simulation, peer-teaching, and culminates in ambulatory clinical experiences and reflective practice. All interns from categorical internal medicine, preliminary neurology and physical medicine and rehabilitation programs, residents and fellows from occupational medicine, family medicine, geriatric and rheumatology programs, and students from the physician assistant and advance practice nursing programs participate each year. Evaluations include self-assessments and a 2-station observed structured clinical examination (OSCE). In 2015-16, a 40-item multiple-choice test, which included 28 questions relating to gout, was developed and incorporated into the existing scheme of pre- and post-course assessments.

Results: In 2015-16 to date, 70 trainees have participated in the MSK Education Week. Response rates for the pre-course and post-course gout knowledge assessment were 96% (n = 67) and 93% (n = 65) respectively. Mean pre-course score for questions related to gout were 50% and mean post-course score was 85% with p-value for pre- vs. post-course scores <0.001. Response rates for the pre-course, post-course and retrospective self-assessment surveys were 97% (n = 68), 83% (n = 58), and 53% (n=37) respectively; these results are shown in the Table below as well as a correlation with the objective test scores at completion of the course. Our analysis was limited to the subjects who completed all pre- and post-course self and knowledge assessments.

	Mean Pre-course Ratings		Mean Post-course Ratings	Spearman's rank correlation coefficient for Gout-# self-rating vs Post-course multiple choice test score n = 34
	Prospective (range, s.d)	Retrospective		
Gout-1: I can perform an appropriate evaluation of patients with gout	3.3*** (1-5, 0.9)	2.8*** (1-4, 1.8)	4.3 (3-5, 0.7)	-0.09
Gout-2: I can develop an appropriate plan for patients with gout	3.2*** (1-5, 1.0)	2.8*** (1-4, 1.0)	4.3 (3-5, 0.6)	-0.15
Gout-3: I understand when to refer patients with gout for specialty care	3.0*** (1-5, 1.0)	2.6*** (1-4, 1.1)	3.9 (2-5, 0.7)	0.05

*** P<0.0001 in comparison to post course

Conclusion: Increases in self-assessment of knowledge, as well as in written test scores, were observed following participation in the MSK Education Week. There was no correlation between improvement in these two measures, which may be attributable to a ceiling effect associated with nearly universal high self-assessment ratings at the end of the course.

Rheumatology Elective Time in a 4+1 Residency Structure: Evaluating Impact of a Novel Residency Schedule Structure on Rheumatology Resident Education

Nora Taylor[1] and Erica McBride[2], [1]The George Washington University, Washington, DC, [2]Department of Medicine, The George Washington University, Washington, DC

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Models of residency education in the United States are evolving nationwide to limit conflicting care responsibilities and enhance the outpatient internal medicine resident experience. One newer model of training is known as the X+Y model with X (inpatient) weeks to Y (ambulatory clinic) weeks (e.g. 4 inpatient weeks followed by 1 outpatient week) repeated in a continuous cycle over the course of residency. [1] Despite the increasing adoption of an X+Y training model, little is known about how it impacts subspecialty rheumatology elective time and resident rheumatology education needs. This needs assessment sought to determine how

residents at The George Washington University (GWU) felt rheumatology education was impacted in the new X+Y structure.

Methods: Two surveys, were conducted utilizing Survey Monkey in March of 2015 and again in June of 2016. [2] Surveys consisted of 9-10 questions with responses via Likert scale or multiple choice with section for free text response.

Results: 27/98 (27%) of residents responded to the March 2015 survey conducted in the first year of the 4+1 residency structure, 19/27 (69%) of residents reported extreme or moderate dissatisfaction with rheumatology exposure in the 4+1 residency structure. 0/27 (0%) felt they had adequate time for electives in the new structure. 18/27 (66%) rated themselves as likely or definite in their plans to seek rheumatology elective. 16/27 (59%) resident respondents reported decreased opportunity for rheumatology exposure in a 4+1 structure. To achieve rheumatology education, the requested models for education included addition of a rheumatology half day clinic to their +1 week (9/27 (33%)) with the second most popular choice being the addition of more rheumatology noon conference lectures (7/27 (25%)), however 12/27 (44%) felt noon conference was not an effective training method. 17/25 (68%) third year residents responded to the 2016 follow up survey. 4/17 (24%) of residents found subspecialty elective time decreased in the newer residency model with majority of residents 13/17 (64%) noting elective time the same or increasing. 8/17 (47%) of residents felt satisfied with the amount of rheumatology exposure they receive in the new 4+1 structure with 9/17 (53%) feeling dissatisfied or unsure if they had sufficient exposure. 6/17 (35%) reported an educational half-day within their +Y week would best meet their rheumatology education needs. 6/17 (35%) cited more morning report cases as the optimal rheumatology learning format. Only 3/17 (18%) felt rheumatology elective time would best satisfy their learning needs.

Conclusion: Dissatisfaction with degree of rheumatology training and exposure were evident in both surveys. Traditional rheumatology elective was not cited as a popular way for residents to meet their rheumatology education needs. Rheumatology educators need to consider novel ways of adopting internal medicine resident rheumatology education to evolving residency structures.

Advocacy 101: Engaging Rheumatology Fellows in Health Policy and Advocacy

Sarah Doaty[1], Sharon L. Kolasinski[2], William F. Harvey[3], Adam Cooper[4] and E. Blair Solow[5], [1]Rheumatology, UCLA, Los Angeles, CA, [2]Division of Rheumatology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [3]Rheumatology, Tufts Medical Center, Boston, MA, [4]American College of Rheumatology, Atlanta, GA, [5]Rheumatology, UT Southwestern Medical Center, Dallas, TX

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Healthcare delivery and health policies in the United States are evolving rapidly. Rheumatology fellowship programs lack formal curricular content to educate trainees about legislative and regulatory healthcare policies that will have a profound impact on the future of academic and community practices.

Methods: A web-based survey was sent via the American College of Rheumatology (ACR) Fellows in Training (FIT) listserve in June and July 2015. The survey queried fellows enrolled in U.S. rheumatology training programs about their knowledge of and participation in health policy and advocacy. Survey results guided the design of an educational session called Advocacy 101 for fellows and program directors in October 2015 in conjunction with the ACR Advocates for Arthritis fly-in. Curriculum included introduction to state and federal legislative and regulatory policies as well as education on how to be an effective advocate. Participants were asked to take educational content from the event and hold a teaching session at their home institution. Participants also shared their experiences at the 2015 ACR Annual Meeting FIT roundtable sessions and the 2016 ACR State of the Art meeting Advocacy Workshop. A second survey was sent to fellows in April 2016.

Results: Survey response rates increased from 19% to 39% between 2015 and 2016. The majority of respondents were in adult training programs with nearly half (46% in 2015, 47% in 2016) reporting plans for a career in academics. Forty percent (up from 35% in 2015) reported that they were aware of advocacy efforts through the ACR. The top reason (64%) for non-participation in health policy and advocacy efforts in 2015 was lack of knowledge on how to get involved. This decreased to 39% of respondents reporting the same barrier in 2016. Other barriers to participation in 2016 included lack of time and familiarity with the issues. Only 7% felt their participation would have no effect, down from 16% the previous year. The health policy issues that 2016 participants identified as most important were patient access to medication (83%), patient access to insurance (68%) and physician reimbursement (58%). Fellows preferred in-person teaching sessions and online modules to email correspondence for education on these topics. The percentage of individuals who were familiar with and contributed to RheumPAC increased.

Conclusion: Engagement in health policy and advocacy efforts is critical to continued recruitment of trainees into the field of rheumatology, support for education and research, and advancement of clinical practice. Current training program curricula do not prepare fellows for the new challenges of our changing health care system. Advocacy 101 is the first program designed to educate and engage rheumatology fellows in health policy and advocacy endeavors. Fellows express an interest in becoming involved but view their lack of time and knowledge of the issues as their biggest barriers. Fellows indicate that ACR-sponsored events and formal curricula would be an effective way to gain knowledge on health policy and advocacy. Advocacy 101 is the first step in addressing this need.

A Pediatric Rheumatology Fellow Educating Pediatric Primary Care and Emergency Room Providers about Pediatric Lupus: A Local, Pilot Adaptation of the Lupus Education Advancement Project (LEAP)

Katherine Steigerwald[1], Amy Caron[2], Diane Gross[3], Zoon Naqvi[4] and Yonit Sterba[5], [1]Pediatrics, The Children's Hospital at Montefiore, Bronx, NY, [2]Lupus Research Institute, New York City, NY, [3]S.L.E. Lupus Foundation/Lupus Research Institute, New York, NY, [4]Albert Einstein College of Medicine, Bronx, NY, [5]Pediatric Rheumatology, The Children's Hospital at Montefiore, Bronx, NY
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Pediatric systemic lupus erythematosus (SLE) accounts for approximately 10-20% of all cases of SLE. It is more common in African American and Hispanic patients, who together comprise the majority of our Bronx population. It can be a challenging diagnosis for providers to make but early recognition is especially important, as pediatric patients typically have more severe disease than adults. The objectives of this project are for pediatric primary care and emergency room providers to be able to recognize the symptoms and signs of lupus, to initiate a work-up, and to identify high-risk patients who would benefit from prompt referral to pediatric rheumatology.

Methods: First, a comprehensive, interactive presentation on pediatric lupus and a relevant knowledge assessment tool, consisting of 9 multiple-choice questions, were developed. These new materials were tested on a small group of providers affiliated with a nearby, community hospital. Then, formal seminars were scheduled with groups of providers affiliated with The Children's Hospital at Montefiore during regular, weekly meeting times. These included pediatric primary care, adolescent medicine, and pediatric emergency medicine providers. At the seminars, participants were asked to complete voluntary, de-identified pre and post assessments, and were informed about completing an online version in 4-6 weeks (follow-up assessment). Paired t-tests were used to calculate the changes in knowledge for matched data. Participants were also asked to comment on their intent to make practice changes.

Results: Eighty-one providers attended the 8 seminars, and 57 matched pre and post assessments were collected. Of participants who completed the post-assessment, 94.9% agreed that the seminar improved their medical or practice knowledge. Of those with matched responses, 96.4% demonstrated an increase in knowledge on the assessment tool, with a score difference of 3.02 on a 9-point scale ($p < .001$). In addition, of participants who completed the post-assessment, 90.4% indicated that they will make changes that will benefit patient care as a direct result of the seminar. The mean follow-up assessment scores remained higher than the pre-assessment scores for 7

out of 9 questions. Lastly, of those who completed the follow-up assessment, 40% indicated that they are more likely to think of lupus in the differential diagnosis.

Conclusion: After a brief educational intervention, pediatric primary care and emergency room providers demonstrate knowledge gains, some of which are sustained. Importantly, they are also more likely to consider lupus in this high-risk population.

Table 1. Knowledge Assessment Tool Scores, On a 9-Point Scale

(Includes Matched and Unmatched Data)

	N	Mean Score	Std. Deviation	Minimum Score	Maximum Score
Pre	60	4.63	1.64	1.00	9.00
Post	60	7.65	1.23	4.00	9.00
Follow-up	5	6.40	1.52	4.00	8.00
Total	125	6.15	2.07

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Education - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In 2008, 18% of rheumatology fellowship program (RFP) program directors (PDs) included musculoskeletal ultrasound (MSUS) in their training programs. Overall goal of this study was to assess the current state and ascertain the needs for MSUS education among RFPs. The objective of this study was to determine if fellowship program size impacts inclusion of MSUS in training.

Methods: Out of two surveys sent via Qualtrics™ in 2015, a 13-item needs assessment survey was sent to all RFP PDs determining implementation of MSUS teaching including machine accessibility, faculty training, and institutional support. The second survey assessed teaching and evaluation methods used. For the first survey, Fischer's Exact Test was used to test differences between fellowship programs based on size. Small programs were defined as programs with 1-2 fellows yearly, while big programs were those with at least 3 fellows yearly.

Results: Out of 113 RFPs, 103 (91%) PDs responded to the needs assessment survey. In total, 94% of RFPs are currently offering some form of MSUS training. Of 73 small programs, 91.8% offered MSUS training; 97.1% of big programs offered MSUS training. By large, there was no statistically significant difference between small and big programs (p=0.429). Majority of both small and big programs (81.8 vs. 93.9%) cited at least one faculty who was competent in performing MSUS (p=0.212). Majority of the teaching was done by a key clinical faculty member other than the PD (39.7% vs. 54.5%). Majority owned an US machine (72.1 vs. 87.9%; p=0.037). When asked if they wanted MSUS to be part of the Rheumatology fellowship training curriculum, majority wanted its inclusion however most wanted it

only to be optional (66.2% vs. 66.7%), as compared to those wanted it to be a standard requirement (29.4% vs. 30.3%).

Conclusion: MSUS has become prevalent among RFPs. The size of a fellowship program is not a factor in determining inclusion of a MSUS teaching program. Small programs have comparable capacity to include MSUS in teaching programs when compared to big programs. There is openness to including MSUS in Rheumatology fellowship training, whether as an optional or standard part of the curriculum.

Exploring Perceptions of a Rheumatoid Arthritis Specific Smoking Cessation Programme

Pip Aimer[1], **Lisa K. Stamp**[2], Simon Stebbings[3], Vicky Cameron[1], Sandra Kirby[4] and Gareth Treharne[5], [1]Medicine, University of Otago, Christchurch, New Zealand, [2]University of Otago, Christchurch, New Zealand, [3]Department of Medicine, Dunedin School of Medicine, University of Otago, Dunedin, New Zealand, [4]Arthritis New Zealand, Wellington, New Zealand, [5]Psychology, University of Otago, Dunedin, New Zealand

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - ARHP Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Premature mortality rates in individuals with rheumatoid arthritis (RA) are significantly higher in current smokers compared to those who have never smoked, making smoking cessation an important consideration in RA management. The aim of this study was to determine which aspects of a novel three-month RA smoking cessation intervention were most useful and to identify areas for improvement.

Methods: Thirty-eight current smokers (19 intervention and 19 control) with RA were enrolled in a pilot randomized controlled trial involving a novel three-month psychosocial smoking cessation intervention delivered by two community based Arthritis Educators. Nicotine replacement therapy (NRT) was offered to all participants as usual care regardless of randomization. Despite no significant difference in smoking cessation rates (26% intervention vs 21% control; p=0.70), there was a high quitting rate among all participants. Here we examine the efficacy through interviews with the participants and Arthritis Educators, using a mixed qualitative methodology. There were three sources of data: 1) interview notes from contacts between the Educators and 19 intervention participants during the smoking cessation intervention; 2) interview notes from the two follow-up interviews at three and six months post-randomization between the researcher and all study participants; and 3) exit interviews between the researcher and the two Educators. Interview data was analyzed thematically using a combination of deductive and inductive approaches to identify themes.

Results: Sixteen intervention and 19 control participants completed the six month follow-up. Support was individualized for each participant and their support choices were monitored by the Educators. A comparison between the acceptance and usefulness of individual intervention components as informed by the participants who accepted each component is shown in Figure 1. The individualized support and advice from the Educators were the key intervention components most valued by the participants and the Educators alike. This was followed by the generic smoking cessation components and education about the links between smoking and RA. The use of NRT as a common treatment to both intervention and control groups was the most commonly reported facilitator of smoking cessation. Participants who identified as being ready to quit smoking had more success at smoking cessation. The Educators were positive about ongoing provision of the smoking cessation intervention with minor changes.

Conclusion: This research highlights the strategies that can be focused on for improving smoking cessation rates in people with RA. Successful quitters were ready and motivated to quit smoking regardless of their randomization status. Support offered by the Educators was critical from the viewpoint of participants who received the intervention.

Promoting Self-Management Techniques for Osteoarthritis Pain: a Pilot Study of Nurse Practitioner Led Coping Skills Training

Christine A. Stamatos[1,2] and Particia Bruckenthal[3], [1]Medicine, Division Rheumatology, Northwell Health, Great Neck, NY, [2]Northwell Health, Great Neck, NY, [3]School of Nursing, Stony Brook University, Stony Brook, NY
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Arthritis is the leading cause of chronic pain and disability in the United States. Two thirds of patients report inadequate pain control. Coping Skills Training (CST), a well recognized self-management program traditionally delivered by mental health providers, decreases pain and disability and improves self-efficacy. Yet, access to CST remains limited. The purpose of this pilot study is to evaluate the feasibility and effectiveness of nurse practitioners (NPs) delivering group CST in a suburban rheumatology private practice.

Methods: A convenience sample of 39 osteoarthritis patients with chronic pain participated in a 10-week CST program delivered by a

trained adult NP. There were approximately 10 patients in each of 4 groups. The feasibility of delivering group CST was measured through completion of at least 50% of the program. Effectiveness was assessed through change scores from pre and post treatment measures of pain, depression, coping, and self-efficacy using paired t-tests.

Results: The sample was primarily Caucasian (92%), female (87%), 60 years of age with 13 years of moderate to severe osteoarthritis (71.8%) and most carrying co morbid rheumatologic conditions (72%). Overall, subjects reported being very satisfied with the program, group process, content and leadership by the NP. Non-completers (n=17) were not statistically different at baseline than completers and described mostly logistical issues and medical problems as reasons for attrition. For those who completed the program (n=22), there was a significant improvement in pain, depression, coping, and self-efficacy. Table 1 Feasibility of Group Process for 10 Week Program, N=22

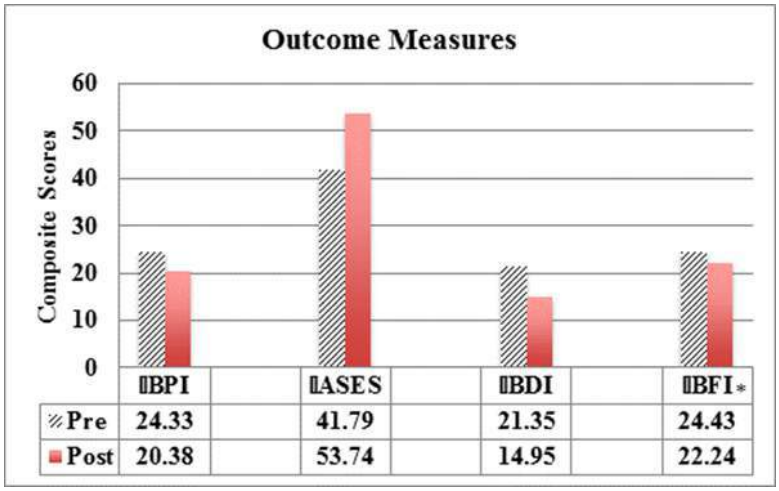
Figure 1 Outcome Measures



BPI: Brief Pain Inventory, ASES: Arthritis Self Efficacy Scale, BDI: Beck Depression Inventory, BFI: Brief Fatigue Inventory. P value < .05 for all except Fatigue. * There was no significant change on this measure.

Conclusion: This pilot study provides preliminary evidence to support the use of adult health NPs to deliver CST to patients with chronic pain seen in private practice settings. Additionally, it has the potential to broaden the scope of advanced practice nursing and dramatically increase access to this important self-management technique.

The Effect of Nurse-Led Follow-up in Rheumatoid Arthritis. a Systematic Review and Meta-Analysis of Randomized Controlled Trails

Annette de Thurah[1,2], Bente Appel Esbensen[3,4], Ida K Roelsgaard[4], Tove F Frandsen[5] and Jette Primdahl[6,7], [1]Department of Rheumatology, Aarhus University Hospital, Aarhus, DK, Aarhus, Denmark, [2]Department of Clinical Medicine, Aarhus University, Aarhus, DK, Aarhus N, Denmark, [3]Copenhagen Center for Arthritis Research (Copecare), Rigshospitalet, Copenhagen, DK, Copenhagen, Denmark, [4]Department of Clinical Medicine, University of Copenhagen, Copenhagen, DK, Copenhagen, Denmark, [5]The knowledge Center of Odense University Hospital, Odense University Hospital, Odense, DK, Odense, Denmark, [6]King Christian X's Hospital for Rheumatic Diseases, Graasten, Hospital of Southern Jutland, DK, Graasten, Denmark, [7]Institute for Regional health Research, University of Southern Denmark, Odense, DK, Odence, Denmark

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Due to a longer life expectancy in general, the treatment burden of RA is growing, and although treatment is generally becoming more effective and better tolerated, many countries experience an unmet demand for rheumatologists and a current demand for greater cost-effectiveness. For this reason alternatives to conventional outpatient physician-led follow-up have been investigated, i.e. nurse-led follow-up. Thus, the aim was to conduct a systematic review and meta-analysis, investigating the efficacy of nurse- versus physician-led follow-up in the treat to target strategy in RA.

Methods: A systematic literature search was performed using the databases: Medline, Embase, the Cochrane Central Register of Controlled Trials, PsycINFO, CINAHL, Web of Science, Scopus, and. Eligible trials were all randomized controlled trails reporting on the effect of nurse-led follow-up in managing disease control in RA in comparison to physician-led follow-up at hospitals or medical clinics. This implied nurse-led follow-up for out-patients with RA where nurses performed assessment of tender and swollen joints, evaluated blood-samples and monitored the medical treatment in order to evaluate the patients' disease activity as part of the consultation. Nurses included rheumatology nurses, nurse practitioners, clinical nurse specialists and advanced nurse practitioners. Physicians included rheumatologists and younger physicians involved in follow-up care of patients with RA.

Results: Eight articles, reporting five studies with 1044 participants in total, were included. All but one study included stable patients who were in remission at baseline. Overall, no difference in disease activity was found after 48-52 weeks (MD -0.07 (95% CI: -0.23; 0.09)) (Figure 1). After 84-104 weeks a small statistical, but not clinical relevant difference, was seen in favor of nurse-led follow-up (MD -0.29 (95% CI: -0.53; -0.04). No difference in patient satisfaction was seen after 48-52 weeks (SMD -0.17 (95% CI: -1.00; 0.67). After 84-104 weeks a statistical significant difference was found in favor of nurse consultations.

Conclusion: Overall no difference was found on the effect of disease activity whether RA patients were offered nurse- or physician led follow-up, but the patients tended to become more satisfied over time in nurse-led follow-up. This evidence supports the understanding that routine disease monitoring of RA patients in stable phase can include specialist nurses. Development of a Taxonomy of Patient Engagement in Health Research

Background/Purpose: The emergent practice of patients engaging in the conduct and decision-making aspects of health research has been accentuated in this decade. Its practice deems to improve the relevance, appropriateness, and knowledge translation of research by incorporating the patient perspective. However, systematic reviews (SRs) have highlighted a lack of common language across studies reporting this practice,[1, 2] making it challenging to examine the evidence in this area. To address this shortcoming, this study aimed to develop a taxonomy of patient engagement in research.

Methods: We systematically searched 6 electronic databases for relevant documents published January 1980 – July 2015. We also searched 4 key journals, reference lists, and the grey literature. Eligible documents were in English, with information relevant to patient engagement in research. We targeted theories, frameworks and models as well as SRs and commentaries related to the practice, to base our taxonomy. Content analysis was performed using 3 predetermined categories: 1) *Who* are the patients?; 2) *How* do patients engage?; and 3) *When* do patients engage?, that were formed based on prior readings. For example, one article emphasized that these 3 categories cover the context and process of patient engagement in research.[3] The first author reviewed, extracted, and organized the data under each category. The data was analyzed for unique descriptors, then combined into themes. The descriptors were then defined and their relationships explored.

Results: A total of 29 documents (21 frameworks/models, 4 SRs, 1 commentary, and 3 empirical studies) contributed descriptors to the taxonomy. Each document provided descriptors in some themes, but none provided descriptors in all themes. Some documents contributed to defining and explaining the interconnections of the descriptors. These documents included models of information flow and communication between patients/public and researchers, community/patient/public engagement continuum, and the division of control and power over the research process. The results, summarized in Table 1, contain the categories '*Who?'* described by type of affiliation; '*How?*' described by the initiation, mechanism, and degree of engagement; and '*When?*' described by the stage of research cycle divided across three research phases.

Conclusion: This taxonomy presents descriptors for diverse forms of patient engagement in research. Researchers could use this taxonomy to select options of patient engagement in research to plan their studies, then use its descriptors to communicate the context-specific contributions of patients. Future research should validate this taxonomy.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is the most common type of inflammatory arthritis in the U.S., affecting 4% of the population. Gout also has a large impact on health care costs in the U.S. with $6 billion dollars spent annually. Over 2 million visits to primary care providers (PCP) each year are gout related. Despite modern advancements and the availability of reference tools, the current care from PCPs is felt to be suboptimal in the U.S. Barriers to improving care in gout include limited education during medical training, perception of non-importance by providers, and the lack of PCP continuing medical education. In an attempt to address limited education during training, we developed a digital adjunctive teaching tool, GoutPro, on the topic of gout. Utilizing a clinically integrative model proposed by *Khan et al*, it takes into consideration different learning styles, current guidelines on gout, interactive activities and clinical problem solving. The overall the goal of our teaching intervention is to improve medical trainee knowledge and interest in gout.

Methods: 15 medical residents and students from the University of Minnesota participated in a 1 hour GoutPro teaching session. The session was a Fellow led didactic using our GoutPro software. GoutPro is a hybrid software that incorporates presentation ability, audience participation, clinical simulation and mini-games. GoutPro is structured with lecture content on slides with multiple choice questions integrated evenly throughout. Within the lecture content, we also incorporated competitive scored mini-games to increase audience participation and satisfaction. At the end of the session, there was a simulation in which participants made clinical decisions based on an evolving scenario. Feedback was provided on choices participants made at the end. Participants utilized their smart devices to operate GoutPro as a means of interacting anonymously during the session. Our primary outcome measure was participant satisfaction assessed by post-session survey. Our secondary outcome measure was level of interest in the topic of gout, educational value of the tool, and usefulness of the tool also assessed by a post-session survey. A descriptive analysis of the data was performed.

Results:

Table 1. GoutPro Feedback	1 Strongly Disagree	2 Somewhat Disagree	3 Neutral	4 Somewhat Agree	5 Strongly Agree
I was satisfied with the GoutPro session	-	-	-	4	11
My level of interest in the topic of gout care has increased	-	-	-	6	9
The GoutPro session was fun	-	-	-	-	15
The GoutPro session was interactive	-	-	-	8	7
My knowledge base on the topic of gout has increased	-	-	-	2	13
The GoutPro session is likely to change my future management of gout	-	-	-	1	14

Conclusion: In conclusion, the GoutPro session was effective, fun, interactive and educational. All participants were satisfied with the session. Our study demonstrates that GoutPro can be used as a teaching tool to increase participant satisfaction and interest. Further studies will be needed to assess change in knowledge and quality measures.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Education - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The purpose of this study was to investigate the effects of an educational program using T2T (Treat RA to Target, T2T) strategy on Korean patients with moderate to severe rheumatoid arthritis

Methods:

Patients with moderate-severe RA were randomly assigned to an educational intervention group or conventional care group. The intervention was a nurse-delivered 9 month educational program consisting of 3 monthly sessions lasting 30~40 minutes each and monthly telephone counseling. Assessments occurred at baseline and every 3 months with both two groups, but only intervention group was completed 9 month- education follow up. Primary outcome variables were as follows: disease activity (DAS28), pain (VAS 100mm), functional disability (Korean Health Assessment Questionnaire, KHAQ), fatigue (FACIT-Fatigue scale), illness perception (Brief Illness Perception Questionnaire, BIPQ), self-esteem (self-esteem questionnaire) and quality of life (Short form Health Survey 36, SF-36). We used the ANOVA test with repeated measures to evaluate the outcome variables in comparison between groups and follow-up times.

Results: Patients in the interventional group (n=33) had significant improvement in disease activity (DAS28) (p=.029), pain(p=.023), fatigue(p=.019), illness perception(p=.000), quality of life (physical function: p=.028, role physical: p=.035, bodily pain: p=.007, general health: p=.003, vitality: p=.009, social function: p=.001, mental health: p=.037) compared to patients in conventional care group(n=33). There was no significant difference between the groups and follow-up times in functional disability, self-esteem and SF-36 subscale of role emotion

Conclusion: This patient educational program using T2T strategy consisting of nurse-delivered individual session had statistically significant benefits for disease activity, pain, fatigue, illness perception and quality of life in Korean patients with moderate to severe rheumatoid arthritis. The results suggested that patient educational program using T2T strategy contribute to positive clinical outcome as a good practical nursing intervention.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Education - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Adherence to DMARDs is suboptimal and declines over time, preventing patients from reaching remission. Patient navigators, non-health professionals trained in advocacy, care coordination and basic disease management, have been shown to improve diabetes and heart failure control and cancer screening. We piloted a 6-month intervention, Med Assist, to assess whether rheumatology patient navigators could improve DMARD adherence.

Methods: We enrolled patients ≥18 years old at an academic rheumatology center with a systemic rheumatic disease, initiating a new oral DMARD within the prior 6 months. Two patient navigators communicated by phone or in person with patients every 2-4 weeks depending on need, for 6 months. Navigators assessed medication use and barriers to care and provided tailored strategies to improve medication adherence. Patients completed validated surveys at baseline and at 6 months. These included the Morisky Medication Adherence Scale (MMAS-8, <6=poor adherence, 6-<8=borderline, 8=high), Mental Health Inventory (MHI-5, <68 indicates depressive symptoms), Beliefs about Medicines Questionnaire, Brief Illness Perception Questionnaire (cognitive and emotional representations of illness), and disease activity indices (SLAQ for SLE, RADAI for RA). We used paired t-tests to compare baseline and 6-month survey scores. We examined the association of age, race/ethnicity, insurance and MHI-5 with change in MMAS-8 score using multivariable linear regression.

Results: We studied 69 patients with rheumatic diseases who engaged with the navigator and completed baseline and 6-month MMAS-8 surveys. The mean age was 55 (±16) years, 93% were female, 50% were white, 11% Hispanic and 7% black; 14% had Medicaid, 32% Medicare and 37% commercial insurance. The mean baseline MMAS-8 score was 6.7 (± 1.3), indicating borderline adherence, and the mean MHI-5 was 60.8 (± 9.1), suggesting prevalent depressive symptoms (**Table**). At 6 months, there was no significant change in MMAS-8 or MHI-5, or in measures of RA or SLE disease activity. We observed stronger beliefs about medicine efficacy (p=0.03) and a higher illness perception score (p=0.01) at 6-months compared to baseline. Our multivariable model demonstrated a small but statistically significant change in MMAS-8 for each 5-year increase in age (β=0.14, p=0.02).

Conclusion: While this pilot demonstrated the feasibility of a rheumatology-specific navigator, we did not find a significant improvement in DMARD adherence at 6 months. We observed enhanced beliefs about DMARD efficacy, but also a more negative view of the impact of rheumatic diseases on patients lives. A randomized, controlled trial of a rheumatology-specific navigator with longer follow-up is needed to determine whether stable DMARD adherence may demonstrate a beneficial effect, compared to the usual trend in the literature of poorer DMARD adherence over time.

Table. Survey results for baseline and 6-month post rheumatology-specific patient navigator intervention			
Survey*	**Baseline** - Mean (SD)	**6-month Follow-up** - Mean (SD)	**p-value****
Morisky Medication Adherence Scale (MMAS-8, N=69)	6.7 (1.3)	6.4 (1.6)	0.09
Mental Health Inventory (MHI-5, N=48)	60.8 (9.1)	60.5 (8.9)	0.83
Beliefs about Medicines (N=48)	11.8 (4.7)	11.6 (4.9)	**0.03**
Brief Illness Perception (N=47)	45.7 (9.8)	47.1 (8.0)	**0.01**
*MMAS-8 range 0-8, <6 is poor adherence, 6-<8 borderline and 8 is high; MHI-5 range 0-100, <68 signifies depressive symptoms; Beliefs about Medicines Questionnaire range 5-25, higher scores indicate stronger beliefs in DMARD efficacy; Brief Illness Perception Questionnaire range 0-80, higher scores indicate a more threatening view of the rheumatic disease. **Determined using paired t-tests

Development of a Shared Decision Making Tool for Osteoporosis Treatment

Sonam Kiwalkar, Internal Medicine, Rochester General Hospital, Rochester, NY
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In this era of modern medicine, health care providers and patients are partners in making decisions about treatment. It is imperative that evidence-based medicine be translated into a patient-friendly format, in which pros and cons of treatment options are compared. A simple-to-follow decision aid allows integration of patient preferences, values and circumstances with up to date science, keeping in mind the challenge of integrating this system in a busy clinical practice. Previous studies have shown that this approach enhances patient and provider satisfaction.

Methods: Several prior studies have explored the factors that matter when patients make treatment choices—these include adverse effect profile, efficacy, cost of medication, and opinion of heath care provider. Currently there is no decision aid available for osteoporosis that incorporates all the treatment options approved by the Food and Drug Administration (FDA) and considers the American College of Rheumatology (ACR) – Glucocorticoid Induced Osteoporosis 2010 guidelines. We included clinical risk factors for development of osteoporosis, computed a list of osteoporosis medications approved by FDA, searched through meta-analyses for evidence based efficacy and effect (odds ratio), cost, and side effects of the agents. We referenced National Osteoporosis Foundation Guidelines (NOF) and US

Preventive Services Task Force (USPSTF) for screening and treatment guidelines, and for glucocorticoid induced osteoporosis we referred the ACR 2010 guidelines.

Results: We created a personalized evidence-based shared decision making tool, envisioned to be used at an outpatient visit in primary care or specialty center. The clinician and patient start by documenting clinical risk factors, after which, with the help of a computer algorithm, the 10 year risk of a major osteoporotic fracture or hip fracture is calculated. A personalized report is generated which uses NOF guidelines to determine whether initiation of medication is advised. Next, the patient and provider review efficacy of medications tailored specifically to the patient's risk of an osteoporotic fracture within 10 years and how it would be altered by taking a particular medication (Fig 1). The side effect profile, form, frequency and cost of medications are included. Finally, after the patient makes an informed decision in conjunction with the clinician, an individualized report can be printed and be given to the patient with specific instructions at the end of visit.

Conclusion: We developed an interactive, colorful, easy to follow, online tool, integrating evidence based medicine and patient preferences, which has the potential to help providers in delivering optimal patient care. We are in the process of validating the tool and gathering patient and provider satisfaction scores at our institution.

Session Date: Monday, November 14, 2016

Session Title: Education - ARHP Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients are not aware of the important role of disease activity in Rheumatoid Arthritis (RA) for long term clinical outcomes. This not only prevents them from taking a more central role in the care for their own health, it also hinders rheumatologists in adhering to the tight control principle. In order to improve daily clinical practice, an improvement strategy should address patient-level barriers to tight control adherence.

Methods: The strategy was developed through a step-wise approach, in collaboration with all stakeholders and by addressing barriers to tight control on patient level. Strategies that have already proven to be successful in other chronic diseases were taken into consideration. First patient-level barriers to tight control were defined and evidence and example materials were explored. Next, a draft version was developed and improved through applying the International Patient Decision Aids Standards (IPDAS) criteria. Then, the draft was further improved by consulting an expert panel, patient research partners, and rheumatology professionals several times. The layout of the strategy was developed by consulting laymen, hospital communication departments, and patients.

Results: The DAS-pass strategy consists of two components. The first component, decision supportive information for patients, includes an informational leaflet and a patient held record. The leaflet is designed to educate patients about tight control and its importance for clinical outcomes. It aims to increase patients knowledge on tight control, to empower patients to be more involved in their own disease management, and to improve patients' medication beliefs. With the patient held record, patients can keep track of their own disease activity scores, their RA medication (changes), and on topics to be discussed with their physician. The patient held record aims to increase understanding of the tight control principle by increasing involvement and information uptake. The second component is guidance by a specialized rheumatology nurse. By discussing the decision supportive information (component 1) during an individual consult with each patient, the nurse aims to stimulate patients to communicate about their disease activity during visits, to individualize the decision supportive information to the patients' needs, and to offer the opportunity to ask questions or ask for additional support.

Conclusion: The DAS-pass strategy is a patient centered-strategy that was developed to improve tight control in daily clinical practice. By empowering and educating patients, it aims to improve communication about tight control between patients and rheumatologists, and to enable patients to take the initiative in tight control. We consider the DAS-pass strategy promising as it was developed systematically: theory based and in cooperation with the stakeholders. Research on the evaluation of the effects of the DAS-pas strategy in a Randomized Controlled Trial is currently ongoing. Acknowledgements*:* The input of all stakeholders that have helped in the development of the DAS-pas strategy is very much appreciated.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - ARHP Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: eHealth is a broad term referring to the application of information and communication technologies in the health sector, ranging from health records to telemedicine and multiple forms of health education, support, and tools. By providing increased and anytime access to information, opportunities to exchange experiences with others, and self-management support, eHealth has been heralded as transformational, creating informed, engaged, and empowered "patients as partners," equipped to take part in shared decision-making, and effectively self-manage chronic illness.1 The objective of our study is to examine how eHealth affects patient-provider relationships, and its ethical and practical ramifications.

Methods: We interviewed healthcare professionals (HCPs) about their experiences with eHealth and its impact on the office visit. Eligible participants had a caseload with >25% of patients with arthritis and multi-morbidity, in order to address issues of managing complex chronic conditions and coordination of care. In-depth interviews used a flexible, semi-structured discussion guide, and follow-up

interviews served to clarify and expand upon initial discussions. All interviews were audiotaped and transcribed verbatim. Constant comparisons and a narrative approach guided the analyses and a relational ethics conceptual lens was applied to the data to identify emergent issues.

Results: 12 HCPs (nurses, fellows, physician; 6 male, 6 female) participated. Years of practice varied from one to 29 (median = 13), and all worked in an urban or suburban setting. eHealth tools accessed most frequently were online educational resources for patients (used by all participants in some form), followed by online resources for HCPs like curated scientific summaries on diagnostic criteria, clinical therapies, and dosage calculators. HCPs generally did not see how social media could be useful to their practice. Analysis revealed 3 emergent themes: 1) HCPs shared some commonalities in how they conceptualized an "ideal" engaged patient as medically literate, bringing "useful" data to consultations, and whose evolution is largely a product of the rise of eHealth; 2) Fears of eHealth technology disrupting existing practice habits and uncertainty about liability and confidentiality issues were a barrier to the adoption of new technology; 3) Most HCPs saw eHealth tools as facilitating a shift towards a patient-provider relationship where shared decision-making is the new norm. Perceptions on the usefulness and impact of eHealth technologies varied from doubtful to enthusiastic. All declared a primary concern for best possible patient outcomes, and some saw eHealth as integral to reaching that goal.

Conclusion: HCPs see eHealth technologies broadly as agents of change, for better or for worse, however, the perceived direction of that change is neither clear nor uniform given the varied experiences of this group. The value of these technologies was largely assessed through a relational ethics perspective, as the patient-provider relationship and its outcomes remained the primary concern of all HCPs. SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Education - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Individuals impacted by arthritis have identified social role participation (e.g. relationships, leisure activities, employment) as an important quality of life outcome. There is evidence that education programs are effective for patients with arthritis in terms of improved function and quality of life. The Toronto Western Hospital Spondyloarthritis Program developed a novel interactive e-Learning education program for patients with axial Spondyloarthritis (axSpA) with input from patients and an interdisciplinary team of health care professionals. The purpose of this study was to measure the impact of the axSpA e-Learning patient education program on patients' perception of social roles and participation.

Methods: Fifty-six adult patients with axSpA attending a tertiary academic spondyloarthritis clinic were randomly assigned to one of two groups: 1) e-Learning intervention, in addition to usual care, where patients were emailed a link to the online patient education module to be completed at their leisure; or, 2) usual care (i.e. control group). All patients completed outcomes measuring Social Role and Participation (SRPQ, Gignac et al. 2011) at baseline, immediately after completing the e-Learning module, and at 6 to 12 months thereafter. The SRPQ includes 12 role domains with 3 dimensions: 1) role importance, 2) restriction to role participation, and 3) satisfaction with social role performance. Univariate and bivariate analyses were conducted on SAS version 9.2.

Results: Twenty-three patients with axSpA completed the e-Learning module and thirty-three patients continued with usual care. Overall, mean (SD) age was 42.3 (12.9) years, 69.6% were male, mean (SD) disease duration was 12.9 (10.2) years and 75% had a post-secondary education. Comparison by study group at baseline showed that importance of "relationship with other family members" was lower in the intervention group compared to controls ($p = 0.02$). Otherwise there were no significant differences between groups at baseline. Immediate follow-up measures indicated lower perceived importance in the intervention group with respect to: "plan/attend social events" ($p = 0.007$); "having a paid job" ($p = 0.005$); "relationship with other family members" ($p = 0.02$); and "fully participating in all aspects of life" ($p = 0.02$) The intervention group reported lower satisfaction with "type of paid work that you are able to have" ($p = 0.03$). Otherwise, no significant differences were noted between control and intervention groups at immediate follow-up. At 6-12 months follow-up, the intervention group reported less physical difficulty "participating in hobbies" ($p = 0.04$) and "engaging in activities with children/grandchildren" ($p = 0.04$). In addition the intervention group identified "intimate relationships" ($p = 0.02$) and "fully participating in all aspects of life" ($p = 0.02$) as less important.

Conclusion: Although there are significant differences in the levels of importance of several social role subscales, the reported differences are relatively small. Long-term findings of less physical difficulty with some social role subscales indicate potential long-term benefits of the e-Learning module to patients with axSpA.

Impact of E-Learning on Knowledge, Self-Efficacy and Exercise Behaviours of Patients with Axial Spondyloarthritis: Results from a Longitudinal Randomized Control Trial

Laura Passalent[1,2], Rita Kang[3], Daeria Lawson[4], Christopher Hawke[1,5], Ahmed Omar[6,7], Arane Thavaneswaran[4], Nigil Haroon[8,9] and Robert D Inman[7,10], [1]Allied Health, Toronto Western Hospital, Toronto, ON, Canada, [2]Physical Therapy, University of Toronto, Toronto, ON, Canada, [3]Patient and Family Education, Toronto Western Hospital, Toronto, ON, Canada, [4]Toronto Western Hospital, Toronto, ON, Canada, [5]Department of Physical Therapy, University of Toronto, Toronto, ON, Canada, [6]Rheumatology, University of Toronto, Toronto, ON, Canada, [7]Rheumatology, Toronto Western Hospital, University of Toronto, Spondylitis Clinic, Toronto, ON, Canada, [8]Rheumatology, Toronto Western Hospital, Toronto, ON, Canada, [9]Medicine, Rheumatology, University of Toronto, Toronto, ON, Canada, [10]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Education - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: There is a growing body of evidence to support the effectiveness of education programs for patients with arthritis. Despite this, there has been little development or investigation into education strategies specifically for patients with axial spondyloarthritis (axSpA). A number of studies examining education strategies for patients with various forms of arthritis have involved an interdisciplinary approach and suggest positive impact on disease activity, function and overall health. Furthermore, the use of an electronic format for education has been shown to be preferred over other methods of education for patients with axSpA. As such, the Toronto Western Hospital Spondylitis Program developed an interactive web-based e-Learning education module for patients with axSpA with input from patients and an interdisciplinary team of health care professionals and consists of evidence-based topics including diagnosis, treatment and self-management for axSpA. The purpose of this study was to measure the effect of the axSpA e-Learning patient education module with respect to: 1) knowledge of axSpA; 2) chronic disease self-efficacy, and 3) exercise behaviour.

Methods: Fifty-six adult patients with axSpA attending a tertiary academic spondylitis clinic were randomly assigned to one of two groups: 1) e-Learning intervention, in addition to usual care, where patients were emailed a link to the online patient education module and were asked to complete the module at their leisure; or, 2) usual care (i.e. control group). All patients completed outcome questionnaires at baseline, immediately after the completion of the e-Learning module and at 6-12 months thereafter. Outcome measures included: the Ankylosing Spondylitis (AS): "what do you know" knowledge questionnaire; Stanford Chronic Disease Self-Efficacy Scale, and the Stanford questionnaire for Exercise Behaviours.

Results: Twenty-three patients with axSpA completed the e-Learning education module, in addition to usual care, and 33 patients continued with usual care. Overall, mean (SD) age was 42.3 (12.9) years, 69.6% were male, mean (SD) disease duration was 12.9 (10.2) years and 75% had a post-secondary education. There were no statistically significant differences in the above outcome measures between the two groups at baseline or immediately following the completion of the e-Learning module. At the 6-12 month follow-up there was an overall increase in the number of minutes dedicated to all types of exercise the week prior to completing the outcome measures in the intervention group compared to controls, with a significant increase in the average minutes dedicated to bicycling as a form of exercise from a mean of 5.2 minutes to 34.6 minutes, p=0.02.

Conclusion: The results of this study demonstrate the addition of the axSpA e-Learning patient education module to usual care is equivalent to usual care provided at a tertiary academic spondylitis clinic and has potential to provide benefit to patients with axSpA who have limited access to specialty care. Long-term results suggest a significant impact on exercise behaviours in patients with axSpA who completed the e-Learning module.

The Development of an Interdisciplinary Treatment Program for Fibromyalgia in a Tertiary Medical Center Focused upon Rheumatology and Internal Medicine

Jessica Gehin[1], Andy Abril[2,3], Fernando Rivera[4], Benjamin Wang[3] and Barbara Bruce[1], [1]Department of Psychiatry and Psychology, Mayo Clinic, Jacksonville, FL, [2]Mayo Clinic, Jacksonville, FL, [3]Division of Rheumatology, Mayo Clinic, Jacksonville, FL, [4]Division of Consultative and Diagnostic Medicine, Mayo Clinic, Jacksonville, FL

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Education - ARHP Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia syndrome (FMS) appears to be undertreated despite the mounting evidence to support the efficacy of interdisciplinary treatment. Why are patients not receiving effective care? Practice needs included a lack of standardized assessment and treatment for patients with Fibromyalgia, inefficient management of patients being referred to Rheumatology for Fibromyalgia creating less availability of Rheumatologists on the consult service as well as reducing availability of appointments for other rheumatologic patients needed for resident teaching as well as low satisfaction for physicians employed in the care of these patients without the support of an interdisciplinary team. The present study was designed to describe the development of a successful interdisciplinary treatment program for Fibromyalgia patients and provide clinical information on the first 600 patients treated in this program between October 2014 and April 2016.

Methods: The collaborative structure of the interdisciplinary team and the goals of the program are illustrated. Patients referred to a tertiary medical center for evaluation of fibromyalgia symptoms, which were subsequently diagnosed with FMS by meeting the 2010 ACR criteria, enrolled in a 2-day interdisciplinary treatment program, served as subjects in this study. All patients in this study met the ACR Classification Criteria for Fibromyalgia. Patients completed the Fibromyalgia Impact Questionnaire - Revised (FIQR), the Center for Epidemiological Studies Depression Scale (CES-D), and the Pain Catastrophizing Scale (PCS) at the time of admission to the program. Patients were seen in a collaborative care model with trained psychiatric nurses and physicians for diagnosis and then received cognitive behavioral strategies and education in a 2-day course led by health psychologists and nurses.

Results: Physician feedback revealed that at one year, rheumatology consults had significantly greater availability, a varied patient population was now being seen in the residency program, and physician satisfaction was very high. Of the 600 patients that participated in the Fibromyalgia Treatment Program, the average age of patients was 49 years with a range from 17 to 92. The majority was female (90%). Duration of fibromyalgia symptoms on average was 10 years at the time of referral. Forty-three percent of the patients were regional, 32% national, 24% local and 1% international. The FIQR results revealed severe levels of impairment (62.08); CESD scale scores indicated significant depressive symptoms with an average score of 26; and PCS scores were at elevated levels of pain catastrophizing with an average score of 25. Patient and family satisfaction was uniformly high.

Conclusion: A successful interdisciplinary program can be developed in a medical practice. The improvement in physician and patient satisfaction in this care model is substantial. Large numbers of patients with Fibromyalgia are still not receiving interdisciplinary care locally producing continued difficulties in functioning and psychological distress.

Survey on the Understanding and Practice of T2T for Nurses Engaged in Medical Treatment of Rheumatoid Arthritis

Mie Fusama[1], Kayoko Higashi[1], Keiji Maeda[2], Norikazu Murata[3] and Hideko Nakahara[2], [1]Division of Nursing, NTT West Osaka Hospital, Osaka, Japan, [2]NTT West Osaka Hospital, Osaka, Japan, [3]Yukioka Hospital, Osaka, Japan
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Education - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In order to achieve treatment goals in patients with rheumatoid arthritis (RA), the guidance for "treatment to target (T2T) by measuring disease activity and adjusting therapy accordingly" was proposed.[1)] However, patients with RA also face various other problems such as side effects of drugs, psychological problems and issues of daily living. These problems cannot be resolved by doctors alone and, therefore, collaboration with medical staff, especially nurses, is essential. As a first step toward better rheumatic care, the nurses understanding of T2T is considered to be important.We evaluated the understanding and practice of T2T for nurses engaged in rheumatic care.

Methods: This is a cross-sectional survey conducted in Japan. Registered nurses consulting patients with RA were selected randomly for this study between May and September 2013. A self-administered survey was carried out to check the understanding of T2T, DAS28 and patient guidance. A series of data analyses were performed based on the Wilcoxon rank sum test and Pearson chi-square.

Results: 103 nurses (one male and 102 female) were enrolled. While 19 (18.4%) of the nurses knew the concept of T2T precisely, 47 (45.6%) understood partially and 37 (35.9%) did not know it at all. In comparison with 37 nurses who did not know about T2T, 66 nurses who knew about T2T showed higher knowledge about DAS28 ($p<0.0001$). The ratio of experience of the DAS calculation was also statistically significantly higher in nurses with knowledge of T2T compared with those without T2T knowledge ($p<0.0001$). Nurses with thorough knowledge of T2T statistically significantly engaged in guidance of daily life ($p=0.018$), therapeutic agent ($p<0.0001$) and health care system ($p=0.004$) compared with those who did not. Regarding the explanation of RA, there is no statistically significant difference between nurses with and without the knowledge of T2T ($p=0.126$).

Nurses who did not know about T2T statistically showed a significant tendency to consider that doctors should assess patients' joints scores compared with those with a thorough knowledge of T2T ($p=0.045$). However, both nurses agreed that the benefits of the assessment of joint scores by nurses is broadening nursing care and saves time for doctors and promotes awareness of the patients' condition before consultation. Most nurses think that they can assess joint scores technically with sufficient training.

Conclusion: This study indicates that understanding the concept of T2T is necessary to expand the role of nurses and to develop the technical knowhow for nurses involved in rheumatic care, leading to better QOL for patients with RA. [1] Smolen JS, et al. Ann Rheum Dis. 2010; 69: 631-7.

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic cutaneous lupus erythematosus CCLE is a group of immune mediated inflammatory disorders of the skin that often induce permanent disfigurement, leading to a substantial negative impact on patientsÕ quality of life. CCLE comprises discoid lupus erythematosus (DLE), lupus erythematosus profundus or lupus panniculitis (LEP), lupus erythematous tumidus (LET) and chilblain lupus erythematosus (CHLE). Relative to SLE, epidemiologic studies on CCLE are rare and limited to populations without racial diversity. This study provides minimum estimates of the incidence of DLE in particular, and CCLE in general, in a predominantly white and black population in the Southeastern United States.

Methods: The Georgia Lupus Registry is a Centers for Disease Control and Prevention-funded registry conducted to estimate the burden of lupus in a large diverse population of the Southeastern United States. Multiple sources, including dermatology and rheumatology practices, multispecialty healthcare facilities, and dermatopathology reports were used to ascertain potential new cases of CCLE from 2002 through 2004. Cases with a clinical or clinical-histological diagnosis of DLE were classified as definite DLE. Cases ascertained exclusively from dermatopathology reports were categorized as probable DLE. Age-standardized rates were determined and stratified by race and sex for DLE in particular and CCLE in general.

Results: The overall age-adjusted incidence of definite and combined (definite and probable) DLE were 2.9 and 3.7/100,000 person-years, respectively. Overall age-adjusted estimate for combined CCLE was 3.9/100,000 person-years. Black-to-white and female-to-male incidence ratios were 5.4 and 3.1 for definite DLE.

Incidence of DLE and CCLE in Fulton/DeKalb, Georgia (01/01/2002-12/31/2004)

	Definite DLE			*Combined DLE (definite and probable)*			*Combined CCLE (definite and probable)*

Black Male	30	2.8 (1.9,4.0)	2.8 (1.9,4.0)	35	3.2 (2.3,4.5)	3.3 (2.4,4.5)	39	3.6 (2.6,4.9)	3.7 (2.7,5)
White	20	0.9 (0.6,1.4)	0.9 (0.6,1.4)	33	1.5 (1.1,2.1)	1.4 (1,2)	37	1.7 (1.2,2.3)	1.6 (1.2,2.3)
White Female	17	1.6 (1.0,2.5)	1.6 (1,2.5.0)	24	2.2 (1.5,3.3)	2.2 (1.5,3.3)	26	2.4 (1.6,3.5)	2.4 (1.6,3.5)
White Male	3	0.3 (0.1,0.8)	0.2 (0.1,0.7)	9	0.8 (0.4,1.5)	0.7 (0.4,1.4)	11	1.0 (0.5,1.7)	0.9 (0.5,1.6)

Incidence rates are per 100,000 person-years (95% confidence intervals [95%CI]). Age-adjusted rates used the 2000 projected US population. The definite definition for discoid lupus erythematosus (DLE) consisted of cases with a clinical or clinical-pathological diagnosis of DLE. The combined definition for DLE included cases validated as definite and those ascertained through pathology reports (probable). Combined chronic cutaneous lupus (CCLE) included definite and probable cases of all types of CCLE, including DLE. Three cases of Asian race and 7 of unknown race were excluded from the estimates by race

Conclusion: Our findings underscore striking racial disparities in the susceptibility for CCLE, with black people experiencing between three and five-fold increased incidence of CCLE in general and DLE in particular, compared to white people. Gender differences were consistent with those reported previously, with a 3 times higher risk of DLE in females compared to males.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Identifying individuals as early as possible in the development of an autoimmune disease may lead to important opportunities. This study utilizes an established population-based registry to evaluate the burden of individuals who do not meet criteria for SLE but may be at higher risk of being diagnosed later.

Methods: The Georgia Lupus Registry (GLR) is designed to more accurately estimate the incidence and prevalence of SLE in Atlanta, Georgia. The state allowed investigators and trained abstractors to access protected health information without patient consent. Sources of potential cases included hospitals (20), rheumatologists (35), nephrology groups (10), dermatology groups (20), commercial labs, and population databases. Databases were queried for the International Classification of Diseases, Ninth Revision, (ICD-9) code 710.0 (SLE), as well as 695.4 (discoid lupus), 710.8 (other specified connective tissue disease), and 710.9 (unspecified connective tissue disease), as well as serologies and pathology results suggestive of SLE. Antiphospholipid antibody syndrome was searched for if a consistent code was used at a particular facility. Those with less than 4 American College of Rheumatology (ACR) criteria for SLE and without a final physician diagnosis of a specific connective tissue disease were analyzed. Rates were determined for incidence (2002-2004) and prevalence (2002) and age adjusted using the 2000 US population. Age adjusted estimates and 95% confidence intervals were calculated by the direct method using R (routine ageadjust.direct).

Results: 220 individuals were prevalent in 2004 with an overall age-adjusted rate of 14.2 per 100,000 person-years. 99 individuals were incident in 2002-04 with a rate of 2.1. Similar to SLE, the highest rates were in women and blacks. The rate ratio of prevalent women to men was 4.9 and was 2.2 in blacks to whites, lower than seen in SLE. (Table 1) The most frequent ACR criteria manifestations were ANA (56.4% and 57.6% in prevalent and incident individuals, respectively), hematologic disorder (39.1%, 35.4%), and arthritis (30%, 32.3%). There were no statistically significant differences between blacks and whites.

Conclusion: This is the first population-based evaluation of those not fully meeting ACR criteria for SLE in the US. The prevalence and incidence rates were 15% and 30%, respectively, of that which were seen in those validated as having SLE from the same general population. This suggests a significant population at higher risk of being diagnosed with SLE in the future can be identified. Studies are ongoing to determine the outcomes of these patients.

Rates of individuals not fully meeting classification criteria for systemic lupus erythematosus in Atlanta, Georgia, categorized by race/sex* (prevalence in 2004, incidence in 2002-04)

Race/Ethnicity, sex	Catchment population (person-years)	No. of cases	Crude rate (95% CI)	Age-adjusted rate (95% CI)
PREVALENCE				
Overall	1610314	220	13.7 (12,15.6)	14.2 (12.5,16.1)
Women	822408	185	22.5 (19.5,26)	22.5 (19.5,26)
Men	787906	35	4.4 (3.2,6.2)	4.6 (3.3,6.3)
Black	783405	131	16.7 (14.1,19.8)	18.2 (15.5,21.5)

A Systematic Review of Rheumatic Disease Epidemiology in the Indigenous Populations of Canada, the United States, Australia and New Zealand

Cairistin McDougall[1], Kelle Hurd[1] and Cheryl Barnabe[2], [1]University of Calgary, Calgary, AB, Canada, [2]Division of Rheumatology, University of Calgary, Calgary, AB, Canada

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Two important reviews have summarized the epidemiology of rheumatic disease (Peschken 1999) and RA (Ferucci 2005) in Indigenous populations of North America. Our objective was to update these reviews, incorporate non-medical databases, and expand the scope to include Indigenous populations of New Zealand and Australia.

Methods: A systematic search was performed in medical (Medline, EMBASE, CINAHL), Indigenous and conference abstract databases (to June 2015). Search terms for Indigenous populations were combined with terms for inflammatory arthritis conditions, connective tissue disorders, crystal arthritis, and osteoarthritis. Studies were included if they reported on the incidence or prevalence of rheumatic disease in Canadian, American, Australian or New Zealand Indigenous populations.

Results:

A total of 5,269 titles and abstracts were reviewed, of which 504 underwent full-text review and 88 met inclusion criteria. Prevalence rates of RA in Alaskan Native populations ranged from 0.6 to 2.4%, mostly similar to those estimated in the general population. RA prevalence was estimated at 2.2 to 6.8% in Blackfeet, Chippewa and Pima American Indian populations, higher than in the general population of the United States. Reported rates in Canadian First Nations ranged from 1.0 to 7.1%, increased compared to the general population by at least two-fold. The prevalence of RA in Australian Indigenous populations was 2.7% compared to 1.9% in non-Indigenous people. New Zealand Maori RA prevalence was estimated at 3.3%. Contemporary studies of SLE found prevalence rates to be 149-159 per 100,000 in Alaskan Natives and 138-263 per 100,000 in Native American populations, increased from historical studies. Canadian Indigenous SLE prevalence was 42-348 per 100,000, and in Australian Indigenous populations was 13-93 per 100,000, at least double that of non-Indigenous populations. Incidence rates of SLE (per 100,000) were 7 in Alaska Natives, up to 30 in American Indians, 11 in Australian Indigenous and up to 7 in Canadian First Nations populations. Spondyloarthropathies affected 0.2-2.7% of Alaska Native populations, and <0.04% of American Indian populations studied; in Canadian Inuit, spondyloarthropathy prevalence was estimated at 0.9%. Ankylosing spondylitis prevalence was estimated at 3.0% in Pima American Indian populations, and 2.3% in Canadian Haida populations, but just 0.4% in First Nations in Alberta, and 0% in New Zealand Maori. Crystal arthropathy prevalence is comparatively low in Alaska Native and Canadian First Nations in contrast to New Zealand Maori populations, where prevalence was 6.4 to 11.1%, significantly higher than non-Maori or European populations. Osteoarthritis prevalence was estimated at 6-22% in Canadian First Nations, 1.5% in Canadian Inuit, 7-32% in Australian Indigenous populations, and 4-6% in New Zealand Maori over 50 years of age.

Conclusion: Rheumatic disease prevalence in North American, Australian and New Zealand Indigenous populations is significantly higher than that of non-Indigenous populations, but with variation in estimates across tribal ancestry relevant to health services planning.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There have been several studies which demonstrated the impact of birth on the risk of certain diseases such as asthma or cardiovascular diseases. However, rheumatic diseases have not yet been thoroughly investigated in terms of association with birth month. In this study, we sought to determine whether birth month or season could affect the risk of rheumatologic diseases.

Methods: The birth month patterns of patients with rheumatic diseases were compared with to those of general population. We utilized the claims data of Health Insurance Review and Assessment Service (HIRA) which covers nearly 90% of total population in Korea. The associations between birth month/season and 32 diseases were investigated using logistic regression.

Results: Our dataset included 17,247,458 (male 8,224,670; female 9,022,788) individuals from HIRA database from January, 1997 to August, 2015. Among 27 rheumatic diseases, 8 diseases including Crohn's disease (CD), ulcerative colitis (UC), rheumatoid arthritis (RA), systemic lupus erythematosus, polymyalgia rheumatica(PMR), ankylosing spondylitis (AS), multiple sclerosis, gout, fibromyalgia (FMS) were significantly associated with birth month ($P<0.05$). In terms of seasonality, CD, UC, RA, Sjogren's syndrome, PMR, AS, Gout, and FMS demonstrated significant difference. CD, UC and AS showed higher prevalence in individuals born in winter and lower prevalence in summer. On the other hand, people who were born in summer showed higher possibility to have gout and FMS compared to those born in winter. In consistent with previous reports, type 1 diabetes is more prevalent in those born in winter. Angina and myocardial infarction showed higher prevalence in patients born in spring and lower in fall. This consistency reflects the relevance of our dataset and methodology.

Conclusion: We found significant impacts of birth month/season on various rheumatic diseases. Seasonal variation of infective agents, sun exposure or food ingestion during gestation or early infancy may explain the association between birth month/season and certain disease development.

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity has become alarmingly common over the past four decades in the U.S., with a notable rise in obesity prevalence starting in the late 1980s. Obesity is related to increased risk of several autoimmune diseases, likely via generation of inflammatory adipokines, but prior studies have not evaluated obesity as a risk factor for SLE. We aimed to prospectively evaluate whether obesity is associated with increased SLE risk, particularly during the years in which obesity prevalence was rising most drastically.

Methods: We conducted a prospective cohort study of women in the U.S. Nurses' Health Studies (NHS, 1976-2012, aged 30-55 at baseline; NHSII, 1989-2013, aged 25-42 at baseline). Incident SLE was confirmed by ACR 1997 criteria. Body mass index (BMI, kg/m^2) was reported at baseline and on biennial questionnaires. We excluded women who did not report BMI at baseline. Cumulative average BMI category, updated every two years, was the primary exposure: 18.5 to <25 (normal [reference]), 25 to <30 (overweight), ≥30 (obese). Cox proportional hazards models estimated HRs (95% CIs) for SLE by cumulative average BMI category, adjusting for time-varying age, race, smoking, alcohol intake, household income, age at menarche, oral contraceptive use, menopausal status and post-menopause hormone use. Analyses were conducted separately in each cohort, and results were meta-analyzed with a DerSimonian-Laird random effects model. We performed a median trend test for SLE risk across increasing BMI categories. In secondary analyses, follow-up started in 1988 (NHS)/1989 (NHSII) when obesity prevalence in the U.S. was increasing most dramatically.

Results: We identified 154 SLE cases in NHS and 113 cases in NHSII. Obesity was present at enrollment in 8.4% (NHS) and 11.8% (NHSII). Mean age at enrollment was 42.7 years (SD 7.1) in NHS and 34.4 years (SD 4.6) in NHSII. 92% of subjects were White in each cohort. At SLE diagnosis, 46.1% (NHS) and 61.1% (NHSII) were anti-dsDNA positive. Obesity was significantly associated with SLE risk in NHSII (HR 1.86, 95% CI [1.17-2.94], p trend 0.02), but did not increase SLE risk in NHS (HR 1.09, 95% CI [0.64-1.84], p trend 0.47). Meta-analysis of NHS+NHSII revealed a significant trend for increased SLE risk by increasing BMI category (p trend 0.03) (**Table**). When follow-up started in the late 1980s, meta-analysis of NHS+NHSII revealed increased SLE risk among obese women (HR 1.78, 95% CI 1.21-2.63, p trend <0.01).

Conclusion: We observed a significant risk of SLE among obese women in NHSII, which started enrollment later than NHS. Obese women were at 78% elevated risk of developing SLE when follow-up started in both cohorts in the late 1980s, suggesting that secular trends in obesity prevalence were associated with increased SLE risk.

SLE risk by cumulative average BMI category: Meta-analysis of Nurses' Health Study (NHS) and Nurses' Health Study II (NHSII)

	Cumulative Average BMI, kg/m^2			
	18.5 to <25	25 to <30	≥30	p trend

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Azathioprine (AZA) and mycophenolate mofetil (MMF) are commonly used immunosuppressants for moderate-to-severe SLE. Overall adherence among SLE patients has been shown to be poor but few studies examine adherence patterns over time by specific immunosuppressant. We applied an innovative method, group-based trajectory modeling (GBTM), to investigate longitudinal, dynamic patterns and predictors of adherence among new users of AZA and MMF in a U.S. nationwide cohort of Medicaid enrollees with SLE.

Methods: We identified prevalent SLE patients in the Medicaid Analytic eXtract, which includes demographics, claims and pharmacy data for enrollees from most U.S. states (2000-2010). We determined new use of AZA or MMF based on ≥6 months of enrollment with no prior use, and required ≥1 year of follow-up after first dispensing (index date). Predictors were determined during the 6 months pre-index date. We assessed overall adherence using the proportion of days covered (PDC ≥80%=adherent) and used logistic regression adjusting for age, sex and race/ethnicity to compare adherence to MMF vs. AZA. We applied GBTM to examine monthly nonadherence patterns (≥80% days covered/month=adherent), beginning at the index date. Multivariable multinomial logistic regression models adjusted for sociodemographics, comorbidities, medication and healthcare use, preventive care, state and year, were used to determine predictors of adherence trajectory patterns.

Results: There were 2360 new users of AZA and 2135 of MMF. Mean age of AZA users was 36 (±12), 92% were female, 47% black, 25% white and 20% Hispanic; mean age of MMF users was 34 (±12), 90% were female, 45% black, 24% white and 21% Hispanic. 14.9% of AZA users were adherent (PDC ≥80%) vs. 17.7% of MMF users (p=0.01); the odds of adherence (PDC ≥80%) were 1.25 times higher (95% CI 1.06-1.47) for MMF vs. AZA. For both AZA and MMF, 4-group trajectory models had the lowest BIC and posterior probabilities >80% indicating the best fit (**Figure**). 46% of AZA users and 23% of MMF users were persistent nonadherers (group 1); 17% of AZA users and 20% of MMF users were persistent adherers (group 4). Multivariable multinomial regression models (persistent nonadherers (group 4)=ref) demonstrated that females vs. males, younger vs. older ages and black race and Hispanic ethnicity vs. white had significantly increased odds of nonadherence to AZA, but not to MMF. More emergency department visits and ever corticosteroid use increased the odds of nonadherence to MMF, but not to AZA.

Conclusion: In this cohort, persistent adherence to either AZA or MMF in the first year of use was rare. We observed even poorer overall adherence among AZA users compared to MMF with distinct nonadherence patterns for each drug and different associated demographic and utilization predictors. Further studies are needed to determine whether drug-related characteristics contribute and whether adherence should factor into prescribing choice.

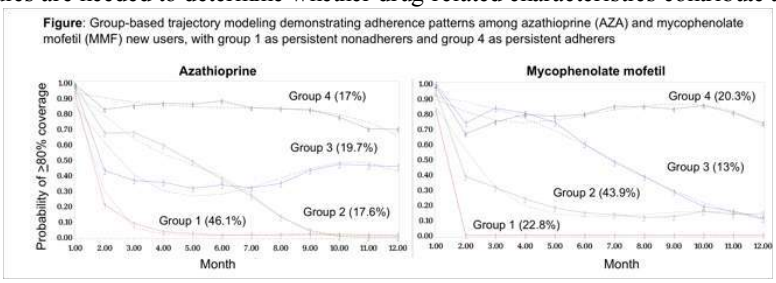

Figure: Group-based trajectory modeling demonstrating adherence patterns among azathioprine (AZA) and mycophenolate mofetil (MMF) new users, with group 1 as persistent nonadherers and group 4 as persistent adherers

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anxiety and depression are often present in chronic rheumatic diseases. Recognition of these psychological disorders is fundamental for proper patient management. The absence of screening leaves more than >50% of patients with depression unidentified. Patient Help Questionnaire-9 (PHQ-9) and General Anxiety Disorder-7 (GAD-7) are two validated self-applied questionnaires that are appropriate to assess the presence of, depression and anxiety, respectively. Objectives. 1) To assess the prevalence of depression and anxiety in a hospital based outpatient Rheumatology clinic and 2) To provide the attending physician with appropriate instruments that allow a rapid orientation on the psychological status of her/his patient.

Methods: Consecutive patients that attended our outpatient Rheumatology clinic from March to June 2016 were invited to participate in this cross-sectional study. Participants filled out PHQ-9 and GAD-7 in the waiting room. The prevalence and severity of anxiety and depression were calculated for the most prevalent diagnoses.

Results: A total of 410 patients were recruited; 339 (82.8%) were female. Overall, 191 (46.6%) patients reported depressive symptoms (PHQ-9 >5). Of them, 87 (21.2%) were classified as having moderate depression or higher (PHQ-9 >10). Prevalence of depression and anxiety among study participants according to each rheumatic disease is depicted in Table 1. Prevalence of moderate or severe depression was significantly different among various rheumatic diseases (p = 0.001). Regarding anxiety symptoms, they were reported in 168 (40.7%); 67 (16.2%) of them had moderate or severe anxiety.

Conclusion: This cross-sectional study shows that anxiety and depression are frequent in the Rheumatology clinic. We demonstrated that the use of a self-applied screening tool can help clinicians to properly detect depression and anxiety associated with diverse rheumatic diseases. Special attention should be paid to patients with fibromyalgia and osteoarthritis.

Disease	N	Moderate or severe depression	Moderate or severe anxiety
SLE	99 (24.1 %)	16 (16.2 %)	12 (12.1 %)
RA	107 (26.1 %)	26 (24.3%)	17 (15.9%)
FM	87 (21.3 %)	**30 (34.5 %) p= 0.001**	**27 (31 %) p=0.001**
OA	69 (16.8 %)	**25 (36.2 %) p= 0.001**	**22 (31.9 %) p=0.001**
SSc	18 (4.4 %)	13 (26 %)	8 (16 %)
Inflammatory myopathies	14 (3.4 %)	4 (28.6 %)	2 (14.3 %)
Osteoporosis	49 (12 %)	14 (28.6 %)	9 (18.4 %)
APS	42 (10.2 %)	**1 (2.4 %) p= 0.001**	3 (7.1 %)

Table 1. Prevalence of depression and anxiety among study participants according to each rheumatic disease. (SLE – Systemic lupus erythematosus, RA – Rheumatoid Arthritis, FM – Fibromyalgia, OA – Osteoarthritis, SSc – Systemic sclerosis, APS – Antiphospholipid syndrome.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Epidemiology and Public Health - Poster II

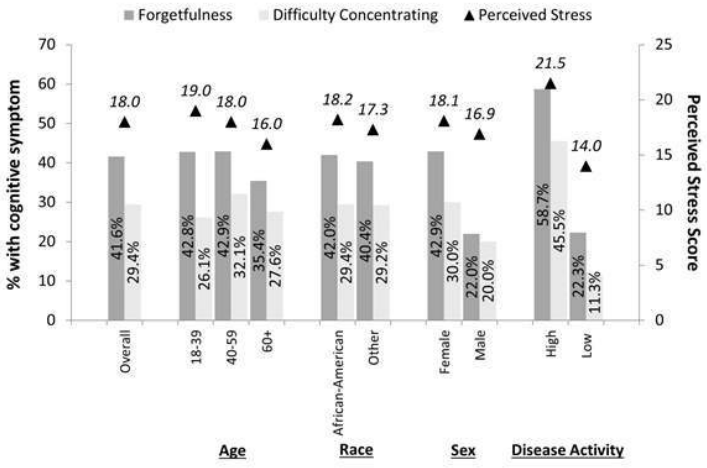
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Higher stress is associated with lower cognitive functioning in many populations. We examined associations of perceived stress with cognitive symptoms among adults with systemic lupus erythematosus (SLE), a chronic, complex autoimmune disorder.

Methods: We obtained cross-sectional data for 799 Atlanta-area SLE patients ≥18 years old on scores from the validated Perceived Stress Scale (PSS; range, 0-40 with higher scores=higher stress) and two self-reported cognitive symptoms: forgetfulness [severe/moderate vs. mild/none; from the Systemic Lupus Activity Questionnaire (SLAQ)] and difficulty concentrating (all/most vs. some/little/none of the time; from the Lupus Impact Tracker). We estimated mean PSS scores and percentages of patients with cognitive symptoms, overall and by age (18-39, 40-59, and 60+), race, sex, and high vs. low disease activity [≥ vs. < median SLAQ score (=15), after excluding the forgetfulness item]. We used multivariable logistic regression to estimate the odds ratios (ORs) for the associations between PSS score (minimal clinically important difference=0.5*SD=4.0 points) and cognitive symptoms.

Results: Overall, 41.6% and 29.4% of participants reported forgetfulness and difficulty concentrating. Women were twice as likely to report forgetfulness (P=0.004) and those with high vs. low disease activity were ~3- and 4-fold more likely to report forgetfulness (P<0.001) and difficulty concentrating (P<0.001), respectively (Figure). Mean PSS scores were lower in the oldest SLE patients (P=0.002) and those with low disease activity (P<0.001). With adjustment for age, race, sex, education, income, and disease activity, each 4.0-point increase in PSS score was associated with 1.3- and 2.1-fold higher prevalence of forgetfulness (OR=1.33, 95% CI 1.21-1.47) and difficulty concentrating (OR=2.12, 95% CI 1.83-2.44). No substantial differences in this association by age, race, sex, or disease activity were noted, and interaction terms were not statistically significant.



Conclusion: SLE patients, particularly those with high disease activity, report a substantial burden of cognitive symptoms. These symptoms are associated with higher perceived stress, regardless of disease activity or other patient characteristics. This relatively young patient population may be susceptible to cognitive symptoms often linked with geriatric syndromes, for which stress may represent a modifiable risk factor.

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic illness that has been associated with high hospital readmission rates. Based on a recently published (Arth Rheumatol (2014) 66:2828) electronic database analysis of Medicare/Medicaid hospital discharges, 16.5% of patients with the ICD-9-CM code 710.0 for SLE were readmitted to any hospital within thirty days. We propose a retrospective, observational study to assess the rate of and predictive factors influencing a thirty-day hospital readmission for adult patients with SLE.

Methods: All index admissions, defined as hospital admissions from adult patients (≥ 18 years of age) who had a primary or secondary ICD-9-CM diagnosis of 710.0 from October 1, 2012 to December 30, 2014, were discovered through data mining. Individual electronic patient charts from these admissions were manually reviewed to determine if the patient fulfilled the 1997 ACR revised criteria for SLE. Hospitalizations were excluded if they were scheduled admissions, resulted in a discharge to acute rehab, maternity related or resulted in death. The remaining hospitalizations were analyzed to determine if they resulted in a thirty-day readmission, using the same methods of determining thirty-day readmission counts performed in the benchmark study of readmission rates in Medicare's fee-for-service program.

Results: 1003 index admissions (obtained from 433 unique patients) met our inclusion criteria. Only 196 of the 433 patients (45.3%) fulfilled criteria for SLE. The other 237 patients (54.7%) did not meet criteria: 185 patients had an inappropriate diagnosis of SLE (i.e., chart review contained sufficient data to support an alternate diagnosis), 34 patients had limited cutaneous lupus, and 18 patients had insufficient data to either confirm or refute a diagnosis of SLE. After application of exclusion criteria, 88 patients remained, accounting for 293 admissions, broken down into 221 index admissions (75.4%) and 72 thirty-day readmissions (24.6%). Of the 88 patients, 33 patients (37.5%) had ≥1 thirty-day readmission. Demographic data including age (p=0.92), gender (p=0.75), race/ethnicity (p=0.82), median household income by zip code (p=0.078) and primary expected payer (p=0.322) was compared between the groups. Of those with ≥1 thirty-day readmission, 11 were deceased (33.3%) compared to 3 deceased in those without a thirty-day readmission (5.5%) (p=0.0005).

Conclusion: We discovered a 37.5% rate of thirty-day readmission in patients meeting the 1997 revised criteria for the diagnosis of SLE. Among patients with ≥1 thirty-day readmission, a lower mean household income per zip code (p=0.078) was observed, approaching significance. All cause mortality was significantly increased in patients with SLE and ≥1 thirty-day readmission (p=0.0005). Additionally, our study revealed a 54.7% rate of miscoding of hospital records for adult patients with a primary or secondary diagnosis of SLE designated by the ICD-9-CM code 710.0, questioning the validity of using ICD-9-CM codes to identify patients with SLE.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with autoimmune inflammatory rheumatic diseases (AIIRDs) are at increased risk for developing infections. The pathophysiology of the primary disease process, as well as the immunosuppressive agents used in management of these conditions both contribute to this increased risk. Routine vaccine administration can prevent severe infections in this patient population.

Our aim was to determine the rates of influenza and pneumococcal polysaccharide vaccine administration in the patients followed in the rheumatology clinics at SUNY Downstate Medical Center (SUNY DMC), as well as the factors associated with vaccine uptake.

Methods: A retrospective chart review was performed on 296 eligible patients during the period between October 2014 and January 2015. Demographic data including age, gender, number of clinic visits during the period, autoimmune rheumatic diagnosis, frequency of primary care follow-up and immunization status with influenza and pneumococcal vaccines were collected. An additional survey was administered to 39 established clinic patients over the period covering March 8 to April 4, 2016. Data collected included age, sex, ethnicity, level of education, influenza and pneumococcal vaccination status, physician referral for vaccination and reasons (if applicable) for refusal of immunization.

Results: Of the 296 participants, 271 (91.6%) were female, with 266 (89.9%) on immunosuppressive therapy. The majority of the patients had the diagnosis of systemic lupus erythematous (n=165; 55.74%) and rheumatoid arthritis (n=97; 32.77%). The prevalence of influenza virus and pneumococcal vaccination were low at 18.92% (n=56) and 14.53% (n=43) respectively. Among the participants surveyed, the most common reason for refusal of the influenza vaccination (60%) was concerns about subsequent illness.

Conclusion: This study demonstrated that the rates of influenza and pneumococcal vaccination in patients with AAIRDS followed at SUNY DMC rheumatology clinic are lower than that of the general population. The main factor affecting the rate of immunization was found to be concerns for acquired illness from the vaccines. This information can be used by clinicians to develop interventions to ensure increased vaccine uptake, including improved verbal patient education as well as the dissemination of printed materials with important facts about immunization.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: *Pneumocystis jirovecii* pneumonia (PJP) is most frequently associated with AIDS, however, this infection also occurs in a variety of rheumatologic conditions in the context of immunosuppressive therapy. The mechanisms of immune compromise in patients without AIDS who have PCP are usually multifactorial, related to underlying cytotoxic therapy and malnutrition. PCP infection has been extensively studied among AIDS patients, however, not many studies have evaluated its occurrence in the setting of underlying rheumatologic diseases.

Methods: The study cohort included a consecutive series of patients without AIDS and malignancy or organ transplantation who were assessed at a single institution for a first episode of PCP infection. Medical records were examined to determine underlying immunosuppressive disorders, corticosteroid dosage, associated infections, and subsequent respiratory failure and in-hospital mortality.

Results: The study included 54 patients (mean age at presentation 62.8 years; 54% male) with mean follow up of 2.5 years. Conditions associated with a first episode of PCP were rheumatoid arthritis (30%), inflammatory bowel disease (17%), systemic lupus erythematosus, polymyalgia rheumatic (7%) and giant cell arteritis (6%). Regardless of the underlying condition, corticosteroids had been administered systematically in 45 patients (83%) within 3 months before the diagnosis of PCP. The median daily corticosteroid dose was 27.5 mg. Predominant symptoms on presentation were cough (78%) and shortness of breath (76%). The majority of the patients (87%) on immunosuppressive therapy did not receive any prophylaxis for PCP infection. There were 25 patients (46%) that improved upon institution of therapy while 14 patients (26%) died as a result of infection.

Conclusion: In this large consecutive series, systemic administration of corticosteroid therapy, even in the moderate doses may increase

susceptibility to PCP infections. Consideration should be given to instituting PCP prophylaxis (when not contraindicated) in patients for whom prolonged systemic corticosteroid therapy is prescribed.

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) seems associated with an increased risk of cardiovascular disease. These data are mainly based on studies mostly from North America. The aim of this study was to investigate the prevalence of subclinical atherosclerosis in a large cohort of SLE patients in France.

Methods: In this retrospective cohort study, 282 SLE patients underwent screening for subclinical atherosclerosis from January 2014 to April 2016. The presence of subclinical atherosclerosis was evaluated using a carotid ultrasound examination with measurement of intima media thickness (IMT) and electron-beam computed tomography to screen for coronary artery calcification (CAC). CAC was divided in 4 categories: 0; 1- 99; 100 – 399 and ≥ 400. SLE characteristics and cardiovascular risk factors were included in a regression analysis to determine the importance of SLE specific features in the occurrence of subclinical atherosclerosis in the female subpopulation.

Results: From the eligible cohort of 282 patients, 19 patients (6.7%) were excluded because of the presence of prior cardiovascular events. 263 (240 women, 91.3%) patients free from cardiovascular disease were included. The mean age of the study population was 42.6 +/- 13.2 years. 35.4% suffered from arterial hypertension, 20.6% were current smokers, 5.3% had diabetes, 26.2% had a dyslipidemia and 2.3% had a familial history of cardiovascular disease. The mean BMI was 24.8 kg/m² +/- 5.4. 58.8 % of the study population had disease duration of at least 10 years and 25.5% had a SLICC score > 0. 89% of the patients were treated with hydroxychloroquine, 53.6% with corticosteroids and 28.5% with at least one other immunosuppressive agents. The prevalence of carotid plaques was 20.3% (19.2% in women and 32% in men, p = 0.17). The median value of the IMT was 0.53 mm (IQR [0.47; 0.60]). 25% of the patients had a CAC > 0: 17.3% between 1 – 99; 5.2% between 100 - 399 and 2.4% ≥ 400. Using multivariable logistic regression analysis the presence of carotid plaques in women was significantly associated with age with an adjusted Odds ratio (OR) for each supplementary year of 1.12 (95%CI, 1.07;1.16), controlling on smoking habit. CAC score > 0 in women was significantly associated with age (OR per year = 1.14, 95% CI [1.09; 1.19]) and current treatment with immunosuppressive drugs (OR = 2.70; 95%CI [1.08; 6.71]), controlling on smoking habit. IMT was significantly associated with age, with the presence of diabetes and lupus nephritis. Patients with diabetes had a mean IMT that was 116 µm (95% CI, 49;184) higher than those without diabetes. Treatment with glucocorticosteroids and the presence of an antiphospholipid antibody syndrome was not associated with an increased risk for subclinical atherosclerosis.

Conclusion: In this retrospective cohort, the CAC and IMT did not seem to be elevated compared to published series of SLE patients. Besides an expected association with classical atherosclerotic risk factors including age, diabetes, and smoking, disease-related factors such as treatment with immunosuppressive agents and lupus nephritis are associated with subclinical atherosclerosis.

Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with autoimmune diseases (AID) have a high burden of cardiovascular disease leading to premature morbidity and mortality. But it is unclear if it is due to a higher prevalence of cardiovascular disease, to a worse case fatality or to a different management after an index event. The primary aim of the study is to assess the prognostic implications of the presence of AID both during the hospitalization and after discharge after an acute coronary syndrome (ACS). The secondary objectives included the assessment of the prevalence of AID in patients with ACS, their clinical profile and the management of this index event

Methods: The study included consecutive patients admitted after ACS from January 2011 to December 2015 at the University Hospital Virgen de la Arrixaca, Murcia (Spain). For AID patients, in-hospital management and ACS presentation was compared to non-AID patients. We also compared in-hospital and major adverse events during follow-up (death, recurrent non-fatal myocardial infarction, stroke and major bleeding, between groups). A multivariate Cox regression model was performed to assess the independent role of the presence of AID in the occurrence of the events of interest.

Results: Of 2236 patients included with ACS, 78 had AID (3.3%): 24 rheumatoid arthritis, 10 inflammatory bowel disease, 7 ankylosing spondylitis, 6 psoriatic arthritis, 5 polymyalgia rheumatica, 2 systemic lupus erythematosus and 20 miscellanea. Mean age of AID patients was 67 ± 13 years and median evolution of the disease was 10 [4-14] years. Seventy percent of AID patients were taking corticosteroids, 50% disease modifying antirheumatic drugs, 22% non-steroidal anti-inflammatory drugs and 8 biological theraphy. No significant differences were found in clinical and demographics characteristics between groups except for a higher percentage of atrial fibrillation and chronic obstructive pulmonary disease in AID patients. Compared to non-AID patients, AID patients had similar clinical ACS presentation and no differences were found with respect to revascularization strategies or medical treatment at discharge. With respect to prognosis the two groups had comparable rates of adverse events during hospitalization (10% vs 10%, p=0.920) with no statistically significant differences in any single event studied. However after a follow-up of 397 [375-559] years, AID patients had higher rate of combined adverse events (44% vs 28% p<0,001). After multivariate adjustment the presence of AID was associated with increased total mortality (hazard ratio 2.1, 95% CI 1.2 to 3.7, p=0.008) and it was also a borderline risk factor for higher bleeding complications (hazard ratio 2.2, 95% CI 0.9 to 5.5). The presence of AID was not an independent risk factor for neither stroke or recurrent non-fatal myocardial infarction.

Conclusion: The presence of AID did not change ACS presentation and clinical management. Although AID is not associated with worse outcomes during hospitalization it is independently linked to higher total mortality and a trend to an increased risk of major bleeding during follow-up

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although the diagnosis of pure class V lupus nephritis (LN) is generally thought to portend a favorable prognosis, outcomes on a population-level are not well known. We evaluated the outcomes of those with only class Va/b and class Vc/d disease with a focus of end stage renal disease (ESRD) and death on a population level.

Methods: The Georgia Lupus Registry (GLR) is a population-based registry designed to more accurately estimate the incidence and prevalence of systemic lupus erythematosus (SLE) in Atlanta, Georgia, by partnering with the state health department, allowing records to be reviewed without patient consent. Trained abstractors documented demographic and clinical information from potential SLE patients who were prevalent in 2002 and incident in 2002-04. Renal biopsy results (WHO criteria) were obtained from the medical record as well as local and regional commercial nephropathology labs. Those with a concurrent LN class other than V were excluded. Patients were matched to the state death certificate database through 2013 and the United States Renal Data System for ESRD through September 2012.

Results: Among prevalent patients with class V LN, many resulted in ESRD 35/129 (27.1%) and death 34/129 (26.4%). Among incident patients with class V LN, 3/31 (9.7%) developed ESRD and 6/31 (19.4%) died. There was no significant difference in age, race, ACR criteria manifestations, or outcomes between Va/b and Vc/d in prevalent and incident SLE patients. There were significantly more females with class Vc/d compared to Va/b in prevalent patients. Though not statistically significant in incident patients, more females had class Vc/d compared to Va/b (81.3% vs. 66.7%).

Conclusion: This is the first population-based evaluation of class V only SLE with surveillance for outcomes up to 13 years. Individuals with pure class V LN have relatively high prevalence of ESRD and death with no difference in outcomes between Va/b and Vc/d. Differences in age, race, and ACR manifestations were not seen between the two groups. There were significantly more females with class Vc/d compared to Va/b in prevalent patients. More study is required to understand the factors responsible for poor health outcomes among persons with class V nephritis.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis and osteoporotic fractures are significant comorbidities in patients with systemic lupus erythematosus (SLE). Hip fractures are being increasingly recognized as a complication of dialysis raising concern for similar events among patients with SLE who progress to end-stage renal disease (ESRD). The intention of this study was two-fold: (1) to compare the frequency of incident osteoporotic fractures in patients with ESRD with and without SLE, and (2) to identify risk factors for osteoporotic fractures in patients with SLE and ESRD.

Methods: A retrospective cohort of adults starting dialysis between 2006-2008 enrolled in Medicare Part D without a previously filled prescription for osteoporosis medications were selected from the U.S. Renal Data System (USRDS). The International Classification of Diseases, 9th Revision (ICD-9) codes were used to identify patients in the hospital claims dataset with a diagnosis of SLE prior to starting dialysis. A 5% control sample was randomly selected for comparison due to a sizable proportion of patients without a diagnosis of SLE. Potential risk factors for osteoporotic fractures including demographic and clinical factors and medication use were determined using ICD-9 codes from hospital claims, Medical Evidence Report and Medicare Part D. Incident fracture was defined as an ICD-9 code for a non-traumatic, non-pathologic fracture within 5 years of follow-up. Fractures were grouped by location: upper extremity, lower extremity (excluding hip), hip and vertebral.

Results: There were 1,311 (0.5%) patients starting dialysis between 2006-2008 with a diagnosis of SLE. After applying exclusion criteria and including random selection of 5% of controls, there were 649 patients with SLE and 3,992 patients in the control group. Fractures occurred in 10.5% of SLE patients compared to 11.9% of controls. In multivariable analyses, there was no significant difference in the incidence of osteoporotic fractures in patients with SLE compared with controls (p=0.08, RR 0.40, CI 0.66-1.08). Among patients with SLE, fractures of the hip were most common (46%) followed by those of the upper extremity (21%), vertebrae (19%) and lower extremity (14%). In the control group, fractures of the hip (49%) outnumbered those of the lower extremity (25%), upper extremity (17%) and vertebrae (9%). In multivariable adjusted analyses, female gender (p=0.05, RR 2.08, CI 1.00-4.32) and older age (p=0.03, RR 1.02, CI 1.00-1.04) were associated with increased fracture risk. However, race, ethnicity, dialysis type, tobacco and alcohol use, BMI, Charlson Comorbidity Index, prevalent fractures or medication use (corticosteroids, opioids, selective serotonin reuptake inhibitors, proton pump inhibitors, anticonvulsants, diuretics, sedatives, oral hypoglycemics) (p>0.10 for all) were not significantly associated with fracture risk.

Conclusion: Patients with SLE and ESRD do not have an increased risk for osteoporotic fractures compared to patients with ESRD alone. Hip fractures are the most common fracture site in patients with SLE and ESRD. In patients with SLE and ESRD, female gender and older age are associated with increased fracture risk.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic pain is one of the most common symptoms reported in patients with SLE. Treating pain in these individuals can be complex and difficult to manage and often require opioid therapy. The present research, to our knowledge, is the first investigation into the impact of opioid use in the management of patients with SLE and chronic pain.

Methods: This prospective 5 year longitudinal outcome study of 275 SLE patients at the University of New Mexico included 24% (chronic opioid use) and 76% (no opioid use). Inclusion criteria were patients fulfilling ACR criteria for SLE, aged18-80. Patients diagnosed with any other autoimmune disease were excluded. Outcomes were determined at 5 years after enrollment in the study. Statistical differences were determined with Student t-test and categorical data with Fisher's exact method. Associations were determined initially with univariate regression analysis and then multivariate models were created to determine independent and dependent variables.

Results: No statistical signficance was observed in age, age of onset, disease duration, race, family history of autoimmune disease, alcohol use, ANA titer, dsDNA titer, aPL positivity, anti-ribosomal P, RNP, anti-Smith, Ro/SSA, La/SSB, Scl-70, Coombs, active or chronic kidney disease, or joint pain between opioid and non-opioid SLE groups. SLE patients that used opioids had a signficantly higher rate of tobacco use and duration, criteria average for SLE diagnosis, average pain scores, morning stiffness, SLICC and SLEDAI indices, cocaine use, non-compliance, and total deaths. Logistic regression analysis predicting death revealed hazard ratios 2.6 and 1.1, when comparing opioid use and total SLEDAI respectively; and hazard ratios 2.5, 1.1, and 1.6, when comparing opiod use, total SLEDAI, and non-compliance respectively. Univariate Cox Model estimated the probability of death in SLE patients revealed statistical significance for opioid use and non-compliance, hazard ratios 3.2 and 1.8 respectively. Multivariate Cox Model analysis estimating the probability of death with covariates; opioid use and total SLEDAI (both statistically significant, hazard ratios 2.6 and 1.1 respectively), opioid use and alcohol use (only opioid use was statistically significant, hazard ratio 3.3), opioid use, cocaine use, and alcohol use (only opioid use and cocaine use were statistically significant, hazard ratios 3.0 and 3.2 respectively), and lastly opioid use, non-compliance, and total SLEDAI (only opioid use and non-compliance were statistically significant, hazard ratios 2.5 and 1.1 respectively). The marginal survival for SLE patients not taking opioids was 88% (12% dead) versus 65% (35% dead) patients taking opoiods. The Kaplan-Meir survival curve revealed higher probability of survival for SLE patients that did not use opioids.

Conclusion: This study indicates that opioid use in SLE is associated with higher mortality, total SLICC and SLEDAI disease activity scores, increase cocaine use, and non-compliance. These data suggest the need for education and safe opioid prescribing strategies in SLE patients with chronic pain.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatic diseases comprise a diverse group of about 150 degenerative, autoimmune and autoinflammatory diseases. Sexual dysfunction affects about 70% of patients with rheumatic diseases and is related to both anxiety and depression. However there are few studies which analyze in depth the sexuality of patients with rheumatic diseases.

Methods:

A cross-sectional study where the patients enrolled in two clincal settings (public heatlh insurance and social security service). We evaluated every patient with a rheumatic disease by the classification criteria ACR / EULAR which may apply. The presence of sexual dysfunction was assessed with the questionnaire 'Female Sexual Function Index (FSFI)' proposed by Rosen. The FSFI is a self-administered aimed at assessing female sexual response questionnaire in six domains: sexual desire, sexual arousal, vaginal lubrication, orgasm, sexual satisfaction and pain. The FSFI contains 19 questions that assess sexual function in the last four weeks. A total of ≤26 indicates sexual dysfunction . An historical comparison with an aged matched control group was conducted.

Results:

We included 356 women with a mean age of 48.9 years (SD 13.2). The 76.7% of those evaluated were represented by the following diseases: Rheumatoid Arthritis (195, 54.8%) Systemic Lupus Erythematosus (43, 12.1%), Osteoarthritis (21, 5.9%) and Primary Sjögren's syndrome, (14, 3.9%). The median FSFI score was 14.1 (IQR 12), the percentage of women with sexual dysfunction was 94.9%. Median and IQR scores of every item were as follows: Desire 4.8 (2.4), Excitation 1.5 (3.3), Lubrication 2.4 (2), Orgasm 1 (3.6), Satisfaction 2.4 (1.2) and Pain 0.2 (4.4). There was no difference between the different rheumatic diseases studied and FSFI score or the percentage of patients with sexual dysfunction. There is a negative correlation (Spearman rho -0.31 p = 0.01) between age and the total score; and a positive one (0.434 p = 0.01) with the Desire item and negative (-0.391 p = 0.01) for pain item. The was statistical diference between the rheumatic cohort and the historical aged matched control group (14.1 vs 25.2 (p = 0.001)).

Conclusion:

Compared with other reports on the prevalence of rheumatic diseased sexual dysfunction is high and the score is very low compared with healthy. It is necessary to investigate and act on this problem that had family and psychosocial implications in our patients.

Projected 2015 Prevalence of Physician-Diagnosed Primary SjöGren's Syndrome Based on 1976-2005 Annual Incidence Rates in a Well-Defined U.S. Population

Divi Cornec[1], Eric L. Matteson[2] and Cynthia S. Crowson[3], [1]Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN, [2]Rheumatology, Mayo Clinic, Rochester, MN, [3]Health Sciences Research, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Estimates of prevalence of primary Sjögren's syndrome (pSS) are conflicting, ranging from 1 to more than 8 cases

per 10,000 according to different population-based studies. No prevalence data for the U.S. population are available so far. The objective of this work was to estimate the 2015 point prevalence of primary Sjögren's syndrome (pSS) in a population-based study performed in the United States.

Methods: This study was performed in a well-defined U.S. population which counted approximately 157,000 inhabitants as of January 1, 2015. Individual medical record review of all cases was previously performed to obtain the total number of incident pSS cases by physician diagnosis from 1976-2005 (1). Prevalence estimates for this study are based on the same source population, assuming that the disease was not associated with excess mortality, as previously shown, and that migration in or out of the census population was independent of disease status. Annual incidence rates were stable for the 1976-2000 period but increased over time between 2000 and 2005 (figure). Therefore, different prevalence estimates were computed according to stable or increasing incidence rate scenarios between 2006 and 2015. Prevalence was age- and sex-adjusted to US white 2010 population.

Results: A total of 105 pSS cases were diagnosed in this population between 1976 and 2005, with annual incidence rates varying between 2 and 8 cases/100,000/year (figure). Using several scenarios for incidence estimates between 2006 and 2015 based upon previous data (table), the projected 2015 prevalence in this population ranged between 9.5 and 36.9 per 10,000. The prevalence was estimated between 0.6 and 3.1 per 10,000 in males and between 18.0 and 69.1 per 10,000 in females.

Conclusion: Our estimated prevalence range is substantially higher than previously published population-based pSS prevalence studies conducted in other geographical area. This finding could reflect important variations of physician diagnosis during the 40-year period during which incidence rates were previously assessed in this population. New epidemiological population-based studies are warranted, using validated and consensual classification criteria for case ascertainment. **Reference:** (1) Nannini C et al, BMJ Open. 2013 Nov 25;3(11):e003569.

Figure. Annual pSS incidence rates 1976-2005, adapted from reference 1.

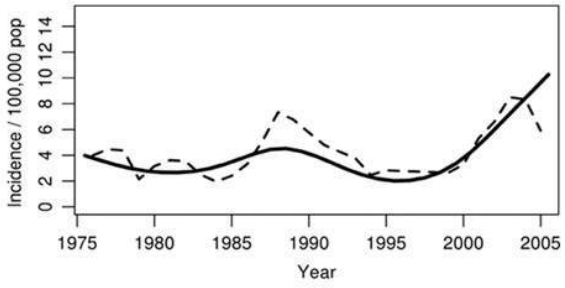

Table. Estimates of 2015 point prevalence of pSS in a US population according to different projections of annual incidence rate for the 2006-2015 period.

	Prevalence rate per 10,000 population* (95% confidence interval)		
Prevalence estimate based on:	**Female**	**Male**	**Overall**
Age and sex specific incidence rates for 1976-1999 (incidence rates were stable in this time period)	18.0 (14.2, 23.2)	0.6 (0.0, 2.0)	9.5 (7.5, 12.3)
Age and sex specific incidence rates for 1976-2005 (this rate is a bit higher due to the increase in incidence rates after 1999)	20.0 (16.2, 25.2)	1.5 (0.0, 2.9)	11.0 (9.0, 13.8)
Age sex and calendar year specific incidence rates for 1976-2005 (projecting flat rate after 2005)	28.5 (21.5, 36.2)	3.0 (1.0, 7.3)	16.0 (12.2, 20.1)
Age sex and calendar year specific incidence rates for 1976-2005 (projecting increasing rate after 2005 based on trajectory from 2000-2005)	69.1 (42.4, 165.4)	3.1 (1.5, 1984.4)	36.9 (20.4, 933.6)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren syndrome (pSjS) is an autoimmune disease involved multiple organs, including exocrine glands, lungs, and bone marrow. Patients with pSjS are vulnerable to fatigue and pain over extremities with deterioration of life quality. However, the risks of osteoporotic fracture remain unclear. We performed this cohort study In order to evaluate the incidence rate (IR) and risk factors of osteoporotic fractures in patients with pSjS.

Methods: A cohort study was performed by using the Taiwan National Health Insurance database. pSjS was classified as a catastrophic illnesses after verifying by a review committee. Patients with pSjS with catastrophic validation after 1997 were enrolled. Patients with other autoimmune diseases (systemic lupus erythematous, rheumatoid arthritis, etc.) or operation of fracture before enrollment, were excluded from analysis. Age and gender-matched controls without pSjS were selected as control group. The primary endpoint was the first time of osteoporotic fracture. Other risks factors, including comorbidities and medications history, were examined by using Cox proportional model.

Results: Total 3367 pSjS patients (mean 53.23 years, female 85.5%) and 22182 age, gender matched patients without pSjS were evaluated. The median follow-up time was 9.76 years. Among pSjS group, 243 patients had vertebral fractures (IR 71.18 per 1,000 person-years), 84 patients had hip fractures (IR 24.15 per 1,000 person-years), and 40 patients had radius fractures (IR 11.46 per 1,000 person-years). The incidence rate ratios of vertebral fractures (1.54, 95% CI 1.30-2.39, p<0.001) and hip fractures (1.41, 95% CI 1.10-1.79, p=0.005) revealed significant differences, but not of radius fractures (1.13, 95% CI 0.79-1.58, p=0.463). pSjS patients experienced fractures at older ages compared with control group (p<0.001). Multivariable Cox regression analyses revealed that older age, female, end-stage renal disease, and using higher doses of corticosteroid (>7.5mg per day) were associated with increasing risks of developing fractures.

Conclusion: pSjS patients had higher IR of vertebral and hip fractures, but not of radius fractures. Patients who were older, female, in end stage renal disease, or using higher doses of corticosteroid, were of elevating risks in developing fractures.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There are few studies comparing oral manifestations in patients with Cutaneous Lupus (CL), Systemic Lupus Erythematosus (SLE) and Dermatomyositis (DM). Our objective was to determine signs in the oral cavity that could allow us to guide a particular diagnosis

Methods: Two dermatologists described the semiological findings of photographs of the oral cavity of a total of 116 patients (96 patients with Lupus and 20 patients with DM). All patients with SLE fulfilled at least 4 ACR classification criteria. We analyzed 4 areas: gums, soft palate, hard palate and buccal mucosa. For each of these areas the evaluators described the presence of the following clinical findings: red macules, red dots, telangiectasias, pigmented light brown macules, pigmented dark brown macules, discoid lesions, whitish streaks, white patches, mucosal folds, fine cobblestone and thick cobblestone (Fig. 1, 2, 3). We tried to find mucosal clinical features that differentiate

patients with strictly CL with those with CL and SLE, and with those with strictly SLE. Also we compared oral features of patients with SLE (with or without skin involvement) of those with DM, since sometimes these 2 clinical entities are very similar. Patients were divided into 3 different groups: SLE with and without cutaneous involvement; CL with and without systemic manifestations and subjects with DM and SLE with or without cutaneous manifestations. X^2 or Fisher exact test was used. A p value < 0.05 was considered significant

Results: Of all 84 patients with CL (with or without SLE), discoid mucous patches were only seen in patients with CL with SLE (15.4% vs 0%, p=0.008). Light and dark brown macules on gums were more frequent in patients with CL without SLE (48.3% vs 23.1% p=0.033 and 27.6% vs 7.7% p=0.033, respectively). Of all 38 SLE patients (with or without CL), red spots on hard palate and thick cobblestone on gums were more common in patients with SLE with CL (69.2% vs 33.3% p=0.037 and 53.8% vs 16.7 % p=0.031, respectively). White mucous streaks were more frequent in patients with SLE without CL (41.7% vs 3.8%, p=0.008). When comparing 38 SLE patients and 20 patients with DM, the mucosal folds on hard palate were only in SLE patients (15.8% vs 0%, p=0.084)

Conclusion: There are signs in the oral cavity that help us to differentiate CL from SLE, and SLE from DM

Session Date: Monday, November 14, 2016
Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies suggest exposure to ultraviolet (UV) radiation may be a risk factor for dermatomyositis (DM) and autoantibody phenotypes, based on differences in prevalence associated residential environmental UV levels in proximity to diagnosis. However, the role of individual determinants of exposure and susceptibility is unknown.

Methods: We analyzed data from adult patients (ages 18-65) in a national myositis patient registry (including 658 dermatomyositis [DM], 451 polymyositis [PM], and 309 inclusion body myositis [IBM]) diagnosed through 2011. A questionnaire collected data on geographic residence, sun sensitivity (tendency to experience severe or painful sunburns), history of sunburn in the 12 months prior to diagnosis, and history of specific jobs, longest job and hobbies (specified as outdoor and other) prior to diagnosis. Using a job-exposure matrix and consensus review blinded to myositis subgroup, jobs and hobbies were rated for sun exposure intensity (high, moderate, low, or none), with a certainty level assigned to each estimate (high or low). Maximum residential UV exposures were identified for the 12 months prior to diagnosis for cases diagnosed after 1990, using data on UV-B Erythemal irradiances from the NASA Total Ozone Mapping Spectrometer (TOMS). Comparing DM with PM and IBM patients, odds ratios (OR) and 95% confidence intervals (CI) were estimated for sunburn and UV exposures in the year prior to diagnosis using logistic regression models adjusted for age, skin tone, and sex. Stratified models explored the potential modifying role of maximum residential UV levels and sun sensitivity on recreational/occupational exposures.

Results: Sunburn in the year prior to diagnosis was reported by 41% of DM compared with 28% of PM/IBM patients (OR=1.55: 95%CI 1.22, 1.96). DM was associated with high or moderate sun exposures from outdoor recreation or hobbies in the year prior to diagnosis (OR=1.38: 95%CI 1.08, 1.76, vs. PM/IBM), and together, high or moderate recreational or occupational sun exposure was associated with DM vs. PM/IBM (high OR=1.61: 95%CI 1.08, 2.42; moderate OR=1.37: 95%CI 1.05, 1.79). The association of DM with moderate recreational/occupational exposures was most apparent in patients with higher environmental UV levels (OR=1.56: 95%CI 1.06, 2.30) and those who reported being less likely to have severe sunburns (OR=1.62: 95%CI 1.16, 2.26). Sensitivity analyses showed the associations with occupational or recreational exposures remained after excluding patients reporting any sunburn in the year prior to diagnosis, and in analyses limited to high certainty exposure estimates.

Conclusion: These findings suggest that sunburn and high intensity sun exposures from recreational or occupational activities within a year prior to diagnosis may be associated with greater risk of developing DM compared to other myositis subtypes. Results support investigation of the role of sun exposures in relation to environmental UV, individual susceptibility and protective behaviors, in the risk of DM.

Major comorbidities of idiopathic inflammatory myositis: A population-based study using 10 years of follow up from the national health insurance in Korea

Jeong Seok Lee[1], Min Jung Kim[1], Hee Young Lee[2], So Yeon Ahn[3], Yeong Wook Song[1], Eun Bong Lee[1], Eun Young Lee[1], Yun Jong Lee[4], Eun Ha Kang[4].

[1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea. [2]Center for Preventive Medicine and Public health, Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Korea. [3]Medical Research Collaborating Center, Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Korea. [4]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Korea.

Background/Purpose: Patients with idiopathic inflammatory myositis (IIM) suffer from comorbidities such as interstitial lung disease (ILD), cancer, and infections related to immunosuppressive agents. We evaluated incidence rate ratio (IRRs) and characteristics of major comorbidities in IIM compared to non-IIM Koreans.

Methods: A retrospective cohort study was performed using the 2005-2014 National Health Insurance Service database covering more than 99% of Korean population. Incident IIM (n = 4088) was identified by at least two visits (first visit date = index date) to the tertiary hospitals under ICD9 codes of IIM with at least 1 year devoid of such code preceding the index date. Age- and sex-matched subjects were enrolled as the unexposed at 10:1 ratio. The occurrence of ILD, cancer, herpes zoster, and tuberculosis, and death was captured using ICD9 code, disease-specific medication, and/or government-approved qualification for co-payment reduction on these outcomes.

Results: Newly diagnosed IIM patients was 4,088 (male 39.3%, age at diagnosis 51.0¡¾15.3), in 2005-2014. Most patients (> 90%) defined as such were found to have muscle biopsy, electromyogram, or multiple laboratory examinations on muscle enzymes. Their incidence rate of the above outcomes was significantly elevated; IRRs were 36.8 [95% confidence interval: 33.9-39.9] for ILD, 2.1 [2.0-2.2] for cancer, 2.2 [2.1-2.3] for herpes zoster, 3.5 [3.3-3.7] for tuberculosis, and 4.9 [4.7-5.1] for mortality. ILD and cancers were associated with shortened survival while herpes zoster and tuberculosis were not. Among cancers whose incidence rate more than 1.0 case per 1000 person-year, the most common type of cancer was metastasis of unknown origin (MUO) (6.3 [3.9-10.1]) followed by lymphoma (4.9 [3.0-7.9]) (Table 1). The temporal relationship between cancer and IIM was highest in stomach cancer showing the majority occurring within one year of IIM diagnosis (82.8%) (Fig1). Among cancers whose incidence rate more than 10.0 cases per 1000 person-year, lung cancer and metastasis of known primary cancers showed the highest incidence rate ratio and strong temporal relationship with IIM.

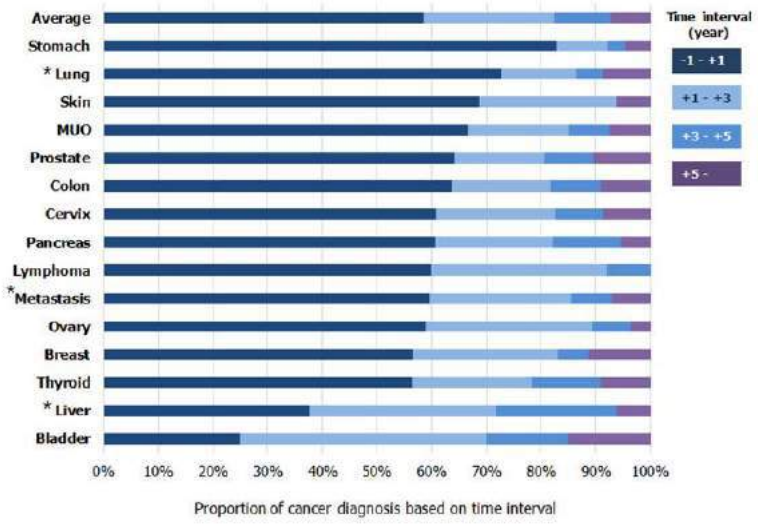
Conclusion: This is the first report of the nation-wide population based evaluation of IIM in Korea. The incidence of ILD, cancers, zoster, and tuberculosis was exceptionally higher in IIM than non-IIM. ILD and cancers were associated with worse survival. Advanced cancers with metastasis were strongly associated with IIM, showing high IRR in MUO and metastasis of known primary cancers.

Table 1. Common type of cancers in IIM patents with incidence rate higher than 1.0 case per 1000 person-year.

Organ	Incidence rate (number of cases per 1000 person-year)	Incidence rate ratio [95% confidence interval]
MUO	1.9	6.3 [3.9-10.1]
Lymphoma	1.8	4.9 [3.0-7.9]
Skin	1.1	3.5 [2.0-6.3]
Liver	17.0	3.4 [3.0-4.0]
Metastasis of known primary cancers	25.1	3.0 [2.7-3.4]
Ovary	4.0	2.9 [2.2-3.9]
Lung	10.0	2.9 [2.4-3.5]
Pancreas	4.0	1.5 [1.2-2.0]
Breast	3.8	1.4 [1.1-1.9]

MUO: metastasis of unknown origin (ICD9 code: C80). Metastasis: secondary malignant neoplasm of known primary sites (ICD9 code: C78, C79).

Figure 1. Time interval between IIM and cancer diagnosis among cancers with incidence rate of higher than 1.0 case per 1000 person-year.



MUO: metastasis of unknown origin (ICD9 code: C80). Metastasis: secondary malignant neoplasm of known primary sites (ICD9 code: C78, C79). *Cancers with incidence rate higher than 10.0 cases per 1000 person-year

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients who are diagnosed with scleroderma, undergo multiple hospitalizations during their lifetime. It still remains an incurable disease, however, numerous advances in its management have improved life expectancy and quality of life in affected patients. Hence, it is important to provide an updated surveillance data of this disease burden on inpatient hospitalizations, costs and mortality rate.

Methods: The National Inpatient Sample database for adult patients with principle discharge diagnoses of Systemic Scleroderma (ICD 9-CM CODE: 710.1) from the years 1993-2013 was analyzed. Spearman's correlation technique was applied using SAS 9.3 for Windows OS to determine statistical correlation of the number of hospital discharges, length of stay and hospital costs over time during these years.

Results: Total number of patients admitted with principle discharge diagnoses of systemic scleroderma decreased from 1910 in 1993 to 1665 in 2013(rho = 0.189, p=0.41). The mean length of stay for these patients did not show any statistically significant difference. The in-hospital mortality was noted to be significantly decreased from 9.63% in 1993 to 8.40% in 2013 (rho=0.681, p =.0007). The mean charges per hospital stay for adult systemic scleroderma patients increased from $14184 in 1993 to $86080 in 2013 (rho=.987, p <.0001). The aggregate charges (i.e. the national bill) increased from $41,517,946 in 1997 for adult systemic scleroderma patients to $143,104,818 in 2013.

Conclusion: A significant decrease was noted in hospital mortality in adult patients with systemic scleroderma. This is accompanied with major increase in cost of hospitalization during this time. This change can be attributed to increase in use of pharmacologic agents including immune-modulators and anti-fibrotic therapy, increased use of hematopoietic stem cell transplantation, advances in organ based treatment e.g. use of ACE inhibitors in scleroderma renal crisis, screening of these patients leading to early detection of complications and initiation of treatment. Also, multi-disciplinary approach to management including pulmonologists, gastroenterologists, nephrologist, dietician and social worker evaluation in hospital adds to the cost burden. A decrease in total number of admissions for adult patients with systemic scleroderma was noted. This may be attributed to better outpatient management for these patients. More data is required to study the trends in hospital admissions in these patients. Further research is required on cost effective management in patients with systemic scleroderma.

Session Date: Monday, November 14, 2016
Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: There is scarce information on the epidemiology of polymyalgia rheumatic (PMR) and giant cell arteritis (GCA) in Latin America. To estimate incidence and prevalence rates of PMR and GCA in a large university hospital–based health management organization in South America.

Methods: Global, age-specific, and sex-specific incidence and prevalence rates were calculated for members of a Medical Care Program

(HIMCP), age ≥ 50 years. Incidence study followed members with continuous affiliation ≥ 6 months from January 2000 to December 2015 until he/she voluntarily left the HIMCP, PMR or GCA were diagnosed, death, or study finalization. Cases from the Rheumatology Section database, electronic medical records, laboratory database, temporal artery biopsy and pharmacy database were filtered with the 2012 EULAR/ACR criteria for PMR or the ACR 1990 criteria for GCA. Prevalence was calculated on January 1, 2015.

Results: : In the study period 176,558 persons contributed a total of 1,046,620 person-years, of who 825 developed PMR for an overall incidence rate (cases per 100,000 person-years) of 78.8 (95% CI 73.4–84.2), 90.1 (95% CI 82.9–97.2) for women, and 58.9 (95% CI 51.1–66.6) for men. Ninety persons developed GCA for an overall incidence rate of 8.6 (95% CI 6.8–10.4), 11.1 (95% CI 8.5–10.6) for women, and 4.2 (2.2–6.3) for men. On January 1, 2015, 899 prevalent PMR cases and 100 prevalent ACG cases were identified from a denominator population of 80335 HIMCP members. Prevalence rates of PMR (percentage of cases in the sample population) were 11.2 per 1000 (95% CI 10.4–11.9) overall, 12.7 (95% CI 11.8–13.7) for women, and 8.2 (95% CI 7.2–9.3) for men, and prevalence rates of GCA were 1.2 per 1000 (95% CI 1–1.4) overall, 1.5 (95% CI 1.2–1.9) for women, and 6.3 (95% CI 3.4–9.3) for men. Patient's characteristics and incidence and prevalence rates per gender and different age groups are shown in table 1 and figures 1 and 2 respectively.

Conclusion: This study's incidence and prevalence rates are in the upper range of the rates found around the world. Our peak incidence age for PMR was in the eighth decade for both sexes and for GCA was in the seventh decades for both sexes.

Figure 2. Prevalence of PMR and ACG per age groups per1000 inhabitants

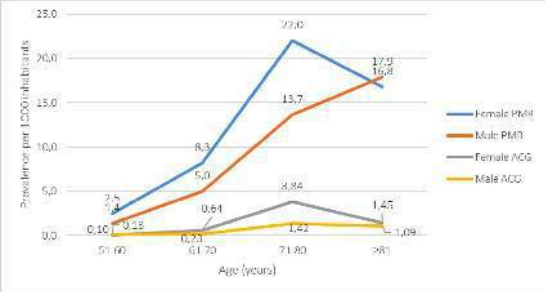

Table 1. Patient Characteristics in incident cases

Variable	PMR (n=825)	ACG (n=90)
Females, n (%)	603 (73.1)	74 (82)
Mean age at diagnosis (SD)	75.4 (7.9)	75.6 (11.1)
Bilateral shoulder aching, n (%)	798 (96.7)	-
Bilateral pelvic girdle (hip) aching, n (%)	602 (73)	-
Peripheral synovitis (distal swelling, tenosynovitis or arthritis), n (%)	107 (13)	-
PMR symptoms, n (%)	825 (100)	53 (59)
Abnormal erythrocyte sedimentation rate, n (%)	700 (85)	87 (97)
Mean erythrocyte sedimentation rate (SD)	56.7 (25.3)	69.8 (25.1)
Median Methylprednisolone initial dose (IQR)	8 (0-8)	40 (20-40)
Median months on steroid treatment (IQR)	20 (13-31)	29 (19-40)
Jaw claudication, n (%)	-	48 (54)

Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Increasing evidence suggests that characteristic changes in retinal vessel morphometry are biomarkers for vascular health. Polymyalgia Rheumatica (PMR) has been associated with increased risk of vascular disease in some epidemiological studies, but to date there are limited data on objective changes in blood vessels in patients with this condition. This study examines the retinal vessel morphology of individuals with PMR in a population-based cohort.

Methods: The study was conducted in participants diagnosed with PMR identified from the EPIC-Norfolk cohort, a population-based study of 25,639 men and women aged 40-79 years, recruited between 1993-1997. Diagnoses of PMR were established through electronic linkage to laboratory, hospital care episodes and questionnaire responses, supplemented by chart reviews during follow-up to 2015. In 2006-2011 digital retinal photography was undertaken and analysed using a validated automated system, which measures vessel width in arterioles and venules respectively. Gaussian modelling was used to determine vessel widths. An ensemble classifier of bagged decision trees was used to classify vessels into probabilities of being either venules or arterioles. Associations were analysed using multi-level linear regression, adjusted for gender and age, allowing for within person clustering.

Results: In total, 10,494 good quality images were obtained from 5959 participants were analysed. Median arteriolar and venular widths were 68.5µm (5^{th} to 95^{th} centiles 49.4, 91.0µm), and 99.1µm (5^{th} to 95^{th} centiles 83.1, 116.4µm) respectively. There were 298 incident diagnoses of PMR (72.5% female) during the follow-up period. The median age at diagnosis was 75.6 years of which 140 had good quality retinal imaging. Those with PMR diagnoses showed wider venules compared to those without disease (mean difference 3.1µm. 95% CI 1.1,5.1µm); there were no appreciable differences in arteriolar diameter (mean difference 0.3µm, 95% CI -2.1,2.8 µm).

Conclusion: These results provide the first objective evidence of a biomarker for vascular health in patients with PMR, a disease in which there is an absence of adequate clinical process and outcome measures. Although limited by the cross-sectional design, the findings indicate that retinal morphometric analysis could prove a useful monitoring tool for vascular complications in patients with rheumatic disease.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Epidemiology and Public Health - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common systemic vasculitis in people ³ 50 years of age and the disease is associated with potentially life-threatening complications. Nevertheless, most studies have shown little or no significant difference in the mortality rates observed between GCA patients and non-GCA subjects. However, the epidemiology is changing as the elderly population increases. The aim of this study was to investigate the epidemiology of GCA in an expected high-incidence region over time.

Methods: This is a retrospective cohort study of patients diagnosed with GCA in the hospitals of Bergen Health Area (Helse Bergen) during 1972-2012. The International Classification of Diseases (ICD)-coding system was used to identify patients from hospital records, ICD-8 (446.4) for 1972-1987, ICD-9 (446.5) for 1987-1998 and ICD-10 (M31.5-6) for 1999-2012. The diagnosis was verified according to ACR 1990 classification criteria by review of patient charts. Patient outcomes were documented by reviewing patient charts from time of diagnosis until death or end of study (31 Dec 2012). Information on time and cause of death was collected from the Norwegian Cause of Death Registry. Standardized mortality ratio (SMR) was calculated using the observed patient mortality and the death rates of the Norwegian population (age- and gender-matched) per 100 000.

Results: Eight-hundred twenty patients satisfied the ACR classification criteria for GCA. Among these there were 71 % females and 29 % males. Five-hundred twenty-eight patients (64 %) had a positive temporal artery biopsy (TAB) and 206 patients (25 %) had a negative TAB. For the remaining 86 patients (11 %) TAB was not performed or TAB results were inconclusively or insufficiently reported. Patient characteristics are presented in table 1. Four-hundred forty-three patients (54 %) died during the follow-up period. Median survival time was 12 years (95% CI 11-13). The overall SMR was 1.1 (95% CI 1-1.2). Female sex, younger age at time of diagnosis and high (>85) ESR at the time of diagnosis were found to be associated with increased mortality. Neither TAB-result nor decade of diagnosis showed statistically significant effect on survival. SMRs and median survival times are presented in table 2.

Conclusion: We did not find statistically significant difference in the overall mortality of GCA-patients compared to the general Norwegian population, but our results indicate that gender, age and level of ESR at the time of diagnosis may have prognostic impact.

Table 1. Patient characteristics

	Overall n=820	Female n=585	Male n=235
Mean age at onset of GCA (SD)	72.9 (8.7)	73.4 (8.4)	71.7 (9.3)
ACR criteria fulfilled (%)	820 (100)		
Age ≥ 50 at disease onset (%)	816 (99.5)	583 (99.7)	233 (99.1)
New onset headache (%)	592 (72.2)	418 (71.5)	174 (74.0)
Temporal artery tenderness (%)	378 (46.1)	265 (45.3)	113 (48.1)
Decreased temporal pulse(%)	230 (28)	170 (29.1)	60 (25.5)
ESR ≥ 50 (%)	740 (90.2)	525 (89.7)	215 (91.5)
Biopsy showing vasculitis (%)	528(64.4)	378 (64.6)	150 (63.8)
Giant cells in biopsy (%)	243 (29.6)	185 (31.6)	58 (24.7)
Mean ESR (SD) n=810	84.1 (27.6)	83.7 (27.9)	85.1 (27.0)
Mean CRP (SD) n=626	90.3 (63.4)	87.5 (62.3)	97.7 (65.2)
Jaw claudication (%)	181 (22.1)	134 (22.9)	47 (20)
Polymyalgia Rheumatica (%)	246 (30)	195 (33.3)	51 (21.7)
Peripheral Arthritis (%)	35 (4.3)	25 (4.3)	10 (4.3)
Visual disturbance (%)	149 (18.2)	106 (18.1)	43 (18.3)
Blindness one or both eyes (%)	33 (4)	24 (4.1)	9 (3.8)
Scalp necrosis (%)	6 (0.7)	4 (0.7)	2 (0.9)
Number of deaths 1972-2012 (%)	443 (54)	311 (53.2)	132 (56.2)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hemophagocytic lymphohistiocytosis (HLH) is a rare syndrome of excessive immune activation associated with high mortality. Early diagnosis and treatment can reduce mortality among these patients. In our study, we analyzed the rate of mortality independently and according to the cause in patients with HLH.

Methods: Pubmed database with the MeSH terms ("lymphohistiocytosis, hemophagocytic"[MeSH Terms] OR ("lymphohistiocytosis"[All Fields] AND "hemophagocytic"[All Fields]) OR "hemophagocytic lymphohistiocytosis"[All Fields] OR ("hemophagocytic"[All Fields] AND "lymphohistiocytosis"[All Fields])) AND cases [All Fields] were queried which yielded 466 results. Case series referenced from these studies were also studied. 74 studies were identified out of which the studies with a sample size smaller than 10 were excluded. 48 studies were kept with a total of 1983 patients. Meta analysis was performed to combine the mortality rates of all studies and studies of patients with the same cause. The results were presented in a Forest plot. Prior to the meta analysis, the heterogeneity test on mortalities

was conducted to choose a fixed or random effects model. I^2, a common heterogeneity measure, was reported with 25%, 50%, 75% suggesting low, moderate, and high heterogeneity.

Results: The combined mortality rate for all studies was 41.99% [95% confidence interval (CI) 36%> 49%]. In studies of patients with EBV infection (n=4), the combined mortality rate was 44% (95% CI 18%>74%) whereas the mortality rate in studies with other infections (n=4) was 46 % (95% CI 13-83%). The mortality rate in patients with hematological malignancy (n=8) was higher at 60% (95% CI 44%>74%]. For studies of patients with autoimmune diseases (n=2) and in transplant (n=4) patients, the combined mortality rate was 11% (95% CI 5%>21%) in patients with autoimmune disease and 38% (95% CI 27%>51%) in transplant patients. I^2 for the mortalities of all studies and each cause was presented as follows: $I^2 = 0\%$ (p=0.764) for autoimmune disease, $I^2 = 94.8\%$ [89.6%; 97.4%] (p<0.0001) for EBV infection, $I^2 = 75.2\%$ [50%; 87.7%] (p=0.0002) for hematological malignancy, $I^2 = 75.2\%$ [50%; 87.7%] (p=0.0002) for infection malignancy, $I^2 = 89.2\%$ [75.1%; 95.3%] (p<0.0001) for other infection, and $I^2 = 0\%$ [0%; 52.1%] (p=0.811) for transplant. The heterogeneity test result remained significant but for the causes of autoimmune disease and transplant.

Conclusion: Based on our results, mortality is higher in patients with hematological malignancy compared to patients with other causes, whereas it is lower in patients with autoimmune disease.

Low Body Mass Index and Smoking Are Associated With a Lower Risk of Sarcoidosis: A Population-Based Nested Case-Control Study

Background/Purpose: Sarcoidosis is a systemic disorder characterized by the presence of non-caseating granuloma. The etiology of sarcoidosis is unknown. It has been hypothesized that the interaction between genetic predisposition and environmental factors plays an essential role in the pathogenesis. Recent studies have found an association between body mass index, smoking and risk of sarcoidosis although the results were conflicting. Moreover, most of studies were referral-based studies that could be at risk of selection bias.

Methods: 345 patients (50% female; 90% Caucasian, 5% African-American; mean age 45.6 years) with incident sarcoidosis in 1976-2013 in a geographically well-defined population were identified based on comprehensive individual medical record review. Inclusion required physician diagnosis supported by histopathology and radiologic features of intrathoracic sarcoidosis, compatible clinical presentation, and exclusion of other granulomatous diseases. 345 sex and age-matched controls (50% female; 95% Caucasian, 1% African-American; mean age 45.4 years) were also identified from the same underlying population. Index date for controls was the same as diagnosis date of corresponding cases. Data on body weight, height and smoking status (never, prior and current smoker) were abstracted from clinical notes and health information questionnaires completed by patients. Overweight was defined as body mass index (BMI) ≥ 25 kg/m^2 but < 30 kg/m^2. Obesity was defined as BMI ≥ 30 kg/m^2. BMI within 1 year before to 3 months after index date was used in this study. Odds ratios (ORs) with 95% confidence intervals (CIs) for the association between smoking status, overweight and obesity and sarcoidosis with adjustment for age, sex and African-American race were calculated.

Results: Information on smoking status was available in 94% of subjects. Among cases, 60% were never smokers, 21% were former smokers and 19% were current smokers. Among controls, 42% were never smokers, 22% were former smokers and 36% were current smokers. Current smokers had a lower risk of sarcoidosis with adjusted OR of 0.34 (95% CI, 0.23 – 0.51) compared with participants who never smoked and adjusted OR of 0.39 (95% CI, 0.27 – 0.56) compared with participants who never smoked and former smokers.

BMI within the defined period was available in 74% of subjects. Among cases, 41% were obese, 33% were overweight and 26% had normal/low BMI. Among controls, 24% were obese, 41% were overweight and 35% had normal/low BMI. Subjects with obesity had a higher risk of sarcoidosis compared with those with normal/low BMI with adjusted OR of 2.47 (95% CI, 1.54 – 3.96). However, overweight was not significantly associated with a higher risk of sarcoidosis compared with subjects with normal/low BMI (adjusted OR 1.12; 95% CI 0.71 – 1.75).

Conclusion: Obesity was associated with a higher risk of sarcoidosis while smoking was associated with a lower risk in this cohort. The potential causal relationship of these exposures to the risk of developing sarcoidosis requires further investigation.

Risk of Hospitalized Infection Among Patients With Sarcoidosis: A Population-Based Retrospective Cohort Study

Background/Purpose: Increased risk of infection has been observed in several autoimmune disorders. Immune dysregulation and use of immunosuppressive agents, especially glucocorticoids, are thought to be responsible for the increased risk. It is unclear whether patients with sarcoidosis, another relatively common immune-mediated chronic inflammatory disorder characterized by the presence of non-caseating granuloma, might also be at an increased risk of infection.

Methods: 345 patients (50% female; 90% Caucasian, 5% African-American; mean age 45.6 years) with incident sarcoidosis in 1976-2013 in a geographically well-defined population were identified based on comprehensive individual medical record review. Inclusion required physician diagnosis supported by histopathology and radiologic features of intrathoracic sarcoidosis, compatible clinical presentation, and exclusion of other granulomatous diseases. 345 sex and age-matched comparators (50% female; 95% Caucasian, 1% African-American; mean age 45.4 years) were also identified from the same underlying population. Medical records of both cases and comparators were individually reviewed for first hospitalized infection for each type of infection (and not multiple infections per patient). The cumulative incidence of hospitalized infection adjusted for the competing risk of death was estimated. Cox proportional hazards models with adjustment for age, sex, calendar year, current smoking, diabetes mellitus, hypertension, dyslipidemia and obesity were used to compare the rate of development of hospitalized infection between patients with sarcoidosis and the non-sarcoidosis comparison cohort.

Results: Hospitalized infection after index date occurred in 84 cases and 47 comparators. After adjusting for age, sex and calendar year, the risk of at least one hospitalized infection after index date was significantly increased among patients with sarcoidosis with adjusted hazard ratio (HR) of 2.00 (95% CI, 1.41 – 2.84). Further adjustment for current smoking, diabetes mellitus, hypertension, dyslipidemia and obesity yielded adjusted HR of 2.09 (95% CI, 1.33 – 3.28). Sensitivity analysis including only hospitalized infection that occurred at least 6 months after index date to reduce the likelihood of detection bias was also performed. When only these cases were considered, the adjusted HR was essentially unchanged (HR 1.97; 95% CI, 1.38 – 2.82). Patients in this cohort were at significantly increased risk especially for some types of infections including pneumonia, gastrointestinal and soft tissue infections as shown in table 1.

Conclusion: Risk of hospitalized infection is increased among patients with sarcoidosis. How this risk should be addressed in clinical practice requires further investigations.

Subtype of infection	HR (95% CI) for all events after index , adjusting for age, sex and calendar year	HR (95% CI) for events that occurred at least 6 months after index date, adjusting for age, sex and calendar year
Sepsis	1.66 (0.78 – 3.56)	1.74 (0.79 – 3.84)
Septic arthritis	4.43 (0.42 – 46.94)	4.43 (0.42 – 46.94)
Osteomyelitis	3.31 (0.34 – 31.95)	3.31 (0.34 – 31.95)
Pneumonia	1.99 (1.15 – 3.43)	1.97 (1.13 – 3.45)
Pyelonephritis	1.62 (0.78 – 3.34)	1.62 (0.78 – 3.34)
Soft tissue infection	2.39 (1.04 – 5.51)	2.27 (0.98 – 5.27)
Gastrointestinal infection	2.66 (1.32 – 5.38)	2.57 (1.27 – 5.22)
Intra-abdominal infection	3.23 (0.33 – 31.4)	3.23 (0.33 – 31.4)

AA Amyloidosis: An Evaluation of Epidemiology and Prevalence in the US and EU5 Countries

WIlliam Andrews[1], Denis Garceau[2], Tomascz Sablinski[3], Paul Zhang[4] and Todd Waldman[4], [1]Auven Therapeutics, Hopkinton, MA, [2]Auven Therapeutics, Montreal, QC, Canada, [3]Auven Therapeutics, St. Thomas, Virgin Islands (U.S.), [4]Navigant Consulting, Inc., New York City, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Epidemiology and Public Health - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: AA amyloidosis (AAA) is a rare, systemic form of amyloidosis, which mostly occurs secondary to chronic inflammatory conditions, predominantly systemic arthritides. AAA is characterized by abnormal deposition of amyloid A proteins, which can be deposited in a variety of organs, most often the kidneys. While there is currently no approved treatment for AAA, treatment of the inflammation can reduce manifestations of AAA in some patients[1]. As with most rare diseases, understanding the epidemiology and prevalence of the disease is difficult, but is critical to improving the ability to diagnose the disease in a timely manner such that optimal treatment can be provided to patients[2]. As there is no clear source that defines the prevalence of AAA, we sought to evaluate prevalence in the US and EU5.

Methods: Five different methodologies were evaluated for use in the estimation of prevalence of AAA, three of which were chosen as robust approaches for regionally specific estimations. The methodologies used included: 1) Evaluation of AAA diagnosis rate via renal biopsy with extrapolation to that regional population based on overall rate of renal biopsy, 2) Assessment of multiple regional centers of excellence with patient registries or databases, with extrapolation to those regional populations, and 3) A survey of 270 US physicians, including nephrologists, rheumatologists, and gastroenterologists, to assess numbers and rates of AAA patient diagnoses.

Results: Estimates suggest that there are 9,100-15,500 AAA patients currently under the care of a physician in the US and approximately 6,200 patients in the EU5. Data reveal that 40-68% of the primary conditions in AAA patients are arthritic in nature, and suggest that US rheumatologists are managing close to 30% of AAA patients. Approximately half of US rheumatologists are currently managing AAA patients. Rheumatologists are generally more aware than other specialists of the signs of AAA, the first sign of which is typically the development of kidney disease. Patients are then referred to a nephrologist for confirmation of the diagnosis, which is most often done by renal biopsy. Compared to the US, care in the EU5 is more highly centralized and patients are often referred to an AAA center of excellence.

Conclusion: Understanding the prevalence of a rare disease is typically difficult due in large part to the small numbers of patients spread

out across the globe. Other reasons are low awareness of the disease and regional variations in clinical practice. In addition, global registries are not in place for most rare diseases. This research suggests an AAA prevalence of 9,100-15,500 patients in the US and approximately 6,200 in the EU5. In the US, rheumatologists are managing a large portion of the patients. Bringing together centers of excellence and thought leaders to develop a global patient registry would help to further define the epidemiology and prevalence of AAA, and increase awareness of this rare but devastating disease. Session Date: Monday, November 14, 2016

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sensitive and specific blood biomarkers to detect the initial stages of osteoarthritis (OA) and to predict the future development of the disease are not available in clinical routine. Consequently, there is a considerable interest in the identification of new markers. In OA, studies investigating the altered expression of regulatory RNA that may be used clinically are scarce. MicroRNAs (miRs) are small non-coding RNAs of approximately 22 nucleotides in length that can silence gene expression by binding to complementary sequence on target messenger RNA transcripts resulting in translational repression or target degradation. They are easily accessible and stable. So, we studied the differential expression of circulating miRs in subjects with and without OA in the OFELY cohort.

Methods: The study group included French women belonging to the population-based cohort OFELY (Os des FEmmes de LYon). Expression levels of serum miR were measured in 10 healthy women without OA at any site (knee, lumbar spine, hip and hand) and in 10 women with a Kellgren & Lawrence score of 2 and 3 (early and intermediate knee OA) and OA at others sites. The evaluation of the OA disease was performed by radiography for spine disc degeneration and knee OA, by clinical examination for hand OA and by questionnaire for hip OA. These evaluations have been performed at the same visit, 8 years after recruitment of the cohort. Both groups were matched for age (healthy: 61.9 ± 3.03 and OA: 63.9 ± 3.4 p=0.17) and menopausal status. According to the manufacturer's protocol (EXIQON, Denmark) for the Next Generation Sequencing (NGS) method, RNA isolation was performed from 400 µl of serum followed by the library preparation and amplification and the µRNA sequencing (Illumina platform). Measurements were expressed as Tags per million (TPM), which is a unit used to measure expression in NGS experiments. The number of reads for a particular miR is divided by the total number of mapped reads and multiplied by 1 million (Tags Per Million, TPM).

Results: We identified 421 miRs with an expression level ≥ 1 TPM and 241 with an expression level ≥ 10 TPM. When we compared the two groups, 22 miRs showed differential expression ($p<0.05$) between controls and OA patients. After Benjamini-Hochberg False Discovery Rate (FDR) correction has-miR-139-5p, has-miR-1299 and has-miR-200a-3p remained significantly different between OA patients and controls ($p<0.05$, FDR at 5%) (Table).

names	Log Fold change	P-value	FDR	Healthy average TPM	OA average TPM
has-miR-139-5p	0.734682	0.000126	0.043432	90.1	143.3
has-miR-1299	-3.38328	0.000201	0.043432	12	0.8
has-miR-200a-3p	-1.881	0.000328	0.047335	77.2	29.4

Conclusion: With a NGS screening approach, we identified 3 miRs that are differentially expressed in women suffering from OA compared to healthy women. The next step will be the measurement of these specific miRs in the entire cohort to determine the clinical utility of these markers.

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: CD40 and CD40L (CD154) are tumor necrosis factor (TNF) family members involved in the pathogenesis of various autoimmune diseases. While this pathway is active in established RA, its activity and potential role in early disease pathogenesis is unknown.

Methods: RNA-seq analysis was used to identify the expression of *CD40* and *CD40LG* in synovial tissue biopsies from various stages (seropositive arthralgia, undifferentiated arthritis, early RA and established RA) during the progression of RA. Gene Set Variation Analysis (GSVA) was used to determine if CD40-CD40L signaling is active in the biopsies, using human immature dendritic (iDC) and B cell genes induced by soluble CD40L as reference sets.

Results: *CD40LG* and the active full-length *CD40* isoform were increased in synovial tissue biopsies from early RA, established RA, and undifferentiated arthritis cohorts in comparison to healthy donors. In contrast, levels of the dominant-negative truncated *CD40* isoform were reduced in the same synovial tissue samples. Transcriptome characterization of soluble CD40L (sCD40L)-stimulated human iDCs identified *GPR120* and *KDM6B* as novel potential targets involved in CD40-CD40L signaling. We also compared sCD40L transcriptional profiles in iDC and naïve B cells and found that different set of genes respond to sCD40L stimulation in these two cell types. Finally, using GSVA we found that CD40L-responsive genes in B cells and iDC are significantly enriched in synovial tissue mRNA from early RA, established RA and undifferentiated arthritis patients.

Conclusion: The CD40-CD40L pathway is activated in the early stages of RA, and agents inhibiting this pathway may bw effective in established RA, early RA, and undifferentiated arthritis.

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is associated with a rare but potentially life-threatening lung disease, MTX-pneumonitis (MTX-P). MTX-P is an idiosyncratic hypersensitivity reaction to MTX inducing inflammation, cytokine release and the activation of CD4+ T-lymphocytes within the lung parenchyma. Clinical risk factors are associated with the development of MTX-P; they are however, poorly predictive, there is therefore a need for improved markers of disease susceptibility. Epidemiological studies have provided evidence that MTX-P may be a genetically susceptible disease. To date, only one locus has been associated with MTX-P in a Japanese population (HLA-A 31:01). To identify genetic predictors of MTX-P we conducted a genome wide association study in a United Kingdom (UK) population.

Methods: Cases of MTX-P were recruited from a UK-wide multi-centre study. Cases were physician diagnosed MTX-P. Controls were recruited from the Rheumatoid Arthritis Medications Study (RAMS), a multi-centre observational study in the UK. Controls were participants with RA taking MTX for at least 1 year without the development of MTX-P and were age:sex matched 3:1 to cases. Genotyping was performed using the Illumina Infinium HumanCoreExome BeadChip array (Illumina, San Diego, USA). Bioinformatic analysis was undertaken to identify associated SNPs with potential functional significance.

Results: 65 cases and 195 controls were recruited. The study has an 80% power to detect an allele with frequency 0.30 and allelic odds ratio of 3.0. Following quality control, data for 236,308 SNPs in 62 cases and 172 controls remained. 48 cases (77%) retrospectively fulfilled either the Carson et al. or Searles et al. unvalidated criteria for MTX-P. Three SNPs were associated with MTX-P at $P<10^{-5}$. Rs6593803 ($p = 1.85 \text{ X } 10^{-7}$, OR = 3.13) maps near *GJA5* (figure 1), rs9299346 ($p = 1.76 \text{ X } 10^{-6}$, OR = 2.76) in *GRIN3A* and rs1624005 ($p = 6.54 \text{ X } 10^{-6}$, OR = 2.59) maps near *LRFN5*. rs6593803 affects *GJA5* expression, a subunit of the gap junction connexin 40. Transgenic mice deficient in connexin 40 and 43 ($cx40^{--}/cx43^{--}$) have a reduced life span due to lung abnormalities including pulmonary fibrosis, alveolar wall thickening and increased lung fibroblasts, histopathological findings similar to MTX-P.

Conclusion: 3 SNPs were associated with MTX-P at borderline significance levels. Further studies should prioritise investigating the role of rs6593803 in MTX-P.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While several transcriptional profiling studies of synovial biopsies have been reported from RA patients with advanced disease, there is relatively little data available from patients with early disease before treatment with DMARDs or on the effects of treatment with DMARDS. Such data may advance our understanding of RA pathogenesis and promote precision-medicine based treatments for early disease.

Methods: Biopsies from subjects with early RA (<12 months from diagnosis at baseline with an average disease duration of 17.6 weeks) before and after triple DMARD (tDMARD) therapy were collected by arthroscopy (n=19 paired samples at baseline and 6 months post-treatment). These biopsies as well as those from subjects with normal synovium (n=28) or those diagnosed with osteoarthritis (n=15) were profiled by total RNA sequencing. Comparison of RA biopsies before and after treatment and comparison with non-RA controls were performed. Pathway enrichment and upstream regulator analysis were used to understand gene changes and to generate hypotheses for future experimental confirmation.

Results: Over 5000 genes were identified with differential expression between baseline RA samples and normal controls (with 5% FDR and 2 fold-change cutoffs). A subset comprising less than 500 of these genes was modulated by tDMARD treatment in the subjects (n=17) who achieved good or moderate response at 6 months as assessed by EULAR criteria. The gene set whose expression was modulated by treatment was enriched for genes involved in immune system and T cell activation pathways. Interestingly, many genes with increased expression in RA samples remained elevated after treatment compared to normal controls. Based on this finding, we also identified gene expression patterns in treated patients with low disease activity (DAS28 < 3.2) that differentiates them from normal controls. These gene

signatures may help identify novel drug targets to improve rates of treatment induced disease remission.

Conclusion: Through genome-wide transcriptomics profiling, we identified signatures that characterize synovial tissue from RA patients with early disease. Analysis of gene expression after 6 months of tDMARD treatment highlight consistent alterations in expression of genes related to immune response and T cell activation. Our results provide novel insight into the biology of joints from early RA patients and the mechanism of tDMARD action in this patient population with high unmet clinical need.

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Measurements of immune cell proportions from whole blood can be used to detect pharmacodynamic effects, as a marker for prognosis and to aid in understanding therapeutic response in patients with disease. Profiling of immune cell types from whole blood in clinical trials is traditionally accomplished with low resolution tests such as complete blood count (CBC). Although FACS yields more comprehensive profiling it is challenging to execute in large trials. Mathematical deconvolution techniques have been developed to estimate the proportion of constituent cell types from whole blood using microarray expression profiling (Abbas et al., 2005, Newman et al., 2015) and RNA profiling by next-generation sequencing (NGS) (Gong et al., 2011). Here we extend the technique using RNA-Seq of naïve and activated immune cells to derive cell and activation specific gene signatures.

Methods: Immune cells from lymphoid and myeloid lineages were isolated from multiple healthy donors. Naïve cells were stimulated to induce an activated state. RNA from 102 samples were harvested and profiled by NGS. The deconvolution algorithm leverages a set of genes and associated expression levels to infer cell abundances. Multiple filters were used to ensure specificity and sensitivity during gene identification and matrix generation (Figure 1).

Results: We assessed the ability of the deconvolution algorithm to discriminate pure cell types (T, B, NK, Monocytes and Neutrophils) on an independent RNA-Seq dataset of cells sorted from whole blood from Systemic Lupus Erythematosus (SLE), Multiple Sclerosis and Normal Healthy subjects comprising 191 samples. It achieved an average positive predictive value of 100% and an average negative predictive value of 95% (Table 1). Further validation is planned using whole blood samples analyzed in parallel by FACS and RNA-Seq. We applied this method to a large publically available RNA-Seq dataset of 99 SLE subjects (Hung et al., 2015). We were able to identify a higher proportion of activated T-cells (defined by CD3/CD28 stimulation) in SLE subjects and those corresponded with interferon activity levels as determined by the authors (Figure 2).

Conclusion: Whole blood deconvolution using RNA-Seq may be a useful method for immuno-phenotyping by proxy when FACS is unavailable.

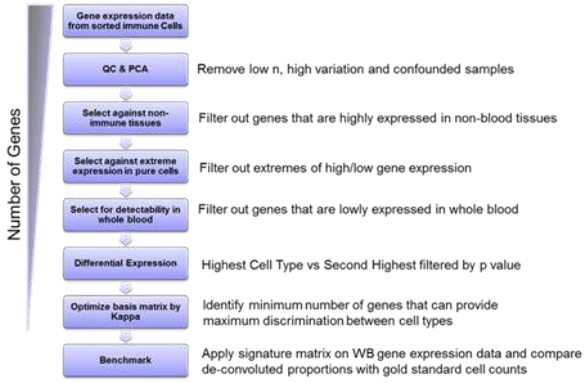

Figure 1: Gene Filtering Strategy for Deconvolution

Table 1: Deconvolution Algorithm Performance on Pure Cells

Pure Cell Type	Specificity	Sensitivity	Accuracy	PPV	NPV	Samples
T Cells	100%	97%	99%	100%	98%	67
B Cells	100%	12%	84%	100%	84%	34
NK Cells	100%	73%	97%	100%	97%	22
Monocytes	100%	97%	99%	100%	99%	34
Neutrophils	100%	85%	97%	100%	97%	34

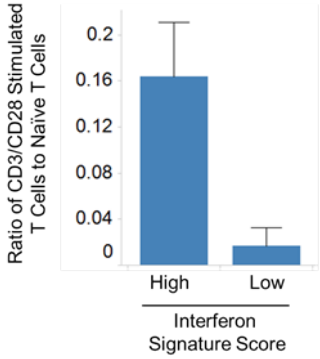

Figure 2: Activation state of T Cells inferred by deconvolution corresponds to interferon signature status
Hung et al., 2015 classified 99 SLE subjects into Interferon High (75) or Interferon Low (24) by qPCR assay of three genes (Kennedy et al., *Lupus Sci Med.* 2015). A deconvolution algorithm was used on whole blood RNA-Seq to estimate proportions of Naïve T Cells and T Cells with a CD3/CD28 activation transcriptional phenotype. Bar height represent the ratio of activated to naïve T Cell subsets; error bars are SEM.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Genetics, Genomics and Proteomics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We have presented evidence that the frequency of helper T (Th)17 cells increased and the cells had already been activated in vivo in patients with Behcet's disease (BD). Major proinflammatory cytokines, such as IL-1β, IL-23 and TNFα, significantly increased IL-17 production of T cells of BD patients. Recently, some researchers clarified the relationships among several gut bacteria, skewed Th17 cell function and local inflammation in autoimmune disease models, presumably through the overproduction of several proinflammatory cytokines in the intestinal immune system. We conducted fecal metagenomic analysis of BD patients and compared the data with those of normal individuals (NI) to assess whether unfavorable compositional and functional changes of gut microbiota (Dysbiosis) exist in BD patients.

Methods: We explored fecal microbiota of 12 patients with BD and 12 NI by sequencing of 16S rRNA gene. We calculated relative abundance of bacterial taxa and the diversity of each sample (alpha diversity) and each group (beta diversity). We compared the relative abundance of bacterial taxa with fecal secretary IgA (sIgA) concentrations and a BD disease activity index in BD patients. Then we predicted metagenome functional content from the 16S rRNA gene data using a bioinformatics software package (PICRUSt).

Results: The sequencing data showed that the family Lactobacillaceae, the genera Bifidobacterium and Eggerthella increased significantly in BD. The order Clostridia and the genus Megamonas significantly increased in NI. Fecal sIgA concentrations increased significantly in BD patients compared with those in NI. None of the relative abundance of bacterial taxa correlated with fecal sIgA concentrations or the BD activity index of patients with BD. There was no significant difference in alpha diversity between BD and NI. An exploratory analysis showed a significant difference between the two groups (BD and NI) in beta diversity. Bacterial genome function analyses revealed that glycolysis/glycogenesis and fatty acid metabolic pathways exceeded in BD patients compared with NI.

Conclusion: Lactic acid producing bacteria, such as Bifidobacterium and Lactobacillus, were suggested to decrease short chain fatty acid production of microbes belonging to the class Clostridia, some of which were reported to be essential for the differentiation of regulatory type T cells. Recently, glycogen and several short chain fatty acids were reported to play a role in the activation of T cells through the regulation of metabolic pathway. We suggest that low short chain fatty acid concentrations with bacterial metabolic alterations may have a relationship with the skewed Th cell differentiation of BD.

Differential Synovial Expression Patterns in Early Osteoarthritis Predict Pain and Progression of Joint Damage

Arjen B. Blom[1], Martijn H. van den Bosch[1], Hans Cats[2], F van den Hoogen[3], Floris PJ Lafeber[4], Wim B. van den Berg[1], Peter L. van Lent[1] and Peter M. van der Kraan[1], [1]Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands, [2]Hengstdal 3, Sint Maartenskliniek, Ubbergen, Netherlands, [3]Rheumatology, Radboud UMC, Nijmegen, Netherlands, [4]Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Genetics, Genomics and Proteomics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The cause for chronic pain in OA is largely unknown. Over 50% of osteoarthritis (OA) patients show synovial

inflammation, even at early stages of the disease. However, if and how this synovial activation contributes to joint pathology and pain, is not known. We aimed to identify pathways that predict progression of cartilage damage and osteophyte (OP) formation in OA. In addition, we identified association between gene expression and pain in a cross-sectional approach.

Methods: From 25 patients with knee OA that entered the CHECK Cohort study (Cohort Hip and Cohort Knee) synovial biopsies were collected at baseline. CHECK is a prospective 10-year follow-up study on patients with early osteoarthritis-related complaints initiated by the Dutch Arthritis Foundation. Progression over 5 years was determined radiographically based on change of joint space width (JSW) and OP size in these radiographs. Pain was assessed at baseline and after 5 years by the WOMAC pain questionnaire. Synovial samples from baseline were studied using histology and microarray (affymetrix U133-plus-2.0), and Functional Annotation Clustering (FAC).

Results: We identified patients as progressors or non-progressors, either based on JSW (respectively n=13 vs n=8) or OP size (respectively n=10 vs n=11) at baseline and t=5yrs. Among the genes that were differentially expressed by OP progressors were MMP1, 2, 3, 9 and -14, which were not found in JSW-progressors. Specifically in JSW-progressors, macrophage markers (e.g. CD14, S100A8, S100A9, MHC class II genes) were positively associated with progression. This indicates that expression of these factors predict progression of cartilage damage in OA patients. Using FAC we identified inflammatory response, macrophage differentiation, blood vessel formation, ossification and cell migration to be enriched in JSW-progressors. Blood vessel formation, ossification and cell proliferation were enriched in OP-progressors. Histologically, the JSW-progressors showed a thicker synovial lining and cellularity was higher in the sublining compared to non-progressors and OP progressors. Both JSW-progressors and osteophyte-progressors showed increased vascularisation compared to non-progressors. FAC analysis pointed out that dendrite formation (p=0.036), ossification (p=0.027) and wnt signaling (p=0.0065) were annotation clusters that were related to pain at Baseline. Moreover, we found neuronprojection/dendrite formation (p=0.0044), skeletal morphogenesis (p=0.018) and neuron differentiation (p=0.038) enriched in synovium of patients with pain after 5 years. When only upregulated genes were tested these patients showed strong enrichment of inflammatory genes ($p=6.4*10^{-12}$) and axogenesis (p=0.005).

Conclusion: We found evidence for a difference in underlying processes in the synovium regarding progression of cartilage damage and progression of osteophyte formation. The presence of macrophages, in the lining layer, is associated with progression of cartilage damage, whereas synovial expression of MMPs correlated to progression of osteophyte formation. Pain at t=5 yrs was predicted by several nerve fiber related processes and strongly by inflammation.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Genetics, Genomics and Proteomics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease of unknown etiology that causes inflammation and irreversible damage in joints and other organs. Methotrexate (MTX) is the first-line therapy used in the treatment of RA. However, not all patients respond to MTX, and a tool to predict MTX responders would help clinicians identify the 50-60% of patients that require additional therapy. Because MTX affects evolutionarily conserved pathways that are present in both humans and bacteria, it is plausible that the microbiome may be affected by MTX or directly metabolizes the drug, which is a folic acid analogue. Additionally, gut bacteria have been shown in prior studies to metabolize many pharmacologic drugs. We hypothesize that the microbiome contributes to inter-individual variations in clinical outcome. Here, we focus on the response of bacteria to MTX and ask whether bacteria can metabolize MTX.

Methods: First, we tested the *in vitro* growth of a panel of 25 gut bacterial isolates in response to MTX. The minimal inhibitory concentration (MIC), or the concentration of MTX required to completely suppress bacterial growth, was identified for each isolate. Second, we used HPLC to ask whether gut bacteria metabolize methotrexate. In select cases, we also used UPLC-MS-MS to learn the identity of MTX metabolites.

Results: Methotrexate inhibited the growth of 19 of the 25 isolates examined. Minimal inhibitory concentrations ranged from 2 ug/ml to >900 ug/ml *in vitro*. At the Phylum level, Bacteroidetes tended to be sensitive and Firmicutes tended to be resistant to antimicrobial effects of MTX (Fisher's exact test, p=0.03). We next asked whether these species metabolize MTX, and found that 5 possessed this ability. At least two species metabolized MTX into polyglutamated methotrexate, which is a novel finding that has not been described previously in the literature. Interestingly, there was no association between bacteria that were resistant to MTX and those that metabolized it.

Conclusion: These findings suggest that methotrexate is an antibacterial in addition to being a chemotherapeutic agent and an immunosuppressant. Additionally, gut bacteria can metabolize MTX, perhaps even before this drug enters a patient's bloodstream. The metabolite found in our study was polyglutamated MTX, which prior studies have shown to be associated with patient response. Our ongoing studies will examine the *in vivo* implications of these findings, but this supports the hypothesis that a patient's response to methotrexate may be influenced by their gut microbiome. Thus, the microbiome may be an important factor in predicting patient response to MTX and perhaps other rheumatologic medications as well.

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a clinically heterogeneous disease with few treatment options. Current treatments are not fully effective and show highly variable responses. Drug repurposing is based on the comparison of gene expression signatures of blood, PBMCs or separated cell types from cases with a disease with gene expression signatures made with various cancer cell lines treated with different drugs. It has been an effective technique for the identification of new therapeutic approaches. We present a systematic drug repurposing analysis based on gene expression signatures derived from blood cells of SLE patients to discover potential new drug candidates and target genes.

Methods: We collected and processed a compendium of gene expression data sets of SLE from the NCBI Gene Expression Omnibus database. We selected data sets of adult and juvenile SLE cases from different micro-array platforms to obtain a heterogeneous group of data from which to identify a common signature. We used R to process each data set independently, making normalization, transformation to logarithmic scale, quality control, and differential expression analysis. The genetic signatures obtained were queried independently on the Lincscloud database, which contains tens of thousands of drug and genetic perturbation-caused profiles, and obtained a list of drugs and genes based on similarity scores for each SLE signature. A positive similarity score represented a genetic pattern similar to the SLE signature, and a negative similarity score represented an inverse genetic profile. A negative score was therefore considered to revert the genetic profile of SLE. The median of the similarity score of each independent experiment was then calculated to obtain a unique list of genes and drugs. Drug targets were annotated using a file created in R from three drug databases to classify the drugs into groups. The Enrichr web tool was used to obtain the pathways involved when analyzing the knock-in and knock-down experiments.

Results: We obtained drugs never or little studied to treat SLE and drugs undergoing intensive research. Results were not dependent of cell type or SLE heterogeneity, as we selected genes conserved across all SLE signatures queried. Phospoinositol 3 kinase (PI3K) and mammalian targets of Rapamycin (mTOR) inhibitors were the most significant groups of drugs obtained. When we analyzed the biological pathways obtained with the knock-in and knock-down experiments we found pathways impaired in SLE, such as the interferon and immune signaling pathway, the translational process, but also, pathways related to the PI3K signaling pathway or the Insulin signaling pathway. So, these results are complementary and consistent with those observed with the drugs. PI3K acts in important processes related to the development of SLE, such as immune signaling, the lymphocyte differentiation and proliferation or apoptotic processes.

Conclusion: Our results suggest that PI3K inhibitors affecting biological pathways impaired in SLE are the best potential therapeutic option. This work has received support from the EU/EFPIA Innovative Medicines Initiative Joint Undertaking (PRECISESADS, grant n. 115565).

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

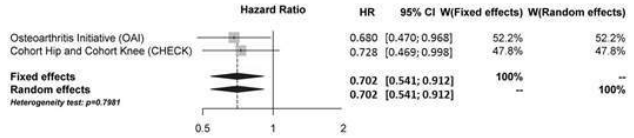
Session Time: 9:00AM-11:00AM

Background/Purpose: The study of the mitochondria in the context of osteoarthritis (OA) attracted much attention. In this study we aimed to evaluate the influence of the mitochondrial DNA haplogroups in the risk of incident knee OA and to explain the functional consequences of this association to identify potential therapeutic targets.

Methods: The influence of the haplogroups in the rate of incident knee OA at eight years in 2579 subjects from the Osteoarthritis Initiative (OAI) and 635 subjects from the Cohort hip and Cohort knee (CHECK) was assessed. Incident knee OA was defined as a new onset KL grade ≥ 2 during 96 months follow-up. Finally, a subsequent meta-analysis was conducted to synthetize results. Transmitochondrial cybrids carrying the haplogroups J and H were constructed to study the influence of the mitochondrial background in different OA-related features using an extracellular flux analyzer

Results: The haplogroup J associates with a decreased risk of incident knee OA in subjects from the OAI (HR=0.680; 95% CI=0.470–0.968; P<0.05) and CHECK (HR=0.728; 95% CI=0.469–0.998; P<0.05). The subsequent meta-analysis including 3214 cases showed that the haplogroup J associates with a lower risk of incident knee OA (HR=0.702; 95% CI=0.541-0.912; P=0.008) (Figure 1). Cybrids with the haplogroup H show higher mitochondrial respiration and glycolysis leading to an increased ATP production. On the contrary, haplogroup J shows a significantly lower free radical production, higher cell survival under oxidative stress conditions and lower grade of

apoptosis as well as lower expression of the mitochondrially-related pro-apoptotic gene BBC3



Conclusion: The haplogroup J reduces the risk of incident knee OA. This mitochondrial variant constitutes a protective phenotype against the development of OA and his beneficial physiological effects could be emulated to identify potential therapeutic targets to treat OA.

Session Title: Genetics, Genomics and Proteomics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic drugs have revolutionised the treatment of Rheumatoid Arthritis (RA), however these therapies are expensive and exhibit a high non–response rate (30%). Currently there are no specific biological markers which distinguish non-response early after initiating treatment. The aim of this study was to identify serum protein levels which change when disease activity score is reduced by biologic drug treatment. These proteins may give mechanistic insight into molecular events after failed therapeutic intervention.

Methods: Sera and disease activity scores (DAS28-ESR) were collected from n=25 RA patients at baseline and six months after anti-tumour necrosis factor alpha treatment. EULAR response criteria were used. Untargeted (unbiased) label free LC-MS/MS based proteomics was used initially to discover sera proteins differentially expressed at six months in responders and non-responders. Multiple reaction monitoring (MRM) assays were designed and tested on a triple quadrupole mass spectrometer.

Results: Over 500 proteins were identified in each of the pooled serum samples using the untargeted label free LC-MS/MS approach. Statistical analysis of the data revealed a list of 155 proteins that were significantly differentially expressed between good and non-responders ($p<0.05$). 55 of these proteins were shortlisted for development of targeted MRM assays, and assays were successfully developed for 47 proteins.

Conclusion: The approach outlined here and the initial results obtained indicate the power of a combined mass spectrometry strategy for comprehensive serum proteome analysis to determine quantitative changes, discover novel protein signatures and develop a multiplexed protein assay capable of monitoring response to biologic treatments. Such biologic drug response markers could minimise the use of

expensive biologic drugs in patients who do not gain benefit and reduce adverse side effects.

Session Time: 9:00AM-11:00AM

Background/Purpose: Diagnostic biomarkers are decision-making tools in clinical lab routine and are of growing importance for clinical management of patients. In autoimmune diseases, one important class of biomarkers are autoantibodies (AAB) directed against human autoantigens. Apart from diagnostic antigens used in clinical routine, additional AAB reactivities to more than 100 human antigens relevant for disease are described in literature. Obviously, the autoimmune profile of humans covers a huge number of AABs, which display an enormous resource to identify novel marker candidates. Here, we describe a new screening platform SeroTag for discovery of novel AABs in healthy controls and autoimmune diseases. By selecting 100+ AABs a comprehensive autoimmune landscape will be outlined to define diseases and disease subgroups according to their intrinsic, highly differentiated AAB pattern.

Methods: SeroTag utilizes over 8,000 human proteins as antigen collection in bead-based suspension arrays (Luminex FlexMap 3D) to allow for high-throughput (HTS) serum sample processing with high accuracy, followed by standard and advanced data mining procedures. Recombinant antigens were covalently coupled to magnetic, color-coded beads and serum samples were incubated with several multiplex bead mixes each representing 400 different antigens. We screened over 6,000 serum samples from patients with autoimmune diseases such as SLE (n= >1,000), SSc (n= >450), RA (n= >1,500), SjS (n= >100) and over 1,000 healthy individuals to confirm known and to discover novel AABs.

Results: In SLE, SjS, SSc and RA, and also in healthy controls, novel autoantigens were discovered in several independent discovery studies and subsequently validated in separate validation studies. Antigens showing reproducible, significant reactivity compared to active and passive controls were selected in a stepwise marker refinement approach. Examples include BICD2 and KDM6B/JMJD3 as novel antigens in SSc with 20-30% prevalence, TMPO and MVP in SLE with 15-25% prevalence, and several novel protein targets of anti-citrullinated peptide antibodies.

Conclusion: HTS AAB screening is a valuable tool for “omics”-type biomarker discovery and verification in autoimmune diseases. Utilizing a technical platform capable to analyze thousands of antigens in thousands of patients, a high-resolution landscape of autoimmunity can be drawn. Over 50 novel autoantigens were discovered and validated in RA, SLE, SSc, and a set of novel autoantigens with high prevalence in healthy controls is presented. In combination with known AABs our findings show potential for improved and earlier diagnosis, differential diagnosis, and disease subgrouping. Distinct sets of AABs are utilized for biomarker support in the development of novel medicines for autoimmune diseases.

Background/Purpose: The role of genetic factors in the occurrence and/or severity of sHLH is not yet known. Therefore, from 2010 to 2016, we performed a national, prospective, cohort study to analysis HLH-associated genes (*Lyst, perforine, Munc 13-4, syntaxine-11, STXBP-2, SH2D1, XIAP, Rab-27, Itk)* in sHLH.

Methods: We included 190 adults and 15 children fulfilling adapted Histiocyte Society criteria. Data collected included: (i) clinical and biological features, (ii) malignant, autoimmune or infectious associated diseases, (iii) treatment and evolution at M0 and M12. HLH associated-genes could be sequenced in 185 patients and analyzed in 147. Mutational profiles of Non Synonymous (NS), rare variants (frequency < 1% or 5% in reference populations) were compared to control populations issued from the "1000 genomes" project and in house repositories.

Results: Heterozygous (n=111) and homozygous (n=2) rare variants were identified in 80 patients. For 26 patients, rare variants were localized in 2 or 3 genes. Compared with control populations, overall rare variants frequency didn't differ significantly. However, rare variants (frequency < 1% or < 5%) affecting 2 or more genes in patients were significantly different from controls ($p<0.0002$ and $p< 0.03$). Combinations of rare variants were enriched with *perforin* and *RAB27a* or *STXBP2* genes. sHLH were associated with hematologic malignancies and autoimmune diseases in 51 and 20 cases respectively, and idiopathic in 75 cases with infectious trigger in half of the cases. Severity of sHLH (relapsing cases, ICU transfer, or death) is significantly correlated with the presence of combination of rare variants (p=0,0043), especially in the groups of autoimmune diseases or idiopathic.

Conclusion: In conclusion, genes of primary HLH may also be involved in sHLH physiopathology and outcome.

Session Title: Genetics, Genomics and Proteomics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In order to search for susceptibility loci, we undertook a genome wide association (GWA) scan to identify genetic factors predisposing to Psoriatic Arthritis (PsA) and its clinical subsets in italian population.

Methods: This is a multicenter italian study involving 9 rheumatological centres localized in the main four macro-areas of Italy. We enrolled 835 consecutive PsA patients diagnosed according to CASPAR criteria. The control group consisted of 773 sex and geographical origin matched people recruited from healthy blood donors. Each sample was genotyped using the SNPs microarray Illumina CoreExome24 BeadChip. A whole-genome screening of common variants (SNPs) and structural variants (CNVs) on each cohort was performed. Moreover PsA patients were stratified according to their clinical patterns as peripheral (PPA), axial (APA), or mixed involvement (APPA).

Results: The association studies showed 40 markers with $p<7.40\times10^{-5}$ located on chromosome 6 in HLA-B region among PsA patients vs healthy controls. We found highly significant association with rs3916765 ($p=5.39 \times 10^{-12}$, OR 2.669, 95%CI =2 – 3.56), exm-rs12191877 ($p=4.87 \times10^{-10}$, OR 1.731, 95%CI =1.46-2.06), rs13191519 ($p=7.76 \times 10^{-9}$, OR 1.609, 95%CI =1.37-1.89), exm-rs4947248 ($p=1.98 \times10^{-9}$, OR 1.56, 95%CI = 1.35-1.80). Moreover, in PsA patients we identified signals of association from a region on chromosome 15q21 harboring USP8 gene ($p=6.25 \times 10^{-9}$, OR 1.627, 95%CI =1.38-1.92). Among these identified risk variants, two were strongly associated only with PPA [exm-rs12191877 ($p=1.27 \times10^{-9}$,OR 1.76, 95%CI =1.46-2.11), rs3916765 ($p=2.55 \times 10^{-11}$, OR 2.68, 95%CI =1.99-3.61)] but not with mixed clinical pattern. Moreover , PsA patients with mixed clinical pattern did not shown associations on chromosome 6 in HlA-B region. No SNPs association was found comparing axial or mixed form with healthy controls.

Conclusion: We have confirmed a strong association with PsA and high number of loci located on chromosome 6. A new association was found on chromosome 15. We found no association with SNPs localized in HLA-C region as already observed in other GWA studies. Replication of these variants in multiple larger populations is necessary.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : Risk factors are known for many diseases, but the etiologies of most autoimmune diseases remain unknown and are idiopathic. Pathogenesis of disease likely involves complex interplay between genetic and environmental risk factors. Specifically, Epstein Barr virus (EBV) has suggestive associations with many autoimmune diseases, and EBV infection is nearly ubiquitous in adults. The molecular mechanisms underlying these associations, however, remain unclear.

Methods: We tested the hypothesis that some autoimmune variants might act by altering the binding of the EBV-encoded transcription factor ZTA, consequently resulting in downstream changes in gene expression. To this end, we comprehensively characterized the DNA binding of ZTA to both methylated and unmethylated DNA sequences using protein binding microarrays (PBMs). Based on these data, we identified plausible causal variants for multiple sclerosis (MS), systemic lupus erythematosus (SLE), and juvenile idiopathic arthritic (JIA) predicted to alter ZTA binding. From among these, we identified variants located within likely regulatory regions in EBV-infected B cells using publically available functional genomic datasets. We screened these candidate variants using electrophoretic mobility shift assays (EMSAs) to identify general differential binding of nuclear factors, and validated differential ZTA binding using EMSA-supershift and DNA Affinity Precipitation Assays coupled with Western blots (DAPA-Westerns).

Results: These experiments revealed three genetic variants, associated with MS, SLE, and JIA, respectively, exhibiting stronger ZTA binding to the risk allele. We provide data showing that each of these variants is associated with genotype-dependent expression in EBV-transformed B cell lines. Using luciferase reporter assays, we further demonstrate that the autoimmune risk alleles result in greater promoter activity.

Conclusion: Collectively, these data demonstrate for the first time that differential binding of a viral protein to a disease-associated genetic variant can result in altered levels of host gene expression in ways that are predicted to influence autoimmune disease risk of MS, SLE, and JIA. Since ZTA is a viral protein, and is expressed throughout human life subsequent to EBV infection, but only in virus infected cells, these results offer a potential therapeutic target for multiple autoimmune diseases.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Genetics, Genomics and Proteomics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: One of the main limitations of the association studies in autoimmunity is the difficulty in identifying genetic risk variants with modest effects, given the large sample size required and the relatively low prevalence of these diseases in the general population. This limitation has been partially overcome by combining GWAS data from different pathologies as a single phenotype, thus providing the statistical power lacking in GWAS datasets of a specific disease. This approach has already been successfully applied in the study of several autoimmune diseases with common genetic backgrounds. During the last years, genome-wide association studies (GWAS) have identified a number of common genetic risk factors for rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). However, the genetic overlap between these two immune-mediated diseases has not been thoroughly examined thus far. The aim of the present study was therefore to identify novel shared risk loci between RA and SLE by performing a combined meta-analysis including previously published GWAS datasets of both diseases.

Methods: We performed a large-scale meta-analysis of GWAS data from RA (3,911 cases and 4,083 controls) and SLE (2,237 cases and 6,315 controls). Statistical analyses were performed with PLINK V.1.07. First, disease-specific meta-analyses were performed combining RA datasets, on one hand, and SLE datasets, on the other hand, by an inverse variance-weighted method. Subsequently, a combined RA–SLE meta-analysis was conducted. Those SNPs with p values lower than 1×10^{-5} in this combined meta-GWAS and p values lower than 0.01 in each disease meta-analysis were selected for replication in additional datasets comprising 13,641 RA cases and 31,921 controls and 1,957 SLE patients and 4,588 controls.

Results: The rs9603612 genetic variant, located nearby the *COG6* gene, an established susceptibility *locus* for RA, reached genome-wide significance in the combined analysis including both discovery and replication sets (P-value=2.95E-13). *In silico* expression quantitative trait *locus* analysis revealed that the associated polymorphism acts as a regulatory variant influencing *COG6* expression in monocytes. Moreover, protein-protein interaction and gene ontology enrichment analyses suggested the existence of overlap with specific biological processes, specially the type I interferon signalling pathway. Finally, genetic correlation and polygenic risk score analyses showed cross-phenotype associations between RA and SLE.

Conclusion: In summary, the present study adds COG6 to the list of risk factors shared between RA and SLE. Our results highlight the existence of a relevant genetic correlation between both diseases as well as the influence of common molecular mechanisms in their pathophysiology. Since common genetic pathways are implicated in RA and SLE, a reclassification of patients from a genetic point of view will lead to more specific and effective therapeutic procedures.

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Through genome-wide association scans (GWAS), more than 120 genes have been found to be associated with rheumatoid arthritis (RA). This study aims to search for novel risk alleles in Singapore Chinese RA patients positive for anticitrullinated peptide antibodies through next-generation sequencing of these genes.

Methods: Targeted sequencing of 128 genes was performed in 48 RA cases and 45 healthy controls. These genes were selected based on RAvariome database and literature review. The target exons and 5' non-coding regulatory regions were enriched using the Nimblegen SeqCap EZ kit (Roche) followed by parallel sequencing using Miseq (Illumina). Variant detection and annotation were conducted with the Genome Analysis Toolkit (GATK) and ANNOVA. Association analysis was determined with PLINK.

Results: A dataset of 696 high quality variants consisting of 14.2% non-synonymous, 68.5% coding synonymous/UTRs and 16.6% up- or downstream of gene was obtained. We focused our analysis on rare or low frequency variants (MAF<5%) that are not reported in previous GWAS studies. Risk association analysis identified 13 de novel non-synonymous variants. Among these, in the exons of AHNAK2 (rs77454674, rs201071549, rs144426530, rs144488514), AFF3 (rs117712488), PTPRC (rs148561683), FCRL3 (rs79895668) and ARAP1 (rs2291288) are variants predicted to be deleterious. In our non-exonic analysis, we found 7 risk associated low frequency variants (P<0.05). Two variants upstream of RUNX1 (rs56151547) and CCR6 (rs6931699) are found within the chromatin activation H3K4me3 mark and may be associated with epigenetic regulation.

Conclusion: We identified novel rare variants in RA that will be validated in a larger cohort.

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We have developed an antigen microarray technology to study antibody profiles to elucidate and diagnose clinical

states of SLE patients – the iCHIP® SLE-key® assay[1]. Our first product is the SLE-Key® Rule-Out test with 94% sensitivity, 75% specificity, and a negative predictive value (NPV) of 93%[2]. Here our goal was to determine whether particular antibody reactivities are associated with SLE disease activity index (SLEDAI) and can be used to monitor SLE disease activity.

Methods: We analyzed data from serum samples of 232 SLE patients (SLEDAI 0-25) tested on the iCHIP® containing ~200 antigens. Intensities were measured for both IgG and IgM autoantibodies. Two types of analyses were performed. For a dichotomous analysis, we defined two groups of patients: low SLEDAI (SLEDAI ≤2 [n= 123]) compared to moderate-high SLEDAI (SLEDAI >2 [n=109]). For each of the 382 features, we fit a univariate logistic regression model and estimated the odds ratio (OR), indicating the relationship between binding to a specific antigen and the subject's SLEDAI score. An OR significantly above or below 1 indicates a strong association between the feature and the dichotomous SLEDAI variable. We calculated the FDR-adjusted p-values for each univariate test, and constructed a FDR-adjusted confidence interval for the features with an adjusted p-value < 0.05 using a confidence level of 0.995. We also calculated the Pearson correlation coefficient between the intensity score for each feature and the continuous SLEDAI score.

Results: Thirty six individual antibody reactivities successfully separated between low and moderate-high SLEDAI groups in the dichotomous analysis. Nineteen of these features displayed OR>1 (mean 1.39±0.18), while the remaining 17 features displayed OR<1 (mean 0.53 ±0.08). IgG isotype was most prominent in both groups, while IgM isotype frequency increased in the latter group. Among the serologic reactivities with the largest OR were connective tissue antigens such as collagen III (IgG), vitronectin (IgG), laminin (IgG) and collagen IV (IgG) (OR 1.64-1.78); the reactivities with the smallest odds ratios were TNF receptor (IgG; 0.39) and GLP1 (IgM; 0.42). Autoantibodies to ssDNA (IgG), dsDNA (IgG and IgM), U1snRNP (IgG), Sm (IgG), and histones (IgG), which all showed significant OR, also significantly correlated with the SLEDAI score (correlation coefficients 0.46-0.57). In addition, 13 proprietary oligonucleotide sequences correlated with disease activity, with a median SLEDAI correlation coefficient of 0.44.

Conclusion: This initial proof of concept study shows that the SLE-key® microarray can detect individual autoantibody reactivities associated with high or low SLEDAI scores. Based on these results we are using the iCHIP®microarray technology to screen hundreds of antigens from relevant molecular pathways to establish a multivariate classifier for disease activity monitoring. **References:** (1)Fattal et al; Immunology, 2010 (2)Putterman et al., Journal of Immunological Methods, 2016 **Acknowledgements**: The authors wish to acknowledge the Innovative Medicines Initiative Joint Undertaking under grant agreement n° 115308 BIOVACSAFE.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interferon (IFN) signature has been established in the peripheral blood of the patients with systemic lupus erythematosus (SLE) by transcriptome analyses, indicating a role of the IFN pathway in the pathogenesis of SLE. On the other hand, contribution of the IFN pathway to anti-neutrophil cytoplasmic antibodies (ANCA) - associated vasculitis (AAV) has not been established. We previously reported association of a single nucleotide polymorphism in *interferon regulatory factor 5* (*IRF5*) gene with susceptibility to myeloperoxidase (MPO)-ANCA-positive AAV in a Japanese population, suggesting a potential role of the IFN pathway in AAV. In the present study, we conducted a transcriptome analysis to examine the contribution of the IFN pathway to AAV and compared the results with

those of SLE.

Methods: Total RNA was extracted from the whole blood of Japanese individuals including 6 patients with microscopic polyangiitis (MPA), 8 patients with SLE and 14 healthy controls using the PAXgene kit. The mRNA levels of the IFN signature genes, previously reported to be differentially expressed in SLE, were analyzed using the Agilent SurePrint G3 Human GE microarray. P values were calculated by Welch's t-test, and Benjamini-Hochberg false discovery rate (FDR) correction was applied for multiple testing.

Results: In MPA, 68 (17.3%) among the 392 probes for the IFN signature genes were upregulated (P_{FDR}<0.05 and fold change [FC] ≥1.5), showing significant enrichment when compared with 1515 (7.6%) upregulated probes among the 20053 probes in total (Fisher's exact test P value=9.8E-11). In SLE, 159 out of 392 IFN signature probes (40.6%) were upregulated. Of particular interest, although upregulation of IFN signature gene probes was observed both in SLE and MPA, the sets of upregulated genes showed substantial difference. Cluster analysis showed differential expression patterns in IFN signature genes between MPA and SLE. Principal component analysis using the IFN signature probes confirmed distinct MPA and SLE clusters. When the expression levels of each probe was compared between SLE and MPA, 3228 (16.1%) probes were upregulated in SLE compared with MPA. Among such differentially expressed genes, IFN signature genes showed significant enrichment (115 out of 392 genes, 29.3%, P=3.4E-11).

Conclusion: Although IFN signature was observed also in the peripheral blood of MPA, a substantial proportion of IFN signature genes were differentially expressed between MPA and SLE.

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS) is a chronic autoimmune disorder in which exocrine dysfunction can lead to chronic, debilitating dryness. Expression studies in SS have identified the dysregulated expression of coding and non-coding transcripts enriched in

innate and adaptive immune response pathways, yet their relationship to clinical features of SS remains poorly understood. By applying statistical approaches to RNA sequencing (RNA-seq) data for 3748 differentially expressed (DE; FC>2 or <0.5, q<0.05) transcripts in SS, we sought to identify transcripts whose expression correlates with objective dryness measures used in the 2002 American-European Consensus Group (AECG) SS classification criteria, including whole unstimulated salivary flow (WUSF), lissamine green (LiG) staining, and Schirmer's (Sch) tear migration.

Methods: Normalized expression data from a whole blood SS RNA-seq study was obtained for 57 cases and 11 healthy controls who underwent multidisciplinary clinical evaluation for the 2002 AECG classification criteria. Objective dryness measures (WUSF, LiG, & Sch) were normalized by $\log_2$ transformation and correlation analysis (Spearman for WUSF and LiG; Pearson for Sch) was performed for each clinical measure against all 3748 DE transcripts. Both r or $\boldsymbol{\rho}$ and a FDR-corrected p-value, or q-value, were calculated. Significantly correlated transcripts were defined by q<0.05.

Results: For WUSF, the significant positive correlation between WUSF rate and the expression of 2 non-coding transcripts was observed: the small Cajal body-specific RNA 5 (*SCARNA5*; s=0.50, q=0.018) and the uncharacterized antisense lncRNA RP11-137H2.4 (s=0.50, q=0.018). For LiG, positive correlation was observed for 31 transcripts (0.42<s<0.51, 0.017<q<0.05) mostly represented by interferon-inducible (IFI) protein-coding genes (*e.g. IFIT3, OAS3,* and *IRF7),* although the pseudogene *ZDHHC4P1* and its neighboring IFI gene *EPSTI1* showed significant positive correlation. For LiG, the only negatively correlated transcript was the sodium bicarbonate transporter *SCL4A10* (s=-0.43, q=0.045). For Sch, 3 transcripts (*CARD16*, *HMGB2*, and *BLC2A1*) were negatively correlated (-0.51<s<-0.49, 0.018<q<0.019), while *IQCH* was positively correlated (s=0.49, q=0.019).

Conclusion: We have identified SS-associated transcripts whose expression correlates with clinical measures of dryness. For WUSF, the ncRNA *SCARNA5* is situated within an intron of the Crohn's disease-associated gene autophagy-related 16-like 1 (*ATG16L1*). Although IFI genes have previously shown correlation with WUSF, the *ZDHHC4P1* pseudogene could regulate neighboring SS-associated IFI gene *EPSTI1*. For Sch, *CARD16* is a caspase inhibitor that influences apoptotic responses that induces NF-kB activation in inflammation, while *BLC2A1* has been shown to slow apoptotic responses. Further transcript characterization will allow us to assess their potential as biomarkers or surrogates of objective clinical measures for SS.

Session Title: Genetics, Genomics and Proteomics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The "interferon signature", marked by transcriptional upregulation of interferon (IFN)-inducible (IFI) genes, is a common finding in Sjögren's syndrome (SS) that is associated with anti-Ro production. Recent studies have implicated long non-coding RNAs (lncRNAs) as novel transcriptional regulators of IFI genes, yet their contribution to dysregulated IFN responses in SS remains unknown. In this study, we used RNA sequencing (RNA-seq) to characterize the relationship between lncRNAs and IFN transcriptional responses in anti-Ro-positive SS (SS^{Ro+}) and to prioritize lncRNAs for functional evaluation.

Methods: We used RNA-seq to generate whole-blood transcriptional profiles for 27 SS^{Ro+} patients and 27 healthy controls (HCs). Sequences were aligned to the human genome using TOPHAT and identified differentially expressed (DE) transcripts (FC >2 or <0.5 and q<0.05) using DEseq. For those DE IFI transcripts with a coefficient of variation (CV) >100% from a subset of 64 IFI transcripts, we calculated Pearson's correlation statistic, r, against the 267 DE antisense and 793 DE long-intergenic non-coding RNAs and identified those showing positive (r >+0.70) and negative (r <-0.60) correlation with FDR-corrected significance <0.05. To confirm DE of specific targets, we utilized qRT-PCR in an independent cohort of 16 SS^{Ro+}cases and 36 HCs to determine the relative expression of specific transcripts. Statistical significance was determined using an unpaired t-test in Prism.

Results: For the 19 DE IFI transcripts with CV>100%, we identified 6 DE lncRNAs whose expression is significantly correlated with IFI transcripts, including both overexpressed [*MX1-AS1* (FC=4.12), *OAS123-AS1* (FC=3.35), *NRIR* (FC=2.73), *GBP5-AS1* (FC=2.51)] and underexpressed [*ERC1-AS1* (FC=0.45), *linc-DCP1B* (FC=0.50)] lncRNAs. For only the overexpressed lncRNAs, we noted correlated expression with DE IFI genes in their immediate proximity, such as *MX1-AS1* (*MX1*, r =0.95), *OAS123-AS1* (*OAS1*, r=0.92; *OAS2*, r=0.91; *OAS3*, r=0.86), *NRIR* (*RSAD2*, r=0.77; *CMPK2*, r=0.80), and *GBP5-AS1* (*GBP5*, r=0.96). We have replicated the finding of *NRIR* upregulation in an independent cohort of SS^{Ro+} cases and HCs (p=4.8x10^{-3}), and replication is in progress for the remaining targets.

Conclusion: In this study, we have identified 6 novel SS lncRNAs showing significant co-expression with transcripts found within the IFN signature. Previous studies have implicated *NRIR* in the negative regulation of a subset of IFI genes that include the neighboring genes *RSAD2* and *CMPK2*. The proximity of additional overexpressed lncRNAs to well-defined IFI genes known to be dysregulated in SS and other autoimmune disorders bolsters the argument that these lncRNAs have regulatory roles and mediate IFI transcriptional responses. Further elucidation of the relationship between lncRNAs and expression differences in both peripheral blood and exocrine gland tissue has the potential to identify peripheral biomarkers that define specific clinical and transcriptional features resulting from IFI gene dysregulation.

Session Date: Monday, November 14, 2016

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout and hyperuricemia (serum urate > 7 mg/dL) typically present in the context of one or more comorbidities including type-2 diabetes, chronic renal disease, hypertension and obesity. The joint prevalence of these comorbidities with hyperuricemia is for some trait pairs more than double their marginal prevalence in the general population. However, the extent to which this association reflects genetic or environmental sources is unknown. The purpose is to derive marker-based heritability and genetic correlation estimates between, serum urate (SU), serum creatinine (SC), systolic blood pressure (SBP), blood glucose (BG) and body mass index (BMI), using whole genome regression (WGR) models of clinical data and genotypes from single nucleotide polymorphisms (SNPs).

Methods: We computed these estimates from a subset of the Framingham Heart Study, consisting of SNP genotypes from the Affymetrix500 array and clinical data measured on a total of 8,200 combined records from cohort 0, exam 13 (N = 1,396), cohort 1, exam 6 (N = 3,237) and cohort 3, exam 1 (N = 3,567). These data were fit with Bayesian multi-trait WGR models. Briefly, the model assumed two random components, one associated to the genetic factors ($\boldsymbol{\mu_k}$, for the kth subject) of BMI, SBP, BG, SU and SC; and the other to the environmental, or random residual errors ($\boldsymbol{\varepsilon_k}$). From these random components individual trait heritabilities and their genetic correlations with 95% posterior credible regions (CR) were estimated.

Results: With the exception of age and SBP the mean values of the traits were similar among the three cohorts. The mean (SD) for SU, BMI, SC and BG was 5.3 (1.5), mg/dL, 27.2 (5.2) kg/m^2, 0.8 (0.2) mg/dL, and 98.1 (23.5) mg/dL, respectively. Individuals in cohort 3 were on average (SD) younger, 40.2 (8.9) years, and had lower SBP, 115 (14) mm Hg, than those from cohort 1: 63.0 (6.7) years, and 138 (21) mm Hg. The highest marker based estimates of heritability (CR) were for SU, 0.35 (0.29, 0.42), SC, 0.46 (0.38, 0.54) and BMI, 0.42 (0.38, 0.47). The heritability of BG, 0.21 (0.17, 0.26) and SBP, 0.28 (0.24, 0.33) were lowest of the five traits analyzed, which, with the exception of SC, were all similar to family or pedigree-based heritability estimates reported in the literature. The three highest magnitude bivariate genetic correlations (CR) involved BG, with SU, 0.32 (0.18, 0.46), with SBP, 0.28 (0.15, 0.41), and with BMI 0.41 (0.30, 0.51), and their phenotypic associations involved minimal contribution from environmental (random residual) sources. The highest magnitude environmental correlations were for BMI with SU, 0.42 (0.36, 0.47) and BMI with SBP, 0.23 (0.19, 0.27) and contributed most, compared with genetics, to the phenotypic association of these traits.

Conclusion: Genetic sources of covariance between traits associated with hyperuricemia, gout and its comorbidities are substantial and consistently involve genes associated with BG. BMI consistently accounts for the environmental portion of the phenotypic associations. Therefore the etiology of gout and hyperuricemia may have an axis involving type-2 diabetes with a significant genetic component and one involving obesity that is primarily environmental.

Session Date: Monday, November 14, 2016

Session Title: Genetics, Genomics and Proteomics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Extensive evidence has correlated epigenetic alterations in articular tissues with both the presence and progression of human osteoarthritis, but data regarding extraarticular tissues are lacking. Given recent findings implicating systemic inflammation in OA, we sought to characterize the DNA methylome of OA patients' peripheral blood to ascertain whether PBMC methylation patterns were associated with rapid progression of human knee OA.

Methods: Peripheral blood mononuclear cell (PBMC) DNA was obtained from baseline blood draws of 72 OA patients enrolled in the Osteoarthritis Initiative (OAI) longitudinal study. All patients had baseline symptomatic and radiographic OA. 36 rapidly-progressive OA patients, defined as >= 1.0mm radiographic joint space loss or joint replacement within the first 24 months of follow-up were compared to 36 non-progressive OA patients defined as <= 0.5mm radiographic joint space loss over 48 months of follow-up. Sets were frequency matched for age, sex, race, BMI, and baseline K/L grade among the larger OAI cohort.

DNA methylation was quantified with Illumina HumanMethylation 450k arrays. Preprocessing was done in ChAMP, SNP-dependent and sex chromosome CpG sites were excluded from analysis, batch effects were corrected with frozen surrogate variable analysis. The estimateCellCounts function of minfi was utilized to ensure differential methylation results were not skewed by PBMC subset differences. GLMnet was used to derive machine learning-based algorithms correlating methylation of CpG sites with rapid progression, and correlations were validated on a random split of 30% of cases. This machine learning strategy was repeated 40 times and results compared. Genes associated with differential methylated sites and progression predictors were then submitted to Ingenuity (IPA) for ontological analysis.

Results: Our analysis identified 44 CpG sites as meeting our criteria for differential methylation, 35 of which were hypomethylated. Most were located within CpG islands or nearby shores or shelves, or upstream enhancers. The 14 associated genes were involved in canonical pathways including B cell development, antigen presentation, tRNA splicing, T helper cell differentiation, and IL4 signaling, among others. Many CpG sites were selected by our machine learning algorithms, the majority of predictive capability being provided by 29 CpG sites selected in at least 5 iterations of the model. Over multiple splits of data into training and testing sets, the predictive modeling strategy achieved a mean error rate of 33.3% on previously unseen validation data. The average receiver operating characteristic (ROC) curve of the model demonstrated an AUC of 0.75 for prediction of rapid progression. Ontologic analysis of genes selected by this algorithm were enriched in various pathways including the role of osteoblasts, osteoclasts, and chondrocytes in RA, NFAT signaling, EGF signaling, IL-10 signaling, TLR signaling, IL-6 signaling, and neuropathic pain signaling, among others.

Conclusion: Our data suggest that differential DNA methylation may be a readily-accessible biomarker for prediction of future radiographic progression in symptomatic knee OA patients. Further work will need to be done to confirm this pattern, and to define the specific cell populations which may be driving this differential methylation. These data further support the association of epigenetic modifications with human osteoarthritis.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-cyclic citrullinated peptide (CCP) antibody is a marker used in the diagnosis of RA, and it may be useful in identifying patients who are likely to have severe disease activity and joint damage.[1] This study compared RA-related healthcare utilization between patients with RA who are anti-CCP antibody positive versus negative.

Methods: Using electronic medical records from the Henry Ford Health System (HFHS), patients newly diagnosed with RA (International Classification of Diseases, Ninth Revision, Clinical Modification diagnosis code 714.0x) were identified between 1/1/09 and 12/31/14. The first RA diagnosis date was the index date. Patients were required to have 12 months of continuous activity in the HFHS (6 months pre- and 6 months post-index). Baseline anti-CCP test was used to categorize patients as positive or negative for anti-CCP antibodies. RA-related healthcare utilization evaluated in the post-index period included: laboratory testing (RF, CRP and ESR), outpatient visits, emergency room visits and hospitalizations. Statistical comparisons between the cohorts were conducted with chi-square tests for categorical variables and t-tests for continuous variables.

Results: The analysis included 103 anti-CCP-negative and 248 anti-CCP-positive patients with RA. Mean age was 58.5 years and 78.9% were female. The anti-CCP-positive cohort had a higher proportion of Black patients than the anti-CCP-negative cohort (44.4 vs 34.0%, p<0.0001). Joint pain was present in 39.3% of patients. Inflammatory back pain was higher in the anti-CCP-negative compared with the anti-CCP-positive cohort (14.6 vs 7.7%, p=0.0465). During follow-up, compared with the anti-CCP-positive cohort, a higher proportion of the anti-CCP-negative cohort was tested for RF (41.7 vs 19.4%, p<0.0001), CRP (71.8 vs 58.5%, p=0.0185) and ESR (66.0 vs 52.0%, p=0.0161). Among those tested, higher proportions of the anti-CCP-positive cohort than the anti-CCP-negative cohort had positive test results (RF: 83.3 vs 25.6%, p<0.0001; CRP: 68.3 vs 58.1%, p=0.1361; and ESR: 82.2 vs 60.3%, p<0.0001); significance was not reached for CRP. RA-related healthcare utilization occurred mainly in the outpatient setting. The proportion of patients with any outpatient physician office visit and the mean (SD) number of visits were highest in the anti-CCP-positive cohort compared with the anti-CCP-negative cohort (96.8 vs 88.3%, p=0.0019 and 5.3 [3.1] vs 3.6 [2.9)], p<0.0001). Most outpatient visits were to a rheumatologist, and the proportion of patients with a visit and mean (SD) number of visits were higher in the anti-CCP-positive compared with the anti-CCP-negative cohort (93.5 vs 73.8%, p<0.0001 and 4.4 [2.5] vs 3.3 [2.3], p=0.0003). Other healthcare utilization in outpatient and other settings was similar between the two cohorts.

Conclusion: Patients with RA who are anti-CCP positive had laboratory results indicative of higher inflammation and disease activity, which likely led to the higher healthcare utilization in the outpatient office setting. Future studies may evaluate differences in treatment outcomes and costs by anti-CCP serostatus. 1. Niewold TB, et al. *Q J Med* 2007;**100**:193–201.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient registries both disease-and drug-based complement information obtained from clinical trials. Long-term

outcomes studies can provide information useful for patients. The Agency for Healthcare Research and Quality (AHRQ) has developed a guide to standardized registries in order to optimize their quality. Objectives: To identify worldwide registries assessing patients with rheumatoid arthritis (RA) and describe their collected and reported variables. To evaluate the reporting of quality components in RA registries.

Methods: We performed an environmental scan to identify registries collecting data on patients with RA. The sample of registries was identified through: i) Google, ii) PubMed, and iii) clinicaltrials.gov. We also manually searched the list of references of selected reviews on this topic. One author selected the registries and two additional investigators reviewed the list for accuracy and provided additional registry names and references. Registry characteristics and variables were summarized and their differences explored to provide a preliminary assessment of their current strengths and limitations. We also evaluated the quality components of each registry using the basic elements of good practice developed by AHRQ. We considered the domain as reported when at least one of the following items was provided: i) planning, ii) design iii) data elements and sources, and iv) ethics, privacy and governance. Descriptive statistics were performed.

Results: We identified 90 worldwide registries. Out of the total, 59% (53) were patient-based registries and 41% (37) drug-based registries. Drug-based registries primarily evaluating biologic therapies and 83% of them, also included patients with other inflammatory arthritis with biologic treatment. The reported information was different if it was a patient or a drug-based registry: Radiological information, seropositivity, measures of socio-economic status, work disability and patient reported outcomes such as functional capacity; were more frequently reported in patient-based registries ($p<0.05$). On the other hand, comorbidities and biologic related outcomes such as adverse events and response, were most liked to be reported in drug-based registries ($p<0.05$). We have not found any difference between both registries in reporting in: self-reported patient disease indices, quality of life, fatigue, sleep, depression and stiffness. Regarding reporting of quality domains, the domain most frequently reported in all registries was data elements and sources (82%). Planning, design and ethics, privacy, and governance were reported less frequently (12%, 19% and 27%, respectively). We have not found any significant difference in reporting between drug and patient-based registries.

Conclusion: Our preliminary results showed that a broad variety of outcomes are collected in registries of patients with RA. Efforts should be made to standardize and to enhance the quality of collecting and reporting elements of good practice for RA patient registries.

A Systematic Review of Consumer Perceived Health Service Needs Related to Osteoarthritis

Michelle C Papandony[1], Anita E Wluka[1], Flavia M Cicuttini[1], Yuanyuan Wang[1], Louisa Chou[1], Kalupahana L Seneviwickrama[1], Kaye Lasserre[2], Andrew Teichtahl[1,3] and Andrew M Briggs[4], [1]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia, [2]Monash University, Melbourne, Australia, [3]Baker Heart IDI, Melbourne, Australia, [4]Arthritis and Osteoporosis Victoria, Melbourne, Australia

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a common cause of pain and disability. The patients' perception of health care influences their involvement in management, affecting health outcomes and health system utilisation. Thus it is important to understand the consumer's perceived health service needs in OA. The aim of this systematic review is to identify evidence regarding the consumers' perceived health service needs regarding OA.

Methods: A systematic literature review of the MEDLINE, PsychINFO, EMBASE and CINAHL databases was performed to capture information regarding consumer perceived health service needs related to OA (1990 to May 2015). Themes were identified to provide a

systematic review of the existing literature.

Results: 1053 manuscripts were identified by the search strategy, of which 18 articles were relevant. Of these, 7 studies used quantitative methods, 10 used qualitative and 1 used mixed methods. These themes emerged (> 2 papers): 1) Patients' valued being in an individualised relationship with their practitioner. Insufficient practitioner knowledge, an emphasis on analgesic therapies, rejection of alternative medicine options, and poor practitioner communication skills resulted in consumer dissatisfaction. 2) Complementary and alternative medicine use was prevalent amongst OA patients, primarily driven by desire for analgesic relief. The accessibility, empathy, interpersonal skills and holistic patient approach to care contributed to patient satisfaction with complementary and alternative medicine. 3) Attitudes towards medication use was variable. Fear of side effects was the biggest concern. Baseline pain levels and financial constrains impacted the choice of medication used. 4) Patients perceive a need for physiotherapy and exercises for OA, however accessibility was the main barrier to this. This review generated limited studies on geriatric populations and patients from developing countries or non-English speaking backgrounds. There was a paucity of data relating to patient waiting times for specialist review, specialist fees and medication costs and the ease of medication administration.

Conclusion: Health service delivery in OA is largely driven by patient perceived needs. Aligning perceived needs with health care requirements is important in order to obtain better outcomes in OA. This review revealed that many patient perceived health service needs are aligned with current OA management guidelines. It also identified the barriers to health service implementation. This review also highlights significant gaps in the literature relating to a number of consumers' perceived needs. A better understanding of these needs may guide the provision of relevant services for those with OA, with the view to optimize patient outcomes and healthcare system utilisation and efficiency.

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Services that actively seek out and identify patients with fractures following a minimal trauma injury have been promoted as the most effective means of addressing the wold wide increasing incidence of osteoporotic fractures. Implementation however has been hampered by the paucity of information about the cost effectiveness of this approach

Methods: *Design*: To undertake a detailed costing of operating a fracture liaison service (FLS) and compare the total direct cost of re-fracture management of a cohort of patients (n=515) processed over a 6 month period, and followed for 3 years with the refracture management costs of a contemporaneous cohort of patients (n=414) seen at a hospital without a FLS. *Determination of costs*: Components of the care and entered as a cost centre in a microcosting model created in a Microsoft® Excel workbook. The model compared costs between the FLS and Usual Care. Sensitivity analyses were performed on a number of variables that had uncertain value. Cost of labour, infrastructure and consumables were calculated from the relevant public sources. Medical consultations, investigations and treatment costs were derived from reference tables of the Australian Medical and Pharmaceutical Schedules of Benefits. Costs of re-fracture management were derived from published costing of fracture treatments in Australia. Health inflation calculations for 2015/16 were done with reference to the Total Health Price Index and Industry Wide Index (AIHW). To allow comparison of the different cohort sizes the FLS costs were spread over 3 years and given for every 1,000 patients processed.

Results: Table 1. Component costs of FLS per 1000 patients processed

Cost Centre /Activity	Cost ($ AUS)
Reviewing emergency department records	$30,143
Contacting patients	$42,732
Clinical assessment and treatment	$364,707
Follow up	$23,018
Total	**$468,601**

Table 2. Comparison of costs of treatment between a hospital with a fracture liaison service (FLS) and usual care (Per 1,000 patients)

	Re-fractures over 3 years	Total Cost	Saving
	(n)	($AUS)	($AUS)
Hospital with FLS	150	$2,883,937	
Usual Care (no additional cost)	212	$3,421,653	$537,716
5% of Usual Care patients treated	212	$3,518,584	$634,648
15% of Usual Care patients treated	212	$3,712,447	$828,510

Conclusion: From the perspective of the health system a FLS generates a significant gain, in opportunity costs with a rounded net positive of effect of $540,000 - $830,000 per 1,000 patients processed.

Session Title: Health Services Research - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The care of adolescents and young adults with systemic lupus erythematosus (SLE) is particularly challenging. The disease may be severe, adolescent patients have complex medical and psycho-social needs, and they must navigate the transition to adult services. To inform patient-centered care we aimed to identify the healthcare and research priorities of adolescents and young adults with

SLE and describe the reasons underpinning their priorities.

Methods: Face-to-face, semi-structured interviews and focus groups were conducted with patients with SLE, aged from 14 to 30 years, from five centers in Australia. In five allocation exercises, participants allocated ten tokens (i.e. votes) to 1) research topics (medical management, prevention and diagnosis, lifestyle and psychosocial), 2-4) research questions associated with research topics, and 5) healthcare specialties, and discussed the reasons for their choices. Descriptive statistics were calculated for votes and qualitative data was analyzed thematically.

Results: From the 26 participants, there was an undifferentiated allocation of votes to research topics and associated research questions. They allocated their votes towards medical and mental health specialties in the management of SLE, whilst fewer votes were given to allied health. Seven themes underpinned participants' priorities: improving service shortfalls, strengthening well-being, ensuring cost efficiency, minimizing family/community burden, severity of comorbidity or complications, reducing lifestyle disruption, and fulfilling future goals.

Conclusion: Young patients with SLE value comprehensive care, in particular, rheumatology, nephrology and mental health. Research on improving psychological health and self-management of symptoms may improve treatment satisfaction and health outcomes for adolescents and young adults with SLE.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a chronic inflammatory disorder associated with elevated levels of serum uric acid (sUA), resulting in urate crystal deposits in soft tissues. Uncontrolled gout can result in bone erosion, joint destruction, kidney stones, uric acid nephropathy, and other organ damage. Gout is treatable with medication and lifestyle change. Long-term sUA monitoring is needed to confirm that patients are achieving target levels (≤6 mg/dL, or <5 mg/dL in more severe cases). The study objective is to describe incident cases of gout and characterize these patients by sUA testing during the subsequent 5 consecutive years.

Methods: Data from Clalit Health Services were used to identify incident cases of gout (1/1/2003-31/12/2009) among members ≥25 years old with continuous enrollment in Clalit for 1 year prior to and 5 years subsequent to diagnosis (index date). Cases were identified based on the following criteria: a) 1 diagnosis of gout from a hospital or specialist visit; or b) ≥2 diagnoses of gout from a general practitioner (GP) visit and either elevated sUA (>6 mg/dL) or a purchase of colchicine or allopurinol. Cases were excluded if a member was concurrently diagnosed with a disease known to affect sUA (eg, renal insufficiency, cancer, Familial Mediterranean Fever). sUA testing practices during the 5-year follow-up period were defined as: full (≥1 test per year), moderate (≥1 test per year for 3 or 4 years), low (≥1 test per year for 1 or 2 years) and no testing (no tests performed). Demographics, clinical characteristics, comorbidities, concurrent medications, and healthcare utilization were examined and stratified by testing practices. Chi-square tests were used to test for differences between groups.

Results: We identified 15,598 incident gout cases meeting the inclusion criteria. Mean age was 59.3±14.5 years, 79.7% were male, and 35.7% were of higher socioeconomic status. Patients' clinical history indicated that 15.2% were current smokers and 32.4% were obese.

Prevalence of pre-existing comorbidities including CVD, diabetes and hypertension was 26.8%, 20.8%, and 52.5% respectively, and mean Charlson Comorbidity Index was 0.9±1.3. The distribution of annual sUA testing over the 5-year follow up in this cohort was: 5,445 (34.9%) patients had full testing, 6,678 (42.8%) had moderate testing, 3,196 (20.5%) had poor testing, and 279 (1.8%) had no testing. At the end of follow-up, 25.6% of patients' last documented sUA was ≤6 mg/dL. Among patients in the groups with sUA ≤6 or ≥10 mg/dL, close to 39% had full testing, while among those with sUA between 6.1-9.9 mg/dL, full testing ranged from 31.6%-35.7%.

Conclusion: Consistent with previous findings, gout patients in Clalit were on average older adults, predominately men and with concurrent comorbidities. Over three-quarters of newly diagnosed gout patients performed an annual sUA testing during at least 3 of the 5 years of follow-up. Further study is required to assess the association between regular testing and health outcomes.

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The association between inflammatory markers such as CRP or ESR and joint damage has been widely established in RA. Autoantibodies such as RF and anti-cyclic citrullinated peptide (anti-CCP) are also associated with severe joint damage. However, there are limited data on the association between markers of inflammation and autoantibodies. The objective of this analysis was to evaluate the association between CRP and anti-CCP using clinical practice data sets.

Methods: Two data sets were used: a single academic center, prospective, observational cohort registry of patients (pts) with RA, and the Optum Clinformatics Data Mart (Optum), which includes the Optum Medicare data. The registry was established in 2003 and primarily comprises pts with established RA. In Optum, pts with two ICD-9 codes for RA (714.0) and a prescription for a DMARD between Jan 2007 and Dec 2014 were identified. For inclusion in the current study, pts were required to have anti-CCP and CRP baseline values. The high normal concentration for anti-CCP was 19 U/ml in both data sets, and for CRP it was 5 mg/L in the registry and 4.9 mg/L in Optum. Pts meeting inclusion criteria were placed into CRP groups (grps) by quartiles and anti-CCP positivity was evaluated in each grp. Additional sensitivity analyses were conducted by grouping pts into two CRP grps, i.e., CRP ≥5 vs <5 mg/L. Multivariate logistic and linear regression for anti-CCP positivity were evaluated with CRP as an independent variable and controlling for baseline covariates. In the registry analysis, we adjusted for age, sex, race, BMI, Charlson co-morbidity index, RA duration, DAS28 (CRP) and treatment with biologic DMARDs. In Optum, we adjusted for age, sex, region, incident RA, co-morbidities, use of steroids, use of NSAIDs, use of salicylates and initiating a DMARD within 90 days after the index date.

Results: A total of 1309 pts from the registry and 3798 from Optum were included in the analysis. Pts in the high (vs low) CRP grps were older (mean [SD] 60.1 [13.2] vs 51.4 [14.0] yrs in the registry; 60.0 [15.7] vs 54.4 [14.9] yrs in Optum), had more males (23 vs 13% in the registry; 30 vs 21% in Optum) and a greater proportion of pts was anti-CCP positive (Figure). Based on multivariate logistic models, pts in CRP grp 3 vs grp 1 (odds ratio [95% CI] 2.08 [1.43, 3.03], p<0.001) and grp 4 vs grp 1 (1.87 [1.23, 2.84], p=0.003) had significantly higher odds of being anti-CCP positive in the registry. Similar findings were observed in Optum: grp 2 vs grp 1 (1.37 [1.15, 1.63], p<0.001); grp 3 vs grp 1 (1.68 [1.42, 2.00], p<0.001); and grp 4 vs grp 1 (2.09 [1.76, 2.48], p<0.001). The findings from the linear regression model and sensitivity analysis were consistent with those of the logistic regression model.

Conclusion: Analyses based on two independent data sources indicate that there is an association between CRP and anti-CCP levels in pts with RA. Pts with a high CRP level are more likely to be anti-CCP positive, with a higher anti-CCP level.

Clinician-Led Development of a Standardised Term Set for Rheumatic and Musculoskeletal Disorders Allows Easy Creation of Large-Scale ICD-10 and Snomed CT Mapped Datasets from Routinely Collected Clinical Data

Ira Pande and Ian Gaywood, Department of Rheumatology, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Health Services Research - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Clinicians use a range of different terms to describe the same clinical concept. Whilst these variations seldom lead to confusion among clinicians they make it difficult to aggregate, analyse and share clinical data. The ability to create and share large data sets has become increasingly important in the age of personalised medicine when it is not possible to collect enough data from a single centre to tease out the importance of phenotypic variations. Similar restrictions apply when studying geographical and temporal trends in case mix.

Methods: Working with the British Society for Rheumatology (BSR) the authors have developed a list of diagnostic terms (standard term set (STS)). The BSR Specialised Adult Rheumatology Specification was used as template. The principles underlying the structure of the STS are that it should reflect anticipated use cases for the collected data, the set should serve equally the needs of general rheumatology departments & highly specialised units, the set should allow broad concepts and more granular ones to be collected with equal ease and that it should be mapped to ICD 10 and SNOMED CT as fully as those instruments permit. A hierarchical structure to the STS allowed aggregation of many concepts to a single parent while retaining the ability to separate out conditions of particular interest. The STS will form the core of a much richer data model for RMDs which will include minimum data sets for each concept in the STS and capture comorbidities, phenotypic variables and outcome measures. In this phase the authors have made no attempt to capture diagnostic uncertainty, detailed phenotype, secondary diagnosis or co-morbidities. Where there was a need to reflect new knowledge or new classification of diseases the authors have also undertaken a programme of SNOMED CT content improvement in collaboration with the UK Health and Social Care Information Centre (HSCIC) to improve representation of current concepts and ring fence it for ease of future use. The authors also developed a synonym table which maps physicians combined clinical vocabulary to the matching STS. The final set for the first phase of this coding project was arrived at after a number of iterative editorial cycles with valuable input from local musculoskeletal coding leads for ICD 10, HSCIC and lead clinicians from pilot sites. The STS was released to pilot sites in early 2016

along with a detailed cover note, reference guide for users, agreed “minimal data set” and hyperlinks to ICD 10 and SNOMED CT browsers. Minimum data set in this pilot phase comprised of patient identifiers, demographics, appointment date and type, diagnosis and outcome.

Results: The first 3 months of the pilot have shown that large volumes of data can be collected and shared using the STS with minimal additional workload for the clinician. It has been successfully implemented in various clinic settings ie community, district general hospital and large teaching hospitals. It serves the purpose of both general & special interest clinics. The STS can be used to capture data using paper, electronic & digital care records. It can be used by a single user or entire department. For the first time it has allowed clinical data collected during routine outpatient consultations to be used for a variety of secondary purposes including case-mix analysis, commissioning, workforce planning, audit and identification of research cohorts. Data collection is ongoing. Results will be presented at the ACR meeting.

Conclusion: Clinicians should lead the development of health informatics solutions. Software developers should work closely with health professionals to build platforms that collect data as part of routine care using models that place data in context so as to maximise secondary use ie data collected once can be used with equal ease to provide care for an individual or study trends at a population level.

Prescribing for Children with Rheumatologic Disease: Differences Between Pediatric and Adult Rheumatologists

Heather Van Mater[1], **Stephen Balevic**[2], Gary Freed[3] and Sarah J. Clark[4], [1]Pediatrics/ Pediatric Rheumatology, Duke University Medical Center, Durham, NC, [2]Rheumatology/Pediatric Rheumatology, Duke University Medical Center, Durham, NC, [3]University of Michigan Health System, Ann Arbor, MI, [4]Pediatrics & Communicable Diseases, University of Michigan Health System, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Health Services Research - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatologic diseases affect 300,000 children in the United States and are associated with significant morbidity.[1,2] Due to a national shortage of pediatric rheumatologists (PR),[2] an estimated half of US children with rheumatologic disease are being cared for by adult rheumatologists (AR).[2,3] However, many AR report being uncomfortable caring for children and do not perceive themselves as up to date.[4] How variations in treatment relate to subspecialty, fellowship training, and information resources are not known.

Methods: Two parallel, cross sectional mail surveys with a focus on juvenile idiopathic arthritis (JIA) were administered to a random sample of 193 PR and 500 AR using the American College of Rheumatology membership file. Bivariate analysis was conducted for items common to both surveys.

Results: The response rate was 62.1% for AR (N=306) and 72.3% for PR (N=138). Only 23% of responding AR (N=69) reported caring for children with JIA. Of these, 94% strongly agreed/agreed that they are comfortable diagnosing JIA; however, only 76% report being comfortable treating JIA. Clinical vignettes highlighted several prescribing differences (Table 1). Forty-eight percent of AR, and 31% of PR, felt medications to treat JIA did not have clear dosing guidelines. Though PR initiated DMARDs and biologics earlier, after three months the selected treatments for JIA were quite similar. Co-management of JIA patients by adult and pediatric rheumatologists is infrequent and its acceptance seems limited.

Conclusion: Nearly a quarter of surveyed adult rheumatologists care for children with JIA, with most limiting their practice to older children. There was more discomfort in treating JIA than diagnosing it, and there were significant prescribing differences. Both adult and pediatric providers reported a lack of adequate dosing/treatment resources. Easily accessible and up-to-date treatment and dosing guidelines, as well as exposure to pediatric rheumatology in fellowship, would further enhance the care of children with JIA and facilitate collaboration between adult and pediatric providers. 1. Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Twenty-five pediatric rheumatologists (PR) service a population of 14 million Ontarians. Patients may travel up to 1500 km to be seen by a PR practising in tertiary healthcare centres. To facilitate care to patients living in distant communities we propose using a new model: local Advanced Clinician Practitioners in Arthritis Care (ACPAC) using telemedicine to engage with PRs. There are more than 50 ACPACs in Ontario who may be able to provide pediatric patient care via this model. The following are results from the first phase of this project: a stakeholders' needs assessment for a new Model of Care (MOC) for pediatric rheumatology in Ontario.

Methods: Three stakeholder groups were anonymously surveyed: (1) Adult rheumatologists' opinions on treating pediatric patients; (2) ACPACs' interest and availability to see pediatric patients; and (3) Patients'/caregivers' perception of visit burden and their knowledge and attitudes towards alternate MOCs. Surveys were distributed to patients/caregivers who travelled >25 km for their appointment one of two tertiary healthcare facilities: The Hospital for Sick Children (SickKids) in Toronto, Ontario or London Health Sciences Centre (LHSC) in London, Ontario. Quantitative data were summarized using descriptive statistics and qualitative data were analyzed using grounded theory.

Results: 91/186 (49%) adult rheumatologists responded, of which 18 (20%) indicated that they saw pediatric patients. The majority indicated that they would prefer that some or all of their pediatric patients be cared for by a pediatric rheumatologist. 27/44 (61%) ACPACs responded, of which 6 (22%) indicated that they would have salary/time to receive additional training or hold additional clinics to see pediatric patients.

Patient/ Caregiver Survey	Number of Respondents	Travelled >50km	Travelled >200km	Would use telemedicine to avoid cost of clinic visit	Not aware of availability of telemedicine	Comfortable seeing an ACPAC	Spent >$50 travelling to their appointment	Missed ≥1 day of work
Toronto	111/134 (83%)	89/111 (80%)	13/111 (12%)	36/110 (33%)	86/111 (77%)	104/111 (94%)	36/111 (32%)	53/99 (54%)
London	130/131 (99%)	103/128 (80%)	16/128 (13%)	33/119 (28%)	96/126 (76%)	125/126 (99%)	53/130 (41%)	66/116 (57%)

Several themes were identified including the importance of seeing the healthcare team in person for physical examination, hesitancy to use telemedicine due to lack of experience, and preference for an assessment closer to home. Some indicated that telemedicine may be appropriate for certain situations such as follow-up visits or bloodwork results. Those who indicated a preference for telemedicine indicated that it would reduce time away from school/work. Parents indicated that jobs were in jeopardy due to missed time and that the high cost of parking was a deterrent.

Conclusion: A MOC integrating ACPACs, telemedicine, and PRs may improve local access to pediatric rheumatology care while reducing the burden of travel and cost to families. Barriers to this new model include the lack of awareness about the role of telemedicine and how it can be combined with ACPACs to facilitate a patient appointment.

Allopurinol Use and the Risk of Stroke in the Elderly

Jasvinder A. Singh[1] and Shaohua Yu[2], [1]Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the effect of allopurinol use on the risk of stroke in the elderly

Methods: We used the 5% random sample of Medicare beneficiaries from 2006-2012 to study the association of new allopurinol initiation and incident stroke. We used multivariable-adjusted Cox regression models adjusted for age, gender, race, Charlson index, and cardio-

protective medications (beta-blockers, ACE inhibitors, diuretics, statins) to calculate hazards ratio (HR) with 95% confidence intervals (CI). Sensitivity analyses adjusted for coronary artery disease (CAD) risk factors including hypertension, hyperlipidemia, diabetes, and smoking instead of Charlson index.

Results: Among 28,488 eligible episodes of incident allopurinol, 2,177 ended in incident stroke (7.6% episodes). In multivariable-adjusted analyses, allopurinol use was associated with 9% lower hazard ratio for stoke, 0.91 (95% CI, 0.83 to 0.99). Compared to no allopurinol use, allopurinol use durations of 181 days to 2 years, 0.88 (95% CI, 0.78 to 0.99) and >2 years, 0.79 (95% CI, 0.65 to 0.96) were significantly associated with lower multivariable-adjusted hazard of stroke. Sensitivity analyses adjusted for CAD risk factors confirmed these findings. In subgroup analyses, significant associations were noted between allopurinol use and the risk of ischemic stroke, 0.89 (95% CI, 0.81 to 0.98); no significant associations were noted for hemorrhagic stroke, 1.01 (95% CI, 0.79 to 1.29).

Conclusion: Allopurinol use was independently associated with a lower risk of stroke overall, more specifically ischemic stroke in the US elderly. This protective effect is evident after 6-months of allopurinol use, and the protective effect increases with longer duration of use. Future studies need to examine underlying mechanisms for this novel effect.

Impact of Comorbidity on Health-Related Quality of Life and Healthcare Expenditure in Patients with Rheumatoid Arthritis

Eric Nyarko[1] and J An[2], [1]College of Pharmacy, Western University of Health Sciences, Pomona, CA, [2]Western University of Health Sciences, Pomona, CA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is known to be associated with an increased risk of comorbidity, premature mortality, and disability. We investigated the effect of comorbidity on health-related quality of life (HRQOL) and total healthcare expenditure (TE) in patients with RA.

Methods: Adult RA patients were identified from the Medical Expenditure Panel Survey 2010 to 2012 data. Twenty-six comorbid conditions were identified including cardiovascular, endocrine, respiratory, psychological, cancer, skin, vision, and gastrointestinal disorders. The Short Form (SF)-12 physical component summary (PCS) and mental component summary (MCS) scores for HRQOL, and TE (2012 USD) were summarized based on the number of comorbidity as well as type of comorbidity using descriptive statistics. Outcomes were further investigated using multivariable regression analyses. Adjusted mean PCS/MSC scores and TE were reported along with bootstrapped confidence intervals. All analyses considered sampling strata and weights in survey design.

Results: A total of 1,982 patients with RA were identified representing 18 million US population. The mean (SE) age was 61.2 (0.53) years and mean (SE) duration of RA was 17.2 (0.57) years. Approximately 30.5% had 1 to 2, 34.5% had 3 to 4 and 23.6% had ≥5 comorbid conditions. The most prevalent comorbidities were cardiovascular (73.4%) and endocrine disorders (35.6%). The mean (SE) PCS/MCS scores for RA with comorbidity were lower compared to RA without comorbidity [PCS: 32.3 (0.58) vs. 37.5 (1.93), p=0.012; MCS: 42.8 (0.59) vs. 47.3 (1.66), p= 0.013]; whereas the mean (SE) TE for RA with comorbidity was higher compared to RA without comorbidity [TE: $ 13,951 ($729) vs. $7,947 ($1,393), p<0.001]. Having multiple comorbidities was associated with a significant impact on both HRQOL and TE (Table). Adjusting for confounders, having ³ 5 comorbid conditions was associated with a decrease in PCS/MCS [PCS: -6.75 for ³ 5 comorbidities vs. none; MCS: -7.15 for ³ 5 comorbidities vs. none, respectively] and an increase in TE compared to no comorbidity [$4,637 for 3-4 comorbidities vs. none, $13,842 for ³ 5 comorbidities vs. none, respectively]. Only selected types of comorbidity were associated with changes in MCS/PCS or TE.

Conclusion: Majority of RA patients have at least one comorbidity and substantial number of patients had multiple comorbid conditions. Presence of comorbidity in RA was associated with significant impact in both HRQOL and TE. The impact was higher as the number of comorbidity increases regardless of the type of comorbidity. Table. Adjusted Means (95% Bootstrapped CI) of Health-Related Quality of Life and Total Healthcare Expenditure by Number of Comorbid Conditions

Number of Comorbid Conditions	Physical Component Score	Mental Component Score	Healthcare Expenditure (2012 USD)
None	35.2 (32.0 – 38.1)	46.8 (43.2 – 49.7)	$8,189 ($6,018 - $10,744)
1-2	35.1 (33.5 – 36.5)	42.9 (41.1 – 44.5)	$8,376 ($6,848 - $9,797)
3-4	31.6 (30.3 – 32.9)	42.8 (41.3 – 44.2)	$12,767 ($11,333 - $14,408)
5 or more	28.4 (27.1 – 29.9)	39.6 (38.0 – 41.5)	$21,329 ($18,527 - $24,845)

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is an ongoing effort worldwide to effect quality improvement to address secondary prevention of fractures. Patients who have incurred fractures attributed to osteoporosis have low rates of diagnostic screening and treatment for osteoporosis. An LLUMC Osteoporosis Clinical Working Group spearheaded by the divisions/departments of Rheumatology, Endocrinology, Orthopedics and Geriatrics was established February 2016, with one of the main arms being the Fracture Liaison Service. We determined the most common problems related to primary and secondary prevention, and management. We reviewed the most recent volumes of fractures seen in the hospital through the electronic medical record (EMR).

Methods: A consensus meeting between collaborating specialties was held to discuss system-based practice challenges in managing osteoporosis issues. An October 2015-April 2016 EMR review by our Patient Safety and Reliability Office was done utilizing International Statistical Classification of Diseases and Related Health Problems version 10 (ICD-10) codes to determine: 1) numbers of fracture patients seen at emergency room and/or hospital, 2) hospital stay length, 3) anatomic sites, and 4) procedural interventions done.

Results: The needs identified in our healthcare system are: 1) improving education of patients about the need to diagnose and treat osteoporosis; 2) improving access to healthcare providers committed to addressing osteoporosis and improving rates of screening and compliance with therapy among patients; 3) improving accessibility to DXA results. A High-Risk Osteoporosis (HRO) line of service generating consults for both inpatient and outpatient services, including interdisciplinary providers, is in progress. FLS certification was obtained by a rheumatologist. Four target groups identified are: 1) Patients who have sustained fractures, 2) Men with osteoporosis, 3) Postmenopausal women needing screening and 4) Patients on steroids. Steps to address solutions include: EMR coordination to optimize consult generation and DXA access, partnership development with Physical Therapy, Emergency Medicine, Hospitalist Medicine, General Medicine, Pulmonology, Ophthalmology, Obstetrics and Family Medicine. EMR review revealed 261 fracture encounters; 136 (52%) encounters for femoral fractures (134 initial, 2 subsequent), and 32 (12.3%) vertebral fracture encounters (31 initial and 1 subsequent). Six vertebral fracture encounters were coded as “age related osteoporosis”. Eight encounters were linked to steroid use codes (4 femur, 2 vertebral, 1 radius and tibia each). Most common length of hospital stay was 3 days (62 encounters; range 1-20 days).

Conclusion: A large number of patients with fractures presented to LLUMC within a seven month period. Interdisciplinary coordination to address specific patient groups with or prone to osteoporosis have been developed. Tracking of outcomes to this initial effort includes

improving bone density screening rates, education of patients, and compliance with therapy. Improving ICD10 coding by providers can help facilitate tracking of outcomes.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: This retrospective healthcare claims analysis examined treatment patterns of innovator infliximab (IFX) and biosimilar infliximab (CT-P13) in a Turkish rheumatologic disease population after CT-P13 availability in July, 2014.

Methods: Adult patients (pts) with ≥1 diagnosis code (ICD-10-CM) for rheumatoid arthritis (RA) were identified in a national Turkish healthcare database during the study period (01DEC2010-01DEC2015). Eligible pts had continuous medical/pharmacy enrollment ≥12 months before and ≥6 months after IFX or CT-P13 initiation (index date). Patients were naïve to IFX or CT-P13 (i.e. had no IFX or CT-P13 within 12 months before the index date). Demographics, concomitant diseases and medications, and treatment patterns, eg., dose, interval, discontinuation, and switch were summarized. Confirmed discontinuation was defined as a switch to another biologic medication or the absence of an index biologic claim for ≥120 days without censoring.

Results: Key results are shown in the Table. A total of 1044 patients initiated either medication. The majority (80%; n=831) initiated IFX. The IFX cohort had a mean age of 42 years; 56% were women and mean follow up was 12 months. The CT-P13 cohort consisted of 213 pts with mean age of 43 years; 58% women; and mean follow up of 9 months. Approximately one-third of pts in each cohort had a concomitant diagnosis of ankylosing spondylitis (AS; TABLE). Other concomitant diseases and medications appeared balanced between cohorts. Pts in the IFX cohort had an average of 5.2 infusions and mean dose of 4.7 vials per infusion approximately every 8 weeks. Pts in the CT-P13 cohort had an average of 3.6 doses and mean dose of 5.8 vials per dispensing approximately 9 weeks apart. A confirmed discontinuation occurred in 55% of the IFX cohort; driven in part by switching. 24% of IFX pts had ≥ 1 biologic switch with 8% initially switching to CT-P13. Time to any discontinuation or censoring of IFX is shown in the Figure and Table. In the CT-P13 cohort, a confirmed discontinuation was observed in 63%; 31% switched to another biologic therapy; and 20% initially switched to IFX. Time to any discontinuation or censoring of CT-P13 is shown in Figure and Table.

Conclusion: These findings in a single country indicate that real world utilization patterns may differ between innovator IFX and CT-P13, with predominantly more patients initiating IFX; greater overall CT-P13 discontinuation and a higher proportion of patients switching from CT-P13 to IFX. Further studies are needed to understand the reasons for these observed differences. Table

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Health Services Research - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We compared the quality of care received by SLE patients at two settings within the same academic institution (lupus clinic or general rheumatology clinic) using validated SLE quality indicators (QI).

Methods: 150 consenting, consecutive patients fulfilling the ACR classification criteria for SLE receiving longitudinal care at Rush University Rheumatology outpatient clinic and subspecialty Lupus clinic were recruited. A validated QI survey was updated, modified and administered during participantsÕ routine visit. Retrospective rheumatology medical chart reviews were done for complete evaluation of performance on each QI. The overall performance rate (total number of QIs met by total number of QIs that the participants were eligible for) and performance on 20 QIs were calculated for the two groups and compared using non-parametric tests. P-value <0.05 was considered significant.

Results: 77 patients from sub-specialty lupus clinic and 73 patients from general rheumatology clinic participated. Patients receiving care at lupus clinic had longer disease duration [9.8 ± 7.1 vs. 7.0 ± 7.2 years; P= 0.02] and met more number of ACR criteria [5.3 ± 1.6 vs. 4.6 ± 1.0; P= 0.001] compared to patients from general rheumatology clinics. The overall performance rate was significantly greater among lupus clinic SLE patients [85.8% (IQR: 19.6%) vs. 70.2% (IQR: 11.5%), P= 0.001]. Differences noted among the two groups were in counseling for use of sunscreen (98.7% vs. 83.6%, p=0.001), testing for antiphospholipid antibodies (71.4% vs. 37%, p< 0.001), recommendation for pneumococcal vaccine if on immunosuppressive medication/s (84.8% vs. 48.8%, p< 0.001), bone mineral density test performance (94.2% vs. 54.5%, p<0.001), counselling about drugs (92.2% vs. 80.8%, p=0.04), prescribing a steroid sparing agent and angiotensin-converting enzyme (ACE) inhibitor if eligible(100% vs. 82%, p< 0.007 and 94.4% vs. 58.3%, p=0.03, respectively) and assessment of cardiovascular disease risk (40.3% vs. 15.1%, p=0.01) (Figure 1; Table 1). Patients from lupus clinic were less often on corticosteroids as compared to patients from general rheumatology clinic (32.5% vs. 47.9%, p=0.05).

Conclusion: SLE patients seen in the dedicated lupus clinic had better overall and specific QI performance relative to general rheumatology clinics. This may suggest greater recognition among lupus clinic physicians of the importance of preventive care and disease monitoring among SLE patients. Figure 1: Differences in performance of QIs between Lupus clinic and General Rheumatology clinic (p-value <0.05)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Active juvenile idiopathic arthritis (JIA) is commonly associated with high healthcare costs in children. The disabling consequences and multimorbidities often manifest, however, in adulthood. Combining a large clinical dataset on patients at a rheumatology clinic with administrative data on healthcare utilization and costs allows investigating the disease burden to the society. Our aim was to explore the multimorbidities and detailed clinical characteristics in adult JIA patients and to investigate which factors affect their healthcare utilization.

Methods: The patients attending Jyväskylä Central Hospital rheumatology unit, Finland, are enrolled prospectively in a structured digital database, from which we identified all JIA patients. Data is collected systematically on factors such as date of diagnosis, laboratory tests, questionnaire scores, joint counts, functional capacity, and medications on most rheumatology unit visits. We combined this population-based clinical data with well-recorded administrative data on all public healthcare visits, both in primary and specialty care, on fiscal year 2014 to depict healthcare utilization. The data includes visits to physicians and allied health care professionals in outpatient care as well as inpatient care. Diagnoses are recorded as either ICPC-2 or ICD-10, and also converted to a broader disease classification. Associations between clinical characteristics and healthcare costs were investigated with logistic regression.

Results: Of 182 JIA patients (74% women, mean age 34.9 ± 13.6 (SD)), we have data on healthcare utilization from 2014 on 102 (56%) patients with 80% coding coverage. Median number of healthcare contacts (1 contact = 1 disease discussed during an appointment or inpatient episode) was 12 (min = 1, max = 212). When drawing the difference between low and high healthcare utilizors at the upper quartile (75^{th}percentile), the only factor associated with high healthcare utilization was ever having received biologics (OR 9.47, 95% CI 2.43-49.35, $p < 0.01$) compared to never received. Total healthcare costs in euros (€) did not differ between those less than 30 years of age and over 30 ($p = 0.12$). Of the healthcare contacts with recorded diagnostic codes (rheumatic diagnoses excluded), mental health disorders accounted for 1 in 4 and cardiovascular diseases for 1 in 10. The main mental multimorbidity was depression (52% of all contacts for mental disorders). The main cardiovascular multimorbidity was cardiac arrythmias (57% of all contacts for cardiovascular diseases).

Conclusion: Mental health disorders are common in adult JIA patients. Healthcare professionals should pay attention to mental wellbeing, particularly in young adults with JIA. Further analyses on utilization data from 2012 to 2014 are currently underway for investigating other factors associated with increased healthcare utilization in a larger dataset.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Health Services Research - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is commonly associated with rheumatoid arthritis (RA) and can have significant morbidity and mortality. The objective was to calculate the prevalence, incidence and healthcare costs of RA-related ILD (RA-ILD) in the US.

Methods: We used data from the MarketScan Commercial and Medicare Supplemental Databases from 2004-2013. In each year, patients meeting 1 of the following criteria were considered to have RA-ILD: (A) ≥2 claims with a diagnosis of pulmonary fibrosis (ICD-9-CM 515, 516.3, 516.31) or rheumatic lung disease (ICD-9-CM 714.81) plus ≥2 claims with a diagnosis of rheumatoid arthritis (ICD-9-CM

714.xx excluding 714.3x and 714.4x) or (B) ≥2 claims with a diagnosis for rheumatic lung disease. Patients with 6 months of continuous enrollment prior to first RA-ILD diagnosis in the database and with no claims for pulmonary fibrosis or rheumatic lung disease during that period were classified as incident patients. Patients with evidence of other lung diseases were excluded. Demographic characteristics were measured on date of first RA-ILD diagnosis and clinical characteristics were based on diagnosis, procedure, and drug codes on claims over 12 months for patients who had 12 months of enrollment. All-cause healthcare resource utilization and costs were calculated over 5 years for incident patients with sufficient enrollment. All-cause mortality was assessed for patients who could be linked to Social Security Administration death data.

Results: Prevalence of RA-ILD ranged from 3.2 to 6.0 cases per 100,000 people (Table 1) and incidence ranged from 2.7 to 3.8 cases per 100,000 people. Mean age was 64-66 years across study years; the majority of patients were female (66%-70%). Common comorbidities included gastro-esophageal reflux disease (46%-54%), dyslipidemia (35%-52%), acute bronchitis/pneumonia (34%-38%), and hypertension (41%-61%). The majority of patients had a chest computed tomography (CT) scan (50%-59%) or chest x-ray (69%-80%) over a 12 month period. There were 750 incident patients with 5-year follow-up data; Over 5 years, 72% had an inpatient admission and 76% had an emergency room visit. Mean total 5-year costs were $173,405 per patient (SD $158,837). Annual per-patient costs were highest in years 1 and 5 (Table 2). At 5 years after first diagnosis in the data, 66.7% of patients were alive.

Conclusion: Prevalence of RA-ILD increased over time. For patients who could be followed over a 5-year period, utilization and costs were somewhat stable over time, although inpatient admissions were more common and costs were higher in year 1.

Table 1.

Year	Prevalence of RA-ILD per 100,000 People
2004	3.51
2005	3.73
2006	3.18
2007	3.39
2008	3.52
2009	4.62
2010	4.95
2011	5.35
2012	5.20
2013	5.95

Table 2.

All-Cause Healthcare Costs of Incident RA-ILD Patients

	Year 1	Year 2	Year 3	Year 4	Year 5
Inpatient admissions	$10,437	$6,379	$6,179	$9,332	$8,739
Emergency room visits	$307	$306	$345	$395	$460
Outpatient office visits	$1,987	$1,670	$1,597	$1,578	$1,579
Other outpatient services	$13,188	$12,801	$12,302	$13,404	$14,646
Outpatient pharmacy	$11,072	$11,084	$11,182	$11,116	$11,321
Total healthcare costs	$36,991	$32,240	$31,604	$35,825	$36,744

The Economic Burden of Dermatomyositis and Polymyositis in the US

J. Bradford Rice[1], Alan White[1], Philip Galebach[1], Andrea Lopez[1], Patricia Schepman[2], Breanna Popelar[3], **Michael Philbin**[4] and Elaine Boing[2], [1]Analysis Group, Inc., Boston, MA, [2]Affiliated with Mallinckrodt Pharmaceuticals at the time this study was conducted, Hazelwood, MO, [3]Xcenda, L.L.C., Palm Harbor, FL, [4]Mallinckrodt Pharmaceuticals, Hazelwood, MO

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Dermatomyositis and polymyositis (DM/PM) are inflammatory myopathies that can lead to persistent muscle weakness and disability. Although significant healthcare resource utilization (HCRU) and work loss among DM/PM patients have been reported, the economic burden to the national population has not been explored. The aim of this study was to provide a contemporary estimate of the total and incremental direct medical cost burden of DM/PM in the US. Total and incremental indirect work-loss burden attributable to DM/PM were also analyzed.

Methods: Patients aged 18-64 years with a first diagnosis of DM/PM between 1/1/1998 and 3/31/2014 were selected from a large, de-identified, privately-insured administrative claims database (OptumHealth Reporting and Insights). Propensity score (1:1) matching of DM/PM patients with non-DM/PM controls from the same database was performed to reduce baseline differences in demographic characteristics, comorbidities, HCRU, and costs. Healthcare costs (inpatient, outpatient/physician office, emergency department, other, pharmacy) and indirect work loss (disability days, medically-related absenteeism) were compared between matched DM/PM patients and controls from the payer perspective over 12 months post-diagnosis. The prevalence of DM/PM in the US was estimated from the recent literature.

Results: A total of 2,587 DM/PM patients who met the sample selection criteria were matched with a control. Overall, commercial payers incurred $23,064 in total healthcare costs per DM/PM patient during the 12-month outcome period. Relative to controls, DM/PM patients had, on average, $7,368 (47%) higher total healthcare costs ($23,064 vs. $15,695; $p<0.001$). Paired with US population statistics and estimates of DM/PM prevalence (ranging from 14.8 to 19.5 DM/PM cases per 100,000 persons), results of this analysis suggest that DM/PM patients impose a total direct medical cost burden of approximately $457 to $602 million (in 2013$) to commercial payers, or approximately $146 to $192 million in excess costs over matched controls. Further, work loss among DM/PM patients amounted to $3,621 in annual costs, $633 (21%) more than the non-DM/PM patients ($3,621 vs. $2,988; $p<0.001$).These results suggest that DM/PM patients impose an indirect cost burden of approximately $76 to $100 million to employers in work-loss costs, or approximately $13 to $17 million in excess work-loss costs compared with matched controls. The estimated total costs (direct and indirect) of DM/PM range from $533 to $702 million a year.

Conclusion: DM/PM is associated with substantial economic burden in the US population due to significantly increased healthcare costs and work loss. Moreover, results of this analysis potentially underestimate the excess burden of DM/PM because a few high-cost DM/PM patients could not be matched. Also, the actual national cost of DM/PM is likely understated as this study excluded individuals 65 years and older, out-of-pocket costs, supplemental insurer payments, and informal caregiving. Finally, only costs in the 12 months following diagnosis were assessed; costs may increase due to changes in disease severity over time.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic sclerosis (SSc) are at high risk of developing interstitial lung disease (ILD) and/or pulmonary hypertension (PH). These two lung manifestations are associated with significant morbidity and are the leading causes of death in SSc. In this study, in addition to describing survival experience, we sought to assess the financial burden by determining all-cause healthcare costs in patients with SSc with and without coexistent ILD and/or PH.

Methods: We used data from the MarketScan Commercial and Medicare Supplemental Databases from 2004-2014. Patients with ≥2 claims with a diagnosis of SSc (ICD-9-CM 710.1) were identified. Patients with 6 months of continuous enrollment prior to first SSc diagnosis in the database and with no claims for SSc during that period were classified as incident patients. Patients with ≥2 claims with a diagnosis of ILD (ICD-9-CM 515, 516.3, 516.31, 517.2) and no diagnoses of other respiratory conditions were classified as having ILD. Patients with ≥2 claims with a diagnosis of PH (ICD-9-CM 416.0) were classified as having PH. Those without claims for these conditions in the 6 months prior to first diagnosis of ILD or PH in the database were considered incident. All-cause mortality was assessed for incident patients who could be linked to Social Security Administration death data. All-cause healthcare costs were calculated over a 5-year follow-up period for incident patients with sufficient enrollment.

Results: There were 11,752 incident SSc patients, 1,808 SSc patients with incident ILD, and 1,223 SSc patients with incident PH. Average age at first diagnosis of SSc, ILD, and PH was 55 years, 57 years, and 60 years, respectively. Among those who could be linked to death records (n=4,605; n=715; n=525), median survival time was 11.3 years, 8.8 years, and 6.0 years. Per-patient all-cause healthcare costs over a 5-year follow-up were lowest for newly diagnosed SSc patients and highest for SSc patients with newly diagnosed PH ($101,839; $191,107; $254,425). Yearly per-patient costs are presented by service type in Tables 1-3.

Conclusion: In comparison to those with SSc alone, the presence of ILD and/or PH is associated with significant increases in healthcare costs and a worse survival experience. Table 1.

All-Cause Healthcare Costs of Incident SSc Patients (N=1,957)

	Year 1	Year 2	Year 3	Year 4	Year 5
Inpatient admissions	$4,691	$3,780	$3,770	$4,492	$6,101
Emergency room visits	$337	$290	$290	$311	$261
Outpatient office visits	$1,392	$1,164	$1,153	$1,168	$1,173
Other outpatient services	$9,060	$7,779	$7,327	$7,869	$8,677
Outpatient pharmacy	$5,418	$5,822	$5,973	$6,486	$7,055
Total healthcare costs	$20,898	$18,836	$18,513	$20,325	$23,268

Table 2.

All-Cause Healthcare Costs of SSc Patients with Incident ILD (N=219)

	Year 1	Year 2	Year 3	Year 4	Year 5
Inpatient admissions	$7,693	$7,643	$3,502	$7,735	$22,609
Emergency room visits	$450	$474	$461	$425	$344
Outpatient office visits	$1,794	$1,410	$1,458	$1,455	$1,567
Other outpatient services	$14,051	$13,375	$12,387	$9,485	$14,578
Outpatient pharmacy	$11,260	$13,013	$13,476	$14,112	$16,348
Total healthcare costs	$35,248	$35,916	$31,285	$33,212	$55,446

Table 3.

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Psoriatic Arthritis Screening and Evaluation (PASE) Tool is one of the most frequently used tools to screen psoriasis patients for signs and symptoms of psoriatic arthritis (PsA). PASE has been used in dermatology outpatient settings, in large-scale epidemiological studies, and in clinical trials and has been translated into more than 20 different languages. The original PASE included 15 questions addressing two separate domains including symptoms (7 questions) and function (8 questions). Given the demonstrated efficacy of the tool for early identification of PsA, we sought to determine the optimal cut off score and generate a shorter version in efforts to improve adoption and implementation in the clinical setting as PASE-2.

Methods: Eligible patients included those adults aged 18-85 with a diagnosis of psoriasis or psoriatic arthritis, who presented at an academic dermatology clinic. The PASE questionnaire was administered to 190 consecutive patients. From survey responses, we conducted a principal component analysis to guide revision of the tool. Principal component analysis identified a one-factor solution which accounted for 57.5% of total variance. Questions with factor loading below 0.75 were removed. A Youden index was used to guide selection of the appropriate total survey score cutoff for sensitivity and specificity for identifying inflammatory arthritis. Receiver operating characteristic (ROC) curves were calculated for individual questions and for the revised PASE-2 as a whole.

Results: 190 patients with dermatologist-diagnosed psoriasis completed the PASE tool (110 males and 80 females, median age 55). We identified 7 questions for removal, yielding an 8-item questionnaire. Remaining items inquire about joint stiffness, joint function, joint pain and/or swelling, joint warmth/erythema, migratory joint pain, work and activity-related changes. The area under the ROC curve for the 8-item tool was 0.81 (Figure). Selecting a new total score cutoff of 19 or greater provided a sensitivity of 0.84 and specificity of 0.63 for the identification of psoriasis patients at risk for PsA. This is compared to a sensitivity and specificity of 0.82 and 0.73 from the original 15-item PASE tool.

Conclusion: We conducted a principal component analysis to develop an 8-question PASE-2. The improved sensitivity of the PASE-2 highlights the potential for better screening for PsA in the psoriasis population while minimizing survey burden to physicians and patients and thereby increasing adoption of the tool. Further studies will be needed in larger populations to improve the adoption of screening to help improve patient outcomes.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Health Services Research - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with high healthcare costs, but little is known about how the costs compare to other chronic rheumatic diseases. We combined a large, population-based clinical dataset on patients at a rheumatology clinic with an administrative database in order to compare healthcare utilization in patients with rheumatoid arthritis, psoriatic arthritis, juvenile idiopathic arthritis, and axial spondyloarthritis.

Methods: The data is on the adult population of the City of Jyväskylä, Finland (population 135 000). Their primary care is delivered at the local healthcare centers, which rely on the Jyväskylä Central Hospital (JCH) when specialist treatment is needed. The rheumatic specialist care is served in the JCH rheumatology unit, where clinical data is systematically recorded in a structured digital database. Well-recorded administrative data with costs data in euros (€) from fiscal year 2014 includes information on all public healthcare visits to physicians and allied healthcare professionals, both in primary and specialty care. Also inpatient care is included. With the Kruskal-Wallis test, we compared costs associated with healthcare utilization for adult patients with RA, psoriatic arthritis (PsA), juvenile idiopatic arthritis (JIA),

and patients with axial spondyloarthritis or spondyloarthropathies (AS+SpA). We recognized high healthcare utilizing proportions in each and explored their clinical characteristics.

Results: The cost distribution was similar in all studied diseases (p = 0.62), and the distribution was widest in RA. The cost distribution was similar also in women (p = 0.31) and in men (p = 0.59). In RA (n = 967), 9% utilizes as much as the remaining 91%. Corresponding figures are 9% and 91% for PsA (n = 190), 10% and 90% for AS+SpA (n = 257), and 16% and 84% for JIA (n = 102). The high healthcare utilizing proportions were characterized by lower functional capacity measured with HAQ index (0-3) and higher pain (VAS 0-100), as well as higher disease activity, measured with DAS28. In addition, a larger proportion of these patients had at some point received biologics compared to patients with lower utilization. Mental health disorders were common multimorbidities in all studied diseases, particularly in young adults, as cardiovascular multimorbidities were particularly prevalent in older age groups.

Conclusion: Healthcare utilization is similar for RA, PsA, JIA, and AS+SpA. Approximately one tenth of patients utilizes as much as the remaining 90%. Higher healthcare utilization is characterized by patient perceived health measures. To limit the costs caused by healthcare utilization, disease activity should be minimized, improving functional capacity with reducing HAQ and pain. Moreover, costs of active treatment might be saved by reducing the healthcare utilization.

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematous (SLE) is a heterogeneous disease with high morbidity and mortality affecting approximately 20-150 cases per 100,000 people. The risk of early death in patients with SLE is two times greater than the general population. Long-term SLE treatment is often complex with frequent medication changes, which are challenging especially given the cognitive and neuropsychiatric deficits affecting 25-60% of lupus patients. Across wide spectrums of educational backgrounds, patients need multiple skill sets to understand health recommendations, manage their disease, and avoid poor health outcomes. Health literacy, numeracy, and patient engagement are key components of patient proficiencies necessary to support constructive communication between physician and patient.

Methods: Through the Ohio State University IRB-approved Lupus Registry, we recruited patients to complete health literacy, numeracy, and patient activation measures. 65 patients completed measures of health literacy (sTOFLA), subjective numeracy (SNS) measuring patient's perception of their math ability, objective numeracy (ONS) that is patient's actual math ability, and patient activation (PAM) measuring patient engagement. Cronbach's alpha was used to assess reliability and internal consistency of measures; alpha above 0.7 are considered acceptable.

Results: All patients demonstrated adequate health literacy (scores above 23; Cronbach's alpha= 0.77) compared to the 12% of population as estimated by the National Assessment of Adult Literacy. Patients' ONS was low (mean score=3 out of 8 possible; Cronbach's alpha= 0.92) and consistent with mean scores for high-school-only educated individuals. PAM scores averaged at 3.3 (out of 4 possible), suggesting patients want to be engaged in their disease. See Table 1 for correlations; values are likely due to small sample size.

Conclusion: Minimal literature exists to describe health literacy in SLE patients, and even less describes numeracy and engagement. It is clear that, despite adequate health literacy and patient activation, these patients still perform poorly on math-related questions. PAM and SNS have a positive correlation suggesting that patients who are more engaged also perceive their math ability to be better. SLEDAI scores while not statistically significant are negatively correlated with PAM scores, suggesting patients who are less engaged have higher disease

activity scores. Relations with SLICC scores require more data collection, which is ongoing. These data suggest that patients with poor PAM scores have high disease activity scores; other trends are promising. These data point towards the potential to modify patient skill sets and improves outcomes in future research. Table 1:

		Health Literacy	SNS	ONS	Patient Activation
SNS	Pearson correlation coefficient r	0.35			
	P value	0.01			
	N=	63			
ONS	Pearson correlation coefficient r	0.48	0.40		
	P value	<0.0001	0.001

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyperuricemia is associated with worsened outcomes in heart failure (HF) patients. However, little is known regarding the association between gout and HF itself. This analysis assesses the impact of gout control on the rate of hospitalization for acute HF in a prevalent gout population.

Methods: This retrospective database analysis used data from the Clinical Practice Research Datalink-Hospital Episode Statistics (UK) from Jan 1, 2009 to Dec 31, 2011. Patients were required to have evidence of "prevalent established gout" (ie, treated with urate-lowering therapy (ULT) or eligible for ULT based on ACR guidelines) between Jan 1, 2009 and Dec 31, 2009 and be aged ≥18 on index date (Jan 1, 2010). Follow-up extended from Jan 1, 2010 to Dec 31, 2011. HF rate was calculated as the percentage of eligible patients having at least 1 HF-related hospitalization over the course of the calendar year. In each calendar year, patients were considered to have controlled gout if they had no elevated serum urate acid (sUA; ≥6 mg/dL), no diagnosis of tophus, and no flare documented. Uncontrolled gout was defined as

at least 1 elevated sUA or 1 tophus diagnosis during the year. In this analysis patients with no documented sUA were considered not evaluable. To mitigate the limited availability of sUA data, a sensitivity analysis was conducted using an alternate definition of control status: if sUA was available, controlled was defined as no elevated sUA, no flare, and no tophi and uncontrolled was defined as ≥1 elevated sUA, tophus or flare; if sUA unavailable, controlled defined as medication possession ratio (MPR)>80% and uncontrolled defined as 0%<MPR≤80%. Here, patients with no documented sUA and MPR=0% were not evaluable. The odds ratio of HF was modeled in each post-index year using logistic regression models, with adjustment for control status (in previous or current year), gender, age, and Charlson Comorbidity index as covariates.

Results: A total of 29,758 eligible gout patients were identified. Within the subset of patients with available sUA (4,762 in 2010 and 4,385 in 2011), the HF rate was consistently lower in patients whose gout was controlled in the ongoing year (adjusted OR: 0.253 in 2010 [p=0.032]; 0.268 in 2011 [p=0.019]). The sensitivity analysis conducted using MPR as a proxy for control in a larger population (26,999 patients in 2010 and 26,176 patients in 2011) yielded similar results (OR: 0.387 in 2010 [p<0.001]; 0.462 in 2011 [p<0.001]). There was a trend for patients being controlled in the previous year to have a lower HF rate in the current year but this effect was not significant.

Conclusion: This study suggests that patients with controlled gout have a lower risk of being hospitalized for HF. Further investigations would be required to validate this finding on larger samples.

Heart Failure Rate Stratified Per Gout Control Status

Year of Heart Failure Assessment	Stratification Variable	Controlled gout N patients at risk	Controlled gout Heart Failure Rate	Uncontrolled gout N patients at risk	Uncontrolled gout Heart Failure Rate
2010	Control status in 2010 (base case)	1,937	0.15% [0.03% - 0.45%]	2,825	0.60% [0.35% - 0.96%]
	Control status in 2010 (sensitivity analysis)	18,719	0.19% [0.13% - 0.27%	8,280	0.46% [0.32% - 0.63%]
	Control status in 2009 (base case)	1,960	0.10% [0.01% - 0.37%]	5,512	0.27% [0.15% - 0.45%]
	Control status in 2009 (sensitivity analysis)	17,256	0.24% [0.17% - 0.32%]	11,546	0.29% [0.20% - 0.40%]
2011	Control status in 2011 (base case)	1,827	0.22% [0.06% - 0.56%]	2,558	0.70% [0.42% - 1.11%]
	Control status in 2011 (sensitivity analysis)	18,598	0.28% [0.21% - 0.37%]	7,578	0.57% [0.41% - 0.76%]
	Control status in 2010 (base case)	1,937	0.26% [0.08% - 0.60%]	2,825	0.57% [0.32% - 0.92%]
	Control status in 2010 (sensitivity analysis)	18,719	0.36% [0.28% - 0.45%]	8,280	0.42% [0.29% - 0.59%]

Validity of the Short Form 6D Utility Measure in Early Axial Spondyloarthritis

Cécile Gaujoux-Viala[1], Laure Gossec[2], Christel Castelli[3], Cédric Lukas[4], Françoise Barchechath-Flaisler[5], Jean-Pierre Daures[6] and Maxime Dougados[7], [1]Rheumatology Department, University Hospital of Nîmes and EA2415, Montpellier University, Nîmes, France, [2]Paris 06 University and AP-HP, Hôpital Pitié Salpêtrière, Paris, France, [3]BESPIM, Nîmes University Hospital and EA2415, Nîmes, France, [4]Rheumatology, CHU Lapeyronie and EA2415, Montpellier University, University of Montpellier, France, [5]Nîmes University Hospital, Rheumatology Department, Nimes, France, [6]EA2415, Nîmes, France, [7]Paris Descartes University, Paris, France

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Health Services Research - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The quantification of health improvements is essential, notably in the current context of increasingly expensive therapies and more and more limited resources. Preference-based measures of health have become important for estimating health states in calculating quality-adjusted life years (QALYs), an essential component of cost-utility analysis. The SF-6D is an indirect preference-based health-related quality of life instruments increasingly being used for economic evaluation of clinical interventions and health programs. Data on economic as well as QoL outcomes among early axial Spondyloarthtritis (axSpA) patients remain scarce. Objectives: To evaluate the validity of an utility measure, the SF-6D, in early axSpA especially concerning the ability of this measure to reflect the change in patients' condition over time.

Methods: DESIR (Devenir des Spondyloarthropathies Indifférenciées Récentes) is a French, multicentre, longitudinal cohort of 708 patients with early inflammatory back pain suggestive of axSpA. SF-6D utility measures were assessed in 607 patients over 1 year. To investigate whether the change in SF-6D is a valid measure of change in axSpA health status, we used Spearman's product-moment correlation to compare change scores for SF6D with those for external measures of health, the HAQ, SF36 physical component, SF36 mental component and AS-QOL from baseline to 6 and 12 months. Responsiveness was tested by the effect size (ES) at 6 and 12 months for the entire sample and subgroups by disease evolution (increase or decrease-stabilization in BASDAI). Bootstrap methods were used to estimate 95% confidence intervals [95% CI]. Sensitivity to change of the HAQ was calculated as a benchmark.

Results: At baseline, mean value of SF-6D was 0.69±0.12 (range 0.30 to 0.95). The distribution was near normal. Few missing values were observed: 2.4%. No floor or ceiling effects were evidenced. Correlations of the SF6D change with change in HAQ and physical component of SF-36 scores were moderate at 6 months (r=-0.42 and 0.44, respectively). Correlations with change in mental component of SF-36 and AS-QOL scores were good (r=0.60 and -0.60, respectively). Correlations were stable over 1 year. For the entire sample at 6 months, the SF-6D was more sensitive to change than the HAQ: ES 0.36 [95% CI 0.28;0.44] versus -0.22 [-0.28;-0.17]. The SF-6D was more responsive than the HAQ for improved condition: ES 0.45 [0.37;0.54] vs -0.32 [-0.38;-0.26] without difference for patients with deteriorated condition: ES SF-6D -0.23 [-0.41;-0.04] vs 0.33 [0.18;0.50] for HAQ. Results were similar at 12 months.

Conclusion: The SF-6D is valid and able to reflect the change in patients' condition over time, especially improvement, in patients with early inflammatory back pain suggestive of axSpA.

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic autoimmune diseases (SADs) are heterogeneous conditions with peculiar characteristics that share several clinical features. It is suspected that SADs share similar molecular abnormalities, however, until now, the cross-sectional study of SADs has been hampered by the difficulty to establish common a clinical groundwork. A challenge of such studies is the generation of a CRF capable of capturing similarities and diversities without being redundant with the diagnosis themselves or, conversely, too detailed. We present a framework used within the Innovative Medicines Initiative Joint Undertaking (IMI JU) project PRECISESADS to develop a CRF that balances compactness and granularity to allow the identification of diseases clusters based on molecular features. A similar decisional process can also be applied when building the data structure for registries and the CRF content we developed can be used to align registries or studies data focussing on the transversal analysis of SADs.

Methods: The following steps were performed: 1) Bioinformatics gave insight into the analysis plan and suggested the key rules for data collection. Briefly, unsupervised clustering analysis is planned; missing and redundant data are to be avoided as much as possible; yes/no answers are preferred to open entry fields; data should focus on elements necessary to implement the analysis and limit the number of extraneous ("nice to know") elements. 2) A working group of experts on SADs (RA, SLE, SSc, SjS, UCTD/MCTD/APS) was established. A first broad set of transversal items to the different diseases (n = 130) was created and divided in 8 domains (constitutional symptoms, gastrointestinal, vascular, heart and lung, nervous system, skin and glands, muscle-skeletal, therapy). 3) The items were ranked and reviewed via a Delphi technique and the top ranking items were selected after convergence was reached. 4) The core items were discussed by all the members of the consortium to gain consensus among the stakeholders, and suggestions were gathered. 5) A final set of items was

created, digitalized and pilot tested. 6) The final CRF was released along with explicit data definitions.

Results: Convergence among experts was obtained after 3 tiers and a core set of 28 items was generated. This set was enriched by additional baseline demographic and enrolment data, comorbidities, essential laboratory tests and some disease-specific clinical data. The final CRF proved to be flexible and easy to compile. The average rate of missing data (median, IQR) was 1.9% (0.83 - 7.95). Missing data were: 1.66% (1 - 2.2) in the core set and 0.83% (0.66 - 1.91) for comorbidities. Higher missing rates were observed for lab results: 10% (1.28 - 17.32) and for the additional non-transversal data: 17.03% (14.57 - 24.25).

Conclusion: We describe a seamless procedure to build a core data set transversal to different SADs. This set may be used with few modifications or integrations as data standards for studies or registries that plan to analyze different SADs at once. The generalisation of this core data set may allow a better comparison across studies and contribute to evolving medical knowledge in the field of SADs. www.precisesads.eu

Session Title: Health Services Research - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Comparison of Secukinumab vs Adalimumab in a cost per responder analysis based on a matching-adjusted indirect comparison of efficacy data for the treatment of psoriatic arthritis at 48 weeks from the US perspective Jeff Greenberg [1], Efthalia Nikoglou[2], Praveen Gunda[3], Jacqueline Palmer[4], Steffen Jugl[5] [1] New York University school of medicine, New York NY USA

[2] Novartis Ireland Ltd, Dublin, Ireland

[3] Novartis Healthcare Pvt. Ltd., Hyderabad, India

[4] Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA

[5] Novartis Pharma AG, Basel, Switzerland

Background/Purpose: The objective of this analysis was to estimate and compare the long-term cost per responder based on the American College of Rheumatology outcomes (ACR 20/50/70) following 48 weeks of psoriatic arthritis (PsA) treatment with the anti-IL-17A antibody Secukinumab relative to the anti-TNF antibody Adalimumab.

Methods: The cost per responder for each treatment, namely Secukinumab and Adalimumab was estimated by dividing the drug acquisition cost for the course of treatment with its response rate. Drug costs were estimated on the basis of the official US drug acquisition costs and the number of doses required for 48 weeks. The long-term response rates were estimated using a matching-adjusted indirect comparison (MAIC) technique based on the data from FUTURE 2 and ADEPT clinical trials of Secukinumab and Adalimumab respectively. MAIC analysis matched the age, weight, race and gender distribution, PASI score, HAQ-DI score, PsA duration (years), swollen joint count, CRP

, proportions of patients using methotrexate, with psoriasis ≥3% body surface area, presence of dactylitis, presence of enthesitis and TNF-naive at the baseline. A sensitivity analysis was also conducted by varying the choice of baseline characteristics (includes all variables except PsA duration (years), swollen joint count, and CRP) used in MAIC analysis.

Results: The effective sample sizes after matching the baseline characteristics were 15, 25 for Secukinumab 150 mg, Secukinumab 300 mg respectively, while the sample size for Adalimumab was 151. MAIC analysis showed ACR (20/50/70) response rates were significantly higher for Secukinumab 150mg and 300mg compared to Adalimumab at 48 weeks. ACR 20 response rates were 79%, 82% and 56% ACR 50 response rates were 68%, 73% and 44%, whereas the ACR 70 response rates were 39%, 50% and 30% for Secukinumab 150mg, Secukinumab 300 mg and Adalimumab respectively (**Figure 1A)**. Sensitivity analysis also showed higher response rates for Secukinumab 150mg and 300mg compared to Adalimumab. Among PsA patients, cost per ACR20 responder were $72,906, $70,993 and $80,412 cost per ACR50 responder were $85,480, $79,760 and $103,561, whereas costs per ACR70 responder were $150,276, $115,934 and $151,890 for Secukinumab 150mg, Secukinumab 300mg and Adalimumab respectively (**Figure 1B**). Sensitivity analysis also produced similar results.

Conclusion: ACR (20/50/70) response rates were significantly higher for Secukinumab 150mg and 300mg compared to Adalimumab at 48 weeks. The long term cost per responder for all ACR outcomes at 48 weeks were consistently lower for secukinumab (150,300mg) vs. adalimumab. These findings indicate that Secukinumab represents a cost-efficient treatment choice for PsA patients in the US.

Figure 1: Predicted response rate (A) and cost per responder (B) analysis of ACR (20/50/70) for Secukinumab vs Adalimumab for the treatment of psoriatic arthritis at 48 weeks in principal analysis

Causes and Predictors of Early Readmission in Systemic Lupus Erythematosus

Angelica Nangit[1], Michael Weisman[2], Mariko Ishimori[2], Brennan Spiegel[3] and Connie Lin[4], [1]Rheumatology, Cedars Sinai Medical Center, Reseda, CA, [2]Rheumatology, Cedars-Sinai Medical Center, Los Angeles, CA, [3]Gastroenterology; Health Policy and Management, Cedars-Sinai Health System and UCLA School of Medicine and Public Health, Los Angeles, CA, [4]Internal Medicine, Cedars Sinai Medical Center, Los Angeles, CA

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Health Services Research - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose : Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that is largely heterogeneous and can affect virtually any organ system. Each year about one-third of individuals with SLE are hospitalized, and it is one of the highest rated causes of readmission in the United States. We took an in-depth look at SLE patients admitted to Cedars-Sinai Medical Center (CSMC) who required early readmission to assess whether there were any opportunities that could have prevented readmission, as well as identify which patients are at highest risk for readmission.

Methods : We performed a retrospective cohort study to look at inpatient records of SLE patients at CSMC between January 2012 and July 2014. We identified patients with SLE that were readmitted within 30 days of discharge and whose primary hospitalization included an ICD-9 diagnosis of SLE (710.0). These readmitted patients were compared to patients with lupus who did not require early readmission. Finally, we used stepwise logistic regression to calculate which variables were associated with early readmission.

Results : The study group included 154 patients in the early readmission group, and 301 patients in the group that was not readmitted. The main causes for early readmission included cardiovascular, renal, and infectious complications. Age and gender did not play a significant role, however the readmission group had significantly more African American patients and more patients with publicly funded insurance. Immunosuppressive use, key laboratory values such as low hemoglobin, elevated creatinine, and lower albumin were also associated with early readmission.

Conclusion: We found higher rates of readmission among African Americans and patients with MediCal insurance. We also found that elevated creatinine, low hemoglobin, and low albumin levels were associated with readmission. Immunosuppressive use also correlated with readmission. Data collected in this study will allow for identification of patients at highest risk for early readmission, which will provide an opportunity to improve the discharge process and transitions in care in the lupus patient population.

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Diagnosis of RA is difficult in American Indian (AI) patients who often have atypical autoantibodies (e.g. ANA) with erosive arthritis. Soluble mediators may serve as alternative markers for earlier identification of RA from other conditions affecting AI patients. This study characterized soluble mediator profiles of AI RA patients to identify pathogenic mechanisms of disease and develop early diagnostic algorithms for use by healthcare providers to direct patients toward individualized therapies.

Methods: The serum levels of RF, anti-CCP, and 26 soluble mediators from AI patients with RA (n=59), arthralgias (n=28), polyarthritis/osteoarthritis (n=31), or AI healthy controls (n=116) were measured using ELISA or multiplex assays. Comparisons were made using Kruskal-Wallis testing with Dunn's multiple comparison. To identify factors that distinguished AI RA patients from healthy controls or patients with other forms of arthritis, random forest modeling was performed using autoantibodies and soluble mediators that differed significantly between the groups. One model used autoantibodies, a second used soluble mediators and a third used both to classify AI RA patients from other AI arthritis groups. Each model was developed using 300 trees, $\sqrt{x}$ variables at each split (where x=number of incorporated variables), and a terminal node size of 1. Top predictive classifiers were identified using the prediction step of VSURF function in R 3.3.0. Sensitivity, specificity, positive and negative predictive values were calculated based on 50 random forests using the top predictive identifiers for each model.

Results: When comparing AI RA patients and controls, the soluble mediator model outperformed the autoantibody model with an accuracy of 93.2% vs 88.1%. The combined model outperformed the autoantibody model with an accuracy of 92.7%. IL-8, TGF-beta, SCF, MCP-3, and IL-1RA were identified as the top predictive classifiers when using the soluble mediator model. IL-8, RF(IgM), anti-CCP, and TGF-beta were identified as the top predictive classifiers when using the combined model. When comparing RA patients to AI patients from other arthritis groups the combined model outperformed the autoantibody model (82.5% vs 78.3%) with anti-CCP, RF (IgM), SCF, resistin, and TNFRII as top predictive classifiers. The soluble mediator model did not differentiate patients with RA from the other arthritis groups, suggesting some AI patients with polyarthritis have similar immune dysfunction without meeting classification criteria. IL-8 levels best distinguished patients and controls and SCF levels best distinguished RA patients from other diseases.

Conclusion: Adding soluble mediators to traditional autoantibodies improves the accuracy of diagnostic modeling in AI RA patients when compared to AI controls or AI patients with other forms of arthritis. These data support the hypothesis that soluble mediator profiles of AI RA patients can be used to identify mechanisms of disease and to develop early diagnostic algorithms for use by healthcare providers to direct patients toward individualized therapies. The study was funded by Native American Research Centers for Health.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The 2015 Workforce Study (WFS) sought to expand our current understanding of the rheumatology workforce utilizing an integrated, patient-centered approach to workforce modeling. Primary data from rheumatology patientsÕ perspectives was collected to help inform access to care issues.

Methods: The 2015 WFS used several primary and secondary data sources, including the ACR member database, state licensure registries, 2005 ACR workforce study results, professional organization information and peer-reviewed literature. These data were supplemented with survey data collected from adult, young adult and parents of pediatric rheumatology patients with assistance from the Arthritis Foundation. Face, content, and criterion validity was established through a team of rheumatology/survey research professionals. Overall internal reliability was established (Adult Survey: r=0.82; Pediatric/Young Adult Survey: r=0.85).

Results: Respondents were from 49 states representing all major regions of the U.S. (Adult=564; Young Adult=76; Pediatric=292); not all respondents answered every item. A majority self-identified as having private insurance. Approximately 48% (n=274) of adult, 55% (n=160) pediatric, and 40% (n=30) young adult patients were diagnosed by a rheumatologist, with the remainder diagnosed by their PCP or a non-rheumatology specialist. While a majority were able to see a rheumatologist within 3 months of onset of symptoms, there were still 30% (n=155) of adults, 26% (n=77) pediatric, and 26% (n=20) young adults who had over a 4 month wait to see a rheumatologist. When asked about the ease of obtaining regular follow-up appointments, 78% (n=430) of adults reported they were able to make routine appointments within the timeframe recommended by their rheumatologist, whereas only 57% (n=193) pediatric and young adult patients were able to do so. 50% (n=283) adults, 57% (n=165) pediatric, and 61% (n=46) young adults indicated it was somewhat to very difficult to make an urgent care appointment. 67% adults (n=372) adults and 55% (n=202) pediatric/young adults went to their PCP for urgent care if they could not see their rheumatologist. 13% (n=72) adults, 7% (n=17) young adults, and 57% (n=166) pediatric patients indicated there was not a rheumatologist within 25 miles from their home. 31% (n=90) pediatric patients reported having to travel more than 2 hours. In addition to travel time, respondents reported major travel costs related to fuel and missing work (Table 1).

Conclusion: Access to care is a substantial issue for patients, with major potential impact on quality and outcomes. There are substantial direct and indirect costs for patients in obtaining rheumatologic care, especially for pediatric patients. These data realistically enhance our understanding of access to care challenges for rheumatology patients.

Table 1. Travel Time and Costs of Patient Care

Time to get to Specialist*	Adults		Young Adult		Parent of Child	
	N	%	N	%	N	%
Between 45-60 mins	36	51.4	4	5.3	27	9.3
Between 1 to 2 hours	27	38.5	6	7.9	47	16.25
Between 2 to 3 hours	2	2.9	2	2.6	43	14.8
Between 3 to 4 hours	2	2.9	2	2.6	20	6.9
More than 4 hours	3	4.3	---	---	26	9.0
Additional Patient Costs**	**Adults**		**Young Adult**		**Parent of Child**	
	N	%	N	%	N	%
Fuel Costs	179	31.1	36	47.4	200	68.6
Overnight lodging	1.0	1.7	4	5.3	59	20.0
Missing work for appointments	181	31.5	43	56.6	210	71.7
Child care	14	2.4	6	7.9	85	29.0
Other	149	25.9	10	13.2	54	18.6

Note: *Only answered by those who reported they traveled more than 25 miles to rheumatologist. **Respondents were allowed to choose more than 1 response, thus percentages do not add up to 100%

"There Are Still a Lot of Things That I Need": A Qualitative Study Exploring Opportunities to Improve the Health Outcomes of First Nations People with Arthritis Seen at an on-Reserve Outreach Rheumatology Clinic

Adalberto Loyola-Sánchez[1], Lynden Crowshoe[2], Tyler White[3], Diane Lacaille[4] and Cheryl Barnabe[5], [1]Rheumatology, University of Calgary, Calgary, AB, Canada, [2]Family Medicine, University of Calgary, Calgary, AB, Canada, [3]Siksika Health Services, Siksika, AB, Canada, [4]Rheumatology, Arthritis Research Canada, Richmond, BC, Canada, [5]Division of Rheumatology, University of Calgary, Calgary, AB, Canada

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: A rheumatology specialty clinic embedded in a primary health care clinic on a First Nations reserve was established six years ago to improve access to care and reduce arthritis outcome inequities. Although the clinic has proved successful to achieve inflammatory arthritis physician-derived disease control targets during a 24-month follow-up period, patient-reported pain, disease severity and physical function did not significantly improve. The objective of this study was to explore remaining care needs from patient and provider perspectives, to inform enhancements to the model of care in this clinic.

Methods: A qualitative study with patients and their family members (n=10), health providers (n=14) and administrative staff (n=10) was performed. Thirty-four in-depth interviews were conducted to reach thematic saturation. Interviewing was assisted by semi-structured guides to focus on personal narratives and perceptions of needs and solutions. Interviews were audio recorded, transcribed verbatim and coded to find meaningful concepts. Concepts were then grouped into themes, which were validated using a member-checking strategy. An inductive interpretation was then conducted using "health service quality" and "cultural competency" theoretical frameworks.

Results: Four main themes of improvement areas were identified (see Table). The first three themes were related to the concept of health service quality: service organization, communication between patients and providers, and holistic patient support mechanisms integrating mainstream and traditional knowledge. Participants stressed that in order to realize treatment goals and thereby reduce health disparities, it was important to improve the administrative and inter-personal quality of existing services. Suggested strategies included administrative and organizational accommodations, health-interpreter services, cultural training and cultural immersion for providers, coordination with traditional healers, use of community health workers, culturally competent health promotion activities and involvement of family and other community members in the management of arthritis. The last theme identified was the need to enhance service availability and expand the scope of provided services beyond the health clinic, such as exercise programs and support groups.

Conclusion: Enhancements to an existing model of care needed to better meet the needs of the community, which could reduce arthritis outcome disparities in an outreach specialty clinic, were identified. Improved service organization, communication strategies, holistic patient support mechanisms and an expansion of services outside of the health clinic were suggested.

Enhancement Required	Illustrative Participant Quote
Service organization	*"There's a fragmentation and disintegration of health services on reserve." (Male, clinical services)*
Communication between providers, patients and their families	*"That (a) client agrees with you…that does not mean you know that person, you have to learn how to think Indian, think like an Indian to know that person…(we need someone)to speak for you if (you) do not understand…" (Female, RA patient)*
Support for patients to adequately manage their disease in a holistic manner, integrating mainstream and traditional knowledge	*"I need to understand more…I need to meet other people who are living this…mentally, I am traditional, I got to sweat, I leave things on creators hands… I am trying to figure out how to help her…It is a chronic disease…it is not going to get better…I want to prepare to help her anyway I can" (Male, husband of a woman with RA)*
Expansion of services outside of the health clinic	*"They do not have support groups out here for smoking, dieting, they do exercising but…even arthritis support groups that would be easier to associate with other people with arthritis cause they know exactly what are you going through… becoming more acceptable in the society to have arthritis…I think exercises for peoples needs… there are certain exercises that we can do and we cant do." (Female, client)*

Mortality in Indigenous Populations of Canada, the United States, Australia, and New Zealand with Rheumatic Disease: A Systematic Review

Kelle Hurd[1] and Cheryl Barnabe[2], [1]University of Calgary, Calgary, AB, Canada, [2]Division of Rheumatology, University of Calgary, Calgary, AB, Canada

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Indigenous populations of Canada, America, Australia, and New Zealand share similar experiences of colonization impacting their rheumatic disease clinical outcomes. The objective of our systematic review was to describe mortality in Indigenous populations with rheumatic conditions.

Methods: A systematic search was performed in medical (Medline, EMBASE, CINAHL), Indigenous and conference abstract databases (to June 2015). Search terms for Indigenous populations were combined with terms for inflammatory arthritis conditions, connective tissue disorders, crystal arthritis, and osteoarthritis. Studies were selected for data extraction if they reported measures of mortality (e.g. mortality rate, survival rates, potential years of life lost). Meta-analysis was not performed due to heterogeneity in the reporting of measures in each study, and a narrative summary was prepared.

Results: A total of 5,269 titles and abstracts were reviewed, of which 504 underwent full-text review and 12 (n=5 Canadian First Nations with SLE; n=2 Native Americans with SLE; n=1 Native Americans with RA; n=1 Native Americans with scleroderma; n=3 Australian Indigenous with SLE) were included for data extraction. First Nations ethnicity was associated with higher mortality compared to Caucasians in all Canadian SLE studies, reflected by a higher crude proportion of deaths (n=3 studies), increased risk of death after adjustment for covariates (hazard ratios 2-3, relative to Caucasians, n=2 studies), higher odds of death (n=1 study) and increased potential years of life lost (n=2 studies). First Nations people with SLE were more likely to have shorter disease duration and be younger at death, and die of SLE complications (27% vs 16%). Risk of death was 43% higher In Native Americans with SLE compared to Caucasians in age and sex adjusted models, and in models with an expanded list of covariates. Risk was highest in women ages 45-65 years. Crude death rates and causes of death were reported in the three studies of Australian Indigenous people with SLE; in these cohorts created through case-finding, Aborigines had higher death rates than Caucasians, mostly related to SLE complications. The RA study in Pima Indians included a comparison of mortality rates between RA and non-RA subjects, with an age and sex-adjusted mortality rate ratio of 1.28 (95%CI 1.01 to 1.62). The one study in Native Americans with scleroderma reported a crude death rate, with nearly all deaths related to progressive disease.

Conclusion: In Canada, America and Australia, Indigenous populations with rheumatic diseases have higher mortality rates. Several studies identified the underlying rheumatic disease as contributing to the deaths. We did not identify any studies disentangling the proportional attribution of rheumatic disease severity from the underlying higher mortality rates in Indigenous populations. The future research agenda should seek to clarify this important issue while expanding the scope to include more rheumatic diseases and populations.

Does Preconsult Electronic Exchange Affect Postconsult Diagnosis?

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent publications have suggested that implementation of an electronic consultation (E-Consult) system can

improve communication between primary care clinicians and subspecialists, reduce wait times, and improve access to care, particularly in safety net hospital systems. Provider-consultant-provider communication through the E-Consult system before any face-to-face interaction is termed a preconsult exchange. Preconsult exchanges can help reduce unnecessary face to face visits, but often require a substantial, potentially uncompensated, time commitment on the part of the reviewer, and have not yet been found to affect the outcome of patients who have been accepted for face-to-face consultation. As a measure of the utility of the preconsult exchange, we conducted a retrospective study to determine whether changes in diagnosis were more likely among those who had electronic exchange compared to those who did not.

Methods: Harbor UCLA is one of the safety-net hospitals of Los Angeles County, serving primarily minority uninsured and Medicaid patients. The hospitals and their community partner clinics provide integrated services for patients, and in order to facilitate subspecialty access, the Department of Health Services adopted an E-Consult system similar to one used at San Francisco General Hospital since 2007. We identified new patients to our clinic who were referred to us via the E-Consult system, then identified those for whom there was preconsult exchange and those for whom there was not. We then conducted a retrospective cohort study of patients accepted for face-to-face evaluation using available data from the E-Consult system and from our electronic medical record. The primary outcome was the odds of diagnosis change after face to face evaluation based on whether a patient had a preconsult exchange or not. Secondary outcomes examined whether a change in diagnosis was associated with a prior diagnosis of a rheumatic condition. Because E-Consult exchanges are asynchronous, obtaining sufficient information to close a consult can often take days to weeks. As an additional measure of this time cost, we compared mean times between consult initiation and face-to-face evaluation.

Results: Between November 2014 and March 2016, 230 patients were seen for face-to-face evaluation for which an E-Consult had been submitted. 68 of these E-Consults were identified as having had an exchange and 162 had not. Odds of a change in diagnosis after face to face consultation were higher for the group who received preconsult exchange but were not statistically significant (Figure 1). Odds of change in diagnosis were no different among those who had a prior rheumatologic diagnosis and also preconsult exchange versus those who did not. Patients for which there was a preconsult exchange were seen a mean 15.5 days later (mean 119.5 days between consult initiation and visit for patients with a preconsult exchange versus 104.1 days for those who did not; se = 11.6 days, p = 0.18).

Conclusion: As E-Consult systems become more widely adopted, particularly among resource limited safety net systems, providers and payers will need clarification on the benefits of preconsult exchange beyond currently available data, which primarily emphasizes improved access but does not address quality or cost (in dollars or in time). Although this study did not meet statistical significance for its endpoints, the results do suggest a trend towards utility of preconsult exchange in sorting patients who need a rheumatologist evaluation, but at a cost of delayed face to face consultation.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Healthcare Disparities in Rheumatology - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Ethnic disparities in outcomes of RA patients have been attributed to delayed presentation to specialty care and access to DMARDs, greater disease burden, and less years of education. Recent literature supports a role for socioeconomic status (SES) as a determinant of RA disease status, including clinical disease activity measures, mortality, seropositivity, and treatment delays. The purpose of this analysis was to delineate the association of SES to referral time and start of first DMARD in a diverse cohort of RA patients.

Methods: Ethnic Minority RA Consortium (EMRAC) participants with recorded dates of initial RA symptom, diagnosis and first disease-modifying drug (DMARD) were abstracted for analysis. Socio-demographic (age, gender, race, years of education, tobacco use), and RA disease status (disease duration, erosions, tender and swollen joints, RAPID3) at enrollment was documented. An estimate of SES was derived from the median housing income of the city of each enrollment site. Median incomes less than two-fold the 2014 poverty line ($47,700) defined lower SES status. Delays of ³ one-year for diagnosis and DMARD initiation were both defined from date of initial RA symptom. Logistic regression was used to model the association between risk factors and a one-year delay of diagnosis and DMARD initiation.

Results: 269 EMRAC participants with self-reported race/ethnicity and disease history were evaluated; 202 (75%) were female. The average values for the following parameters were: age 60.4 (±15.8) years, disease duration 13.6 (±10.8) years, and education 12.5 (±3.0) years. A majority (200 [74.4%]) of EMRAC participants were enrolled at sites serving lower than the twice poverty line. Significant differences in participantsÕ age, education years, disease activity and race were observed between SES groups (**Table**). Based upon the logistic regression model, being below the twice poverty line was significantly associated with the increased odds of ³ one-year diagnosis delay [3-fold increase; odds ratio (OR) = 4.0, 95% CI: (1.6, 10.1), P=0.003)] as well as increased odds of DMARD initiation delay [1.4 fold increase, OR = 2.4, 95% CI: (1.1, 5.06), P=0.027)]. There was no association between either diagnosis or DMARD delay and race. However tender joint counts were associated with increased odds of DMARD delay (per tender joint increase OR 1.1, 95% CI (1.01, 1.14), P = 0.028).

Conclusion: In a diverse ethnic cohort, disparity in income as an estimate of SES was a strong predictor of delay in referral to a rheumatologist and start of first DMARD. Policies that improve access to specialty care and RA medications must be paralleled by improvements in overall SES of individuals in order to minimize the impact of disease. **Table. Enrollment Characteristics by being Below or Above the Poverty Line**

	Median Below	At or Above	P
N	200 (74%)	69 (26%)	
Age (years)	58.2 (13.3)	64.5 (19.2)	**0.009**
Duration (years)	13.8 (9.9)	13.2 (13.0)	0.71

Evaluation of a Pre-Assessment Tool to Define the Spectrum of Autoimmune Diseases in an Underserved Environment

Gary Craig[1], Keith Knapp[2], Karen Ferguson[1], Ruben Tavares[3], Mary Bell[4] and Sergio Schwartzman[5], [1]Discus Analytics LLC., Spokane, WA, [2]Arthritis Northwest PLLC., Spokane, WA, [3]Rheumatology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada, [5]Rheumatology, Hospital for Special Surgery, New York, NY
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Healthcare Disparities in Rheumatology - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: American rheumatology practice patterns vary considerably. One challenge is practitioner shortage, thus a patient-self-administered screening tool would fill an unmet need if it identified patients with the highest likelihood of having an inflammatory disease (ID).

Objective: To assess the appropriateness of referral patterns and concurrently to evaluate a previously published screening tool, Early Inflammatory Arthritis-3 (EIA–3)[1].

Methods: The US rheumatology database, JointMan® captures inflammatory/non-inflammatory diagnoses of referred patients at a large Washington State rheumatology practice. All patients at the practice fill in an electronic version of the EIA-3 tool. This published screening questionnaire estimates the likelihood of having an inflammatory disease [JIA, RA–fulfilling ACR criteria, Unspecified inflammatory arthritis, SpA, CTDs, SLE] vs non-inflammatory disease [OA, FM, CPPD]. The evaluating clinician was not aware of the EIA-3 results. The results were later correlated to the clinician's diagnosis. Based on the confusion matrix, effect sizes (sensitivity, specificity and likelihood ratios) were calculated and compared to published results[2].

	Inflammatory diagnosis only	Non-inflammatory diagnosis only	Both inflammatory and non-inflammatory diagnoses
Referral Recommended	485	148	92
Referral Not Recommended	104	82	45

Confusion matrix displaying patient counts in all categories

Results: There were 956 patients with a mean age of 55; 66.32% female; 77.82% Caucasian. Of those,726 patients had inflammatory diseases [137 also had non-inflammatory disease]; 230 had non-autoimmune disease. The EIA-3 suggested referrals for 725 patients and no referral for 231.

	JointMan Effect Size		Tavares et al. 2013 Effect Size	
Sensitivity	0.823		0.855	
Specificity	0.357		0.873	
Precision	0.766		N/R	
Likelihood Ratio + (95% CI)	1.280	(1.154 - 1.419)	4.167	(4.144-1.191)
Likelihood Ratio - (95% CI)	0.495	(0.387 - 0.633)	0.158	(0.079-0.238)

Effect size table for the JointMan and Tavares datasets

Description	Count	%
Unspecified Inflammatory Polyarthropathy	235	40.73%
Rheumatoid Arthritis	177	30.68%
Osteoarthrosis	75	13.00%
Connective Tissue Disease	67	11.61%
Psoriatic Arthropathy	67	11.61%
Ankylosing Spondylitis	27	4.68%
Fibromyalgia	23	3.99%
Inflammatory Spondylopathy NOS	22	3.81%
Lupus	13	2.25%
Pauciarticular Juvenile Rheum Arthritis	10	1.73%
IBD Associated Arthritis	7	1.21%
Pseudogout (CPPD)	3	0.52%
Reactive Arthritis (Reiter's Disease)	2	0.35%
Systemic Rheumatoid Arthritis NEC	1	0.17%
Polyarticular Juvenile Rheumatoid Arthritis	1	0.17%

The diagnosis distribution for patients who were recommended for a referral to a rheumatologist. Some patients had multiple diagnoses.

Conclusion: In this study, primary care physicians adeptly referred appropriate ID patients to less accessible rheumatologists (EIA-3 use only modestly increased preselection of ID patients). It is possible that an electronic patient generated screening tool may help primary

providers referring ID patients in less preselected populations (as in the first EIA-3 trial where non-inflammatory diseases were more common).

Knee Pain and Patient Preference for Knee Replacement: Healthcare Access Matters

Manjinder Kaur[1], Erin Ashbeck[2], Di Ran[2], C. Kent Kwoh[3] and Ernest Vina[4], [1]Internal Medicine, University of Arizona, Tucson, AZ, [2]University of Arizona, Tucson, AZ, [3]Rheumatology, University of Arizona, College of Medicine, Tucson, AZ, [4]Rheumatology, University of Arizona, Tucson, AZ

First publication: September 28, 2016

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Total knee replacement (TKR) is a cost-effective intervention for end-stage knee osteoarthritis (OA). Objectives were to estimate the effect of knee pain severity on willingness to undergo TKR and the impact of healthcare access.

Methods:

The Osteoarthritis Initiative (OAI) is an observational study of participants with or at risk for knee OA. Knee pain severity in the past 30 days was assessed using a numerical rating scale (0-10). Willingness to undergo TKR was ascertained at the 72 month visit. Participants with no history of TKR were included in cross-sectional analyses. Adjusted odds ratios (OR) and 95% confidence intervals (CI) were estimated using logistic regression models. Stratified analyses were conducted to evaluate whether healthcare access modified the association between knee pain severity and willingness to undergo TKR, as well as a likelihood ratio test for interaction between knee pain and components of healthcare access.

Results:

The 3530 participants were predominately White (81.2%) and African American (16.7%), with mean age 66.6 years (sd 9.0), and 58.6% female. More than 90% of participants had health insurance.

Participants with severe knee pain, compared to participants without knee pain, expressed less willingness to undergo TKR (OR 0.70, 95% CI 0.55-0.90) with adjustment for age and sex. This association attenuated after further adjustment for comorbidity, and depression (OR 0.80, 95% CI 0.61-1.03) and when further adjusted for health insurance, prescription coverage, healthcare provider, education, income, employment, race, and marital status (OR 0.92, 95% CI 0.68-1.24).

Among participants without health insurance coverage, severe knee pain was associated with significantly decreased odds of willingness to undergo TKR after adjustment for demographic, clinical, healthcare access, and socioeconomic factors (OR 0.08, 95% CI 0.01-0.56) (Figure 1). Similarly, among participants without prescription coverage, those with severe knee pain were significantly less willing to undergo TKR (OR 0.12, 95% CI 0.03-0.41). No association between knee pain and willingness was observed among those with health insurance (OR 1.03, 95% CI 0.73-1.38) and with prescription drug coverage (OR 1.10, 95% CI 0.79-1.53), suggesting that health insurance

and prescription drug coverage modify the association between knee pain severity and willingness to undergo TKR (interaction p=0.015 and p=0.003, respectively).

Conclusion:

Among participants with health insurance and with prescription drug coverage, no evidence of an effect of knee pain severity on willingness to undergo TKR was found. Among participants without health insurance and/or without prescription drug coverage, those reporting severe knee pain were less willing to undergo TKR. This finding reinforces the influence of health insurance on preferences and receipt of appropriate medical care.

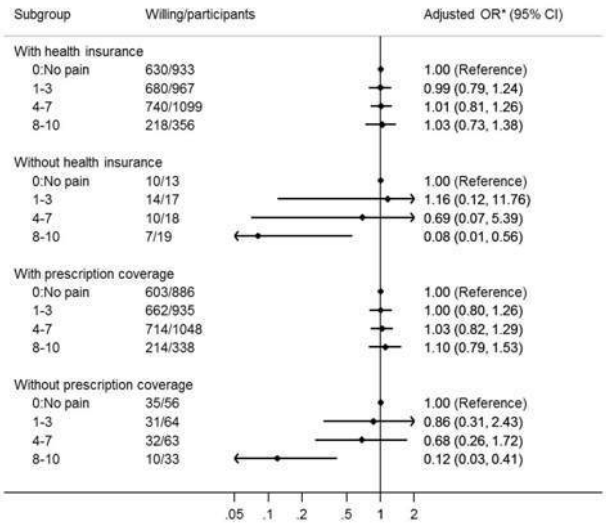

Figure 1. Willingness to undergo knee replacement and knee pain severity, by healthcare access.
P-values for interaction between: pain severity and health insurance coverage (0.003), pain severity and prescription medicine coverage (0.015)
* Adjusted for age(<65 vs. >=65), gender, education, income, current employment, comorbidity, CESD, marital status, health insurance, prescription coverage, health care provider

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In 2015, the Center for Medicare and Medicaid Services released claims data on payments to over 950,000 health care providers paid through Medicare Part B. This study investigated 2013 Part B utilization and costs among rheumatology providers in the state of Illinois, and links between utilization data and local demographics.

Methods: Publicly available 2013 Medicare Part B reimbursement data was compiled through ProPublica Treatment Tracker (https://projects.propublica.org/treatment/). Providers identified by Medicare as rheumatology providers in Illinois (n=191) with

individual practitioner payment and service data were used for analysis. Practice location as defined by Medicare-assigned zip code was used to search 2013 census data (http://www.census.gov) for geographic distributions of race/ethnicity, education, and income. Six provider level outcomes were investigated. Both services delivered and payments were examined for: A) rheumatoid arthritis (RA) biologics; B) osteoarthritis (OA) viscosupplements, and; C) totals billed to Medicare. T-tests investigated differences in mean outcomes between providers who did versus did not order services. Multivariable regression analyses investigated geographic factors associated with any ordering (0/1; logistic regressions) and continuous payments (generalized linear models; gamma family, log link) of RA biologics and viscosupplements.

Results: Total of 191 Illinois rheumatology providers were identified by Medicare for 2013. The top ten providers accounted for 26.5% of total Medicare payments and 32% total number of services. Significant differences between Part B RA biologic utilizers (n=38) and non-utilizers (n=153) existed for: total number of services (mean 42763 vs 4598, p<0.001); services per patient (81 vs 15, p<0.001); total payments ($770,342 vs 108,196, p<0.001); and payment per patient ($1,510 vs 333, p<0.001). Similar data existed for viscosupplements utilizers (n=44) vs non-utilizers (n=147) in terms of: total number of services (mean 3213 vs 6257, p<0.001); services per patient (54 vs 20, p<0.001); total payments ($600,052 vs 132,141, p<0.001); and payment per patient ($1,048 vs 423, p<0.001). There were correlations between biologic utilization for RA and viscosupplements for OA in both total payments (rho = .52, p<0.001) as well as number of services (rho = .48, p<0.001). In adjusted regression analyses, a 1% zip code-level increase in percent white race/ethnicity was associated with both a 4% increase in the odds of any RA biologics orders (p=0.002) and a 6% increase in RA biologics payments (p<0.001).

Conclusion: We observed dramatic differences in 2013 Medicare Part B utilization among rheumatology providers in Illinois for RA biologic and OA viscosupplement use. In adjusted regressions analysis, percent white race was positively associated with RA biologic use. Further research is needed to better understand health care utilization in rheumatology and its relation to population demographics. This study did not investigate quality of care or patient outcomes and did not examine medications not covered under Part B. Payments do not reflect provider profit as providers may incur substantial overhead costs.

Disparities in Total Knee Replacement: Population Losses in Quality-Adjusted Life Years Due to Differential Offer, Acceptance, and Complication Rates in African Americans

Hannah Kerman[1], Savannah R. Smith[2], Jeffrey N. Katz[3] and **Elena Losina**[4], [1]Orthopaedic and Arthritis Center for Outcomes Research, Brigham and Women's Hospital, Boston, MA, [2]Orthopedic and Arthritis Center for Outcomes Research, Brigham and Women's Hospital, Boston, MA, [3]Orthopaedics, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Orthopaedics, Brigham & Women's Hospital, Boston, MA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Total knee replacement (TKR) is an effective treatment for persons with end-stage knee osteoarthritis (OA). Differences in offer, acceptance, and complication rates for TKR have been documented for racial minorities compared to Whites within the US; however, there has been no translation of these differences into population level lossess of quality-adjusted life-years (QALYs).

Methods: We used the Osteoarthritis Policy Model (OAPol), a validated computer simulation of knee OA, to estimate QALYs lost in African American (AA) men and women compared to Whites (W) due to differences in TKR offer, acceptance, and complication rates.The data on complications, offer and acceptance of TKR were derived from published literature. TKR offer ranged from 10% in AA persons with advanced knee OA to 23% in White persons. Willingness to undergo TKR (acceptance) ranged from 58% for AA men to 84% in W men (Table). Published complication rates ranged from 4.3% in Whites to 6.5% in AA persons undergoing TKR. We validated OAPol model estimates using national data on TKR utilization from the Healthcare Cost and Utilization Project. Future QALYs were discounted at 3%/year. We estimated per person QALY losses due to differential offer, acceptance, and complication rates in AA men and women and calculated population-level person-years lost by multiplying QALY losses by the number of AA men and women with advanced knee OA

in the US. Loss was defined as the QALY difference seen using AA rates of offer, acceptance, and complication, compared to W rates. The population size for those with advanced symptomatic knee OA was obtained from published data (310,000 AA men and 600,000 AA women).

Results: Current utilization of TKR leads to 16,000 QALYs gained for AA men and 50,000 QALYs for AA women (Table). The disparity between offer levels observed in AA and W populations with advanced knee OA may lead to a loss of 71,000 QALYs for African Americans. The increased complication rates experienced by the AA population could lead to a loss of 3,000 QALYs. Assessing the combined effect of lower offer rate and increased complictions for the AA population reveals a QALY loss of 20,100 for AA males and 57,100 QALYs for AA women, leading to over 77,000 QALYs lost overall.

Conclusion: Documented differences in TKR offer rates in conjunction with increased complication rates in racial minorities leads to substantial QALY losses. Increasing the offer of TKR among African American persons and decreasing the complication rates to levels observed in White populations may lead to additional 120% gains in quality-adjusted life years. Programs focused on decreasing the disparities in TKR offer and complications rates in African Americans with diagnosed advanced symptomatic knee OA are urgently needed and such efforts could result in large population-level benfits for racial minorities.

Table. Quality-adjusted life year losses due to lower rates of TKR offer and acceptance and higher rates of complications among African American men and women

				Population QALY Losses				
Cohort	Population Size	Offer	Accept	Current TKR Utilization	Lost to Low Offer	Lost to Low Accept	Lost to High Comp.	Lost to Low Offer and High Comp.
AA-M	310,000	10%	58%	15,700	18,200	7,200	1,300	20,100
AA-W	600,000	10%	63%	49,700	53,340	10,100	2,000	57,500
AA-Both				65,000	71,000	17,300	3,300	77,200

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-TNF treatment is available for Ankylosing Spondylitis (AS) for many years now, but the data on long term follow up in daily practice are limited. To determine treatment survival and adverse events of anti-TNF treatment in AS patients in a large peripheral hospital in daily practice. Also, gender differences in drug survival and side effects were studied.

Methods: Retrospective data were collected from AS patients treated with etanercept, infliximab and adalimumab in the period of January 2004 until January 2014 in the Kennemer Gasthuis. Statistical analyses were performed with Kaplan Meijer survival curves to describe the drug survival and occurrence of adverse events in time.

Results: In total 122 ankylosing spondylitis patients were included with 159 treatment episodes (defined as time on drug) over a 10 year time period. The mean treatment duration was 51 months (range 1-127 months). Females showed a significant shorter treatment period compared to males (33.4 vs. 44.9 months) (Figure 1). Overall, 21% of the patients stopped the TNF alpha inhibitor after a mean period of 15 months, mainly due to inefficacy (53.7%). Only 6 patients stopped because of infections (mild) and no patients had malignancies. Female patients switched more often compared to male patients (26.9% vs. 16.3%). Females had a significantly higher risk (26%) at

developing infections compared to males (19%).

Conclusion: Over a mean treatment period of 4.3 years (51 months), nearly 80% of the patients treated with anti-TNF treatment continued using these drugs. Females showed a significant shorter treatment period compared to males (33.4 vs. 44.9 months). The most important stop reason was inefficacy. Women developed significantly more often infections during anti-TNF treatment than men.

Female Gender Is Associated with a Poorer Response to TNF-Inhibitors in Ankylosing Spondylitis

T. Rusman[1], M. Nurmohamed[2], J.C. van Denderen[3], I. Visman[4] and I.E. Van der Horst - Bruinsma[2], [1]Rheumatology, VU University medical centre, Amsterdam, Netherlands, [2]Amsterdam Rheumatology immunology Center |Departments of Rheumatology VU University Medical Center & Reade, Amsterdam, Netherlands, [3]Center for Rheumatology and Rehabilitation, Jan van Breemen Institute, Amsterdam, Netherlands, [4]Amsterdam Rheumatology and Immunology Center, VUmc and Reade, Amsterdam, Netherlands

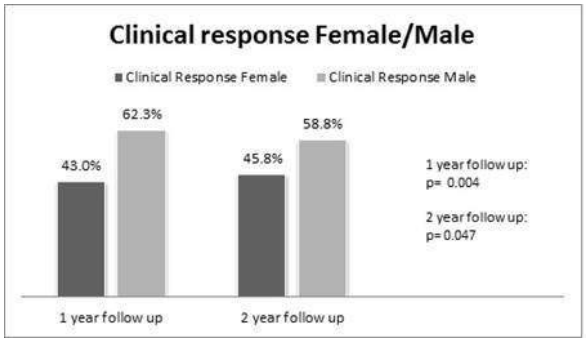
SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Healthcare Disparities in Rheumatology - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM



Background/Purpose: Limited data is available on the influence of smoking, Body Mass Index (BMI) and gender on disease activity and

response to TNF inhibitors in ankylosing spondylitis (AS). This study aims to determine whether these factors influence time of diagnosis, disease activity and response to TNF inhibitors.

Methods: In a prospective study, disease activity data (Ankylosing Spondylitis Disease Activity Score (ASDAS and BASDAI)) were collected from patients included in a real life observational cohort, who started or switched treatment TNF inhibitors. Data were collected at baseline, 6, 12 and 24 months. Independent T-tests and linear regression analyses were performed to assess the different factors their influence on time of diagnosis diagnosis and change in disease activity.

Results: In total 312 consecutive AS patients were included with a mean follow-up of 18.9 months. Most patients (172, 55%) showed improvement after the start of TNF inhibitors whereas, 86 patients (27.7%) had a clinically important improvement (i.e. decrease in ASDAS > 1.1) and 86 (27.7%) a major clinical improvement (decrease in ASDAS > 2.2). BMI was significantly correlated with time of diagnosis (p=0.016; 95%CI: 0.07 – 0.65): an increase of BMI with three points extended the AS diagnosis with one year. Smoking and gender were not correlated with the baseline ASDAS. BASDAI and BASMI at baseline were both influenced negatively by BMI. Gender was significantly associated with the clinical response (BASDAI50% or a 2 point decrease) to TNF treatment (p=0.041). More male patients showed clinical improvement on TNF treatment compared to female patients: at one year follow up 62.3% vs. 43.0 % and at two year follow 58.8% vs. 45.8% (figure1). Adjustment for BMI as confounder lead to a stronger statistical significance for gender difference in clinical response (p=0.022).

Conclusion: The most interesting finding was that females had a significantly lower clinical response to TNF treatment compared to males. Furthermore, high BMI not only extended the AS diagnosis up to one year, but also negatively influenced the BASDAI and BASMI scores. It seems that BMI and female gender are associated with clinical response to TNF treatment.

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a drive to offer all patients the opportunity to participate in clinical research. We aimed to investigate the eligibility, screening and participation of rheumatology patients in clinical research studies in a single academic rheumatology department to identify targets for improving patient engagement with research

Methods: Methods: This study was conducted in two phases. Phase 1 was a retrospective analysis of study screening logs over 12 months. In phase 2; the outpatient population was surveyed using a questionnaire to identify the motivators and barriers to research participation. Comparisons were made using chi-squared tests and logistic regression models where appropriate.

Results: In phase 1 of the study we identified 1025 patients who were eligible for screening (median [IQR] age 47 [18-85] years; 87% female); 566 (55%) had been screened for any study. Of these, 217/566 (38%) were subsequently enrolled. Enrollment varied by ethnicity. Reasons for screen failure included study ineligibility (54%) and patient factors (29%). There was significant variation in these reasons by ethnicity (P=0.047), however this was not clearly due to patient factor (P = 0.091). Females were more likely to be ineligible (OR [95%

CI] 1.78 [1.08, 2.95]) and increased age was associated with declining research participation (OR 0.98 [0.95, 0.998]). In phase 2, 152 participants including 117 (77%) women, responded to our survey (overall response rate 25% [Caucasians 45%, Non-Caucasians 7%]). Their median [IQR] age was 50 [17-84] yrs and our sample included 111 (73%) Caucasians and 41(27%) non-Caucasian ethnicity. Overall, 50 (33%) had ever been invited to research, of whom 71% participated. The key motivational factors were to contribute to scientific knowledge (94%), to help other patients (89%) and personal health benefits (47%). The major factors for non-participation were study ineligibility (47%), stopping/changing current medication (33%), inadequate information about the study (27%) and inconvenience (27%). Overall, 87/152 (57%) were happy to participate in future studies .The main influencing factors were potential help to others (98%),contributing to scientific knowledge(96%),quality of information given about the study (79%) and understanding of what study involved (76%). Non-Caucasians were less likely to participate (p=0.052); however, main spoken language (p=0.102) and employment status (P=0.395) had no influence on deciding whether to take part in research. We also found that Caucasians were significantly more likely to be approached to research (P=0.004) and previous research experience had a positive impact to participate in future research (P=0.001).

Conclusion: Our study identified a number of barriers to research participation. Almost half of patients were never even considered or screened for research eligibility, and many failed screening. This may reflect study case mix/design; however there was also variability in participation according to ethnicity. Strategies to facilitate a universal research offer and support study involvement will need to account for ethnic variation in patient characteristics and beliefs about research.

Association of Traditional Chinese Medicine Use and Adherence to Prescribed Western Medications in Chinese-American Rheumatology Patients

Kai Sun[1], Henghe Tian[2], Yuo-Yu Lee[3], Jennifer Leng[4] and Lisa Mandl[5], [1]Internal Medicine, Hospital for Special Surgery, New York, NY, [2]Internal Medicine, New York University School of Medicine, New York, NY, [3]Epidemiology and Biostatistics, Hospital for Special Surgery, New York, NY, [4]Immigrant Health and Cancer Disparities laboratory, Memorial Sloan Kettering Cancer Center, New York, NY, [5]Rheumatology, Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chinese-Americans are one of the fastest growing immigrant groups in the US. They often use Traditional Chinese Medicine (TCM), but whether that affects medication adherence is unknown. This question is important because data suggest that ethnic Chinese have more severe SLE and RA than Caucasians, and thus nonadherence could be especially problematic. This study evaluates whether TCM use is associated with nonadherence to western medicines prescribed for chronic rheumatic diseases among Chinese-American patients. Secondary aims are to explore differences in self-reported health status between TCM users and non-users.

Methods: Recruitment was from a rheumatology clinic that serves a predominantly Chinese-American immigrant population. A bilingual Mandarin/English speaker evaluated TCM use, medication adherence, patient-reported outcomes from the Patient-Reported Outcomes Measurement Information System (PROMIS), and other patient-level factors, all administered with validated instruments available in English and Mandarin. Inclusion criteria included speaking Mandarin or English, prescription of ≥ 1 medication by the rheumatologist, and being actively followed for a systemic rheumatic disease or OA of hands, knees, or hips. Those with only fibromyalgia, neck/back pain, or other soft tissue diseases were excluded. Adherence was analyzed as low, medium or high based on the 8-item Morisky Medication Adherence Scale.

Results: Seventy-three enrolled, mean age 56y (range 22-97), 59% female, 77% Medicaid, and only 21% spoke English. Diagnoses included RA (37%), spondyloarthropathies (22%), SLE (15%), SS (7%), gout/pseudogout (7%), OA (3%), and other (9%). Forty-nine percent reported TCM use in the past year, most commonly massage (53%), acupuncture (47%), and herbs (44%). There was a trend for TCM use to be more common in SLE vs. RA (65% vs. 37%, p=0.5) and TCM users had a shorter disease duration (5.3 vs. 11.2 years, p=0.03). Overall, 70% reported nonadherence to rheumatic medication. In multivariate analysis adjusting for patient characteristics, TCM

use was not associated with lower adherence (OR 0.34, 95% CI 0.09-1.26), while herb use was associated (OR 5.3, 95% CI 1.09-25.87). TCM users also had worse PROMIS scores in anxiety (mean T-score 52 vs. 46, p=0.01) and depression (mean T-score 52 vs. 46, p=0.007), and a trend for worse pain (mean T-score 58 vs. 56, p=0.2), fatigue (mean T-score 55 vs. 51, p=0.1), function (mean T-score 43 vs.47, p=0.1), and worse ability to participate in social roles and activities (mean T-score 55 vs.59, p=0.06).

Conclusion: In this group of poorly integrated Chinese-American rheumatology patients, most were non-adherent with western medicines, but only herb use was associated with non-adherence. This could reflect two divergent beliefs towards TCM. In general TCM is "complementary", but herb may be seen as an "alternative" to western medicine. In addition, TCM users had worse scores in several important self-reported health domains. This may indicate unmet needs, particularly in mental health. These associations should be explored longitudinally, including the association of TCM use and adherence on disease activity.

Reliability and Validity of the Patient Health Questionnaire-9 for Assessment of Depression in Socioeconomically Disadvantaged Latinos with Rheumatoid Arthritis Living in the United States

Sarah Ormseth[1], Taylor Draper[2], Elizabeth Hernandez[1] and George A. Karpouzas[3], [1]Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, [2]Psychology, Loma Linda University, Loma Linda, CA, [3]Harbor UCLA Medical Center, Torrance, CA

Session Title: Healthcare Disparities in Rheumatology - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Depression is highly prevalent in rheumatoid arthritis (RA). The Patient Health Questionnaire-9 (PHQ-9) is a simple screening tool widely used in medical settings and validated in multiple ethnic and linguistic groups. However, its measurement properties have not been assessed among low socioeconomic status (SES) Spanish-speaking Latinos with RA. We investigated factor structure, reliability and validity of the Spanish-language PHQ-9 in low SES Latinos with RA living in the US.

Methods: We evaluated 447 patients from a single center. On the PHQ-9, participants rated from 0 (none) to 3 (almost daily) their feelings of depressed mood and 8 other symptoms of depression (see Table 1). Total scores (0-27) correspond to depression severity levels: minimal (0-4), mild (5-9), moderate (10-14), and moderately severe to severe (>=15). Internal consistency and reliability were examined with Cronbach's alpha and corrected item-total correlations. Confirmatory factor analysis (CFA) assessed the hypothesized unidimensional factor structure. Multi-group CFA examined the generalizability of the factor structure across distinct patient subgroups. Convergent validity was explored via correlations among PHQ-9 scores and measures of health-related quality of life (Physical and Mental Components of the 36-Item Short Form Health Survey), disability (Health Assessment Questionnaire disability index), activity impairment (Work Productivity and Activity Impairment Questionnaire), fatigue VAS, pain VAS, patient and evaluator global assessments of disease activity, and Disease Activity Score 28 (DAS28-3 ESR).

Results: Patients were 89% female with a mean age of 52.6 years and mean RA duration of 10.7 years. The internal consistency of the PHQ-9 was good (a =.91) and all corrected item-total correlations reached an acceptable level (Table 1). CFA showed the one-factor solution provided a good fit to the data: S-Bx^2(27) = 67.85, p <.05, CFI =.971, TLI =.961, RMSEA =.058 with all significant factor loadings (Table 1). Multi-group CFA demonstrated the factor structure can be generalized across age groups, RA disease duration and levels of disease activity. Convergent validity was supported by significant associations of PHQ-9 scores and severity levels in the expected directions with related measures (Table 2).

Conclusion: Findings support use of the PHQ-9 as a brief, low-burden screen for depression in low SES Spanish-speaking Latinos with

Table 1. Standardized factor loadings and descriptive statistics for PHQ-9 items

PHQ-9 Item	CFA Factor Loading	Item Mean (SD)	Item-Total Correlation	α if Item Deleted

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Healthcare Disparities in Rheumatology - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Although physical therapy (PT) is recommended for managing symptomatic knee osteoarthritis (sxKOA), little is known about correlates of PT utilization among adults with sxKOA. This study aimed to: (1) describe the prevalence of PT utilization among adults with sxKOA enrolled in an exercise trial and (2) identify sociodemographic and clinical correlates of PT utilization for sxKOA.

Methods : This cross-sectional study is a secondary analysis of data from a randomized controlled trial (RCT) of 350 adults (aged >=18 years) with physician-diagnosed sxKOA (median WOMAC pain=5, range=0-20, and median WOMAC function=22.5, range =0-68) recruited from a large tertiary medical center and an ongoing prospective cohort study. Patients completed baseline demographic and medical history questions and whether they had utilized PT to manage sxKOA (yes/no). Logistic regression was used to develop a parsimonious set of correlates of PT utilization, with all models adjusted for body mass index and age. We evaluated all race by predictor and gender by predictor pairwise interactions.

Results : Of 350 patients, 249 (74%) were Caucasian, 72% female, 50% obese or very obese, mean age was 62.5 years (SD=11.3). The median duration of KOA symptoms was 10 years (<1 to 65). 147(42%) had received a knee joint injection, 175 (50%) had a prior knee injury, and 182 (52%) reported PT utilization for their KOA. Factors independently associated with increased odds of PT utilization were: female gender, having a college education, history of a knee injury, duration of KOA symptoms, and having family members with KOA. Individuals who were Caucasian and had received a joint injection were 3.69 times more likely to have utilized PT; this relationship did not exist for non-Caucasians (Table 1). Employment tended to be associated with a reduced likelihood of PT utilization.

Conclusion : Of persons with sxKOA that enrolled in an exercise intervention, roughly half reported prior PT utilization. Demographic and clinical features were associated with PT utilization for adults with sxKOA; strongest correlates were female gender, higher education, and longer duration of KOA symptoms. Differences by race in the link between joint injection and PT may reflect a reduced likelihood of health interventions for sxKOA among non-Caucasians. More research is needed to facilitate PT utilization among adults with sxKOA, especially men and those with lower educational attainment. Limitations of this study include the use of a convenience sample enrolled in an RCT, the potential for misclassification of PT utilization due to self-report and inability to determine whether lack of utilization was due to clinicians not offering PT or patients not attending PT. Diverse characteristics of the sample allowed for evaluation of PT utilization by race.

Implicit Biases Influencing Service Provision in Physical Therapy for Low Back Pain

Maude Laliberté[1], Barbara Mazer[2], Tatiana Orozco[3], Gevorg Chilingaryan[4], Bryn Williams-Jones[1], Matthew Hunt[4] and Debbie Ehrmann Feldman[5], [1]Université de Montréal, Montréal, QC, Canada, [2]McGill University, School of Physical and Occupational Therapy, Faculty of Medicine, Montreal, QC, Canada, [3]Université de Montréal, Montreal, QC, Canada, [4]McGill University, Montreal, QC, Canada, [5]School of Rehabilitation, Université de Montréal, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Healthcare Disparities in Rheumatology - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The management of physical therapy (PT) services may raise concerns about equity. Previous research suggests that certain individuals have less access to services and receive inferior quality care compared to others due to their age, gender or socio-economic status (SES). Insurance status may also influence the clinical practice of PT professionals. Our study aimed to determine whether patient-related factors (age, gender, SES) and the source of reimbursement for PT services (insurance status) influence waiting time, frequency and duration of PT treatment for low back pain.

Methods: We conducted an empirical cross-sectional online survey of Canadian PT professionals. 846 PT professionals completed a survey containing one of 24 different clinical vignettes (i.e., patient case scenarios with low back pain) chosen at random, and a 40-item questionnaire about how they would treat the fictional patient in the vignette, as well as details on their professional clinical practice. Each vignette described a patient with low back pain but with variations in patient characteristics (age, gender, SES) and insurance status (none, private insurance, workers' compensation board (WCB)).

Results:

The age, gender and SES of patients did not make any difference in how participants would provide service. However, patients with no insurance coverage would wait longer ($p=0.002$) for access to PT in private clinics, while patients with WCB insurance would be seen more frequently ($p<.0001$) than patients with private insurance or no insurance, in both public and private clinics. However, when explicitly asked, study participants stated that insurance status, age or chronicity of the condition were not factors associated with treatment access, frequency or duration.

Conclusion: The study findings demonstrate an implicit professional bias in favour of preferentially treating patients with low back pain who have insurance; the resulting inequity in access highlights the urgent need for national guidelines to ensure equity in access to and provision of PT services.

Session Title: Healthcare Disparities in Rheumatology - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: While studies report that SLE affects primarily women, males with SLE represent 4-22% of SLE patients. Support & education has improved self-management & coping strategies, including sexual health (SH) issues. Beliefs about what it means to be a male having a "women's disease" can undermine good preventative & SH care for men with SLE. Further, despite research demonstrating higher mortality for males, males with SLE tend to seek medical attention & supportive care less often than females. A hospital-based support & education program, ongoing since 1994, conducted a pilot survey to identify self-reported needs & concerns for men with SLE.

Methods: Ten males with SLE were recruited to participate in a pilot, semi-structured 30 min phone interview; consisting of 6 scripted open-ended questions, focused on: SLE knowledge, impact, communication with doctor & partners, SH & interest in male specific programing.

Results: Three males were African-American, 3 Latino & 1 Asian; mean age 26, mean years since diagnosis 9. All males demonstrated good baseline understanding of SLE & describing it as "unpredictable" & a "women's disease." The areas of their lives most affected by SLE, included: physical limitations, personal relationships & work/school. Other themes related to masculine/cultural stereotypes, suggesting that seeking care or asking for help is "weak." "I am told to man up, seeing a therapist is taboo in my family." All males agreed these views contributed to increased physical activity despite known limitations, to combat feelings of weakness. All males reported attending primarily "female support groups"& expressed inability to relate to women's experiences with SLE due to different life concerns, "there is no sense of connection." When asked about SH concerns, fears about infertility & feeling uncomfortable talking to their doctors or partners about these issues were shared. All men were concerned about medication side effects contributing to SH & other health factors. Additionally, all males reported never talking directly with their rheumatologists regarding SH & SLE. When asked why, the majority indicated they preferred to be asked directly by providers. All expressed a desire for more tailored SH education as it relates to their SLE & a male specific support group addressing the following areas: communication issues with doctors & partners, strategies for sexual decision making & general SH topics. When asked if they would attend said programming, all replied affirmatively.

Conclusion: Despite our small sample size, our pilot shows an unmet need for this population, which potentially impacts on psychosocial, SH, disease self-management & outcomes. Despite some (primarily Web based) support forums for males with SLE, no peer reviewed literature was found reporting on the efficacy of these interventions. The next step is to develop a more robust needs assessment to address barriers & best interventions in partnership with the rheumatology community.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of this study was to investigate bone microarchitecture variables of cadaveric vertebrae using ultra-

high field MRI (7 Tesla).

Methods: Twenty four vertebrae (L2, L3, L4) from eight cadavers were studied using 7 Tesla MRI. Their Bone Mineral Density (BMD) were investigated using dual energy X Ray absorptiometry. Then, all specimens underwent mechanical compression tests to failure and the failure load (in Newton) and constraint (in Mpa) were measured. Bone Volume Fraction (BV/TV), Trabecular Thickness (Tb.Th), and Trabecular Spacing (Tb.Sp) were measured in MR images using a Digital topological analysis (Bone J). Measurements were performed by two observators in order to characterize the inter-rater reliability. Statistical analyses were performed using SPSS. Correlations between variables were analyzed using Spearman correlations and Stepwise regression. A p value of 0.05 was considered as significant.

Results: The inter-rater reliability for bone microarchitecture parameters quantification was good. Tb.Th and Tb.Sp measured using high-field MRI were 0.52±0.18 and 0.48 ± 0.10 respectively while the BV/TV fraction was 0.52 ± 0.13. The mean BMD was 0.86 ± 0.20 g/cm^2. The failure load and the constraint measured during the compression tests were 2600 ± 1267N and 1.57 ± 0.81 Mpa respectively. Interestingly, the variables measured during the mechanical tests were significantly. The failure load and constraint measured during the compression tests were significantly correlated with the BMD. Regarding the bone indices quantified using high-field MRI, a significant linear relationship was observed between the trabecular spacing and the BMD ($R^2 = 0.23$, $p = 0.01$) and the constraint values to failure ($R^2 = 0.18$, $p = 0.04$). A stepwise regression with backward elimination demonstrated that combining BV/TV and BMD improved the relationship with the constraints from an adjusted $R^2 = 0.384$ for BMD alone to an adjusted $R^2 = 0.41$ for BMD + BV/TV.

Conclusion: In the present study, we demonstrated for the first time that the variables characterizing the vertebral bone microarchitecture quantified using ultra-high field MRI were significantly correlated with biomechanical parameters. In addition, we illustrated that the vertebral bone strength was better described by a variable combining BMD and trabecular bone spacing.

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: With implementation of tight control strategies and defined treatment targets in rheumatoid arthritis (RA) care, a majority of early RA patients may reach remission and traditional predictors of joint damage might no longer be present. The aim of our study was to identify baseline parameters predictive of 2-year radiographic progression in an early RA population treated by a semi-personalized treat-to-target strategy.

Methods: DMARD naive RA patients with <2 years from first patient reported swollen joint, who fulfilled the 2010 ACR/EULAR criteria, were included in the ARCTIC study. Patients were followed for 24 months with treatment according to an aggressive algorithm targeting clinical remission (DAS <1.6 and SJC44=0), and in half the patients an additional target was imaging remission (absence of ultrasound PD signal). Patients with risk factors for progressive joint destruction (ACPA or RF positive with baseline erosions, or MRI bone marrow edema) could be escalated more rapidly from MTX monotherapy to biologics. Radiographs were scored by two readers using the van der Heijde-Sharp score (vdHSs), with cut-off 1 unit or more change/year to be classified as progression. Potential baseline predictors were analyzed for collinearity, and remaining variables assessed by univariate logistic regression. Variables with univariate $p<0.25$ were included in the multivariate model building, and $p<0.05$ was required to remain in the model.

Results: Mean [SD] disease duration for the 222 patients was 7.2 [5.4] months, and mean DAS based on 44 joints was 3.5 [1.2]. 72% were RF and 82% ACPA positive. 41% had radiographic progression at 24 months, while DAS remission was reached by 68%. In 16%

treatment was escalated more rapidly due to baseline risk factors. In univariate models, gender, age, smoking, RF, tender joints, 44 SJC, ESR, total GS-score, total PD-score and vdHSs at baseline had p<0.25, while BMI, disease duration<3months, ACPA and patient global had p>0.25. In the multivariate model, RF positivity (OR 2.27, p=0.022), total vdHSs (OR 1.08, p=0.017) and ultrasound GS score (OR 1.03 per unit, p=0.019) were independent baseline predictors of radiographic progression at 24 months (table). Ultrasound PD was not an independent predictor in secondary models built without GS or in separate models for the two strategy arms, neither as a continuous nor dichotomized variable according to the mean (9.8) and median (7) baseline score.

Table: Multivariate model for baseline predictors of radiographic progression at 24 months (corrected for age and gender). Radiographic progression occurred in 92/222.

	Univariate		Multivariate	
Baseline variables	**OR [CI]**	**P-value**	**OR [CI]**	**P-value**
US GS-score (0-96)	**1.03 [1.01, 1.05]**	**0.005**	**1.03 [1.00, 1.05]**	**0.019**
RF positivity (IgM/IgA)	**1.78 [0.96, 3.29]**	**0.07**	**2.27 [1.13, 4.57]**	**0.022**
Total van der Heijde Sharp score	**1.11 [1.06, 1.17]**	**<0.001**	**1.08 [1.01, 1.14]**	**0.017**

Conclusion: RF positivity, radiographic joint damage and ultrasound gray-scale score were independent baseline predictors of joint damage in early RA patients treated according to an aggressive treatment regimen aiming for remission. This indicates that further individualization of treatment based on risk factors might be needed to optimize disease outcomes, also in treat-to-target strategies.

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is an unmet need for reliable assessment of structural progression in the sacroiliac joints (SIJ) of patients with axial spondyloarthritis (SpA), but radiography is unreliable and lacks responsiveness. The Spondyloarthritis Research Consortium of Canada (SPARCC) SIJ Structural Score (SSS) is developed and proved to be a new reliable scoring method for evaluating structural lesions based on magnetic resonance imaging (MRI). In this study, we tried to record the features of structural lesions using SSS and to validate SSS in Chinese patients with axial SpA.

Methods: Three readers (two radiologists and one rheumatologist) investigated fat metaplasia, erosion, backfill and ankylosis seen on MR images from 423 patients. All these patients fulfilled the 2009 ASAS classification criteria for axial SpA. The SSS method for assessment of these four kinds of structural lesions was based on T1-weighted spin echo MRI, and dichotomous scoring (lesion present/absent) of five consecutive slices through the cartilaginous portion of the joint. Scoring ranges were fat metaplasia (0-40), erosion (0-40), backfill (0-20), and ankylosis (0-20).

Results: There were 342 male and 81 female patients included. The mean age of them was 26.2±8.4 years old. Their symptom duration was 4.7±6.1 years. The total SSS score (sum of four kinds of lesions) of them was 18.4 ± 9.1. 372 (88.0%) were recorded with fat
