SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis is a chronic systemic inflammatory disease often treated with conventional systemic and biologic drugs that may variously be ineffective, be inaccessible, or pose significant safety/tolerability risks. The phase 3b LIBERATE (Evaluation in a Placebo-Controlled Study of Oral Apremilast and Etanercept in Plaque Psoriasis) study (NCT01690299) evaluated the efficacy/safety of apremilast (APR) or etanercept (ETN) vs. placebo (PBO) in biologic-naive patients with moderate to severe plaque psoriasis.

Methods: In the double-blind, double-dummy study, patients were randomized (1:1:1) to PBO, APR 30 mg BID, or ETN 50 mg QW through Week 16; thereafter, all patients switched to or continued APR (PBO/APR, ETN/APR, APR/APR). The primary endpoint was achievement of a ≥75% reduction from baseline Psoriasis Area and Severity Index score (PASI-75) at Week 16 with APR vs. PBO; secondary endpoint was PASI-75 achievement at Week 16 with ETN vs. PBO. Additional physician global assessments (PGA) of disease activity were conducted using the static (sPGA), lattice system (LS-PGA), and scalp (ScPGA) instruments; nail disease was evaluated using the Nail Psoriasis Severity Index (NAPSI). Responses were assessed at Weeks 16 and 52 using the last-observation-carried-forward (LOCF) methodology.

Results: 250 patients received ≥1 dose of study drug, had baseline PASI and ≥1 post-treatment PASI evaluations, and were included in the analysis set (PBO n=84; APR n=83; ETN n=83). At baseline, 66.4% (n=166; PBO n=58; APR n=54; ETN n=54) of patients had an ScPGA score ≥3 (moderate to very severe) and 59.2% (n=148; PBO n=46; APR n=52; ETN n=50) had a NAPSI score ≥1. At Week 16, PASI-75 achievement was significantly greater (P<0.0001) with APR (39.8%) or ETN (48.2%) vs. PBO (11.9%). This study was not designed/powered for APR vs. ETN comparisons; Week 16 PASI-75 achievement did not differ significantly between APR and ETN (P=0.2565, post hoc). At Week 16, APR and ETN produced significantly greater achievement of 0/1 ratings (clear/almost clear) vs. PBO in sPGA, LS-PGA, and ScPGA (clear/minimal) (**Table**). Improvements in nail psoriasis were also achieved with APR and ETN at Week 16 (**Table**). At Week 52, PASI-75 response was sustained in APR/APR (50.6%) and ETN/APR (55.4%) patients; 46.4% of PBO/APR patients had a PASI-75 response (**Table**). sPGA, LS-PGA, and ScPGA responses achieved at Week 16 were generally sustained through Week 52 with APR (**Table**). Continued APR treatment over 52 weeks resulted in further improvements in nail psoriasis (**Table**). Overall, adverse events were comparable among the 3 treatment arms. Adverse events with APR and ETN were consistent with their known safety profiles.

Conclusion: APR demonstrated significant efficacy vs. PBO at Week 16; with continued APR treatment, therapeutic responses were generally sustained at Week 52. Efficacy was maintained in ETN patients who switched to APR.

LIBERATE Efficacy Outcomes			
Patients Achieving Response, % (LOCF)			
Week 16	**PBO n=84**	**APR n=83**	**ETN n=83**
PASI-75	11.9	39.8*	48.2*

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-inflammatory biologic agents have been shown to provide significant benefit in controlling disease activity in psoriatic arthritis (PsA) and inhibiting progression of joint damage. Due to their unique protein structures, biologics have varying capacities to generate anti-drug antibodies (ADAbs), which may affect clinical outcomes. A systematic literature review was conducted to explore the immunogenicity of biologics in PsA, with a focus on the frequency of ADAb formation, the potential effects on safety and efficacy, and predictive factors.

Methods: MEDLINE, EMBASE, and Cochrane databases, conference proceedings and review articles were searched for randomized controlled trials (RCTs) and observational studies in PsA published before 4 September 2015 of abatacept (ABA), adalimumab (ADA), certolizumab pegol (CZP), etanercept (ETN), golimumab (GLM), infliximab (INF), rituximab (RTX), secukinumab (SEC), tocilizumab (TCZ), ustekinumab (UST), and CT-P13.

Results: Of 21,889 publications screened, 14 studies in PsA were retained (randomized controlled trials, n=8; prospective cohort studies, n=6). No published studies with immunogenicity data for ABA, CZP, CT-P13, RTX, or TCZ in PsA were identified. ADAb rates varied widely among studies of other biologics in PsA studies, with the highest frequency in studies of ADA (7–54%) and INF (15–33%) and the lowest in studies of ETN (0%) and SEC (0–0.2%) (table).[1-14] Concomitant use of methotrexate was associated with lower rates of ADAbs against ADA,[5] GLM,[7] INF,[5,8] and UST.[13] Patients with ADAbs against ADA,[1-5] INF,[5,8,9] and UST[13] had lower serum drug levels and poorer efficacy outcomes than those without antibodies. ADAbs against ADA[2] and INF[8,9] were also associated with increased rates of adverse events.

Table. Summary of immunogenicity findings in biologic studies in PsA.

Source	ADAbs n/N (%)	ADAb+ correlation with serum level	ADAb+ correlation with MTX	Clinical relevance
ADA				
van Kuijk et al, 2010[1] (OS)	4/22 (18)	↓ serum drug levels	NR	↓ clinical response
Hoxha et al, 2014[2] (OS)	1/15 (7)	NR	NR	↓ clinical response/↑ AEs
Rosas et al, 2014[3] (OS)	4/10 (40)	↓ serum drug levels	NS	↓ clinical response
Vogelzang et al, 2014[4] (OS)	23/103 (22)	↓ serum drug levels	NR	↓ clinical response
Zisapel et al, 2014[5] (OS)	26/48 (54)	↓ serum drug levels	↓ ADAb+ with MTX	↓ clinical response
ETN				
Mease et al, 2014[6] (RCT/LTE)	0/101 (0)	–	–	–
Zisapel et al, 2014[5] (OS)	0/21 (0)	–	–	–
GLM				
Kavanaugh et al, 2014[7*] (RCT/LTE)	20/335 (6)	NR	↓ ADAb+ with MTX	NR
INF				
Kavanaugh et al, 2007[8] (RCT)	26/173 (15)	NR	↓ ADAb+ with MTX	↓ clinical response/↑ AEs
Garces et al, 2013[9] (OS)	3/9 (33)	NR	NR	↓ clinical response/↑ AEs
Zisapel et al, 2014[5] (OS)	5/24 (21)	↓ serum drug levels	↓ ADAb+ with MTX	↓ clinical response
SEC				
McInnes et al, 2014[10] (RCT)	0/28 (0)	–	–	–
Mease et al, 2015[11] (RCT)	1/587 (0.2)	–	–	–
UST				
Gottlieb et al, 2009[12] (RCT)	14/124 (11)	NR	NR	No correlation with ISRs
Zhu et al, 2013[13†] (RCT)	72/927 (8)	↓ serum drug levels	↓ ADAb+ with MTX	↓ clinical response/ no correlation with ISRs

*Report of 5-year long-term extension of GO-REVEAL study †Report of pooled findings of P-SUMMIT 1 and 2
AE, adverse event; ISR, injection site reaction; LTE, long-term extension; OS, observational study; NR, not reported; NS, not significant; RCT, randomized controlled trial.

Conclusion: Based on this literature review, the prevalence of ADAbs was higher with ADA and INF than with other biologics in PsA, with potentially clinically relevant consequences; ADAbs were not reported with etanercept and their prevalence was low with GLM, SEC, and UST. The immunogenicity of these agents is an important (albeit not the only) consideration when selecting therapy, dose and dosing regimen, and use of background anti-proliferative agents.

Validation of a Two-Question Patient Reported Outcome Measure for Psoriasis

Jessica Mounessa[1], Darren Lynn[1], Jessica Walsh[2], Mena Hashim[1], Ryan Duong[3], Robert Dellavalle[1] and **Liron Caplan**[1], [1]Denver Veterans Affairs Medical Center and UC Denver SOM, Denver, CO, [2]Division of Rheumatology, Salt Lake City Veteran Affairs and University of Utah Medical Centers, Salt Lake City, UT, [3]Rheumatology, Denver Veterans Affairs Medical Center and UC Denver SOM, Denver, CO

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While the psoriasis area and severity index (PASI) is the most commonly used assessment tool for psoriasis severity, it has been criticized for its subjectivity and complexity. Expert training is needed to minimize errors, as well as inter-rater and intra-rater variability. It also burdens the provider and does not incorporate the patient's perspective. We validate a simplified two-item palmPASI against previously established standardized measures of psoriasis involvement.

Methods: Adult patients (18 years or older) with psoriasis or psoriatic arthritis (PsA) in the Veterans Affairs Program to Understand the Longterm outcomes in Spondylo-ARthritis (PULSAR) registry participated in this study. Subjects complete a two item "palmPASI" questionnaire, using a 10-point scale to describe how psoriasis affected the patient and the degree of surface area involvement. These palmPASI scores were then compared to formal four-component PASI scores (erythema, induration, scaling, and involved area of lesions), as determined by health care personnel, as well as the Psoriasis Symptom Inventory (PSI) and Dermatology Life Quality Index (DLQI). Correlations were analyzed using Spearman correlations. The relationship between clinical feature and palmPASI scores was analyzed using logistic regression.

Results: A total of 352 subjects completed the palmPASI and a convenience sample of 40 were examined with the formal PASI. Strong correlations exists between palmPASI and PASI (Spearman's rho=0.75, $p<0.001$; see Figure 1), PSI (Spearman's rho=0.73, $p<0.001$), and DLQI (Spearman's rho=0.77, $p<0.001$). Psoriasis area score was highly correlated with the four-component PASI (Spearman's rho=0.75, $p<0.006$). The test-retest reliability of the palmPASI was excellent (rho=0.93, $p<0.001$). African-Americans and those with elevated c-reactive proteins demonstrated higher palmPASI scores.

Conclusion: Assessment of psoriasis and psoriatic arthritis disease activity is crucial when determining treatment efficacy in clinical research. The palmPASI incorporates patient perspectives, requires less than 10 seconds to score, and demonstrates validity when compared against standard psoriasis instruments. This instrument could potentially serve as a reliable and simple standardized tool to guide evidence-based management.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Axial involvement is less well studied in peripheral spondyloarthritis where chronic back pain is not the predominant symptom, such as in psoriatic arthritis (PsA). Our aim is to describe occurrence of back complaints in newly diagnosed psoriatic arthritis patients and its impact on quality of life for those with chronic back pain (CBP) and inflammatory back pain (IBP).

Methods: Baseline data of incident PsA patients was used from the Dutch south-west Psoriatic Arthritis Registry (DEPAR)

study between August 2013 to March 2016. Trained research nurses took a standardized history and physical examination. Presence of IBP was determined using the Assessment of Spondyloarthritis international Society (ASAS) criteria for IBP. Quality of life was assessed using the Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL), and the Short-Form 36 (SF36) subscales.

Results: In total, 323 patients had a baseline assessment. Average age was 50.4 years (SD 13.7) and 50% were male. 212 patients reported having or having had back pain (65%). 103 patients (32%) reported having back pain for more than 3 months at present or in the past twelve months, which is significantly more than in the general population (21%, P<0.0001 (1)). 33 (10%) fulfilled the ASAS-IBP criteria. We compared patients without back pain (n=111) to CBP patients, and within CBP patients we compared the IBP subgroup (n=33) and the non-IBP subgroup (n=70). CBP patients were more often female (60% vs 41%, p<0.001), and had more often at least one tender enthesis on the LEI and/or MASES (64% vs 34%, p<0.001). Quality of life was significantly worse, as reflected in lower median ASQoL scores (6 and 5 vs. 2, p=0.0001) and lower SF36 subscores compared to patients without back pain. IBP patients had significantly worse scores only on the mental health subscale compared to non-IBP patients with CBP.

Conclusion: chronic back pain is common in psoriatic arthritis and occurs more often in female patients. It has a severe impact on quality of life as assessed by both disease-specific and generic questionnaires, while the difference between inflammatory and non-inflammatory back pain groups is less pronounced.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Tight Control of PsA (TICOPA) study was the first to address treat to target in PsA using the minimal disease activity (MDA) criteria, confirming a benefit in terms of disease activity, function and quality of life. Median changes in modified Sharp-van der Heijde radiographic scores were 0 in both groups. Our aim was to investigate further whether treating to target or achieving low disease activity states predicts radiographic change in the TICOPA study.

Methods: 206 patients with early PsA (<2 years disease duration) were randomised 1:1 to tight control (4 weekly review, treatment escalated to MDA) or standard care (12 weekly review, no set treatment). Radiographs of the hands and feet were taken at week 0 and 48 and scored by consensus using the modified Sharp-van der Heijde (mSvdH) score. Disease states examined included the MDA criteria, Disease Activity in Psoriatic Arthritis (DAPSA) remission and Very Low Disease Activity (VLDA) defined as meeting all 7 of the MDA cutpoints at any timepoint. Bootstrapped quantile regression, adjusting for baseline values and minimisation factors, was used to compare radiographic scores defined according to treatment or disease states at the 50^{th}, 75^{th} and 90^{th} quantiles.

Results: For tight control vs standard therapy, there was no difference in radiographic progression at the median. There was a trend towards reduced progression in total mSvdH score at the 75^{th} & 90^{th} quantiles but this was not significant (see figure and table). For some of the low disease activity states, change in total SvdH score was significantly different at the median for most and at the 75^{th} and 90^{th} quantile (see figure and table). In all cases the trend was towards less progression in the low disease states. Changes in erosion scores were non-significant.

Conclusion: There was no significant difference in radiographic outcome seen with tight control although progression was numerically lower. Achieving MDA, DAPSA remission or VLDA was significantly predictive of total SvdH score for median and some 75/90^{th} quantile scores. Radiographic progression was consistently numerically lower in those achieving the disease states. The lack of effect on erosion scores is likely to reflect the TICOPA study design including a population with early milder disease (30% oligoarthritis), no placebo comparison and a step up treatment protocol. These data suggest a potential impact of tight control and achieving low disease activity states on radiographic outcome but should be interpreted with caution.

SvdH total score	Coefficient (95% CI)	P value	Coefficient (95% CI)	P value	Coefficient (95% CI)	P value
Quantile tested	50		75		90	
Tight control	0.00 (-0.68, 0.68)	1.0	-0.78 (-2.24, 0.68)	0.291	-1.22 (-4.63, 2.18)	0.480

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Up to 40% of patients with inflammatory arthritis on TNF-α inhibitor (TNFi) treatment fail to respond either due to primary inefficacy or loss of response. Based on our previous work (1-2) and others (3), one explanation is immunogenicity leading to the development of anti-drug antibodies (ADAb) and subsequent low drug levels, which has been described in RA. Few data exist on whether such pharmacological tests correlate with treatment response in PsA. Furthermore, the value of measuring such biomarkers may be different between monoclonal antibodies and TNF receptor proteins. Our aim was to (i) evaluate whether the presence of ADAbs/drug levels predict treatment response in patients with PsA treated with TNFi drugs (ii) identify factors that may be associated with drug levels.

Methods: 75 patients were available from the Outcomes of Treatment in PsA Study Syndicate (OUTPASS) (n=49 adalimumab; n=26 etanercept), a national UK prospective observational cohort. Serum samples were collected at 3, 6 and 12 months following initiation of TNFi therapy. ADAbs were measured using radioimmunoassay (RIA) and random (non-trough) drug levels using ELISA assays at 3, 6 and 12 months. Disease activity (DAS28) scores were measured at each visit. Patient self-reported adherence to TNFi was measured at each time-point. Generalised estimating equation (GEE) was used to test the association between ADAbs and drug levels, both biomarkers and treatment response [as assessed by change in DAS28 score between pre-treatment and 12 months post-treatment (ΔDAS28)] and the association between longitudinal/baseline factors with drug levels.

Results: 264 serial samples were suitable for pharmacological testing (n= 174 adalimumab; n=90 etanercept). Mean age was 51±12 years; 61% were female; median BMI 28.9 (IQR 26.0-34.9). 20% (n=10/49) of adalimumab-treated patients were positive for ADAbs, but none were detected in etanercept-treated patients. There was no significant association between etanercept drug levels and ΔDAS over 12 months [β= -0.039 (95% CI -0.31, 0.23), p=0.77]. Using GEE, adalimumab drug levels were significantly associated with ΔDAS28 over 12 months [β= 0.055 (95% CI: 0.011, 0.099) p=0.014], but was not independently associated with ADAb level [β=-0.0015 (95% CI: -0.0031, 0.000047), p=0.057]. Adalimumab concentrations between 4.5-8.5 mg/L were associated with an optimal treatment response at 6 months using concentration-effect curves. Factors that remained significantly associated with adalimumab drug levels were ADAb level [β=-0.0073 (95% CI: -0.0014, 0.18), p<0.0001] and BMI [β=-0.15 (-0.29, -0.00450, p=0.043] in the final GEE model (adjusting for age, gender, adherence, BMI).

Conclusion: TNFi drug-level testing on samples taken at random time-points in the treatment cycle in adalimumab-initiated PsA patients may be clinically useful in determining treatment response over 12 months; interestingly, both the presence of ADAbs and BMI were inversely associated with drug levels. Identification of a drug level threshold for optimal response may help tailor adalimumab therapy for PsA patients in the future. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Minimal disease activity (MDA) is an important goal for patients with rheumatologic disorders, including psoriatic arthritis (PsA). The assessment of MDA could potentially help guide therapeutic modifications as a part of treat-to-target strategies. The availability of data from a large PsA cohort in an observational study of routine clinical care offered a unique possibility to investigate the potential value of MDA as an instrument for guiding treatment decisions during daily clinical practice.

Methods: We analyzed data from a large German multicenter observational study of patients with active PsA who initiated adalimumab (ADA) therapy during routine clinical care. Patients with active disease (Disease Activity Score-28 joints [DAS28] ≥3.2), joint involvement, and adequate MDA data were included in these evaluations. MDA was defined as meeting 5 of 7 criteria as reported by Coates et al. (*Ann Rheum Dis*2010;69:48-53), with slight modifications to criteria for pain, function, and enthesitis to reflect available data. Patients were followed for up to 24 months.

Results: Of 1684 patients with PsA who initiated ADA, the mean age was 50 years, 51% were female, and the disease duration was 9.5 and 18.1 years for arthritis symptoms and psoriasis, respectively. A total of 597/1684 (35.5%) patients achieved MDA at month 6. This proportion increased slightly during the 24-month study (454/1098 [41.3%] at month 12; 348/764 [45.5%] at month 24), likely due to responder bias. Pain was the most difficult criterion to achieve and the absence of enthesitis was the criterion most likely to be fulfilled (Table 1). Correlation analyses for month 6 data found that PGA ≤2 had the highest correlation with the achievement of MDA (Pearson correlation coefficient=0.72), followed by TJC ≤1 (0.61) and pain ≤1 (0.60), while absence of enthesitis (0.21) and BSA ≤3% (0.31) had the lowest correlations with MDA (P<0.001 for all analyses). Among patients with complete data available for all time points from month 6 to month 24 (n=554), 214 (38.6%) achieved an MDA at month 6. Of the patients who achieved MDA at month 6, 118 of 214 (55.1%) also had an MDA at all subsequent time points (months 9, 12, 18, and 24). Of the patients who did not achieve an MDA at month 6 (n=340), 201 (59.1%) failed to achieve an MDA at any subsequent time point.

MDA Criteria	**% of patients (n=1684)**
Tender joint count (TJC) ≤1	46.6%
Swollen joint count (SJC) ≤1	70.1%
Body surface area (BSA) ≤3%	64.8%
Patient pain score ≤1 on a 0-10 point scale*	21.1%
Patient global disease activity (PGA) ≤2	40.1%
Funktionsfragebogen Hannover score ≥83% remaining function†	47.4%
No enthesitis‡	88.8%
*Published criterion is ≤15 points on a 100 point scale †Published criterion is Health Assessment Questionnaire ≤ 0.5 ‡Published criterion is tender entheseal points ≤ 1	

Conclusion: MDA criteria provide a stable assessment of therapeutic response during ADA therapy; most patients who achieved MDA at month 6 experienced sustained MDA, while most patients who did not achieve MDA at month 6 did not reach MDA at any subsequent time point. PGA had the highest correlation with MDA, while enthesitis had the lowest. Our data confirm the relevance of assessing MDA in patients with PsA and indicate that MDA may be useful in guiding therapy in treat-to-target strategies.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The information on the population-based prevalence of Psoriatic Arthritis (PsA) is limited. Large population-based databases provide an opportunity to study the epidemiology of PsA, however, strict validation procedures for case ascertainment are required. We aimed to examine the validity of a diagnostic code for PsA in Clalit Health Services (CHS) database in Israel and to estimate its point prevalence in the general population.

Methods: CHS database, Israel's largest public health fund serving 4.3 million enrollees (>50% of Israel's population), has real-time input from pharmaceutical, medical and administrative operating systems. CHS database was searched for all individuals who received their initial diagnostic code of PsA (ICD-9 code 696.0) in 2014. Cases were divided according to the type of specialist (rheumatologists, family physicians, dermatologists, orthopedics) who assigned the diagnostic code of PsA.. Approximately 25% of the cases in each subspecialty group were selected at random for the validation of a diagnostic code of PsA. All medical records of these patients were thoroughly read by two rheumatologists. Based on this information a decision was made whether the PsA diagnosis was 1) definite/probable PsA; 2) not PsA; 3) no data to verify the diagnosis of PsA. We calculated the positive predicted value (PPV) and the 95% confidence interval in each group. Several algorithms were examined to determine the method resulting in the highest PPV. The sensitivity and specificity for the selected algorithm were calculated and the point prevalence of PsA in the general population and its 95% confidence interval (CI) were estimated.

Results: 869 individuals who received a diagnosis of PsA in 2014 were identified. 205 cases were selected for validation based on the specialty of the physician who assigned the diagnosis. The proportion of ICD-9 codes that could be confirmed

by reviewing the medical records was 94%. The PPVs for a diagnostic code assigned by a rheumatologist or given during hospitalization was: 90.5% (95% CI 82.3%, 95.3%), orthopedics 18.2% (95% CI 3.2%, 52.2%) dermatologists 13.3% (95% CI 2.3%, 41.6%) and family physicians 50% (95% CI 29.6%, 70.3%). The selected algorithm comprised the PsA code assigned by a rheumatologist, or a permanent diagnosis code assigned by a family physician combined with use of DMARDs, or PsA code given during hospitalization. This algorithm had sensitivity and specificity of 88.7% and 88.1%, respectively. Using the validated algorithm, 3874 PsA patients were identified among a population of 4,296,000 enrollees in the CHS database, reflecting prevalence of 90 per 100,000 (95% CI 87, 93 per 100,000).

Conclusion: Data within electronic medical records can be used to accurately identify patients with PsA. The estimated prevalence of PsA in the general population in Israel is 0.09%. This figure is consistent with other population-based estimates.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) often develops between the 3rd to 5th decades of life. However, little is known about PsA activity and prognosis among patients who develop it at an older age. Hence, our aims were: 1) To evaluate disease activity of late onset PsA (LoPsA) patients at presentation and during follow-up, and 2) To evaluate prognosis after several years of follow-up, compared to younger onset PsA patients (YoPsA).

Methods: The study population included patients from a large longitudinal PsA cohort**.** The patients are followed prospectively according to a standard protocol and all data are stored in a computerized database. Only patients who started their follow up in the PsA clinic within 2 years from diagnosis were included. Patients were divided into two groups: 1) Late onset PsA (LoPsA) – defined as disease onset after the age of 50, 2) Younger onset PsA (YoPsA) – defined as disease onset before age 50. Disease activity over time was calculated according to the adjusted mean active joint count. Patients were compared at presentation, and after 5 years of follow-up. Descriptive statistics are provided and multivariate logistic regression models were developed to compare the two groups.

Results: Five hundred and sixty six patients were included at presentation, 177 above the age of 50 years and 389 below 50 years. The LoPsA group included more women (53% vs 41%, p=0.01). The LoPsA had significantly higher BMI (30.7 ± 7.4 vs 28.2 ± 6.1, p<0.001), more clinically damaged joints at presentation (0.9 ± 2.2 vs 0.3 ± 1.6, p=0.001) and higher modified Steinbrocker score (mSS) (4.3 ± 7.9 vs 1.8 ± 1.4, p=0.0001) (Table 1). Multivariate logistic regression analysis showed that the following variables were independently associated with being in the LoPsA group at presentation: less males (OR 0.4, p=0.001), less HLA-C*06 (OR 0.3, p=0.008), longer psoriasis duration (OR 1.04, p=0.0003), higher BMI

(OR 1.1, p=0.002) and higher mSS (OR 1.1, p=0.009). After 5 years of follow-up, the LoPsA patients showed a non-significant trend for higher adjusted mean active joint count compared to the YoPsA (7.1 ± 7.3 vs 5± 5.2, p=0.07) as well as higher mean mSS compared to the YoPsA (0.7 ± 1.7 vs 0.3 ± 1.3, p=0.02). Multivariate logistic regression analysis revealed higher adjusted mean active joint count (OR 2.04, p=0.049) and higher mean mSS score (OR 2.4, p=0.009) in the LoSpA group compared to the YoPsA group. .

Conclusion: The LoPsA patients at presentation are characterized by female predominance, higher BMI, more damage and less HLA-C*06. After 5 years of follow-up the LoPsA patients are associated with worse prognosis manifested by higher disease activity and more damage.

Table 1: Characteristics of LoPsA and YoPsA at presentation

Variable	YoPsA (n=389)	LoPsA (n=177)	P value
Age at PsA diagnosis, years ± s.d.	34.8 ± 8.5	58.4 ± 7.7	
Age at psoriasis, years ± s.d.	25 ± 10.6	42.4 ± 16.7	<0.001
Females gender, n (%)	159 (41%)	93 (53)	0.01
BMI, mean ± s.d.	28.2 ± 6.1	30.7 ± 7.4	<0.001
Smoking history, n (%)	164 (45)	83 (50)	0.3
Actively inflamed joints count, mean ±s.d.	7.9 ± 8.4	8.7 ± 9.9	0.4
Tenosynovitis, n (%)	85 (22)	34 (19)	0.51
Dactylitis, n (%)	126 (33)	36 (21)	0.003
Damaged joint count, mean ± s.d.	0.3 ± 1.6	0.9 ±2.2	0.001
Modified Steinbrocker score, mean ± s.d.	1.8 ± 4.3	4.3 ± 7.9	0.0001
Sacroiliitis, n (%)	80 (22)	45 (27)	0.3
PASI, mean ± s.d.	5.3 ± 7.8	6 ± 9.8	0.4
Nail involvement, n (%)	150 (39)	67 (38)	0.9
CRP, n (%) positive	56 (46)	24 (34)	0.13
ESR, n (%) positive	142 (43)	71 (46)	0.5
HLA-B*27 (%) positive	44 (14)	16 (12)	0.5
HLA-C*06 (%) positive	79 (26)	24 (18)	0.087

LoPsA – Late onset PsA, YoPsA – Young onset PsA, BMI – Body mass index, PASI – Psoriasis activity severity index, CRP – C reactive protein, ESR – Erythrocyte sedimentation rate

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: RAPID3 (routine assessment of patient index data) is a patient self-report index which is feasible in busy clinical settings to assess severity and change in clinical status in many rheumatic diseases, including RA, OA, gout, AxSpA. RAPID3 (0-30) includes 3 0-10 measures: a health assessment questionnaire (HAQ) or its multidimensional version (MDHAQ) measuring physical function and two 0-10 visual analogue scales (VAS) for pain and patient global estimate. A score of ≤3 (of 30) identifies near remission (NR) in rheumatoid arthritis. RAPID3 is correlated significantly with other PsA measures; a RAPID3Ps has also been investigated with the addition of a skin VAS for PsA. The Minimal Disease Activity (MDA) criteria for PsA require achievement of 5 of 7 cutpoints in 7 measures: the three RAPID measures; tender joint count (TJC); swollen joint count (SJC); enthesitis count and skin measure. Our aim was to compare patients achieving RAPID3 and RAPID3Ps near remission and MDA criteria in PsA in individual patients in the Tight Control of Psoriatic Arthritis (TICOPA) trial.

Methods: Data from TICOPA were analysed to identify patients achieving RAPID3 and RAPID3Ps NR, and the patients were compared to those achieving the MDA criteria. MDA was achieved if patients achieved 5 of the 7 following cut points: TJC ≤1; SJC ≤1; enthesitis ≤1; PASI ≤1; HAQ function ≤0.5; global VAS ≤20 and pain VAS ≤15. Frequency of residual active disease in the RAPID3 NR states was investigated. A measure of acute phase response is not included in either measure, but CRP levels were assessed to recognize whether an active acute phase response was missed.

Results: The percentage exact agreement (PEA) between RAPID3 NR and MDA was 83.8, 89.8, 87.1, 85.2 at 12, 24, 36, 48 weeks respectively. Adding the skin component to create RAPID3Ps and using the equivalent NR cutpoint (4/40) led to PEA of 85.1, 88.0, 88.5 and 85.1 respectively. Very few patients (2.2-3.8%) were in RAPID3NR but not MDA due to high physician assessed outcomes. For patients in RAPID3NR at the end of the study, residual disease activity is shown in the table. Levels of skin disease in this population were very low with PASI of 0 in 94% of these patients.

Conclusion: RAPID3NR and RAPID3PsNR shows good agreement with the MDA criteria in PsA. The addition of a psoriasis measure did not change the results meaningfully in this population, but may be more infortative in patients with more severe skin disease. The RAPID3 NR definition does allow significant residual disease in a few patients but may be useful as an adjunct to physician examination when monitoring disease activity.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: PASDAS is a composite disease activity measure (range 0–10) for psoriatic arthritis (PsA). Recently, PASDAS disease activity cutoffs were proposed and a minimal disease activity (MDA) state for PsA was also defined as a target for treatment. We aimed to establish a cutoff value of PASDAS that defines MDA state, to validate previously defined PASDAS cutoffs for low and high disease activity (3.2 and 5.4), and to define PASDAS cutoffs reflecting disease activity in our cohort.

Methods: All patients meeting CASPAR criteria were prospectively recruited from a PsA clinic and items necessary to complete the PASDAS and the MDA were evaluated. For aim 1, ROC curve analysis determined the optimal PASDAS cutoff discriminating patients based on MDA state. This analysis was subsequently repeated twice changing the discriminating criteria to meeting 6 of 7 and all 7 of the 7 MDA criteria. For aim 2 sensitivity and specificity of the previously defined PASDAS cutoffs for high and low disease activity were determined. For aim 3 patients were dichotomized based on the decision to escalate treatment by the treating physician (indicator of high disease activity). ROC curve analysis (90% specificity) estimated the PASDAS cutoff for high disease activity. Further, the median value of PASDAS for each treatment change group estimated PASDAS cutoffs for low and high disease. Lastly, ROC curves (90% specificity) estimated PASDAS cutoffs using patient's global assessment of disease activity (PGA) as an external standard (<10 low; ≥10 moderate <60; ≥60 high). The mean values obtained by the 3 methods defined the final PASDAS cutoffs.

Results: 178 patients [53.9% male, mean age 56.8 years, disease duration 17.6 years, mean (SD) PASDAS 3.29 (1.29), 48.9% in MDA] were recruited. See table 1. PASDAS of <3.2 defined MDA (AUC- 0.96, sensitivity 88% [95% CI: 80-93%], specificity 92% [95% CI: 84-96%], Youden index- 0.80). For MDA based on meeting 6 of 7 criteria and all 7 of 7 criteria PASDAS scores of 2.6 and 2.1 maximized sensitivity and specificity, respectively. The published PASDAS cutoffs showed the following sensitivities and specificities (%), respectively: low- 100, 56; high- 12, 99 (PGA as external criterion). ROC curve analysis using treatment escalation as discriminating variable estimated a PASDAS high disease activity cutoff of 4.7 (AUC- 0.76). Median PASDAS of escalation and no-escalation groups were 4.17 and 2.86, respectively. When using PGA, PASDAS cutoffs for low and high disease were 2.08 (AUC- 0.95) and 4.14 (AUC- 0.93), respectively. The final PASDAS cutoffs (mean of 3 methods) for low and high disease activity cutoffs were 2.5 and 4.3, respectively.

Conclusion: A PASDAS score <3.2 reflects MDA. MDA based on stricter criteria may better reflect low disease activity state. Previously defined PASDAS cutoff for low disease activity state has high sensitivity while high disease activity cutoff has high specificity. Our cohort produced lower cutoffs.

Table 1: Cutoff values of PASDAS obtained from various methods.

Cutoff	ROC curve (MDA 5/7)	ROC curve (MDA 6/7)	ROC curve (MDA 7/7)	ROC curve (treatment escalation)	Median Scores	ROC curve (PGA)	Final PASDAS (means)
MDA state	3.2	2.6	2.1	-	-	-	-
Low disease activity state	-	-	-	-	2.86	2.08	2.5
High disease activity state	-	-	-	4.7	4.17	4.14	4.3

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Depression and anxiety are well known comorbidities in psoriasis (PsO) and psoriatic arthritis (PsA) with higher prevalence in PsA. Patients with PsA have a worse quality of life than PsO, and the presence of joint pain is associated with higher rates of depression[1]. Previous studies suggested that disease control may reduce symptoms of depression in PsO[2]. Minimal disease activity (MDA) is a desirable state when treating patients with PsA, giving better outcomes as a target overall[3]. To date, no study has evaluated the effect of depression/anxiety on MDA in PsA. The aim of the study was to 1) Compare depression/anxiety scores between patients with MDA to those not in MDA (NMDA) in PsA. 2) Assess the effect of disease related variables, treatment, and depression and anxiety scores on MDA state.

Methods: PsA patients fulfilling the CASPAR criteria were recruited. Patients were assessed for depression/anxiety using the Hospital Anxiety and Depression Scale (HADS-A and HADS-D) and Penn State Worry Questionnaire (PSWQ). Medical history including previous diagnosis or treatment for depression and anxiety, and risk factors of depression was taken. Patients underwent joint and skin assessments and completed questionnaires on health and quality of life. We compared the HADS-D and HADS-A scores and the % of patients with normal (0-7), borderline (8-10) and abnormal (11-21) categories between patients with MDA to those with NMDA, and anxiety by using PSWQ scores and the % of patients in low (16-39), moderate (40-59) and high (60-80) worry categories. Data were analyzed using Mann Whitney, Fisher's exact, Chi-square tests and logistic regression analyses.

Results: 100 PsA patients were recruited, 40 patients were in MDA (age 52±10.6 years, male 55%) and 60 patients in NMDA (age 52±10.6 years, male 55%). TJC68 and SJC66 were lower in MDA compared to NMDA group (P<0.001) with no significant difference in the other 5 items of MDA, the number of patients on DMARD, biological treatment, and depression and anxiety medications. The % of patients with normal, borderline and abnormal HADS-D scores were 95%, 5% and 0 in MDA group vs. 80%, 15% and 5% in NMDA (P=0.084), respectively. Mean HADS-D score was significantly lower in MDA compared to NMDA (2.5±2.4 vs. 4.22±3.4, P=0.009). The % of patients with normal, borderline and abnormal HADS-A scores were 92.5%, 7.5% and 0 in MDA vs. 76%, 17% and 7% in NMDA (P=0.078), respectively. Mean HADS-A score was lower in MDA compared to NMDA. The number of patients in low, moderate and high worry categories and the mean PSWQ scores were similar in both groups. Logistic regression analyses revealed significant relationship between lower TJC (B=0.508 (CI95% 0.37-0.7) P<0.001), lower HADS-D (B=0.841 (CI95% 0.71-0.99) P=0.043) and MDA state.

Conclusion: This is the first study assessing the effect of depression and anxiety on MDA. We found lower depression scores in patients with MDA compared to those in NMDA and significant relationship between depression and MDA state. Our results suggest the importance of recognizing depression in PsA since psychological well-being may contribute to MDA state. **References:**

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this analysis was to investigate differences in baseline demographic and clinical characteristics of patients with psoriatic arthritis (PsA) who responded to biologics vs those who were non-responders using the US-based Corrona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) registry.

Methods: This analysis included all patients with PsA aged ≥ 18 years enrolled in the Corrona PsA/SpA registry between March 2013 and March 2016 who were receiving biologics at the time of enrollment (baseline) and had ≥ 2 follow-up visits (at 6-month intervals). Responders were defined as those patients who remained on their index biologic and achieved minimal disease activity (MDA) at the second follow-up visit (mean [SD] follow-up, 15.7 [3.7] months) from baseline.[1] Information on demographics, clinical characteristics, patient-reported outcomes and past/current treatments were collected for all patients at baseline enrollment. Statistical comparisons between responders and non-responders were examined by *t*-tests for continuous variables and chi-square tests (or Fisher's exact tests) of independence for categorical variables.

Results: There were 148 patients with PsA in the Corrona PsA/SpA registry that met the inclusion criteria. At the second follow-up visit 34 patients (23.0%) were classified as responders and 114 patients (77.0%) were considered non-responders. The majority of patients were receiving anti–tumor necrosis factor agents at registry enrollment (96.6%). At

baseline, responders and non-responders were similar with regards to age, sex, race, disease duration, prevalence of comorbidities (cardiovascular disease, any cancer, diabetes and serious infection), multiple disease measures (e.g., enthesitis and dactylitis counts, Clinical Disease Activity Index and acute phase reactants) and prior/current treatments. Compared with non-responders, responders to biologics had significantly milder disease at the time of registry enrollment as measured by mean tender joint count (3.4 vs 7.2), patient-reported pain (35.7 vs 51.2), patient-reported fatigue (42.4 vs 54.1), Health Assessment Questionnaire score (0.6 vs 1.0), Bath Ankylosing Spondylitis Disease Activity Index score (3.4 vs 5.0) and Bath Ankylosing Spondylitis Functional Index score (2.0 vs 4.0) (**Table**).

Conclusion: This study from the Corrona PsA/SpA registry found that only 23.0% of patients achieved MDA with their index biologic at the time of the second follow-up visit (mean [SD] follow-up, 15.7 [3.7] months) and were considered responders. Both cohorts were similar with regards to several baseline demographic and clinical characteristics; however, responders generally had less severe disease at enrollment compared with non-responders.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: ACTIVE is the first apremilast (APR) trial that evaluated time to onset of efficacy beginning at Wk 2 in psoriatic arthritis (PsA) patients (pts) who were biologic-naïve and may have had ≤1 prior conventional disease-modifying antirheumatic drug. We report the study results through Wk 52.

Methods: Pts were randomized (1:1) to APR 30 mg BID or placebo (PBO). At Wk 16, pts whose swollen and tender joint counts (SJC/TJC) had not improved ≥10% were eligible for early escape (investigator discretion): PBO pts received APR, and APR pts continued on APR. At Wk 24, all pts entered the active treatment phase with APR. The primary endpoint was ACR20 response at Wk 16. Other assessments included changes in DAS-28 (CRP), SJC, TJC, and HAQ-DI, morning stiffness duration/severity, and enthesitis, as measured by the Gladman Enthesitis Index (GEI; 0=no enthesitis, 6=all 6 sites active). Along with collection of safety data, tolerability adverse events (AEs) of diarrhea were further characterized.

Results: A total of 219 pts were randomized (APR: n=110; PBO: n=109); 84.5% completed Wk 24 (APR: n=87; PBO: n=98). Separation in the proportion of ACR20 responders to APR vs PBO was noted at Wk 2 (16.4% vs 6.4%; *P*=0.0252), the first post-baseline (BL) visit. Early onset of response to APR was observed across clinical assessments, with improvements in DAS-28 (CRP), SJC, HAQ-DI, enthesitis, and morning stiffness severity (Table). At Wk 16, APR showed significant reduction in PsA disease activity and manifestations vs PBO, with an ACR20 response rate of 38.2% vs 20.2% (*P*=0.0040); DAS-28 (CRP) change of −1.07 vs −0.39 (*P*<0.0001); SJC change of −44.8% vs 1.9%; HAQ-DI change of −0.21 vs −0.06 (*P*=0.0229); improvement in morning stiffness severity in 46.4% vs 26.6% of pts; and GEI change of −1.5 vs −0.4 (*P*=0.0014). With continued APR exposure, the Wk 52 ACR20 response rate was 63.3%, ACR50 and ACR70 response rates were 32.4% and 14.0%, and percent change in SJC was −74.5%. Among APR pts with BL enthesitis, 62.8% reached a GEI of 0. Overall incidence of AEs in the PBO-controlled period was generally similar between APR and PBO. The most commonly reported AEs in ≥5% of pts with APR vs PBO were nasopharyngitis (8.3% vs 6.4%), nausea (8.3% vs 1.8%), headache (7.3% vs 3.7%), hypertension (6.4% vs 6.4%), and diarrhea (14.7% vs 11.0%); using a protocol-defined characterization of diarrhea (≥2 watery/liquid stools/day), overall incidence was lower for APR and PBO (11.0% and 8.3%). Serious AEs were lower with APR vs PBO (2.8% vs 4.6%). In general, no increase was seen in AE incidence/severity with longer-term exposure to APR.

Conclusion: In biologic-naïve pts treated with APR, onset of effect was observed starting with Wk 2, with sustained improvements across PsA manifestations, including morning stiffness and enthesitis through Wk 52. AEs were consistent with those reported for other APR phase III PsA and psoriasis studies.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pooled safety data from the psoriasis (PsO) and psoriatic arthritis (PsA) clinical trial programs of secukinumab (SEC), through approximately 1 year, have been reported previously.[1,2] Specifically, the exposure-adjusted incidence rates (EAIRs) of adverse events (AEs) and serious adverse events (SAEs) for PsO and PsA were 252.9 and 7.8, and 210.3 and 9.0 per 100 patient (pt)-years, respectively. Here we present updated analyses following additional exposure (with a 25 Dec 2015 data cut-off), either from a larger study pool (PsO) and/or an extended follow-up period (PsO, PsA).

Methods: The updated PsO pool consisted of 4 Phase II and 9 Phase III studies in pts with moderate-to-severe plaque PsO, including 2 active comparator studies with etanercept (ETN) and ustekinumab (UST), respectively; the PsA pool consisted of 2 PBO-controlled Phase III studies in pts with active PsA. SEC doses differed in the studies and included intravenous (3–10 mg/kg) or subcutaneous (75–300 mg) loading, followed by subcutaneous maintenance dosing (300, 150, or 75 mg). PBO pts were re-randomized to SEC between 12–24 weeks in the various studies. EAIRs were calculated to minimize the impact of between-group differences in treatment exposure.

Results: In both the PsO and PsA pools, the most frequently reported AEs with SEC were non-serious infections, including nasopharyngitis and upper respiratory tract infection, headache, and arthralgia (Table). The EAIRs of AEs of special interest, including Crohn's disease, *Candida* infections, serious infections, neutropenia, major adverse cardiac events, and malignancy, with SEC (reported in the Table) were similar across PsO and PsA studies, and comparable to those reported previously.[1,2]

Conclusion: Treatment with SEC was well tolerated in PsO and PsA patients. This longer-term safety assessment was consistent with previous reports,[1,2] and did not identify any new safety signals. The long-term safety profile of SEC was comparable across PsO and PsA patients, allowing a broader understanding of the safety of SEC in these two closely related disease populations. **References:** 1. Van de Kerkhof PCM, et al. *J Am Acad Dermatol* 2016;75:83–98; 2. Mease PJ, et al. A*rthritis Rheumatol* 2015; 67 (suppl 10):A2886

Table. Summary of pooled safety across 13 PsO studies and 2 PsA studies (entire safety period)

	PsO			PsA

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While rheumatoid arthritis (RA) has been linked to an increased incidence of osteoporosis (OP) and fracture, few studies have examined the risk of fracture associated with psoriasis and psoriatic arthritis (PsA). In this study, we determined the risk of fracture among patients with PsA, psoriasis and RA compared with the general population.

Methods: A longitudinal cohort study was conducted in The Health Improvement Network (THIN), a primary care medical record database in the United Kingdom, to determine the risk of fracture (all, hip, and vertebral) using data from 1994-2014. Patients aged 18-89 with a diagnosis of PsA, RA, or psoriasis were selected. Diagnosis codes for PsA, RA, and psoriasis have been validated in THIN. Up to 5 unexposed controls matched on practice and start date within the practice were selected for each exposed patient. Cox proportional hazards models were used to calculate the adjusted hazard ratios (aHR) for each outcome. Multivariable models were constructed to include known risk factors and potential confounders (p-value<0.05 and changed the main effects by >10%).

Results: Patients with PsA (N=9,788), RA (N=39,306), psoriasis (N=158,323) and unexposed controls (N=821,834) were identified. Patients with RA had a significantly elevated risk of fracture: all, hip, and vertebral aHR: 1.23 (1.18-1.28), 1.55 (1.40-1.72), 1.53 (1.30-1.80) respectively. Those with mild psoriasis had significantly elevated risk of all fractures and hip fracture: aHR 1.07 (1.05-1.10) and 1.13 (1.04-1.22). Patients with severe psoriasis had significantly elevated risk of all fracture and vertebral fracture: aHR 1.26 (1.15-1.39) and 2.23 (1.03-1.33). Patients with PsA had a significantly elevated risk of all fracture: aHR 1.26 (1.06-1.27). Patients with PsA had an elevated aHR for hip fracture (1.17; 0.86-1.59), however, this was not statistically significant. These results were robust to several sensitivity analyses.

Conclusion: Patients with PsA, severe psoriasis and RA have an elevated risk for fracture. These results underscore the importance of screening for osteoporosis among patients with these inflammatory conditions.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a multifaceted disease. Affecting joints, skin, entheses and dactylitis, its impact on health-related quality-of-life (HRQoL) could be substantial. Up to now, the joints have been the main focus of treatment, while other disease facets were expected to improve along with DMARD treatment. Our aim is to describe HRQoL in newly diagnosed PsA patients taking into account swollen joints, tender entheses, dactylitis and the extent of skin involvement.

Methods: Baseline data of incident PsA patients was used from the Dutch south-west Psoriatic Arthritis Registry (DEPAR) study between August 2013 and March 2016. HRQoL was assessed by 8 subscales of the Short-Form 36 (SF-36) questionnaire (0-100, higher score represents a better HRQoL). Patients were classified in arthritis subtypes (i.e. mono-, oligo- or polyarthritis) by their rheumatologist. Entheses were evaluated using the Leeds Enthesitis Index (LEI) and Maastricht Ankylosing Spondylitis Enthesitis Score (MASES; positive if tender entheses >1). Psoriasis was evaluated using the Psoriasis Area Severity Index (PASI; mild: 0-7; moderate/severe: >7) and dactylitis using the Leeds Dactylitis Index (LDI).

Results: 271 patients completed the SF-36 at baseline. Their average age was 50.4 years (SD 13.7) and 50% were male. 256 patients had arthritis: 62 had monoarthritis (M), 125 oligoarthritis (O) and 69 polyarthritis (P). Psoriasis was mild in 74% and moderate/severe in 13%. At least one digit with dactylitis was present in 12% of the patients. A tender enthesis was present in 47% of patients. Mean scores of the subdomains in the SF-36 were similar across the different arthritis-groups, with slightly worse scores for polyarthritis compared to mono- and oligoarthritis. However, when stratifying these groups for the presence of a tender enthesis, HRQoL decreased substantially for all groups across all subdomains of the SF-36, with a median difference of 14.3 points. Irrespective of joint involvement, a tender enthesis (n=127) decreased the mean scores of all subdomains significantly compared to the non-tender enthesis group (n=144, p=0.0001). Severity of psoriasis and presence of dactylitis did not lead to significantly different SF-36 values compared to those not affected.

Conclusion: Having tender entheses impacts HRQoL severly in both its physical and mental dimensions in incident untreated PsA.

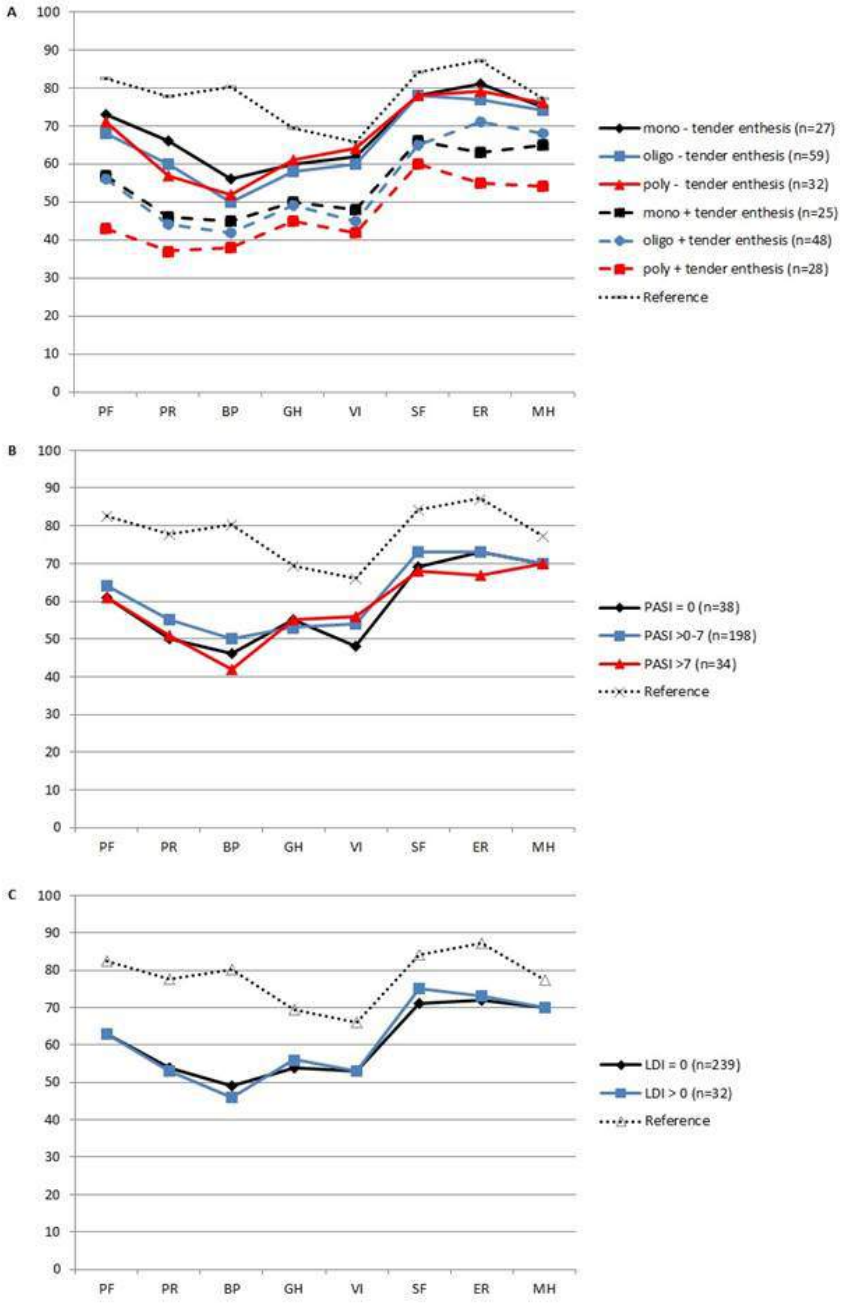

Figure 1. Health related quality of life in patients with monoarthritis (mono), oligoarthritis (oligo), and polyarthritis (poly), with and without presence of a tender enthesis, in different Psoriasis Area Severity Index (PASI) categories and different Leeds Dactylitis Index (LDI) categories. Measured by physical functioning (PF), physical role functioning (PR), bodily pain (BP), general health (GH), vitality (VI), social functioning (SF), emotional role functioning (ER), and mental health (MH) (SF-36)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ustekinumab (UST), an anti IL12/IL23 monoclonal antibody, is a relatively new biologic used for the treatment of psoriasis (PSO) and psoriatic arthritis (PSA). Its safety profile in real world practice has not been well characterized to date. We assessed the incidence rate (IR) of acute myocardial infarction (AMI) in ustekinumab users and compared it to the corresponding rate for patients treated with tumor necrosis factor inhibitors (TNFi).

Methods: We conducted a retrospective, new user design cohort study of PSO and PSA patients initiating UST or TNFi using 2010-2014 Market scan and 2006-2014 Medicare data. To be included in the cohort, patients have to have at least 12 consecutive months of medical and pharmacy coverage before first prescription date of UST or TNFi (index date). Patients were excluded if they have any of the following: inflammatory disease other than PSO or PSA, prior MI, prior PCI/CABG, malignancy (except non-melanoma skin cancer), HIV, or organ transplant. A sensitivity analysis had more stringent exclusions for patients with past evidence for acute coronary syndrome, angina, or coronary atherosclerosis. Follow up started at index date and ended at earliest of: discontinuation of the index drug (90 days after days of supply), switch to another biologic, the outcome, loss of insurance coverage, death, or end of study (12/31/2014). Patients contributed to only one episode of one specific drug but could contribute to multiple drugs, and standard errors were adjusted to account for this clustering. AMI was identified using diagnosis codes from hospital discharge (Primary or non-primary). Incidence rates (IR) were calculated by dividing number of outcomes by person year exposed. Crude and multi-variable adjusted hazard ratios (HR) were calculated with Cox proportional hazard regression, controlling for potential confounders.

Results: The final cohort included 46,338 initiations of UST or TNFi (17,750 from Medicare, 28,588 from Market scan) representing 39,469 unique patients. Demographic characteristics of the cohort were: age 50.2 (14.9) years, women 54.8%. A total of 181 MIs occurred in 41,302 person years, resulting in an overall IR of 4.38 (3.79, 5.07) per 1000 person years. The crude IRs were 4.62 (2.87, 7.43) for ustekinumab and 4.36(3.74, 5.08) for TNFi (Table). Compared to TNFi, and after multivariable adjustment for potential confounders, the rate of MI for UST-treated patients was not significantly different (HR=1.26, 95% CI 0.76, 2.10) compared to TNFi users (referent). Sensitivity analysis yielded similar results.

Conclusion: In patients with psoriasis and psoriatic arthritis, the rate of myocardial infarction associated with ustekinmab was comparable to the corresponding rate in TNFi users.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis (PsO) is a chronic immune-mediated skin condition affecting ~3% of adults worldwide. Up to a third of PsO patients go on to develop psoriatic arthritis (PsA), a heterogeneous inflammatory arthritis characterized by concomitant bone erosion and osteoproliferation. Although multiple advances have been made in the pathogenesis and therapeutics of these disorders, it is currently not possible to predict which individuals will progress from PsO to PsA. The role of the microbiome as a potential trigger for autoimmunity and rheumatic disease has recently been implicated. The goal

of this study was to characterize the cutaneous microbiota of patients with PsO and PsA (in both psoriatic plaques and unaffected skin) to determine if there are characteristic features related to disease phenotype.

Methods: Skin swabs from subjects with PsO (n=29) and PsA (n=62) were collected from both psoriatic plaque lesions and contralateral unaffected skin. 16S rDNA was extracted per protocol (MoBio, USA) and amplicons targeting the hypervariable V4 region were sequenced using MiSeq (Illumina) to define the microbiota composition. The obtained 16S rRNA sequences were analyzed using the Quantitative Insights into Microbial Ecology (QIIME) pipeline. Taxonomic relative abundance was determined to compare their prevalence among different phenotypes using Kruskal-Wallis statistical analysis. Alpha diversity plots and weighted Unifrac analysis (beta diversity) of cutaneous bacterial communities were generated. False discovery rate analysis was applied to identify unique differentiating taxa.

Results: Baseline characteristics were comparable in both groups. PsO samples had, on average, a similar number of operational taxonomic units as compared to PsA samples. Beta diversity plots did not demonstrate statistically distinct clustering of microbial communities between PsO and PsA subjects, PsO and PsA nonlesional skin, or PsO and PsA lesional skin. Staphylococcus and Corynebacterium were the most abundant genera across all samples. However, several genera were statistically more abundant in PsO compared to PsA lesions, including unclassified Bradyrhizobiaceae ($p<0.0006$), Rahnella ($p<0.0006$), unclassified Prevotellaceae ($p<0.001$), and Parvibaculum ($p<0.002$). Rothia was more abundant in PsA ($p<0.02$).

Conclusion: Our results characterize, for the first time, the cutaneous microbial composition of individuals with PsO compared to those with PsA both in psoriatic lesions and unaffected skin. Although we did not find overall community differences among the various phenotypes, our preliminary observations point towards differences in specific genera, which are characteristically more abundant in PsO. Further in-depth analysis is required to better understand the significance of this dysbiotic process in PsA and whether it contributes to the pathogenesis of the psoriatic disease spectrum. Current efforts are devoted to incorporating healthy controls into our analysis, and analyzing the cutaneous microbiome (and metagenome) across multiple body sites, multiple visits, as well as pre- and post-immunosuppressive/biologic therapy.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: CHS-0214 is a proposed biosimilar of etanercept, a fusion protein inhibiting tumor necrosis factor. This Phase III multi-center study compared the efficacy and safety of CHS-0214 with commercial, European-sourced etanercept in patients with moderate/severe chronic plaque psoriasis (PsO), including patients with psoriatric arthritis (PsA).

Methods: Patients were randomized to CHS-0214 or etanercept 50 mg SC BIW for 12 weeks (Part 1) and then QW for 36 weeks (Part 2). The percent change in Psoriasis Area and Severity Index (PASI) and the PASI75 at Week 12 were the primary endpoints. The 95% confidence interval (CI) of the treatment difference had to be within the prespecified margin to establish equivalence of CHS-0214 to etanercept. The changes in Health Assessment Questionnaire – Disability Index (HAQ-DI) and hs-CRP were evaluated in patients with PsA.

Results: In 7 countries, 521 patients (102 [19.6%] with PsA) were randomized, and 456 patients (84 [18.4%] with PsA) were evaluable for efficacy at 12 weeks. The PASI75 response rate at 12 weeks was similar for CHS-0214 (64.5%) and etanercept (62.3%). The 95% CI of the treatment difference (-6.36, 11.21) was within the pre-defined equivalence range (-18.0, 18.0). In patients with PsA, the PASI75 response rate was 67.4% for CHS-0214 and 61.0% for etanercept. The mean percent change in PASI at 12 weeks was similar for CHS-0214 (-76.7) and etanercept (-73.4). The 95% CI (-7.63, 0.80) was within the pre-defined equivalence range (-12.5, 12.5). In PsA patients with body surface area (BSA) <2.0 m^2, the mean percent change in PASI was -80.0 for CHS-0214 and -72.0 for etanercept; in PsA patients with BSA ≥ 2.0 m^2, the results were -76.4 for CHS-0214 and -69.9 for etanercept. Mean HAQ-DI scores in patients with PsA were 0.8 and 0.9 at Baseline and decreased to 0.6 and 0.7 at Week 12 for CHS-0214 and etanercept, respectively. Mean hs-CRP scores in patients with PsA were 6.5 and 11.7 at Baseline and decreased to 3.4 and 3.8 at Week 12 for CHS-0214 and etanercept, respectively. Overall, 73.2% of the 261 subjects in the CHS-0214 arm and 76.5% of the 260 subjects in the etanercept arm experienced a treatment emergent adverse event. The majority of the treament emergent adverse events were mild or moderate in severity. No deaths were reported.

Conclusion: This study demonstrated equivalence of CHS-0214 to etanercept with respect to the primary efficacy endpoints. PASI results were similar in patients with PsA as compared with the full study group. Improvement in HAQ-DI and hs-CRP were seen in patients with PsA. Overall both treatments were well tolerated.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Given the difficulties non-rheumatologists experience to early refer psoriasis patients at risk for Psoriatic Arthritis (PsA) we aim to explore patients experience of musculoskeletal symptoms and understand patients' self-management of symptoms preceding the diagnosis of PsA through a qualitative study to provide a state of the art view on current medical practice eliciting room to improve early detection of PsA.

Methods:

A semi structured interview was developed based on the available literature and informal conversations with patients. The following data was collected from newly diagnosed PsA patients participating in the **D**utch south w**E**st **P**soriatic **AR**thritis cohort (DEPAR): medical history, physical load, previous and current joint and tendon complaints, general complaints, disabilities and emotional status and its influence on their daily life.

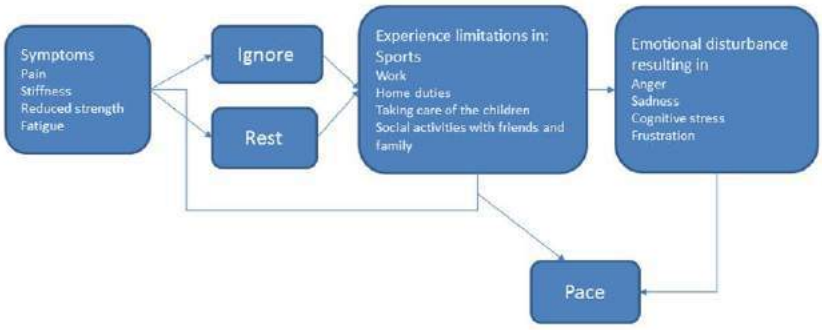
Results:

24 Newly diagnosed PsA patients (median age 52; 54% male; median duration of symptoms four years; 17% mono-, 21% oligo, 29% poly arthritis, 25% dactylitis, 4% axial and 8% enthesitis) participated in this study.

Patient at first did not involve their GP as they attributed their symptoms to physical exertion, obesity or other morbidity. If symptoms continued or worsened they involved their GP. Symptoms of the shoulders, wrists, back, hips and knees were first referred to physiotherapist or other specialists before they were seen by a rheumatologist, often taking years. While patients with hand symptoms were referred to the rheumatologist more quickly, as were patients with rapid accumulation of complaints.

Figure 1 shows the different ways patients dealt with their symptoms before visiting the GP. Patients experience pain, stiffness, loss of strength and fatigue. Some patients decide to proceed with physical activity which often resulted in more pain and inability to perform daily activities. Some choose to avoid all physical activities that causes pain. And others choose to pace their activities. Ultimately, most of our patients ended up choosing for the latter. However, all patients experienced disability which often resulted in stress, frustration, sadness or anger.

Figure 1. Patient journey



Conclusion:

Patients and physicians are not alerted that symptoms of the large joints may be underlying PsA. Patients often first see physiotherapist and other specialist before they finally arrive at the rheumatologist. In the period preceding the diagnosis all patients struggle with pain and other symptoms impacting their daily life. Initially, they choose different coping strategies. While over time they all choose to pace their activities at the cost of losing wellbeing.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Of the multiple manifestations of psoriatic arthritis (PsA), enthesitis and dactylitis are hallmark features that affect many patients (pts), can lead to pain and disability, and may be particularly difficult to manage; the effectiveness of conventional DMARDs for these manifestations is not well documented. Apremilast (APR) is a phosphodiesterase 4 inhibitor that regulates immune responses in PsA; the phase III PALACE trials compared APR efficacy/safety with placebo (PBO) in pts with active PsA despite prior conventional DMARDs and/or biologics. We report the impact of APR treatment over 156 wks on enthesitis and dactylitis in a pooled analysis of the PALACE 1-3 studies.

Methods: Pts were randomized (1:1:1) to PBO, APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use (yes/no). The PBO-controlled phase continued to Wk 24, with an early escape option at Wk 16. At Wk 24, all remaining PBO pts were re-randomized to APR30 or APR20. Double-blind APR treatment continued to Wk 52; pts could continue APR for up to an additional 4 years during an open-label extension phase. Data for pts entering the study with pre-existing enthesitis or dactylitis were pooled across PALACE 1-3, as pre-specified, to allow for a robust analysis. Enthesitis was evaluated based on the Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) (range: 0-13), which indicates the number of painful entheses out of 13 enthesis sites. The dactylitis count (range: 0-20) is the number of digits (hands/feet) with dactylitis present (0=absence, 1=presence). Analyses at Wk 24 used LOCF for missing values and data for early escape pts; Wk 52 and Wk 156 were based on data as observed.

Results: Among pts with enthesitis (n=915) or dactylitis (n=610) at baseline and ≥1 post-baseline value, baseline mean MASES ranged from 4.4 to 4.8 and dactylitis counts ranged from 3.2 to 3.4. At Wk 24, mean change in MASES was −1.3 for APR30 (P=0.0194 vs PBO) and −0.9 for PBO, with 27.5% (APR30) and 22.5% (PBO) of pts achieving a MASES score of 0. Mean change in dactylitis count was −1.8 for APR30 (P=0.0097 vs PBO) and −1.3 for PBO, and a dactylitis count of 0 was achieved by 46.2% of APR30 and 39.0% of PBO pts. Sustained improvement in enthesitis and dactylitis severity was seen in pts who were receiving APR30 at Wk 156, as shown by reductions in MASES and dactylitis counts (Table). Mean % change in MASES with APR30 was −65.2%, and 55.0% of APR30 pts achieved a MASES score of 0. At Wk 156, mean % change in dactylitis count was −83.6% with APR30, and dactylitis counts decreased to 0 in 79.6% of pts. Data for APR20 demonstrated similar results.

Conclusion: The majority of pts (63%) entering the PALACE 1-3 studies had active enthesitis and 42% had dactylitis. APR30 BID demonstrated both early and long-term benefit, up to 156 wks, in treating enthesitis and dactylitis, including resolution of baseline disease in many pts.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) has a substantial impact on the physical functioning of affected individuals, though there are limited data on how this relates to impact on valued activities. Our aim was to assess the relationship between physical functioning and work impairment in people with PsA.

Methods: Data were drawn from an international study of rheumatologists and dermatologists, and their PsA patients across 11 countries (USA, EU, Turkey, Japan, South East Asia, Mexico, Australia and Middle East). Physicians provided diagnosis and patient demographics and their perception of PsA severity, recorded as mild, moderate or severe. Patients reported their employment status, completed the Health Assessment Questionnaire Disability Index (HAQ-DI), and Work Productivity & Activity Impairment questionnaire (WPAI). HAQ-DI scores were compared by physician reported PsA severity. Patients were stratified by their HAQ-DI score into six subgroups (<0.6; 0.6 <1.1; 1.1<1.6; 1.6 <2.1; 2.1 < 2.6; 2.6 <3); employment status and the four WPAI components (work time missed, impairment while working, overall work impairment, and activity impairment) were described by HAQ-DI subgroups.

Results: 1499 patients of working age with a mean age of 44.75yrs (SD 10.15) were analyzed. Patient physical functioning decreased with more severe PsA (HAQ-DI Mean (SD): mild, 0.46 (0.60); moderate, 0.87 (0.69); severe, 1.09 (0.69); *p<0.0001*). HAQ-DI sub-group analysis demonstrated significant differences in employment status with employment

decreasing as HAQ-DI score increased, and the rate of unemployment or retirement due to PsA increasing as HAQ-DI increased *(p<0.0001)* (Figure 1). In employed patients, the percentage of work time missed due to PsA significantly increased as HAQ-DI score increased (Figure 2), as did percentage of impairment while working, and overall work impairment. Among employed and unemployed patients a similar relationship was seen for percentage of activity impairment. All HAQ-DI and WPAI relationships were significant in the overall sample, and on a regional level, categorized as the USA, the 5EU countries, and the rest of world *(p <0.0001)*.

Conclusion: This analysis confirms a strong inverse relationship between physical functioning, employment levels and work productivity in PsA patients. This suggests that strategies to reduce disability in PsA will not only benefit patients but will also have a beneficial societal and economic impact.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, acts to regulate immune activity in psoriatic arthritis (PsA) patients. PALACE 1 (NCT01172938), 2 (NCT01212757), and 3 (NCT01212770) compared the efficacy and safety of APR with placebo (PBO) in patients with active PsA despite prior conventional disease-modifying anti-rheumatic drugs (DMARDs) and/or biologics. This pooled analysis of PALACE 1-3 assessed the long-term safety of APR treatment in patients treated for up to 3 years.

Methods: Patients were randomized (1:1:1) to receive PBO, APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use (yes/no). The PBO-controlled phase continued to Week 24; PBO patients were re-randomized to APR30 or APR20 at Week 16 (early escape) or Week 24. Double-blind APR treatment continued to Week 52; patients could continue APR during an open-label, long-term treatment phase. Visits in years 2 and 3 were scheduled at 13-week intervals.

Results: A total of 1,493 patients were randomized and received ≥1 dose of study medication (PBO: n=495; APR30: n=497; APR20: n=501). At the 3-year data cut for PALACE 1-3, 1,441 patients in Weeks 0 to ≤52, 1,028 in Weeks >52 to ≤104, and 865 in Weeks >104 to ≤156 received APR. During the Weeks 0 to ≤52 APR-exposure period, adverse events (AEs) occurring in ≥5% of APR-exposed patients were diarrhea, nausea, headache, upper respiratory tract infection, and nasopharyngitis (Table). Most diarrhea and nausea events were reported within the first 2 weeks of treatment and usually resolved in 4 weeks without medical intervention. The frequency of gastrointestinal AEs decreased with longer exposure (i.e., Weeks >52 to ≤104 or >104 to ≤156; Table); other AEs occurring at ≥5% in the initial period either decreased in frequency or remained stable with prolonged exposure (Table). Most AEs were mild or moderate in severity for up to 156 weeks of APR exposure. Rates of depression remained very low, consistent with earlier findings. The rate of serious AEs (SAEs) was 8.4% during Weeks >104 to ≤156 of APR exposure; most SAEs occurred in 1 patient each. Rates for SAEs of special interest (major cardiac events, malignant neoplasms, serious opportunistic infections) were very low and comparable to those in the first year of treatment. The discontinuation rate due to AEs was 1.8% during Weeks >104 to ≤156 of APR exposure. Marked laboratory abnormalities were infrequent, and most returned to baseline with continued treatment.

Conclusion: APR demonstrated a favorable safety profile and was well tolerated for up to 156 weeks. The incidence of AEs remained stable or decreased with long-term exposure to APR.

Acknowledgment: We thank Adewale O. Adebajo for his work on the original abstract.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with psoriatic arthritis (PsA) and psoriasis (PsO) are at increased risk of cardiovascular diseases (CVD) and the risk is higher in patients with severe disease phenotypes[1,2]. A population based study has suggested that PsA, PsO and RA have similar risks for the development of major CV events, therefore CV risk should be addressed in all patients affected by these conditions[3]. The association between psoriatic disease and CV morbidity is poorly understood and studies estimating long-term risk of CVD in PsA and PsO are scarce.The aim of the study was to compare CV risk factors and 10-year CVD risk scores between patients with PsA to those with PsO alone.

Methods: PsA patients fulfilling the CASPAR criteria and PsO with disease duration <10 years were enrolled consecutively from Rheumatology and Dermatology clinics. Fasting bloods were obtained for glucose, insulin, lipids, homocysteine and NT-proBNP. Detailed medical history including items related to comorbidities and known risk factors was taken. Patients underwent thorough physical examination, joint and skin assessments and completed questionnaires on health and quality of life on ipads using a web-based tool. We compared risk factors for CVD between PsA and PSO patients and assessed 10-year CV risk using the Atherosclerotic Cardiovascular Disease (ASCVD) and Framingham Risk Score (FRS). Multiple regression analyses were performed to evaluate the effect of traditional risk factors not included in ASCVD and FRS and disease-related parameters on 10-year CV risk.

Results: 162 patients (100 PsA and 62 PsO) were recruited with mean age 52 (±10.4) for PsA and 40 (±14.7) years for PsO. Mean disease duration for PsA was 17.9 (±10) years. There were significantly more patients with hypertension and metabolic syndrome in the PsA group, and the waist/hip ratio, the number of smokers and patients taking DMARDs and/or biological treatment were also higher compared to PsO. The mean FRS and ASCVD were significantly higher in PsA as compared to PsO (6.04± 6.4% vs. 3.24±5.5%, P=0.007; 6.97±8% vs. 3.98±5%, P=0.008, respectively). Multiple regression analysis revealed that waist/hip ratio had significant effect on FRS and HOMA-R had significant relationship with ASCVD in both diseases. After adjustment for age and sex, we found higher proportion of patients with hyperlipidaemia (P=0.02) and insulin resistance with higher mean HOMA-R in PsO, however FRS and ASCVD scores were similar. We found that HOMA-R and treatment did not show association with 10-year CV risk, and that waist/hip ratio, but not BMI had significant effect on FRS in PsO (β=0.36, P=0.01).

Conclusion: We found similar 10-year risk of CVD in PsA and PsO patients using FRS and ASCVD and that waist/hip ratio had significant effect on FRS. Our results highlight the value of measuring waist/hip ratio and suggest that traditional modifiable risk factors, such as central obesity should be managed appropriately to reduce long-term CVD in psoriatic disease. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: ABT-122 is a novel dual-variable domain immunoglobulin (DVD-IgTM), which specifically neutralizes both TNF alpha (TNFα) and interleukin-17A (IL-17). Drugs individually neutralizing TNFα or IL-17 have demonstrated efficacy in patients with Psoriatic Arthritis (PsA). The objective of this work was to quantitatively characterize the relationship between ABT-122 or adalimumab serum concentrations and the respective ACR20/50/70, PASI50/75/90 and DAS28 (CRP) responses following treatment in subjects with PsA who have had an inadequate response to methotrexate.

Methods: Subcutaneous (SC) doses of ABT-122 120 mg every week (EW; N=71) and 240 mg EW (N=73) were evaluated in this 12-week randomized, double blind, placebo (N=24) controlled Phase 2 study, with adalimumab 40 mg SC every other week (EOW, N=71) as an active comparator. Serial ABT-122 and adalimumab serum concentrations collected every other week and time course of efficacy data collected at weeks 3, 5, 7, 10, and 12, were analyzed using non-linear mixed-effects modeling. The relationships of ABT-122 and adalimumab average serum concentrations (C_{avg}) during the dosing interval and the ACR20/50/70 and PASI50/75/90 responses as well as dropouts were characterized using Markov models, where active therapies enhanced transition of the status of patients to higher levels of response (e.g. no response to ACR20, ACR20 to ACR50, ACR50 to ACR70). For DAS28 (CRP), indirect response models with ABT-122 and adalimumab suppressing the response were utilized.

Results: The 120 and 240 mg EW doses of ABT-122 provided 2-fold and 4-fold higher molar serum concentrations compared with adalimumab 40 mg EOW dose. There was no evidence of different maximal effects between ABT-122 and adalimumab with available data. The EC_{50} values (the concentrations associated with 50% of maximal effect) on the transition rates between ACR responses for ABT-122 and adalimumab were 6.5 nM (relative standard error [RSE]= 170%) and 13.0 nM (RSE = 61%), respectively. Analyses provided similar results for PASI responses with EC_{50} for the transition rates to higher PASI response (no response to PASI50, PASI50 to PASI75) for ABT-122 and adalimumab as 27 nM (RSE= 91%) and 34 nM (RSE = 58%), respectively. The IC_{50}, concentrations associated with 50% of maximal reduction of DAS28(CRP) responses, for ABT-122 and adalimumab were 60 nM (RSE = 18%) and 32 nM (RSE = 24%), respectively, with maximum inhibition of the baseline DAS28(CRP) level fixed to 45% based on observed data. These analyses indicate that the ACR, PASI and DAS28 (CRP) responses of ABT-122 approximately plateau at an ABT-122 dose of 120 mg EW in PsA patients. Combined analyses across studies in subjects with background MTX and either rheumatoid arthritis or PsA (ABT-122 dose range of 60 mg EOW and 240 mg EW) provided similar results.

Conclusion: The exposure-response relationships of efficacy for ABT-122 and adalimumab were not distinguishably different in subjects with PsA on background MTX. Overall, there was no clear evidence that inhibition of the IL-17 pathway provides significant incremental efficacy benefit in presence of TNF inhibition.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with psoriasis (PsO) and psoriatic arthritis (PsA) have an increased prevalence of cardiovascular (CV) risk factors, metabolic syndrome (Metsy), and higher risk for subsequent major CV adverse events[1]. PsA patients have more severe subclinical atherosclerosis compared to those with PsO alone[2]. Previous studies showed higher prevalence of coronary artery plaques in PSO, and in rheumatoid arthritis without diagnosis of coronary artery disease (CAD) compared to controls[3,4]. However, no study to date has compared coronary plaque burden in PsA patients asymptomatic to CAD to controls. The objectives were 1) Study the presence, extent and type of coronary plaques as measured by coronary CT angiography (CCTA) in PsA without symptoms of CAD as compared to controls. 2) Compare plaque measurements between patients with Metsy to those without Metsy (NMetsy) and to controls. 3) Investigate the effect of disease related variables on coronary plaques.

Methods: 50 PsA patients (25 Metsy - 25 NMetsy) and 25 controls without CAD (age and sex-matched) underwent 64-slice CCTA. Plaque localisation, the number of patients with plaque and of affected coronary vessels were assessed. Plaque type was classified into calcified (CP), mixed (MP) and non-calcified plaque (NCP)[5]. Plaque volume was measured for each plaque type and was added to give a total volume (PV) in mm^3. The number of segments with plaque per patient (segment involvement score (SIS 0-15)) and segment stenosis score (SSS 0-60) were calculated. Kruskal-Wallis test, rank correlations and linear regression analyses were used to study the effect of Metsy and PsA related variables on coronary plaques.

Results: Mean age of PsA patients and controls was 58(±8.3) and 57(±5.6) years, the 2 groups were comparable for CV risk factors. 78% of PsA vs 44% of controls had plaques (P=0.007) and the number of patients with affected coronary vessels were higher in PsA (P=0.015). Mean PV, SIS and SSS were higher in PsA (P=0.002, P=0.032, P=0.004; respectively). There were more PsA patients with MP and MP volume was higher compared to controls (P=0.006). Plaque measurements in PsA patients with or without Metsy were similar. Plaque presence, PV and SSS were significantly higher in both Metsy and NMetsy patients compared to controls. Max CRP during the disease correlated significantly with PV, SIS and SSS in PsA. Disease duration, max TJC and max CRP had significant effect on the number of affected coronary vessels (P=0.034, P=0.049, P=0.022, respectively). Linear regression analyses revealed no significant relationship between PV and Metsy, whilst diagnosis of PsA (B=0.324 (CI95% 0.05-0.597) P=0.021) and max CRP (B=0.01 (CI95% 0.004-0.019) P=0.006) were independent predictors of PV.

Conclusion: This pilot study is the first to assess coronary plaques in PsA using CCTA. PsA patients asymptomatic for CAD had a higher presence and extent of plaques, particularly MP, compared to controls. Our results suggest that PsA may result in accelerated coronary plaque formation independent of metabolic disease. **References:**

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Axial involvement in psoriatic arthritis (PsA) is a controversial issue. Lack of unanimity in the definition has led to a wide range of levels of prevalence in the different series published. On the other hand, although radiographic progression in patients with spondylitis is widely known, the different radiographic characteristics of both entities advise against establishing a parallelism between the evolution of the different lesions or the clinical factors which may have an influence on them. Our objectives werw radiographic progression over four years in a group of patients with PsA and axial involvement and relate radiographic damage with clinical and analytical factors.

Methods: Prospective study with patients diagnosed with PsA according to the CASPAR criteria. Axial involvement was defined as the presence of inflammatory back pain along with sacroiliitis and/or syndesmophytes. Patients with less of five years of evolution from the onset of symptoms were included in the study. The radiographic damage was measured with the PASRI method. The difference between both measurements was four years (+ 1 month). The assessment was carried out by two observers (CM et al.). The clinical factors measured were: age, sex, peripheral involvement, smoking , use of NSAIDs (continuous vs. on-demand), biological treatment, measures of activity (BASDAI), function (BASFI) and mobility (BASMI). The following analytical variables were measured: VSG, PCR, B-CrossLaps, P1NP and HLA-B27. From a radiological perspective, the presence of a dorsal or lumbar fracture was also assessed according to the semiquantitative Gennant method.

Results: The study included 45 patients with PsA and axial involvement. The average age of patients was 53.5 years (SD: 12.9), and 31 patients were men. The kappa coefficient between both raters was 0.70. Radiographic progression was higher

in men (3.13 vs. 1.14, p=0.04; in the multivariate analysis: p=0.04, OR: 0.61, 95%CI: 0.39-0.98) and in smokers (active and ex-mokers) (3.81 vs. 1.14, p=0.04; in the multivariate analysis: p=0.04, OR: 0.61, 95%CI: 0.48-0.93). Also, the presence of vertebral fracture was associated to patients with a higher radiographic progression (4.85 vs. 1.82; p=0.001; in the multivariate analysis: p=0.008, OR: 0.59, 95%CI: 0.39-0.87). No differences were found regarding the presence of peripheral manifestations (2.32 vs. 3.57, p=0.3), peripheral joints erosions (2.61 vs. 3.1, p=0.4), continuous use of NSAIDs (1.67 vs. 2.91, p=0.3), biological prescription (2.04 vs. 3.72, p=0.3) or HLA-B27 (2.00 vs. 2.79, p=0.5). A correlation was observed between radiographic progression and the initial PASRI score (p=0.001) and between progression and a lower P1NP concentration (p=0.02). Twelve patients did not show radiographic progression. These patients showed lower initial PASRI scores (5.35 vs. 12.6, p=0,001; in the multivariate analysis: p=0.03; OR: 0.73, 95%CI: 0.55-0.98) and a lower P1NP concentration (38.7 vs. 61.1; p=0.006: in the multivariate analysis: p=0.01; OR: 1.05, 95%CI: 1.008-1.096).

Conclusion: As in patients with spondylitis, male gender, smoking and the presence of initial damage were associated to a higher radiographic progression. Also, these patients were associated to a higher rate of vertebral fracture and lower levels of P1NP. Radiographic progression was not associated to inflammatory parameters, peripheral manifestations or to the treatment used. Approximately 25% of the patients did not show radiographic progression.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Ustekinumab (UST), an anti IL12/IL23 monoclonal antibody and apremilast, an inhibitor of phosphodiesterase 4 are two relatively new agents used for the treatment of psoriasis (PSO) and psoriatic arthritis (PSA). Potential differences in their risk profiles with respect to serious infection risk compared to tumor necrosis factor inhibitors (TNFi) have been suggested but minimally evaluated in real-world settings.

Methods: We conducted a retrospective, new user design cohort study of PSO or PSA patients initiating apremilast or one of the target biologic DMARDS using 2010-2014 Market scan and 2006-2014 Medicare data. To be included in the cohort, patients have to have at least 12 consecutive months of observable (Enrolled in Medical and pharmacy) before the initiation date (index date). Patients were excluded if they have any diagnosis code for inflammatory disease other than PSO or PSA, malignancy or HIV or organ transplant. Follow up started at index date and ended at earliest of: discontinue of the index drug (90 days after days of supply) or switch to another drug, the outcome, lose of full insurance coverage, death, and end of study. Patients contributed to only one episode of one specific drug but could contribute to multiple drugs. Hospitalized

infection was identified using ICD-9 diagnosis code from hospital discharge (Primary or secondary). Sensitivity analysis was conducted by limiting outcome to primary discharge diagnosis code. Incidence rates (IR) were calculated by dividing number of outcome by person year exposed. Crude and multi-variable adjusted hazard ratios (HR) were calculated with COX proportional hazard regression with robust estimate.

Results: The final cohort included 50,125 initiations of therapies of interest (19,922 from Medicare, 30,203 from Market scan) represented by 40,501 unique PsO/PsA patients. Patient's demographic characteristics were: age 50.4 (14.9) in years, women 54.4%. A total of 2,191 hospital infections occurred in 41,650 person years, resulting in an overall IR of 5.26 (5.04, 5.49) per 100 person years. IRs ranged from 4.36 (3.74, 5.08) for ustekinumab to 8.78 (8.00, 9.64) for infliximab (Table). Compared to adalimumab, the multivariable adjusted HR were 0.77 (0.43, 1.38) for apremilast, and 0.99 (0.83, 1.17) for ustekinumab (Table 1). Infliximab was associated with a significantly increased risk for hospital infection compared to adalimumab.

Conclusion *:* In patients with psoriasis and psoriatic arthritis, the comparative rates of hospitalized infection were generally comparable between TNFi and ustekinmab, although rates were highest for infliximab. Apremilast was associated with a numerically lower risk for serious infection compared to adalimumab. Table: Incidence rate and hazard ratio for hospital infection associated with medications for psoriasis and psoriatic arthritis

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis (Pso) and psoriatic arthritis (PsA) are complex, multi-system diseases for which an ever-increasing landscape of therapies exists. Little is known about the population level time-trends in use of these agents. We aimed to examine trends in the use of systemic therapy – both conventional and biologic drugs – for psoriasis and psoriatic arthritis.

Methods: Using claims data (2004-2013) from a large nationwide US commercial health plan, we selected patients with 1) Pso without PsA and 2) PsA based on 2 diagnosis codes separated by 7-365 days. In each group, we identified 3 hierarchical treatment groups based on their topical or systemic treatment in a 12-month baseline period prior to the 2nd PsA or Pso diagnosis date (i.e., index date): 1) topical or ultraviolet (UV) therapy only, 2) conventional immunomodulating drugs, and 3) biologics. In the Pso and PsA groups, we calculated the proportion of each treatment groups at baseline and the proportion of a specific conventional or biologic immunomodulating agent over time.

Results: We included 49,950 Pso and 9,706 PsA patients. Mean age (SD) was 46.9 (13.3) years for Pso and 48.2 (11.1) years for PsA. Sixty percent of patients with PsA also had psoriasis. Overall, for baseline treatment of Pso, 82.8% used topical or UV therapy only, 6.8% had conventional immunomodulating drugs and 10.4% used biologic drugs. Baseline treatment of PsA included 18.0% topical or UV therapy only, 32.2% conventional immunomodulating drugs and 49.8% biologic drugs. No substantial time trends were noted in either group. Methotrexate was the most commonly used conventional immunomodulating drug in both Pso (48.7% in 2005 to 61.5% in 2013) and PsA (83.2% in 2005 to 74.2% in 2013) groups. For Pso, etanercept was the most commonly used biologic drug, albeit with a decreasing trend (87.9% to 39.4%), and adalimumab was the 2nd most commonly used drug (2.2% to 28.4%) from 2005 to 2013. Ustekinumab use in Pso has increased from 0.2% in 2009 to 27.7% in 2015 (**Figure 1**). Among biologic drug users for PsA, etanercept, adalimumab and infliximab were the three most commonly used agents across all years. Ustekinumab use in PsA has increased from 0.3% in 2009 to 6.5% in 2013 (**Figure 2**).

Conclusion: Over the past decade, we noted a substantial trend in the patterns of biologic treatment for both Pso and/or PsA. The change in the use of different biologic drugs among patients with Pso has been more pronounced over time compared to PsA, most likely related to the availability of ustekinumab.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis (Pso) is one of the most common chronic inflammatory skin disease in Europe. Psoriatic arthritis (PsA) is closely associated to Pso; the skin manifestation appears usually years before PsA-related symptoms emerge. Up to 30% of Pso patients develop PsA; its concrete prevalence is still unclear. Questionnaires for detection of PsA (PASE, PEST, GEPARD) are validated tools for use in dermatology practice with different sensitivity and specificity levels. Fluorescence-optical imaging technique is a new method to detect changes in microvascularisation of the hands as potential early marker for subclinical musculoskeletal inflammation.

Methods: This interims analysis includes 150 Pso patients (diagnosis confirmed by dermatologist) without pre-existing diagnosis of PsA but risk factors for its development (nail psoriasis and/or joint pain or swelling within the last 6 months) from a prospective, multicentre study (XCITING) in Germany. Patients are examined by rheumatologist (clinical examination and ultrasound) to determine PsA-diagnosis. FOI is performed in addition to standard examinations and analysed by an independent experienced reader. The results for PASE, PEST and GEPARD questionnaires as well as for FOI in comparison to the diagnosis of PsA by rheumatologist are compared to survey their sensitivity, specificity and their positive and negative predictive values for detection of PsA.

Results: In 46.4 % of the Pso patients with risk of development of PsA (as defined in inclusion criteria) PsA was diagnosed by rheumatologist using clinical examination and ultrasound. For detection of PsA, PASE questionnaire had a sensitivity of 44.3% and a specificity of 64.2% whereas its positive predictive value was 51.7%, its negative predictive value 57.1%, respectively. Sensitivity of PEST was calculated with a value of 12.9% whereas its specificity was 80.3%; its positive predictive value was 36%, its negative predictive value 51.6%. GEPARD had a sensitivity of 64.3% and a specificity of 38.3% for detection of PsA. Its positive predictive value was 47.4%, its negative predictive value 55.4%. FOI had a specificity of 27.2% and a sensitivity of 51.4%. Its positive predictive value was 37.9%, its negative predictive value 39.3%, respectively.

Conclusion: In this cohort of patients with active Pso and risk of development of PsA, more than 40% of the patients were classified as PsA by rheumatologist using clinical examination and ultrasound. The highest positive and negative predictive values for detection of PsA were detected for use of PASE questionnaire. FOI as new imaging marker had low specificity but marked sensitivity for detection of PsA compared to the questionnaires keeping in mind that only the hands are captured with the device; FOI reached positive and negative predictive values of 37.9 and 39.3%, respectively. For use in clinical routine care, combination of both, FOI and questionnaires might be useful for sufficient PsA diagnosis and exclusion or diagnosis of other types of arthritides of the hands that might be distinguished by use of FOI.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is associated with increased morbility and mortality and an accelerated atherosclerosis. Influence of anti-TNFalpha treatment (a widely used therapy in PsA) in subclinical atherosclerosis is still unclear. The aim of this study was to evaluate subclinical atherosclerosis progression before and after 5 years of anti-TNFalpha treatment.

Methods: Twenty-seven consecutive PsA patients were evaluated before TNF blockers therapy (T0), after 2 years (T1) and after 5 years (T2) of treatment. Subclinical atherosclerosis was evaluated through carotid duplex scanning, analyzing intima-media thickness (IMT) and flow-mediated dilation (FMD). IMT values were expressed as IMT mean (cumulative mean of all the IMT mean in every analyzed carotid segment) and M-MAX (cumulative mean of all the higher IMT in every analyzed carotid segment). Response to therapy was studied by the evaluation of tender and swollen joints (Tj and Sj), DAS 28 (disease activity score), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Metrologic and metabolic data were collected. For the statistical evaluation of parameters over time (T0 vs T1, T1 vs T2) Student's T test for paired data was used.

Results: From T0 to T1 there was a significant deterioration in both IMT-mean and M-MAX (0.72±0.15 vs 0.91±0.37 and 0.89±0.18 vs 1.06±0.39 respectively, $p<0.01$). At T2 IMT-mean did not change significantly (0.91±0.37 vs 0.92± 0,34, p=ns), while M-MAX worsened further (1.06±0.39 vs 1.10±0.35, $p<0.05$). No significant variation in FMD values was observed during the 5 year follow up (T0 vs T1: 5.40±1.93 vs 5.37±1.66, p=ns; T1 vs T0: 5.37±1,66 vs 5.40±1.89, p=ns). Noteworthy, systolic blood pressure and Body Mass Index remained stable from T0 to T2 (132.03± 19.67 vs 132.32± 13.46, p=ns, and 26.33±4.03 vs 25.96±3.41, p=ns), while diastolic blood pressure decreased (79,57±8,73 vs 74.40±6.83, p=0,001). A good response to treatment was evident already at T1, with a significant decrease of: Tj (8.10±5.56 vs 2.09±2.32, $p<0.01$), Sj (3.85±3.84 vs 0.25±0.72, $p<0.01$), DAS 28 (4,16±0.67 vs 2.30±0.82, $p<0.01$) and CRP (11.25±9.16 vs 2.91±1.72, $p<0.01$). The efficacy was preserved from T1 to T2 in terms of Tj (2.09±2.32 vs 1.72± 2.05, p=ns), Sj (0.25±0.72 vs 0.50±0.92, p=ns), DAS 28 (2.30±0.82 vs 2.40±0,9, p=ns), CRP (2.91±1.72 vs 2.73 ±2.51, p=ns).

Conclusion: Our data revealed that in patients with PsA, despite treatment with TNF blockers, there is still a gradual, albeit slight progression of subclinical atherosclerosis assessed by ultrasonography. Other inflammatory mechanisms not related to TNF may be responsible of the progression in atherosclerotic disease.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease with varied response to therapy. We examined predictors of remission at one year among patients with PsA initiating a TNF inhibitor (TNFi).

Methods: Patients with PsA enrolled in the Corrona Registry between 2005-2013 with were followed from initiation of a TNFi (etanercept, adalimumab, infliximab, certolizumab, or golimumab) to the visit closest to 12 months from therapy initiation. The outcome of interest was Clinical Disease Activity Index (CDAI) ≤ 2.8 at one year (remission). Given concern about use of the 28-joint count in PsA patients with low joint counts, patients were required to have at least three tender or swollen joints for inclusion. Covariates of interest included baseline demographics (e.g., age, gender, work status), disease manifestations (e.g., enthesitis, dactylitis), patient reported outcomes (e.g., pain, fatigue, function), comorbidities (e.g., hypertension, diabetes), concurrent therapy (methotrexate, NSAIDs, glucocorticoids), and previous biologic use. Univariable associations between covariates and achieving remission at 12 months were tested. Covariates with p-value ≤0.10 and ≤10 missing values were included in a multivariable logistic regression model and removed individually until all remaining variables were significant ($p<0.05$).

Results: Among 1742 TNFi initiations, 725 patients met inclusion/exclusion criteria. Mean age at therapy initiation was 51.5 (SD 12.3) and 56% were female. Mean baseline CDAI was 20 (IQR 14.5-28), median PsA duration was 5 years (IQR 2-11), and 36% had erosions at baseline. The outcome (CDAI≤ 2.8) was achieved by 17% (N=121). Baseline characteristics and differences by outcome are shown in Table 1. In the multivariable model (Table 2), working full time was positively associated with achieving remission (OR 2.30, 95%CI: 1.44-3.68) and baseline pain (OR 0.98 per unit increase in 100 mm VAS), body mass index (OR 0.95 per unit increase, 0.92-0.98), female sex (OR 0.64, 0.41-0.99), previous biologic use (OR 0.58, 0.38-0.90), and baseline CDAI (OR 0.97 per unit increase, 0.95-0.99) were negatively associated with achieving remission.

Conclusion: Among PsA patients initiating a TNFi, ≤25% achieved remission by 12 months. Female gender and higher pain and global scores were previously linked to switching therapies and obesity was associated with lower likelihood of achieving remission; we confirm these findings in this multicenter study representative of care in the US. This is the first study to report that working full time was associated with remission.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The Composite Psoriatic Disease Activity Index (CPDAI), a composite disease outcome measure in psoriatic arthritis (PsA) (1),has proved to be a valid and discriminative tool to assess disease activity in PsA. Definitions of disease activity statesare lacking, however therecently developed minimal disease activity state (MDA) as a treatment target has been shown to improve outcome in patients with PsA (2). CPDAI has arbitrary cutoff points to classify disease states into mild, moderate and severe disease but these cutoff points have not been validated. Measuring Outcome in Psoriatic Arthritis (MOPsA) is a new web-based tool which can be used in the assessment of PsA.MOPSA calculates both MDA and CPDAI based on patient reported outcomes and assessment by physicians

Methods: We evaluated consecutive PsA patientsincluded in the MOPSA database.Data collected included joint counts, patientpain and global activity ratings, erythrocyte sedimentation rate, the health assessment questionnaire (HAQ) the psoriasis area severity index (PASI), the Bath ankylosing spondylitis disease activity index (BASDAI), the dermatology life quality index (DLQI), the Psoriatic Arthritis Quality of Life (PsAQoL). TheclinicalDisease Activity Index for Psoriatic Arthritis (cDAPSA) was calculated. Recently published cut off values for DAPSA were used to classify patients into remission (REM), low (LDA), moderate (MoDA) or high (HDA) disease activity. Based on the distributions of CPDAI in each of these clinical DAPSA assigned states, we defined the cut points between groups. Disease activity parameters were compared among the different constituted CPDAI states. Changes of treatment at the index visit was also evaluated

Results: Eighty-sevenPsA patients, 41 (52%) males, mean age 49 years (SD: 12 years) were included. Mean CPDAI differed significantly between patients classified as REM, LDA, MoDA or HDA ($p<0.001$)Cdapsa. Based on the distributions of CPDAI in these groups, we propose cut-off values of <2 for REM, >2 and <4 for LDA, >4 and < 7 for MDA and >7for HDA.With these cut off values 22%, 44%, 14% and 19% of the patients were in REM, LDA, MoDA and HAD, respectively. The table shows results for different disease activity parameters among the four CPDAI states. None of the patients classified as in remission by CPDAI changedDMARDs at the index visit, while 33%, 42% and 53% of patients in LDA, MoDA, and HAD, did undergo a treatment change. **Table:**Disease Activity Parameters according to CPDAI state

Disease Activity Parameter	All Patients (n=87)	Remission (n=20)	Low Disease Activity (n=39)	Moderate Disease Activity (n=12)	High Disease Activity (n=16)
Fulfilling MDA criteria, n (%)	33 (38)	19 (57,6)	14 (42.4)	0 (0)	0 (0)
Mean Tender Joint Count (TJC 68) (SD)	4.2 (6.1)	0.3 (0.9)	2.2 (1.7)	9.75 (10.8)	10.3 (4.7)
Mean Swollen Joint Count (66) (SD)	1 (2.5)	0 (0)	0.72 (1.3)	0.88 (1.7)	3.2 (4.8)
Mean Patient Pain (VAS 0-10) (SD)	3.5 (2.7)	2.45 (2.6)	3.1 (2.6)	4.25 (2.3)	5.4 (2.7)
Mean Patient Global Assessment (VAS 0-10) (SD)	3.5 (2.4)	2.4 (2.3)	3.3 (2.1)	4.3 (2.3)	4.8 (2.6)
Mean HAQ (SD)	0.6 (0.7)	0.175 (0.23)	0.42 (0.5)	0.85 (0.8)	1.5 (0.6)
Mean BASDAI (SD)	1.5 (2.3)	0.22 (0.69)	0.56 (1)	2.1 (2.6)	4.8 (2.2)
Mean PASI (SD)	2.8 (3.4)	0.7 (1.9)	2.6 (2.6)	5.6 (5.5)	3.7 (2.9)
Mean Clinical DAPSA (SD)	12.4 (10.4)	5.15 (4.3)	9.3 (4.2)	19.2 (14.1)	23.6 (11.7)
Mean DLQI (SD)	3.5 (5.6)	1.1 (2.1)	3.1 (4.3)	5.1 (7.2)	6.1 (8.4)
Mean PASQOL (SD)	4.2 (5)	0.85 (1.9)	2.9 (3.7)	6.3 (6)	9.9 (4.8)
Mean erythrocyte sedimentation rate,(SD)	12.2 (9.6)	10.3 (7.6)	11.3 (10.1)	13.9 (11.6)	15.1 (8.2)

Conclusion: CPDAI constitutes a disease-specific,validated and feasible tool for PsA assessment. In thisstudy, we provide criteria for disease activity states that showed good performance in clinical practice

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The majority of patients (pts) with psoriatic arthritis (PsA) experience psoriatic skin manifestations, which add to the already high burden of disease. The RAPID-PsA trial (NCT01087788) of certolizumab pegol (CZP) in PsA has shown CZP to be efficacious in improving skin manifestations over 96 weeks (wks) of treatment.[1] Here, we report long-term efficacy data for skin manifestations over 4 years of the RAPID-PsA trial.

Methods: The phase 3 RAPID-PsA trial was double-blind and placebo-controlled to Wk 24, dose-blind to Wk 48 and open-label (OL) to Wk 216. Pts had active PsA and had failed ≥1 DMARD; up to 40% of pts could have received 1 prior anti-TNF. Pts originally randomized to CZP (200 mg Q2W or 400 mg Q4W, following 400 mg loading dose at Wks 0, 2, 4) continued on their assigned dose in the OL period. Here we report outcomes assessing the skin manifestations of PsA in CZP-randomized pts with skin involvement at baseline (≥3% body surface area affected by psoriasis [BSA]). Data are shown as observed case (OC) and with imputation: NRI for categorical measures and LOCF for continuous measures.

Results: Of the 409 pts randomized, 273 received CZP from Wk 0, 166 of whom had baseline skin involvement (≥3% BSA). At baseline, these patients had an average of 24.2% BSA and a mean PASI score of 12.0. Severe skin involvement (≥3% BSA and PASI ≥10) was seen in 71 pts at baseline, with an average of 38.7% BSA affected and a mean PASI score of 22.3 amongst these pts. In pts completing the study, early improvements in PASI responses observed to Wk 24[1] were sustained to Wk 216 following treatment with either dose regimen (Table). Even when conservative imputation methods (NRI) were used, PASI responses were largely maintained, with an increased proportion of pts achieving the most stringent outcome, PASI100 (NRI; Wk 24: 22.3%, Wk 216: 28.3%). Similar sustained improvements were observed in both mean BSA and mean PASI score (Table). At Wk 48, 77.5% of pts with severe skin involvement at baseline (PASI ≥10) achieved a PASI75 response, compared with 54.7% of pts with less severe baseline skin involvement (PASI <10) (NRI). The heightened response in the most severely affected pts remained evident at Wk 216 (PASI75 [NRI]: PASI ≥10: 59.2%, PASI <10: 46.3%).

Conclusion: Improvements in the skin manifestations of PsA, as seen at Wk 24,[1] were maintained over 4 years of CZP treatment with both dose regimens, with additional improvements observed at Wk 216 in the proportion of pts achieving the most stringent measure, the PASI100 response. The increased PASI75 response rate previously observed in pts with severe skin involvement relative to those with less severe skin manifestations was also maintained to Wk 216. **References:** 1.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis is a chronic immune-medicated inflammatory condition that affects 2-3% of the population , which is characterized by rash, silver scaling of the skin and can lead to psoriatic arthritis. There are multiple regimens for the treatment of psoriasis including biologic agent, phototherapy and apremilast. Apremilast is an oral phosphodiesterase inhibitor that has been approved as a mono therapy by the FDA in March 2014 for the treatment of psoriatic arthritis and September 2014 for the treatment of moderate to severe plaque psoriasis. While monotherapy with biologic agents is effective for many patients with psoriasis some patients are not satisfied by the outcome and require combination therapy. No data exist on the safety of apremilast as a component of combination therapy with biological therapies. The aim of the study was to determine the safety of apremilast in combination of biologic therapies in the treatment of plaque psoriasis and psoriatic arthritis.

Methods: This was retrospective study, open label study carried out at a single center. Twenty-two patients diagnosed with plaque psoriasis and psoriatic arthritis according to American college of Rheumatology criteria-participated. Apremilast was added to their current biologic agent. Patients were permitted to continue their current biologic treatment.

Results: : 22 patients were treated by biologic agents then added Apremilast with a mean treatment of 8 months (1 Month is the shortest and 24 Months is the longest). Out of these 22 patients, 14 Females (63.6%) and 8 males (36.4%) were in the study. Out of these 22 patients, 5 patients were on ustekinumab and apremilast (27.3%), 3 patients out of the 5 experienced nausea and/or sever diarrhea (50%) and 1 out of the 3 stopped apremilast (33.3%). 6 patients were on adalimumab and apremilast (36.4%), 1 out of the 6 patients experienced nausea (12.5%) but tolerated and 0 patients stopped it. 2 patients were on etanercept and apremilast (9.1%) and 0 patient experienced side effect and was well tolerated. 2 patients were on certolizumab pegol and apremilast (9.1%), 1 patient stopped apremilast due to stomachache (50%). 4 patients were on infliximab and apremilast (18.2%) and 0 patients experienced side effect. 3 patients were on golimumab and apremilast (13.6%) weight loss was observed in 1 patient (33.3%), 1 patient couldn't tolerate and stopped the apremilast (33.3%). 19 patients (86.4%) continued on apremilast with good improvement. 3 patients (13.6%) stopped apremilast due to GIT side effects nausea and/or diarrhea and stomachache. weight loss was observed in 1 patient (4.5%). Nausea and/or Diarrhea were reported by 5 patients (22.7%). No major side effects of cancer or sever infection were reported. There is a mean decrease in the C-reactive protein of 8.68. Patients reported improvement of the rash and pain by more than 50% .

Conclusion: Apremilast can be safely and effectively combined with biologic agents in patients with plaque psoriasis or psoriatic arthritis not responding adequately to these agents alone. No major side effects of cancer or sever infection were reported other than nausea and/or vomiting that were manageable in some patients

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Objective: Therapeutic decisions are based on efficacy, but clinicians need to consider medication safety in this process. Here, we report ustekinumab (UST) integrated safety data in patients (pts) with psoriatic arthritis (PsA), Crohn's disease (CD), and psoriasis (PsO). We also compare a subset of PsA pts with & without baseline methotrexate (MTX).

Methods: Integrated safety data from 3 PsA, 5 CD, & 4 PsO trials were analyzed. PsA studies included the Ph2 trial [CNTO743T10] & the 2 Ph3 trials (PSUMMIT 1 & 2) with 222, 615 & 312 pts exposed to UST, respectively. The percentage of pts in the Ph2 study that received MTX was 20.5%. No concomitant DMARDs with the exception of MTX (approximately 50% of pts in each study) were permitted in the 2 Ph3 studies. In the 5 CD trials (Ph2/3Ph3) 1749 pts were exposed to UST. In the 3 Ph3 CD trials, pts received one dose of UST 130mg or ~6mg/kg IV at induction (UNITI-1 & UNITI-2), then 8 weeks later, entered the maintenance phase (IM UNITI) and received UST 90mg SC q8w or q12w for 44 weeks. The percentage of pts on background MTX in UNITI-1 was 9.2% & in UNITI-2, 4.8%. In the PsO studies (1Ph2/3Ph3), a total of 3117 pts received UST 45mg or 90mg SC; *no concomitant DMARD therapy (including MTX) was permitted.* The PsO studies were completed through 5-years of follow-up. All pts who received at least 1 dose of UST are included in this analysis. Safety events are reported in events per 100-pt years. 95% CI for events per 100 PY were estimated.

Results: Through 1 year of follow-up, a total of 1018 PsA pts were treated with UST, of which 465 were co-treated with MTX. Of the 1749 CD pts treated with UST, 139 received MTX. Discontinuation rates of UST due to adverse events (AEs) were comparable across disease states irrespective of MTX use (Table). AE rates (95% CIs for events/100 PY) were noted to be significantly lower in the UST vs PBO groups across the 3 diseases irrespective of MTX use-UST (420.39, 423.45) vs PBO (534.80, 570.44). Serious adverse event rates (SAEs) were also significantly lower in the UST vs PBO across the 3 diseases-UST (14.25, 16.56) vs PBO (24.05, 32.18). Infections and Serious infections (SIs) had numerically lower event rates in UST vs. PBO across the 3 disease states-UST (122.16, 128.72) vs PBO (120.94, 138.27) and UST (2.10, 3.05) vs PBO (2.76, 6.00), respectively (Table). Major adverse cardiovascular events (MACE) did not appear to significantly differ in both PBO & UST pts in PsA, PsO and CD. Event rates of malignancy (excluding non-melanoma skin cancer) were comparable across all disease states. No deaths in PsA or CD were reported.

*MACE adjudicated events includes CV death, non-fatal MI, or non-fatal stroke; **In the psoriasis studies, no concomitant DMARD therapy (including MTX) was permitted. ^includes data from the time of crossover, ^^includes data from the first UST dose onward for patients who crossed over from PBO

Conclusion: UST demonstrates a favorable safety profile in an integrated safety data analysis across the PsA, CD, & PsO phase 2 & 3 clinical trials. The use of UST in PsA appears to be safe & well-tolerated, with fewer event rates of SAEs & SIs noted vs PBO. Despite higher overall rates of SAEs & SIs observed in CD pts, the data do not suggest an influence of UST on either.

Association Between Biologic Therapies and Major Adverse Cardiac Events or Cardiac Heart Failure in Psoriatic Arthritis or Psoriasis: A Meta-Analysis

Benedicte Champs, Rheumatology, Medecine Toulouse Purpan Hospital, Lescure d'albigeois, France
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Association between biologic therapies and major adverse cardiac events or cardiac heart failure in psoriatic arthritis or psoriasis: a meta-analysis. [1]Champs B, [1]Degboe Y, [1]Ruyssen-Witrand A, [2]Barnetche T, [1]Cantagrel A, [1]Constantin A. 1 Centre de Rhumatologie, CHU Purpan & Université Toulouse III - Paul Sabatier, Toulouse, France. 2 Centre de Rhumatologie, CHU Bordeaux & Université Bordeaux, France

Background/Purpose: Patients with psoriatic arthritis (PsA) or psoriasis have an increased risk of cardiovascular morbidity and mortality. The short-term impact of biologic therapies on cardiovascular events is still debated. The objective of this meta-analysis was to investigate the association between biologic therapies and major adverse cardiac events (MACEs) or congestive heart failure (CHF) in PsA or psoriasis patients.

Methods: Study screening was performed using MEDLINE and Cochrane, from database inception to April 2016, including randomized controlled trials (RCTs) of anti-IL12/23 (briakinumab, guselkumab and ustekinumab), anti-IL17 (brodalumab, ixekizumab and secukinumab) or anti-TNF (adalimumab, certolizumab, etanercept, golimumab and infliximab) agents for the treatment of PsA or psoriasis. Two investigators independently performed data extraction of MACEs and CHF events

reported during the placebo-controlled phase of biologic therapies. These outcomes were presented as risk differences with their 95% confidence interval for each selected study. Meta-analyses were carried out independently in PsA or psoriasis, using the inverse variance method. Heterogeneity was tested with the Cochran's Q-test and evaluated by the I^2 statistic. We used RevMan 5.3 for the meta-analysis calculations. P-values less than 0.05 were considered statistically significant.

Results: On 415 studies initially screened, 56 studies were finally selected: 16 in PsA (1339.54 patient-years [P-Y]) and 40 in psoriasis (5128.96 P-Y). Compared with placebo, no significant difference was observed in MACEs in patients receiving anti-IL12/23, anti-IL17 or anti-TNF agents, neither in PsA nor in psoriasis. However, in psoriatic patients, 11 MACEs were observed in the anti-IL12/23 group (946 P-Y) compared to 0 in placebo group (493 P-Y), with 0.01 [-0.00 to 0.02] event / P-Y risk difference, which is not statistically significant (Figure). Similarly, no significant difference was observed in CHF incidence in patients receiving biologic agents, neither in PsA nor in psoriasis.

Conclusion: Even if there was no statistically significant difference in the incidence of MACEs or CHF in patients receiving biologic therapies during the placebo-controlled phase of RCTs, physicians must remain aware of the risk of MACEs or CHF when initiating a biologic therapy in PsA or psoriasis.

Figure: Meta-analysis of MACEs in psoriasis with anti-IL12/23 agent compared to placebo.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA), Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) are an inflammatory arthritis causing joint damage and disability. Non-adherence to disease modifying anti-rheumatic drugs (DMARDs) remains a significant barrier to improving clinical outcomes in these diseases. We aimed to compare adherence to DMARDs and associated factors in PsA and other rheumatic diseases.

Methods: This was a cross-sectional study of people with rheumatic disease receiving DMARDs. Patients with PsA (n=108), RA (n=54) and AS (n=54) were recruited from two tertiary rheumatology centers in Turkey (Trakya and Uludag Universities). The patients who met the classification criteria were enrolled in this cross-sectional study. The Beliefs about Medicines Questionnaire (BMQ), Illness Perception Questionnaire-Revised (IPQ-R), Medication Adherence Rating Scale (MARS) were used for the assessment.

Results: Patient characteristics and treatments shown in Table 1. The Specific Necessity was significantly lower in the PsA patients than in AS ($p < 0.001$) and RA ($p < 0.001$) patients. General Overuse and General Harm scores were significantly higher in PsA patients than in AS (p values <0.001) and RA patients (p values, 0.04 and 0.1). These scores were also higher in RA group than in AS group (p values 0.05 and 0.02, respectively). There was no significant difference between groups in the Specific Necessity scores and MARS scores for DMARDs. In PsA patients, illness coherence and timeline cyclical scores were significantly higher than in RA patients (p values, <0.001 and 0.033, respectively). Illness coherence score was significantly lower in RA patients than in AS patients ($p<0.001$). Treatment control score was significantly higher in RA patients than AS ($p=0.029$) patients. In other IPQ subscales there were no significant differences between groups seen in Table 2 and Table 3. In PsA group, the score of BMQ- Specific Necessity negatively correlated with total score of MARS ($r= -0.244$, $p=0.01$). The other correlations between MARS and BMQ scores there were no significant differences.

Conclusion: In conclusions, PsA patients do not have strong belief in personal need for the DMARDs when compared to RA and AS. Also, PsA patients have more concerns about medicines are overused and being harmful.

Table 1: Patient characteristics and treatments

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab (SEC) and infliximab (INF) are approved for the treatment of active PsA in adults with an inadequate response to conventional DMARDs. There are no head-to-head (H2H) randomized controlled trials (RCTs) between SEC and INF. In the absence of a H2H RCT, matching-adjusted indirect comparison (MAIC) can be used to generate comparative effectiveness data in the short and long term. MAIC adjusts for differences in baseline patient characteristics by using individual patient data (IPD) from one or more trials to match the treatment population of another trial. The aim of this MAIC was to assess the relative effectiveness of SEC 150 mg and 300 mg versus INF 5 mg/kg in patients with active PsA using data from the FUTURE 2 and IMPACT 2 RCTs.

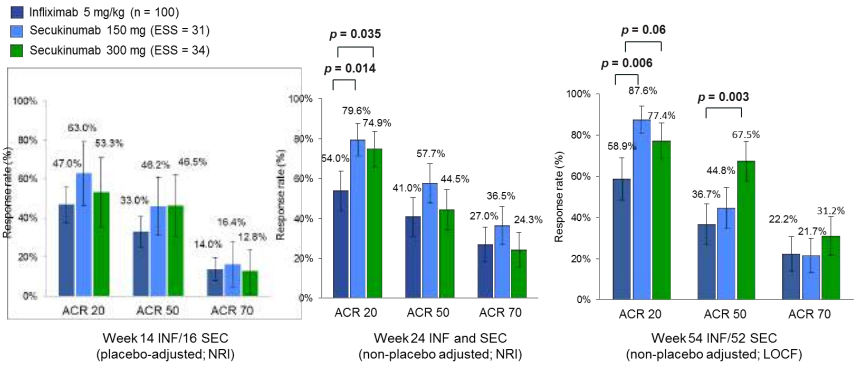
Methods: IPD from the SEC arms of FUTURE 2 (75 mg, n = 99; 150 mg, n = 100; 300 mg, n = 100) were weighted to match baseline characteristics of the INF arm of IMPACT 2 (n = 100); placebo arms were also matched (FUTURE 2, n = 98; IMPACT 2, n = 100). Logistic regression was used to determine weights for age, body weight, sex, race, methotrexate use, presence of psoriasis on ≥ 3% of body surface area, mean PASI score, Health Assessment Questionnaire Disability Index (HAQ-DI) score, dactylitis, enthesitis and previous use of anti-TNFs. Recalculated outcomes from FUTURE 2 (150 mg effective sample size [ESS]: 31; 300 mg ESS: 34; placebo ESS: 15) were compared with published aggregate outcomes

from IMPACT 2 at weeks 14/16, 24 and 54/52 (the closest data points available for comparison). Placebo-adjustment was valid only until week 14/16 because patients could switch to active treatment as early as week 16 in both trials. ACR outcomes are presented as response rates (%) and pairwise comparisons using odds ratios (ORs).

Results: The ACR 20 response at week 14/16 with placebo was 8% in FUTURE and 11% in IMPACT 2, indicating a good match. After placebo-adjustment, at week 14/16 there was no difference in ACR 20 response rate between SEC and INF. At week 24, there was evidence of higher ACR 20 response rates for SEC 150 mg and 300 mg than for INF (OR [95% CI]: 3.33 [1.28–8.69]; $p = 0.014$ and OR: 2.55 [1.07–6.08]; $p = 0.035$, respectively). At week 54/52, there was evidence of a higher ACR 20 response rate for SEC 150 mg (OR [95% CI]: 4.92 [1.56–15.48]; $p = 0.006$) and a higher ACR 50 response rate for SEC 300 mg (OR [95% CI]: 3.59 [1.56–8.29]; $p = 0.003$) than for INF.

Conclusion: This MAIC showed higher ACR 20 response rates for SEC 150 mg and 300 mg than for INF at week 24, and higher ACR 20 (150 mg) and 50 (300 mg) response rates than for INF (non-placebo-adjusted) at week 54/52. There was no evidence of differences in the short-term placebo-adjusted phase. Key limitations of this MAIC are that placebo-adjustments were valid only until week 14/16, week 24 was the only common time point for which outcomes were reported for both RCTs, and the ESS for SEC was low. H2H RCTs remain the gold standard for comparing treatments.

MAIC ACR response rates at weeks 14/16, 24 and 54/52



All *p* values are based on pairwise comparisons using ORs. We avoid strict thresholds when interpreting statistical *p* values, as per the American Statistical Association definition (7 March 2016), but interpret values from 0.1 to 0.001 as weak to moderate evidence and, < 0.001 as strong evidence.
ACR, American College of Rheumatology response criteria; ESS, effective sample size; LOCF, last observation carried forward; NRI, non-responder imputation; OR, odds ratio.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose : Early achievement of minimal disease activity (MDA) is recommended as a valid treat-to-target approach in psoriatic arthritis (PsA). The purpose of the current analysis was to evaluate disease progression in PsA patients among non-achievers of MDA treated with anti-TNF agents under Canadian routine practice.

Methods : Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with Infliximab (IFX) or Golimumab (GLM), or with ustekinumab (UST) for PsA. Eligible people for this analysis included PsA patients treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010 or with UST enrolled since 2014 and with available MDA information at 6 and 12 months of treatment. MDA was defined as the fulfillment of ≥5 of the following criteria: TJC28≤1, SJC28≤1, PASI≤1 or BSA≤3, Pain (VAS)≤15mm, PtGA (VAS)≤20mm, HAQ ≤0.5, tender entheseal points ≤1. Pairwise comparisons in disease parameters were assessed with the non-parametric Wilcoxon test. Variables associated with improved DAS28 and MDA achievement were examined using general linear models and logistic regression, respectively, wherein variables showing a statistical trend (P<0.150) in univariate analysis were considered in multivariate analysis to identify predictors.

Results: A total of 106 patients (55.2% male and 88.7% bio-naïve) were included with a mean (SD) age and disease duration of 49.6 (11.4) and 5.6 (6.9) years, respectively. The proportion of patients who achieved MDA at 6 months was 49.1% (n=52) while 50.9% (n=54) did not achieve MDA. Among patients with MDA at 6 months, 75.0% had sustained MDA at 12 months and among the non-achievers, 14.8% achieved MDA at 12 months of treatment. Disease parameters over time among the non-MDA achievers at 6 months are described in Table 1; overall, no statistical changes were observed between 6 months and 12 months. Multivariate logistic regression analysis showed that lower baseline HAQ (OR=0.459, P=0.071) and MDA achievement at 6 months were associated with higher odds (OR=12.604; P<0.001) of MDA achievement at 12 months of treatment. Multivariate general linear models showed that MDA achievement at 6 months (B=-0.770, P=0.042) and being bio-naïve (B=-2.296, P=0.001) were significant predictors of DAS28 improvement at 12 months of treatment.

Conclusion: The results of the current analysis have shown that achievement of MDA at 6 months is critical for MDA achievement/maintenance at 12 months highlighting the importance of intensive treatment early on. Furthermore, these results highlight the importance of treatment optimization in cases where MDA is not achieved. Table 1: Disease Parameters for MDA Non-Achievers at 6 Months of Treatment

Disease Parameter, mean (SD)	Visit			P-Value
	Baseline	Month 6	Month 12	12 mos vs 6 mos
SJC28	5.57 (5.02)	1.83 (2.63)	2.52 (3.89)	0.243
TJC28	8.92 (6.91)	4.93 (6.11)	4.50 (5.35)	0.968
Pain, mm VAS	55.24 (23.55)	45.30 (19.87)	42.43 (26.71)	0.385
PtGA, mm VAS	59.00 (23.62)	44.61 (22.15)	41.74 (25.49)	0.533
HAQ-DI	1.29 (0.57)	1.15 (0.52)	1.19 (0.56)	0.135
PASI	3.02 (4.43)	1.24 (2.48)	1.27 (1.86)	0.242
Enthesitis Count	1.96 (3.55)	1.67 (3.55)	1.76 (3.11)	0.436
DAS28	4.71 (1.38)	3.62 (1.18)	3.58 (1.40)	0.780

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory diseases such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA), including ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA), can impact significantly on patients' (pts') ability to perform work-related tasks in both paid employment and the household.[1,2] Previous results show improvements in work and household productivity with certolizumab pegol (CZP) in pts with established RA,[3,4] PsA[5] and axSpA.[6] We examined the comparative economic burden of RA, PsA and axSpA and the impact of CZP on productivity after 1 year (yr) in pts of working age.

Methods: Baseline (BL) and 1 yr data from: RA: PREDICT (NCT01255761),[3] RAPID 1 (NCT00152386),[4] RAPID 2 (BL data only, NCT00160602);[4] PsA: RAPID-PsA (NCT01087788);[5] axSpA: RAPID-axSpA (NCT01087762).[6] Pts received CZP loading dose (400 mg at Weeks [Wks] 0, 2, 4), followed by 200 mg Q2W+MTX (RA), or 200 mg Q2W or 400 mg Q4W (PsA/axSpA). The arthritis-specific Work Productivity Survey (WPS),[7] administered Q4W from BL, assessed the impact of disease on workplace and household productivity. Disease burden at BL and WPS responses (LOCF imputation) over 52 wks (RA) and 48 wks (PsA/axSpA), in CZP-treated pts stratified by age and employment status, are summarized descriptively.

Results: At BL, 582/1372 (42%) RA pts, 166/273 (61%) PsA pts, and 157/218 (72%) axSpA pts were employed outside the home. BL demographics were typical of each disease population; mean age of employed pts and pts unemployed due to arthritis/other conditions was similar (Table). Employed pts reported similarly high disease burden at BL across RA, PsA and axSpA (Table); by age, highest absenteeism was in pts aged 35–45 yrs (mean days/month: 3.1 [RA], 2.3 [PsA]) and 25–35 yrs (mean days/month: 2.4 [axSpA]) and presenteeism in pts under 35 yrs (mean days/month: 7.7 [RA], 6.5 [PsA], 7.1 [axSpA]). Compared to employed pts, unemployed pts reported a higher burden on household work and social activities, with highest burden in pts unemployed due to arthritis (Table). Similar improvements were seen in work and household productivity after 1 yr of CZP treatment, regardless of employment status, across all diseases (Table).

Conclusion: RA, PsA and axSpA pts of working age reported comparably high burden of disease on work and household productivity at BL; household burden was greater in disease-disabled pts. CZP treatment leads to comparable improvements in work and household productivity over 1 yr across RA, PsA and axSpA employed and disease-disabled pts. **References:** 1. Mau W. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a complex rheumatic disease with severity that ranges from mild to severe. The mild form of PsA can be referred to as oligoarticular (OLIGO), whereas more severe cases are considered polyarticular (POLY) form. Furthermore, peripheral joint and axial involvement are also recognized in PsA. This analysis examined OLIGO vs. POLY differences and presence of axial involvement at initiation of golimumab (GLM) for the treatment of PsA in a Canadian routine clinical practice setting.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with Infliximab, GLM, or ustekinumab for PsA. PsA patients treated with GLM who were enrolled since 2010 were eligible for the analysis. OLIGO involvement was defined as (≤2 SJC) and POLY (>2 SJC), while axial involvement included spinal symptoms or spondylitis with peripheral arthritis. Minimal disease activity (MDA) was defined as the fulfillment of ≥5 of the following criteria: TJC28≤1, SJC28≤1, PASI≤1 or BSA≤3, Pain (VAS)≤15mm, PtGA (VAS)≤20mm, HAQ ≤0.5, tender entheseal points ≤1.

Results: A total of 201 PsA patients were included in this analysis; 30.8% had oligoarthritis, 68.0% had polyarthritis, while 26.0% had axial involvement at baseline. Baseline parameters are described by axial involvement and articular involvement (Table 1). Increased baseline disease activity was observed among patients with axial involvement for MDGA, PtGA, pain, and presence of enthesitis ($p<0.05$). Patients with polyarthritis were older, less likely to have been previously treated with a biologic, and had significantly ($p<0.05$) higher SJC28, TJC28, morning stiffness, MDGA, PtGA, pain, DAS28, HAQ, and enthesitis at GLM initiation. At 6 months, statistically significant between group differences were observed for MDA achievement. There were significantly lower proportions of patients achieving MDA among patients with axial involvement (26.7% vs. 61.8%, $p=0.020$) and polyarthritis (35.9% vs. 80.0%, $p<0.001$). Multivariate logistic regression analysis showed that patients with oligoarticular involvement (OR=3.92; $p=0.035$), younger age (OR=0.96; $p=0.051$), and lower baseline HAQ (OR=0.32; $p=0.007$) were associated with higher odds of MDA achievement at 6 months of treatment while axial involvement did not have a significant impact.

Conclusion: The results of the current analysis highlight that differences exist in the baseline patient profile based on the presence or absence of axial involvement and POLY involvement among PsA patients treated with GLM. Furthermore,

OLIGO disease was identified as a significant independent predictor of MDA achievement with almost a four-fold higher likelihood of achieving target relative to patients with polyarthritis.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: PsA, a chronic immune-mediated inflammatory disease, can be progressive and destructive, resulting in physical deformities, impaired function, decreased quality of life, and increased mortality. Ixekizumab (IXE) is an IgG4 monoclonal antibody that binds with high affinity and specificity to the proinflammatory cytokine IL-17A. Data are presented from a phase 3 trial (SPIRIT P1; NCT01695239) with IXE in patients (pts) with active PsA. The objective is to explore the impact of IXE, as assessed by disease activity composite measures, up to 52 weeks (wks).

Methods: 417 bDMARD-naive adult pts with active PSA, were randomly assigned 1:1:1:1 to subcutaneous administration of either 80 mg IXE every 4 wks [Q4W] or every 2 wks [Q2W], each with a 160 mg starting dose at Wk 0; adalimumab (ADA) 40 mg Q2W [active comparator]; or placebo (PBO) in the Double Blind Treatment Period (DBTP; Wks 0-24). Of these pts, 381 continued into the Extension Period (EP; Wks 24-52). PBO- and ADA treated pts were randomly re-assigned

(1:1) to 80 mg IXEQ4W or IXEQ2W at Wk 16 (inadequate responders) or Wk 24; ADA-treated pts started IXE, after an 8-wk wash-out period, at Wk 24 (inadequate responders) or Wk 32. Investigators were blinded as to the criteria for inadequate response. Disease activity was measured at Wks 24 and 52 by composite measures including the following: minimum disease activity (MDA) as measured with the Psoriasis Area and Severity Index (MDA_{PASI}) and with the static Physician Global Assessment of psoriasis (MDA_{sPGA}), and modified Composite Psoriatic Disease Activity Indices (CPDAI-12 and CPDAI 14 [see Table 1 footnote]). Analyses for the DBTP were conducted on the Intent-to-Treat Population, defined as all randomly assigned pts; analyses for the EP were conducted on the EP Population, defined as all pts who received at least 1 dose of study drug during the EP. In the DBTP, treatment comparisons were made by a logistic regression model for categorical data with missing values imputed by nonresponder imputation; a mixed model for repeated measures analysis was used for continuous data.

Results: At Wk 24, CPDAI 12 and CPDAI-14 total scores (assesses domains of peripheral arthritis, skin disease, enthesitis, dactylitis [and spinal disease for CPDAI-14 only]) for pts receiving IXEQ4W, IXEQ2W, or ADA, were significantly improved compared with results for pts receiving PBO (Table 1). Similarly, at Wk 24, significantly more pts receiving IXEQ4W, IXEQ2W, or ADA achieved MDA_{sPGA} and MDA_{PASI} compared with pts receiving PBO (Table 1), and percentages of pts receiving IXEQ4W or IXEQ2W who achieved MDA_{sPGA} and MDA_{PASI} were sustained through Wk 52 (Table 2). Results for MDA_{sPGA} were similar to results for MDA_{PASI} within each treatment group.

Conclusion: IXE provides sustained improvement of disease activity, as measured by various composite measures, for up to 52 wks in bDMARD-naive pts with active PsA.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment goals for long-term control of skin and joint symptoms in active psoriatic arthritis (PsA) include clinically important changes in DAS-28 (CRP), achievement of remission in DAS-28 (CRP), reduction in swollen joint count (SJC), and decrease in skin disease.[1] PALACE 3 (NCT01212770) included PsA patients (pts) with active joint disease and an active skin lesion at the time of enrollment. We report the impact of apremilast (APR) on PsA manifestations over 4 years.

Methods: Pts were stratified by baseline (BL) DMARD use (yes/no) and psoriasis involvement of the body surface area (<3%/≥3%) and randomized (1:1:1) to placebo (PBO), APR 30 mg BID (APR30), or APR 20 mg BID (APR20). After the 24-week PBO-controlled phase, all pts were treated with APR30 or APR20 and could enroll in the long-term extension. Efficacy assessments were conducted through Week 208.

Results: 505 pts were randomized and received ≥1 dose of study medication (PBO: n=169; APR30: n=167; APR20: n=169). A total of 91% (227/249) of pts starting the fourth year of APR therapy completed the Week 208 visit. Pts treated with APR30 demonstrated sustained decreases in disease activity at Week 208, as shown by mean change from BL in DAS-28 (CRP) of −1.66; 80.3% achieved good/moderate EULAR response and 50.4% achieved DAS-28 (CRP) remission. Sustained effect on inflammation at Week 208 was also demonstrated by mean/median percent changes in SJC, a marker of inflammatory activity, of −77.4%/−100.0% (Table); 64.8% of pts had an SJC 0 or 1. Decreases in disability and maintenance of functionality were shown by sustained improvements in Health Assessment Questionnaire-Disability Index (HAQ-DI) scores (Table). A continued effect on skin disease was shown by decreases in skin involvement, as measured by the Psoriasis Area and Severity Index (PASI); 54.7% of APR30 pts had BL PASI >5 and 27.3% had BL PASI >10; at Week 208, 64.5% had PASI <3 and 77.4% had PASI ≤5. PASI-75 and PASI-50 response rates also signified clinically significant relief (Table). In pts treated with APR20, similar findings were observed at Week 208. No new safety concerns were identified through 208 weeks of APR30 therapy. During Weeks >156 to ≤208 of APR30 exposure, the only AE occurring in ≥5% of pts was nasopharyngitis; most AEs were mild or moderate in severity. Serious AEs occurred in 7.2% of APR30 pts Weeks >156 to ≤208, similar to rates in earlier study periods. Few discontinuations due to AEs (0.7%) occurred over Weeks >156 to ≤208. The APR20 safety profile was similar to that of APR30.

Conclusion: Over 208 weeks, APR demonstrated sustained and clinically important improvements in PsA signs and symptoms, including physical function and associated psoriasis, among pts continuing the study. APR was generally well tolerated with an acceptable safety profile. **Reference:** 1. Gossec et al. *Ann Rheum Dis*. 2015 Dec 7. doi: 10.1136/annrheumdis-2015-208337.

	Outcomes at Week 208
	APR30 n=129*
DAS-28 (CRP), mean change	−1.66
DAS-28 (CRP) <2.6, n/m (%)	64/127 (50.4)
SJC, mean % change	−77.4
TJC, mean % change	−64.4
HAQ-DI (0-3), mean change	−0.42
HAQ-DI MCID ≥0.30, n/m (%)	63/129 (48.8)
HAQ-DI MCID ≥0.35, n/m (%)	63/129 (48.8)
ACR20, n/m§ (%)	85/128 (66.4)
ACR50, n/m§ (%)	51/128 (39.8)
ACR70, n/m§ (%)	31/127 (24.4)
PASI-75, n/m (%)‡	28/62 (45.2)
PASI-50, n/m (%)‡	42/62 (67.7)

Data as observed.
*The n reflects the number of pts treated with APR30, regardless of when APR was started (BL, Week 16, or Week 24) and who had data available at Week 208; actual number of pts available for each end point may vary. §Denominators vary slightly due to availability of sufficient data for each level of ACR response assessment. ‡Examined among pts with psoriasis involvement of the body surface area ≥3% at BL and having data at Week 208.
n/m=number of responders/number of pts with sufficient data for evaluation; TJC=tender joint count; ACR20/50/70=20%/50%/70% improvement in modified American College of Rheumatology response criteria; PASI-75/50=≥75%/≥50% reduction from BL PASI score.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: COMPLETE-PsA is an ongoing observational study planning to enroll 670 psoriatic arthritis (PsA) patients (pts) from ~40 sites across Canada. Main objectives are to compare the real-life effectiveness of adalimumab (ADA) to traditional non-biologic DMARDs and to describe the PsA burden of illness. The goal of this analysis is to describe the demographics and baseline disease parameters of the cohort and to report preliminary Canadian data on the real-life effectiveness of ADA in PsA.

Methods:

This was a pre-specified interim analysis of pts enrolled between 8/2011−8/2015. Eligible pts are adults with active PsA with ≥3 tender and swollen joints, active psoriatic skin lesions or confirmed history of psoriasis, who are anti-TNF naïve and require a change in current treatment. Pts are followed for up to two years as per routine care with suggested assessments at months 3, 6, 9, 12, 18, and 24. Data captured include disease activity (28 tender [TJC28] and swollen [SJC28] joints, HAQ, physician [PGA] and patient [PtGA] global assessment, morning stiffness, psoriasis body surface area [BSA], PASQ, and DLQI), periarticular manifestations, quality of life (SF-36, BDI-II), and work limitations (WLQ).

Results:

Of the 319 pts (ADA n=181, DMARD n=138) included in the analysis, 236 (74%) had available 6-month data. At baseline, mean age was 51.0 yrs (SD 12.3), 51.7% were female, and mean disease duration was 4.2 yrs (SD 6.5). There were no significant differences between treatment groups. Family history of PsA (14.2%) and arthritis subtype (64.2% symmetric polyarthritis) were also comparable.

Within the ADA group, 79.6% were treated with a concomitant DMARD (MTX: 65.7%; HCQ: 18.2%; SSZ: 16%; LEF: 9.4%; AZA: 1.7%; Gold: 1.1%) at baseline, while 63.5% had been previously treated with a DMARD (33.1% with 1 DMARD, 18.8% with 2, 11.6% with ≥3). Within the DMARD group, the following DMARDs were used: MTX (85% of pts), HCQ (18.0%), SSZ (18%), LEF (15.8%), and AZA (1.5%); with 33.8% using ≥1 DMARDs.

At baseline, ADA pts had significantly higher DAS28 (4.9 vs. 4.5; P=0.017), SJC28 (8.5 vs. 6.0; P<0.001), morning stiffness (88.5 vs. 58.7 min; P=0.008), PtGA (56.6 vs. 44.6; P<0.001), HAQ (1.1 vs. 0.9; P<0.001), and lower SF-36 score (26.6 vs. 27.4; P=0.003) but statistically comparable CRP, ESR, TJC28, BSA, PGA, PASQ, and DLQI. Productivity loss was higher in the DMARD group (17.8% vs. 16.4%; P=0.021).

By 6 months, 8% of pts in the DMARD group vs. 2.8% in the ADA group (P=0.035) were discontinued. At 6 months, significant improvements were observed in almost all disease parameters. Adjusting for baseline values, ADA pts had significantly lower DAS28 (2.6 vs. 3.7; P<0.001), TJC28 (3.0 vs. 5.8; P=0.001), SJC28 (1.4 vs. 4.2; P<0.001), PGA (16.9 vs. 34.5; P<0.001), PtGA (29.3 vs. 39.9; P=0.030), HAQ (0.64 vs. 0.93; P<0.001), PASQ (9.5 vs. 10.7; P=0.015) and DLQI (2.2 vs. 4.1; P=0.015) vs. pts in the DMARD group.

Conclusion: PsA pts initiating ADA in Canadian routine clinical care have more severe disease compared with those initiating traditional DMARDs. However, over 6 months, ADA treatment had better retention, and was more effective in reducing symptom severity and improving outcomes.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF inhibitors (TNFi) are effective treatment in radiographic and non-radiographic axial spondyloarthritis (r-axSpA and nr-axSpA). Nr-axSpA have lower response rate in case of absence of sacroiliitis on magnetic resonance imaging (MRI) or elevated C-reactive protein (CRP) but TNFi efficacy in the absence of clinical, biological or radiological objective signs of axSpA is unknown. The main objective of our study was to compare BASDAI 50 TNFi response rate at 3 months in axSpA depending on the presence or not of objective signs of axSpA.

Methods: Nr-axSpA patients fulfilling ASAS 2009 criteria, without any objective signs defined as the absence at the time of TNFi initiation of radiographic and MRI sacroiliitis, elevated CRP level, dactylitis, anterior uveitis and treated inflammatory bowel disease were included in this retrospective bicentric study between January 2001 and September 2015. They were matched base on a ratio of 1:1, on age, sex and type of TNFi, with axSpA patients having at least one objective sign. Patients had to be treated for at least 3 months with an anti-TNF. The primary outcome of our study was the TNFi efficacy, defined as an achievement of 50% improvement of the initial Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) at 3 months. The secondary outcomes were BASDAI 50 achievement over one year and assessment of predictive factors of TNFi response.

Results: We included 84 nr-axSpA patients without any objective sign and 84 axSpA patients with objective signs. Patients were mostly women (76.2%) with a mean ± standard deviation age of 42 ± 11 years. BASDAI 50 achievement rates were significantly higher in patients with objective signs than in patients without, at 3 months (45.1% versus 13.7%, $p<0.0001$) and over one year (61.9% versus 21.4% considering all time point for evaluation, $p<0.0001$). In the total population, positive predictive factors of a BASDAI 50 response achievement at 3 months in univariate analysis were a radiographic sacroiliitis [16/47 (34%) responders versus 22/114 (19.3%) non responders, $p=0.038$], a sacroiliitis on MRI [19/33 (57.6%) responders versus 18/97 (18.6%) non responders, $p < 0.0001$], an elevated CRP [16/48 (33.3%) in responders versus 20/114 (17.5%) in non responders, $p = 0.025$] and a lower mean BASDAI at TNFi initiation [5.4 (1.5) in responders versus 6 (1.5) in non responders, $p = 0.017$]. Overweight or obesity and sacroiliitis on MRI were respectively a negative and positive predictive factors of TNFi efficacy in multivariate analysis in the all population [OR = 0.32, 95%CI (0.11, 0.96), $p = 0.041$ and OR = 6.92, 95%CI (2.41, 19.82), $p < 0.0001$, respectively].

Conclusion: Our study confirms the existence of patients diagnosed with nr-axSpA, according to clinical arm of the ASAS criteria, in whom TNFi have a very low efficacy and should not be used if no objective sign is present at treatment initiation. We also stated high BMI (≥ 25 kg/m^2) as a negative predictive factor of TNFi efficacy.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatic inflammatory arthropaties such as Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Spondyloarthrities (SpA) are chronic diseases that require adequate therapies, sometimes biological drugs, to minimize inflammation and disease progression. The adherence to biologicals is supposed to be better than adherence to synthetic DMARDs, mainly methotrexate. The purpose of this study is to evaluate adherence to subcutaneous biological therapies and to assess the relationship between adherence and different demographic and clinical aspects, and its effect on clinical outcomes.

Methods: Observational retrospective study of 272 clinical records of patients with inflammatory rheumatic diseases on subcutaneous biological treatment, were reviewed. Demographic, clinical characteristics and comorbidities were compiled. Disease activity was classified as low, moderate and high based on DAS 28 in patients with peripheral arthritis and BASDAI in patients with axial SpA. Adherence was obtained for the last year from the Hospital Pharmacy registry (FARHOS). Adherence was randomly rated as good >80% of compliance, medium 60-79% and fair <59%. 11 patients not actually under biological treatment were excluded from analysis. Statistical analyses were performed using SAS for Windows statistical software, version 9.2.

Results: From the 261 patients evaluated, 52% were female, mean aged 54 + 13.9 SD years (range 19-86). 35.6 % had RA diagnosis, 32% PsA, 29.5% axial SpA and, 6% peripheral SpA and 1% non-radiographic axial SpA. Median time of disease progression was 10.7 years. 34% presented more than two comorbidities.39% were under adalimumab, 38 % etanercept, 7.3% golimumab, 5.4% certolizumab, 4.6% tocilizumab, 2,7 % abatacept and 1% ustekinumab. 68 % were on their first biological drug, 25% on the second, and the rest had more than one biologic agent previously prescribed. 46 received concomitant synthetic DMARD. Overall adherence to biological treatment, was good, 93%, and there was no correlation between adherence and diagnose, gender, age, time of disease progression, concurrence of more than two comorbidities, cotreatment with synthetic DMARD, type of biological drug or previous treatment with other biologicals. There has been found correlation between disease activity (DAS, BASDAI) and adherence as shown in the table, P 0.0038 (Chi Square).

Conclusion: The overall adherence to subcutaneous biological therapies is very good and non-compliance has an impact in the disease activity as has been observed in this study. Therefore, it is important to check adherence when clinical response is poor to subcutaneous biological therapies and we must consider the implementation of tools to monitor adherence in order to identify non-compliant patients, quite relevant for clinical decision making.

Adherence / D. Activity	<59%	60-79%	>80%	TOTAL
LOW	2%	4%	61%	67%
MODERATE	0.5%	3.2%	11.3%	15%
HIGH	2%	2%	14%	18%

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

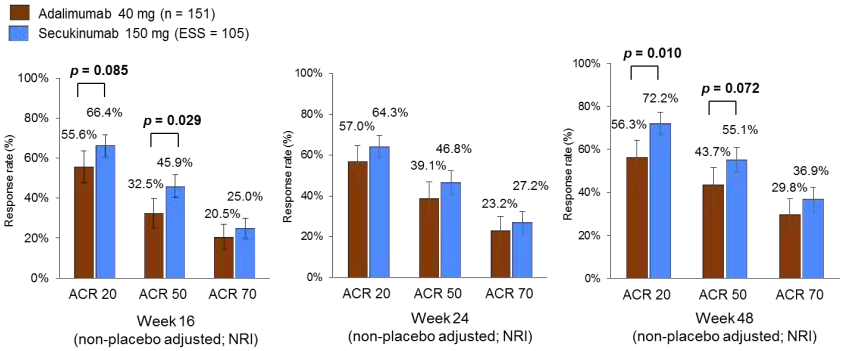
Background/Purpose: Secukinumab (SEC) and adalimumab (ADA) are approved for the treatment of active PsA in adults with an inadequate response to conventional DMARDs. A head-to-head randomized controlled trial (RCT) between SEC and ADA was recently announced (EXCEED 1) but until the results are available, matching-adjusted indirect comparison (MAIC) can be used to estimate short- and long-term comparative effectiveness. MAIC adjusts for differences in baseline patient characteristics by using individual patient data (IPD) from one or more trials to match the population of another trial. The aim of this MAIC was to assess the relative effectiveness of SEC and ADA in active PsA using data from FUTURE 1, FUTURE 2 and ADEPT RCTs.

Methods: IPD from the pooled SEC 150 mg arms of FUTURE 1 (n = 202) and FUTURE 2 (n = 100) were weighted to match the published baseline characteristics of the ADA 40 mg arm of ADEPT (n = 151). SEC 300 mg was not included because it was not used in FUTURE 1. Logistic regression was used to determine weights for age, body weight, sex, race, methotrexate use, presence of psoriasis on ≥ 3% of body surface area, Psoriasis Area Severity Index score, Health Assessment Questionnaire Disability Index (HAQ-DI) score, dactylitis, enthesitis and previous anti-TNF therapy. Recalculated outcomes with SEC 150 mg from the FUTURE RCTs (estimated sample size [ESS]: 105) were compared with published aggregate ADA outcomes from ADEPT at weeks 16, 24 and 48. Placebo-adjustment was not valid because patients in ADEPT could receive rescue therapy from week 12. Comparisons are presented as response rates (%, non-

placebo-adjusted) and as pairwise comparisons using odds ratios (ORs) and change in mean score from baseline for HAQ-DI.

Results: After matching, ACR 20 and 50 response rates at week 16 were higher for SEC than for ADA (OR [95% CI]: 1.57 [0.94, 2.64]; $p = 0.085$ and OR: 1.77 [1.06, 2.96]; $p = 0.029$, respectively). At week 24, there was no evidence of differences in ACR response between SEC and ADA. At week 48, there was evidence of higher ACR 20 and 50 response rates with SEC than with ADA (OR: 2.01 [1.18, 3.43]; $p = 0.010$ and OR: 1.58 [0.96, 2.61]; $p = 0.072$, respectively) and evidence of greater improvements in HAQ-DI score (SEC: −0.50 [−0.56, −0.45] vs ADA: −0.40 [−0.48, −0.32]; $p = 0.0388$). HAQ-DI results were not available at week 16 and there was no evidence of differences at week 24. These findings were consistent with a sensitivity analysis that also matched for PsA disease duration, swollen joint count and CRP (SEC ESS = 62).

Conclusion: This MAIC showed that SEC 150 mg was associated with higher ACR 20 and 50 response rates at weeks 16 and 48, and greater improvements in HAQ-DI scores at week 48, relative to ADA. Key limitations included not being able to placebo-adjust or include the SEC 300 mg dose and the reduced ESS for SEC. The awaited results from EXCEED 1 are needed to substantiate the findings of this analysis.



All *p* values are based on pairwise comparisons using ORs, *p* values were adjusted for multi-comparisons. We avoid strict thresholds when interpreting statistical *p* values, as per the American Statistical Association definition (7 March 2016), but interpret values from 0.1 to 0.001 as weak to moderate evidence and, < 0.001 as strong evidence.
ACR, American College of Rheumatology response criteria; ESS, effective sample size; NRI, non-responder imputation; OR, odds ratio.

MAIC ACR response rates at weeks 16, 24 and 48

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

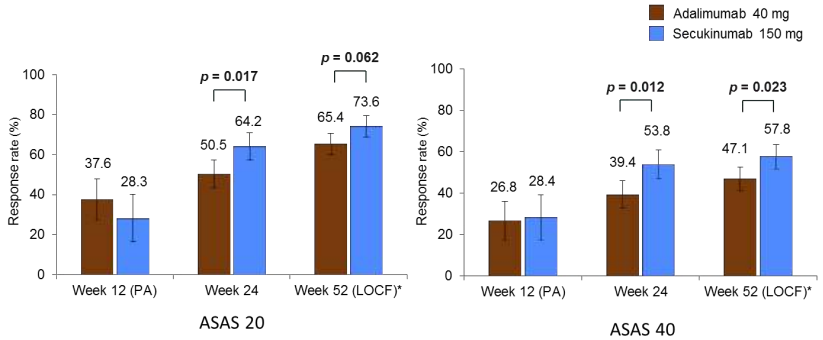
Background/Purpose: Secukinumab (SEC) and adalimumab (ADA) are approved for the treatment of patients with active AS. However, there are no head-to-head randomized controlled trials (RCTs) between SEC and ADA. In the absence of such trials, matching-adjusted indirect comparison (MAIC) can be used to generate comparative effectiveness data. MAIC adjusts for differences in baseline patient characteristics by using individual patient data (IPD) from trials of one treatment to match the population of a different therapy arm of another trial. The aim of this MAIC was to assess the relative effectiveness of SEC 150 mg and ADA 40 mg in patients with active AS.

Methods: IPD from the pooled SEC 150 mg arms of MEASURE 1 (n=125) and MEASURE 2 (n = 72) were weighted to match the published baseline characteristics of the ADA 40 mg arm of ATLAS (n = 208); placebo arms were also matched. Logistic regression was used to determine weights for age, sex, BASFI, CRP and previous anti-TNF therapy. Recalculated SEC 150 mg outcomes (effective sample size [ESS] = 120; placebo ESS = 120) were compared with published aggregated ADA data at weeks 12, 16, 24 and 52. Placebo-adjusted results were valid only until week 12 as patients receiving placebo in ATLAS could switch to open label ADA (69% had switched by week 24). Therefore, all comparisons beyond week 12 were non-placebo adjusted. Imputation methods for missing data were matched between trials. NRI was available for all binary outcome data except for ADA at week 52 which was LOCF only and included placebo switchers. This was matched by including placebo switchers for SEC at week 52. Comparisons are presented as response rate (%) and pairwise comparisons using odds ratios (ORs).

Results: At week 12 there were no differences in placebo-adjusted response rates between SEC and ADA. At week 16, there was a higher ASAS 20 non-placebo adjusted response rate for SEC relative to ADA (OR [95% CI]: 1.60 [1.01–2.54], $p = 0.047$). At week 24, there were higher ASAS 20 and ASAS 40 non-placebo adjusted response rates for SEC relative to ADA (OR [95% CI]: 1.76 [1.11–2.79], $p = 0.017$ and OR [95% CI]: 1.79 [1.14–2.82], $p = 0.012$, respectively). At week 52, there were higher ASAS 20 and ASAS 40 non-placebo adjusted response rates for SEC relative to ADA (OR [95% CI]: 1.48 [0.98–2.22], $p = 0.062$ and OR [95% CI]: 1.54 [1.06–2.23], $p = 0.023$, respectively). A sensitivity analysis that included BASDAI score in the baseline matching showed similar findings.

Conclusion: This MAIC showed that SEC 150 mg was associated with higher (non-placebo-adjusted) ASAS 20 response rates at weeks 16, 24 and 52 and ASAS 40 at weeks 24 and 52 relative to ADA. No differences in placebo-adjusted response rates were evident at week 12. Substantial switching of placebo patients to active therapy in ATLAS precluded analysis of placebo-adjusted data beyond week 12. This exploratory analysis requires confirmation by a head-to-head RCT.

MAIC ASAS 20 and ASAS 40 response rates at weeks 12, 24 and 52



SEC 150 mg ESS (from MEASURE trials): n = 120 (weeks 12 and 24) and n = 177 (week 52).
ADA 40 mg (from ATLAS trial), n = 208 (weeks 12 and 24) and n = 311 (week 52)

*Includes placebo switchers (ATLAS and MEASURE trials).

Week 16 ASAS 20 data not shown as there was no corresponding ASAS 40 outcome. All *p* values are based on pairwise comparisons using ORs. We avoid strict thresholds when interpreting statistical p values, as per the American Statistical Association (7 March 2016), but interpret values between 0.1–0.001 as weak to moderate evidence, and < 0.001 as strong evidence.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Improving and preserving patient (pt) physical function is an important goal in managing psoriatic arthritis (PsA). Apremilast (APR) has been shown to improve signs and symptoms, quality of life, and functional disability in DMARD/biologic-experienced (PALACE 1-3 [PAL1-3]) and DMARD-naive (PALACE 4 [PAL4]) pts with active PsA.

We report long-term functional status for pts continuing APR up to 3 yrs.

Methods: Pts were randomized (1:1:1) to placebo (PBO), APR 30 mg BID (APR30), or 20 mg BID (APR20). PBO pts were re-randomized to APR30 or APR20 at Wk 16 (early escape) or Wk 24. HAQ-DI scores were assessed throughout the study for mean change from BL, proportion of pts reaching MCID, and proportion reaching scores ≤1.0 (below clinically significant disability), ≤0.5 (minimal disability), and ≤0.25 (general population). PAL1-3 data were pooled. Wk 16 APR30 data vs PBO were analyzed by LOCF. Wk 156 data are as observed. Mean change and MCID outcomes are for all pts receiving APR30 at any time during the study; disability level data are for pts randomized to APR30 at BL.

Results: PAL1-3 (biologic/DMARD experienced) and PAL4 (DMARD naïve) pts were similar in BL SJC/TJC and DAS-28 (CRP), indicating active PsA. PAL1-3 pts had longer mean duration of PsA and psoriasis, higher PASI scores, and greater corticosteroid use at BL. Despite longer PsA duration in PAL1-3 vs PAL4 (7.4 vs 3.4 yrs), clinically significant BL physical disability was similar: mean HAQ-DI 1.2 (PAL1-3) vs 1.1 (PAL4). At Wk 16, physical function significantly improved with APR30 vs PBO: mean HAQ-DI change −0.23 vs −0.08 (PAL1-3) and −0.21 vs 0.03 (PAL4) (both $P<0.0001$). Significantly more APR30 vs PBO pts reached MCID ≥0.30 and ≥0.35 in both populations. Marked disability at BL was seen in some pts randomized to APR30, with HAQ-DI scores up to 2.63-2.88. More PAL1-3 vs PAL4 APR30 pts had BL HAQ-DI >1.0 (60% vs 54%), >1.5 (31% vs 21%; marked difficulty/need for assistive devices), and >1.75 (19% vs 10%; major disability), highlighting need for early, effective treatment. Few APR30 pts in PAL1-3 or PAL4 had BL scores ≤0.5 (18%-22%) or ≤0.25 (10%-14%). At Wk 16, disability levels shifted; more APR30 vs PBO pts achieved HAQ-DI ≤1.0 (56% vs 48% [PAL1-3]; 60% vs 52% [PAL4]). At Wk 156 in PAL1-3 and PAL4 pts, 62% and 65% achieved HAQ-DI ≤1.0, 38% and 45% achieved ≤0.5, and 28% and 42% reached ≤0.25 (Table). LOCF analyses confirmed Wk 156 results.

Conclusion: With APR30 treatment, physical disability improved early and functionality was maintained over time up to 3 yrs. Most pts achieved HAQ-DI ≤1.0; many attained minimal/mild physical impairment. Over 40% of DMARD-naïve pts randomized to APR30 at BL had functional ability comparable to population norms after 3 yrs; shorter disease duration and no prior DMARD/biologics use in this population suggests that earlier APR treatment may increase the likelihood of maximal functionality for some pts.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, a fully human anti–IL-17A monoclonal antibody, previously demonstrated higher minimal disease activity (MDA)[1] response rates and sustained improvements in patient reported outcomes[2] among active psoriatic arthritis (PsA) patients (pts) through Week (Wk) 52 in the FUTURE 2 study. This *post-hoc* analysis is further exploring the impact of secukinumab on individual components of MDA and its relationship with patient-reported outcomes among those who achieved or did not achieve MDA response through Wk 52.

Methods: 397 pts with active PsA were randomized to subcutaneous (s.c) secukinumab (300 mg, 150 mg, or 75 mg) or placebo at baseline, Wks 1, 2, and 3, and every 4 wks (q4w) from Wk 4.[2] Pts were considered in MDA when they met at least 5 of 7 pre-defined criteria.[1] The proportion of pts achieving each individual criterion of MDA and the proportion of pts achieving all seven criteria of MDA were calculated at Wks 24 and 52. Additionally, SF-36 MCS, SF-36 PCS, FACIT-Fatigue, PsAQoL, and DLQI were assessed in MDA responders and non-responders at Wks 24 and 52 using mixed-model for repeated measures (MMRM) analyses.

Results: In the pooled secukinumab (300 mg and 150 mg) MDA responder group, tender entheseal points ≤1 (96%), HAQ-DI ≤0.5 (95%), and PASI ≤1 (91%) were the individual components of MDA that consistently achieved the greatest response rates followed by swollen joint count ≤1 (87%), patient global VAS ≤20 (87%), tender joint count ≤1 (80%), and patient pain VAS ≤15 (78%) at Wk 24. A similar trend for the pooled secukinumab MDA responder group was observed at Wk 52. Among the MDA responders 40% (27/68) and 33% (30/93) met all of the seven components at Wks 24 and 52, respectively in the overall study population. Greater improvements in SF-36 MCS and PCS, PsAQoL, FACIT Fatigue, and DLQI scores were seen among MDA responders compared to non-responders at Wks 24 and 52 (Figure).

Conclusion: In pts treated with secukinumab, the individual components most frequently associated with MDA response were related to enthesitis, skin, and functional status and the arthritis-related components were also achieved by many pts. A high proportion of pts achieved and maintained their MDA response through Wk 52 and amongst those 33 to 40% were able to meet 7/7 MDA criteria. Achieving MDA with secukinumab was associated with greater patient-reported quality of life outcomes indicating MDA may be a patient-relevant outcome References: 1. Coates LC et al. *Ann. Rheum. Dis.* 2016;75 S2:605. 2. Strand V et al. Poster presented at XIX PANLAR Panama 2016, April 10–14, 2016, Panama City,

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - ARHP Poster

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Conventional treatments include NSAID and physiotherapy remain the mainstay of treatment in Ankylosing Spondylitis (AS). After the failure of conventional therapy, DMARD therapies are recommended for better outcomes in patients with AS. The aim of this study was to compare the effectiveness of DMARD therapies on NSAID intake, quality of life, and physical functioning and to investigate the relation between disease status parameters and functional outcomes.

Methods: A total of 68 patients were assessed using tools to measure disease (the Bath Ankylosing Spondylitis Disease Activity Index [BASDAI], Functional Index [BASFI], and Metrology Index [BASMI]), physical functioning (Health Assessment Questionnaire for the Spondylarthropathies [HAQ-S]), fear of movement (Tampa Scale for Kinesiophobia [TSK]), and quality of life (Ankylosing Spondylitis Quality of Life Scale [ASQoL]) status from the patient's perspective. To calculate NSAID intake, the type of NSAID, dose, percentage of days with intake were recorded, along with DMARD therapy, age, body mass index (BMI), and disease duration. The NSAID equivalent scoring was calculated according to recommendations from longitudinal clinical studies. The drug therapy groups were compared using the Kruskal-Wallis test and the Chi-square test. Correlation between the scales was evaluated by Spearman's correlation coefficient.

Results: A total of 68 patients (36 women, 32 men; mean age:44.37±10.06 years; mean disease duration:9.63±8.63 years) treated with 4 different DMARDs (Adalimumab+Golimumab=17; Infliximab =17; Etanercept =14; Sulphasalazine =20) were included. NSAID intake was significantly lower in the Infliximab therapy (INFX) (mean:29.34±86.13) compared to the Adalimumab+Golimumab therapy (ADA+GO) (mean:33.25±76.04;p=0.011); the Etanercept therapy (ETA) (mean:33.47±58.23;p=0.041) and the Sulphasalazine therapy (ST) (mean: 74.54±83.30;p=0.002). ASQoL scores were significantly lower in the INFX (mean:3.65±6.17;p=0.011), the ADA+GO therapy (mean:4.35±6.99;p=0.048) and the ETA therapy (mean:4.00±6.13;p=0.013) compared to the ST (mean:10.00±7.07). HAQ-S scores were significantly lower in the ETA therapy (mean:0.34±0.50; p=0.013) and the ADA therapy (mean:0.35±0.44;p=0.024). BMI (p=0.475), disease duration (p=0.551), TSK (p=0.132), BASDAI (p=0.069), BASFI (p=0.271), and BASMI (p=0.769) were similar between DMARD therapies. Age (r=0.400; p=0.001) and disease duration (r=0.255;p=0.037) were correlated with BASMI. There were significant positive correlations between BMI and HAQ-S (r=0.268; p=0.027), BASFI (r=0.245;p=0.044), and ASQoL (r=0.283;p=0.019). TSK was correlated with ASQoL (r=-0.261;p=0.031).

Conclusion: The results suggest that the ability of specific DMARDs to decrease NSAID intake might be considered clinically relevant. The INFX therapy had superior results on NSAID intake and quality of life while the ETA and the ADA+GO therapy were more effective on physical functioning independent of BMI, disease duration, fear of movement, and disease activity. In addition, patients with AS had fear of movement that affect health-related quality of life in spite of the positive results of drug therapies.

SESSION INFORMATION
Session Date: Monday, November 14, 2016

Session Title: Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - ARHP Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Cervical inflammatory pain is very common and rarely studied in patients with Psoriatic Arthritis (PsA). The purpose of our study was to evaluate the prevalence of Inflammatory Neck Pain (INP) in patients with PsA and its association with clinical features.

Methods: Patients with PsA according to CASPAR criteria ≥ 18 years, belonging to RAPSODIA cohort were included. Sociodemographic data, clinical features and treatment received were recorded. Peripheral joints assessment was performed by counting 66/68 swollen/tender joints and the following indexes were calculated DAS28, DAPSA, CPDAI and MDA. Cutaneous involvement was evaluated by PASI and BSA, and nail by PNSS. The presence of dactilitis and enthesitis (MASES) was assessed. Spinal disease activity (BASDAI), functional capacity (HAQ and BASFI) and quality of life (PsAQol and ASQoL) were evaluated with appropriate self- administered questionnaires. The presence of INP was defined as pain in the cervical region with classical inflammatory characteristics and was evaluated as a dichotomous variable (yes/no). Radiographs of the spine and pelvic region were performed and read by a single blinded physician according to BASRI and mSASSS indexes.

Results: 110 patients were included, 56 men (50.9%) with a median age of 55 years (IQR 44.7-63.2). Inflammatory neck pain was reported by 32 patients (29.1%), and it was significantly more frequent in those with mixed involvement (axial and peripheral) (68.8%) vs those with only peripheral involvement (31.3%), p = 0.01. Patients with INP had poorer quality of life for ASQoL (6.1 ± 3.6 vs 6 ± 5.3, p = 0.04) and PsAQoL (8.9 ± 6 vs 6 ± 6, p = 0.02), worse functional capacity (BASFI 4.6 ± 2.5 vs 3.3 ± 2.8, p = 0.03), and higher disease activity [(BASDAI 5.4 ± 2.7 vs 3.8 ± 2.7, p = 0.007) and CPDAI (8.2 ± 3.5 vs 6.3 ± 3.7, p = 0.03)]. MDA was less frequently met by patients with INP (7.1% vs 29.3%, p=0.02). In the logistic regression analysis, fulfillment of ASAS criteria for axSpA was the only variable associated with INP (OR = 7.96, 95%CI: 1.6-40.4, p = 0.01).

Conclusion: A third of patients in this cohort had INP, and it was significantly more common in those fulfilling ASAS criteria for axSpA.

Session Date: Monday, November 14, 2016
Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In NZM2328 (NZM), a mouse model of proliferative lupus glomerulonephritis (GN), lupus GN can be categorized to four stages, i.e. normal, acute GN (aGN), early chronic or transitional GN (tGN) and chronic GN (cGN). There is a high incidence of lupus GN in homozygous C1q deficiency and a marked incidence of severe lupus GN in presence of anti-C1q Ab in man. Interrogation of the microarray data from dissected NZM glomeruli indicates the C1q transcripts are increased in all stages of GN. At aGN this increase may be accountable by infiltrating macrophages. The reason for the increase in C1q transcripts at both tGN and cGN is not clear.

Methods: Podocytes, mesangial and endothelial cells were sorted from anti-GBM treated NZM mice and normal controls by flow cytometry with Abs specific for these populations. Q-PCR (C1qa, C1qb and C1qc) was performed on sorted cells. Similarly Q-PCR for C1q was performed on tubular cells isolated by laser microdissection from C57BL/6, NZM and NZM.Lc1R27 (R27), a NZM congenic line resistant to the progression of aGN to cGN despite the presence of immune complexes and complement activation. In situ hybridization (ISH) was performed with C1qc riboprobe. Immunofluorescence (IF) was done on kidneys with cell-specific and anti-C1q Abs tagged with different flourochromes and analyzed by confocal microscopy. Similarly IF was done on human renal biopsies and on urinary cells from normal and lupus patients. IF staining was also done on podocyte lines derived from NZM transformed by a temperature sensitive virus containing the SV40 large T Ag.

Results: C1q mRNA was detected in podocytes isolated from the kidneys of NZM treated with anti-GBM Abs. ISH collaborated this finding. At the protein level, C1q expression was shown by confocal microscopy with Abs to C1q and synaptopodin, a podocyte-specific protein. Similarly the presence of C1q was shown in podocytes of NZM kidneys with tGN and cGN but not in NZM or R27 kidneys with aGN. The presence of C1q was shown in one of four NZM podocyte cell lines. With "normal" renal tissue from patients with renal cell carcinoma and lupus GN renal biopsies (Classes II-IV), C1q expression by podocytes was limited to biopsies with Class III or IV lupus GN. The presence of C1q positive podocytes in the urine of five lupus patients with severe proteinuria and telescopic cellular elements (presumably class IV) was demonstrated. Similarly increased expression of C1q by tubular cells in severe GN was documented.

Conclusion: *C1q is shown for the first time to be made by podocytes.* Its expression is detected in two models of immune complex mediated GN. Its expression is detected in podocytes from kidney biopsies and in patients' urine. The expression of C3 in podocytes and in tubular cells in diseased kidneys was also found. The function of these expressed complement components in lupus GN remains to be determined in view of the recent documented role of C1q and C3 in CNS. Our findings suggest locally produced complements may have more profound effects on the kidney. The presence of C1q positive podocytes suggests that this can be useful as a biomarker for diagnostic purpose and for monitoring the effectiveness of therapy.

Disturbance of Renal Circadian Rhythm in Lupus Nephritis

Rakesh Mishra[1], Ramalingam Bethunaickan[2], Weijia Zhang[3] and **Anne Davidson**[4], [1]Feinstein Institute, Manhasset, NY, [2]Autoimmune and musculosketal diseases, Feinstein Institute for Medical Research, Manhasset, NY, [3]Nephrology, Mount Sinai School of Medicine, New York, NY, [4]Autoimmunity and Musculoskeletal Diseases, Feinstein Institute for Medical Research, Manhasset, NY

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Circadian rhythm is a universal phenomenon that allows organisms to anticipate and respond to changes in their environment by regulating sleep and feeding patterns, blood pressure, metabolism, detoxification and response to pathogens. In the kidney intrinsic circadian rhythm of a subset of genes is associated with circadian regulation of GFR, blood pressure, urine pH, Na and K excretion and detoxification of drugs. We found a disturbance of expression of key clock transcriptional regulators in the kidneys of mice with SLE nephritis. The purpose of these experiments was to determine how this abnormality affected transcriptional regulation of renally expressed genes and immune cell homeostasis.

Methods: We studied NZB/W mice at the age of 12 weeks (without proteinuria) and 30 weeks (with 300mg/dl proteinuria). Kidneys and blood were harvested at 4 hour intervals. Kidneys were perfused with PBS and used to generate RNA, protein lysates and single cells for flow cytometry analysis. Whole blood counts were performed in a BD analyzer and white blood cell subtypes were analyzed using flow cytometry. RNA was analyzed using RNASeq and real-time PCR. Lysates were analyzed for expression of BMAL1 and Per2.

Results: Young NZB/W mice have normal circadian oscillation of peripheral WBCs. Circadian oscillation of peripheral blood RBCs, lymphocytes and neutrophils was likewise normal in the nephritic mice. There was a marked increase of circulating renal macrophages in the nephritic mice but circadian rhythm of $Ly6C^{hi}$ vs $Ly6C^{lo}$ cells followed a normal pattern. Kidneys of young NZB/W mice displayed a normal circadian pattern of expression of the master transcriptional regulators of circadian rhythm including Bmal1, Clock, Per and Cry genes. By contrast, kidneys from the nephritic mice had attenuated rhythm of these genes with inversion of the normal pattern. This abnormality was confirmed in two different sets of mice using qPCR. To determine how this affected general gene expression in the kidneys we performed mRNASeq of whole perfused kidneys. Of the 18952 genes detected by RNASeq, 2442 genes (12.9%) were regulated in a circadian fashion in young mice and 2074 (10.9%) in nephritic mice. There was little overlap in the two genesets, confirming a marked dysregulation of normal circadian patterns of renal gene expression. Although many of the genes that were upregulated in nephritic compared with young mice at any time of the day were associated with immune and inflammatory processes, analysis of the genes whose circadian rhythm was dysregulated in nephritic mice indicated that most are involved in metabolic rather than immune processes.

Conclusion: Circadian dysfunction in the setting of lupus nephritis may have important implications for the delivery and metabolism of therapeutics. Because circadian transcriptional regulators can influence the severity of inflammation and fibrosis, dysfunction of the renal circadian clock might also contribute to the progression of renal injury and may therefore be a potentially druggable target for therapeutic intervention.

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We made the novel observation that glycosphingolipid (GSL) levels and neuraminidase (NEU) (an enzyme that mediates GSL catabolism) activity/expression are altered in the kidneys and/or urine of lupus mice and human patients with proliferative nephritis compared to their non-nephritic counterparts and healthy controls. Specifically, elevated GSL levels were observed in the mesangial region of glomeruli. We hypothesize that activation of mesangial cells (MCs) in the progression of lupus nephritis is mediated in part by NEU1-mediated LacCer elevation, contributing to renal inflammation in lupus nephritis.

Methods: NEU1 expression and the GSL Lactosylceramide (LacCer) levels in kidney sections were analyzed by immunohistochemistry and immunofluorescence. MES13 mouse MCs were: 1) incubated with the GSLs LacCer and glucosylceramide (GlcCer) over time and cytokine gene expression measured by real-time RTPCR; and 2) transfected with increasing amounts of an expression vector for NEU1, and IL-6 production was measured in the media by ELISA, while cellular LacCer levels were measured by Supercritical Fluid Chromatography coupled with tandem mass spectrometry. Primary MCs were grown from glomeruli isolated from kidneys of pre-nephritic MRL/lpr mice. Once established and verified to be MCs, the primary MCs were analyzed between passages 6 and 10 following activation with heat aggregated IgG (HA-IgG, a mimic of immune complex deposition) for IL-6 and MCP-1 production by ELISA, Neu1 message levels by real-time RTPCR, and NEU1 expression and cellular localization by immunofluorescence.

Results: NEU1 and LacCer were observed to be highly expressed in MCs on renal sections of nephritic MRL/lpr mice by immunohistochemistry. Using the mouse MES13 MC line, we demonstrate that exogenous addition of LacCer and GlcCer increases the expression of several cytokines, including IL-6. Over-expression of NEU1 increases LacCer levels and IL-6 production. In primary MCs from pre-nephritic lupus mice, Neu1 expression, IL-6 production and MCP-1 production are significantly increased following addition of HA-IgG in a dose-dependent manner. IL-6 production is significantly increased within 6 hours following addition of HA-IgG stimulation. Importantly, addition of an FDA-approved inhibitor of NEU activity significantly and dose-dependently inhibited HA-IgG-induced IL-6, but not MCP-1 production. NEU1, typically located in the lysosomes, is translocated to the plasma membrane in some cell types upon activation. Analyses of changes in cellular localiation of NEU1 in HA-IgG-activated lupus prone MCs is pending.

Conclusion: Together these results suggest that immune complex activated IL-6 production of MRL/lpr lupus prone MCs is mediated by NEU-mediated GSL catabolism. Targeting NEU activity, or NEU1 specifically, may reduce MC cytokine production and thus renal inflammation in lupus nephritis.

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The role of complement in Systemic Lupus Erythematosus (SLE) is complex as complement deficiencies in early components of the classical pathway cause lupus with high penetrance, yet terminal complement activation at the level of the glomeruli causes kidney inflammation and damage in SLE. Aberrant accumulation or processing of dying cells that expose nucleosomes is thought to stimulate the production of lupus autoantibodies. To determine the relative contributions of excess dying cells, complement and autoantibodies, we created novel genetic models of lupus that contained one or more of these abnormalities, all on the C57BL/6 background.

Methods: Bicongenic mice were created by crossing mice deficient in the apoptotic cell (AC) opsonin, MFG-E8 (that accumulates AC in the germinal centers of the spleen), to *sle1* mice (that produce autoantibodies to chromatin). These mice were then backcrossed to either C1q or C3 KO mice to create triple mutants. Anti-chromatin and anti-ds-DNA autoantibodies were measured by ELISA assay (n=20-30 per group). Autoantibodies specificities were determined on pooled sera (n=15-20 per strain) with the Autoantigen Microarray Super Panel (UT Southwestern Microarray Core). AC accumulation in the spleen and kidneys was detected by TUNEL staining (Roche). Kidney damage was evaluated by blood urea nitrogen (Amplite, AAT Bioquest), immuno-fluorescence for complement C3 (MP Biomedicals) and IgG2c (Jackson Immunoresearch), PAS staining and electron microscopy (E/M) (University of Washington Histology and Specialized Pathology Services).

Results: *sle1*.MFG-E8 double mutant mice had significantly higher anti-DNA autoantibodies compared to sle1 mice alone ($P<0.001$). When *sle1*.MFG-E8 mice were crossed to C1q or C3 KO to create triple mutant mice, anti-chromatin and anti-DNA autoantibodies increased further (triple mutants compared to double mutants; $p<0.05$). In addition, when these strains were compared on an autoantigen array, the triple mutants demonstrated a significant broadening in antigenic specificity to include aggrecan, collagens, alpha-actinin, and others. Both triple mutant mouse strains showed AC accumulation in the kidneys and developed severe glomerulonephritis as determined by PAS staining. E/M analysis confirmed leukocyte infiltration and electron dense deposits near podocytes with podocyte destruction, as well as extensive tubular damage. Immunofluorescence analysis C1q triple mutants had abundant C3 deposition in the glomeruli, likely via activation of the alternative pathway, F4/80+ cell infiltrates in the interstitial and periglomerular space, and very prominent IgG2c deposits.

Conclusion: These studies reveal a stepwise contribution of all three elements studied here to lupus-like disease, and indicate that defective clearance of dying cells coupled with autoantibody production and impaired early complement function leads to a severe glomerulonephritis. Whereas it is likely that C3 activation contributed to nephritis in triple mutants lacking C1q, triple mutants lacking C3 also showed broadening of the autoantibody repertoire and developed intense nephritis suggesting that IgG FcgR engagement is sufficient to result in severe kidney damage.

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: High mobility group box 1 (HMGB1) is a ubiquitous non-histone nuclear protein that exerts proinflammatory functions in the extracellular milieu. Here we evaluate the efficacy of neutralizing anti-HMGB1 monoclonal antibody (mAb) whether it ameliorates lupus activities including nephritis and serological abnormalities in MRL/lpr lupus-prone mice.

Methods: We administered the anti-HMGB1 mAb (5 mg/kg weight) neutralizing ICAM-1-inducing activity of HMGB1 *in vitro* or class-matched control IgG2a intravenously twice a week from 4 to 15 weeks. Urine albumin was monitored every 2 weeks and histological evaluation of kidneys was conducted at 16 weeks. Anti-ds DNA antibody titers, cytokines and chemokines were also evaluated.

Lymphadenopathies were also evaluated by 1-(2'-deoxy-2'-[18F]fluoroarabinofuranosyl)cytosine ([^{18}F]FAC) PET/CT at 12 weeks.

Results: Anti-HMGB1 mAb tended to reduce the albuminuria compared to an isotype control at 16 weeks. Consistent with the urinary albumin excretion, the glomerular complement deposition was improved. However therefre no significant differences in the IgG depositions and renal pathological scores between the two groups. Regarding serological abnormalities, the anti-dsDNA antibody titers, cytokine and chemokine levels were not altered. Moreover, antagonizing HMGB1 treatment failed to show significant reduction of plasma HMGB1 level and was insufficient to suppress the translocations of HMGB1 in the kidney. The plasma HMGB1 level in this model mouse tended to be high compared to C57BL/6 mice. Although therefre no significant differences in the glomerular infiltrations of F4/80 positive cells, the infiltrations of Ly-6B positive cells and Ly-6G positive area were significantly decreased by anti-HMGB1 mAb. Renal mRNA expressions of cytokine and chemokine, such as IFN-alpha, TNF-alpha and IL-6, were unaltered by the treatment with anti-HMGB1 mAb. The weights of lymphoid tissues were almost similar and [^{18}F]FAC PET/CT revealed the similar accumulations in cervical and axilla lymph nodes in the two groups.

Conclusion: Anti-HMGB1 mAb demonstrated therapeutic potential against lupus nephritis through inhibiting neutrophil recruitments, but the abundance of HMGB1 release in this model mouse might blunt the effectiveness.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Mucosal-associated invariant T (MAIT) cells are innate T cells that are restricted by MHC-related molecule-1 (MR1) and express a semi-invariant TCRa chain: Va7.2-Ja33 in humans and Va19-Ja33 in mice. Previously, we have demonstrated that MAIT cells played a protective role against experimental autoimmune encephalomyelitis, an animal model of human multiple sclerosis. We have found that MAIT cells are activated in patients with systemic lupus erythematosus (SLE) and that the activation state of MAIT cells correlated with SLE disease activity index (SLEDAI) score. Therefore, we conducted this study to clarify functions of MAIT cells in a lupus model by using FcgRIIB$^{-/-}$ Yaa mice.

Methods: FcgRIIB$^{-/-}$ Yaa mice were crossed to MR1 deficient mice lacking MAIT cells, and disease progression was compared between MR1-/- FcgRIIB$^{-/-}$ Yaa and FcgRIIB$^{-/-}$ Yaa mice. Serum anti-dsDNA antibody levels were measured by anti-dsDNA- ELISA Kit (Libis) and urinary microalbumin were evaluated by SIEMENS DCA 2000. At the time of sacrifice, the severity of nephritis and dermatitis were assessed by histologically. Haematoxylin-eosin staining of skin sections were graded on a scale of 1 to 3 for acanthosis; 1 to 2 for hyperkeratosis, interface liquefaction, inflammation, dermal cellularity, presence of dilated vessels with hemorrhage; 0 to 1 for ulcer or erosion. For statistical analysis, all data were analyzed using GraphPad Prism (GraphPad), and differences between the groups were assessed using the Mann-Whitney U test. The significance level was set at $p < 0.05$. Associations between 2 variables were analyzed using Spearman correlation.

Results: MR1-/- FcgRIIB$^{-/-}$ Yaa mice showed exacerbated inflammation in the skin lesions. There was a high degree of inflammatory cells infiltration into the skin and a significant worsening of dermatitis score in MR1-/- FcgRIIB$^{-/-}$ Yaa mice compared to FcgRIIB$^{-/-}$ Yaa mice. There were no differences in serum levels of anti-dsDNA antibody, proteinuria, and kidney histopathology.

Conclusion: The present study demonstrates that dermatitis was exacerbated in MR1-/- FcgRIIB$^{-/-}$ Yaa mice, indicating that MAIT cells may have a suppressive effect on skin inflammation. Because MAIT cells have recently been found in human skin, MAIT cells may be useful therapeutic targets for the treatment of lupus dermatitis.

Down-Regulation of microRNA-200a-3p, Targeting C-Terminal Binding Protein-2 (CtBP2), Is Involved in Hypoproduction of IL-2 in SLE-Derived T Cells

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease caused by genetic and epigenetic mechanisms. MicroRNAs (miRNAs) are small non-coding RNAs, post-transcriptionally regulate the stability of target genes via base-pairing with mRNA 3'-untranslated regions (3'-UTRs), and have been reported to be implicated in the development of autoimmune diseases. To identify candidate miRNA and its target in unbiased fashion, we conducted the RNA sequencing using CD4+ T cells from spleen of MRL/lpr (MRL) lupus model mice and C57BL/6J (B6) mice as a control. Here we newly determined candidate disease-related miRNA, miR-200a-3p, which was significantly downregulated in MRL mice. Since its target genes, CtBP and ZEB were also upregulated in MRL mice and play an important role to suppress IL-2 as a transcriptional co-suppressor complex, we examined the role of miR200-3p in increased expression of CtBP2/ZEB and subsequent defects of IL-2 production in lupus T cells.

Methods: Functional analyses were performed by transfection of miR-200a-3p mimics in EL4 mouse T cell line. The expression levels of miR-200a-3p and its target gene were examined using TaqMan Quantitative PCR (qPCR). The transcript and protein level of IL-2 under the stimulation with phorbol 12-myristate 13-acetate (PMA) (10ng/ml) and ionomycin (1uM) was examined by qPCR and ELISA respectively. Promoter activity was evaluated with luciferase plasmid containing IL-2 promoter region. Specific binding of CtBP/ZEB to IL-2 sequence that negatively regulates IL-2 expression was evaluated by electrophoretic mobility shift assay (EMSA) and chromatin immunoprecipitation (ChIP) assay.

Results: We confirmed the lower expression of miR-200a-3p ($p<0.0001$) as well as the higher expression of CtBP2 ($p<0.05$) in MRL mice compared with B6 mice using qPCR. The expression level of ZEB2 was also tended to decreased ($p=0.56$) while ZEB1 ($p<0.01$) was downregulated in MRL mice by qPCR. In EL4 cells with miR-200a-3p overexpression, the expression level of ZEB and CtBP2 mRNA was significantly downregulated, while IL-2 mRNA level was upregulated by q-PCR. IL-2 concentration in the supernatant from stimulated EL4 cells was also higher under the treatment of miR-200a-3p by ELISA. IL-2 promoter activity was elevated by miR-200a-3p overexpression by luciferase assay. EMSA demonstrated that specific binding of ZEB1, ZEB2 and CtBP2 to IL-2 gene was decreased after miR-200a-3p overexpression. Finally, ChIP assay revealed that the complex of CtBP2 in regulatory sequence of IL-2 was augmented in MRL mice compared with B6 mice, while the complex was downregulated in EL4 with miR-200a-3p overexpression.

Conclusion: Collectively, IL-2 production was elevated after miR-200a-3p overexpression by targeting ZEB1, ZEB2 and CtBP2. Our data suggest that downregulation of miR-200a-3p causes IL-2 suppression through ZEB1, ZEB2 and CtBP2 in SLE T cells, which could involve the lupus pathogenesis by dysregulation of T cells.

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Impaired fibrinolysis in systemic lupus erythematosus (SLE) contributes to disease magnifications including increased risk of thrombosis and tissue ischemia. Aberrant complement activation is a major factor in tissue injury in SLE. Previous work has focused on the role of complement activation in tissue injury due to ischemia in the MRL/*lpr*mice, an autoimmune prone mouse strain with a propensity to develop lymphadenopathy, glomerulonephritis, and polyarthritis. Complement inhibition at varying points in the cascade resulted in differing efficacies in tissue injury attenuation of tissue injury. A potential role for thrombin, a coagulation component was identified. The current work elucidates the mechanism by which the two pathways interact to contribute to hypercoagulability and increased risk of thrombosis in SLE.

Methods: Complement C1q inhibitor and coagulation inhibitors targeting the intrinsic and extrinsic pathways (Tissue Factor Pathway Inhibitor (TFPI) and Anti-thrombin III) were used to evaluate and compare resulting tissue pathology, generation of secondary inflammatory mediators involved ischemic/reperfusion injury. Using a superior mesenteric artery ischemia model, we compared the pathology of mesenteric ischemia/reperfusion (IR) induced tissue injury between immune competent (C57BL/6) and autoimmune prone (B6.MRL/*lpr*) mice after administration of complement or specific coagulation pathway inhibitors. The pathology was assessed by immunohistochemistry/ immunofluorescence analysis and western blot analysis of complement and coagulation components.

Results: Tissue Factor Pathway Inhibitor (TFPI) and Anti-thrombin III (ATIII) resulted in reduction of tissue injury, as determined by histopathology scoring. However, TFPI was significantly more effective in attenuating tissue injury in the MRL/*lpr* mice with less edema and villous destruction in the intestine. Western blot analysis was used to determine if there reductions in thrombin levels and if this corresponded with decreased levels of activated complement components. As expected if C5 was the interaction point between the pathways, there were no differences in C3 activation between the groups. The level of C5 activation and thrombin levels are being analyzed. Immunofluorescent analysis of tissue sections confirm these results and assess changes in the molecular components such as C3/Ig deposition, membrane attack complex formation, glycoprotein Ia/IIa exposure, and thrombin localization.

Conclusion: The interaction between thrombin and the complement pathway in SLE has significant clinical implications. The results from this study indicate inhibition of the coagulation cascade, prior to prothrombin activation is the most effective point to inhibit tissue injury. Inhibiting with TFPI does not affect C3 activation but reduces edema and disruption of the vascular and lamina propria structure, suggesting a positive feedback loop between the complement and coagulation cascades downstream of C3. Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: MRL/lpr mice develop a chronic inflammatory disease characterized by accumulation of $CD4^-CD8^-B220^+$T cells mimicking human lupus; IL-23 driven IL-17 producing cell contribute to lupus severity in B6/lpr mice, an autoimmune model that is characterized by deficient Fas-mediated apoptosis but without the autoimmune genetic background of MRL/lpr. We previously reported that in MRL.lpr mice, administration of neutralizing IL-23Ab ameliorates lupus severity. The studies presented below sought to explain the profound effect IL-23 has on murine lupus pathogenesis.

Methods: T cells were extracted from the blood of patients who fulfilled at least 4 out of 11 ACR criteria for SLE. We generated MRL/lpr mice that lack the IL-23 receptor by backcrossing the MRL/lpr mouse with a B6.IL-23 receptor (IL23R) deficient mouse for 11 generations. Proteinuria was monitored at regular intervals. Spleens, kidneys and lymph nodes were harvested and used for flow cytometry and histology at different time points. ELISA was used for measurement of cytokines and dsDNA antibody levels in the serum.

Results: Genetic deletion of IL-23R in MRL/lpr mice attenuated lupus nephritis strikingly decreasing the accumulation of double negative T (DNT) cells in the kidneys ($IL23R^{+/+}$MRL/lpr vs. $IL23R^{-/-}$MRL/lpr: 8.38+/-1.76 $x10^4$ cells vs. 2.00+/-0.37 $x10^4$ cells, $p<0.05$). We observed a similar decrease of DNT accumulation in secondary lymphoid organs in IL23R deficient vs the IL23R sufficient mice. Using in vivo BrDU staining and in vitro proliferation experiments, we found that the decrease in the DNT cell population in the spleen and lymph nodes of $IL23R^{-/-}$MRL/lpr vs the $IL23R^{+/+}$ MRL/lpr mice was through 1. Decreased DNT proliferation ($IL23R^{+/+}$MRL/lpr vs. $IL23R^{-/-}$MRL/lpr: 4.61+/-0.83% vs. 1.26+/-0.33%). 2. Increased DNT cell death ($IL23R^{+/+}$MRL/lpr vs. $IL23R^{-/-}$MRL/lpr: 37.13+/- 2.21 % vs. 46.11+/-0.21%), and 3. Decreased conversion of $CD4^+$ T cells into DNT upon stimulation ($IL23R^{+/+}$MRL/lpr vs. $IL23R^{-/-}$MRL/lpr vs. MRL/MPJ: 11.95+/-0.07% vs. 4.90+/- 0.42% ($p<0.05$) vs. 3.19+/-0.07% ($p<0.05$ compared to wild type). Moreover, T cells from IL-23R deficient animals had significantly increased IL-2, and reduced IL-17 production compared to wild type animals. In vitro incubation of MRL/lpr splenocytes with IL-23 not only promoted IL-17 production, as expected, but also downregulated IL-2 production (IL-2 in non-IL23 vs IL-23 treated: 281.67+/-16.26 vs. 151+/-47.03 pg/mL). Conversely, exogenous IL-2 reversed IL-23-induced IL-17 secretion from $IL-23R^{+/+}$ MRL/lpr lymphocytes indicating that IL-23 critically regulates the balance between IL-2 and IL-17 in lupus prone mice. Finally, ex vivo treatment of T cells from SLE patients with IL-23 increased the proportions of IL-17-producing T cells and DN T cells (non-IL23 vs IL-23 treated: 27.72+/- 14.41% vs. 47.85+/- 16.47%) while downregulating the production of IL-2 (non-IL23 vs IL-23 treated: 314+/-198 vs. 220+/-131 pg/mL).

Conclusion: Our results show that IL-23 regulates the production of two pivotal cytokines in murine and human SLE while promoting the production of pro-inflammatory DNT cells, critically influencing the balance between pro and anti-inflammatory cytokines in lupus.

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: TCRαβ+CD4-CD8-T cells (double negative T cells, DNT) have been reported to produce inflammatory cytokines such as IL-17, and infiltrate the kidneys of patients with lupus nephritis. We previously reported that inhibition of the transcription regulator STAT3 ameliorates systemic lupus erythematosus (SLE) by reducing DNT accumulation in MRL/lpr lupus –prone mice. However, the underlying mechanism remains unclear.

Methods: MRL/lpr mice were treated with Stattic, a STAT3 inhibitor, or placebo starting at 8 weeks of age for 4-8 weeks. B6/lpr T cell STAT3 knockout (TCKO) mice were bred by crossing B6-CD4 ^{Cre} Stat3$^{fl/fl}$mice with B6/lpr mice and followed until disease development. Proteinuria and serum dsDNA antibody levels were monitored. Spleens, kidneys and lymph nodes were collected for flow cytometry and histology at different time points. Peripheral blood T cells from SLE patients and healthy controls were used to evaluate the proportion of DNT, as well as PD-1 and IL-17 expression. DNT cells were sorted from B6/lpr STAT3 TCKO and Stattic-treated MRL/lpr mice, and were used to assay glycolysis stress by Seahorse XFp analyzer. Glycolysis associated genes expressions were analyzed by q-PCR.

Results: Stattic significantly attenuated disease activity in MRL/lpr mice, with decreased serum dsDNA antibody levels (Stattic treated vs placebo: 1,634±211 vs. 18,365±2,132U/ml, $p<0.0001$), suppressed crescentic glomerulonephritis, reduced spleen size, and diminished skin lesions. Similar results were found in B6/lpr STAT3 TCKO mice. The number of DNT cells were reduced significantly in B6/lpr STAT3 TCKO mice in both kidneys (wild type vs STAT3 TCKO: 31.3±9.6% vs 17.6±6.5%, $p=0.0005$) and peripheral lymphoid organs (wild type vs STAT3 TCKO: Spleen: 35.4±7.8% vs 26.5±6.1%, $p=0.0051$; Lymph node: 73.1±11.8 vs. 61.5±10.1, p=0.0168). Moreover, IL-17 production and PD-1 expression were significant decreased in DNT cells from B6/lpr STAT3 TCKO mice. Moreover, p-STAT3 was increased in DNT cells from SLE patients compared with healthy control (17.6±2.1% vs. 6.5±1.3%, $p<0.0001$). Accordingly, PD-1, as well as IL-17 expression was upregulated in p-STAT3+ DNT as compared to p-STAT3- DNT from SLE patients. XF glycolysis stress assay revealed that DNT from B6/lpr STAT3 TCKO (or Stattic treated MRL/lpr) mice showed lower extracellular acidification rate and glycolysis capacity than matched controls. In vitro treatment with 2-DG could significantly reduced generation and IL-17 production in DNT from B6/lpr STAT3$^{fl/fl}$ mice, but has less effect on B6/lpr STAT3 TCKO mice. Gene expression analysis shown that HIF1α, GLUT-1, PDK1 mRNA levels were increased in DNT from B6/Lpr STAT3$^{fl/fl}$mice as compared to B6/lpr STAT3 TCKO mice (4.5 ±2.1 fold, 3.1 ±1.0 fold, and 2.5 ±0.7 fold, respectively). Similar increase was seen in SLE patients derived DNT cells as compared to healthy control DNT.

Conclusion: This is the first study to provide evidence that STAT3 regulates the generation, function and pathogenicity of DNT in systemic lupus erythematosus. Specific targeting of STAT3 in SLE T cells may help restore the balance between pro-inflammatory and regulatory T cells, an imbalance that underlies SLE pathophysiology.

Double-Negative T (DNT) Cell over-Expressing PD-1 and Helios Is Responsible for Lupus Tissue Injury in Systemic Lupus Erythematosus (SLE): Direct Proof That Increased Interferon Alpha (IFNα) Expression Is Sufficient to Induce SLE in Ifnα-Transgenic Mice

Ken Tsumiyama[1], Chieri Akiyama[2], Yumi Miyazaki[1], Yasushi Miura[2], Akira Hashiramoto[2] and Shunichi Shiozawa[1], [1]Department of Medicine, Rheumatic Diseases Unit, Kyushu University Beppu Hospital, Beppu, Japan, [2]Department of Biophysics, Kobe University Graduate School of Health Science, Kobe, Japan

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies strongly suggest that interferon α (IFNα) may be the principal driver of SLE, where increased IFNα and IFNα-regulated gene transcripts explain many of the immune alterations seen in SLE patients. However, the causal relationship between IFNα and SLE remains speculative and direct evidence for this causal link is required for more effective intervention of the disease. To directly prove the role of IFNα in inducing SLE, we generated transgenic (Tg) mice that express IFNα under the control of the inducible doxycycline (Dox) promoter.

Methods: The mouse *IFNα a1* (mIFNα) cDNA inserted downstream of the TetOp promoter of pTet Splice vector to generate TetOp-mIFNα. TetOp-mIFNα was microinjected into fertilized eggs of C57BL/6 mice to obtain TetOp-mIFNα Tg mice. The mice were mated with EμSR-tTA Tg mice (FVB/N background), expressing the Tet-transactivator (*tTA*) gene downstream of the Ig heavy chain enhancer and SRα promoter (Felsher and Bishop, Mol Cell 4:199, 1999), resulting in lymphoid cell-specific gene expression (EμSR-tTA) to produce double transgenic TetOp-mIFNα/EμSR-tTA mice of a C57BL6/FVBN background (IFNα Tg C57BL6/FVBN mice). These mice produced IFNα 4 weeks after cessation of 50 μg/mL of Dox. This IFNα Tg mice were also back-crossed to make IFNα Tg mice of C57BL/6 background to guarantee the universality of the result.

Results: IFNα expression alone was sufficient to induce disease with characteristics identical to SLE, i.e., serum anti-double stranded DNA (dsDNA) antibody, immune complexes (IC) and tissue injury including glomerulonephritis accompanied by IC deposition, alopecia, epidermal liquefaction, positive lupus-band skin test and classical splenic onion-skin lesions. In these mice, activated $CD3^+CD4^-CD8^-$ double-negative T (DNT) cells, which were also $TCR\alpha\beta^+B220^+CD1d\text{-teteramer}^-$, expanded significantly. When transferred into naïve recipients, these DNT cells infiltrated to the glomeruli of transgenic mice and induced *de novo* glomerulonephritis and alopecia. These DNT cells had halted differentiation and massively accumulated at the DN1 stage in the thymus. The DNT cell was characterized by the over-expression of PD-1 and Helios, an indicator of autoreactive DNT cell of CD8 T cell origin as shown by Rodriguez-Rodriguez N et al (J Immunol 194:4207, 2015).

Conclusion: The results show that increased expression of IFNα is sufficient to induce SLE, and that DNT cell expressing PD-1 and Helios may play important roles in lupus tissue injury. The study is in collaboration with Dr. Dean W Felsher (Stanford University, Division of Oncology, Department of Medicine and Pathology).

Dendritic Cell-Specific Loss of Caspase 8 Incites Symptoms of Neuropsychiatric Systemic Lupus Erythematosus

Hadijat Makinde[1], Harris R. Perlman[2] and Carla Cuda[1], [1]Northwestern University, Chicago, IL, [2]Department of Medicine, Division of Rheumatology, Northwestern University Feinberg School of Medicine, Northwestern University, Chicago, IL

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies implicate dendritic cells (DCs) in the initiation and persistence of systemic lupus erythematosus (SLE), and although DCs from SLE patients exhibit elevated activation, the factors responsible remain largely unknown. Neuropsychiatric symptoms of SLE (NP-SLE), which affect roughly 40-70% of SLE patients, include headaches, cognitive dysfunction and psychiatric disorders, and may be among the earliest symptoms of SLE. Mice with an underlying defect in Fas (MRL/lpr) display cognitive and affective dysfunction characteristic of NP-SLE. We have shown that DC-specific loss of caspase 8, an enzyme in the Fas pathway classically linked to apoptosis initiation and necroptosis suppression, induces a SLE-like disease that originates from heightened DC activation. However, whether there exists a link between caspase 8 signaling, heightened DC activation and NP-SLE is a mystery. To this end, we examined the neurological consequences of DC-specific caspase 8 deletion.

Methods: Mice with caspase 8 flanked by *loxP* sites ($Casp8^{fl/fl}$, WT) were bred to mice expressing Cre under control of the CD11c gene promoter (Cre^{CD11c}) to generate $Cre^{CD11c}Casp8^{flox/flox}$mice. Neurological deficiency was assessed via 8 tests (exit circle, startle reflex, seeking behavior, beam balancing, round stick balancing, beam walk: 3 cm, beam walk: 2 cm, beam walk:1 cm) with each test providing 0, 0.5 or 1 points depending on the severity of the behavioral deficit and, when combined, provide a neurological severity score (NSS). Cellular infiltration into the brain was assessed using 10-color flow cytometric analysis.

Results: With age, $Cre^{CD11c}Casp8^{flox/flox}$ mice develop an inflammatory disease reminiscent of both classic murine models of SLE and human SLE that is characterized by splenomegaly, lymphadenopathy, autoantibodies, elevated serum cytokines, glomerulonephritis, immune complex deposition in the kidney and proteinuria. Strikingly, $Cre^{CD11c}Casp8^{flox/flox}$mice develop neurological deficiencies, with a 4-fold higher NSS than WT mice. These observed behavioral consequences correlate with increased numbers of microglia, as well as cellular infiltration of not only DCs, but also macrophages, lymphocytes and neutrophils. The cellular infiltration is reminiscent of an acute model of traumatic brain injury, wherein physical damage to the brain promotes leakage of the blood-brain barrier. However, in our case, this breach of the blood-brain barrier is the direct result of DC-specific caspase 8 deletion and chronic systemic inflammation.

Conclusion: Our previous studies showed that DC-specific loss of caspase 8 induced a SLE-like disease that originated from heightened DC activation. We now reveal that deletion of caspase 8 in DCs is sufficient to incite symptoms of NP-SLE that correspond with a breach in the blood-brain barrier and leukocyte infiltration. These data substantiate a novel DC-

specific mechanism whereby caspase 8 controls DC activation to prevent not only end-organ failure and peripheral pathology associated with SLE-like disease, but also NP-SLE manifestations, thereby highlighting a potentially useful target for therapy.

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Skin inflammation appears in cutaneous or systemic lupus erythematosus. Ultraviolet B (UVB) is an important environmental trigger of skin inflammation in lupus. Mechanisms linking UVB to autoimmune inflammation in lupus are not well understood. Neutrophils, the most abundant circulating leukocytes, are the first group of cells to be recruited to the site of photodamage, prior to monocytes and lymphocytes, in response to UVB-irradiation. Studies have suggested that neutrophils may pave the way for the subsequent recruitment of monocytes and lymphocytes. All of these cell types orchestrate and together contribute to the local inflammation at the site of photodamage, and the systemic consequences. However, little is known about the role of neutrophils in UVB-induced skin inflammation. Neutrophil NETosis is a newly characterized neutrophil cell death that releases neutrophil extracellular traps (NETs), which have been shown to be important in autoimmune inflammation, including lupus pathogenesis. NETs develop as release of the decondensed nuclear chromatin from a ruptured nuclear envelope. Recent studies from our and other groups indicate the importance of the actin cytoskeleton in neutrophil NETosis. Rho kinase (ROCK) is known to regulate actin-myosin (actomyosin) networks. Whether ROCK regulates neutrophil NETosis and contributes to UVB-induced skin inflammation has not been investigated.

Methods: To explore the role of ROCK in neutrophil NETosis, we investigated the effects of ROCK inhibition on neutrophil NETosis in vitro in human neutrophils and neutrophil NETosis in UVB-induced skin inflammation in mice.

Results: In vitro, we found that PMA stimulation induced F-actin polymerization and ROCK activation in human neutrophils. In addition, inhibition of ROCK activation attenuated F-actin polymerization. Importantly, inhibition of ROCK by different ROCK inhibitors, or interfering F-actin polymerization with cytochalasin D, significantly alleviated PMA-induced NET formation in human neutrophils. To explore the effects of ROCK in vivo in UVB-induced skin inflammation, we found that exposure of female C57BL/6J WT mice to UVB with a dose of 250 mJ/cm^2/day for 5 consecutive days induces neutrophil recruitment and NET formation which display IL-17 in the dermis of mouse skin. Importantly, application of the dual ROCK1/2 inhibitor HA1077 intraperitoneally (i.p.) attenuated neutrophil recruitment and NET formation in UVB-irradiated mouse skin *in vivo*. Most importantly, ROCK inhibition attenuated neutrophil NETosis among the infiltrated neutrophils in the UVB-exposed mouse skin.

Conclusion: Our preliminary studies therefore elucidated a novel mechanism that ROCK regulates neutrophil NET release, and confirmed the protective role of ROCK inhibition in neutrophil NETosis both in vitro and in vivo. Our findings may provide insights into a novel therapeutic target for treatment of UVB-induced skin inflammation, including lupus.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with significant impairment of health-related quality of life (HR-QoL). Recently, meeting a definition of a Lupus Low Disease Activity State (LLDAS), analogous to low disease activity in rheumatoid arthritis, was preliminarily validated as associated with protection from damage accrual. The LLDAS definition has not been previously evaluated for association with patient reported outcomes. The objective of this study was to determine whether LLDAS was associated with better HR-QoL, and examine predictors of HR-QoL, in a large multiethnic, multinational cohort of SLE patients.

Methods: Data were collected prospectively from 1422 patients at a single visit and analysed cross-sectionally. Disease status was measured using the SLE disease activity index (SLEDAI-2K), physician global assessment (PGA) and SLICC-ACR damage index. HR-QoL was measured using the Medical Outcomes Study 36-item Short Form Health Survey (SF-36v2).

Results: Significant differences in SF-36 domain scores were found between patients stratified by ethnic group, education

level, damage score, or by the presence of active musculoskeletal or cutaneous manifestations. In multiple linear regression analysis, Asian ethnicity ($p<0.001$), higher education level ($p<0.001$), younger age ($p<0.001$) and shorter disease duration ($p<0.01$) were significantly associated with better physical component scores (PCS). Musculoskeletal disease activity ($p<0.001$) was negatively associated with PCS, and cutaneous activity ($p=0.04$) was negatively associated with mental component scores (MCS). Disease damage was associated with worse PCS ($p<0.001$), but not MCS scores. Compared to patients not meeting criteria for LLDAS, patients in LLDAS had higher HR-QoL as measured by better PCS ($p<0.001$) and MCS ($p<0.001$) scores; this remained significant after adjustment for other variables.

Conclusion: Ethnicity, education, and disease damage affect HR-QoL. Musculoskeletal activity is associated with poor physical components of HR-QoL, and cutaneous activity is associated with poor mental components of HR-QoL. Patients in LLDAS have better HR-QoL than those who are not in LLDAS.

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are at increased risk for premature cardiovascular disease. As sedentary behaviour and lack of physical activity (PA) are known cardiovascular risk factors, we studied PA levels in SLE and RA patients, in comparison to healthy controls, using accelerometry.

Methods: For this cross-sectional study, RA and SLE patients were recruited from rheumatology clinics at an academic medical center. Age- and gender-matched healthy controls were recruited through local advertising. RA and SLE patients met the respective ACR classification criteria and disease activity was assessed by the SLEDAI-2K and DAS28-CRP, respectively. PA was assessed by self-report patient questionnaires and measured by triaxial accelerometer worn during waking hours for seven consecutive days. Minutes per day of sedentary, light, and moderate-vigorous physical activity (MVPA) were recorded and compared between SLE, RA, and healthy control participants using ANOVA.

Results: There were 59 participants: 20 SLE patients, 19 RA patients, and 20 healthy controls. Disease activity was quiescent in both patient groups with mean (SD) SLEDAI-2K and DAS28-CRP scores of 2.9 (2.1) and 2.3 (1.4), respectively. All three groups demonstrated high levels of sedentary behaviour, with mean (SD) sedentary time of 10.1 (1.3) hours/day, or 76.4% of total accelerometer wear time. Total MVPA (mean ± SD, minutes/day) was significantly

lower in SLE (34.5 ± 22.7) and RA (41.5 ± 21.3) patients compared to controls (64.9 ± 22.4) (p<0.001). Physical activity guidelines[1] for MVPA (≥ 150 minutes/week) were less frequently met by SLE (2/20, 10.0%) and RA (3/19, 15.8%) patients compared to healthy controls (9/20, 45.0%) (p=0.02). There was no significant difference between SLE, RA and control participants in the amount of time spent in sedentary behaviour (p=0.80) or light activity (p=0.17). Self-reported PA data by patients and controls correlated poorly with accelerometry data, with all participants over-reporting time spent performing MVPA, and underestimating sedentary time.

Conclusion: Given the increased cardiovascular risk, low MVPA and high sedentary behaviour identified by accelerometry among RA and SLE patients with inactive disease is concerning. Investigation of factors impacting PA and sedentary behaviour in RA and SLE patients is necessary, in order to design effective interventions to target this modifiable cardiovascular risk factor in these vulnerable patient populations.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although studies to date have suggested sleep disturbance among individuals with SLE, prior studies have been small and have examined a limited number of outcomes. We examined the relationship between sleep disturbance and a range of patient-reported outcomes (PROs), both concurrently and longitudinally, in a large cohort of individuals with SLE.

Methods: Data from the Lupus Outcomes Study (2010-2012; n = 711), obtained through annual structured telephone interviews, were used. All participants had physician-confirmed SLE. The Medical Outcomes Study Sleep Scale was administered in 2010 and used to calculate the 9-item Sleep Problems Index (SPI) score. SPI scores range from 0 – 100; higher scores indicate greater sleep problems. The following PROs were examined: self-reported disease activity (Systemic Lupus Activity Questionnaire; SLAQ); modified SLAQ (mSLAQ) excluding symptoms of depression, fatigue, and forgetfulness; disability (Valued Life Activities, 0 – 3 scale); single item rating of SLE activity (0 – 10 scale); Fatigue (0 – 100 scale); SF36 Bodily Pain scale score (0 – 100 scale); and depressive symptoms (Centers for Epidemiological Studies Depression scale; CESD). Relationships between SPI and PROs were examined concurrently and longitudinally after 2 years using multiple linear regression controlling for age, sex, race, income, education, lupus duration, baseline self-reported disease damage (Brief Index of Lupus Damage; BILD), oral steroid use, smoking, depression, obesity, and physical inactivity. Analyses of all PROs except SLAQ and mSLAQ also included mSLAQ as a covariate. Longitudinal

models added the baseline value of the dependent variable.

Results: The sample was 93% female, 61% white non-Hispanic, mean age 53 ±13 years, and mean SLE duration 20 ±9 years. Mean SLAQ in 2010 was 10.9 ± 7.4. The mean SPI in this sample was 44.9 ± 13.7, > one standard deviation higher than the population mean of 25.8 ± 18.6[1]. In cross-sectional analysis, sleep problems were significantly associated with poor outcomes for each PRO (Table 1). Additionally, sleep disturbance was associated with worsening of each PRO over a 2-year period.

Conclusion: Sleep problems appear to be linked to a variety of poor patient-reported outcomes concurrently and to worsening of these outcomes over time. Mechanism for this relationship are not known, but sleep problems have been linked to higher levels of systemic inflammation, greater pain sensitivity, and greater fatigue in the general population. Future studies are needed to characterize sleep problems in SLE objectively, and to identify relationships with clinical outcomes. [1] http://gim.med.ucla.edu/FacultyPages/Hays/surveys/SLEEP/

Table 1. Association of Medical Outcomes Study Sleep Scale Sleep Problems Index with Patient-reported outcomes, Concurrently and Longitudinally, Adjusted Models[1, 2, 3]

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ethnic differences in SLE are well known, but little is known about SLE in patients who have immigrated to North America from elsewhere in the world. Increasing rates of migration of individuals at high risk for SLE to Canada raise the potential for increased SLE specific healthcare needs. We aimed to describe immigrant patients within the 1000 Canadian Faces of Lupus Study.

Methods: The 1000 Faces of Lupus cohort is a multi-centre Canadian cohort of >2000 incident and prevalent SLE patients. Sociodemographic variables, ACR classification criteria, SLEDAI scores, SLICC/ACR damage index (SDI) scores, and treatment history are collected using standardized tools. Ethnicity was self-reported. Cross-sectional baseline analyses included t tests and logistic regression.

Results: 1243/ 2048 patients provided information on country of birth and were included. Immigrants made up 20% of participants (254/1243), similar to the percent (20.6%) in the general Canadian population. Immigrants arrived in Canada at a mean age of 16±10 years, and had been in Canada an average of 16±14 years at time of SLE diagnosis. Among immigrants, only 32% were Caucasian versus 73% of the Canadian born patients; OR 0.2, 95%CI 0.13-0.23); while 35% of immigrants were Asian versus 13% of Canadian-born patients; OR 3.5, 95%CI 2.6-4.9). Disease duration (10 vs 9 years) and age at diagnosis (31 vs. 28 years) were similar across groups, but 32% of Canadian-born had disease onset in childhood versus 25% of immigrants; OR 1.5 95%CI 1.0-2.1). Mean ACR criteria (5.3 vs. 5.2) were similar, but immigrants were more likely to have lupus nephritis (42% vs. 27%; OR 2.0, 95% CI 1.5-2.7). Exposure to lupus drugs and self-reported access to care were similar between groups. SLEDAI scores were similar between the groups, but patient-reported disease activity scores (SLAQ) were significantly lower in immigrants (8.5 vs 10.7, mean difference (MD) -2.2; 95%CI -3.0- -1.4), while damage was higher in immigrants (SDI scores 1.4 vs 1.0; MD 0.4, 95%CI 0.1-0.6). Immigrants had higher physical health-associated quality of life (PCS) (41 vs. 37; MD 3.7, 95%CI 0.4-6.9) but mental health-

associated quality of life (MCS) was similar. Comparing immigrant Asians (N=86) to Canadian born Asians (N=118); disease duration was similar, but immigrants were older at diagnosis (25 vs. 15 years), with only 20% having childhood-onset versus 58% of Canadian-born, OR 0.2, 95% CI 0.1-0.3. Number of ACR criteria, frequency of nephritis (50 vs 52%), medications, SLEDAI and SLAQ scores were similar. Immigrant and Canadian-born Asians had similar PCS and MCS scores and self-reported access to care, but immigrants had lower incomes (32% vs 17% low income, OR 2.2, 95% CI 1.1-4.6). SDI scores were higher in immigrants (0.9 vs 0.5; MD 0.4, 95%CI 0.04-0.80).

Conclusion: Our data suggest relatively severe disease with high frequencies of nephritis and damage in immigrant SLE patients. The low proportion of immigrants with childhood onset SLE also suggests barriers to immigration in children with SLE. Statistics Canada predicts that the proportion of immigrants will increase by 50%by 2031; monitoring information about the characteristics of lupus in immigrants is timely and relevant.

Fatigue in Patients with Systemic Lupus Erythematosus Is Independent of Their Disease Activity but Dependent on Their Damage Accrual and Body Mass Index

Adam Munday[1], Zerai G. Manna[1], Sarfaraz Hasni[1], Randall Keyser[2], Liana Wooten[2] and Ann Biehl[3], [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [2]George Mason University Department of Rehabilitation Science, Fairfax, VA, [3]Department of Pharmacy, National Institutes of Health Clinical Center, Bethesda, MD

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is omnipresent in patients with SLE. According to one study 80-90 % of the subjects report some degree of fatigue. This has huge impact on the patient's activities of daily living and overall quality of life. The fatigue associated with SLE was traditionally considered to be a consequence of SLE disease activity and difficult to measure and quantify in clinical practice. Recent recommendations from several international rheumatology societies and patient advocacy groups have focused on improving quality of life by focusing on issues such as fatigue during clinical encounters with SLE patients. The goal of this study is to measure severity of fatigue in our SLE cohort and to identify any predictors of fatigue.

Methods: We administered a well validated tool of fatigue measure Fatigue Severity Scale (FSS) to consecutive, consenting SLE subjects during their routine outpatient visits at a tertiary care center. Their demographic data, lab values, comorbidities and current medications were recorded at the time of visit. A rheumatologist blinded to the patient FSS scores calculated the SELENA-SLEDAI and SLICC/ACR damage index scores. Statistical analysis using SAS Software (SAS Institute Inc. Cary, NC) was done to identify any predictive variables using multiple regression models and a

stepwise multiple regression models.

Results: FSS was collected from 100 unique patients over a period of 9 months (Table 1). The majority of patients reported significant fatigue with minimal or no disease activity. FSS scores were unrelated to SLEDAI, disease duration, and plasma hemoglobin concentration (Table 2). FSS correlated significantly with SLICC/ACR (p=0.0123) and BMI (p=0.0337). Ethnicity, type of medications, comorbidities, and especially fibromyalgia, were found not to be predictive of fatigue in this cohort.

Conclusion: Results of this study suggest that organ damage accrual may be associated with the severity of fatigue in patients with SLE, independently of their disease activity or duration. Overall the results may implicate, in addition to aggressive early treatment to minimize damage accrual, lifestyle modification such as diet and increased physical activity to lower BMI as a potential therapeutic adjunct to improve fatigue in SLE.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Poor sleep quality is an underappreciated complaint commonly observed in patients with SLE. We hypothesize that poor sleep quality contributes to worsening lupus disease activity. The aims of this study are to evaluate the relationship between: 1) subjective sleep measures and active SLE, 2) objective sleep actigraphy and active SLE, and 3) confounding variables that influence sleep quality and active SLE.

Methods: A prospective, longitudinal, observational study was designed to evaluate the relationship between sleep quality and SLE disease activity. Analysis was restricted to the first study visit. 127 subjects from the Lupus Clinic at Washington University who met ACR or SLICC criteria for SLE were enrolled. Patients with hepatitis B/C, HIV, cirrhosis, ESRD, or pregnancy were excluded. Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), Patient Reported Outcomes Measurement Instrument System (PROMIS)-Sleep Related Impairment (SRI), and PROMIS-Sleep Disturbance (SD) survey instruments were administered to measure patient reported subjective sleep quality. 39 actigraphy watches recorded objective sleep data (sleep efficiency) over 7 days. SLEDAI 2K Responder Index-50 (S2K RI-50) assessed SLE disease activity (S2K RI-50 >4 = active SLE). Pearson Correlation measured the correlation between individual measures of sleep quality and SLE activity. Univariate and multivariate regression analyses explored predictors of active SLE and

poor sleep.

Results: Of the sleep surveys, SRI (Pearson coefficient 0.20, p=0.026) and SD (Pearson 0.20, p=0.031) both correlated with active SLE, whereas ESS (p=0.66) and PSQI (p=0.74) did not. Univariate linear regression of SRI showed that active SLE predicted an increase in SRI that was significant but with modest effect (r^2=0.042, p=0.026) whereas PROMIS-Fatigue (r^2=0.69, p<0.0001) and PROMIS-Anxiety (r^2=0.34, p<0.0001) comorbidities had a stronger effect on predicting SRI. In multivariate linear regression, only the effect of fatigue remained significant (p<0.0001). Univariate and multivariate analyses of predictors of SD showed similar results. Sleep efficiency measured by actigraphy was nearly significant with active SLE (Pearson coefficient -0.30, p=0.064) due to underpowered sample size (n=39). However, sleep efficiency poorly correlated with the subjective sleep surveys: SRI (Pearson -0.18, p=0.28), SD (Pearson -0.19, p=0.26), ESS (Pearson -0.16, p=0.33), PSQI (Pearson -0.33, p=0.09).

Conclusion: Our study reinforces that poor sleep quality remains a problem in SLE patients. We found that the SRI and SD surveys correlated with active SLE, but when considering confounding variables, fatigue best explained the relationship between poor sleep. Interestingly, despite the low sample size, we nearly achieved statistical significance when examining sleep efficiency via actigraphy to active SLE. Furthermore, sleep efficiency poorly correlated with the patient-reported sleep surveys. Thus, these data suggest that sleep quality is an unappreciated need in patients with SLE, and that current, validated sleep surveys may not best represent poor sleep quality for these patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite improvements in medical care leading to improved survival, systemic lupus erythematosus (SLE) adversely affects patients' health related quality of life (HRQoL). To explore the impact of clinical characteristics on reported HRQoL and fatigue, we performed a post hoc analysis (HO-16-17189) based on the long-term continuation study (GSK study 112233; NCT00724867) of the BLISS-76 randomized controlled trial (RCT) in the US.

Methods: In the continuation study, patients who received active drug in the RCT continued to receive the same doses of belimumab (1 or 10 mg/kg IV, every 28 days; all 10 mg/kg post-Mar 2011) plus standard of care (SoC) (belimumab/belimumab group). Patients previously receiving placebo received belimumab 10 mg/kg IV (placebo/belimumab group). HRQoL and fatigue assessments included Short Form-36v2 (SF-36) Medical Outcomes Survey and Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue. In the post hoc analyses, subgroup

assessments were based on treatment (placebo/belimumab or belimumab/belimumab); responders (SLE Responder Index [SRI]-4 response within 1 year); high disease activity (high anti-dsDNA, low C3/C4); flare (SLE Flare Index); steroid dose (0 to 7.5 mg/d, ≥7.5 mg/d); damage (Systemic Lupus International Collaborating Clinics/American College of Rheumatology [SLICC] Damage Index [SDI]; 0, 1, and ≥2) at baseline (BL). Mixed-effect models were used to obtain means over time, with adjustments for disease duration and activity, BL HRQoL scores, age, gender, and race.

Results: The modified intent-to-treat population comprised 268 patients; 140 completed the continuation study. Statistically significant associations were observed between treatment groups and change from BL in SF-36 Physical (PCS) and Mental component (MCS), and FACIT scores (all $p<0.01$; **Table**). Responders and those with high disease activity reported numerically larger improvements from BL in HRQoL scores. Reported HRQoL scores were similar between all other subgroups at BL.

Table: Impact of key clinical characteristics on HRQoL from BL to Year 6 Week 48 (adjusted means)

	Treatment group Change from BL to Year 6 Week 48		Responder[1] (SRI-4 responder at Year 1) Change from BL to Year 6 Week 48		High disease activity at BL (high anti-dsDNA, low C3/C4) Change from BL to Year 6 Week 48	
	Placebo/belimumab (N=58)	Belimumab/belimumab (N=127)	No (N=70)	Yes (N=89)	No (N=119)	Yes (N=66)
Mean (SD)						
SF-36v2 PCS	1.98	5.77*	4.30	5.21	3.92	5.81
SF-36v2 MCS	-1.10	3.51†	0.90	2.77	1.18	3.57
FACIT-Fatigue score	-0.53	5.75‡	3.02	4.98	2.85	5.31

[1]Patients with a BL Safety of Estrogens in Lupus Erythematosus National Assessment SLE Disease Activity Index (SELENA-SLEDAI) score <4 were excluded from the responder subgroup analysis;
*p=0.0019; †p=0.0027; ‡p=0.0002 (p values vs placebo/belimumab). All other p values were not statistically significant.

Conclusion: Differences in SF-36 and FACIT outcomes between treatment subgroups must be considered in light of differing BL scores: those for the placebo/belimumab arm were at time of entry into the extension study, following successful SoC treatment; whereas the belimumab/belimumab arm BL scores were at entry into the RCT. Further analyses, using comparable BL scores (at RCT entry) for all treatment groups will better characterize this patient subgroup. The lack of significant associations based on response status could partly be explained by the definition of 'responders', which was based on clinician assessments and may not have fully captured the patient experience. For all other subgroup analyses, sample sizes were small and not powered to show significant associations. Study funded by GSK/Human Genome Sciences, Inc. Nicole Cash, MRes PhD, Fishawack Indicia Ltd, UK, provided editorial assistance, funded by GSK.

Session Time: 9:00AM-11:00AM

Background/Purpose: To study the effect of disease remission on quality of life and organ damage in patients with systemic lupus erythematosus.

Methods: Consecutive patients who fulfilled the ACR classification for SLE were recruited from our lupus out-patient clinics. Their remission status was determined according to the European consensus (DORIS definition): (1) Complete remission (clinical SLEDAI=0, serology inactive); and (2) Clinical remission (clinical SLEDAI=0, serology active). These two categories were further divided into those who required ongoing immunosuppressive treatment (prednisone ≤5mg/d or other immunosuppressive agents) and who did not. The duration of the remission status was also verified by medical record review. The increase in SLE organ damage (SDI) score since 5 years prior to recruitment was compared between patients who were and were not in clinical remission for at least 5 years. Participants were randomly selected for assessment of quality of life by using both the validated version of SF36 and the LupusPRO (version 1.8) and comparison was made between those who did and did not achieve clinical remission for ≥5 years by the independent Students' t-test.

Results: A total of 618 SLE patients were studied (92% women; age 45.5±8.1 years, SLE duration 11.8±8.1 years). All were ethnic Chinese. At the last clinic visit, clinical remission (serology active) was present in 227 (37%) patients (median duration 28 months) and complete remission (clinical and serology inactive) was present in 232 (38%) patients (median duration 48 months). Clinical and complete remission for ≥5years was achieved in 55 (9%) and 98 (16%) of the patients, respectively. 40 (26%) patients with remission ≥5 years were taken off all medications. No significant differences in the cumulative frequencies of organ manifestations since SLE diagnosis were observed between patients with clinical/complete remission for ≥5years and <5 years. However, patients with remission ≥5 years were significantly older (48.6±13.5 vs 44.5±14.7 years; p=0.002) and had a longer SLE duration (16.8±7.8 vs 10.3±7.5 years; p<0.001). In patients with remission for ≥5years, the increase in SDI score over the preceding 5 years was significantly lower than those with remission for <5 years (0.18±0.47 vs 0.50±0.90; p<0.001). 88 patients with remission ≥5 years and 283 patients with remission <5 years were assessed for quality of life at random. The physical component (61.7±21.6 vs 53.6±21.1; p=0.03) and mental component (61.0±21.8 vs 54.6±20.9; p=0.02) scores of the SF36 were significantly higher in patients with remission ≥5 years. On the other hand, scores of the health related domains (81.1±15.7 vs 73.1±16.1; p<0.001) but not the non-health related domains (57.6±18.4 vs 58.6±14.8; p=0.64) of the Chinese LupusPRO were significantly higher in patients with remission ≥5 years compared to those with remission <5 years.

Conclusion: In this cross-sectional study of Chinese patients with SLE, long-lasting clinical remission was present in a quarter of patients, the majority of whom were on maintenance immunosuppressive medications. Those with clinical remission for more than 5 years had less organ damage accrual over time and better health related quality of life.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Systemic lupus erythematosus (SLE) have significant impairment in quality of life (QOL). Health related QOL (HRQOL) is one of the four established core outcomes in SLE. Generic PRO instruments such as Short Form 36(SF-36), SF-6D, EuroQOL (EQ-5D) and the Functional Assessment of Chronic Illness Therapy (FACIT-Fatigue)) have been shown to be valid and reliable in SLE. The purpose of this study is to determine minimal clinically important difference (MCID) of SF-36 and FACIT-fatigue against varied physician assessed DA indices, using data sharing resource from Glaxo-Smith-Kline (GSK), collected during Belimumab clinical trial – BLISS 52.

Methods: Longitudinal data from BLISS 52 clinical trial from 867 SLE patients was acquired from GSK for purpose of these analyses. DA measures (SLEDAI, BILAG) were used as anchors. MCID estimates were obtained against all possible predefined DA and composite DA endpoints used in SLE clinical trials. Mixed model analysis was utilized for the first 4 visits, one month apart for these analyses for individual DA anchors. For SELENA-SLEDAI Flare Index (SFI) and composite measures, 6,069 observation data from 7 visits were used.

Results: 867 SLE patient data consisting of 95% women, with mean (SD) age 35.5 (11.1) yrs., were available. Nearly 65% were Asian or White ethnicity. Median (IQR) SLEDAI, BILAG were 10.0 (4.0) and 17 (11.0) respectively. Median (IQR) MCS, PCS, FACIT-Fatigue were 40.3 (14.3), 41.7 (12.9) and 34.0 (14.0) respectively. MCID against SLEDAI and SRI are shown in table 1 and table 2 respectively. Results for MCID against BILAG are not included in the table but will be available for presentation. SF36 domains and FACIT-fatigue were responsive to improvement in DA endpoints – SELENA-SLEDAI, SFI, BILAG and composite measures. SF36 domains and FACIT-Fatigue were not consistently responsive to worsening in DA.

Conclusion: Our study provides SLE specific MCIDs against commonly used DA measures and further reinforce the need for use of disease specific MCID over "generic" values of improvement/worsening by 2.5 and 5.0 in domain and composite scores of SF36.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Neuropsychiatric systemic lupus erythematosus (NPSLE) involves a wide range of peripheral and central neuropsychiatric manifestations. Depression is one of those and is very common in patients with SLE. The aim of this study was to determine if depression increases the risk of lupus flare in our patient population at Temple University Hospital, which is predominantly African American, and also to determine if therapy for Depression impacts SLE flares.

Methods: Data were collected from patients with SLE who fulfilled at least 4 SLICC criteria, at each clinic encounter from January 2013 to December 2015. Patients' demographics, medical, surgical and social history, medication list and laboratory results were included. Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and Systemic Lupus International Collaborating Clinic (SLICC) Damage Index (SDI) were also extracted and analyzed as they were incorporated into our Epic Care EHR and routinely extracted to facilitate disease monitoring.

Results: Out of 209 patients present in the lupus cohort, 38 patients had a diagnosis of depression in their medical history. On review of these patient charts, 32 patients were included (6 excluded for having only 2 visits). 34 patients with diagnoses of lupus randomly selected from our cohort and without depression acted as control. The majority of our patients with concurrent lupus and depression were in the 40^{th} and 50^{th} decade of life. Only 62.5% (20/32) of patients were on antidepressants. SLEDAI analysis revealed that 62.5% (20/32) patients had at least a lupus flare and 75% (9/12) of these patients were not on any antidepressants, whereas those on antidepressants 55%(11/20) had lupus flare. The two groups were not statistically different (chi-square, p= 0.083). Interestingly lupus patients with depression compared to patients without depression, had statistically more flares (chi-square, p= 0.027). On our analysis though higher SLICC scores were common in lupus patients with depression, it did not reach significance (chi-square, p= 0.392). Also on comparing other comorbidities including HTN, diabetes, infections and social factors such as smoking, these were more common in lupus with depression (chi-square, p=0.041).

Conclusion: Prevalence of depression is high in SLE patients. We confirmed that Lupus patients with depression have significantly more flare compared to those without depression. Although it has been shown that the risk of lupus flare is high in those untreated for depression, in our cohort there was no statistical significance compared to those not on antidepressants. Other factors besides treatment that played a significant role in our cohort was presence of comorbid illnesses. Depression might be considered an independent risk factor for Lupus flares.

Poor Body Image in Lupus: Is It Disease Activity, Damage, Sleep, Pain, Fatigue, Stress, Function, Medications, Depression or Fibromyalgia?

Stacy Weinberg[1], Nisarg Gandhi[2], Meenakshi Jolly[3], Winston Sequeira[2] and Shilpa Arora[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology, Rush University Medical Center, Chicago, IL, [3]Rush, Chicago, IL

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have poorer body image (BI) than age matched

controls. Few studies have been done looking at the effect of disease activity, damage, sleep, stress, pain, fatigue, function, medications, depression and fibromyalgia (FM) in SLE patients. These 10 variables are frequently correlated, and their individual effect on BI is difficult to tease out. To improve BI in SLE, we need to better understand where we need to focus our attention among these 10 variables to guide development of specific interventions. We aimed to evaluate the relative role of disease activity, damage, sleep, stress, pain, fatigue, function, medications, depression and FM on BI in SLE patients.

Methods: 115 SLE patients receiving rheumatology care at two academic medical centers were recruited. Each patient completed the following: Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT), Perceived Stress Scale (PSS), Patient Health Questionnaire (PHQ-9 for depression), Insomnia Severity Index (ISI), pain inventory and LupusPro. Body image and physical function was measured using the BI (BILS) and Physical health (PH) domains of LupusPRO. Disease activity and damage were assessed using SELENA-SLEDAI (SS) and SLICC/ACR Damage Index (SDI). Charts were reviewed to evaluate if the patient had been diagnosed with FM by a rheumatologist. Multivariate regression analyses (including stepwise modelling) were conducted with BI as the dependent variable for (a) all patients, and for patients (b) without and (c) with FM.

Results: 115 SLE patients with mean (SD) age of 40 (14) yrs. Ninety percent were women, and 15% had concomitant FM. Over 60% were currently on prednisone. Mean (SD) SS and BILS score were 4.8 (4.1) and 74.5 (27.7) respectively. For all patients, with all 10 variables in the regression analysis, PSS remained the single independent inverse predictor of BI after adjusting for other 9 variables. On stepwise regression, PSS and Pain were predictors of BI (Table 1). Among SLE patients without FM, the SS, PSS, PHQ were independent predictors of poor BI, after adjusting for the other 6 variables. On stepwise modeling, only PSS, PHQ, and SS were predictors of BI among non-FM SLE patients. When SS was replaced by SS arthritis, rash, alopecia items in this model, PSS, PHQ and active rash were found to be independent predictors. Among SLE patients with FM, none of the 9 variables independently predicted poor BI. On stepwise modelling PH was a predictor of BI in SLE patients with FM.

Conclusion: PSS (and not FM or steroid use) is an important and independent predictor of BI for all SLE patients. Among SLE patients without FM, besides PSS, active disease (rash specially) and depression are also important drivers of poor BI.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is a major patient complaint in SLE, often severely impacting quality of life and activities including work. In this study, we analyze neuropsychiatric (NP) symptoms in relation to fatigue in SLE together with measures of disease activity, organ damage and potential contributing factors such as pain, psychiatric co-morbidities and sleep quality.

Methods: Measurements of fatigue were performed using the Fatigue Severity Scale (FSS) and the Visual Analogue Scale (100mm) (VAS). NP manifestations were defined according to NPACR case definitions. Disease activity, organ damage, health related quality of life and co-morbid conditions were recorded. Pain was recorded using the VAS (100mm). Depression and anxiety were evaluated with the Hospital Anxiety and Depression scale (HAD). Sleep disturbances were assessed using the Karolinska Sleep Questionnaire (KSQ). Cerebrospinal fluid was obtained in 33 patients who consented to lumbar puncture. Linear regression analyses were performed with VAS fatigue and FSS as outcome variables.

Results: 72 SLE patients and 26 matched healthy controls were included in this cross-sectional study. VAS fatigue and FSS were closely correlated ($r=0.63$, $p<0.001$). An increased VAS fatigue in the SLE group was associated with the following NP manifestations; cerebrovascular disease ($p=0.047$), headache ($p<0.01$), cognitive dysfunction ($p=0.008$) and depression ($p=0.006$). Furthermore, higher VAS fatigue scores correlated with increased HAD anxiety and HAD depression scores ($p<0.001$), lower EQ5D scores ($p<0.001$) and higher pain scores ($p<0.001$). However, there were no correlations between VAS fatigue score and age, disease duration, organ damage, co-morbidity or disease activity. Detection of CSF oligoclonal bands did not correlate with fatigue scores. Although most correlations were similar when using the FSS as outcome we found small differences compared to VAS fatigue; presence of autonomic neuropathy correlated with increased FSS ($p=0.049$) and there was no significant correlation between FSS and headache ($p=0.163$). In addition, a reduced overall sleep quality was seen comparing SLE patients and healthy controls using the KSQ ($p<0.001$). An increased FSS and VAS fatigue score in the SLE group correlated with scores in 3 sub-indices of the KSQ; insomnia ($p<0.001$), repeated awakenings ($p<0.001$) and daytime sleepiness ($p<0.001$). Finally, lower EQ5D scores was associated with increased both FSS and VAS fatigue scores ($p<0.001$ for both).

Conclusion: NP involvement in SLE may contribute to fatigue development in these patients, hypothetically mediated in part by a reduced sleep quality. Other factors, such as pain and concomitant psychiatric disease are also implicated, while disease activity may be of less importance.

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is a common symptom of Systemic Autoimmune Rheumatic Disease (SARD) and has been proposed to result from the elaboration of pro-inflammatory factors in these conditions. Patients with SARD have a protracted pre-clinical phase during which progressive immunologic derangements occur culminating in disease, however it is unknown at what point during this progression that fatigue develops and whether it is associated with any specific immunologic changes. The objective of the current study was to determine whether ANA^+ individuals who lack sufficient symptoms for a SARD diagnosis suffer from fatigue and assess the correlation between fatigue, autoantibody profile, and the presence of an interferon signature.

Methods: Healthy ANA^- controls and ANA^+ (≥1:160 by immunofluorescence) participants with no (ANA No Symptoms, ANS), at least one symptom (Undifferentiated Connective Tissue Disease, UCTD), or meeting SARD classification criteria were recruited. Fatigue was assessed using a modified version of the FACIT-F questionnaire and the presence of fibromyalgia determined using the modified 2010 ACR criteria questionnaire (score ≥ 13). Peripheral blood IFN-induced gene expression was quantified by NanoString and the normalized levels of 5 ubiquitously expressed IFN-induced genes summed to produce an IFN5 score. ANAs and levels of specific autoantibodies were measured by the hospital laboratory.

Results: Fatigue and fibromyalgia were assessed in 117 individuals (22 healthy controls (HC), 30 ANS, 25 UCTD, 40 SARD). All ANA^+ subjects were significantly more fatigued than HC (FACIT-F score (mean ± SD): HC = 49.45 ± 5.54, ANA^+ subjects = 28.78 ± 14.52, $p < 0.0001$) and this was true for each of the subsets examined independently. None of the HC and 35.8% of the ANA^+ subjects had fibromyalgia ($p = 0.0004$), with similar proportions in all ANA^+ subsets. As many of the ANA^+ subjects with low fatigue scores also had fibromyalgia, we assessed whether fatigue was present in ANA^+ subjects without fibromyalgia. Even in the absence of fibromyalgia, all ANA^+ subsets were significantly more fatigued than HC (HC = 49.45 ± 5.54, ANS = 40.61 ± 11.31, UCTD = 34.62 ± 12.62, SARD = 33.24 ± 11.66, all $p < 0.05$), with no significant differences between subsets. There was no association between the FACIT-F score in ANA^+ subjects (as a group or the individual subsets) and the titre of ANA, number of different autoantibody specificities, or IFN5 score, either in the presence or absence of fibromyalgia.

Conclusion: Fatigue is common in ANA^+ individuals who lack sufficient criteria for a SARD diagnosis and cannot be solely attributed to fibromylagia or the extent of the immunologic derangement.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

The Impact of Comorbidities on Quality of Life in Systemic Lupus Erythematosus in the first 10 years

Background/Purpose: The Medical Outcome Survey Short Form 36 (SF-36) is one of the most widely used tools for measuring patient reported outcomes. Our previous studies have shown that SF-36 improves in the first 2 years of an inception cohort and stabilizes in years 2-5 However the accrual of comorbidities in SLE increases over 8 years. The aim of this study is to assess quality of life(QoL) in a multinational multicenter cohort over years 4-10 of disease and assess the impact of comorbidities on QoL.

Methods: An international research network comprised of 33 centres from 11 countries has followed an inception cohort of SLE patients yearly according to a standardized protocol between 2000 and 2016. Clinical and laboratory features of SLE, comorbidities, and SF-36 are gathered in a standardized protocol annually. Comorbidities including atherosclerotic vascular events (AVEs), osteoporosis, osteonecrosis and diabetes are assessed using the SLICC/ACR Damage Index (SLICC/DI). Attribution of a vascular event to atherosclerosis (AS) is made on the basis of lupus disease being inactive at the time of the event, and/or the presence of typical AS changes on imaging or pathology and/or evidence of AS elsewhere. Diagnosis of osteoporosis is based on abnormal bone mineral density and osteonecrosis was confirmed using joint symptoms associated with abnormal imaging consistent with osteonecrosis. Diabetes diagnosis is based on therapy, regardless of treatment type. The outcomes assessed include all 8 domains, physical component scores (PSC) and mental component scores (MCS) of SF-36. In order to test for change in SF-36 over the 10-year period, linear mixed models were run separately for the composite scores. Each model adjusted for repeated measures by patients and by centre. The impact of AVEs, osteoporosis, osteonecrosis and diabetes. on component scores was assessed using univariate and multivariate regression models

Results: 416 patients constitute the study population, of which 88.9% female, the mean disease duration at enrolment was 5.4 ± 4.3 months and the mean age at diagnosis was 34.6 ± 13.4 years. The race/ethnicity distribution was as follows: 55.3% Caucasian, 13.9% Black, 18.3% Asian, 9.4% Hispanic and 3.1% other. No significant change in SF-36 domains or component scores over years 4-10 were seen (Table 1). However, in a multivariable linear regression the presence of osteonecrosis (PE; 95% CI) (-8.6; -16.0, -1.3) (p=0.021) and osteoporosis (-15.0; -26.0, -4.3) (p=0.006) significantly impact the mean PCS. The comorbidities did not impact the MCS

Table 1. SF-36 domains and component scores over years 4-10

Years since Baseline Visit	4	6	8	10
Physical Component Summary	42.78	43.01	42.61	42.51
Bodily Pain	64.83	65.40	64.80	64.09
General Health	53.18	52.85	52.48	52.66
Physical Function	71.46	72.69	71.93	70.58
Role Physical	60.20	61.98	62.24	61.58
Mental Component Summary	47.51	48.02	48.23	47.84
Role Emotion	71.47	72.16	73.96	70.23
Social Function	72.57	73.68	72.57	73.23
Vitality	51.97	52.82	51.90	52.00
Mental Health	69.22	70.71	71.14	70.48

Conclusion: In an inception cohort SF-36 QoL measures do not change significantly over years 4-10 of their disease. However the comorbidities osteonecrosis and osteoporosis significantly impact the PCS.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with frequent involvement of the central nervous system. Among the items included in the nomenclature for neuropsychiatric SLE, mood disorders have been identified. Despite the fact that depression is prevalent in SLE, its importance and impact may be underestimated. There are previous reports from Asia and North America about the association of depression with poor Health-Related Quality of Life (HRQoL) in SLE patients. However, there are few reports about this matter from Latin-American patients. The aim of the study was to evaluate whether depression is associated with poor HRQoL in Latin-American SLE patients.

Methods: In a cross-sectional single center study, we evaluated 94 SLE patients, who were seen in our Rheumatology Department between March 2015 and June 2016. SLE was defined by the 1997 revised and updated ACR criteria.

Demographic and clinical data were obtained from interview, physical exam and chart review. Disease activity was ascertained with the systemic lupus erythematosus disease activity index (SLEDAI), and disease damage was ascertained with the SLICC/ACR damage index (SDI). Depression was measured with the Beck's test, which determined its severity varying from minimal (0-13) to severe (29-63) and HRQoL with the SF-36. Univariable and multivariable linear regression models were performed in order to evaluate the association between depression and HRQoL Multivariable analyses were adjusted for age, disease duration, socioeconomic status, SLEDAI, SDI, use of prednisone, antimalarials and immunosuppressive drugs.

Results: Ninety-four SLE patients with a mean age of 45.50 (SD: 12.24) years. Almost all of them were mestizo, only one was African Latin-American. The mean SLEDAI was 4.97 (SD 4.15), the mean SDI was 0.91 (SD 1.21), the mean physical component of the SF36 was 46.43 (SD 18.97) and the mean mental component of the SF36 was 48.65 (SD: 17.71), mean Beck's test was 6.44 (SD 7.25). Univariable and multivariable associations between Beck's test and components of SF-36 are depicted in Table 1. Table1: Association of depression with HRQoL

	Univariable		Multivariable*	
	B (95% CI)	p value	B (95% CI)	p value
Physical Component Score	-1.07 (-1.55; -0.59)	<0.001	-1.02 (-1.47; -0.57)	<0.001
Mental Component Score	-1.12 (-1.56; -0.68)	<0.001	-1.14 (-1.54; -0.74)	<0.001
Physical Functioning	-1.24 (-1.87;-0.61)	<0.001	-1.18 (-1.72; -0.63)	<0.001
Physical Role	-1.14 (-2.2; -0.02)	0.046	-1.04(-2.09; -0.004)	0.049
General health	-0.84 (-1.3; -0.37)	<0.001	-0.84 (-1.28; -0.40)	<0.001
Bodily pain	-1.12 (-1.71; -0.53)	<0.001	-1.02 (-1.59; -0.44)	<0.001
Vitality	-0.94 (-1.37; -0.51)	<0.001	-0.96 (-1.38; -0.55)	<0.001
Social Role	-1,36 (-1.9; -0.80)	<0.001	-1.42 (-1.96; -0.88)	<0.001
Emotional Role	-1.53 (-2.6; -0.43)	0.006	-1.50 (0.50; -2.49)	0.003
Mental Health	-0.88 (-1.34; -0.42)	<0.001	-0.92 (-1.37; -0.48)	<0.001

CI: Confidence Interval*Adjusted by age, disease duration, socioeconomic status, SLEDAI, SDI, use of prednisone, antimalarials and immunosuppressive drugs.

Conclusion: In SLE patients, the presence of depression is associated with a worse HRQoL, independently of other risk factors.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Neuropsychiatric (NP) disease in patients with SLE includes cerebrovascular events (CerVE). We determined the frequency, attribution and risk factors for CerVE in a large, multi-ethnic/racial, inception cohort of SLE patients with long-term followup.

Methods: A prospective study of new onset SLE patients was performed by an international network of 32 academic centers in 11 countries. Patients were evaluated at enrollment and annually for up to 17 years. Data were collected at each assessment on demographic and clinical manifestations, medications, SLE disease activity index-2000 (SLEDAI-2K) and Systemic Lupus International Collaborating Clinics (SLICC)/ACR damage index (SDI). Nervous system events were recorded using the ACR case definitions for 19 NP syndromes. These included the following CerVE: (i) Stroke; (ii) Transient ischemia; (iii) Chronic multifocal ischemia; (iv) Subarachnoid and intracranial hemorrhage; (v) Sinus thrombosis. Pre-defined rules determined the attribution of NP events to SLE and non-SLE causes. Demographic variables, clinical variables, medications and NP related lupus autoantibodies were examined as potential predictors of the risk of SLE CerVE by univariate and multivariate Cox regression analyses.

Results: Of 1,826 SLE patients, 88.8% were female, 48.8% Caucasian, 16.8% African, 15.4% Hispanic, 15% Asian and 4% other. At enrollment the mean±SD age was 35.1±13.3 years, SLE duration was 5.6±4.2 months, SLEDAI-2K was 5.3±5.4 and SDI was 0.31±0.73. The mean follow-up was 6.5±4.1 years. Over the study 929 (50.9%) patients had 1,844 NP events of which 573 (31.1%) in 378/1826 (20.7%) patients were attributed to SLE. CerVE were the fourth most frequent NP event: 82/1,826 (4.5%) patients had 109 events of which 103/109 (94.5%) were attributed to SLE and 44 (40.4%) were identified at the enrollment visit. The incidence of first and recurrent CerVE was 5.8/1000 and 32.7/1000 person years respectively. The predominant events were stroke [60/109 (55.0%)] and transient ischemia [28/109 (25.7%)] followed by subarachnoid and intracranial hemorrhage [9/109 (8.3%)], chronic multifocal ischemia [9/109 (8.3%)] and sinus thrombosis [3/109 (2.8%)]. Multivariate analysis identified significant associations between CerVE and concurrent NP events attributed to SLE (HR (95% CI): (3.18; 1.72-5.88), concurrent non-SLE NP events (2.75; 1.55-4.89) ($p<0.001$), patients of African ancestry at US SLICC sites (2.95; 1.44-6.06) ($p=0.003$) and increased cumulative organ damage score (excluding NP variables) ($p=0.04$). There was a significant association between lupus anticoagulant at enrolment and the risk of first CerVE (4.4; 1.8-10.9) but not with recurrent events (0.87; 0.34-2.24) ($p=0.012$) likely due to the greater use of anticoagulants following the initial CerVE event (94%) compared to at the time of the initial events (37%).

Conclusion: CerVE are the fourth most frequent NP event in SLE, are usually attributable to lupus and occur frequently around the time of SLE diagnosis. Risk factors include other concurrent NP events, African ancestry and lupus anticoagulant.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mortality in systemic lupus erythematosus (SLE) has improved over the last decades. Outcome measures as damage became more important. **Objectives:** To study the manifestations of damage from the point of view of the timing of its appearance.

Methods: In the first transverse phase of RELESSER, accumulated information on 400 variables per patient at the time of the last evaluation was collected. Among these SLICC/ACR Damage Index (SDI) items were included. We evaluated damage manifestations in each system and the temporal relationship of their appearance with the time of diagnosis of SLE. Cumulative incidence function for damage by the Aalen-Johansen method was estimated. Bootstrap technique was used to calculate the p-values to compare rates os accumulation of damage over time.The impact on mortality was studied controlling for sex, race, age at diagnosis and delay of diagnosis of SLE, with a model of multivariate Cox regression. The rate of increase or accumulation of damage is significantly higher ($p<0.001$) higher short time after SLE diagnosis. The

proportion of patients with damage in at least 1 system at 5 and 10 years was 18.9% (17.3-20.4) and 29.2% (27.3-31.1). That is while in the 1st year 7.4% of patients present damage in any system, only 2.9% per year do so since the 1st to the 5th year after diagnosis and, between the 5th and 10th year there was only an annual increase of damage of 2.1%. The risk of death is multiplied by 2.04 (1.7-2.3) at the time that a new system is damaged. When entering into a multivariate model the damage in each systems a statistically significant impact on neuropsychiatric, renal, pulmonary, CV systems and malignancy was found, with multiplicative risk factors of 2.0, 1.8, 2.8, 1.7 and 2.7, respectively.

Results: 2,662 SLE patients had the dates of presentation of each event of damage: 2,417 (91.0%) women, 2,402 (92.8%) Caucasian, mean age (±SD) 34.0 (±13.6) years at the time of diagnosis. The mean follow-up duration was 115.6 (±50.8) months and 112 (4.2%) patients died. At the time of the study 917 (34.4%) patients had at least 1 manifestation of damage, the average number systems per patient with at least 1 manifestation of damage was 0.54 (±0.92) and the average score was 0.65 SDI (±1.2). The systems more frequently damaged were musculoskeletal (MS) (11.9%), ophtalmic (7.8%) and cardiovascular (CV) (5.9%). In the 1st year after SLE diagnosis, the cumulative incidence (CI 95%) of damage in at least 1 system was estimated in 7.4% (6.4-8.4), at 5 years 18.9% (17.3-20.4) and after more than 10 years 29.2% (27.3-31.1).The systems damaged at earlier stages, 1 year after SLE diagnosis, were: MS 1.7% (1.2-2.2), neuropsychiatric 1.3% (0.8-1.7) and renal 1.2% (0.8-1.6). The CV and cutaneous systems also had relatively early damage, 0.9% (0.6-1.3) and 0.8% (0.5-1.2) respectively.

Conclusion:

Damage occurs already in early stages of the disease. It appears early in MS, neuropsychiatric and kidneys. The increase or accumulation of damage is greater in the 1st year after the diagnosis of SLE. The accumulation of visceral damage increases the mortality rate.

ACR Abstract Authors: Shawn G. Kwatra[1], Wei Fu[2], Michelle Petri[2] [1]Department of Dermatology, [2]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD **Title:** Smoking as a Predictor of Cutaneous

Activity in Systemic Lupus Erythematosus

Background/Purpose: Smoking is associated with increased disease activity in patients with systemic lupus erythematosus (SLE) and cutaneous lupus erythematosus (CLE) in cross-sectional analyses. We sought to determine the associations between smoking status, presence of cutaneous activity, and SLE disease activity among patients enrolled in a US-based SLE Cohort featuring a large African-American population.

Methods: The Hopkins Lupus Cohort was queried for demographic information, clinical information, and laboratory parameters between current smokers and never smokers. SLE patients that developed rash vs. those that did not (according to the validated SLEDAI criteria for rash) were compared with smoking status and the following co-variables: age, ethnicity, sex, ESR, urine protein/creatinine ratio, anti-Ro, anti-La, anti-DNA, Low C3, and Low C4.

Results: Current smokers vs. never smokers Current smokers were significantly more likely than never smokers to have an active rash (49.58% vs. 36.31%, p <0.0001) and ESR > 20 (p < 0.0006). Non-smokers were significantly more likely to have anti-Ro antibodies as compared to current smokers with no significant differences found in additional co-variables. SLE Patients who developed new rash during the course of follow-up vs. patients without rash SLE patients who developed a new rash were significantly more likely than SLE patients without a rash to have a younger age of SLE diagnosis (p < 0.0015), higher SLEDAI continuous score (5.53 vs. 2.26, p < 0.0001) and SLEDAI score ≥ 2 (100% vs. 57.04%, p < 0.0001), Urine protein creatinine ratio > 0.5 (p 0.0256), anti-dsDNA ≥ 10 (36.12% vs. 23.78%, p<0.0001), low C3 < 79 and low C4 < 12 with no significant differences in percentage of patients positive for anti-Ro and anti-La antibodies. Association between Smoking and New Rash Smoking was significantly associated with new rash in SLE patients after adjusting for sex, ethnicity, and hydroxychloroquine use (p < 0.0001). Duration from SLE diagnosis to new rash were compared between current smokers and never smokers. Both non-parametric Kaplan-Meier curve and a parametric Weibull curve demonstrated current smokers developed rash significantly earlier than never smokers. The hazard of developing a rash is 40% higher among current smokers than never smokers, with the effect persisting after adjusting for sex and ethnicity.

Conclusion: Current smokers with SLE are significantly more likely than non-smokers to have an active rash. The hazard of developing a rash is 40% higher among current smokers than never smokers. SLE patients who developed rash as compared to patients that did not develop a rash had significantly increased SLE disease activity and several laboratory abnormalities including increased urine protein creatinine ratio > 0.5, anti-dsDNA ≥ 10, low C3 < 79 and low C4.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The pathophysiology of brain damage SLE is complex. The aim of this study was to determine brain atrophy progression and the association with Th1 and Th2 in systemic lupus erythemathosus (SLE) patients.

Methods: Consecutive SLE patients followed at the Rheumatology unit of the State University of Campinas were enrolled in this follow-up study. Healthy volunteers, matched by age and sex, were included as control group. A complete clinical, laboratory and neurological evaluation was performed in all subjects. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current therapy. MRIs were repeated in all individuals after a mean follow-up time of a minimum of 12 months. Sagittal T1-weighted images were used for volumetric measurements (Neuroline®). Volumes smaller 2 standard deviation from the means of controls were considered abnormal. Sera cytokines Th1 (TNF-α, IFN-γ, IL-12) and Th2 (IL-4, IL-6, IL-10) were performed by enzyme linked immunosorbent assay (ELISA) at the end of the study. Total dose of corticosteroids and other immunosuppressant medications used since the onset of disease were calculated by data obtained by careful review of the medical charts. Data were compared by non-parametric tests.

Results: Eighty-five SLE patients (81 women; mean age of 41.14±11.08 years; range 24-73) and 59 (52 women; mean age of 40.14±13.42 years; range 18-69) healthy controls were included. At the first MRI, 38 patients had active disease (mean SLEDAI scores of 3.71± 4.24; range 0-16). 60 (70.5%) had SDI≥1. Neuropsychiatric manifestations were observed in 31 (36.4%). aCL were positive in 35.5%. Mean total dose of corticosteroid dose was 41.95± 34.09g (0-13.58). Mean cerebral (1056.45± 86.75cm^3 and corpus callosum volume 11.57±2.1cm^3) were significant smaller at baseline when compared to controls (cerebral 1086.37± 165.77cm^3; corpus callosum 14.67±14.33 cm^3 volume; $p<0.01$). We observed a significant greater progressive loss of cerebral (2.3±1.08%), and corpus callosum volume (5.83%±4.97%) in SLE patients when compared to controls (cerebral volume change=0.32±1.73%; p=0.028 and corpus callosum volume change=0.03±0.19%; $p<0.001$). There was an association between IL-12 and progressive brain atrophy (p=0.008) and a direct correlation between sera IL-12 levels and percentage loss of brain volume (rs=0.3; p=0.015). We did not observe an association between brain or corpus callosum atrophy and aCL (p=0.688; p=0.094), total dose of corticosteroids (p=0.479; p=0.647, respectively), or other cytokines, clinical, laboratory manifestations and treatment.

Conclusion: IL-12 was associated with progressive loss of brain volume in SLE, suggesting immunological basis for global atrophy in SLE. Cytokines act as crucial mediators in the bidirectional signaling between the immune system and the brain and may be considered biomarkers for brain damage in SLE.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Individuals with systemic lupus erythematosus (SLE) are frequently hospitalized. Determining factors associated with hospitalization rates may help to identify patients at highest risk for poor outcomes and improve healthcare resource utilization.

Methods: The Georgians Organized Against Lupus (GOAL) is a cohort of validated patients with SLE living in Atlanta, predominantly derived from the population-based Georgia Lupus Registry. Since 2011, participants are surveyed annually on sociodemographics, health insurance, the Self-Administered Brief Index of Lupus Damage (SA-BILD), and the Systemic Lupus Activity Questionnaire (SLAQ). Those with accumulation of any organ damage during the study period were deemed a Damage Progressor (DP). Patients were matched to the Georgia Hospital Discharge Database to capture all hospitalizations throughout the state from 2011 through 2013. Multivariable Poisson regression analyses were performed to explore the independent effect of demographic and disease-related factors on the hospitalization rate (HR), defined as the number of hospital admissions per 1000 person-years, and on the incidence rate ratio of hospitalizations.

Results: 731 individuals were surveyed. 94% were female, 79% black, 35% had a high school education or less, and 45% lived below the Federal poverty level. Mean ages at SLE diagnosis and survey completion were 32.8 and 46.6 years, respectively, with mean disease duration of 13.8 years (±9.3) at the time of survey completion. 35% had private insurance, 47% public insurance (Medicare and/or Medicaid), and 17% were uninsured. Baseline self-reported disease activity was mild, moderate, and severe in 26%, 23%, and 50% of participants, respectively. While 25% had no organ damage at baseline, 38% had mild and 37% had severe damage. 345 individuals were hospitalized during the 3-year study period. The overall unadjusted HR per 1000 person-years was 668 and the HRs were 806 and 559 for those who were and were not a DP, respectively (p=0.01). The ratio of HRs for those who were DPs relative to those who were not DPs was 1.33 (95% CI: 1.02-1.73, P=0.04) after adjusting for confounders. Ages 18-34 at baseline, public insurance enrollment, severe disease activity, severe organ damage, and being a DP were independent predictors of increased HRs.

Conclusion: In this population-based cohort, nearly half were hospitalized over the 3-year study period. Notably, gender, race, education and poverty were not associated with increased hospitalizations. Our data suggest organ damage may increase the risk of hospitalizations with a 33% increased rate in DPs. Individuals enrolled in Medicare and/or Medicaid had over double the rate of hospitalizations compared to those with private insurance. The reasons for increased hospitalization with public insurance are unclear and should be explored further.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It has long been known that mortality after years of systemic lupus erythematosus (SLE) is often associated with cardiovascular disease (CVD). Recent studies have also observed excess early CVD, even before SLE diagnosis. This is the first population-based study with large numbers of blacks to evaluate early vs. late CVD.

Methods: The Georgia Lupus Registry (GLR) is a population-based registry of SLE patients living in Atlanta, GA from 2002-04. Patients were validated by meeting ≥4 ACR criteria or 3 ACR criteria with a final diagnosis of SLE by a board certified rheumatologist and were matched to the Georgia Hospital Discharge Database, capturing all hospitalizations throughout the state from 2000 through 2013. CVD related hospitalizations (CVD-H) were identified based on the first 3 admission codes, which included ischemic heart, cerebrovascular, and peripheral vascular diseases. 2 periods were

evaluated. The “Early Period” was defined as the period prior to and within the first 2 years after diagnosis. The “Late Period” was defined as the period afterwards. Multivariable logistic regression analyses were performed to explore the independent effect of demographic and disease-related factors on CVD-H.

Results: 336 incident SLE patients had 34 CVD-H’s during the surveillance period 2000-2013, 16 as Early CVD (6 ischemic heart, 7 cerebrovascular, 3 peripheral vascular) and 18 as Late CVD (4 ischemic heart, 13 cerebrovascular, 1 other vascular). Characteristics of the Early Period were a mean age at SLE and CVD-H of 52.5 and 52.2, respectively. 81.3% were female and 81.3% black. There were less photosensitivity and more serositis, renal disorder, and neurologic disorder in CVD-H compared to other incident patients (data not shown). Multivariable regression analysis showed 30% increased odds of a CVD-H for every 5-year increase in age at SLE diagnosis and over 6-fold increase in odds with neurologic disorder. Characteristics of the Late Period were a mean age at SLE and CVD-H of 40.1 and 45.8, respectively. 100% were female and 94.4% black. There was more renal disorder in CVD-H compared to other incident patients (data not shown). Multivariable regression analysis showed reduced odds (0.22) of a CVD-H with serositis and a nearly 6-fold (5.71) increase in odds with renal disorder. Race was not a factor in either period.

Conclusion: In this population-based cohort, there were significant numbers of CVD events, with nearly equal numbers of CVD-H’s in the Early Period compared to the Late Period. Consistent with previous findings, the Early Period is marked by higher risk in those with late onset of disease. The Late Period had more cerebrovascular events. Other manifestations may help identify those at higher risk for CVD-H’s.

Multivariable logistic regression for the outcome of cardiovascular disease related hospitalizations

	Factor*	OR (95%CI)	P value
Early Period	Age at SLE diagnosis, per 5 years ↑	1.30 (1.11-1.52)	**0.0011**

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, definitions of both Remission and LLDAS have been proposed which include disease activity status and medication intake [immunosuppressive (IS) drugs and corticosteroids]. The aim of this study was to evaluate both on the outcome of SLE patients from a multinational, multi-ethnic Latin American cohort.

Methods: Interval was defined as the period between two SLEDAIs or between one SLEDAI and the end of the follow-up. Four disease activity statuses were defined: Remission off-therapy=SLEDAI=0 without prednisone or IS drugs; Remission on-therapy= SLEDAI=0 and a prednisone dose≤5mg/d and/or IS drugs in maintenance dose; LLDAS=SLEDAI≤4, a prednisone dose≤7.5mg/d and/or IS drugs in maintenance dose; and non-optimally controlled status= SLEDAI>4 and/or prednisone dose>7.5mg/d and/or IS drugs in induction dose. Antimalarials were allowed in all groups. Predefined outcomes were mortality, new damage [defined as an increase of at least 1 point in the SLICC/ACR damage index (SDI)] and severe new damage (defined as an increase of at least 3 points in the SDI). Univariable and multivariable Cox regression models adjusted for possible confounders were performed in order to define the impact of disease activity status, as time-dependent variable, on these outcomes.

Results: One thousand three hundred and fifty patients from this cohort, with at least two intervals, accounted for the 5672 intervals examined. Median length of the intervals was 7.1 months (interquartile rank 5.1-11.7). Median number of intervals per patients was 4 (2-7). The most frequent interval was non-optimally controlled (4446; 78.4%), followed by LLDAS (566; 10.0%), remission on-therapy (553; 9.7%) and remission off-therapy (107; 1.9%). Seventy-nine patients died during the follow-up, 606 presented new damage and 177 severe new damage. Because of the limited number of intervals in the off-therapy group, this group was combined with the on-therapy group. The impact of these disease activity statuses on the pre-specified outcomes is depicted in table 1. Of importance, in multivariable analyses, remission on/off therapy was associated with both, a lower risk of new damage (HR:0.52; 95%CI:0.37-0.72), and of severe new damage (HR:0.32; 95%CI:0.15-0.65); LLDAS was associated with a lower risk of severe new damage (HR:0.46; 95%CI:0.23-0.91). Although the HR were in the right direction for the mortality outcome, the confidence intervals were too wide, probably because of the relative low number of events in this category.

Conclusion: Remission on/off therapy diminished the risk of new and severe new damage, and LLDAS diminished the risk of severe new damage after adjusting for other well-known risk factors of damage.

Table 1: Impact of disease activity statuses on mortality, new damage and severe new damage. Univariable and multivariable analyses

Pulmonary Disease in Late Versus Early Systemic Lupus Erythematosus: A Systematic Review and Meta-Analysis

Jennifer Medlin[1], Karen Hansen[2], Sara McCoy[3] and Christie M. Bartels[4], [1]Internal Medicine, University of Wisconsin Hospitals and Clinics, Madison, WI, [2]Department of Medicine, Division of Rheumatology, University of Wisconsin School of Medicine and Public Health, Madison, WI, [3]Department of Medicine, Rheumatology Division, University of Wisconsin School of Medicine and Public Health, Madison, WI, [4]Medicine, Rheumatology, University of Wisconsin School of Medicine and Public Health, Madison, WI

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Phenotypes often differ in late-onset systemic lupus erythematosus (SLE) compared to SLE features in early-onset patients. Prior studies have suggested that there may be more pulmonary disease in the older onset population. This systematic review and meta-analysis evaluates the differences in pulmonary manifestations between late and early-onset SLE.

Methods: We searched the literature using PubMed, CINAHL, Web of Science and Cochrane Library. We excluded studies that did not include ACR SLE classification criteria, lacked early-onset controls, defined late-onset SLE as <50 years of age, or were not written in English. Two authors rated study quality using the Newcastle Ottawa Quality Scale. We used

random effects models to create Forest plots to compare odds ratios and 95% confidence intervals of pulmonary manifestations by onset age. We specifically assessed interstitial lung disease, serositis, pleuritis, pulmonary embolism, pulmonary hypertension, or a composite of any lung disease. We assessed heterogeneity using I^2.

Results: Thirty six studies, representing 10,504 early-onset and 1,529 late-onset patients with SLE, met eligibility criteria. The prevalence of pulmonary manifestations was higher in the late-onset group as shown in **Table 1**. Interstitial lung disease (ILD) was nearly three times as common (OR 2.56 (1.27, 5.16)) with low study heterogeneity (I^2 23%, p=0.23). Pleuritis (OR 1.53 (1.19, 1.96)) and serositis (OR 1.24 (1.03, 1.51)) were also more common in the late-onset group for which there was low to moderate heterogeneity (I^2 36%, p=0.07 and I^2 43%, p=0.005). The mean Newcastle Ottawa Quality Scale score for study quality was 6.9 ±0.7 (scale 0-9).

Conclusion: Pulmonary manifestations of SLE appear to be more common in late-onset SLE patients compared to their younger peers, particularly ILD. Age-related changes of the immune system, tobacco and antigen exposure history, race, and possible association with Sjogren's syndrome are possible contributors that should be examined in future studies.

Table 1: Meta-analysis summary statistics for pulmonary findings in late vs early-onset SLE

Pulmonary Manifestation	Total cases	Late-onset n=1529	Early-onset n=10504	OR (95% CI)	Heterogeneity I^2 (%), p

Analysis of Influences of Various Factors on the Prognosis of Acute Confusional State of Diffuse Psychiatric/Neuropsychological Syndromes in Systemic Lupus Erythematosus

Gakuro Abe[1], Yoshiyuki Arinuma[1], Hirotoshi Kikuchi[2] and **Shunsei Hirohata**[1], [1]Kitasato University School of Medicine, Sagamihara, Japan, [2]Department of Internal Medicine, Teikyo University School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Neuropsychiatric systemic lupus erythematosus (NPSLE), especially diffuse psychiatric/neuropsychological syndromes (diffuse NPSLE), is one of the most difficult complications of the disease. For the evaluation and the diagnosis of central nervous system manifestations, including NPSLE, MRI is a very useful tool to detect the various abnormalities. We previously disclosed that patients with diffuse NPSLE and MRI abnormalities have

more severe inflammation in the central nervous system compared with those without MRI abnormalities, as evidenced by poorer prognosis. Of note, acute confusional state (ACS) is the most recalcitrant manifestation in diffuse NPSLE. However, it remains unclear whether abnormalities in brain MRI still have any influences in patients with ACS. The aim of this study is to explore the influences of various factors, including brain MRI abnormalities, on the prognosis of patients with ACS.

Methods: Thirty-six patients with ACS admitted to our University Hospitals from 1992 to 2015 were exhaustively enrolled in this study. Their medical charts and brain MRI scans were reviewed. The influences of various factors on the mortality of the patients were analyzed.

Results: During the observation periods (33.7}85.4months, mean}SD), 8 of the 36 patients (22.2%) died. The causes of death were related with the disease activity of SLE, mainly NPSLE, in the 8 patients. All the fatal patients died within 8 months from the onset of ACS (3.00}2.97 months, mean}SD). Notably, all these 8 patients presented brain MRI abnormalities, whereas none of the 18 patients without MRI abnormalities died. Accordingly, the presence of brain MRI abnormalities significantly increased the mortality rate in patients with ACS. To explore in detail the effects of various factors, including MRI abnormalities, on the mortality of patients with ACS, further analysis was carried out using Cox proportional hazards model. As shown in Table, the presence of brain MRI abnormalities, the presence of serum anti-Sm antibodies and serum IL-6 levels significantly increased the risk for mortality in multivariate analysis.

Conclusion: These results demonstrate that patients with ACS of diffuse NPSLE with MRI abnormalities have more severe diseases, resulting in poorer prognoses. The data also indicate that serum anti-Sm antibodies and serum IL-6 are critical factors influencing the prognosis of patients with ACS. **Table**

Effects of various factors on the survival in patients with acute confusional state

	Univariate HR (95% CI)*	p	Multivariate HR (95% CI)*	p

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : Cardiovascular disease (CVD) remains a leading cause of death in SLE. Lupus patients have a 2-3 fold increased risk to develop heart failure compared with matched controls. Both traditional CVD risk factors and SLE itself play an important role in its development and associated excess deaths. Interest has emerged to study potential underlying mechanisms such as the presence of myocardial inflammation in attempts for early intervention when warranted. This study was initiated to evaluate the prevalence of myocardial inflammation in SLE using ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT), and the association of FDG uptake with disease characteristics in SLE patients without clinical CVD.

Methods: Patients <45 years old in the Columbia University Lupus Cohort without clinical evidence of CVD, history of antiphospholipid antibody syndrome, or cardiac related symptoms were invited to participate. All patients met the 1997 ACR SLE Classification criteria. Ten SLE patients underwent cardiac FDG-PET/CT imaging for evaluation of myocarditis by standardized methods. Demographics, SLE-specific characteristics, and CVD risk factors were ascertained. Coronary artery disease was evaluated by the Agatston coronary artery calcium score. The prevalence of myocarditis and its association with SLE-disease characteristics and conventional CVD risk factors was evaluated.

Results: Table 1 depicts the patient characteristics. The mean age was 33±7 years, 80% were female, 80% Hispanic and 20% were non-Hispanic Black. The median SLEDAI-2K and SLICC SDI scores were 2 (1-4) and 0 (0-0), respectively. Median SLE disease duration was 11 years (7-15). None of the patients had hypertension, diabetes, or smoked. Non-specific ST-T abnormalities were seen in 50% of the patients. The mean ejection fraction was 64±4%. Three of the ten patients (30%) had increased FDG myocardial uptake, with a diffuse pattern noted in all (Figure 1). No SLE-specific characteristics were associated with this outcome (Table 1).

Conclusion: This pilot study shows that myocarditis, identified by myocardial FDG-PET uptake, is prevalent in SLE patients without clinical CVD despite low disease activity. This supports the use of FDG-PET/CT imaging in the diagnosis of myocarditis in SLE and to further evaluate the prevalence of myocardial involvement in lupus. **Table 1.** Patient Characteristics and Cardiovascular diagnostic tests (n=10).

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) has a female to male ratio of 9:1. While SLE is more prevalent in females, males with SLE may have increased disease severity and mortality. Mechanisms for these outcomes are not known, as males are often understudied. We assessed differences in comorbidities in males vs. females by performing the first electronic health record (EHR)-based phenome-wide association study (PheWAS) in SLE. Similar to genome-wide

association studies, PheWAS compare two groups using ICD-9 codes in place of single nucleotide polymorphisms.

Methods: We used our validated algorithm of ≥ 4 counts of the SLE ICD-9 code (710.0) and ANA positive ≥ 1:160 while excluding dermatomyositis and systemic sclerosis ICD-9 codes to identify SLE cases in a de-identified EHR called the Synthetic Derivative (SD). The SD contains over 2.5 million subjects with clinical data collected longitudinally over several decades. Our algorithm has an internally validated positive predictive value of 94% and a sensitivity of 86%. PheWAS was performed in males vs. females adjusting for race and current age in logistic regression models and correcting for multiple testing using Bonferroni.

Results: We identified 986 females and 111 males with SLE. Males and females had similar mean current age, age at first SLE ICD-9 code, race breakdown, mean years of follow-up, and number of SLE code counts (Table 1). Adjusting for race and current age, males were more likely to have cardiac codes vs. females including atrial fibrillation odds ratio (OR) = 4.50 (95% CI 2.32 – 8.72), $p = 8.6 \times 10^{-6}$, other chronic ischemic heart disease OR = 4.40 (2.24 – 8.64), $p = 1.7 \times 10^{-5}$, atrial fibrillation and flutter OR = 4.08 (2.12 – 7.83), $p = 2.4 \times 10^{-5}$, and coronary atherosclerosis OR = 3.34 (95% CI 1.87 – 5.97), $p = 4.56 \times 10^{-5}$ (Figure 1). These four codes met the Bonferroni threshold for significance ($p < 1.26 \times 10^{-4}$). There were 51 SLE patients with the atrial fibrillation code, who were all confirmed on chart review. Males and females with atrial fibrillation had similar race breakdown, mean current age, and age at first SLE and atrial fibrillation codes.

Conclusion : These findings demonstrate the ability of PheWAS to uncover novel phenotype associations within a disease. While there is a 5-fold increased risk of cardiovascular disease overall in SLE, the increased relative risk of atrial fibrillation in males vs. females with SLE has not been identified. The odds of atrial fibrillation are two times higher in males in the general population; however, our data show a more pronounced sex difference in SLE patients.

Table 1.

Demographics	Males (n = 111)	Females (n = 986)	p value*
Current age, mean ± SD	52 ± 18	50 ± 17	p = 0.42
Age at first SLE ICD-9 code, mean ± SD	43 ± 18	40 ± 17	p = 0.08
Race/ethnicity (%)			
Caucasian	69%	69%	p = 0.32
African American	27%	26%	
Asian	4%	3%	
Hispanic	0%	2%	
Years of follow-up in the EHR, mean ± SD	8 ± 5	9 ± 5	p = 0.23
Number of counts of the SLE ICD-9 code (710.0), mean ± SD	17 ± 15	19 ± 22	p = 0.73

The Risk of Pulmonary Embolism and Deep Venous Thrombosis in Systemic Lupus Erythematosus: A Population-Based Study

April Jorge, Na Lu and Hyon Choi, Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Prior population-based studies have shown an increased risk for cardiovascular complications in patients with SLE. However, the magnitude of the risk for venous thromboembolism (VTE) has not been well quantified in this patient group, particularly within the general population context. Our objective was to determine the risk of venous thromboembolism (VTE), pulmonary embolism (PE), and deep vein thrombosis (DVT) in individuals with incident systemic lupus erythematosus (SLE) in the general population.

Methods: Using the Health Information Network (THIN) database, a population database that includes 11.1 million patients, 6.2% of the population of the United Kingdom, we conducted a cohort study of all patients with incident SLE and up to 10 age-, sex-, and entry time-matched individuals from the general population. SLE patients were identified by read codes for systemic involvement of lupus, excluding cutaneous-only disease. We compared incidence rates of PE, DVT, and VTE between the two groups and within the SLE group according to SLE disease duration. We calculated hazard ratios (HRs), adjusting for potential confounders including the comorbidities stroke, myocardial infarction, kidney disease, and

malignancy, the use of NSAIDs, aspirin, and glucocorticoids, and for smoking status.

Results: Among 1494 individuals with SLE (87.1% female, mean age 50 years), there were 13 cases of DVT and 14 of PE. Among the 10,473 individuals without SLE, there were 38 cases of DVT and 33 of PE. The incidence rates of PE, DVT, and VTE were 1.6, 1.4, and 2.9 per 1000 person-years in the SLE group, whereas the corresponding rates were 0.5, 0.6, and 1.1 per 1000 person-years among individuals without SLE. Compared with non-SLE individuals, the multivariable HRs among patients with SLE were 3.17 (95% CI, 1.65-6.10), 3.42 (95% CI, 1.72-6.81), and 3.14 (95% CI, 1.94-5.07) for PE, DVT and VTE, respectively. The age-, sex-, BMI-, and entry time-matched HRs for PE, DVT, and VTE were highest during the first year after SLE diagnosis: 14.30 (95% CI, 4.02-50.82), 8.70 (95% CI, 1.74-43.40), and 10.82 (95% CI, 3.91-29.90), respectively.

Conclusion: These findings provide population-based evidence that patients with SLE are at an increased risk of VTE, especially within the first year after SLE diagnosis. Increased monitoring for this potentially fatal outcome and its modifiable risk factors is warranted in this patient population, particularly early after disease onset.

Table 1. Age and sex adjusted risk for PE, DVT, or both (VTE) in SLE according to follow-up period.

Time after diagnosis	PE HR (95% CI)	DVT HR (95% CI)	VTE HR (95% CI)
1 year	11.24 (3.47-36.97)	11.48 (2.56-51.59)	10.44 (4.02-27.12)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, multisystem autoimmune disease characterized by recurrent flares. SLE patients are often treated with glucocorticoids, which place this population at risk of significant bone loss. Low bone mineral density (BMD) predisposes patients to fragility fractures, which may result in severe pain, disability and mortality. The aims of this study are: 1) To determine the prevalence of low bone density and symptomatic fragility fractures in inception patients of the Toronto Lupus Cohort (TLC). 2) To determine the factors associated with low BMD in SLE inception patients.

Methods: Prospectively collected data from the TLC (1996-2015) of inception patients' first BMD were analyzed. For pre-menopausal women/males <50 years, BMD 'below expected range for age' was defined by a Z-score ≤2.0 S.D. For post-menopausal women/males age 50 or older, osteoporosis was defined by a T-score ≤-2.5 S.D and low bone mass by a T-score between -1.0 and -2.5 S.D. Patients' BMDs were defined as abnormal if their Z-score was ≤-2.0 or T-score was <-1.0 S.D, and the remainder as normal. Descriptive analysis and logistic regression were employed to determine factors associated with abnormal BMD.

Results: Of 1807 patients in the TLC, 286 are inception patients with BMD results (mean age 37.9 years ± 13.7); 88.8% are female. The mean duration from SLE diagnosis to time of first BMD is 2.20 ± 2.57 years. The overall prevalence of abnormal BMD is 31.5%. In pre-menopausal women (n=173), the prevalence of BMD below expected range is 17.3%. In post-menopausal women (n=81), the prevalence of osteoporosis and low BMD are 12.3% and 43.2%, respectively. In males <50 years (n=22), the prevalence of BMD below expected range was 27.3%. In males age 50 or older, (n=10), the prevalence of osteoporosis and low BMD were 10% and 80%, respectively. In multivariate analysis, age at first BMD remained statistically significantly associated with abnormal BMD (44.72 ± 17.14 years), with an OR of 1.06 (p<0.0001). Cumulative dose of glucocorticoids up to the date of BMD was also significantly associated with abnormal BMD (11.55 grams/day ± 10.99), with an OR of 1.04 (p=0.009) (Table 1). Of 769 inception patients, 85 (11.1%) experienced symptomatic fragility fractures over the course of their disease.

Conclusion: The prevalence of low BMD is high in SLE patients. Abnormal BMD is associated with older age and higher cumulative glucocorticoid dose. Identifying factors associated with low BMD is important in the development of preventative measures.

Table 1: Variables Associated with Abnormal BMD in 286 SLE Patients

Variables	Abnormal BMD n=90	Normal BMD n=196	Univariate OR* | p value	Multivariate OR* | p value
Age**	44.72 ± 17.14	34.89 ± 10.55	1.06 (1.03, 1.08) | <.0001	1.06 (1.04, 1.08) | <.0001
Female sex	75 (83.3%)	179 (91.3%)	0.47(0.23, 1.00) | 0.05	
Cumulative ACR criteria**	4.49 ± 1.02	4.73 ± 1.10	0.80 (0.63, 1.02) | 0.08	
SDI excluding osteoporosis**	0.85 ± 1.23	0.46 ± 0.88	1.43 (1.12, 1.82) | 0.004	
Treatment with vitamin D**	58 (64.4%)	103 (52.6%)	1.63 (0.94, 2.80) | 0.08	
Treatment with calcium**	58 (64.4%)	103 (52.6%)	1.63 (0.94, 2.80) | 0.08	
Treatment with bisphosphonates**	16 (17.8%)	22 (11.2%)	1.72 (0.85, 3.47) | 0.13	
Treatment with immunosuppressives***	58 (64.4%)	107 (54.6%)	1.51 (0.90, 2.52) | 0.12	
Cumulative dose of glucocorticoids**	11.55 ± 10.99	10.14 ± 8.40	1.03 (1.00, 1.05) | 0.06	1.04(1.01, 1.07) | 0.009

*95% CI in parentheses **Up to time of first BMD ***Immunosuppressives include: azathioprine, methotrexate, cyclophosphamide, mycophenolate mofetil, cyclosporine

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Certain traditional and disease-related factors have been identified to accelerate atherosclerosis in systemic lupus erythematosus (SLE). Due to the lack of long-term prospective studies, the evolution over time and relative importance of these variables in the development of atherosclerotic cardiovascular events (CVEs) is not known. We aimed to determine the evolution of CVE risk factors over 15 years,

Methods: 250 female lupus patients (mean age at enrollment 44.5±12 years, mean disease duration 13.7±9.7 years) and 250 age-matched healthy women (mean age 44.1±14 years) were recruited between 1998 and 2000. All subjects had similarly low (3.2%) 10-year Framingham Risk Score (FRS) Variables assessed at study entry included family history of premature for coronary artery disease (CAD). CAD, hypertension, diabetes, dyslipidemia (total cholesterol, triglycerides, LDL, VLDL, HDL, lipoprotein a), smoking, physical activity, body mass index (BMI), menstrual status, use of oral contraceptives or hormone replacement therapy, serum creatinine, homocysteine and C-reactive protein. For lupus patients, SLEDAI-2K and the 3-year adjusted mean SLEDAI (AMS) (1998-2000 and 2005-2007) were calculated to quantify global disease activity. Additional parameters included antiphospholipid antibodies; information on antimalarials, prednisone and immunosuppressants were also collected. Subjects were followed for 15 years for the development of CVEs [angina, myocardial infarction (fatal, non-fatal), transient ischemic attack, stroke (fatal, non-fatal)]. Analysis was performed with SAS 9.3 software for 2000-2007 and 2008-2015; $p<0.05$ was considered significant.

Results: SLE patients had consistently higher rates of CVEs, the difference becoming greater with longer follow up ($p=0.0001$). CVEs occurred in 41/210 patients (19.5%) and 8/138 controls (5.8%), mostly in the second part (2008-2015) (24/41, 58.5% vs. 17/41, 41.5% in patients, 4 CVEs in each part in controls). Coronary artery disease was more common in SLE (32/210, 15.2% vs. 5/138, 3.6%, $p=0.0041$). There was no significant difference for cerebrovascular disease (10/210, 4.8% vs. 3/138, 2.2%, $p=0.213$). SLE [HR=2.8, 95% CI 1.3-6.3], older age and triglycerides>2.8mmol/L were predictive of CAD in the early phase. In the late phase, hypertension, diabetes, dyslipidemia and high BMI were more prominent in patients who suffered a CVE. Time-adjusted disease activity (AMS) was lower in those late phase patients; however their cumulative prednisone dose between 2000-2007 was significantly higher. Of note, 60% of the new hypertension and all new diabetes cases were attributed to glucocoricoids. Thirty-one deaths occurred in patients (10 due to CVEs) and 6 in controls (none due to CVEs); all CVE-related deaths occurred between 2008 and 2015.

Conclusion: SLE patients had a 4-fold increased risk for CVEs and all-cause mortality as compared to healthy controls after 15 years. Disease-related factors dominate cardiovascular risk during the early stages while traditional factors, partially related to corticosteroid treatment, play a significant role later in disease course.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Decreased heart rate variability (HRV) is a sign of potentially serious cardiac morbidity and is known to reflect autonomic dysfunction and inflammatory dysregulation (1). We have previously reported a cross-sectional association as well as association of changes between disease activity and HRV in patients with systemic lupus erythematosus (SLE) (2). We have not however yet demonstrated a predictable temporal relationship over time between SLE disease activity and HRV in individual patients.

Methods: To prospectively test the hypothesis that clinical improvement is reflected by increased HRV, we designed an ongoing clinical trial to include HRV measurements using a 5 min ECG and HRV parameters calculated in the time domain (RMSSD and pNN50) and frequency domain [high frequency (HF) and the low frequency to high frequency (LF/HF) ratio]. Here we report findings from 32 SLE patients (31 female, age 46.2 +/- 10.9) who have completed a minimum of 2 visits to date. A mixed effects linear model was used to compare the change in HRV parameters between 83 paired visits. Two groups were compared, those with clinical improvement between visits (group 1) and those with same or worse disease activity (group 2). Clinical improvement was defined as >/= 1 letter grade improvement in BILAG between visits with no new BILAG A or B scores.

Results: There was improvement in 14 (17%) of the paired, consecutive visits and no improvement or worsening in 69 (83%) visits. An inverse relationship was observed between clinical improvement and change in RMSSD, change in pNN50 and % change in HF (Table 1). The LF/HF ratio increased significantly between visits of patients in group 1 and decreased between visits in group 2 (4.51±1.95% vs. -0.14±0.83%, respectively; p=0.031).

Conclusion: HRV changes reflect changes in clinical status over time in patients with SLE. These data suggest that HRV may be a simple non-invasive tool for tracking clinical improvement and underscore the role of the autonomic nervous

system in inflammatory pathways. **Table 1.**

Variable	Group 1 visits (n=14)	Group 2 visits (n=69)	P-value
Delta RMSSD (ms)	-87.6±39.4	7.1±17.7	0.027
Delta pNN50 (ms)	-3.18±2.03	0.02±0.92	0.15
Delta HF (%)	-27.0±8.4	-5.7±3.6	0.022
Delta LF/HF (%)	4.51±1.95	-0.14±0.83	0.031

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Many neurologic and neurodegenerative abnormalities are first demonstrable in the olfactory system with loss of smell up to 10 years before the onset of cognitive or motor dysfunction. The aim of this follow-up study was to assess the prevalence and progression of olfactory disorder in SLE compared with healthy controls, to correlate with presence of neuropsychiatric manifestations, disease activity, presence of Anti-P and limbic structure volume reduction during 3 years follow-up.

Methods: Consecutive SLE patients were enrolled in this study. The control group was consisted by age and sex matched healthy individuals. Neurological manifestations were analyzed according to the ACR criteria. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity (SLEDAI), and damage (SDI). Anti-P was performed by ELISA. Olfactory functions were evaluated using the Sniffin' Sticks test, in 3 stages (TDI). We measure the

volumes of the amygdala and hippocampus by MRI scans 3T Phillips scanner. Volumes were processed using FreeSurfer® software. Clinical, laboratory evaluation, the volumes of the amygdala (AG) and hippocampus (HC), olfactory functions and Anti-P was performed every year for 3 year for each patients. $p<0.05$ was considered significant.

Results: We included 83 SLE patients (91.5% female; mean age 39.6 years; SD±11.1 years) and 60 healthy volunteers (90.1% female; mean age 38.6 years; SD±13.3 years) ($p>0.05$). Olfactory changes were observed in 44 (53.0%) SLE patients and in 18 (30.0%) controls ($p=0.001$). SLE patients had significantly lower mean in all three phases (TDI) of the olfactory assessment [mean of 29.04 (SD ± 5.13)] when compared with healthy volunteers [mean of 31.35 (SD ± 4.24)] ($p=0.004$) and decrease in the sense of smell was correlated with age ($p=0.002$; $r= -0.331$), anxiety ($p=0.008$; $r= -0.291$), depression ($p= 0.005$; $r= -0.308$) and index damage ($p= 0.018$; $r= -0.268$). We also observed an association between olfactory changes and SDI ($p=0.049$), photosensitivity ($p=0.038$) and leukopenia ($p=0.002$). Not significant decrease of smell was observed in the follow-up ($p>0.05$). Limbic structure volume reduction were not associated with olfactory changes ($p>0.05$).We did not observed significant decrease in the limbic structures volume between patients [median mm^3: AG 3500.61; HC 7831.64] and controls [AG 3350.62 ($p=0.272$); HC 7391.65 ($p=0.234$)]. The decrease of the limbic volumes in patients was not significant in the follow-up [median AG volume mm^3: T_1 3500.61 ($p=0.16$); T_2 3508.94 ($p=0.12$); and T_3 3461.01 ($p=0.19$)] [median HC volume mm^3: T_1 7831.64 ($p=0.32$); T_2 7680.85 ($p=0.23$); and $T_3$7911.19 ($p=0.27$)]. Anti-P were identified exclusively in SLE patients and were present in 14 (10.8%) of them in the first assessment and remained positive in the two following annual assessments ($p<0.001$). Anti-P was associated with decrease left amygdala volume in the second assessment (T_2) ($p=0.016$) and not associated with decrease of smell ($p=0.390$), CNS involvement ($p= 0.713$) or psychosis ($p= 0.076$).

Conclusion: Smell deficiency has been suggested to be an early and predictive sign in several CNS diseases, and therefore, might be a useful and easy tool for the physician in early diagnosis of CNS involvement in autoimmune disease.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The risk of Herpes Virus infections, both Varicella Zoster virus (VZV) and Herpes simplex virus (HSV), is not known in Systemic Lupus Erythematosus (SLE). This study was initiated to establish the prevalence of HSV

& VZV infections in hospitalized SLE patients.

Methods: This is a retrospective cohort study evaluating the prevalence of VZV and HSV in SLE patients hospitalized at Columbia University Medical Center-New York Presbyterian Hospital. Data from electronic medical records (EMR) were obtained from the Columbia University Medical Center (CUMC) Clinical Data Warehouse between January 2000 and September 2014. A total of 2,013 hospitalized patients were identified in the Data Warehouse as having SLE using a validated method. Patients were classified as having SLE based on the International Classification of Diseases, Ninth Revision (ICD-9) codes, using 2 or more SLE ICD-9 code (710.0 and/or 695.4) or at least 1 SLE ICD-9 code and a nephritis (582 or 583 and subtypes); this method has a positive predictive value for SLE of 0.88. Herpetic zoster infections were identified using ICD-9 code 053 (and subtypes) on discharge diagnosis. Herpes simplex infections were identified using ICD-9 code 054 (and subtypes) on discharge diagnosis.

Results: Of the 2,013 hospitalized SLE patients; there were 59 cases of varicella zoster and 129 cases of herpes simplex. Of the 59 patients with VZV, 28 had complicated zoster infection. Of these cases, 12 patients had CNS zoster, 6 patients had ophthalmic zoster, and 10 patients had disseminated zoster. There was one death from disseminated zoster. Of the 129 HSV cases, one patient had HSV meningitis, 5 patients had ophthalmic HSV infection, 56 patients with oral and/or genital ulcers, and 67 patients had unspecified HSV infections as a discharge diagnosis. Based on these data the prevalence of varicella zoster in SLE was 2.93% and HSV was 6.41%; with a 9.34% overall prevalence of herpetic infections.

Conclusion: The risk of herpetic infections in SLE is 9.34% in a cohort of hospitalized SLE patients with one death from disseminated zoster. Our data suggest that HSV/VZV is not uncommon in SLE and mortality from complicated VZV is high. SLE patients admitted with a vesicular rash or meningeal symptoms should be evaluated for VZV and have a low threshold for initiating anti-viral treatment. The data is insufficient to substantiate the recommendation for prophylactic use of antiviral treatment in SLE except for high-risk patients with recurrent infections. However, we believe the data presented here further substantiates the need for VZV vaccination in SLE patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The annual accrual of comorbidities in patients with SLE is not well described. We report the annual occurrence of these features in an inception cohort of patients with SLE.

Methods: An international research network comprised of 33 centres from 11 countries has followed an inception cohort of SLE patients yearly according to a standardized protocol between 2000 and 2016. Of these, 717 patients followed for a minimum of 8 years constitute the study population. Comorbidities including atherosclerotic vascular events (AVEs), osteoporosis, osteonecrosis and diabetes are assessed using the SLICC/ACR Damage Index (SLICC/DI). AVEs are described and attributed on a specialized form. Diagnosis of an event is confirmed using standard clinical criteria, relevant laboratory data and imaging where appropriate. Attribution to atherosclerosis is made on the basis of lupus disease being inactive at the time of the event, and/or the presence of typical atherosclerosis (AS) changes on imaging or pathology and/or evidence of AS elsewhere. Diagnosis of osteoporosis is based on abnormal bone mineral density and osteonecrosis was based on joint symptoms associated with abnormal imaging consistent with osteonecrosis. Diabetes diagnosis is based on therapy, regardless of treatment type. Descriptive statistics were used.

Results: Of the 717 patients followed for at least 8 years, 90.2% were female, 47.3% were Caucasian, 13.8% were Black, 19.4% were Asian, 16.3% Hispanic and 3.2% other. Their mean age at enrolment was 34.2±13.1 years and SLEDAI-2K at enrolment was 4.17±4.49. The duration from diagnosis to enrolment was 5.9±4.4 months. Table 1. Cumulative SDI, AVEs, Osteoporosis, Osteonecrosis and Diabetes in the first 8 Years of Follow-up (n=717)

Follow-up	SDI (mean±std)	AVE	Osteoporosis	Osteonecrosis	Diabetes
1	0.3±0.7	4 (0.5%)	3 (0.4)	3 (0.4%)	13 (1.8%)
2	0.5±1.0	5 (0.7%)	5 (0.7%)	10 (1.4%)	17 (2.4%)
3	0.6±1.2	10 (1.4%)	7 (1.0%)	15 (2.1%)	17 (2.4%)
4	0.7±1.2	13 (1.8%)	10 (1.4%)	18 (2.5%)	19 (2.7%)
5	0.8±1.3	18 (2.5%)	11 (1.5%)	21 (2.9%)	19 (2.7%)

AVE Caucasian (%)	0.59	0.88	2.06	2.95	3.54	4.13	4.42	5.60
AVE Other (%)	0.53	0.53	0.79	0.79	1.59	1.59	1.59	1.59
Osteoporosis Caucasians (%)	0.00	0.59	1.18	1.77	2.06	3.25	3.55	4.14
Osteoporosis Others (%)	0.79	0.79	0.79	1.06	1.06	1.06	1.32	1.32
Osteonecrosis Caucasians (%)	0.59	1.18	1.18	1.47	1.47	2.07	2.07	2.66
Osteonecrosis Others (%)	0.26	1.59	2.91	3.44	4.23	4.76	5.29	5.82
Diabetes Caucasian (%)	1.77	2.65	2.65	2.95	2.95	2.96	2.96	3.25
Diabetes Other (%)	1.85	2.12	2.12	2.38	2.38	2.91	3.17	3.70

Mean SDI gradually increases over 8 years. The accumulation of AVEs, osteoporosis, osteonecrosis and diabetes all increase progressively over an 8-year period. Caucasians accumulate AVEs and osteoporosis more frequently than all "other" ethnicities. In contrast, all "other" ethnicities accumulate osteonecrosis more frequently than Caucasians. All ethnicities accumulate diabetes at the same frequency.

Conclusion: As expected disease damage and comorbidities in newly diagnosed patients increase over their first 8 years. Different ethnicities accumulate comorbidities at different rates

Loss of Elbow Hyperextension in Females with Early Rheumatologic Disease Was Common in Systemic Lupus Erythematosus and Rheumatoid Arthritis but Rare in Fibromyalgia

John P. Case[1], Heidi Tucker[2] and Congbin Wang[3], [1]Internal Medicine/Rheumatology, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, [2]Rush Medical College, Chicago, IL, [3]Internal medicine, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The elbow extension angle (ELB) is commonly given as 180o although most healthy females exhibit hyperextension(1). The loss of hyperextension (LOH) in a female is the earliest sign of elbow arthritis(2) and can be regarded as evidence of organic disease. Therefore, diseases commonly involving the elbow, such as rheumatoid arthritis (RA) or systemic lupus erythematosus (SLE) might be associated with LOH whilst diseases such as osteoarthritis (OA), which does not alone affect the elbow, or fibromyalgia (FM), a non-organic disorder, would be expected to maintain normal ELB. A trained clinician can estimate the ELB accurately(3). One of us (Case) has been recording the ELB as neutral, hyperextended, or contracted in female patients at the time of 1st rheumatologic contact. To test the hypothesis that ELB may be used as a diagnostic tool in early arthritis we reviewed the scanned electronic medical record at our institution for the period January 1, 2003 – December 31, 2007.

Methods: All outpatient female patients were eligible. The primary rheumatologic diagnosis at the time of last follow-up was used. The ACR disease criteria available during the study period were observed. All study patients with RA and SLE met criteria; FM patients were included if they exhibited diffuse pain with multiple diffuse tender points (not necessarily 11 of 18). The Mann-Whitney U test was used to distinguish disease subgroups, and Spearman's correlation to compare age and duration of disease with LOH. Statistics were done with SPSS.

Results: The charts from 717 patients were available. Of these, 396 had the initial ELB recorded (55%). (Most of the remainder had exclusively lower extremity-directed exams; data not shown.) 106 of these had disease onset of less than one year. They had a mean age of 51.0 (SD 14.1) years and were followed for a mean of 2.1 (SD 3.0) years. The final diagnoses were RA in 31 (29.2%), OA in 20 (18.9%), SLE in 7 (6.6%), FM in 14 (13.2%), other in 34 (32.1%). FM could be distinguished from RA ($p=0.005$) and SLE ($p=0.04$) but not from OA ($p=0.062$). RA could not be distinguished from SLE ($p=0.874$). Only one in 14 FM patients evidenced LOH. These findings are expressed in the Figure. Among the 396 patients with disease of any duration, RA could be distinguished from OA ($p<0.0001$) and FM ($p<0.0001$); FM, however, could not be distinguished from SLE ($p=0.316$). An observed LOH in FM was correlated with duration of disease ($p<0.0001$) but not with age ($p=0.280$).

Conclusion: The hypothesis that early LOH was associated with RA and SLE but not with FM was confirmed. Early FM rarely had LOH whereas RA and SLE commonly did. Measurement of the ELB is potentially a new diagnostic sign in the rheumatologic exam. References:

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To study the clinical characteristics and outcomes of Systemic Lupus Erythematosus (SLE) patients that underwent cardiac surgery.

Methods: Retrospective analysis of 30 SLE patients (ACR classification criteria), who underwent cardiac surgery at a single center. Demographics, comorbidities, clinical, serologic characteristics, cardiovascular risk scores and treatment were recorded. Type of surgery, postoperative complications, mortality and histology were analyzed. **Statistics:** Differences between groups were evaluated with the Student t test or Mann-Whitney U test (continuous variables); chi-square or FisherÕs exact test (categorical variables). Odds ratios (OR) and 95% confidence intervals are presented.

Results: Disease duration at surgery was 2 years. Valve replacement was the most frequent procedure in 16 (53%), followed by pericardial window in 11 (37%). Indications for pericardial window were cardiac tamponade and recurrent pericarditis. **Tables 1** and **2** summarize characteristics of SLE at cardiac surgery. At least one postoperative complication was present in 63% (mainly infections). An aortic cross-clamp time > 76 minutes was associated with at least one postoperative complication (OR 6.4, 95% CI 1.1-35.4, p=0.03). Main valvular histopathological findings in the patients that underwent valve replacement were: myxoid degeneration (n=5), fibrosis (n=5), Libman-Sacks endocarditis (n=3), endocarditis (n=3). Early death occurred in 5 patients (17%) and late in 3 (10%); main causes were sepsis and heart failure. Patients with active disease were associated with pericardial window (OR 12.6, 95% CI 1.9-79, p=0.007); lymphopenia < 1200 (OR 10.1, 95% CI 1.05-97, p=0.04); age < 30 years (OR 7.7, 95% CI 1.2-46.3, p=0.02), NYHA class III (OR 7.0, 95% CI 1.1-42, p=0.03). Patients with postoperative infections were associated with length of hospital stay > 2 weeks (OR 54.9, 95% CI 5.0-602.1, p=0.001); days in ICU > 10 (OR 20, 95% CI 1.6-171.7, p=0.01); duration of mechanical ventilation > 5 days (OR 16.9, 95% CI 1.6-171.7, p=0.01), pulmonary artery systolic pressure > 50 mmHg (OR 7.8, 95% CI 1.4-41.2, p=0.01).

Conclusion: Cardiac surgery in SLE confers high morbidity and mortality. SLE-specific preoperative risk scores should be designed to identify prognostic factors. **Table 1**

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Young woman with lupus (SLE) are at increased risk of early atherosclerosis leading to cardiovascular disease in adult life and consequently higher morbidity and mortality. Recently, it has been demonstrated that visceral adipose tissue (VAT) is associated with increased incidence of metabolic risk in subclinical atherosclerosis beyond its contribution to overall adiposity. Nowadays, a new application of dual-energy X-ray absorptiometry (DXA) is to measure VAT in the android region of a whole body site with high accuracy and strong correlation with computed tomography (CT) to quantify visceral fat. Thus, the objective of this study was assess alterations of visceral adipose tissue (VAT) measured by DXA in juvenile female SLE (JoSLE) patients compared with age-matched healthy controls and evaluate its correlation with disease parameters and treatment.

Methods: Fifty-six JoSLE female patients were evaluated and compared with age-matched female healthy controls. Demographic and anthropometric, disease duration, disease activity score (SLEDAI), cumulative organ damage (SLICC-DI/ACR), glucocorticoid (GC) use and hydroxychloroquine use were recorded by interview and eletronic chart review. Visceral adipose tissue (VAT) was analyzed by dual-energy X-ray absortiometry (DXA, Hologic - using a specific software - APEX 4.0).

Results: SLE patients had mean disease duration of 5.71 ± 3.98 years, mean current prednisone dose of 15.99 ± 18.62 mg/day and cumulative glucocorticoid dose of 6.79 ± 7.13 g, mean SLEDAI of 4.60 ± 5.54 in the last year and eleven (19.6%) patients had SLICC-DI/ACR higher than one. SLE patients and controls were similar regarding age (18.4 ± 3.2 vs. 18.6 ± 3.8 yrs, p=0.808), weight (57.4 ± 10.8 vs. 56.8 ± 9.3 kg, p=0.752), BMI (23.1 ± 3.6 vs. 22.3 ± 3.2 kg/m², p=0.205) and lean mass (36.19 ± 6.60 vs. 36.81 ± 4.24 kg, p=0.420). JoSLE patients presented higher levels of fat mass compared to healthy controls (19.26 ± 6.60 vs. 17.86 ± 6.22 kg, p=0.017), as well as % fat (32.93 ± 6.35 vs. 30.82 ± 5.72 %, p=0.004). Furthermore, SLE patients had higher values of VAT parameters than controls, namely VAT mass (280.55 ± 132.42 vs. 199.60 ± 98.67 g, p<0.001), VAT area (58.19 ± 27.47 vs. 41.41 ± 20.50 cm², p<0.001) and VAT volume (303.36 ± 143.19 vs. 215.78 ± 106.66 cm^3, p<0.001). In SLE patients, VAT volume correlated with disease duration (r=0.313; p=0.019) and SLICC-DI/ACR (r=0.300; p=0.025) but not with SLEDAI (p=0.907), current use of GC (p=0.449), cumulative use of GC

(p=0.346) or hydroxychloroquine use (p=0.385).

Conclusion: JoSLE patients showed higher levels of VAT parameters compared to healthy controls. Its correlation with higher cumulative organ damage index and disease duration could suggest that VAT can be useful to evaluate cardiovascular risk in this group of patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The heterogeneity of SLE in terms of disease characteristics is an issue not only for the diagnostic process but also for disease management. Previously, a SLEDAI score ≥10, herein termed the High Disease Activity State (HDAS), has been shown to predict treatment response to belimumab. Whether HDAS could provide other prognostic information on outcomes is less well understood.

Methods: Using data collected prospectively between 2007 and 2015 from 211 SLE patients, who fulfilled either ACR (97.2%) or only SLICC (2.8%) classification criteria and were seen at a tertiary SLE clinic for ≥1 year, we examined the association of sociodemographic and disease characteristics with ever experiencing HDAS during the observed period. We also investigated the association of ever experiencing HDAS with longitudinal SLE outcomes, including adjusted mean SLEDAI (AMS), flare incidence according to SLE Flare Index, and damage accrual according to the SLICC/ACR Damage Index for SLE. For multivariable analyses of longitudinal outcomes, associations were adjusted for observation time, and the association with AMS was also adjusted for cumulative prednisolone dose.

Results: Patients were observed for a median of 4.5 years (range: 1 – 7.9 years); 42.7% experienced HDAS at least once during the observation period. Among those who experienced HDAS, 31.1% experienced a single episode of HDAS, 33.3% experienced 2 – 3 episodes and the remainder experienced between 4 – 30 episodes of HDAS. The median time to first HDAS was 9 months after enrolment (range 0 – 6.7 years). Females patients diagnosed at ≥45 years had substantially lower odds of ever experiencing HDAS (Odds Ratio, OR: 0.3, 95% Confidence Interval, 95% CI: 0.1 – 0.5; p=0.003). When compared to patients never experiencing HDAS, patients experiencing at least 1 episode of HDAS were more likely to have anti-dsDNA autoantibodies (OR: 5.6, 95%CI: 2.8 – 11.3; p<0.001), have a positive direct antiglobulin test (OR: 2.7, 95%CI: 1.3 – 5.3; p = 0.006) or present with hypocomplementemia (OR: 2.3, 95% CI: 1.3 – 4.0; p=0.005). Patients who experienced at least one episode of HDAS had significantly greater odds of having AMS in the highest quartile (AMS ≥4.3: OR: 10.8, 95%CI: 4.3 - 27.2; p<0.001). Similarly, they were also more likely to experience a greater number of mild/moderate and severe flares during the observation period (number of mild/moderate flares ≥5: OR: 8.0, 95% CI: 3.1 –

21.1; p<0.001; number of severe flares ≥3: OR: 16.7, 95%CI: 4.8 - 57.6; p<0.001). HDAS was associated with substantially greater odds of experiencing neuropsychiatric, renal and vasculitis disease activity (OR>10, p≤0.001 for all) and of accruing new damage (OR: 2.6, 95% CI: 1.4 - 4.7; p=0.002) during the observation period.

Conclusion: Patients who ever experience HDAS represent a distinct clinical cohort with worse longitudinal disease outcomes. The occurrence of HDAS can serve as a prognostic indicator applicable to a heterogeneous lupus population.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) patients have increased risk of advanced atherosclerosis and cardiovascular disease. The mechanism of premature atherosclerosis in SLE is not completely understood, and systemic inflammation representing disease activity and traditional risk factors such as overweight and dyslipidemia have been regarded to contribute. Many SLE patients have low disease activity or sporadic occurrence of mild symptoms after a period of vigorous manifestations derived from autoimmune activation. It has not been evaluated whether SLE patients with mild activity have a risk of atherosclerosis progression, while it's a common situation which many SLE patients are undergoing. Previously we evaluated subclinical atherosclerosis of SLE patients with mild disease activity by Doppler ultrasound 4 years ago. This time we checked them again and assessed which features affects their changes.

Methods: We assessed carotid artery intima-media thickness (cIMT) and carotid plaque by Doppler ultrasonography among sixty-one female SLE patients who were enrolled in the previous work 4 years ago, and analyzed the changes with clinical characteristics.

Results: The SLE disease activity index of the participants was 4.2 ± 3.9, and $25(OH)D_3$ level was elevated than previous study (25.7 ± 6.9 vs 12.7 ± 8.6 ng/mL, $p < 0.001$), while other features were similar. The mean cIMT of SLE patients was 0.39 ± 0.09 mm and 11 patients had carotid plaques, which were not significantly different with previous study. Twenty one patients had the increased cIMT, while 35 patients had decreased cIMT. And new carotid plaque was developed in 7 SLE patients, while the carotid plaque of 10 SLE patients was resolved. The patients with increased cIMT had lower body mass index (BMI) (19.8 ± 1.8 vs 21.7 ± 3.1 kg/m^2, $p = 0.007$), longer disease duration (102.0 ± 42.2 vs 74.8 ± 55.2 months, $p = 0.006$) and higher total steroid dose (18.5 ± 21.6 vs 10.5 ± 22.9 g, $p < 0.001$) compared with those not. The patients having new carotid plaque had lower high-density lipoprotein (HDL) cholesterol levels (41.6 ± 10.2 vs 55.6 ± 15.5 mg/dL, $p = 0.024$) and were taking higher doses of current steroid (8.9 ± 9.5 vs 3.6 ± 4.5mg, $p = 0.008$). On multiple regression analysis, BMI (0.62 [0.42 – 0.91], $p = 0.01$) and HDL cholesterol (0.94 [0.89 – 1.0], $p = 0.02$) were revealed to affect

cIMT increment, and current steroid dose (1.14 [1.01 – 1.28], p = 0.04) were revealed to affect plaque development.

Conclusion: BMI have been known to affect atherosclerosis and vitamin D deficiency has been known to associate with cardiovascular disease. In contrast of other studies, our data showed BMI contributed negatively cIMT increment. The result about BMI was regarded that very low BMI might have a harmful effect to atherosclerosis, considered that mean BMI was much lower (21.0 ± 2.8 kg/m^2) than other studies.[4] The follow up study for SLE patients with low disease activity showed low BMI and HDL cholesterol might be a risk factor for subclinical atherosclerosis and current steroid dose could be associated with plaque development.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Observational studies have indicated a high but heterogeneous prevalence of low bone mineral density (BMD) and vertebral fractures (FV) in patients with systemic lupus erythematosus (SLE). The aim of this meta-analysis was to evaluate the relationship of SLE and BMD, osteoporosis and vertebral fracture risk.

Methods: A systematic review and meta-regression analysis were performed following the Preferred Reporting Items for Systematic Meta- Analyses (PRISMA) guidelines. Articles were identified from electronic databases (PubMed, Embase, VHL, SciELO and the Cochrane Library). The search was conducted using MesH terms, Boolean operators and keywords, which included "systemic lupus erythematosus", "osteoporosis", "bone mineral density" and "vertebral fractures". Prospective longitudinal and cross-sectional studies were considered for review without language restrictions. Articles were screened for suitability and those selected were evaluated by two investigators who extracted information on study characteristics, outcomes of interest, risk of bias and summarized strength of evidence. Data was extracted where studies met inclusion criteria and were of sufficient quality. BMD reported as the mean ± standard deviation evaluated by dual-energy X-ray absorptiometry (DXA) was analyzed including information of SLE cases and controls, treatment, menopausal status and fractures through a meta-regression analysis adjusted by anatomical region. Data were analyzed using the Metafor package in R (3.0.2 version).

Results: In total 54 articles were identified and analyzed (12593 SLE cases/six anatomical regions and 14235 controls/six

anatomical regions). SLE women had less BMD than healthy controls (p< 0,0001), however, in SLE men this difference was absent when they were compared to controls. When only SLE patients were analyzed, the BMD measurements were not statistically different between those with a background of corticosteroid (CTS) therapy and those without CTS therapy. Not surprisingly, postmenopausal SLE patients had lower BMD (lumbar spine and total hip) compared to premenopausal patients (p< 0,0001). The BMD was not different between patients with and without fractures.

Conclusion: This systematic review and meta-regression depicts that women with SLE had higher risk of low BMD than healthy controls. These data did not show that CTS therapy had an impact on BMD.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been well acknowledged that both genetic and environmental factors are important in the pathogenesis of systemic lupus erythematosus (SLE). To elucidate the environmental factors associated with SLE pathogenesis, we investigated the seasonal differences in the disease onset and the exacerbation of SLE.

Methods: In the present study, we retrospectively reviewed the medical records of 122 patients with SLE (88.5% female and the average age of 43 years) fulfilling the 1997 revised ACR classification criteria. The mean observation period was 7.2 years. The disease exacerbation was defined as either a new appearance of clinical manifestations of SLE or the clinical condition requiring the start or dose increment of glucocorticoids by at least 50%.

Results: The disease onset was the most frequently observed in Spring (31.0%) and the least in Fall (16.1%). A total of 167 disease exacerbations were observed among 879 patient-years, and more interestingly, the disease exacerbation was significantly more frequently observed in Spring (38.3%) and significantly less frequently observed in Fall (10.8%) as compared with other seasons. It should be noted that the both disease onset (0.0%) and exacerbation (2.4%) of SLE were the least in September. Disease manifestation at the exacerbation was similar throughout the seasons, and 60.0% of the disease exacerbation did not accompany serological activity defined by the increase in anti-DNA antibody or the decrease in complement activity.

Conclusion: Concordant seasonal differences between the disease onset and the exacerbation implicated the crucial role of environmental factors in the pathogenesis of SLE, possibly through the activation of innate immune systems.

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Non-traumatic osteonecrosis (ON) is a well-recognized complication in systemic lupus erythematosus (SLE). The reported symptomatic ON prevalence is 10-15% and as high as 44% when including asymptomatic lesions. ON causes disability and affects quality of life (QoL). Bones collapse from ON has serious clinical implications and may lead to severe joint damage requiring total joint arthroplasty (TJA). The aim of this study was to identify specific risk factors for ON in SLE patients, in order to better guide monitoring of this debilitating complication.

Methods:

A systematic review was conducted using MEDLINE, PUBMED and EMBASE, searching to February 2015 using the MeSH terms “Osteonecrosis”, “Systemic lupus erythematosus” and synonymous text words. Randomized controlled trials (RCT), case control, cohort and cross sectional studies reporting at least one risk factor for ON were included. Risk factors for ON in SLE patients were compiled. The quality of evidence of each risk factor was assessed using the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) method. The quality of each study was assessed using the Newcastle-Ottawa scale (NOS).

Results:

Of the 536 references yielded, 28 met inclusion criteria. In the literature, the major risk factor associated with ON remains

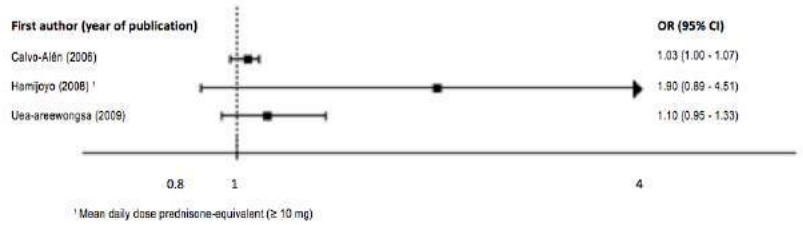
the use of corticosteroids (CS). ON is much more prevalent in SLE than in other systemic conditions requiring the use of CS, suggesting that the use of CS is not the only factor. Multiple other clinical variables were evaluated in studies, including disease activity, arthritis, neuropsychiatric SLE, Raynaud's phenomenon, vasculitis, serositis, gastrointestinal involvement, hypertension, oral ulcers, renal disease, alopecia, antiphospholipid antibodies, antimalarials and immunosuppressive agents. However, for those other risk factors, the research evidence was weak and the association between these variables and the development of ON was controversial (see forest plots).

Conclusion:

Based on the best evidence available, CS use is the only modifiable risk factor clearly associated with ON in SLE patients. Physicians should maintain a high index of suspicion for ON in SLE patients, especially with any history of CS exposure. We suggest adopting a preventive strategy with a judicious use of CS.

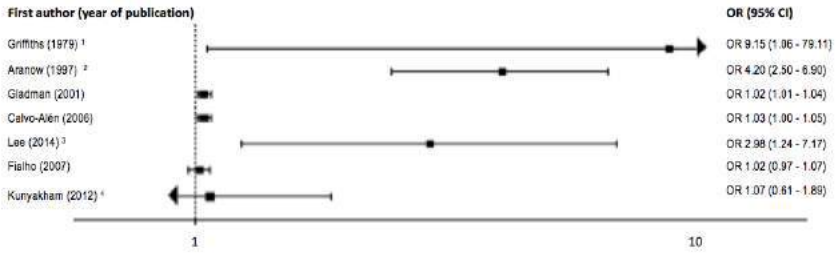
A. Corticosteroids

Mean daily dose of CS



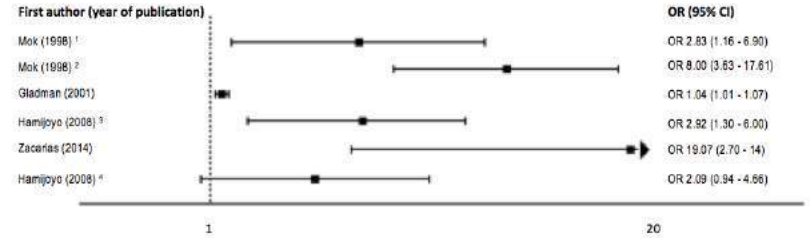
[1] Mean daily dose prednisone-equivalent (≥ 10 mg)

Highest dose of CS



[1] Prednisolone >10 mg/day
[2] Dose over the preceding 5 years of at least 30mg/day
[3] High-dose steroid therapy:>30 mg, but<100 mg of prednisone equivalent per day
[4] High-dose steroid therapy was defined as a steroid dosage equivalent to prednisolone > 30 mg/day at any time during follow-up

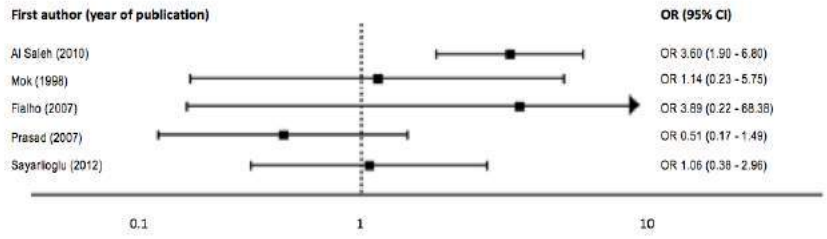
Total cumulative CS dose



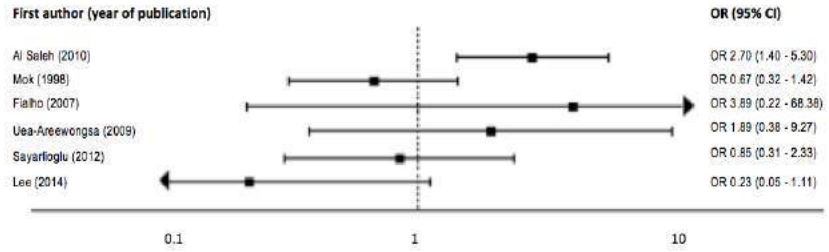
[1]Total cumulative prednisone dose in 1 month > 1.8g
[2]Total cumulative prednisone dose in 4 months > 4g
[3] Mean total cumulative prednisone-equivalent dose ≥ 23.4 g
[4] Mean cumulative prednisone-equivalent dose in first month ≥ 1.37 g

B. Antiphospholipid antibodies

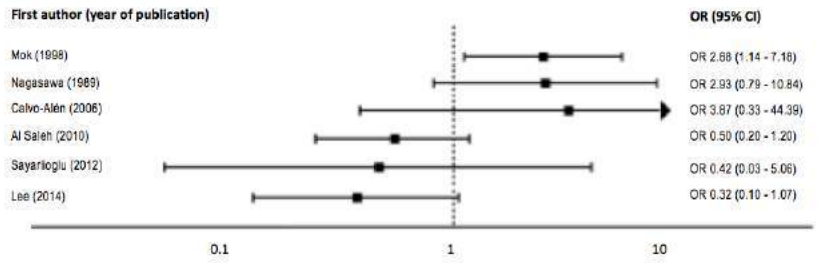
Anti-cardiolipin antibodies IgM



Anti-cardiolipin antibodies IgG



Lupus anticoagulant



C. Medication

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking is a risk factor for systemic lupus erythematosus and in particular for discoid lupus. A recent study, suggested that history of smoking was associated with antiphospholipid antibodies. We investigated the association between smoking and antiphospholipid antibodies in systemic lupus erythematosus as well as the relationship between smoking, antiphospholipid antibodies, and vascular events.

Methods: 2406 patients in a prospective SLE cohort had smoking assessed at baseline (ever, current, never). The lupus anticoagulant was assessed by dRVVT with mixing studies and confirmatory tests. Anticardiolipin and anti-beta2 glycoprotein 1 were measured by ELISA (INOVA). Vascular events were defined as stroke, myocardial infarction, digital gangrene, and deep vein thrombosis.

Results: Table 1 shows the frequency of each antiphospholipid antibody by smoking status. Table 2 shows the association of smoking with thrombotic events among patients with antiphospholipid antibodies. Unadjusted p-values and p-values adjusted for ethnicity are given. Table 1: Association between Smoking and Antiphospholipid Antibodies

	LAC (RVVT)	Anticardiolipin	Anti-beta2 glycoprotein
Ever smoking	245 (28.7%)	411 (48.1%)	149 (30%)
Past smoking	145 (29.3%)	246 (49.8%)	103 (32.4%)
Current smoking	97 (27.6%)	165 (46.6%)	46 (26.3%)
Never smoking	373 (25.3%)	721 (48.9%)	271 (28.6%)
P Value (Ever vs. Never)	0.0734	0.6943	0.5635
P Value (Past vs. Never)	0.0802	0.734	0.1986
P Value (Current vs. Never)	0.3818	0.4361	0.5346
adj. P Value (Ever vs. Never)	0.0933	0.6434	0.6169
adj. P Value (Past vs. Never)	0.1146	0.8189	0.2484
adj. P Value (Current vs. Never)	0.3893	0.4017	0.5779

Table 2: Association between smoking and thrombosis in SLE patients with antiphospholipid antibodies

	Stroke	Myocardial Infarction	Digital Gangrene	DVT
Ever smoking	29 (3.3%)	60 (6.8%)	19 (2.2%)	121 (13.7%)
Past smoking	19 (3.8%)	34 (6.7%)	13 (2.6%)	72 (14.2%)
Current smoking	10 (2.8%)	26 (7.1%)	6 (1.6%)	47 (12.8%)
Never smoking	55 (3.7%)	49 (3.2%)	26 (1.7%)	200 (13.2%)
P Value (Ever vs.Never)	0.6901	0.0001	0.4359	0.6891
P Value (Past vs.Never)	0.9033	0.0008	0.2288	0.5611
P Value (Current vs.Never)	0.4239	0.0009	0.9246	0.8721
adj. P Value (Ever vs.Never)	0.5787	0.0001	0.5037	0.8909
adj. P Value (Past vs.Never)	0.9203	0.0010	0.2349	0.6928
adj. P Value (Current vs.Never)	0.3944	0.0012	0.8303	0.6906

Conclusion: There was no statistically significant association between past or current smoking and antiphospholipid

antibodies in our lupus cohort. Current smokers had a slightly lower frequency of lupus anticoagulant and anti-beta2 glycoprotein 1 than past smokers. Among SLE patients with antiphospholipid antibodies, smoking was associated with myocardial infarction ($p<0.01$), but not with stroke, digital gangrene or venous thrombosis.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus patients are at increased risk for cardiovascular disease (CVD). Chou et al. (Ann Inter Med 2011) found that resting ECG abnormalities, in particular ECG 4-elements (ECG-4), were associated with subsequent CVD events in the general population.

ECG-4 included the following elements: **1)** ST-segment and/or T-wave abnormalities; **2)** left ventricular hypertrophy (LVH); **3)** left axis deviation (LAD) and left anterior fascicular block (LAFB); and **4)** left bundle branch block (LBBB) and right bundle branch block (RBBB). However, ECG-4 did not include Q-wave and we have established **ECG-5** elements which included Q-wave in addition to the elements of ECG-4.

We aimed to determine the prevalence of ECG-4 and ECG-5 in an SLE cohort and to examine the factors associated with ECG-4 and -5.

Methods: A standard digitally recorded 12-lead resting supine ECG was performed on consecutive patients attending the Lupus Clinic between 2012- 2015. A senior cardiologist interpreted coded ECGs using the Minnesota code classification system. Patients with ECG-4 and -5 were compared to those with normal ECG by t-test and chi-squared test Univariate and multivariate Cox regression models and time-dependent multivariate cox regression models were built to assess the associations between the covariates and ECG-4 and -5.

Descriptive analyses of patients' demographics, disease activity and damage, and antibodies abnormalities were studied in ECG-4 and -5. For the analysis we used the clinical/laboratory data available at the date of ECG.

Results: Of 487 patients, 104 (21.4%) and 118 (24.2%) patients had one or more of the ECG-4 and ECG-5 elements respectively**.** A higher prevalence ECG-4 and -5 was identified among older SLE patients and patients with longer SLE disease duration (Table1). The burden of ECG-4 and ECG-5 elements increased with age. In the univariate analyses, patients with ECG-4 and -5 were older, had a longer lupus disease duration, more active SLE disease (Adjusted Mean SLEDAI-2K 2 years prior to ECG), higher SDI and higher cumulative dose of glucocorticoids compared to patients with normal ECG. The multivariate analyses showed that ECG-4 and -5 were associated with older age and higher SLE disease

activity while treatment of hyperlipidemia was protective (Table 2).

Conclusion: We described a novel approach using 5 ECG elements to identify SLE patients at increased risk for CVD events. A high prevalence of ECG-5 (24.2%) was found in this SLE cohort. Controlling SLE disease activity is important since it was associated with ECG-5. Early identification of ECG-5 in SLE patients might allow for better stratification and risk management.

Clinical Implications of Persistent Sinus Tachycardia in Systemic Lupus Erythematous: A Retrospective Study

Santosh Bhusal[1], Bassam Alhaddad[2], Douglas Einstadter[3] and Stanley Ballou[1], [1]Rheumatology, Case Western Reserve University/MetroHealth Medical Center, Cleveland, OH, [2]Rheumatology, Premier Physicians, Westlake OH, Cleveland, OH, [3]Medicine, Case Western Reserve University/MetroHealth Medical Center, Cleveland, OH

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Resting Sinus Tachycardia (ST) is found in approximately 50 % of patients with SLE. Unexplained episodes of intermittent ST could be a manifestation of disease activity. Approximately 13-15 % of patients, however, continue to have unexplained ST that persists beyond the duration of disease flare. The significance of this finding is still under investigation, but may be associated with physical deconditioning, higher SLEDAI scores or occult serositis. We conducted a retrospective study to further elucidate its clinical significance.

Methods: SLE was defined as patients fulfilling SLICC 2012 criteria. Persistent ST was defined as unexplained resting heart rate > 90 bpm in > 50 % of all outpatient visits; a minimum of 8 outpatient visits were required such that transient episodes of tachycardia were excluded. Also excluded were tachycardia episodes with potential explanation e.g. acute illness, severe pain, fever, acute anemia, hyperthyroidism, pregnancy and history of cardiac arrhythmias. A retrospective chart review was performed in patients with a diagnosis of SLE between January 2000 and December 2015. Patients meeting SLICC 2012 criteria and > 8 outpatient visits were dichotomized into groups with or without persistent ST. Multiple variables were compared: demographics; individual components of SLICC 2012 criteria at the first and the latest follow-up; laboratory tests including ENA, APL, ESR/CRP, anemia and nephritis class; pulmonary, cardiac and renal components of SLICC damage index; comorbidities including APS, hypertension, hyperlipidemia and history of deep vein thrombosis; and, hydroxychloroquine, angiotensin converting enzyme inhibitor and beta blocker use. Fisher's exact test was used and two sided p value < 0.05 considered significant.

Results: Charts of 375 patients were reviewed. 106 met inclusion criteria. 17 (16%) had persistent ST. At the time of statistical analysis, complete data was available in 16 patients with persistent ST and 61 patients without. The mean duration of follow up was 6.4 and 7.3 years respectively. Persistent ST was found to be associated with the following in univariate analysis: serositis at presentation (44% vs 14% P 0.017), proteinuria > 500 mg/24 hour at the latest follow up (63% vs 33% P 0.044) and anti-histone antibodies (75% vs 42% P 0.026). Quantitative analysis of maximal proteinuria revealed an association of persistent ST with any proteinuria > 500 mg/24 hr (63% vs 31% P 0.02) as well as nephrotic proteinuria > 3 gm/24 hr (44% vs 18% P 0.045). In addition, class 5 nephritis was more common (25% vs 5% P 0.031) in this group. Other variables trending towards significance include: active urinary sediment/> 5 RBCs/hpf at latest follow up (50% vs 23% P 0.059), anti-DNA antibodies (75% vs 46% P 0.0504) and APS (25% vs 8% P 0.08).

Conclusion: Unexplained persistent ST could be a meaningful clinical sign in SLE. Early in natural history, this may imply the presence of incipient serositis while later on, of an ongoing proteinuric renal disease. A novel finding of high prevalence of anti-histone antibodies in this subgroup needs further scrutiny to discern its significance.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematous (SLE) is a clinically variable autoimmune disease occurring predominantly in women of childbearing age. SLE treatment can range from close clinical monitoring to potent systemic immunosuppressive therapy. CMV is a common, endemic virus endemic that half of the United States population has been exposed to. Patients on immunosuppressive medications are at higher risk for complications from CMV, and published case reports describe significant morbidity and mortality SLE patients with active CMV infections.. Despite the potential for increased risk of CMV infection while immunosuppressed, no studies to date have examined CMV seropositivity and positive viral load prevalence in SLE patients and it is not the standard of care to test for CMV. Robust exist data from the transplant population, a group exposed to similar immunosuppression but not in SLE.

Methods: We recruited participants from The Ohio State University's Lupus Clinic who were. >18 years with confirmed SLE diagnosis. We collected demographic information, laboratory data, SLE history, current medications, and serum CMV immunoglobulin G (IgG) antibody titer. If CMV IgG antibody titer was positive, a CMV polymerase chain reaction (PCR) viral load was measured.

Results: Baseline characteristics of the 75 SLE patients are summarized in **Table 1**. Of the enrolled subjects, 66% had a positive CMV IgG titer, but the viral CMV load has been undetectable for all tested participants (**Table 2)**.

Conclusion: Among the 75 SLE patients tested, CMV IgG seropositivity is 66%, which is comparable to the general population. Among the SLE patients with positive CMV IgG antibodies, none had evidence of active CMV infection by CMV viral load, including patients on immunosuppressive medications. These results differ greatly from the similarly immunosuppressed post-transplant population where 20-60% of patients have acquired acute CMV infections defined by positive viral load. These results suggest that CMV status does not need to be routinely checked in the SLE population unless specifically clinically indicated. **Table 1: Participant Characteristics**

	% (n)or Mean (n)
Age, mean (no.)	39.5 (75)
African American, % (no.)	38.7 %(75)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anemia in systemic lupus erythematosus (SLE) might have various etiologies; however, autoimmune hemolytic anemia (AIHA) is the characteristic hematologic feature. AIHA might be primary or have other etiologies as well. We evaluated the demographic, clinical features and prognosis of SLE patients with AIHA. In addition, their features and prognosis were compared to AIHA patients who were admitted to the Hematology Department of our institution.

Methods: Data about SLE patients with AIHA were obtained from patients' medical records. The diagnosis of SLE was based on 1997 revised ACR criteria. SLE patients with and without AIHA were compared to each other. In addition, medical records of patients with AIHA being followed up at the Hematology Department were screened for their clinical features and outcome.

Results: We included 333 SLE patients (307 females, 26 males, mean age: 37.7±12.4 years). AIHA was diagnosed in 20 patients (6%). Male SLE patients had more frequent AIHA than females (15.4% vs. 4.6%, p=0.04). Coombs test positivity was present in 60 patients (18%). Coombs positivity tended to be more frequent in male SLE patients (30.8% vs. 16.9%, p=0.1). SLE patients with AIHA had more frequent active disease (SLEDAI>4) (75% vs. 42.2%, p=0.006), accompanying thrombocytopenia (45% vs. 14.4%, p=0.003), renal involvement (50% vs. 28.5%, p=0.05), anti-dsDNA positivity (65% vs. 47.6%, p=0.12) and hypocomplementemia (70% vs. 33%, p=0.002). Contrarily, photosensitivity (40% vs. 69.5%, p=0.01) and arthritis (40% vs. 78.7%, p=0.001) were significantly less frequent in SLE patients with AIHA. Fortytwo patients (11.5%) had Coombs positivity without AIHA. Coombs (+) SLE patients had less frequent photosensitivity (53.3% vs. 71.1%, p=0.01); however, more frequent pleural involvement (25% vs. 14.3%, p=0.04), leucopenia (55% vs. 37.3%, p=0.01), lymphopenia (75% vs. 59.8%, p=0.03), anti-dsDNA positivity (70% vs. 44%, p=0.001), anti-ribozomal P positivity (11.9% vs. 4.5%, p=0.05), renal involvement (51.7% vs. 24.7%, p=0.001) and hypocomplementemia (67.3% vs. 27.7%,p=0.001). Two patients presented with AIHA during pregnancy. Survival of SLE patients with and without AIHA were not found to be different. When clinical features of fortyone AIHA patients (27 female, 14 male, mean age: 61.1±18 vs 35.4±10.5) diagnosed at the Hematology Department were compared to SLE patients with AIHA, the former group was significantly older (p<0.001). Being female (85% vs. 65.9%, p=0.1) and relapses (20% vs. 9.8%, p=0.2) tended to be more frequent in the SLE group. SLE patients with AIHA and other AIHAs had similar survival.

Conclusion: AIHA was diagnosed in 6% of our SLE patients. AIHA was more frequent in males and seemed to be associated with active disease, renal involvement, and anti-dsDNA positivity. SLE patients with AIHA were significantly younger than AIHA patients being follwed up at the Hematology Department.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is detected in 0.5-17.5% of patients with systemic lupus erythematosus (SLE). Systemic inflammation may play a dominant role in its development, particularly in the early phases of PAH. Aim of this study was to describe the characteristics of PAH in a defined lupus cohort.

Methods: We identified patients who had been diagnosed with PAH, defined as right ventricular systolic pressure

(RVSP)>40mmHg on at least two separate transthoracic echocardiograms (TTE) using our database of a long term longitudinal prospective cohort study of SLE patients. Patients' charts were hand-searched based on a pre-established protocol to derive PAH cause and symptoms at presentation. Variables including demographics, associated clinical and immunological features, PAH-targeted and systemic treatment as well as survival were retrieved from the database.

Results: Fifty-one patients (47 females) were diagnosed with PAH since clinic inception. SLE was the sole cause (SLE-PAH) in 42 (82.4%) whereas other causes were identified in 9 (17.6%). Mean age of the SLE-PAH patients was 31.2±11.2 years at lupus onset and 38.7±12.3 years at PAH diagnosis. PAH was diagnosed within the first year of SLE in 13 (31%) cases. Main indications for TTE were unexplained dyspnea in 33 patients (78.6%), chest pain in 15 (35.7%), dry cough in 17 (40.5%) and syncope in 3 (7.1%). Mean initial RVSP was 59.2±17mmHg. Right heart catheterization (RHC) was performed in 15 patients [mean systolic pulmonary artery pressure (PAP)=62.7±24.7mmHg, diastolic PAP=25.4±9.4mmHg, mean PAP=39.4±14.8mmHg, pulmonary capillary wedge pressure=9.1±4.7mmHg, pulmonary vascular resistance=901±508 dynes-sec-cm^{-5}]. Upon PAH diagnosis, there was no other lupus clinical manifestation in 11 patients (26.2%, 8/11 had active serology which was concordant with PAH over time). Thirty-one (73.8%) had active involvement of other organs (4 central nervous system, 8 kidneys, 4 heart, 3 lung, 7 vasculitis, 8 musculoskeletal, 17 mucocutaneous and 1 catastrophic antiphospholipid syndrome). Active serology (low complement and/or increased anti-dsDNA titers) was detected in 28 (66.7%) patients, while 29 (69%) had positive anti-RNP, 10 (23.8%) lupus anticoagulant and 13 (31%) anticardiolipin antibodies. Immunosuppressive therapy was administered in 28 patients and was succesful in 24 (85.7%) with a mean RVSP reduction of 17.7±7.3mmHg (from 63.7±19.1 to 44.1±14mmHg) in 6.1±3.1 months. Induction treatment consisted of prednisone (mean initial dose 41.6±16mg/d) in all patients, methylprednisolone pulses in 8, cyclophosphamide pulses in 4 and other immunosuppressants in 12 (8 mycophenolate, 4 azathioprine). PAH-targeted therapy was administered to 5/28 patients (11 in total, 6 phosphodiesterase-5 inhibitors, 7 bosentan, 1 epoprostenol) and was discontinued in two due to PAP normalization. Two-year and 5-year survival was 95.2% and 90.5% respectively.

Conclusion: SLE-PAH was usually diagnosed early in disease course and accompanied by other clinical and serological lupus manifestations. Aggressive immunosuppressive therapy was succesful in the majority of cases.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by disease flares, alternated with periods of clinical remission. In the past years, the "treat-to-target" strategy in SLE patients has been proposed, in order to reach complete remission and prevent long-term damage accrual and mortality. Data regarding demographic, clinical and serological factors associated with complete remission have been discordant and not fully addressed, which represents the aim of the present study.

Methods: A retrospective cohort study was performed. We included patients with SLE according to the ACR classification criteria who entered to our institution between January 2003 and December 2007, with a follow-up of at least 8 years from the time of severe activity (SLE Disease Activity Index-2000 [SLEDAI-2K] ≥ 6). Moreover, severe SLE manifestations not included in the SLEDAI-2K (hemolytic anemia, myelitis, mononeuritis multiplex, myocarditis and diffuse alveolar hemorrhage) were recorded. We studied relevant demographic, clinical and serologic factors at the beginning, at the 3rd, 6th and 12th month, and at the end of the follow-up. We defined "complete remission" as SLEDAI-2K = 0 during at least one year without any immunosuppressive treatment; prednisone 1-5 mg/day and antimalarials were allowed. Flares were defined according to the Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLEDAI criteria. Differences between groups were assessed by Student's T test. Chi square test was used and RR was calculated along with 95% CI. Multivariate analysis was performed.

Results: 114 patients fulfilled our inclusion criteria: 107 (93.85%) were women with a mean age of 30.21±8.3 years and a follow-up period of 117.9±3.14 months. 24 patients (21.05%) achieved complete remission and 5 (4.38%) achieved prolonged remission (≥ 5 years in complete remission). After univariate analysis, the following variables were associated with complete remission: SLEDAI-2K at 3rd month of follow-up (3.09 vs 8.27, p<0.001), total number of disease flares (2.20 vs 4.48, p<0.001), initial urine protein/creatinine ratio (0.47 vs 2.26, p<0.001), proliferative nephritis (RR=0.116 CI 95% 0.016-0.826, p=0.004), lymphopenia at the end (RR=0.440 CI 95% 0.221-0.873, p=0.031) and low C3 at the beginning of the follow-up (RR=0.36 CI 95% 0.167-0.772, p=0.01), treatment with azathioprine (RR=0.353 CI 95% 0.175-0.714, p=0.018) and mycophenolic acid (RR=0.072 CI 95% 0.010-0.513, p<0.001), and articular activity (RR=2.471 CI 95% 1.151-5.305, p=0.021). The variables that remained associated with complete remission after multivariate analysis were SLEDAI-2K at 3rd month of follow-up (RR=0.851 CI 95% 0.737-0.984, p=0.029) and total number of disease flares (RR=0.735, CI 95% 0.563-0.959, p=0.024).

Conclusion: Twenty-one percent of our patients achieved a complete remission. SLEDAI-2K at 3rd month of follow-up and total number of disease flares over the patients' disease course were independently associated with complete remission. Our findings are clinically relevant to encourage an aggressive immunosuppressive treatment and close monitoring at early stages of the disease.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess adherence to treatment in patients with Systemic Lupus Erythematosus (SLE) and to determine its relationship with social, educational levels and disease activity.

Methods: Prospective cross-sectional study. We included consecutive SLE patients (ACR 1997 criteria), over 18 years old , between April and July 2014, receiving at least one specific drug for the disease. Socioeconomic and educational status (education level, years of effective education, social coverage, and socioeconomic status according Graffar scale) - demographic variables (age and sex), related to the disease (time of evolution, current medication and polypharmacy), were studied. To assess adherence to oral medication CQR self-questionnaire was used, and Morisky Green for hydroxychloroquine, steroids and other immunosuppressants (methotrexate, azathioprine, mycophenolate mofetil, cyclophosphamide). Adherence to parenteral medication (cyclophosphamide, methotrexate, rituximab and belimumab) it was made through direct observation. We excluded patients with severe visual impairment and / or previous neurocognitive impairment that could not complete those self-questionnaires. Statistical analysis: Descriptive statistics. Chi-square test and Fisher test, Pearson/Spearman correlation coefficient test and logistic regression model was used.

Results: One hundred and ten patients were includes, 91% female, mean age 37 (± 12.5) years, mean duration of disease of 9.9 (± 7.8) years, mean SLEDAI and SLICC was 2.07 (± 3.3) and 0.9 (± 1.5) respectively. Effective education years were 11.4 (± 4.1) and only one patient was unlearned. Fourty percent of patients were unemployed at the time of the study; 55% had public social coverage but providing medication to 100%; 57% of patients had lower socioeconomic level (50% mid to lower and 7% lower), and certificate of disability from their disease. Eighty percent of patients were receiving hydroxychloroquine, 65% steroids and 20% MMF as immunosuppressant oral more used; 86% of patients were polymedicated. Adherence to treatment, assessed by MG was good for most patients (57% to hydroxychloroquine, 63% to steroids and 56% to other immunosuppressants, respectively). The main cause of lack of adherence to medication was forgetfulness of taking them (24%); 63% of patients had good overall adherence assessed by CQR. Patients with less education level had lower adherence to receive hydroxychloroquine ($p \leq 0.0001$). Polypharmacy patients had lower adherence to oral steroids ($p \leq 0.02$). Adherence to treatment was not associated with age, duration of disease, SELENA SLEDAI, SLICC DI, socioeconomic status or occupation.

Conclusion: Global adherence to treatment in lupus patients was good, evaluated by MG and CQR. Lower educational level was associated with lower adherence to treatment with hydroxychloroquine. Polypharmacy patients had lower adherence to use of oral steroids. Lack of adherence to treatment was not associated with age, duration of SLE, SELENA SLEDAI, SLICC DI, socioeconomic status, or occupation.

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In the era of powerful immunosuppression, opportunistic infections are an increasing concern in Systemic Lupus Erythematosus (SLE). A potentially fatal opportunistic demyelinating disease of the central nervous system, progressive multifocal leukoencephalopathy (PML), results from infection of oligodendrocytes by John Cunningham Virus (JC virus). Reactivation of the latent JC virus was recently described in SLE patients; the incidence of PML was estimated at 4/100,000 SLE discharges. This study was initiated to evaluate the prevalence of PML in adult and pediatric SLE patients at two large academic centers, with a focus on validating PML and SLE diagnoses with clinical information obtained from corresponding medical records, in order to better define the risk of PML in SLE.

Methods: This is a retrospective cohort study evaluating the prevalence of PML in two large academic centers. Patients with SLE were identified using the validated method of either an International Classification of Diseases, Ninth Revision (ICD-9) code of 710.0 or 695.4. All patients with SLE admitted to Columbia University Medical Center (CUMC) between 1986 and 2013 using electronic medical record data (EMR) from the Clinical Data Warehouse, or at Northwell Health (NWH) between 2013 and 2016, were included. Patients with Rheumatoid Arthritis (RA), identified by ICD-9 code 714, were evaluated as the disease control group. Among the case and control groups, cases of PML were identified using ICD-9 code of 046.3. Medication exposure was evaluated in the SLE patients.

Results: A total of 5409 individual SLE patients admitted to CUMC from 1983 to 2013 and 1788 SLE patients admitted to NWH from 2013 to 2016 were identified. Of these 6847 SLE patients, 3 patients also had an ICD-9 diagnosis code of 046.3 for PML. Upon review of the EMR, the diagnosis of PML was substantiated for one patient; the second patient was evaluated for PML but had CSF negative for JC virus and was treated for CNS lupus. EMR admission data could not be retrieved for the third patient and the diagnosis could not be confirmed. None of the 10,776 patients admitted for RA at CUMC had PML. Out of the 5409 SLE patients at CUMC, 212 were also renal transplant recipients and 83 had concomitant HIV/AIDS. Based on inpatient pharmacy records of the 5409 hospitalized SLE patients at CUMC, 59.2% were treated with steroids and 16.09% with immunosuppressants (7.76% mycophenolate, 3.42% cyclophosphamide, 2.88% azathioprine and 2.03% rituximab). Of note, none of the patients with PML had juvenile SLE (jSLE). At CUMC, the prevalence of PML in hospitalized patients is between 1.8-3.7 per 10,000 discharges and 0 at NWH. Based on these data, the combined prevalence of PML in hospitalized SLE patients at the two hospitals is between 1 and 2 per 7,197 admitted patients=1.4-2.8/10,000.

Conclusion: The prevalence of PML in adult SLE patients is less than 3/10,000 patients; PML has not yet been documented in jSLE. These data do not substantiate the need for JC virus screening in SLE patients prior to initiation of immunosuppression. Additionally, our experience emphasizes the need for thorough review of the data obtained from EMR.

Frequency and Factors Associated with Thirty Day Hospital Readmissions Among Systemic Lupus Erythematosus Patients in a Community Hospital in

the California Central Valley

Candice Yuvienco[1], Ololade Oladimeji[2], Ashenafi Legesse[2] and Paul Mills[2], [1]Internal Medicine, Division of Rheumatology, University of California San Francisco, Fresno Medical Education Program, Fresno, CA, [2]Internal Medicine, University of California San Francisco, Fresno Medical Education Program, Fresno, CA

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune condition which has one of the highest rates of hospital readmissions in the United States. There is scant data on the factors affecting early readmissions of SLE patients. One study on SLE patients found a 30-day readmission rate of 17%. Our study was undertaken to identify factors and predictors associated with early (thirty-day) hospital readmissions in patients with SLE in our hospital Community Regional Medical Center (CRMC) in Fresno, California.

Methods: Our study was a retrospective cohort study, which was approved by the IRB. Using hospital discharge database from CRMC, we identified SLE patients by ICD-9-CM diagnosis code 710.0 who had a hospitalization during timeframe January 2010 to May 2015. We evaluated each hospitalization as a possible index event leading up to a readmission. Early readmission was defined as readmission to the hospital within 30 days of previous hospital discharge date. SLE patients who had met criteria for early readmission comprised the Study Group, while SLE patients without early readmission formed the Control Group. Collected variables include patient demographics, type of insurance, laboratory values, use of immunosuppressive medications, teaching service status, rheumatology consultation and diagnoses upon admission and readmission. Diagnoses data collected were classified and analyzed as either Infection or Non-infection. Descriptive analysis was done, and Chi-square test of association (SPSS software) was used to find significant relationships among several variables.

Results: Of the 968 SLE patients identified between Jan. 2010 and May 2015, 539 of them (56%) were hospitalized at least once. Of the 539 patients, 100 (18%) met criteria for the study group with early readmission; 97 closely matched hospitalized patients without early readmission were the control group. All these patients included in the study and control groups met the 1997 Update of the 1982 American College of Rheumatology Revised Criteria for Classification of SLE. Regarding immunosuppressive medications, we found that SLE patients who were on steroids during index hospitalization were less likely to be readmitted within 30 days, $p = 0.027$. We also found that patients who had ever received Cellcept were likely to have early readmission, $p = 0.033$. Patients with diagnosis of infection at the index visit did not have a higher likelihood of early readmission, $p = 0.298$. There was a significant difference in the mean creatinine values between the study group (2.26) and the control group (1.45) $p = 0.044$. No other significant differences were observed for age, gender, length of stay, platelet count, hemoglobin, or lymphocyte counts. Insurance type was not significantly associated to likelihood of readmission, $p = 0.535$. However, it is important to note that the large majority of the insurances for both study and control groups were Medicare/Medical. Early readmission was not significantly associated with the other following variables: use of Imuran, Methotrexate, Plaquenil, disposition at discharge (home/nursing home), Rheumatology consultation, or type of service (teaching or nonteaching). Likelihood of early readmission and the use of cyclophosphamide, cyclosporine, tacrolimus, rituximab, belimumab, IVIG and leflunomide could not be analyzed because there were too few data points in some categories.

Conclusion: Among SLE patients in our hospital, treatment with steroid therapy was associated with less likelihood of early hospital readmission within 30 days of discharge. Cellcept use was related to higher likelihood of early readmission, possibly as an indicator of severity of SLE in the patient population studied. Although infections are known complications of immunosuppression or immune disease, no significant association was found between infection at index hospitalization and early readmission in our patient population. The significant association found between higher mean values of creatinine in the study group compared to the control group may support the possibility of renal disease as a predictor of early readmission. As infections were not found to be significantly associated with early readmissions, this may imply that it

could be lupus-related factors or other comorbidities that may be related to this finding of a high readmission rate (18%) of SLE patients in CRMC. Further studies into the specific factors affecting early readmissions of SLE patients are warranted, which would be avenues for further improvement of quality and transitions of care of lupus patients in the Central Valley.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Classically, it has been thought that sun exposure is a risk factor for developing cutaneous manifestations in Systemic Lupus Erythematosus. On the other hand, in experimental studies UV radiation has a number of immunomodulatory effects and stimulates vitamin D synthesis. Our objective was to examine the mucocutaneous

manifestations of SLE patients from the GLADEL cohort in relation to solar radiation of the place where they lived along Latin America by performing an ecological study.

Methods: GLADEL patients were categorized according to solar radiation (insolation on horizontal surface) of the Rheumatology Center where they were recruited, ascertained between the period of cohort follow up (1995-2004); this was obtained using NASA Surface meteorology and Solar Energy estimator (https://eosweb.larc.nasa.gov/cgi-bin/sse/interann.cgi?email=skip@larc.nasa.gov). Alopecia, photosensitivity, malar rash, discoid lesions, oral ulcers and subacute cutaneous lupus at cohort entry and during follow up were examined in multivariate models in relation to the average daily solar radiation of the city of residence (as a continuous variable) and other possible confounders.

Results: GLADEL cohort included 1480 lupus patients, with a disease duration < 2 years at entry, 89.9 % female (CI 88-91), mean age 29.5 years (SD 12.3), median follow up 52 months (IQR 24-70), from 34 centers of 22 cities of 9 countries in Latin America. Latitudes of these centers varied between -38° S (Mar del Plata, Argentina) and 25.7° N (Monterrey, Mexico) and mean daily solar radiation varied between 4.44 Kwh/m^2/day (Porto Alegre, Brazil) and 6.08 Kwh/m^2/day (Recife, Brazil) (Table 1). When entering the cohort, 1191 patients (80.47 %) had one or more of the cutaneous manifestations mentioned above and 434 patients (29.31%) developed new skin involvement during follow up. In logistic regression analysis after adjusting for age, gender, ethnic group, urban residence, latitude, antimalarial use and antibodies (anti DNA, anti Sm, anti Ro, antiphospholipid, low C3), living in a city with higher daily solar radiation (examined at 1 Kwh/m^2/day increments) was not associated to any of the cutaneous manifestations at disease onset or during follow up (Table 2).

Conclusion: In the GLADEL cohort, the average solar radiation of the city of residence was not associated with an increased risk of developing cutaneous manifestations. Table 1. Latitude and solar radiation of GLADEL patients' cities of residence.

City	Latitude	Mean daily solar radiation (1995-2004) (Kwh/m^2/day)	Lupus patients in GLADEL, N (%)
Monterrey, Mexico	25.68 N	5.28	32 (2.2)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Early diagnosis and treatment of youth with SLE are crucial to prevent organ damage and reduce mortality. Understanding health care utilization prior to diagnosis may inform interventions to minimize diagnostic delay. We determined the frequency and associated factors for health care visits among youth with SLE in the year prior to diagnosis.

Methods: We used national administrative claims data (Optum Labs Data Warehouse) for privately insured U.S. enrollees from May 2000 to December 2013 to identify an incident cohort of youth ages 10-24 years with SLE. Incident cases were defined by ≥ 3 outpatient or inpatient visit claims with an ICD-9 primary diagnosis code for SLE (710.0) > 30 days apart, with ≥ 1 year of preceding continuous enrollment without a code for SLE. The mean number of ambulatory (AMB), emergency (ED), and inpatient (IP) visits in the year prior to the first SLE diagnosis code were compared to visits per year for healthy controls matched 2:1 by age and sex. For each SLE visit type, we also calculated the mean number of visits in

the 3 and 6 months prior to diagnosis, and determined the most frequent primary diagnosis codes in the year prior. We used multivariable negative binomial regression models to examine associations between demographic or disease-related factors and AMB, ED, and IP utilization in the year prior to SLE diagnosis.

Results: We included 724 SLE subjects and 1448 controls comprised of 88% females, with a mean age of 18.6 years (standard deviation, SD 3.7). Compared to controls, fewer youth with SLE were white or from the Midwest; 24% had subsequent diagnoses for nephritis. Youth with SLE had significantly higher mean visits of all types in the year pre-diagnosis compared to controls: 9.5 (SD 10.0) vs 3.0 (4.5) for AMB ($p<0.001$), 3.6 (6.0) vs 0.9 (2.0) for ED ($p<0.001$), and 1.4 (4.4) vs 0.2 (1.5) for IP ($p<0.001$) (Figure). The most common primary diagnosis codes for pre-diagnosis AMB, ED and IP visits were: Other acne [706.1], Primary thrombocytopenia unspecified [287.3], and Fever unspecified [780.6], respectively. Subsequent nephritis was associated with decreased AMB, but increased IP visits. Preceding psychiatric diagnosis was associated with increased AMB and ED visits (Table). Female sex, Asian and Black race were associated with decreased AMB visits.

Conclusion: Youth with SLE have higher rates of health care utilization in the year preceding diagnosis compared to healthy peers. Strategies to improve early identification of youth with SLE, especially those presenting with psychiatric or renal manifestations, may allow earlier treatment and improve outcomes.

Table. Factors Associated with Pre-diagnosis Health Care Utilization in Youth with SLE

Predictors	Ambulatory	Emergency	Inpatient
	Multivariate Incidence Rate Ratio (95% CI)		
Race/Ethnicity			
White	-	-	-
Black	0.8 (0.7-0.98)*	1.2 (0.9-1.6)	1.9 (0.8-4.1)
Hispanic	1.2 (1.0-1.4)	1.1 (0.9-1.5)	1.5 (0.6-3.7)
Asian	0.7 (0.6-0.9)*	0.6 (0.4-0.8)**	0.7 (0.2-2.2)
Age, years			
10-15	-	-	-
16-18	1.1 (1.0-1.4)	1.1 (0.8-1.5)	0.9 (0.4-2.2)
19-21	1.2 (1.0-1.5)*	1.1 (0.8-1.4)	1.8 (0.8-4.2)
22-24	1.2 (1.0-1.4)	1.2 (0.9-1.6)	1.4 (0.6-3.3)
Female	0.7 (0.6-0.8)***	0.9 (0.6-1.2)	0.8 (0.3-2.1)
Region			
Northeast	-	-	-
Midwest	1.0 (0.8-1.2)	1.1 (0.7-1.5)	0.9 (0.3-2.7)
South	1.0 (0.8-1.2)	0.9 (0.67-1.3)	1.2 (0.4-3.5)
West	1.0 (0.7-1.2)	1.1 (0.8-1.7)	0.4 (0.1-1.8)
Highest education (household)			
Less than 12th grade	-	-	-
High school diploma	1.1 (0.6-2.0)	2.7 (0.99-7.2)	0.6 (0.04-8.0)
Less than bachelor degree	1.2 (0.7-2.2)	2.6 (0.96-6.9)	1.0 (0.1-13.7)
Bachelor degree or higher	1.5 (0.9-2.7)	2.6 (0.95-7.0)	0.6 (0.04-9.0
SLE nephritis	0.8 (0.7-0.9)**	1.2 (0.9-1.5)	2.9 (1.4-5.9)**
Seizures or Stroke	1.3 (1.1-1.7)*	1.5 (1.0-2.1)	2.4 (0.8-7.3)
Preceding psychiatric diagnosis	1.4 (1.2-1.7)***	1.8 (1.4-2.3)***	2.1 (0.9-4.9)

Shown are results from multivariable negative binomial regression models examining associations between demographic or disease factors and health care utilization. Separate models (n = 666) were used for ambulatory, emergency, and inpatient visits. * = p <0.05; ** = p < 0.01; *** = p < 0.001

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Very long-term follow-up has rarely been reported in lupus patients. We report on the follow up of (up to 37 years) of our lupus cohort from January 1978 to December 2015.

Methods: We have undertaken an exhaustive case review of our entire cohort of lupus patients at University College London Hospital. Electronic and paper records were reviewed for demographic, clinical and pathological outcomes of our patients. For those patients no longer under active follow up, information was retrieved through telephone consults and discussions with primary care physicians and other rheumatologists.

Results: 673 patients (M 55 F 618) with lupus were included. Patients were predominately Caucasian (58.4%) Afro-caribbean (14.9%) and South Asian (8.8%). Average age at diagnosis was 28.9 years (SD +/- 12.5). Major lupus manifestations were arthralgia/arthritis (90.9.2%), rash (66.2%), photosensitivity (41.5%), serositis (37.8%), oral ulcers (27.3%) and alopecia (23.7%). Over a third of patients had renal involvement (34.6%). 90% confirmed on biopsy. 46% class IV, 22.3% class III and 17.2% class V. 20.8% patients had major CNS involvement at some point in their disease. 93.6% of patients were ANA positive (titre>1:80) . 62.9% were double stranded DNA antibody positive, 48.6% had low C3. Other autoimmune conditions diagnosed in our cohort include hypothyroidism (7.7%), Sjogrens (7%) and anti-phospholipid syndrome (6.8%). 2.5% of patients were also diagnosed with idiopathic thrombocytopenic purpura and 4.6% developed haemolytic anaemia. A large majority of patients were treated with Prednisolone during their disease. Disease modifying drugs including Hydroxychloroquine (85.4%), Azathioprine (39.8%), Mycophenolate (36.8%), Cyclophosphamide (23%), Methotrexate (11.8%) were also used in combination. 19.9% of our patients received Rituximab. The majority of patients remain in active follow up (68.1%). The mean follow up is 15.1 years. 14.7% have died, 8.1% moved away (known location), 5% have moved away (unknown location). Cancer was a major cause of death (31.8%), notably of the breast (16.1%) and lung (14.3%) and Non-Hodgkin's lymphoma (10.7%). The second leading cause of death was infection (30.7%) followed by cardiovascular disease including stroke and myocardial infarction (8%).

Conclusion: Although the outlook for SLE has improved in the past 50 years, it remains a condition with significant morbidity and mortality. The introduction of Rituximab has provided an additional therapeutic strategy beyond conventional immunosuppression but it is not a cure. We await the introduction of more successful biologic therapies to improve the outcome for our patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Our purpose was to investigate cognitive dysfunction (CD) in a cohort of Neuropsychiatric Systemic Lupus Erythematosus (NPSLE) patients (n=16) with severe central nervous system (CNS) involvement that had been previously evaluated prospectively in our department.

Methods: Of a 16 patient cohort with a well documented history of CNS involvement (NPSLE), 11 patients participated in the study. Eleven non-NPSLE patients and 28 healthy controls, all female, with mean age 41.2 (±11.4) years were included. Healthy controls were age, sex and education matched. Participants were administered a 1-hour neuropsychological battery as proposed by the American College of Rheumatology (ACR-SLE battery). Data on depression using the Center of Epidemiological Studies of Depression (CESD) questionnaire, cognitive failures as reported from participants using the Cognitive Failures Questionnaire (CFQ) and levels of fatigue using the Facit Fatigue (FF) questionnaire were also collected. A Visual Analogue Scale (VAS) was used for pain assessment. Patients were evaluated for the presence of anti-dsDNA, Neuromyelitis Optica (NMO)-IgG, anti-ribosomal P and anticardiolipin antibodies (aCL). Presence of concurrent Antiphospholipid Antibody Syndrome (APS) was documented. Disease activity was assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), and permanent damage due to SLE using the SLICC/ACR Damage Index. Analysis of variance was performed in order to assess the statistical significance of the observed differences. Pairwise comparisons were made using the Tukey's HSD test. All analyses were done using the STATISTICA 10.0 software for Windows.

Results: Analysis of variance revealed significant differences between groups in three domains of neuropsychiatric tests: Stroop color, Greek verbal learning test (GVLT) 1,2, Rey osterrieth complex figure (ROCF) copy trial, and in the FF questionnaire. When post-hoc analysis was performed those differences were weakened, however a tendency maintained for the ROCF copy trial (p=0.06). In the patients sample, aCL positive subjects had lower values in the immediate recall trial of the GVLT, (p=0.01) and in the immediate ROCF trial (p=0.02) as compared to the non aCL ones. Also, APS patients had lower digit symbol test and lower CESD results compared to the non APS patients (p=0.01 and 0.04, respectively). Finally higher SDI scores were positively correlated to CESD scores (p=0.0) and SLEDAI scores were moderately negatively correlated to Word Reading Efficiency (WRE) and Stroop color-words scores.

Conclusion: Severe neurological involvement does not produce severe cognitive dysfunction. NPSLE patients showed a tendency to deficient visual-spatial processing. However, in the patient's sample, those with aCL antibodies showed deficits in memory processes. APS patients showed worse psychomotor speed. Both patients with APS and patients with higher SDI scores showed more depression.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is the paradigm of the autoimmune diseases that primarily affects women in a ratio of 9: 1. In England and America the prevalence varies from 12 to 42 cases / 100,000 inhabitants and the incidence of 1-3 cases / 100,000 inhabitants. No data on incidence and prevalence of SLE in Argentina is available. The aim of this study is to determine the prevalence and incidence of SLE in the province of Tucuman, Argentina.

Methods: A cross-sectional study was conducted. Medical records of outpatient and inpatient of 4 hospitals in the province and attended by all doctors of Rheumatology Society of Tucuman (n = 28) except for a center, were reviewed retrospectively. We included patients over 16 years with diagnosis of SLE (4 ACR criteria 1982/1997) residents in the province of Tucuman and with at least two clinic visits between January 2005 and December 2012. We excluded patients with other concomitant diagnosis of autoimmune disease. Demographic variables related to the disease (diagnosis date, age, mortality, cause of death and clinical) were analyzed. The population data were taken from the National Census of 2010. The province of Tucuman has 17 departments with a population of 1,448,716 inhabitants, 45% are in the center area and the remaining 65% distributed in the areas west and south. The population over 16 years is 1,011,188 inhabitants. The prevalence was calculated as the number of cases per 100,000 inhabitants in the period 2005 - 2012 and the annual incidence in the same period.

Results: 353 patients were identified. The mean age at diagnosis was 30.5 ± 11.7 years, 93.5% were women. The prevalence was 25.6 cases / 100,000 inhabitants (95% CI 22.6-28.8) and adjusted for age (≥ 16 years) of 36.7 cases / 100,000 inhabitants (95% CI 32.8-41.1). The annual incidence in 2005: was 1.8 cases / 100,000 inhabitants (95% CI 1-2.9) 2006: of 2 cases / 100,000 inhabitants (95% CI 1.2-3.2), 2007: 1.4 cases / 100,000 inhabitants (95% ; 0.7-2.4), 2008: 2.1 cases / 100,000 inhabitants (95% CI 1.2-2.9), 2009: 2.2 cases / 100,000 inhabitants (95% CI 1.3-3.3), 2010: 2.2 cases / 100,000 population (95 % 1.2-3.3), 2011: of 2.8 cases / 100,000 inhabitants (95% CI, 1.9-4) and 2012: of 4.2 cases / 100,000 inhabitants (95% CI 2.9-5.8). A significant increase of incidence was found comparing the periods 2005 and 2012 (p = 0.0019). Mortality was 9.1%, the most common cause were infections (14/32) .The change rate of deaths corrected by year follow-up is similar to the change in the incidence rate corrected by year of follow up through periods.

Conclusion: The prevalence of SLE in the province of Tucuman was of 36.7 cases / 100,000 inhabitants. The annual incidence in 2005 was 1.8 and in 2012 4.2casos / 100,000 inhabitants. This is the first study of prevalence and incidence of SLE in a population of Argentina.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pneumonia, remains as a main cause of mortality in patients with SLE. There are not specific guidelines for the empiric treatment in these patients. The aim of this study was to establish the epidemiological characteristics, the microbiological isolations and the rate of complications of patients with SLE and pneumonia.

Methods: We retrospectively reviewed medical records of patients with SLE (ACR criteria) and Pneumonia who attended the emergency room in a single tertiary care center, (January 2010 - March 2015). We collected laboratory and clinical data: demographics, treatment and disease activity (SLEDAI-2K). We collected isolation data from the microbiology department and from the medical record to ascertain that the isolation was considered responsible of pneumonia. Patients were followed for 30 days after discharge. A negative outcome was defined as need of mechanical ventilation (MV), septic shock or death during follow-up. Statistics. Descriptive statistics were used.

Results: We included 163 patients (121 women, 74%), who presented 194 episodes of pneumonia. At evaluation the mean ± SD age was 34.6 ± 12.4 years, time since diagnosis of SLE 7.1 ± 8.2 years and SLEDAI 2K was 8 ± 5.6. Duration of hospitalization was 10.7 ± 7.2 days. In 154 of the episodes patients were taken prednisone (mean dose 18 mg). In fifty eight of the episodes (29.8%) was possible to obtain a positive microbiology report. The isolated microorganisms are depicted in table 1. Fifty seven (29%) patients presented a negative outcome: 13 (7%) septic shock, 50 (26%) needed MV and 12 (6%) patients died.

Table 1. Isolated microorganisms in 58 pneumonia episodes in SLE patients

	n	%
Streptococccus pneumoniae	**4**	**6.8**
Pseudomonas aeruginosa	8	13.7
Aspergillus	7	12
Klebsiella pneumoniae	5	8.6
Methicillin-sensitive Staphylococcus aureus	5	8.6
Methicillin-resistant Staphylococcus aureus	4	6.8
E. coli	4	6.8
Strepnotrophomonas	3	5.1
Enterococcus	2	3.4
Moraxella	2	3.4
S. epidermidis	2	3.4
H.parainfluenza	2	3.4
Enterobacter cloacae	2	3.4
Acinetobacter	2	3.4
Mycobacterium tuberculosis	1	1.7
Streptococcus agalactiae	1	1.7
Candida albicans	1	1.7
H. influenza	1	1.7
P. jirovecci	1	1.7
Serratia	1	1.7
TOTAL	58	100

Conclusion: In this study, a high proportion of patients with SLE and pneumonia presented a negative outcome. With an acceptable percentage of episodes with microbiological isolation, we identified a very high incidence of atypical microorganisms, this must be taken into account for empirical antibiotic selection in these patients.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic heterogeneous disease with considerable burden from disease activity and damage. A novel clinical treatment target in the form of the Lupus Low Disease Activity State (LLDAS) has been recently reported (Franklyn et al, Ann Rheum Dis, 2015), with retrospective validation showing that time spent in LLDAS translated to reduced damage accrual. The objectives of this study were to describe the frequency and identify the predictors of attaining LLDAS in a large multinational cohort of patients with SLE.

Methods: Data were collected at the baseline visit of SLE patients enrolled in a longitudinal study in 12 centres across the Asia Pacific. Data were analysed cross-sectionally against the recently published definition of LLDAS, and the frequency and characteristics associated with LLDAS attainment were determined. Stepwise multivariable logistic regression was used to determine predictors of LLDAS.

Results: Of the 1846 patients assessed, criteria for LLDAS were met by 44%. Data revealed that patients with shorter disease duration were less likely to be in LLDAS (OR 0.31, 95% CI 0.19-0.49, p<0.001). Likewise, patients with a history of discoid rash (OR 0.66, 95% CI 0.49-0.89, p=0.006), renal disease (OR 0.60, 95% CI 0.48-0.75, p<0.001), or who had elevated double stranded DNA (OR 0.65, 95% CI 0.53-0.81, p<0.001) or hypocomplementaemia (OR 0.52, 95% CI 0.40-0.67, p<0.001) were less likely to be in LLDAS. When countries were compared, higher national social wealth (OR 1.57, 95% CI 1.25-1.98, p<0.001) as measured by the Gross Domestic Product per capita was positively associated with LLDAS.

Conclusion: In a large multinational SLE cohort, the lupus low disease activity state is observed in less than half of patients at a single point in time. Disease duration and phenotype, as well as national social wealth, are predictive of LLDAS.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The ACR-sponsored RISE (Rheumatology Informatics System for Effectiveness) Registry is an electronic health record (EHR)-based national database of rheumatology clinical visits. De-identified patient data are currently extracted and tabulated from the EHRs of over 50 clinics, representing 250 clinicians. At this time, the majority contributing clinicians are in community-based practices (98.7%). We identified and characterized patients with prevalent systemic lupus erythematosus (SLE) and undifferentiated connective tissue disease (UCTD) in RISE and studied the ICD9 and ICD10 coding.

Methods: We included each patient's last visit in the RISE Registry between April 1 2015 and March 31 2016. For ICD9, SLE and UCTD were defined using 710.0 and 710.9. For ICD10, SLE and UCTD were defined using codes M32.0-M32.9 and M35.9, respectively. Patient characteristics, ICD9 and ICD10 classification from the last visit for each individual patient during this time were included in the analysis. We examined the primary ICD10 rheumatology diagnosis for all patients with an ICD9 code of 710.9 for UCTD.

Results: Patients with prevalent SLE and UCTD in RISE were, on average, in their early fifties and approximately one third were on Medicare. Both groups were around 90% female. Although patients with these diagnoses were predominantly white, those with SLE were more likely to be black than those with UCTD. According to ICD9 codes, 13,416 patients had SLE, and 10,698 had UCTD. Fewer patients had ICD10 codes, likely due to the more recent introduction of ICD10. By ICD10 coding, 10,813 SLE patients and 3,624 UCTD patients were identified. Of SLE patients, 90% of patients were identified using a general SLE ICD10 code: 4,173 had code M32.19 (SLE, other organ), 3,146 had code M32.9 (SLE unspecified), 1,797 had code M32.10 (SLE organ unspecified), and 667 had code M32.8 (other forms of SLE). Smaller numbers of patients were given more specific lupus diagnoses, including 689 with SLE glomerular (M32.14), 174 with SLE lung involvement (M32.13), 81 with SLE pericarditis (M32.12), and 6 with SLE endocarditis (M32.11). Some patients had multiple SLE codes. The ICD10 coding varied for those with an ICD9 code of 710.9 for UCTD. The most common codes were for unspecified systemic connective tissue disease or overlap syndrome (3,624 had M35.9, 816 had M36.8, 516 had M35.8, and 391 had M35.1). Of those identified as UCTD by ICD9 coding, 15.7% had M32 codes for SLE, 14.7% had M35 codes for Sjogren's syndrome, 2.9% had M34 codes for scleroderma, and 2.1% had M33 codes for myositis.

Conclusion: The population within the RISE Registry provides a unique cohort of lupus patients followed, up to this point in the registry, entirely by community clinicians. The transition from ICD9 to ICD10 may result in some changed diagnoses, particularly with some movement from UCTD to more specific diagnoses. RISE includes data on prescribed medications, labs, and patient-reported or physician-reported disease activity measures. Studying this patient group will provide unique insight into the day-to-day community management, prognosis and complications of patients living with SLE throughout the United States. **Table. A Longitudinal Analysis of Change in Lupus Disease Activity Pattern in Hopkins Lupus Cohort Using a Multistate Markov Model Approach

Wei Fu[1] and Michelle Petri[2], [1]Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Rheumatology Division, Johns Hopkins University School of Medicine, Baltimore, MD

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a multi-systemic inflammatory disease with extreme variability of its activity over time. We have described three main patterns: long quiescence (or remission), chronic activity and relapsing-remitting (or flare). Patients may move through a series of these activity states over time. To capture these complex fluctuations, we used a Multistate Markov model to describe and evaluate SLE disease activity patterns over time in a longitudinal lupus cohort.

Methods: SLE patients were followed up quarterly in Hopkins Lupus Cohort for 1- 28 years. Medication, disease activity (by, Physician Global Assessment (PGA) and SLE Disease Activity Index (SLEDAI), C3, C4, anti-dsDNA, antiphospholipid antibodies and urine protein/ creatinine ratio were recorded at each visit. For each patient, visits were divided into 1-year blocks. Any 1-year block with only one visit or patients followed for only 1 year were excluded. SLE disease activity patterns were defined using PGA and SLEDAI: Long Quiescent (LQ), SLEDAI/PGA=0 for all visits within 1-year blocks; Relapsing-Remitting (RR), periods of disease activity (SLEDAI/PGA>0) interspersed with periods of disease inactivity (SLEDAI/PGA=0) within 1-year block; Chronic Active (CA), SLEDAI/PGA scores >0 for all visits within 1-year block. Multistate Markov models were used to provide estimates of relative transition rates and identified predictors of change in disease activity patterns.

Results: 1735 SLE patients were included in this analysis. 92.3% were females, Mean+/-SD Age 32.8 +/- 13.1 years at diagnosis. 52.9% were Caucasian and 40.3% African American, the remainder had other ethnicity, mostly Asian. 127 patients died during follow up. Likelihood of deterioration (from LQ to RR; from RR to CA; from LQ to CA) was greater than improvement (from RR to LQ; from CA to RR; from CA to LQ). At year one, 63.6% remained in LQ, while at year two and year five, 58.2% and 84.1% had deteriorated from LQ pattern to either RR or CA pattern. From the RR pattern, the estimated probability for deterioration (to CA pattern) was higher than improvement (to LQ pattern), regardless of years since SLE diagnosis. Multivariate analysis (see table 1) identified that race/ethnicity (African American), low C3, low C4, ESR >20, taking prednisone or anti-hypertension drug were predictors for deterioration. Plaquenil improved survival.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To find out prognostic factors predicting the outcome of Chinese patients with systemic lupus erythematosus (SLE) at the time of their first admission.

Methods: A database (http://sys.91sqs.com/sle) has been built to collect the medical records of SLE patients by the Lupus Collaborative Group under the supervisor of Jiangsu Rheumatology Association since 2010 (Feng X et al, J Rheumatol 2011; 38:1289-1295). Up to 2015, the hospitalization data of nearly 2,500 SLE patients who first admitted during the 1999-2009 decade in Jiangsu Province, China, were documented. Those with known survival status were extracted for the assessment of potential factors associated with mortality. The independency of factors significantly related was established by multivariate Cox regression analysis.

Results: Totally 1,372 patients from 26 centers were enrolled (Figure 1), in which 92.3% were female and 17.2% were deceased after following-up for a median time of 7.8 years. The main causes of death were infection (30.1%), neuropsychiatric impairment (14.8%), renal failure (14.4%) and cardiopulmonary involvement (8.5%). Ill-defined causes of death, most recorded as cardiopulmonary failure or multiple organ failure, represented 25.4% of the total deaths. Compared with those dead within one year after the hospitalization, patients died later had less neuropsychiatric impairments (7.6% vs. 23.8%) but more cardiopulmonary involvements (12.2% vs. 3.8%). Independent predictors for mortality at the time of first admission were age more than 45 years old [hazard ratio (HR) 1.38], disease duration more than 2 years (HR 1.54), neuropsychiatric involvement (HR 1.93), cardiopulmonary involvement (HR 1.85), anemia (HR 1.53), thrombocytopenia (HR 1.51), hypoalbuminemia (HR 1.47), increased blood urea nitrogen (HR 1.74) and serum creatinine (HR 1.66), whereas the positivity of anti-Sm antibody (HR 0.60), the use of anti-malarial drugs (HR 0.49) and cyclophosphamide (HR 0.60) were protective factors. SLEDAI score, proteinuria or hypocomplementemia was not independently associated with the outcome in this cohort.

Conclusion: Old age, long disease duration and vital organ involvement predict a poor outcome in Chinese SLE patients, while early intervention with cyclophosphamide and anti-malarial drugs is beneficial for long-term prognosis.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster II: Damage Accrual and Quality of Life

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : Cardiovascular disease (CVD) is a leading cause of death in patients with SLE. Lupus patients have a 2-3 fold increased risk of heart failure compared to age matched controls. Although the mechanisms remain unclear, lupus myocarditis (LM) has been proposed as a contributor. ^{18}F-Fluoro-Deoxyglucose Positron Emission Computed Tomography (FDG-PET/CT) imaging has emerged as a novel modality to visualize myocardial inflammation in rheumatic diseases. The current study discusses our experience with FDG-PET/CT scanning in LM.

Methods: A total of eight SLE patients diagnosed with LM by FDG-PET/CT are described in this series. Demographics, SLE-specific characteristics, and CVD risk factors were ascertained. Coronary artery disease was evaluated by the Agatston coronary calcium score and/or coronary catheterization.

Results: Eight SLE patients (mean age 43±12 years) seen at the Lupus Center for complaints of chest pain 4 (50%), intermittent shortness of breath 2 (25%) or palpitations 2 (25%) followed from November 2015 to February 2016, underwent cardiac FDG-PET/CT for evaluation of LM. Six patients were female, 4/8 were Hispanic and 4/8 were non-Hispanic Black. The median SLEDAI-2K and SLICC SDI scores were 5 (2-11) and 1.5 (0-2), respectively. Mean SLE disease duration prior to the diagnosis of LM was 11±6 years. One patient had hypertension and diabetes, and 3 patients

were former or current smokers. Of the 8 patients, 1 had a history of pericarditis and 5 had prior severe lupus activity and organ involvement: 4 had lupus nephritis and 1 had CNS lupus. All patients were ANA positive, 7 ds-DNA+ and 5 were anti-SSA antibody positive. None of the patients had anti-phospholipid antibody syndrome or APL antibodies. One patient had elevated troponins and elevated pro-BNP. Electrocardiographic abnormalities were noted in all patients with 5 having non-specific ST-T changes and sinus tachycardia. Interestingly, only 5 patients had echocardiographic abnormalities: pericardial effusion in 3 (38%), global hypokinesis in 2 (25%) and valvular abnormalities 2 (25%). The mean ejection fraction was 41±16% (Table 1). On cardiac FDG-PET/CT imaging, all patients had diffuse myocardial uptake (Figure 1).

Conclusion: These data propose that cardiac FDG-PET/CT imaging has higher sensitivity than 2-D echocardiography in detecting myocardial inflammation in SLE and support the use of FDG-PET/CT in the diagnosis of myocarditis in SLE.

Table 1. Diagnostic Findings of SLE patients with FDG-PET/CT diagnosed myocarditis (n=8).

Laboratory Data

Dectin-1 on Monocytic Cells Mediates Aberrant Innate and Adaptive Immune Responses in Patients with Systemic Lupus Erythematosus

Mo Yin Mok, Ian Lam, Daniel Luk, Yi Lo and Wai Kin Chan, Department of Medicine, University of Hong Kong, Hong Kong, Hong Kong

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Dectin-1 is a c-type lectin like receptor that signals via syk and is involved in anti-fungal immunity. Dectin-1 was found to trigger experimental inflammatory arthritis, and likely play a role in the pathogenesis of some autoimmune diseases. This study aimed to examine (1) dectin-1 expression on circulating CD14+ monocytes in patients with systemic lupus erythematosus (SLE), (2) the effects of dectin-1 stimulation in ROS production by lupus monocytes and (3) Syk signaling and cytokine profile of dectin-1 stimulated lupus monocyte-derived dendritic cells (MDDCs).

Methods: SLE patients with active and inactive diseases and healthy subjects were recruited. MDDCs were derived from peripheral monocytes in the presence of IL-4 and GM-CSF. Dectin-1 agonists including curdlan, zymosan and toll-like receptor agonists Pam3CSK4 (TLR2) and LPS (TLR4) were used to stimulate monocytes and/or MDDCs. Dectin-1, ROS and phosphorylated-syk (p-Syk) were measured by flow cytometry. Cytokine profile was measured by and multi-bead immunoassay.

Results: The percentage of dectin-1 expressing monocytes was significantly lower in active SLE patients (64.5+24.3%) compared to inactive patients (89.6+7.2%) and healthy controls (91.7+9.5%) (both $p<0.001$). The absolute count of dectin-1 expressing monocytes correlated significantly and inversely with SLEDAI ($r=-0.40$, $p<0.001$), anti-dsDNA antibody level ($r=-0.29$, $p=0.004$), C3 ($r=0.35$, $p=0.001$) and C4 ($r=0.24$, $p=0.02$). Despite this, ROS production upon stimulation by dectin-1 agonists was comparable between these 3 groups. Stimulation of dectin-1 led to activation and maturation of MDDCs with upregulation of HLA-DR and CD86 (all $p<0.001$). SLE MDDCs showed higher p-Syk activation compared to normal MDDCs upon dectin-1 stimulation (6.0+2.0 vs 2.8+1.0%, $p<0.001$). Curdlan-stimulated MDDCs produced higher levels of IL-1β, IL-23 and TNF-α. Adding TLR2 agonist to curdlan, SLE MDDCs produced significantly higher level of IL-1β (327.1+51.5 vs 125.3+88.5, $p=0.009$) and IL-6 (median 39.8 vs 21.7, $p=0.03$) compared to normal MDDCs. Combination of TLR4 agonist and curdlan induced IL-12 and TNF-α in normal MDDCs whereas lupus MDDCs produced predominant IL-6 and TNF-α.

Conclusion: Active SLE patients had significantly lower circulating dectin-1 expressing CD14+ monocytes which produced comparable level of ROS upon stimulation compared to inactive patients and healthy subjects. Dectin-1 agonists led to activation, maturation and higher p-Syk activation in SLE MDDCs. Concomitant dectin-1 and TLR2 stimulation induced production of Th17 promoting cytokines, among which IL-1β and IL-6 were significantly higher in SLE compared to normal MDDCs.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: T cell DNA methylation defects play an important role in the pathogenesis of systemic lupus erythematosus. A CD4+CD28+ T cell subset characterized by overexpression of methylation sensitive genes, including CD11a and the KIR gene cluster, has been recently described in autoimmunity. The goal of this study was to characterize this T cell subset *in vitro* and in patients with SLE.

Methods: The size of the CD4+CD28+KIR+CD11a^{hi} T cell subset was determined by flow cytometry in 49 female lupus patients of European descent. SLEDAI scores were calculated at the time of blood draw, and all patients were genotyped across 43 confirmed lupus susceptibility loci and a total genetic risk score for lupus was calculated. CD4+CD28+KIR+CD11a^{hi} and CD4+CD28+KIR-CD11a^{low} T cells were isolated from peripheral blood samples of normal healthy individuals after *in vitro* treatment with 5-azacytidine, and genome-wide DNA methylation and RNA sequencing was performed in both subsets. RNA sequences in the CDR3 region were used to assess the TCR repertoire.

Results: The CD4+CD28+KIR+CD11a^{hi} T cell subset size correlated with disease activity in lupus patients as measured by SLEDAI score (r=0.36, P= 0.012). Linear regression models suggest that the subset size is a better predictor of disease activity when normalized for total genetic risk in each individual (r=0.42, P=0.003), suggesting that the relationship between KIR+CD11a^{hi} T cell subset size and disease activity in lupus is influenced by genetic risk. Genome-wide DNA methylation analysis identified a total of 31,019 differentially methylated sites in KIR+CD11a^{hi} compared to autologous KIR-CD11a^{low} T cells, with 30,736 methylation sites (99.1%) being hypomethylated. RNA sequencing analysis identified 1,620 overexpressed genes in the KIR+CD11a^{hi} T cell subset, including key pro-inflammatory cytokine genes, adhesion molecules, Fc-gamma receptor genes, Toll-like receptor genes, HLA molecules, and metalloproteinases. Of particular interest, and similar to what is known in lupus T cells, the experimentally derived demethylated KIR+CD11a^{hi} T cell subset demonstrates reduced IL-2 mRNA expression (3.3-fold). Bioinformatics analysis of 718 genes that are hypomethylated and overexpressed in KIR+CD11a^{hi} T cells revealed significant enrichment in pro-inflammatory gene ontologies, pathways, and gene meta-groups. Analysis of the TCR repertoire suggests that the KIR+CD11a^{hi} T cell subset is polyclonal, but with less diverse clonality compared to autologous KIR-CD11a^{low} T cells (mean number of TCR clones 673±72 versus 837±39; P= 0.001).

Conclusion: CD4+CD28+KIR+CD11a^{hi} T cells are polyclonal and demethylated, and characterized by a pro-inflammatory transcriptional profile. These cells are expanded in lupus patients, and interact with total genetic risk to predict and possibly contribute to disease activity.

CD4+ T Cell Lymphopenia Is Associated with Deficient Ubiquitination of the Cell Cycle Inhibibitor p27kip1 By the E3 Ligase Casitas B-Lineage Lymphoma-b in Patients with Systemic Lupus Erythematosus

Diana Gómez-Martín, Jorge Romo-Tena, Javier Merayo-Chalico and Jorge Alcocer-Varela, Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lymphopenia has been associated with the development of autoimmune diseases. Particularly, in patients with Systemic Lupus Erythematosus (SLE) is a common clinical feature. However, the molecular mechanisms related to lymphopenia in SLE have not been fully addressed. Besides, the E3 ligase Cbl-b has been shown to regulate T cell responsiveness and its deficiency has been documented in SLE. The aim of this study was to assess $CD4^+$ T cell number and proliferation regulated by cell cycle inhibitors ubiquitination by the E3 ligase Cbl-b in SLE patients.

Methods: We included 20 patients with SLE (8 in remission and 12 with active untreated disease) according to the classification criteria of the American College of Rheumatology and 20 age and gender-matched healthy controls. Absolute peripheral lymphocyte count was obtained for each subject. PBMCs were isolated by density gradient and effector ($CD4^+CD25^-$) T cells were purified by magnetic selection and stimulated with anti-CD3+anti-CD28 beads. The expression of total ubiquitin, Cbl-b, $p27^{kip1}$ and $p21^{cip1}$ was analyzed by Western blotting. Interaction between Cbl-b, $p27^{kip}$ and $p21^{cip1}$ was addressed by immunoprecipitation (IP). Proliferative responses were assessed by CFSE. Differences were assessed by t Student test and Spearman correlation coefficient was also used. $p<0.05$ was considered as statistically significant.

Results: We found decreased Cbl-b expression in effector T cells from SLE patients in comparison to healthy controls (1.6±0.2 vs 3.8±1.3, p=0.003), which was associated with lower proliferation upon TCR stimulation vs healthy controls (p=0.022). Decreased proliferation and absolute number of effector T cells correlated with Cbl-b expression (r=0.553, p=0.020; r=0.680, p=0.003, respectively). Moreover, this phenomenon was associated with diminished ubiquitination of the cell cycle inhibitor $p27^{kip1}$ in effector T cells from SLE patients when compared to healthy controls. We did not find differences in ubiquitination and expression of another cell cycle inhibitor, $p21^{cip1}$ in comparison to healthy controls. Interestingly, we also found by IP assays, that $p27^{kip1}$ and $p21^{cip1}$ interact with Cbl-b. We found no significant differences regarding to disease activity.

Conclusion: Our data suggest that the deficiency of the E3 ligase Cbl-b is associated with the presence of lymphopenia in SLE patients. This phenomenon is related to decreased ubiquitination of the cell cycle inhibitor $p27^{kip1}$ in effector T cells from SLE patients, which triggers its sustained expression as well as decreased proliferation of lupus lymphocytes. Furthermore, this effect is specific to $p27^{kip1}$, since even though, $p21^{cip1}$ also interacts with Cbl-b, its ubiquitination and

expression was not related to this E3 ligase in SLE patients. To our knowledge, this is the first evidence that suggest deficient ubiquitination as a molecular mechanism of lymphopenia in SLE patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disorder with both genetic and environmental contributions to disease etiology. Patients with different ancestral backgrounds have different clinical presentation and severity, which likely result from variation in immune cell composition or response. Understanding the functional biology of the immune system in SLE patients with variable disease activity is critical to understanding the mechanisms behind disease activity.

Methods: European American (EA) SLE patients (n=20) and African American (AA) SLE patients (n=14) with elevated (SLEDAI >4) and suppressed (SLEDAI≤4) disease activity were matched to healthy controls. Using single cell proteomics by CyTOF, PBMCs were clustered using 33 markers and cell heterogeneity was visualized using viSNE in Cytobank. PBMCs were stimulated with either T cell receptor (anti-CD3/CD28) or B cell receptor (anti-IgG/IgM (Fab')2) stimulation and assessed for pERK, pPLCγ2, and p38 in cell subsets by flow cytometry. Plasma cytokine levels were assessed by 51-plex xMAP assays and ELISAs. FlowJo was used for flow cytometry analysis and Mann-Whitney test was used to compare non-normally distributed data. Analyses were performed using GraphPad Prism and TIBCO SpotFire. All SLE patients met at least 4 SLE ACR classification criteria.

Results: SLE patients were differentiated from healthy controls by elevated frequencies of HLA-DR+CD11c+ monocytes and dendritic cells (p=0.0248) and CD38-CD24-IgD+CD27- naïve B cells (p=0.0326). Compared to SLE-low patients, EA SLE-high disease activity patients had a higher frequency of CD4+ T cells (p=0.0433) and fewer CD56+ NK cells (p=0.0402), which correlated significantly with disease activity (p=0.0305 and p=0.0281, respectively). EA SLE-high disease activity patients also had decreased expression of the inhibitory receptor CD85j on monocytes and B cells (p<0.05), which correlated with elevated Th1, Th2 and Th17-type plasma cytokines (p<0.05). In contrast, AA SLE-high disease activity patients had no differences in NK cell frequencies or CD85j expression, but did have increased frequencies of effector memory CD4+ T cells (p=0.035). Further, CD4+ T cells in AA SLE-high disease activity patients had an

activated phenotype with higher frequencies of CCR6+ (p=0.0127), CD25+ (p=0.0181), CD127+(p=0.0253) and CXCR3+ (p=0.0350) CD4+ T cells compared to SLE-low patients. This activated CD4+ T cell phenotype in AA SLE-high disease activity patients correlated with elevated ICAM-1 (p=0.004) and diminished TGF-b (p=0.035) plasma levels compared to AA SLE-low patients. No significant differences in TCR or BCR signaling were observed between patients with high and low disease activity, but pro-inflammatory cytokines were significantly elevated in both EA and AA SLE-hi patients.

Conclusion: Our results support a model where differences in the regulation of monocytes and/or B cells are associated with SLE disease, but elevated cytokine production through activated CD4+ T helper cell pathways may contribute to heightened autoimmune disease activity in both European American and African American SLE patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The management of systemic lupus erythematosus (SLE) is complicated by a heterogeneous clinical presentation. Currently, mycophenolate mofetil (MMF) is a commonly used medication to treat major organ involvement in SLE, specifically in patients with lupus nephritis. The effectiveness of therapy is determined by clinical response, but the associated modulations of the lupus immune system in MMF responders are not known. This study assesses the systemic immunological changes that occur in SLE patients on MMF.

Methods: SLE patients currently receiving MMF (n=5) or not receiving MMF (n=15) were assessed in a cross-sectional design. Median disease activity and corticosteroid use was not significantly different between treatment groups. All SLE patients meet ACR criteria for classification of disease. Single-cell analysis of cell surface markers were completed by mass cytometry on PBMCs and cellular heterogeneity was visualized using viSNE in Cytobank. Further, phospho-specific flow cytometry was used to measure basal levels of pERK, pPLCγ2, pSTAT5 and p38 and expression following CD3/CD28 (TCR) and anti-IgG and IgM (BCR) stimulation. Soluble mediator levels in plasma were assessed using a 51-plex (Affymetrix) and by ELISA (eBioscience).

Results: Patients on MMF had significant reductions in transitional B cells (IgD+CD24+CD38+CD27-)(p=0.0143) and naïve B cells (IgD+CD38±CD24-CD27-)(p=0.0139) compared to SLE patients not taking this medication. In addition, activation of both monocytes (CD86+HLA-DR+)(p=0.0373) and B cells (CD86+CD19+CD20+) (p=0.05) were reduced in

patients on MMF compared to non-MMF patients. MMF patients also had elevated levels of T cells that expressed CD161 (p=0.0488), a marker known to identify a subset of T regulatory cells, which significantly correlated with increased IL-2 levels in plasma. MMF patients also had reductions in a number of plasma cytokines and soluble mediators including chemokines (MIG, RANTES), growth factors (VEGF-A, SDF-1α, PDGF-BB) and the adhesion molecule VCAM-1 compared to non-MMF patients (p<0,05). Following BCR stimulation, patients on MMF had reduced levels of pSTAT5 (p=0.0367).

Conclusion: Our results indicate that SLE patients on MMF have reductions in both the frequency and activation status of antigen presenting cells and pro-inflammatory soluble mediator pathways, which is accompanied by an increase in T regulatory populations. Together these data provide potential insights to MMF mechanisms of action in SLE patients, define changes in MMF treated patients with suppressed disease activity and suggest immunologic changes that may be found in patients on this background medication.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-system, complex disease believed to be triggered by gene-environment interactions. While we have made considerable progress in investigation of genetic risk for SLE, there remains much to learn about how the environment and genetic variation interact to create that genetic risk. Over 80% of the human genome is believed to express non-coding sequences. Of 46 single nucleotide polymorphisms (SNPs) shown to confer genetic risk for SLE in recent genome-wide association studies, 30 lie within non-coding regions of the human genome. We therefore sought to identify and describe the functional elements (aside from genes) located within these regions of interest.

Methods: We used a next-generation sequencing approach (chromatin immunoprecipitation (ChIP) followed by sequencing) to identify epigenetic marks associated with enhancer function (H3K4me1/H3K4me3/H3K27ac) in adult neutrophils to determine whether enhancer-associated histone marks were enriched within the linkage disequilibrium (LD) blocks encompassing the 46 SNPs of interest. We also interrogated available data in Roadmap Epigenomics for CD4+ T cells and CD19+ B cells to identify these same elements in lymphoid cells.

Results: All three cell types demonstrated enrichment of enhancer-associated histone marks compared to genomic background within LD blocks encoded by SLE-associated SNPs. In addition, within the promoter regions of these LD blocks, all three cell types demonstrated enrichment for transcription factor binding sites above genomic background. In CD19+ B cells, all but one of the LD blocks of interest were also enriched for enhancer-associated histone marks.

Conclusion: Regions of genetic risk for SLE contain functional genomic elements that are involved in the regulation and coordination of transcription on a genome-wide basis. These regions specifically are enriched for epigenetic marks associated with enhancer function, and appear to be correlated with active, dynamic regions of the genome as evidenced by the abundance of transcription factor binding in these regions of interest. Elucidating the specific roles of these non-coding elements within these cell-type-specific genomes will be crucial to our understanding of SLE pathogenesis.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In our previous work, we reported a link between interferon alpha inhibition and decreased expression of B cell activation genes in ex vivo whole blood samples from interferon kinoid-treated SLE patients. Here, we investigated the mechanisms underlying the effects of interferon alpha on B cell activation and differentiation.

Methods: PBMC and purified total (CD20+) or naïve (CD19+ CD20+ IgD+ CD27-) B cells were obtained from healthy controls and SLE patients. The effects of interferon alpha on B cell differentiation were studied by flow cytometry. STAT1 and STAT3 phosphorylation in CD20+ B cells (9 SLE and 5 control individuals) was evaluated by Western Blot. The role of STAT3 on B cell responses to interferon alpha was studied using pharmacological inhibitors (STA21 and S31201) and PBMC from STAT3-deficient individuals (n=5).

Results: Spontaneous levels of STAT3, but not STAT1, phosphorylation were significantly higher in total B cells from SLE patients compared to controls. In purified naïve B cells from controls, interferon alpha induced STAT1 and STAT3 phosphorylation. Interferon alpha also displayed direct stimulatory effects on purified naïve B cells from healthy individuals, as evidenced by a significant induction of cell surface CD38 and CD95 in the presence of the cytokine. Incubation of normal PBMC with interferon alpha induced a B cell differentiation pattern as observed spontaneously in SLE PBMC: decreased naïve, decreased unswitched memory, increased switched memory cells and increased plasmablasts. In addition, expression of cell surface CD95 was significantly induced by interferon alpha in all these B cell sub-populations, except in plasmablasts (unstimulated plasmablasts highly express CD95). Interferon alpha-induced B cell differentiation in total PBMC was significantly inhibited in the presence of STAT3 inhibitors, or in PBMC from STAT3-deficient patients.

Conclusion: Interferon alpha displays direct stimulatory effects on B cell differentiation and activation in SLE. STAT3

phosphorylation mediates the effects of interferon alpha stimulation in naïve B cells, an observation that opens new therapeutic perspectives in SLE.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Type I interferon (IFN) has been implicated in SLE pathogenesis, and the majority of subjects with SLE have elevated expression of type I IFN-inducible genes in their blood. Anifrolumab, a fully human, IgG_1 κ monoclonal antibody against the type I IFN receptor, is in Phase III clinical trials for the treatment of moderate to severe SLE (NCT02446912 and NCT02446899). Understanding other molecular pathways, either dependent on or independent of type I IFN signaling, is critical to elucidating heterogeneous mechanisms in SLE and to identifying subject subsets for personalized disease management.

Methods: Baseline blood samples from adult subjects with moderate to severe SLE from two Phase IIb clinical studies (NCT01438489; N=265, NCT01283139; N=416) were profiled with whole genome array analyses. Type I IFN gene signature status (high or low) was determined by a central laboratory utilizing an analytically validated four gene (*IFI27, IFI44, IFI44L, RSAD2*) qPCR-based test from subjects' whole blood. A predetermined, delta Ct-based cut-off point, in the trough of the bimodal distribution, was utilized to segregate IFN-high from IFN-low subjects at baseline. Blood from healthy controls was stimulated *ex vivo* with IFN-β, IFN-γ, IFN-λ, IFN-ω, or a pool of all IFN-α subtypes, with or without blocking antibodies for each IFN type, to develop IFN-type-specific signatures. Ninety additional cell type and cytokine pathway specific gene signatures derived from the literature were also evaluated with the Phase IIb sample data. A Fisher's exact test was used for enrichment calculations (signatures cut at median), and comparisons were adjusted for multiplicity through false discovery rate.

Results: 79% of SLE subjects in the combined study population were determined to have an elevated type I IFN gene signature. From the type I IFN signature high subjects, 29/95 signatures evaluated had significant enrichment, including those for B cells (q=1.17E-17, OR=6.4), plasma cells (q=6.96E-11, OR=3.9), and CD40L signaling (q=1.07E-08, OR=3.3), relative to type I IFN-low subjects. In stark contrast, type I IFN signature low subjects had enrichment for eosinophils (q=5.4E-6, OR=0.39), and type II IFN (IFN-γ) specifically inducible gene signatures (q=4.6E-3, OR=0.47). These findings were significant in the combined study population, as well as the NCT01438489 study population, and were either significant or similarly trending for the NCT01283139 population (q<0.05).

Conclusion: SLE subjects who are type I IFN high, had elevated concentrations of B cell, plasma cell, and other inflammatory cytokine pathways. Type I IFN-low subjects, by contrast, were enriched for eosinophil and type II IFN pathways. These observations provide new insights into the molecular heterogeneity underlying SLE and suggest new therapeutic approaches, particularly for type I IFN signature low subjects.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: $CD4^+$ T cells play a crucial role in pathological process of Systemic Lupus Erythematosus (SLE). Recently, importance of metabolic reprograming in immunocompetent cells was highlighted. We found that preferential induction of T-bet by IFN-γ is an important factor for shift to glycolysis in activated $CD4^+$ T cells in vitro. In this study, we examine the mechanism by which IFN-γ and T-bet in $CD4^+$T cells involved in pathogenesis of SLE.

Methods: Peripheral blood mononuclear cells were obtained from 19 healthy controls (HCs), 30 patients with bio-naïve active RA and 60 patients with active SLE. The expression of CXCR3, T-bet, mTORC1 phosphorylation and IFN-γ production in $CD4^+$T cells were measured by flow cytometry, and assessed the correlation with clinical characteristics.

Results: We found that $CD4^+$ T cells consisted of 3 subsets of $CD28^+CXCR3^{lo}$ T-bet^{lo} cells (R1), $CD28^+CXCR3^{hi}$T-bet^{int} cells (R2), $CD28^-CXCR3^{int}$T-bet^{hi} cells (R3). The percentage of R3 in SLE patients was significantly higher compared to HCs (HCs; 1.1±0.2%, RA; 5.5±1.8%, p=0.06, SLE; 5.6±1.1%, p=0.02). $CD4^+CD28^-CXCR3^{int}$T-bet^{hi} cells mainly consisted of $CD45RA^-CCR7^-$ effector memory cells and were significantly activated compared to other subsets ($HLA\text{-}DR^+CD38^+$ cells; R1: 2.8±0.6%, R2: 11.2±1.5%, R3: 27.6±2.3%, p<0.0001, ANOVA). $CD4^+CD28^-CXCR3^{int}$T-

bet^{hi} cells from SLE patients showed pronounced IFN-γ production compared to HCs (T-bet^{hi} IFN-γ^{+} cells; HCs: 1.1±0.4%, RA: 1.7±0.6%, p=0.50, SLE: 5.6±1.3%, p=0.04). Interestingly, the ratio of CD4^{+}CD28^{-}CXCR3^{int}T-bet^{hi} cells was significantly correlated with the number of immunosuppressants previously used for the SLE patients, that is treatment-resistant (p=0.03, logistic regression analysis). Phosphorylation of mTORC1, which is important for shift to glycolysis, in CD4^{+} T cells from patients with RA and SLE was significantly increased compared to HCs (ΔMFI of p-mTORC1; HCs: 284.9, RA: 563, p=0.01, SLE: 511.7, p=0.03). T-bet expression was significantly correlated with mTOC1 phosphorylation and IFN-γ production in CD4^{+}T cells from patients with SLE (p-mTORC1: r=0.4718, p<0.01, IFN-γ production: r=0.4915, p=0.01, Pearson).

Conclusion: These results indicated that CD4^{+}CD28^{-}CXCR3^{int}T-bet^{hi} cells might be related to refractory to established therapies in patients with SLE. In addition, these cells are constitutively activated accompanied with shift to glycolysis through IFN-γ-mTORC1-T-bet pathway. We highlight CD4^{+}CD28^{-}CXCR3^{int}T-bet^{hi} cells and their metabolic reprogramming as a potential target for pathological process in SLE.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IFN-alpha is a pathogenic factor in SLE. High serum interferon activity (IFN-high) marks a subgroup of SLE patients strongly associated with double-stranded DNA (dsDNA) antibodies. However, the pathologic differences between IFN-high patients remain largely unknown. It is likely that IFN-high versus IFN-low patients will have differences in basic disease biology and will exhibit different responses to treatment. In this study, we sought to better characterize the IFN-high and IFN-low subgroups in human SLE by studying the stimulated cytokine responses post whole blood stimulation by Toll-like receptor (TLR) agonists.

Methods: SLE patients (n= 32) meeting ACR criteria for SLE and healthy controls (n=10) were recruited. Serum IFN-activity scores were calculated using the WISH assay and used to bin patients as IFN-high and IFN-low. Whole blood was dispensed into tubes coated with the TLR agonists LPS, CpG and R848 (Tru-Culture.) The stimulated IFN-alpha production was measured by WISH. Cytokine production in patient sera and after whole blood TLR stimulation was measured by bead-based multiplex assay.

Results: Of the 32 patients studied, 9 were IFN-high and 23 were IFN-low. Compared to IFN-low, IFN-high tended to be younger (27.3 versus 54.3 years), more associated elevated dsDNA titers (62.5% vs. 47.6%) and low C4 levels (62.5% vs. 13.0%). Usage of hydroxycholorquine and prednisone was similar between groups. Principal component analysis on cytokine levels in SLE patient sera identified distinct clusters according to serum IFN activity. IFN-high patients responded more dramatically to the TLR-4 agonist LPS than IFN-low ($p<0.05$), and controls ($p=0.05$). Post TLR-4 stimulation, IFN-high patients produced more CXCL9 ($p=0.025$), and less IL-12 ($p=0.015$) and VEGF ($p=0.015$) than IFN-low patients. In addition, post TLR-4 stimulation, VEGF and IL-1beta ($p=0.0003$) and VEGF/IL-12($p=0.002$) were positively correlated in the IFN-high group, but not in the IFN-low group. In the IFN-low group, very different cytokine clusters emerged featuring IL-17, for example; IL-17/IL-4 ($p<0.0001$) and IL-17/IL-5 ($p<0.0001$).

Conclusion: We have observed clinical and novel biologic differences between IFN-high and low SLE subgroups. High-IFN SLE patients tend to be younger and more serologically active than their low-IFN counterparts. We demonstrate that IFN-high patients are significantly more responsive to TLR4 stimulation and produce a distinct inflammatory cytokine profile post TLR4 stimulation compared to IFN-low SLE. A recent study demonstrated that anti-dsDNA antibodies bind to TLR4 to activate the NLRP3 inflammasome in monocytes from SLE patients, and this interaction was associated with elevated IL1b and IL-17 secretion (Zhang et al. J Transl Med,2016, 14:156). Taken together with our preliminary findings, this suggests the novel possibility that the NLRP3 inflammasome is aberrantly or differentially activated in IFN-high compared to IFN-low SLE, and may offer novel insight into SLE pathogenesis and targeted treatment. Further studies directed at inflammasome activation in the context of IFN-high and IFN-low SLE are underway.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although the increased expression of type I interferon (IFN)-inducible genes, called “IFN signature”, has been suggested to have important roles in the pathogenesis of systemic lupus erythematosus (SLE), its mechanism still remains unclear. Recent studies in vitro or with mice suggest that tripartite motif-containing 21 (TRIM21), an autoantigen also called Ro52 or SSA1, is involved in the regulation of type I IFN production as an E3 ubiquitin ligase for IFN regulatory factors (IRF). Here, we investigated the pathological role of TRIM21 in SLE.

Methods: We collected peripheral blood mononuclear cells (PBMC) from 20 patients who met the 1997 ACR SLE

classification criteria and 24 healthy controls (HC), and analyzed the mRNA expression of TRIM21, type I IFNs, type I IFN-inducible genes by qPCR. We also quantified protein levels of TRIM21 and IRF proteins in the PBMC from SLE patients and HC by Western blot analysis. To evaluate the degree of ubiquitylation of IRF proteins, PBMC were incubated with a proteasome inhibitor MG-132.

Results: There were no significant differences in age and sex ratio between patients with SLE and HC (41.2 ± 13.9 vs 34.1 ± 10.4 years, $p = 0.09$, and 67% vs 75% (female), $p = 0.73$, respectively). Seven patients (35%) with SLE had anti-TRIM21 autoantibody while all of HC were negative for anti-TRIM21 antibody. The mRNA and protein levels of TRIM21 were significantly higher in PBMC from patients with SLE as compared to HC. Although transcript levels of multiple genes including *MX1*, *IFI27*, *IFI44* and *SIGLEC1*, known as type IFN-inducible genes, were significantly higher in patients with SLE as compared to HC, there was no significant difference in mRNA levels of type I IFNs themselves between SLE and HC. In HC, IFN-α and IFN-β mRNA levels were negatively correlated with the level of TRIM21 transcript ($r = -0.52$, $p = 0.0087$, and $r = -0.48$, $p = 0.018$, respectively). On the other hand, there was no significant correlation between TRIM21 transcript level and IFN-α mRNA ($r = 0.21$, $p = 0.37$) or IFN-β mRNA level ($r = 0.24$, $p = 0.30$) in SLE. To investigate the degrees of ubiquitylation of IRF proteins, PBMC from patients with SLE and HC were incubated with MG-132. Although the protein expression levels of IRF3 and IRF5 were significantly increased by MG-132 in PBMC from HC, the effect of MG-132 was not observed in PBMC from SLE patients.

Conclusion: This study suggests that dysregulation of E3 ubiquitin ligase activity of TRIM21 for IRF proteins may be associated with the increased expression of type I IFN-inducible genes in SLE.

A Novel Graph Theoretic Approach Applied to Modular Repertoire Analysis Identifies a Dual Molecular Progression in Adult SLE Patients, with Distinct Interferon and Neutrophil Transcription Patterns

Ilya Korsunski[1], Noémie Jourde-Chiche[2,3], Peter K. Gregersen[1], Damien Chaussabel[4], Laurent Chiche[5] and Naomi I Maria[6], [1]Center for Genomics and Human Genetics, Feinstein Institute for Medical Research, Manhasset, NY, [2]Vascular Research Center of Marseille, Aix-Marseille Univ., Vascular Research Center of Marseille, Marseille, France, [3]Nephrology, AP-HM, Department of Nephrology, CHU Conception, Marseille, France, [4]Translational Medicine, Sidra Medical and Research Center, Doha, Qatar, [5]internal medicine, Hopital Europeen, Marseille, France, [6]Center for Autoimmune and Musculoskeletal Diseases, Feinstein Institute for Medical Research, Manhasset, NY

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gene expression studies support a pivotal role for type I interferon (IFN) in SLE. Previous work using a modular repertoire analysis based on co-clustered gene sets, has demonstrated that the SLE IFN signature is not restricted to a type I IFN signature, but involves the gradual activation of 3 distinct IFN modules (M1.2, M3.4 and M5.12) driven by various IFN types. The aim of this study was to refine and discover novel modular interactions in adult SLE

patients.

Methods: Consecutive SLE patients fulfilling the ACR criteria were enrolled (n=157 samples). Disease activity (DA) was measured according to the SELENA-SLEDAI score. Microarray data were generated using Illumina beadchips. Modular repertoire analyses were performed using the second generation of a blood modular framework comprising 260 modules. Modules with 20% transcripts differentially expressed compared to healthy matched controls were considered active. A novel graph theoretic approach, previously applied to the analysis of somatic evolution in cancer (unpublished), was used to generate an ordered, branching progression model of modular activation in which upstream module activity predisposes the activation of downstream modules. An SLE-specific graph based on module activation in our dataset was built in order to generate hypotheses regarding disease progression in SLE. Trajectories of a focused subgraph were enumerated and samples were clustered to their most likely trajectory group. Significance to clinical characteristics was evaluated using Fisher's exact test and ANOVA, for categorical and continuous characteristics, respectively.

Results: The graph theoretic analysis revealed two distinct patterns involving IFN and neutrophil related modules. Both patterns involved the upregulation of M1.2 followed by M3.4. At this point, the patterns split into the activation of either M5.12 or the M5.15 neutrophil module. Along the shared trajectory, we observed a monotonic increase in DA, dsDNA titers, and corticosteroid dosage. The subjects on the neutrophil (M5.15) trajectory had a marked increase in DA and corticosteroid dosage, although dsDNA levels were unchanged. Moreover, the neutrophil trajectory also had a larger ($p=0.04$) enrichment for renal involvement (80%) than the M5.12 IFN trajectory (40%).

Conclusion: Our analysis revealed a refinement within the hierarchical structure of the peripheral blood IFN modules previously described. Two subgroups, defined by progression along disjoint paths bolstered by their association to overall DA, active nephritis, dsDNA levels, and corticosteroid dosage, are identified. This suggests a dual mode of disease progression in SLE, with either the completion of IFN signature (to include IFNγ) or the activation of neutrophil path associated with renal involvement. Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone marrow mesenchymal stromal cells (MSCs) are multipotent stem cells that create a special microenvironment for hematopoiesis and immunity. MSCs display robust immunomodulatory properties and transplantation

of human MSC significantly improves nephritis in murine models of lupus. Immunomodulation by MSCs from lupus patients appears to be impaired, but the mechanisms underlying this defect is unknown. Our previous studies identified an IFN-I signature in SLE bone marrow (BM) and peripheral blood. In fibroblasts, prolonged treatment with IFNb, but not IFNα, has been shown to induce senescence through activation of reactive oxygen species (ROS), ATM and p53 DNA damage and repair (DDR) pathways. Here we investigate whether human SLE MSCs undergo senescence, the potential role of IFNb as a mediator in the SLE BM, and the implications for SLE pathogenesis.

Methods: SLE patients fulfilling ACR classification criteria and healthy controls were recruited under an IRB approved protocol (n=6 each). BM MSCs were isolated with low density Ficoll/Hypaque (1.073 g/ml) and grown in tissue culture. MSC phenotype was verified by flow cytometry. MSCs were studied using immunocytochemistry, real-time PCR, western blotting, comet assay for DNA damage, beta-galactosidase assay and RNA interference.

Results: The expression of IFNb was increased 5 folds ($p<0.05$) and IFNβ specific genes were significantly elevated in SLE MSCs. In addition, SLE MSCs displayed significantly reduced proliferation rate, increased production of ROS, increased DDR, and senescence associate secretory phenotype (SASP) as evidenced by increased cytokine production (all $p<0.05$): IL6 (4x), IL8 (8x), GRO1(9x), MCP2 (7x), RANTE1 (5x), GM-CSF (7x). The expression of immunomodulatory factors was significantly reduced (all $p < 0.05$): TGFβ (4x), IDO1 (3x) and LIF (10x). To begin to explore the signalling pathways that may mediate IFNB activation and DNA damage, we examined the level of Mitochondrial Antiviral Signaling Protein (MAVS), an intracytoplasmic nucleic acid sensor (also known as Interferon Beta Promoter Stimulator Protein 1). MAVS was positively correlated with the level of IFNb ($r > 0.9$, $p< 0.01$)， and strikingly, silencing MAVs inhibited IFNb expression and reversed the SASP in SLE MSCs.

Conclusion: The relative contribution of IFNα vs. IFNb to SLE disease pathogenesis remains unclear. IFNb has distinct features as compared to IFNα with higher affinity binding to IFN-I receptors, distinct gene transcripts and induction of senescence in fibroblasts. Our current data suggest that SLE BM MSCs produce IFNb, have increased ROS, DDR and SASP, decreased production of immunomodulatory factors, and elevated levels of MAVS. As a key regulator of IFNb expression, the expression of MAVS is highly correlated with the expression of IFNb. In addition, silencing MAVS disrupts IFNb production and rescues SASP in SLE MSCs. Our novel findings of an IFNb positive feedback loop and related SASP in SLE BM MSCs highlight a novel role for IFNb activation in SLE pathogenesis. Moreover, the essential role of MAVS in the IFNb positive feedback loop suggests dysregulated intracytoplasmic nucleic acid sensing and potential novel therapeutic targets for SLE treatment.

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ro60/TROVE2 is a clinically important member of the nuclear antigen family. It binds synergistically YRNAs, allowing the formation of a stable complex with exoribonuclease polynucleotide phosphorylase. The main known function of TROVE2 is so to perform a quality control of misfolded ncRNA (such as Alu RNAs and pre-5S rRNAs), enhancing the cell survival. For that, anti-TROVE2 antibodies are major targets of the immune system in SLE patients and can be identified years before the disease manifestation, providing advantage of an early diagnosis. Epitope mapping studies showed that TROVE2 has an immunodominant epitope between 169-190 a.a. These amino acids reside in a loop involved in binding single-stranded RNA, so anti-TROVE2 antibodies target a key part for its functional mechanism. Hence, although the underlying cause of the disease is not fully defined, SLE is related to the cellular function of the TROVE2 protein. In this work, we analyze the host-guest binding of the TROVE2-autoantibody system in SLE patients and healthy subjects.

Methods: Cross-sectional prospective study of 20 SLE patients diagnosed according to the SLICC-ACR2012 criteria, from the Rheumatology Department of La Fe Hospital. All patients showed high anti-Ro Ab (SSA) concentrations (>200,0 U/mL). We have also taken 8 healthy individuals as negative controls, who had anti-Ro Ab concentrations <15 U/mL. A sensitive TROVE2-based QCM-D biosensor was developed.

Results: Pre–steady–state analysis revealed an antibody bipolar bridging mechanism for the host-guest binding of the TROVE2-autoantibody system, for the first time. Although Fc receptors (such as Fc-gamma receptors) do not exist on the protein surface, its MIDAS motif is the Fc receptor exposed when the epitope-paratope binding takes place initially. In this molecular recognition, the protein hydration shell dynamics plays also an important role. Furthermore, we demonstrate that the TRIM21a:TROVE2 association is a calcium-dependent adhesion system. Thus, the 'bridging' role in the TROVE2 bound, a feature of pathogenic superantigens, leads to the inhibition of the biological function of the Ro/SSA ribonucleoprotein. The MIDAS motif acts as a YES logic gate, having a key role in the intracellular antibody signaling, activating, or deactivating, the innate immune system.

Conclusion: Our results suggest a distinct pathway of induction of anti–TROVE2 autoimmunity in SLE patients. The different interaction mechanism of autoantibodies in SLE patients would suggest a majority necrosis-induced specificity, and not apoptosis as in healthy subjects. Anti-TROVE2 cell-penetrating autoantibodies will so induce the inhibition of degradative activity of the TROVE2 autoantigen in SLE disease. This one would imply the accumulation of the Alu RNAs, stimulating intracellular RNA sensors to induce inflammatory responses. The originated increase of calcium intracellular level favors the TRIM21a-TROVE2 binding through the PRYSPRY domain and therefore, an inhibitory effect on the TRIM21 physiological function. Financial support by GVA (PROMETEO II 2014/040 and GV15/83 project) and from MINECO and FEDER (CTQ2013-42914-R project) is acknowledged

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The earliest autoantibodies in lupus are directed against the autoantigen Ro60, an RNA binding protein with orthologs that we identified in a subset of skin, oral, and gut commensal species. Thus we hypothesized that commensal Ro60 orthologs may trigger autoimmunity via epitope cross-reactivity in genetically susceptible individuals.

Methods: V4 16S rDNA samples from SLE and control subjects were sequenced using 2x250bp paired-end reads on the Illumina MiSeq platform and also tested for species-specific enrichment for Ro60 bacteria by real-time PCR. Co-immuniprecipitation was performed using human SLE serum and Ro60 ortholog-containing *Propionibacterium propionicum* and *Bacteroides thetaiotaomicron* lysates. A northern blot of the resulting RNA was probed for bacterial Y RNA. Memory CD4 T cells from SLE patients were sorted into CCR6+ and CCR6- populations. Ro60-specific T cell clones were isolated and stimulated with heat-killed bacteria. Germ-free mice in gnotobiotic isolators were monocolonized by oral gavage with *B. thetaiotaomicron*. Serum was tested for anti-Ro60 antibodies by ELISA. Lymphocytes from mesenteric lymph node and spleen were stimulated with recombinant Ro60 and proliferation was assessed using a luminescent cell viability assay.

Results: Ro60-producing oral and gut commensals were prevalent in healthy controls and lupus patients. However, when human serum was used to co-immmunoprecipitate Ro60 and its bound Y RNA from a skin commensal, *P. propionicum*, only antibodies from human Ro60-positive lupus patients bound commensal Ro60. Lack of reactivity in Ro60-negative patients or healthy controls suggested antibody cross-reactivity between human and commensal Ro60. Next, Ro60 autoantigen-specific CCR6+ and CCR6- CD4 memory T cells clones from lupus patients were isolated and expanded using a T cell library assay. Ro60 T cell clones positive for the tissue-homing marker CCR6 proliferated in response to *P. propionicum*, demonstrating T cell cross-reactivity with commensal Ro60. Finally, germ-free mice were monocolonized with *B. thetaiotaomicron*. Mesenteric lymph node and spleen cells from monocolonized mice proliferated in response to bacterial Ro60 and sera contained anti-human Ro60 IgG antibodies.

Conclusion: Ro60 autoimmune T and B cells from human lupus patients reacted with commensal Ro60 *in vitro*, and commensal Ro60 triggered anti-human Ro60 responses *in vivo*. Taken together, these data support that colonization with autoantigen ortholog-producing species may induce and sustain chronic autoimmunity in lupus. This concept may apply more broadly to human autoimmune diseases and could lead to development of novel microbiota-targeted approaches to treat autoimmunity.

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Nucleotide-binding oligomerization domain (NOD) - containing 2 (NOD2) is a NOD - like receptors (NLRs) which plays important role in immune regulation and inflammatory response. There are increasing evidences to show that NOD2 may contribute to the development of numerous auto inflammatory and autoimmune disorders. However, their role in lupus nephritis (LN) is not known. Here, we explored the role of NOD2 in LN.

Methods: Immunohistochemistry was applied to observe the expression of NOD2 in renal biopsies. Real-time quantitative polymerase chain reaction (RT-qPCR) was used to detect the level of NOD2 mRNA in the biopsies. In vitro studies, HK-2 cells (renal tubular epithelial cell-line) were cultured with different inflammatory stimulation, western blot was used to investigate their expression of NOD2 and the following activation of MAPK pathway signals (ERK1/2, p38 and JNK), real-time qPCR was applied to observe the mRNA levels of downstream pro-inflammatory mediators (IL-1b, IL-8, MCP-1, TGF-b1, IL-6) .

Results: (1) Immunohistochemistry staining demonstrated that the expression of NOD2 in LN is higher than that of normal control ($P=0.002$), and the mRNA level of NOD2 in renal tissue of LN patients was higher than that of normal control ($P=0.001$). (2) In vitro studies, the urine and serum from onset LN patients can significantly promote higher NOD2 expression in HK2 cells than that from healthy control ($P<0.001$). In addition, TGF-b1, LPS and muramyl dipeptide (MDP) can also induce higher NOD2 expression in HK2 cells ($P<0.001$, respectively). (3) The activation of NOD2 increased phosphorylation of ERK1/2, p38 and JNK. Moreover, the activation of NOD2 induced the release of pro-inflammatory mediators including IL-1b, IL-8, MCP-1, TGF-b1, IL-6.

Conclusion: Our study showed NOD2 expression was increased in LN patients. The activation of NOD2 can promote the activation of MAPK signaling pathway and release of downstream pro-inflammatory mediators. NOD2 may participate in the pathogenesis of LN.

SLE Bone Marrow Contains Factors That Promote Type I Interferon Activation

Nida Meednu[1], Anna Bird[2], Jennifer Barnard[2], Mariana Kaplan[3] and Jennifer H. Anolik[2], [1]Medicine- Allergy, Immunology and Rheumatology, University of Rochester Medical Center, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY, [3]NIAMS/NIH, Bethesda, MD

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is characterized by the inappropriate activation of type I Interferon (IFN) and increases in apoptosis and NETosis by neutrophils, which in combination with defective apoptotic cell and NET clearance provides an ongoing source of self-antigen. IFN further propagates the disease process by promoting B cell activation, survival, and differentiation into plasma cells (PC). PC produces autoantibodies that form immune complexes (IC) to further stimulate IFN production creating a vicious cycle. Important questions that remain unclear are the site and mechanisms of IFN activation. We have recently demonstrated a prominent IFN signature in the bone marrow (BM) of SLE patients that is more pronounced than paired peripheral blood and correlated with higher serum autoantibodies and disease activity. We hypothesize that BM is a key site of IFN activation in SLE.

Methods: BM supernatant (BMS) and serum were obtained from SLE patients (n=11) and healthy controls (HC, n=4). Plasmacytoid dendritic cells (pDC) were purified from healthy donor blood. To determine if BMS and serum induce IFN production, pDC was cultured with 5% BMS or serum with and without necrotic cell material. Necrotic cell material was generated by repeat freeze-thawed U937 cells. Culture supernatants were collected and IFNα was measured by ELISA. Blocking experiment was performed using 10ug/ml Hydroxychloroquine and 5ug/ml anti-CD32.

Results: We found that BMS from 27% of SLE patients was able to induce pDC to produce IFNα even without adding necrotic cell material (BM: 7.9±2.5, BM + necrotic: 7.7±2.1 ng/ml, n=3). The serum from the same patients also induced pDC to produce IFNα, but this effect was greatly enhanced by necrotic cell material (serum: 5.0±2.3, serum + necrotic: 256.46±153.54 ng/ml, n=3). BMS from 36% of SLE patients did not induce IFN production even with necrotic cell material (BM+necrotic: 0.014±0.007 ng/ml, n=4) although paired serum was able to do so with added necrotic cell material (serum+necrotic: 19.25±9.24 ng/ml, n=4). In contrast, neither BMS nor serum from 36% of SLE was able to induce IFNα production by pDC (serum+necrotic: 0.003±0.001, BM+necrotic: 0.0028±0.0018 ng/ml, n=4). BMS and serum from HC did not induce pDC to produce IFN (serum+necrotic: 0.0007±0.0007, BM+necrotic: 0.0045±0.0042 ng/ml, n=4). Serum autoantibodies were higher in the IFN inducer SLE subjects (average number of autoantibodies present for non-IFN inducer= 1 vs. 3.57 for IFN inducers, p=0.01). The ability of SLE BMS and serum to induce IFN was dependent on endosomal toll-like receptors as treating pDC with hydroxychloroquine inhibited IFN production. The induction was also blocked by anti-CD32 suggesting dependency on FcγRIIa. The relationship to the IFN signature and NETosis is under evaluation. Additionally, we are examining ICs as interferogenic factors in the BM.

Conclusion: These data suggest that the SLE BM contains factor(s) that promote type I IFN production by pDC that correlates with the presence of serum autoantibodies. The mechanisms of IFN induction in the BM appear to be dependent on TLR and FCR signalling and may relate to the presence of immune complexes generated in situ.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with marked disparities in prevalence and disease characteristics among different populations. Those disparities are believed to result from both genetic and environmental factors. The purpose of this study is to identify genetic susceptibility alleles for SLE in the Dominican Republic (DR) population which has a high prevalence for SLE.

Methods: SLE patients (n = 208) who fulfilled the 1997 revised American College of Rheumatology criteria for the classification of SLE and age/sex-matched healthy controls (n = 205) from the DR were recruited for this case-control study. Genomic DNA was prepared from whole blood and subjected to Sequenom MassARRAY iPLEX genotyping analyses for 42 selected single nucleotide polymorphisms (SNPs). The allele frequencies in SLE patients and healthy controls were compared using Pearson Chi-Square or Fisher's Exact test.

Results: Among the 19 human leukocyte antigen (HLA) gene alleles analyzed, HLA-DQA1 (rs 9271366) shows the strongest association with SLE (OR = 5.48, $p = 0.0001$, Pearson Chi-Square test). SNPs at HLA-DRA (rs6903608, rs9268880, and rs9268979) and HLA-DRB2 (rs9271055) also contribute to SLE susceptibility in the DR population ($p = 0.0086$, OR = 2.09; $p = 0.0061$, OR = 2.21; $p = 0.0012$, OR = 2.86; and $p = 0.0059$, OR = 3.27, respectively). Among the 23 non-HLA gene alleles analyzed, SNP1858C/T (rs2476601) in the tyrosine phosphatase, non-receptor type 22 (PTPN22) gene shows the highest odds ratio for SLE (OR = 6.54, $p = 0.038$, Pearson Chi-Square test). SNPs in the STAT4 gene (rs11889341), PMS2 gene (rs1860460), and TNFSF4 gene (rs2205960) also contribute to SLE susceptibility in the DR population ($p = 0.025$, OR = 2.2; $p = 0.032$, OR = 1.7; and $p = 0.035$, OR = 2.39, respectively). However, SNPs in the IRF5 (rs12537284 and rs2070197), BLK (rs13277113), and TNFAIP3 (rs 5029939) genes that have been frequently identified as SLE susceptibility alleles in other populations do not show association with SLE in the DR population ($p = 0.824$, 0.4, 0.468, and 0.896, respectively).

Conclusion: SNPs in the HLA-DQA1, HLA-DRA, and HLA-DRB2 alleles and non-HLA genes PTPN22, STAT4, PMS2, and TNFSF4 contribute to SLE susceptibility in the DR population. However, SNPs in the IRF5, BLK, and TNFAIP3 genes may not contribute to SLE susceptibility in the DR population. This is the first study focusing on SLE patients from the DR who may have unique genetic risk factors for the development of SLE.

Session Date: Monday, November 14, 2016
Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Bacterial infections are a major contributor to morbidity and mortality in SLE, a known trigger of flares and they are often difficult to distinguish from lupus flares as a definitive biomarker is still lacking. Urinary tract infections (UTIs) such as those due to uropathogenic *E. coli* (UPEC), are characterized by the generation of a unique form of amyloid called curli. We have previously demonstrated that curli amyloid can induce or accelerate disease in mouse models of SLE. Curli can strengthen the structure of biofilms and integrate extracellular DNA, which in turn can be both adjuvant and a self-antigen in lupus patients. Curli can elicit a humoral response against themselves. Based on our previous results, we hypothesize that SLE patients can generate anti-Curli/DNA antibodies and that they correlate with flares

Methods: We investigated 34 lupus patients who met at least 4 SLICC criteria, 29 women and 5 men. 17 sex matched healthy controls were used. We developed a novel ELISA to detect anti-curli antibodies by using the curli/DNA complex as antigen. We tested IgG and IgA subclasses. We also performed competitive ELISAs to determine if curli/DNA antibodies cross reacted with classic lupus autoantibodies. Finally, we correlated the levels of anti-curli/DNA antibodies with several clinical parameters including anti-dsDNA antibodies, bacteriuria and disease flares (SLEDAI). Flares were calculated as an increase of at least 3 points in the SLEDAI from the prior visit.

Results: We found that Lupus patients and healthy controls generated anti-curli antibodies of both IgG and IgA subclasses. We also found that anti-curli antibodies recognized human chromatin but not dsDNA. Interestingly, female lupus patients had significant higher levels of anti-curli antibodies than female controls and males with lupus ($p=0.047$ and $p=0.026$ respectively). Remarkably, higher levels of anti-curli antibodies significantly correlated with the levels of anti-dsDNA antibodies ($p=0.029$), persistent bacteriuria ($p=0.035$) and lupus flares ($p=0.024$).

Conclusion: Taken together these results demonstrate that both healthy controls and lupus patients are exposed to curli-forming bacteria and generate systemic and mucosal immune responses (IgG and IgA subclasses) against curli. Moreover, women with SLE have much higher levels of anti-curli antibodies than men possibly due to higher rate of urinary tract infection, especially by *E. coli*. Since many female patients had persistent bacteriuria, bacterial colonization could be a significant pathogenic mechanism in lupus. Finally, the levels of anti-curli antibodies in lupus patients are a promising biomarker of flares.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with protean manifestations,

characterized by production of antibodies against nucleic acids and upregulation of type I interferon-inducible genes in a majority of SLE patients. The principal drivers of this interferon signature are still not well understood. Recent work has shown that oxidized mitochondrial DNA released by neutrophils can stimulate plasmacytoid dendritic cells to produce interferon-α. (1) We hypothesized that cell-free mitochondrial DNA might contribute to type I interferon production in SLE, and we sought to examine whether cell-free mtDNA levels were increased in SLE patients relative to controls, or during disease flares.

Methods: A retrospective analysis was performed using banked plasma samples from 164 patients in the FLARE SLE cohort along with 57 banked plasma samples from healthy donors. All patients in the FLARE cohort meet 4/11 ACR SLE classification criteria. DNA was isolated from the plasma samples and real-time quantitative PCR was performed, amplifying a target sequence in the mitochondrially-encoded gene NADH dehydrogenase I, as previously published. (2) In-depth clinical phenotyping of SLE patients in the cohort was performed and used to define subgroups of SLE patients, as well as the specific disease manifestations present during flares.

Results: No significant difference was seen in cell-free mtDNA in plasma from SLE patients versus healthy donors (HD - 3060.3 copies/uL, N=57, SLE - 3845.5 copies/uL, N=164, p=0.22). However, cell-free mtDNA levels were elevated in a subset of SLE patients with a history of membranous lupus nephritis, including those with a component of proliferative nephritis (WHO class V/III+V/IV+V), relative to patients with proliferative nephritis alone (WHO class III or class IV) (5313.9 copies/uL, N=34 vs. 2062.5 copies/uL, N=17, p=0.02). A subset of 70 patients had multiple samples collected at visits before, during, and after flares of disease activity. Cell-free mtDNA levels rose at the peak of disease activity as assessed by SLEDAI score in 11/16 flares of class V/III+V/IV+V nephritis (p=0.04), while it only did so in 4/11 of the remaining nephritis flares. In contrast, cell-free mtDNA rose at the peak of disease activity in only 4/20 flares where alopecia was present (p=0.02).

Conclusion: Cell-free mtDNA levels are elevated in a subset of SLE patients with a history of membranous nephritis, and were more likely to rise during flares of membranous nephritis versus other types of disease flares. Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The pathogenesis of SLE involves disturbances to the homeostatic balance between the immune effector and regulatory system. The conventional mono-dimensional mechanistic interrogation of one cell type or molecule at a time is inadequate for a multifactorial disease such as lupus where multiple derangements contribute to disease causation and progression. The ability to scrutinise multiple components and both arms of the immune balance simultaneously is a critical unmet need. We hypothesise that abnormalities of different components within the immune-regulatory mechanism contributes to lupus pathogenesis. To address such unmet needs and hypotheses, we employed a multi-dimensional approach to study the immunome of jSLE patients. This approach may have immediate translational value of identifying immune cell subsets relevant for clinical prognostication and elucidation of mechanism to single out therapeutic targets.

Methods: Peripheral blood mononuclear cells from 14 jSLE patients out of a cohort of 58, stratified by clinical scoring (SLEDAI and SLE activity score) into active and inactive disease, were interrogated with multi-dimensional mass cytometry (Cytometry by time-of-flight). Active disease is defined as persistent activity/refractory to treatment, flare or new diagnosis of lupus. Analysis was performed using a machine learning custom software through an unbiased, unsupervised approach based on dimensional reductions followed by automated cell classification, clustering and visualisation.

Results: Significant immunome differences stratified by disease activity were found. In active disease, enrichment of a CD45RA+ (naive) CD38+ CD4+ cell population was observed; indicative of a potential novel T cell involvement in lupus flare. Concurrently, a counterintuitive increase in the natural regulatory T cell (CD25+ CD152+ Foxp3+) population in active disease was found. This observation likely underscores an ineffective attempt of the T regulatory system to overcompensate the inflammatory response. This is in contrast to a greater degree of B regulatory cells (CD19+ IL10+) expansion with inactive disease after CpG oligodeoxynucleotides challenge (inactive: 3.56%, interquartile range (IQR): 3.18% to 6.84%; active: 2.12%, IQR: 2.02% to 2.20%) (not significant, Mann Whitney u test). Significance of these changes will be determined with increasing sample size.

Conclusion:

Our holistic analysis of the adaptive immune system underscores 2 critical points. 1) The presence of naive T cells expansion in association with disease flare underlines a plausible pathologic role that demands further functional analysis. 2) Dichotomy of the adaptive regulatory immunome at the level of the T and B cell suggests a potential ineffectiveness of the T cell based regulatory mechanism in active lupus in contrast to the expansion of the regulatory B cell population observed with quiescent disease. These findings highlighted the importance of further studies required to fulfil the dual translational goals of identifying therapeutic targets by distilling cellular subset for mechanistic study and providing predictive immunome signatures of clinical fate.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to evaluate whether alterations in the splicing-machinery could influence the development and activity of the disease and the atherothrombotic profile of SLE patients.

Methods: An array of selected components of the major- (n=12) and minor-spliceosome (n=4) and associated splicing factors (n=28) was developed, and their expression levels were evaluated using a Fluidigm methodology, in purified leukocytes (monocytes, lymphocytes and neutrophils) from 14 SLE patients and 14 healthy donors. In parallel, an extensive clinical/serological evaluation was performed. Carotid intimate media thickness (CIMT) was used as atherosclerosis marker. Endothelial activity was monitored by laser-doppler flowmetry, netosis was analyzed by fluorescence microscopy, and pro-inflammatory and oxidative stress markers were quantified by flow cytometry and RT-PCR. Then, association of these splicing components with clinical and analytical features were investigated.

Results: As a general feature, a significant reduction in relevant splicing factors and spliceosome components was found in all the leukocyte subtypes of SLE patients. Interestingly, we found a specific altered profile of splicing factors and spliceosome components when compared monocytes (i.e. U2AF1, FBP11, SRSF6), lymphocytes (i. e. RBM22, RB17, SRSF6) and neutrophils (i. e. SRSF10, SND1). Association studies showed that the reduced levels of some components of spliceosome in both monocytes and neutrophils were linked to the occurrence of thrombotic events. In lymphocytes those reduced levels were strongly related to the positivity for anti-dsDNA antibodies in SLE patients, thus suggesting that reduced spliceosome machinery would contribute to increase in altered autoantigen assembly, to which autorreactive T helper cells might react, inducing increased autoantibody production. In addition, reduced spliceosome machinery might derive of the described over-expression of specific anti-spliceosomal autoantibodies in SLE patients. Correlation studies demonstrated an inverse relationship among reduced levels of spliceosome components/splicing factors and high activity of the disease (measured as SLEDAI), endothelial dysfunction, netosis, and increased expression levels of peroxides and peroxynitrites, as well as of altered mitochondrial membrane potential in monocytes and neutrophils. Concomitantly, a direct relationship among reduced levels of spliceosome components/splicing factors in monocytes and neutrophils and low levels of serum complement factors C3 and C4 was established.

Conclusion: These results reveal the existence of SLE-associated spliceosome alterations, which could be related to the development and activity of this autoimmune condition and have influence on the induction of mechanisms that drive atherothrombosis in this disorder.Ongoing studies would clarify the potential physiological implications of these findings, which may provide novel diagnostic-biomarkers and therapeutic-tools to treat SLE. Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a kind of chronic and autoimmune disease with variable multi-system involvement of unknown causes, which is characterized by periods of relapsing-remitting course. Inflammation and vascular abnormalities are the main pathological changes. Part of the SLE patients may present with pulmonary artery hypertension (PAH), which can seriously affect the quality of life and eventually lead to death. The etiology and pathogenesis of PAH is affected by many factors which have not yet been fully elucidated. Till now, there is no highly sensitive and specific biomarker for early diagnosis and prognosis for SLE patients with PAH. The aim of this study is to investigate the plasma level of pentraxin 3 (PTX3) and its clinical significance as a potential biomarker in SLE patients.

Methods: 1) In this study, 46 patients with SLE were enrolled. The diagnostic criteria for SLE were based on the American College of Rheumatology (ACR) revised criteria in 1997 or ACR revised SLE classification standards in 2009. All subjects retained serum and plasma samples, and recorded contemporary clinical manifestations and laboratory data, including duration, clinical symptoms and signs, blood-urine- defecate-test, liver and kidney function, blood lipids, erythrocyte sedimentation rate, C-reactive protein, complement series, antinuclear antibodies (ANAs), anti-ds-DNA antibodies, antiphospholipid antibodies and immunoglobulin, SLEDAI and other data. SLE patients were divided into two groups, activity group and no activity group according to the SLEDAI; further, the activity group was divided into three subgroups, mild, moderate and severe group; all patients were measured by the UCG, PASP≥40mmHg was determined SLE-PAH (add up to 26 cases), while PASP <25 mmHg was the SLE-NPAH (20 cases). 2) 21 healthy subjects were selected as controls. All subjects were collected serum and plasma, stored at -80℃. 3) Enzyme-linked immunosorbent assay (ELISA) and electrochemiluminescence immunoassay (ECLIA) were used to detect plasma PTX3 level and serum NT-proBNP level, respectively.

Results: 1) The levels of PTX3 and NT-proBNP of SLE group were significantly higher than healthy control group (P=0.007 and 0.013, respectively). 2) Among SLE patients, PTX3 and NT-proBNP levels increased significantly of SLE-PAH group than those of SLE-NPAH (P=0.001 and 0.022, respectively). 3) The expression of PTX3 in activity group was higher than non-active group (P=0.029). There was no significant difference among mild, moderate and severe activity SLE group in the expression of PTX3 (P=0.14). 4) There was no significant correlation between the levels of PTX3 and NT-proBNP in patients with SLE-PAH (r=0.098, P=0.655). 5) In SLE-PAH group, the expression of PTX3 was positively correlated with SLEDAI scores (r=0.350, P=0.017), while negatively correlated with serum albumin (r=-0.327, P=0.018) ；PTX3 has no correlation with CRP (r=0.097, P=0.651), but was positively correlated with CRP by adjusting age and sex (r=0.178, P<0.001). 6) Multiple linear regression analysis showed that SLEDAI sores were independent predictors of PTX3 level. 7) Receiver operating characteristic (ROC) curve demonstrated the plasma PTX3 level more accurately than NT-proBNP in distinguishing SLE-PAH from SLE-NPAH .

Conclusion: The circulating levels of PTX3 in SLE-PAH were significantly higher, and positively correlated with CRP level, indicating that PTX3 may be involved in SLE-PAH development. PTX3 may be a sensitive biomarker for SLE-PAH diagnosis.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While most of the confirmed SLE-risk loci are in or near genes with immune system function, a major unanswered question is how these loci influence diverse immune cell subsets. In this study we performed a single cell eQTL analysis in human monocytes to determine impact of some well-established SLE-risk loci in single human monocytes.

Methods: CD14++CD16- classical monocytes (CL) and CD14dimCD16+ non classical (NCL) monocytes from SLE patients were purified by magnetic separation. The Fluidigm C1 System was used for single cell capture and target gene pre-amplification and equal numbers of classical and non-classical monocytes were studied. Real time PCR was used to quantify expression of 90 monocyte-related genes, and the same SLE patients were genotyped for 7 SLE-risk SNPs to enable eQTL analysis. Non-parametric analyses were used with the single cell data in CL and NCL populations separately.

Results:

We observed a large number of significant eQTL associations that surpassed the 5% FDR, supporting the idea that single cell gene expression data allows for robust eQTL discovery. The SLE-associated SNPs demonstrated more eQTLs in NCLs as compared to CLs ($p=2.5x10^{-8}$). For a given SNP, the eQTL associated transcripts differed between cell types ($p<0.001$ for all 7 SNPs for discordance), suggesting that the same SNP resulted in different cellular events between the two monocyte subsets. When comparing eQTL lists between the different SLE-associated SNPs, there was a greater degree of sharing observed in NCLs as compared to CLs. Loci which shared a significant proportion of eQTL associations with each other in NCLs included TNFAIP3, IRF5, IRF7, PTPN22, and SPP1. In CLs, TNFAIP3 shared a large number of eQTLs with SPP1 and ITGAM, although SPP1 and ITGAM showed more limited overlap with each other. Thus, SLE-associated risk loci exert coordinated effects on gene expression within individual human monocytes, and the risk loci interact in different ways in different cell types.

Conclusion: This study emphasizes the strength of single cell gene expression strategy for eQTL discovery. Our study revealed striking differences in the occurrence and interaction between of SLE risk associated eQTLs within different but closely related cell types. This suggests pleiotropic effects from each locus across various immune cell types, and a high degree of complexity when considering how these loci impact the immune system.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Evidence has accumulated that umbilical cord (UC)-derived mesenchymal stem cells (MSCs) show therapeutic effects on systemic lupus erythematosus (SLE). Deficiency in SLE macrophages exhibits excessive activation and inefficient clearance of self nuclear antigens. In this study, we aim to investigate whether UC-MSCs could increase the immunomodulatory function and phagocytic activity of lupus macrophages.

Methods: Blood samples were collected from 9 SLE patients, who fulfilled the SLE diagnostic criteria of American College of Rheumatology in 1999. All patients' Systemic Lupus Erythematosus Disease Activity Indexes (SLEDAI) were above 8. $CD14^+$ monocytes were isolated from peripheral blood of healthy donors (HCs) and SLE patients. We cultured human monocytes for 7 days with macrophage colony-stimulating factor (M-CSF) to generate macrophages, and then co-cultured them for 2 more days with/without UC-MSCs in transwell culture systems. $CD4^+$ T cells isolated from HCs were co-cultured with/without prepared macrophages. After 4 days, the proliferation levels of T cells were detected by flow cytometry. To determine the phagocytic activity of macrophages, apoptotic neutrophils were added into the cultures for 2 hours. The uptake of apoptotic cells were determined by flow cytometry.

Results: Compared with HC macrophages, the immunomodulatory function of SLE macrophages was impaired. SLE macrophages were incapable of suppressing the proliferation of $CD4^+$ T cells effectively. The phagocytic activity of SLE macrophages was also deficient in engulfment of apoptotic cells. Next, we determined the capacities of immunomodulatory and phagocytosis of SLE macrophages co-cultured with UC-MSCs in a transwell system. Flow cytometric analysis showed that SLE macrophages co-cultured with UC-MSCs significantly increased the abilities to suppress the $CD4^+$ T cells proliferation and phagocytic activities to engulf apoptotic neutrophils compared with macrophages cultured alone.

Conclusion: Our results indicate that UC-MSCs promoted the immunomodulatory function and phagocytic activity of macrophages in SLE, providing a novel mechanism for MSC-therapeutic function for SLE.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Excessive deposition of collagen and other connective tissue components in the skin and multiple internal organs is characteristic of Systemic Sclerosis (SSc). Besides the well characterized profibrotic effects of TGF-β, oxidative stress and other factors have been implicated in SSc pathogenesis. NADPH oxidase 4 (NOX4) is one of seven NADPH oxidases responsible for the production of reactive oxygen species (ROS) which are critical mediators of oxidative stress. TGF-β potently stimulates NOX4 expression, making NOX4 a critical downstream regulator of TGF-β profibrotic effects. Unlike other NOX proteins, NOX4 does not require cofactors to mediate its effects and therefore alterations in its effects are due to changes in its expression and production. The purpose of the studies described here was to evaluate the effect of the genetic deletion of *Nox4* in a murine model of TGF-β-induced tissue fibrosis.

Methods: Male and female C57BL6/J control mice and *Nox4* knockout mice in which *Nox4* expression has been eliminated by replacement of exon 4 of the *Nox4* gene with a neomycin cassette were implanted subcutaneously in the right intrascapular region at 4 weeks of age with osmotic pumps containing either saline or 2.5 µg TGF-β1. C57BL6/J mice with normal *Nox4*were similarly implanted with osmotic pumps. These pumps deliver a daily dose of 150 ng TGF-β/day for 28 days. Mice were sacrificed 28 days after the pumps had dispersed their contents. Skin adjacent to the pump implantation site and both lungs were isolated for analysis. A portion of each tissue was fixed in formalin and processed for histopathologic analysis (hematoxyllin/eosin and Masson's trichrome stains). Another sample of each tissue was hydrolyzed for measurement of hydroxyproline content.

Results: Histopathology studies in samples from control C57BL6/J TGF-β-treated mice showed peribronchial fibrosis and diffuse interstitial lung fibrosis. In contrast, *Nox4* knockout mice showed normal lung histology. Similarly, profound dermal fibrosis was evident in skin from C56BL6/J mice implanted with TGF-β pumps but not in skin isolated from *Nox4* knockout mice. Hydroxyproline levels in C57BL6/ control mice skin demonstrated a 104% increase in female control mice and a 59% increase in male control mice in response to TGF-β however TGF-β failed to increase the hydroxyproline content of *Nox4* knockout mice tissues of either sex. In the lung, TGF-β caused increased hydroxyproline levels in female control mice by 83% and by 116% in male control mice whereas no significant changes were observed in *Nox4*knockout mice of either sex.

Conclusion: Genetic deletion of *Nox4* in mice abrogated the ability of TGF-β delivered by subcutaneously implanted osmotic pumps to induce skin or lung tissue fibrosis. This result confirms several recent *in vitro* studies demonstrating a role for *Nox4* as an important mediator of the profibrotic effects of TGF-β-induced tissue fibrosis. Since *Nox4* is constitutively active, increased levels of its expression induced by TGF-β are likely to contribute to the pathogenesis of fibrotic diseases. The results of this study highlight the potential of *Nox4* inhibition as a potential therapeutic target in the treatment of SSc and other fibroproliferative disorders.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Microvascular damage is an early event in Systemic Sclerosis (SSc) pathogenesis and may represent the initiating stimulus for the subsequent establishment and progression of the fibrotic process. Extensive experimental evidence shows the increased expression and production of the pleiotropic growth factor transforming growth factor-β (TGF-β) and of TGF-β-regulated genes in SSc patient tissues however, the effects of cell-specific TGF-β expression in endothelial cells have not been studied. The purpose of these studies was to generate a transgenic mouse strain characterized by the inducible expression of TGF-β signaling specifically in cells of endothelial lineage. The novel transgenic mouse strain (TGFβ^{ca}-Cdh5 Cre) would be utilized for the evaluation of the effect of upregulated TGF-β expression specifically in the microvasculature and to examine directly the role of endothelial cell activation in the development of tissue fibrosis.

Methods: A transgenic mouse strain carrying an inducible constitutively active TGF-β receptor I (TBRI^{ca}) allele was intercrossed with a second mouse strain (B6.Cg-Tg(Cdh5-cre/ERT2)Mlia/J) carrying a Cre-ER^{T2} expression cassette controlled by the endothelial cell-specific Cdh5 promoter. A functional TBRI^{ca}allele is generated by intraperitoneal injection of 4-OH tamoxifen, yielding constitutive and unrestricted TGF-β signaling in all cells of endothelial lineage. The results of the intercross were evaluated by histopathologic staining of skin and visceral tissues, by immunhistochemical staining of lung for α-smooth muscle actin and von Willebrand factor, measurement of tissue hydroxyproline content, and by evaluation of the expression of genes associated with tissue fibrosis, myofibroblast differentiation and TGF-β signaling.

Results: Constitutive TGFβ-1 signaling in endothelial lineage cells resulted in severe and progressive cutaneous and visceral tissue fibrosis compared to saline-injected control mice. Increased collagen deposition and microvascular fibroproliferative changes in the dermis, lungs, myocardium, liver, and kidney were observed by histopathological analysis of these tissues. A 2.2 fold increase in hydroxyproline content of the skin and a 2.8 fold increase in the lung was observed. Increased expression of several profibrotic genes associated with tissue fibrosis and the transdifferentiation and activation of myofibroblasts was demonstrated in total RNA isolated from skin and lungs of these animals.

Conclusion: A remarkable observation was the development of extensive fibrosis in the skin, lungs and other organs in mice with constitutive endothelial cell-specific activation of TGF-β-signaling. Alterations resembling the microvascular pathology characteristic of human SSc were also observed. These results render this transgenic mouse strain a valuable model for SSc as they reproduce the typical cutaneous and visceral tissue fibrosis and severe fibroproliferative microvascular alterations found in SSc. These results also provide new information about the pathogenesis of tissue fibrosis in response to the effect of increased TGF-β expression specifically in cells of endothelial origin.

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

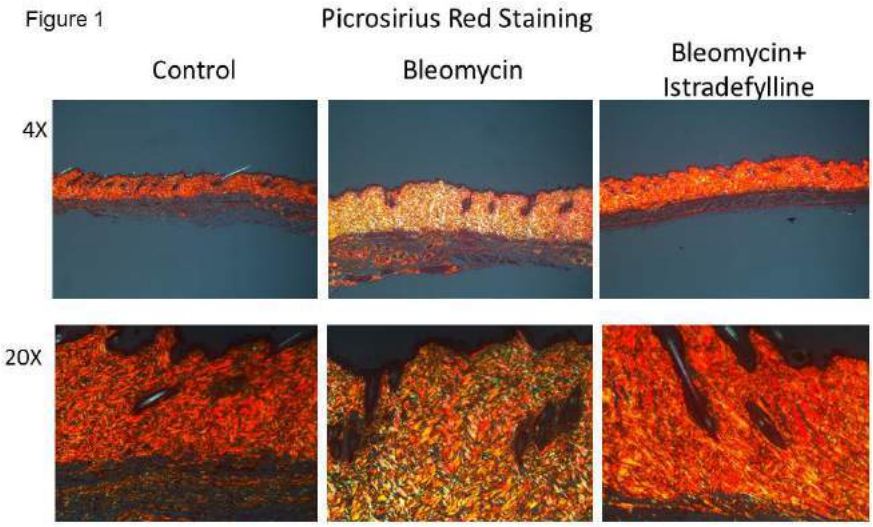
Session Time: 9:00AM-11:00AM

Background/Purpose: Fibrosis of skin and other organs is a hallmark of Scleroderma. We and others have previously reported that A2AR plays a role in skin and organ fibrosis in murine models of scleroderma. A2AR stimulation induces collagen type I and type III (Col1 and Col3) synthesis, mediators of fibrosis and scarring, via a mechanism involving cAMP/PKA/p38-MAPK/AKT. Wnt signaling is important in fibrosis and cAMP and Wnt signaling pathways converge. We therefore asked whether A2AR stimulates Wnt signaling pathways to promote collagen synthesis.

Methods: Total β-catenin, de-phosphorylated β-catenin (canonical activation, de-phospho β-catenin), and phosphorylated β-catenin at Ser552 (non-canonical activation, p-Ser552 β-catenin) levels were determined in primary human dermal fibroblast cytosol and nucleus by western blot and fluorescence microscopy after stimulation by A2AR-selective agonist CGS21680, with / without A2AR-selective antagonist (SCH582611) pretreatment. β-catenin was knocked down by lentiviral transfection with scrambled-siRNA or specific-siRNA, and Col1 and Col3 levels determined by western blot. In vivo effects were studied in a bleomycin-induced dermal fibrosis model using Wnt signaling reporter mice, Tcf/lef1-GFP homogenous mice, and mice were treated with A2AR antagonist (Istradefylline). Morphometric features and levels of hydroxyproline were determined as measures of dermal fibrosis. Fibrosis was confirmed by Picrosirius red stain. Immunohistochemistry for GFP and β-catenin were determined as measures of β-catenin translocation.

Results: CGS21680 stimulation rapidly (15min) increased cellular β-catenin to 176 ± 16 % of control ($n = 6$, $P < 0.05$); Both de-phospho β-catenin (168 ± 30% of control, $n = 6$, $P > 0.05$) and p-Ser552 β-catenin (220 ± 22 % of control, $n = 6$, $P < 0.05$) were increased. CGS21680 stimulated translocation of total, de-phospho, and p-Ser552 β-catenin to the nucleus. A2AR-stimulation increased Col1 synthesis similarly in β-catenin knockdown and scrambled cells. However, β-catenin knockdown abrogated the A2AR-stimulated increments in Col3 synthesis by 73% (66 ± 14% vs. 18 ± 16% increase of Col3, $n = 8$, $P < 0.05$). A2AR antagonist–treated mice were protected from developing bleomycin-induced dermal fibrosis (Figure 1) and there was diminished nuclear translocation of β-catenin in the affected skin (Figure 2).

Conclusion: A2AR stimulation promotes Col3 synthesis via canonical and non-canonical β-catenin activation, leading to dermal fibrosis and scarring. Selectively modifying this pathway represents an attractive therapeutic target in fibrotic



diseases such as scleroderma.

FGF9 / FGFR3 signaling is upstream of several profibrotic pathways and induces fibroblast activation and tissue fibrosis in SSc

Background/Purpose: Systemic sclerosis (SSc) is a chronic fibrotic connective disease of unknown etiology that affects the skin and internal organs. Fibroblast growth factor receptor 3 (FGFR3) belongs to a family of 4 different FGF receptors. Alterations of FGF signaling receptors have been linked to a variety of skeletal dysformations and are also found in some forms of cancer. An FGFR3 isoform binds FGF-1 (acidic FGF) and FGF-9 and binding of one of these FGFs to FGFR3 induces homodimerization and activates the receptor tyrosine kinase function. The purpose of this study was to elucidate the role of FGF9/FGFR3 signaling in Systemic Sclerosis.

Methods: The expression of FGF9 and FGFR3 in skin tissue and in human dermal fibroblasts was determined by real-time PCR, Western blot and immunohistochemistry. Knock-down and overexpression strategies were used to evaluate the effect of both on fibroblast activation. The outcome of mice with fibroblast-specific knockout of FGF9 or non-conditional knockout of FGFR3 was evaluated in bleomycin-induced skin fibrosis; fibrosis induced by overexpression of a constitutively active TGF-β receptor I (TBRIact) and in the Tsk model. FGFR3 pharmacological inhibition with PD 173074 was evaluated in vitro as well as in murine models of fibrosis.

Results: Our results show an upregulation of FGFR3 and in particular of its ligand FGF-9 in the skin of SSc patients. The upregulation of FGF9 was induced by TGFβ in vitro and in vivo and inhibition of TGFβ signaling blocked the upregulation of FGF9 in experimental fibrosis. SSc fibroblasts were more responsive to FGF-9 stimulation with enhanced activation of downstream mediators such as ERK and p38. Stimulation of fibroblasts with recombinant FGF9 or overexpression of a constitutively active FGFR3 induced myofibroblast-differentiation of resting fibroblasts, stimulated the collagen release and induced the expression of profibrotic mediators such as CTGF, ET-1 and IL4R. Inactivation of FGFR3, FGF9 or of the downstream mediators ERK and p38 reduced fibroblast activation and prevented the upregulation of pro-fibrotic target genes. Consistent with the induction of FGF9 by TGFβ and the profibrotic effects of FGF9, fibroblasts lacking FGF9 or FGFR3 were less sensitive to TGFβ stimulation. Inactivation of FGF9 or of its receptor FGFR3 exerted potent antifibrotic effects in several preclinical models. Knockout of FGF9 or FGFR3 ameliorated experimental fibrosis in bleomycin, TBRIact and Tsk animal model. Moreover, pharmacological inhibition of FGFR3 by the selective inhibitor prevented not only progression of fibrosis in experimental fibrosis, but also induced regression of pre-established fibrosis.

Conclusion: We demonstrate a novel role of FGF9/FGFR3 signaling in fibroblast activation and tissue fibrosis. FGF9/FGFR3 signaling is activated in SSc in a TGF-β dependent manner and induces several well-known profibrotic pathways to promote fibroblast-to-myofibroblast transition and collagen release. Pharmacologic or genetic inactivation of FGF9 or FGFR3 ameliorated fibroblast activation and fibrosis in several murine models.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The murine bleomycin (BLM)-induced fibrosis model is the most widely used in systemic sclerosis (SSc) studies. Traditionally, daily subcutaneous injections of BLM for 4-6 weeks are commonly used to induce local dermal inflammation and fibrosis. However, this model has disadvantages such as localized cutaneous fibrosis, rare involvement of the lung, and a requirement for repeated local injections. It was recently reported that systemic delivery of BLM via continuous diffusion from subcutaneously implanted osmotic minipumps can cause fibrosis of the skin, lungs, and other internal organs. However, the mouse strain, dosage of BLM, administration period, and additional important features differ from one report to the next. In this study, we have investigated the dosage of BLM, extent of fibrosis, and time-dependent changes in dermal and pulmonary fibrosis in C57BL/6J mice using the pump model.

Methods: BLM was administered to 8 week-old, male C57BL/6J mice using osmotic minipumps implanted subcutaneously and containing either 100µl saline as vehicle or BLM for 7 days. BLM was administered at 1.0 U/kg, 10 U/kg, 60 U/kg, or 110 U/kg. Pumps were implanted for 7 days. Lung and skin tissues were harvested on days 10, 14, 21, and 28 post-implantation. The extent of pulmonary fibrosis was measured using hydroxyproline assay. The extent of dermal fibrosis was quantified using both hydroxyproline assay and measurement of dermal thickness. Furthermore, the mRNA levels of fibrosis-related genes were measured using real-time PCR.

Results: Mice treated with different concentrations of BLM showed a dose-dependent increase in lung fibrosis by day 28. The levels of collagen in lungs from mice treated with high dose BLM were significantly greater than levels in lungs from mice treated with vehicle or lower doses of BLM. On the other hand, dermal fibrosis was not increased in a dose- or time-dependent manner. Interestingly, marked dermal thickness was induced by low dose BLM while no significant changes were noted with high-dose BLM by day 28. However, dermal thickness was significantly increased 10 days post BLM. Hydroxyproline assay also revealed that the amount of collagen in skin on day 10 was significantly higher than in skin treated with vehicle. However, by day 21 there were no significant differences in dermal thickness or collagen content between the treatment groups.

Conclusion: Our findings show that dermal fibrosis in C57BL/6J mice using the pump model differs with mouse strains, dose of BLM, and duration of the model. The BLM pump model is a powerful tool for the functional analysis of systemic fibrosis and the testing of potential therapies. However, the choice of mouse strains, duration of BLM administration and

dose must be carefully considered when using this model.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultraviolet A1 (UVA1) phototherapy implications for systemic sclerosis still remain the area of research. The aim of the study was to evaluate narrow band 365 nm ± 5 nm light effectiveness and safety for the treatment of dermal fibrosis in bleomycin-induced mouse model of scleroderma using light emitting diodes device.

Methods: DBA/2 strain mice were randomly divided to 6 groups: I – healthy animals; II – control group with bleomycin-induced scleroderma, III and IV – mice with established scleroderma, treated with high- and medium-dose of UVA1 light; V and VI – healthy mice treated with high- and medium-dose of UVA1 light. Light source emitting a narrow band UVA1 light of 365±5 nm and 21 mW/cm² power density was used in the study. Phototherapy was performed 3 times weekly for 5 weeks. The average cumulative doses were 600 J/cm² for medium- and 1200 J/cm² for high-dose treatment. Histological analysis with hematoxylin – eosin staining for dermal thickness measurement was performed. The immunohistochemical staining for p53 and Ki-67 proteins was performed using specific antibodies. Statistical significance was expressed by a P-value < 0.05.

Results: Phototherapy course was well tolerated by the animals. The dermal thickness of mice treated with high- and medium dose of UVA1 was significantly reduced to 272.9 ± 113.2 and 394 ± 125.9 μm, respectively, in comparison to control group II (599 ± 55.7 μm) ($p<0.05$). Parallel data were analyzed of UVA1- treated healthy mice skin: there was no dermal thickness change in both medium- and high-dose groups. The progression of dermal thickness is summarized in Figure 1. In the healthy mice group (I) the percentage of Ki-67-positive cells was 50.4 ± 2.6% and the number of these positive cells were reduced to 36.1 ± 3% in control group (II) after bleomycin injections ($p < 0.05$). The percentage of Ki-67 positive cells after medium- and high-dose UVA1 treatment of scleroderma skin (group IV and III) was 37.2 ± 2.8% and 35.4 ± 3.2%, respectively, and did not differ from the control group (II). The expression of p53 was significantly higher in the skin of control group (II) compared to healthy mice skin (I). After UVA1 treatment of mice with scleroderma, the expression of p53 did not differ in comparison to the control group without phototherapy (II). There was no statistically significant change of both p53 and Ki-67 expression between healthy (I) and UVA1-treated healthy mice skin (groups V and VI).

Conclusion: Medium- and high-dose 365 nm UVA1 effect on reducing dermal thickness is dose-dependent. This irradiation

does not affect dermal thickness in healthy skin. Cell apoptosis (p53) and proliferation (Ki-67) changes in the dermal and subcutaneous layers suggest a favorable narrow light effect in the experimental sclerosis and healthy mice groups. Narrow band UVA1 phototherapy using light emitting diodes device might be the new era of dermal fibrosis phototherapy.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary fibrosis is a severe complication of systemic sclerosis (SSc). Changes in the expression levels of sirtuins (SIRTs), a family of NAD^+-dependent histone deacetylases, have been reported recently in patients with SSc and other fibrotic diseases, implying a possible pathophysiologic role. Out of 7 known human SIRTs, SIRT1 has received the most attention. We have comparatively assessed the mRNA and protein expression of all SIRTs in primary lung fibroblasts from scleroderma patients with pulmonary fibrosis, idiopathic pulmonary fibrosis (IPF), and from healthy controls, and begun addressing mechanistic implications of the observed differences.

Methods: mRNA levels of SIRT1-7 were measured by RT-qPCR in lung tissue and fibroblasts from scleroderma patients with lung fibrosis and patients with IPF, as well as from healthy controls; protein levels were measured by western blotting. Intracellular delivery of SIRT7-encoding plasmid constructs and SIRT7-inhibiting siRNA to cultured adult normal human lung fibroblasts was performed by electroporation. The effects of SIRT7 on mRNA of collagen chains COL1A1, COL1A2, and COL3A1 and on protein levels of type I collagen, with and without stimulation with recombinant TGF-β, were assessed.

Results: mRNA and protein levels of all SIRTs tended to be lower in lung tissues and fibroblasts from patients with fibrosis compared to controls, but the levels of SIRT7 mRNA and protein in pulmonary fibroblasts were significantly lower, particularly in scleroderma ($p<0.001$ for SIRT7 mRNA and $p=0.019$ for SIRT7 protein). SIRT7 overexpression in fibroblast cultures inhibited basal and TGF-β-induced levels of collagen, reducing COL1A1 mRNA levels by 5 to 10 fold, COL1A2 mRNA by 2 to 3 fold, and COL3A1 by 3 to 5 fold; the levels of collagen protein were reduced by ~3 fold. SIRT7 silencing increased collagen protein by ~2 fold.

Conclusion: Pulmonary fibrosis is characterized by lower levels of sirtuins, with a particularly notable decrease in SIRT7 in scleroderma. Overexpression of SIRT7 decreases collagen mRNA and protein levels in cultured lung fibroblasts and attenuates TGF-β-induced increases in collagen. These findings identify SIRT7 as a pathophysiologic contributor to lung fibrosis.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease characterized by vasculopathy and tissue fibrosis. Although the most recognizable manifestation is skin disease, SSc can affect the lungs, heart, gastrointestinal tract and kidney resulting in significant morbidity and mortality. Digital ulcers and gangrene caused by progressive vasculopathy are also critical complications of SSc, strongly affecting physical function. Although animal models mimicking its entire pathology were previously unavailable, we have recently established mice with double heterozygous deficiency of the *Klf5* and *Fli1* genes, both of which are epigenetically suppressed in SSc dermal fibroblasts, spontaneously developing features of SSc, including fibrosis and vasculopathy of the skin and lung, B cell activation, and autoantibody production. In this study, we further investigated if $Klf5^{+/-}$;$Fli1^{+/-}$ mice recapitulate delayed wound healing and cardiac and intestinal involvement characteristic of SSc.

Methods: Four full-thickness excisional wounds per mouse were generated by an 8-mm biopsy punch on the back skin. The process of wound healing was assessed macroscopically and histologically. Angiogenesis and vasculogenesis were assayed by *ex vivo* retinal explant culture assay and *in vivo* matrigel plug assay, respectively. Myocardium, small intestine, and colon samples were analyzed by quantitative reverse transcription PCR, immunoblotting, and immunohistochemistry.

Results: Wound healing was markedly delayed in *Klf5*$^{+/-}$;*Fli1*$^{+/-}$ mice compared with wild type (WT) mice. In scar tissue, vascular network was poorly developed in *Klf5*$^{+/-}$;*Fli1*$^{+/-}$ mice compared with WT mice. However, at day 5 after wounding the number and the diameter of newly formed vessels in granulation tissue were significantly increased in *Klf5*$^{+/-}$;*Fli1*$^{+/-}$ mice compared with WT mice. In *ex vivo* retinal explants culture assay, angiogenesis was markedly accelerated in *Klf5*$^{+/-}$;*Fli1*$^{+/-}$ mice. In contrast, vasculogenesis was impaired in *Klf5*$^{+/-}$;*Fli1*$^{+/-}$ mice when evaluated by *in vivo* matrigel plug assay. Importantly, the stimulation of angiogenesis- and vasculogenesis-related factors suppressed the expression of both KLF5 and Fli1 in human dermal microvascular endothelial cells and murine mesenchymal stem cells, respectively. With respect to visceral organ involvement, apoptotic vascular endothelial cells were evident together with interstitial fibrosis in heart and dysfunction of intestine due to a switch from a contractile to synthetic phenotype of intestinal smooth muscle cells was suspected.

Conclusion: *Klf5*$^{+/-}$;*Fli1*$^{+/-}$ mice mimic delayed wound healing and cardiac and intestinal involvement of SSc. Delayed wound healing seems to be associated with accelerated angiogenesis and suppressed vasculogenesis together with impaired anastomosis of newly formed vessels with pre-existing ones. Cardiac fibrosis and intestinal dysfunction were due to endothelial apoptosis and a phenotypical alteration of intestinal smooth muscle cells, respectively. These results indicate that *Klf5*$^{+/-}$;*Fli1*$^{+/-}$ mice could serve as a reliable tool to investigate the details of disease process underlying SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Immune cell activation plays a crucial role in the pathogenesis of systemic sclerosis (SSc), and macrophages may be important mediators in this complex pathway (1,2). In SSc patients (pts), alternatively activated macrophages (M2) are present in the skin infiltrate, contributing to dermal fibrosis (2). M2 may differentiate from peripheral blood monocytes (PBMs), and are characterized by the expression of specific phenotype markers, such as CD206 (mannose receptor-1), and CD204 (macrophage scavenger receptor) (1). The study investigated the percentages of circulating $CD206^+/CD204^+$PBMs in SSc pts and possible correlations with specific clinical parameters.

Methods: Sera from forty-one SSc pts (36 females/5 males, mean age 62±15 years), who fulfilled the new EULAR/ACR criteria (3), and twenty voluntary healthy subjects (HS - 16 females/4 males, 61±10 years) were collected after EC approval and Informed Consent signed. Lung involvement (DLCO) and specific SSc autoantibodies (anti-centromere/CENP; anti-topoisomerase/Scl70; RNApoly3; fibrillarin; Th/Th0; PM-Scl75) were analysed. Nailfold videocapillaroscopy (NVC) was performed to define the pattern of microangiopathy. PBMs from SSc pts and HS were evaluated by flow cytometry (FC) by investigating cell positive for CD14 (monocyte/macrophage marker), CD206 and CD204. The statistical analysis was carried out using Mann-Whitney non-parametric U-test and correlation test.

Results: Among the 41 SSc pts, 27 showed a "limited" cutaneous involvement (lSSc) and 14 a "diffuse" cutaneous involvement (dSSc). The analysis of specific auto-antibodies yielded 13 pts positive for CENP, 16 pts positive for Scl70, 6 pts positive for the other investigated autoantibodies. Six pts were found Ab negative and excluded from the study. The evaluation by FC of circulating $CD14^+$cells did not show any significant difference between SSc patients and HS. However, in the $CD14^+$cell subset the percentage of $CD206^+CD204^+$cells was significantly increased in SSc pts compared to HS ($p=0.02$). The percentage of these cells was increased in lSSc pts ($p=0.06$), but significantly increased in dSSc pts ($p=0.03$) and inversely correlated with DLCO ($p=0.032$, $R=0.13$). In addition, $CD206^+CD204^+$cells were increased in Scl70-positive pts and significantly increased in CENP positive pts ($p=0.011$). NVC analysis identified 12 SSc pts with an "early" pattern, 14 pts with an "active" pattern and 16 pts with a "late" pattern. The percentage of $CD206^+CD204^+$cells was increased in pts with "early" or "late" NVC pattern ($p=0.09$, $p=0.06$) but significantly increased in those with the "active" pattern compared to HS ($p=0.04$).

Conclusion: The results confirmed the presence of an increased percentage of cells with an M2 phenotype in the peripheral blood of SSc pts. M2 cells seem to correlate with specific lung and skin involvement, autoantibody positivity and an "active" NVC pattern of microangiopathy. **References:** 1 Higashi-Kuwata N et al. Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Scleroderma (SSc) is a chronic autoimmune disease, characterized by excessive fibrosis of skin and internal organs due to uncontrolled proliferation of fibroblasts and deposition of extracellular matrix protein. Till date there is no promising therapy available for treatment of fibrosis in Scleroderma. Herein, we hypothesize that Phosphodiesterase5 inhibitors (PDE5i) attenuate fibrotic phenotype of cutaneous fibroblasts in patients with scleroderma.

Methods: Primary fibroblast cultures from midforearm skin of 13 Patients with scleroderma (as per ACR/LeRoy criteria) and 5 healthy individuals were established. To mimic disease condition fibroblasts were pre-stimulated with Transforming growth factor-beta1 (TGF-β1) (10 ng/ml) for 1 hour followed by further incubation with TGF-β1 and PDE5i; Sildenafil (10μM) and Zaprinast (10μM), for 24 hours (Strategy 1). In another strategy fibroblast were pre-treated with Sildenafil (10μM) and Zaprinast (10μM) for 1 hour followed by incubation with TGF-β1 (10 ng/ml) for 24 hours (Strategy 2). Expression of profibrotic genes; collagen 1 alpha 1 (COL1A1), collagen 1 alpha 2 (COL1A2), Fibronectin, alpha smooth muscle actin-1(ASMA1), connective tissue growth factor (CTGF), and antifibrotic gene; Matrix metalloproteinases 2/Tissue inhibitor of metalloproteinases (MMP2/TIMP) was analyzed with real time PCR and later their protein expressions were confirmed by Western Blot. Further, effect of PDE5i on TGF-β1 downstream signaling; canonical and non-canonical pathways, were analyzed with western blot. ANOVA and Student's t-Test were used for statistical analysis in SPSS 13 software.

Results: TGF-β1 significantly increased the expression of COL1A1, COL1A2, ASMA1, fibronectin, and CTGF at mRNA and protein levels compared to untreated fibroblasts. TGF-β1 induced fibrotic genes expression were significantly higher in SSc fibroblasts compared to healthy fibroblasts. In both Healthy and SSc fibroblasts, Sildenafil and Zaprinast treatment in both the strategies, significantly reduced the mRNA and protein expression of type 1 collagen, ASMA-1, fibronectin and CTGF compared to treatment with TGF-β1. Moreover, Sildenafil and Zaprinast treatment restored the levels of MMP2/TIMP1 in fibroblasts which were suppressed by TGF-β1 treatment. MMP2 level was significantly increased in culture supernatant of Healthy and SSc fibroblasts treated with PDE5i. Sildenafil and Zaprinast both reduced the phosphorylation of Smad3 (canonical) and Erk1/2 (non-canonical) in SSc fibroblasts.

Conclusion: PDE5i, Sildenafil and Zaprinast, not only attenuate the pro-fibrotic phenotype but also increase anti-fibrotic response in TGF-β1 treated cutaneous fibroblasts in SSc patients. Antifibrotic effect of PDE5i is mediated by affecting both canonical as well non-canonical TGF-β1 mediated downstream signaling pathways.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Scleroderma is an autoimmune fibrotic disease, which presents skin manifestations among others. The Wnt pathway plays an important role in inflammation, skin fibrosis, and vasculopathy, and is upregulated in scleroderma. SM04755, a novel, topical, small-molecule Wnt pathway inhibitor was evaluated in a series of preclinical studies to determine its potential to reduce inflammation, dermal fibrosis, and vasculopathy, thereby improving skin health in scleroderma.

Methods: Wnt pathway inhibition of SM04755 was measured using a cell-based reporter assay. Anti-inflammatory activity was evaluated by measuring TNF-α and IL-6 secretion using ELISA in THP-1 monocytes stimulated with Lipopolysaccharides (LPS), and PBMCs stimulated with anti-CD3/anti-CD28. The effect on fibrosis was assessed in TGF-β stimulated human dermal fibroblasts by measuring smooth muscle actin (αSMA), plasminogen activator inhibitor (PAI-1), connective tissue growth factor (CTGF), and collagen expression by qPCR. The effect on myofibroblast differentiation and reversion was measured by immunocytochemistry for αSMA. Pharmacokinetics were evaluated following topical application in rats and mini-pigs by analysis of compound concentrations in skin and plasma. *In vivo* efficacy was evaluated in a subcutaneous bleomycin-induced mouse model of scleroderma by histological measurements of the thickness of various layers of the skin, and CD31 immunohistochemistry for vasculopathy.

Results: SM04755 demonstrated potent (EC_{50}=152nM) and selective inhibition of Wnt signaling. SM04755 inhibited LPS and anti-CD3/anti-CD28 induced TNF-α and IL-6 secretion (EC_{50}=500nM) in THP-1 cells and PBMCs. SM04755 treatment significantly ($p<0.05$) inhibited dermal fibrosis measured by a decrease in TGF-β stimulated αSMA, PAI-1, CTGF, and collagen gene expression in human dermal fibroblasts. SM04755 reduced αSMA stained stress fibers in myofibroblasts (EC_{50}=400nM) thus reversing fibrosis. Single topical application of SM04755 showed skin concentrations >EC_{50} for >24hrs, with minimal systemic exposure or toxicity. In a bleomycin-induced mouse scleroderma model, topical SM04755 treatment after induction of fibrosis significantly ($p<0.01$) reduced thickness of dermis and deep fascia, and increased thickness of the adipose layer, as compared to vehicle, thereby reversing bleomycin-induced dermal fibrosis. SM04755 treatment also reduced vasculopathy measured as a decrease in the endothelial marker CD31 staining in the skin.

Conclusion: SM04755 inhibited inflammation and reversed dermal fibrosis *in vitro*. In a bleomycin-induced mouse scleroderma model, topically applied SM04755 reversed dermal fibrosis, increased adipose tissue, and reduced vasculopathy compared to vehicle, with minimal exposure in the plasma or systemic toxicity. SM04755 has potential as a topical therapy for scleroderma.

Figure. SM04755 reduced the thickness of the dermis and deep fascia relative to control in a bleomycin-induced scleroderma model in mice

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Microvascular injury is one of the first pathological events in systemic sclerosis, and precedes the fibrosis. A consequence of vascular damage is the exposure of subendothelial connective tissue that causes activation of platelets and local serotonin (5-hydroxytryptamine, 5-HT) release. Binding of 5-HT to 5-HT_{2B} receptors on fibroblasts results in increased myofibroblast differentiation and release of excessive amounts of matrix proteins subsequently leading to fibrosis. Thus, pharmacologic inhibition of 5-HT_{2B} receptors may represent a new treatment opportunity for systemic sclerosis. In this study a novel highly selective 5-HT_{2B} receptor antagonist was evaluated for its ability to reduce the

production of matrix proteins in human dermal fibroblasts and to ameliorate fibrosis in the tight-skin-1 model of systemic sclerosis.

Methods: Dermal fibroblasts isolated from patients with systemic sclerosis were cultured with different concentrations of the 5-HT_{2B} receptor antagonist AM1125 with or without 1 μM 5-HT. Anti-fibrotic effects were evaluated by measuring matrix production, myofibroblast differentiation and TGF-β production. The tight-skin-1 model was used to evaluate anti-fibrotic effects *in vivo* using a therapeutic treatment approach. AM1125 was administered at 10 and 50 mg/kg orally, b.i.d. from week 5 to week 10. Hypodermal thickening, myofibroblast counts and collagen production (hydroxyproline) were evaluated at the end of the treatment period.

Results: *In vitro* AM1125 dose-dependently reduced TGF-β, PAI, nuclear SMAD2/3 and collagens in human dermal fibroblasts. In addition, stress fiber formation and α-SMA mRNA were reduced indicating decreased myofibroblast differentiation. Therapeutic treatment with the 5-HT_{2B} receptor antagonist AM1125 at 50 mg/kg reduced hypodermal thickness ($p<0.001$), myofibroblast counts ($p<0.05$) and hydroxyproline content ($p<0.01$) in the tight-skin-1 model. In addition, the lower dose (10 mg/kg) reduced hypodermal thickness ($p<0.001$).

Conclusion: The results demonstrate that the 5-HT_{2B} receptor antagonist AM1125 prevents pro-fibrotic events in human dermal fibroblasts and attenuates dermal fibrosis using a therapeutic treatment approach in the tight-skin-1 model. Thus, 5-HT_{2B} receptor antagonists, exemplified by the novel compound AM1125, could represent a new treatment opportunity for systemic sclerosis.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Adult stem cells, namely those of mesenchymal origin (MSCs), have received attention as an ideal source of regenerative cells because of their multi-potential ability to replicate. Adipose tissue (AT) is an alternative

attractive source of MSCs, due to its abundance and surgical accessibility. Recent studies have shown that autologous fat grafting may be effective in the treatment of specific skin lesions in systemic sclerosis (SSc), but no specific study exists aimed at investigating whether AT-MSCs in patients with SSc maintain normal phenotypic and functional characteristics. Aim of the study was to investigate whether AT-MSCs from patients with SSc (SSc-AT-MSCs) are phenotypically and functionally identical to those from healthy controls (HCs)

Methods: AT samples were obtained from 8 patients with the diffuse cutaneous variant of SSc (dcSSc) and from 5 HCs. Key parameters of AT-MSC phenotype and function were assessed in both MSC populations, including the capacity (a) to express specific MSC surface antigens (CD105, CD73, CD29, CD90, CD44) by FACS analysis, (b) to proliferate (growth kinetics assay), (c) to differentiate along the adipogenic and osteogenic lineages, (d) to suppress in vitro lymphocyte proliferation induced by the mixed lymphocyte reaction (MLR), and (e) to support endothelial cell (EC) tube formation.

Results: AT-MSCs from SSc patients and HC showed similar cell surface phenotype and multilineage differentiation capabilities. Phenotypically, SSc- and HC-AT-MSCs highly expressed CD105, CD73, CD90, HLA-ABC and were mostly negative for HLA-DR expression. When cultured in standard induction medium, both SSc- and HC-AT-MSCs similarly differentiated toward the osteogenic and adipogenic lineages. In MLR assays, no significant differences in AT-MSC-mediated inhibition of proliferation were observed between SSc- and HC-AT-MSCs. Using AT-MSC/EC co-cultures, we observed that both SSc- and HC-AT-MSCs improve tube formation by both HC- and SSc-ECs. This effect was enhanced under hypoxic conditions in all of the co-cultures.

Conclusion: Our study shows that AT-MSCs from patients with SSc exhibit the same phenotypic pattern, proliferative and differentiation potentials, as well as the same immune-suppressive properties than those from HC. The SSc-AT-MSC activity we observed as pro-angiogenic effectors, namely under hypoxic conditions, may suggest that autologous AT-MSCs grafting may represent a future possible therapeutic option in patients with this disorder.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease characterized by systemic fibrosis. The

dysregulation of transforming growth factor-β (TGF-β) signaling causes proliferation of myofibroblasts and results in the uncontrolled release of extracellular matrix. We have published that fucosyltransferase-1 (Fut1), an α-1,2 fucosyltransferase, plays an important role in rheumatoid arthritis synovial fibroblast proliferation. In this study, we examine the role of Fut1 in TGF-β receptor (TGF-βR) fucosylation, downstream signaling pathways, and target genes involved in scleroderma pathogenesis.

Methods: qPCR and ELISA were performed to assess the levels of Fut1 in SSc dermal fibroblasts and patient sera, respectively. To determine fucosylation of TGF-βR1, TGF-βR1 was immunoprecipitated from wild type (WT) dermal fibroblasts and immunoblotted with ulex europaeus agglutinin 1, which detects α-1,2 fucosylated protein. To confirm TGF-bR1 fucosylation, Fut1 was knocked down in SSc dermal fibroblasts using Fut1 shRNA. We evaluated Fut1 involvement in TGF-β signaling, myofibroblast differentiation, and TGF-b-associated target genes in WT and Fut1$^{-/-}$ dermal fibroblasts via immunofluorescence (IF), qPCR, and Western blotting. An *in vivo* wound healing model was performed with Fut1$^{-/-}$ and WT mice and wound healing was assessed over 8 days. To elucidate the role of Fut1 in an animal model of scleroderma, bleomycin was injected intradermally into Fut1$^{-/-}$ and WT mice for 9 days. Mice were euthanized and skin harvested for Masson's trichrome staining and hydroxyproline assay, a quantitative measure of collagen.

Results: Fut1 mRNA and protein were significantly elevated in SSc compared to NL dermal fibroblasts and patient sera, respectively. We found via immunoprecipitation that TGF-βR1 is fucosylated by Fut1. We found less TGF-bR1 in SSc dermal fibroblasts when transduced with Fut1 shRNA, confirming the role of Fut1 in TGF-bR1 fucosylation. TGF-β-induced phosphorylation of Smad2, Erk1/2, and Jnk was markedly reduced in Fut1$^{-/-}$ dermal fibroblasts compared to WT, indicating that Fut1 is essential to TGF-βR1-mediated signaling pathways. Impaired transcription of myofibroblast differentiation inducing genes, Twist2 and Snail, was observed in Fut1$^{-/-}$ dermal fibroblasts. We found a significant decrease in α-smooth muscle actin in Fut1$^{-/-}$ compared to WT dermal fibroblasts as determined by IF and Western blotting, indicating a critical role for Fut1 in myofibroblast differentiation. In the wound repair model, Fut1$^{-/-}$ mouse wounds healed more slowly than WT mouse wounds. Fut1$^{-/-}$ mice developed significantly less bleomycin-induced skin fibrosis and collagen deposition compared to WT mice as determined by Masson's trichrome staining and hydroxyproline assay, respectively.

Conclusion: Fut1 expression is elevated in SSc dermal fibroblasts and patient sera. Fucosylation of TGF-βR1 is critical to myofibroblast differentiation and TGF-β signaling. In addition, Fut1$^{-/-}$ mice exhibit delayed wound repair and diminished bleomycin-induced skin fibrosis, indicating an essential role for Fut1 in SSc pathology. Fut1 may be a novel therapeutic target for SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Since vascular manifestations such as Raynaud's phenomenon and morphological changes on nailfold capillaroscopy often precede the onset of other clinical manifestations of systemic sclerosis (SSc), the identification of pathways linking vasculopathy to organ fibrosis might thus provide important insights into early disease mechanisms and allow early targeted intervention for both fibrotic and vascular events. Recently, activating transcription factor 3 (ATF3), a member of the ATF/cAMP-responsive element binding (CREB) family of transcription factors, which regulates cellular response to stress, was characterized as a downstream mediator of canonical TGF-β signaling in fibroblast activation and tissue fibrosis. In this study we aimed to investigate the role of ATF3 linking vasculopathy to organ fibrosis.

Methods: ATF3 expression in vessels of either human skin samples of SSc patients and healthy volunteers, or murine skin and lung tissue of Fra2 transgenic (tg) mice was analyzed by multi-chanel immunofluorescence (IF) and confocal laser scanning microscopy. Human umbilical vein (HUVEC), human microvascular endothelial cells (HMEC) and smooth muscle cells (SMC) as well as immortalized blood (BEC-TI) and lymphatic (LEC-TI) endothelial cells were transfected with pCMV-ATF3 and pCMV plasmid constructs and cell proliferation and survival were measured by microtiter tetrazolium (MTT) and apoptosis assays, migration by chemotaxis-induced migration assay, and tube formation in a matrigel basement membrane matrix. Additionally, *ex vivo* mouse fetal metatarsal assays were performed using ATF3 knockout and wildtype littermates to study the angiogenetic process.

Results: ATF3 was significantly upregulated in fibroblasts of skin biopsies of SSc patients and of various organs of fibrosis models. ATF3 deficiency ameliorated fibrosis in various mouse models including Fra2 tg mice, a genetic model resembling both fibrosis and vasculopathy. Notably, ATF3 was significantly upregulated in vascular cells of fibrotic tissues of SSc patients and Fra2 tg mice. Multi-color IF and confocal laser scanning microscopy of skin and lung biopsies of SSc patients and Fra2 tg mice revealed an increased expression of ATF3 especially in microvascular endothelial cells and smooth muscle cells. ATF3 overexpression in smooth muscle cells led to an extensively enhanced proliferation and increased migratory capacity whereas endothelial cells showed a SSc-like phenotype with reduced proliferation and migration. After ATF3 overexpression, tube formation capacity was completely altered as assessed by cumulative tube length, tube numbers and capillary sprouting. To investigate vessel outgrowth from a different perspective, we used the *ex vivo* fetal mouse metatarsal assay. ATF3 knockout mice showed a completely altered angiogenic response as assessed by tube length, number of branches and number junctions compared to wildtype controls.

Conclusion: We identified ATF3 as a new profibrotic factor in endogenous activated fibroblasts as wells as in disturbed vasculature suggesting ATF3 as a potential therapeutic target intervening both fibrotic and vascular manifestations.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) has complex aetiology with many potential driving forces, one of which is the microenvironment in lesional skin, in which resident mesenchymal stem cells (MSCs), are exposed to aberrantly expressed growth factors and cytokines, and excessively stiffened and abundant extracellular matrix. We hypothesise that MScs are persistently activated within this microenvironment contributing to chronic aberrant tissue repair and fibrosis. The effects of skin blister fluid (BF) and IL-31, the maximally induced cytokine in SSc BF, were studied in models of interaction between the disease microenvironment and MSCs. MSCs were studied *in situ* using amitotic nuclear division as a marker of their activation.

Methods: Staining of tissue spreads for metakaryotic nuclear divisions was used as a method to identify MSCs in SSc tissues. SSc BF sampled from forearm skin, as well as control BF (each diluted 1:125 in 0.2% DMEM) and IL-31, were studied as possible agonists in scratch wound assays and Western blots for SSc associated proteins. MSCs derived from both adipose and skin biopsy tissue were induced to differentiate into osteoblasts on soft and stiff extracellular matrix representations. Levels of pro-fibrotic factors were measured by qPCR in MSCs exposed to microenvironment representations.

Results: Metakaryotic nuclear divisions were observed in cells associated with fibrillar collagen in the deep dermal layer of SSc skin. SSc BF enhanced migration of MSCs compared with control BF, (~1 and ~0.7 mm^2 respectively p=0.231) and induced αSMA expression in MSCs ~ 3 times more than media only and ~ 1.5 times more than control BF. Collagen I and CTGF expression were also induced in MSCs by SSc BF. In addition, IL-31 enhanced migration of SSc and control dermal fibroblasts in the scratch wound assay (1.3mm^2 SEM=0.08 and 0.45mm^2 SEM= 0.07 in 0.2% DMEM and 50ng/ml IL-31 respectively at 20 hours, p=0.0001), inhibited by Wortmannin and U0126 (1.4mm^2 and 1.3mm^2 respectively, p=0.0001). The same was seen with MSCs, by 24 hours the area of the scratch in IL-31 treated wells was 0.9mm^2 compared to 1.5mm^2 for Wortmannin treatment (p=0.027). IL-31 did not fully reproduce the protein and migratory effects of blister fluid on MSCs. IL-31 had no effect on Collagen I expression (relative density of 0.7 vs 1.0 and 2.4 for 0.2% DMEM and SSc BF respectively). Matrix stiffness enhanced osteogenic differentiation of MSCs, this effect was enhanced further with IL-31 and TGFβ but abolished when treated with CCG1423 (an inhibitor of the matrix sensing protein MRTFA). Stiff matrices also elevated expression of a-SMA and Collagen I mRNA.

Conclusion: Proliferating metakaryotic cells were found to be present in the deep dermis of SSc patients and they may represent activated stem cells. SSc patients BF and SSc associated cytokine IL-31 enhanced pro-fibrotic differentiation of MSCs. Our findings suggest that MSCs may be important in SSc pathogenesis and that factors within the dermal interstitial fluid generate a microenvironment inducing them to create or induce excessive pro-fibrotic cells.

Modelling Healthy and Scleroderma Fibrotic Skin in Vitro: Mechanical Stress Alters Macrophage Cytokine Expression and Triggers Signalling Via the Mechano-Sensing Transcription Factor Myocardin-Related Transcription Factor-a

Angela Tam[1], Shiwen Xu[1], Henry Lopez[1], Korsa Khan[2], Bahja Ahmed Abdi[3], Henrique Rosario[4], Nikita Arumalla[2], Mark Gibson[2], Christopher Denton[2], David Abraham[2], Barbara D Smith[5] and Richard J Stratton[2], [1]Division of Medicine, Centre for Rheumatology and Connective tissue disease, University College London, London, United Kingdom, [2]Division of Medicine, Centre for Rheumatology and Connective Tissue Disease, University College London, London, United Kingdom, [3]Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, University College London, London, United Kingdom, [4]Division of Medicine, Centre of Rheumatology and Connective Tissue Diseases, University College London, London, United Kingdom, [5]Boston University School of Medicine, Boston, MA

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Skin involvement is one of the most prominent clinical features in scleroderma. There is a marked contrast in mechanical stiffness between healthy forearm skin which has a Young's modulus of 4-12kPa, and scleroderma fibrotic skin at 50-80kPa. We have shown that mechano-sensing properties of fibroblasts in scleroderma are mediated by myocardin-related transcription factor A (MRTF-A). This study is to investigate if a mechanically-stressed microenvironment promotes macrophages towards a pathogenic phenotype, and whether MRTF-A mediates this process.

Methods: Control and scleroderma skin sections were immunostained with anti-CD68 and anti-MRTF-A antibodies (n=3). Human PBMC-derived macrophages were cultured in RPMI/M-CSF on 4kPa and 50kPa collagen-fibronectin-coated plates to mimic "soft"/healthy and "stiff"/fibrotic skin, and unpolarised, or activated with LPS(10ng/ml) or IL-10(10ng/ml) for macrophages designated M(0), M(LPS) and M(IL-10) (n=4). MRTF-A expression was assessed by qPCR and Western blot. Conditioned media was profiled by Luminex array for inflammatory cytokines. Mouse bone marrow-derived macrophages (BMDMs) of wildtype (WT) and MRTF-A-null mice were maintained in RPMI/M-CSF on soft and stiff substrates.

Results: We observed increased accumulation of $CD68^+$ macrophages and MRTF-A^+CD68^+macrophages in perivascular areas of scleroderma skin compared to control skin. No significant differences were detected in MRTF-A expression by qPCR between control and scleroderma macrophages, although stiff substrate increased expression of MRTF-A protein. M(LPS) expressed TNF-α and IL-12 mRNA (10-fold lower in expression or undetectable in M(0), respectively), on soft substrate. Macrophages on stiff substrate showed a trend towards decreased LPS-induced TNF-α and IL-12 mRNA. M(LPS) on soft substrate expressed IFN-γ, which was undetectable with M(LPS) on stiff substrate (mean difference (Δ) 0.2075±0.1576pg/ml, $p<0.01$). M(IL-10) on stiff substrate showed increased MCP-1 expression compared to soft (Δ 2590±2233pg/ml, $p<0.05$). M(LPS) on stiff compared to soft substrate showed increased MCP-3 expression (Δ 57.01±49.22pg/ml, $p<0.05$). M(IL-10) on stiff substrate showed a trend towards increased MCP-3 compared to soft

substrate. M(IL-10) on stiff substrate showed increased fractalkine compared to soft substrate (Δ 51.22±36.28pg/ml, $p<0.01$). WT BMDMs displayed a more elongated morphology on stiff compared to soft substrate while MRTF-A-null BMDMs remained rounded on stiff substrate.

Conclusion: MRTF-A is a mechanical stress-responsive transcription factor which regulates cytoskeletal and ECM-related genes. MRTF-A may mediate mechanical stress and macrophage activation in scleroderma. A stiff microenvironment promoted macrophages to change from a pro-inflammatory phenotype towards a pro-healing phenotype marked by the loss or reduced expression of inflammatory markers IFN-γ, TNF-a and IL-12 alongside increased expression of monocyte chemoattractants MCP-1, MCP-3 and the pro-healing macrophage marker fractalkine.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It is well established that measurements of cutaneous microvascular dysfunction (measured with laser Doppler imaging [LDI]) and structural abnormality (measured with nailfold capillaroscopy [NC]) differentiate between primary Raynaud's phenomenon (PRP) and systemic sclerosis (SSc). Spectroscopy to measure free radical induced oxidative stress (OS) and oxygenation (OX) has been less well studied despite both being implicated in SSc pathogenesis. The aim of this study was to evaluate all of these parameters and to determine how the additional information provided by spectroscopy compares to established techniques in a population of patients with SSc (subtyped as limited or diffuse cutaneous (lcSSc, dcSSc) depending upon skin involvement), PRP and undifferentiated connective tissue disease (UCTD) and in healthy controls (HC).

Methods: Perfusion images (dual wavelength [superficial capillary and deeper thermoregulatory microcirculation layers, LDI]) were taken of the hand pre and post local heating. Distal dorsal difference (DDD, digit-dorsum) was calculated at baseline and perfusion increase (POST/PRE) calculated at the digit and dorsum. Nailfold capillaroscopy (NC) was carried

out at 200x magnification over the whole nailbed on the non-dominant ring finger. Capillary density and width were calculated from images using automated software. Spectroscopy (light shone onto the skin with a fibre and collected by spectrometer) was carried out at 9 sites of the body. Oxidative stress (OS) measurements were taken with UV light and erythema (E, pseudo-measure of blood flow) and oxygenation (OX) with white light. Comparisons were made between groups with an ANOVA (STATA).

Results: 92 patients with lcSSc, 47 with dcSSc, 31 with PRP, 35 with UCTD, 61 HC were assessed. Data is presented in table 1. LDI showed smaller values for DDD (thermoregulatory layer) and POST/PRE digit and dorsum (thermoregulatory and capillary layers) for SSc vs HC. NC density was significantly lower and width significantly higher in the SSc vs HC group. OS was significantly increased in 7/9 sites in SSc vs HC groups. E was significantly lower at 8/9 sites for the SSc vs HC group. OX was lower at the digit in SSc vs HC group but overall showed no trend for increase or decrease.

Conclusion: The data confirms microvascular dysfunction and structural changes in SSc in a large data set. In addition these changes are matched by increased free radical stress (OS). These changes now need to be measured prospectively and these studies are underway.

Table 1. LDI, spectroscopy (E, OX, OS) and NC data [Median (IQR)] at the digit and dorsum.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a complex autoimmune disease with heterogeneous clinical manifestations. Over the past seven years our knowledge of the SSc genetic component has greatly increased, mainly thanks to large genetic studies including genome wide association studies (GWASs). However, there is still a large proportion of the SSc heritability that remains unexplained. One of the hypotheses proposed to explain the missing heritability for complex diseases involves rare and low-frequency variants, which are not usually analyzed in GWASs. Next-generation sequencing (NGS) technologies, like whole exome sequencing (WES), have provided a useful strategy for the study of non-common variants. In this regard, Gao *et al*. performed WES on SSc and reported a novel gene, *ATP8B4*, as a risk factor for the disease. Their results pointed out F436L (rs55687265) missense variant as the potential causal variant for the association signal. The aim of the present study was to further evaluate the reported signal of association in a large SSc cohort.

Methods: The complete set of individuals enrolled for this study comprised a total of 7,426 SSc patients and 13,087 healthy controls of European ancestry. F436L (rs55687265) rare variant was genotyped using TaqMan SNP genotyping technology. First, association tests were performed in each of the six different case-control cohorts. An inverse variance meta-analysis under a fixed effect model was performed to combine the results in the different cohorts.

Results: A trend towards association was observed for one of the case-control set (P_{value} = 0.071, OR = 1.58) (Table 1). However, we did not observe any suggestive or significant association signal for the remaining cohorts. Interestingly, we also observed opposite-direction allelic effects across the different populations for the same allele. The meta-analysis combining all the sample sets showed no significant association with the disease (P_{meta} = 0.484, OR = 1.07). Although we did not find statistically significant associations, a possible role of this locus in SSc susceptibility cannot be ruled out, since we did not assess whether other *ATP8B4*variants were associated with SSc susceptibility.

Conclusion: This study could not replicate the association of *ATP8B4* rs55687265 with SSc. Our results highlight the importance of validation of WES results with other sequencing methods as well as replication of the new associations in independent studies in order to identify true disease-causing mutations.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

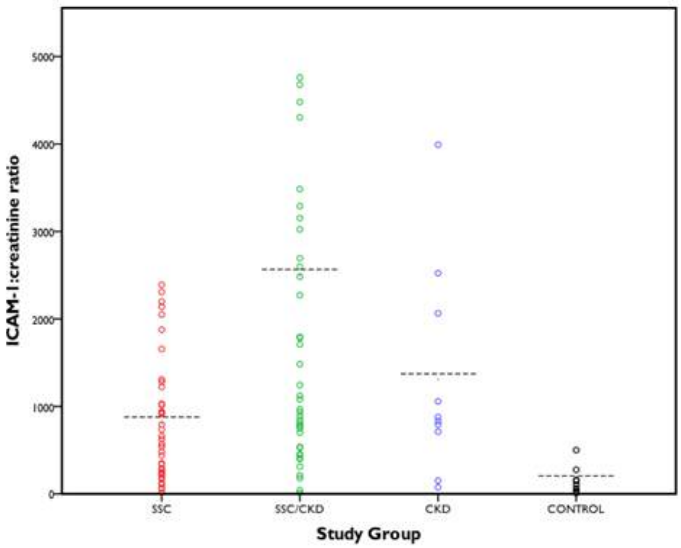
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Renal involvement in systemic sclerosis (SSc) includes scleroderma renal crisis as well as progressive organ fibrosis. Detection and management of these disease complications is challenging and there is a clinical need for biomarkers that reflect renal involvement. The immunoglobulin superfamily adhesion molecules ICAM-1 and VCAM-1 are upregulated in affected tissues in SSc and other connective tissue diseases. Serum levels of ICAM-1 and VCAM-1 have been elevated in previous studies, but in some instances this reflects the multi-organ burden of disease and organ-specific analysis may to be more robust.

Methods: We collected urine and serum from 80 SSc patients, with or without renal disease, and compared them with patients with CKD of other causes (n=10) and healthy controls (n=12). We used bead-based multiplex analysis to measure cell adhesion molecule concentrations.

Results were compared between groups by Kruskal-Wallis test. **Results:** 40 SSc patients had CKD defined by eGFR and urinalysis. Risk factors for renal involvement (SSc-CKD) included diffuse skin involvement and anti-RNA polymerase III antibodies. Serum concentrations of ICAM-1 or VCAM-1 did not differ significantly between SSc-CKD and the three control groups. Urine VCAM-1 concentrations were increased in SSc patients with renal involvement (mean VCAM-1:creatinine ratio 922, SD 953 versus 654, SD 708 for those without renal involvement) but this did not reach significance. Urine ICAM-1 was markedly upregulated in SSc-CKD (mean ICAM-1:creatinine ratio 1601, SD 1394 versus 806, SD 701 for SSc without renal involvement and 1307, SD 1211 for CKD of other causes, $p<0.001$)



Conclusion: This is the first study to examine urinary cell adhesion molecule concentrations in SSc. Our results confirm the potential utility of urine soluble ICAM-1 as a marker of renal involvement in SSc. Together with previous work by our group on urinary chemokines, the finding of raised urine cell adhesion molecules in the absence of raised serum concentrations supports the utility of urine biomarkers in defining localized SSc disease activity.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Acquired tracheal stenosis (ATS) is an unusual disease secondary to inflammatory diseases or to prolonged mechanical trauma. Tracheal mucosa undergoes inflammation and granulation tissue formation with subsequent narrowing of the tracheal lumen. The aim of this study was to analyse the potential role of TGF-β pro-fibrotic pathway in the development of tracheal stenosis.

Methods: Human tissues were obtained by excision of tracheobronchial granulation tissues from patients with benign airway stenosis (n=7) and healthy controls (n=9). We developed a model of tracheal stenosis in adult NZ rabbits, where after a previous incomplete transverse incision the trachea, a circumferential thermal injury to the mucosa with electrocautery was made. To assess the involvement and potential as therapeutic target of pro-fibrotic factor TGF-β1 in this model, rabbits were postoperatively treated with either a peri-tracheal collagen sponge containing a peptide antagonist of TGF-β1 p17 (2mg/ml) or control vehicle. Animals were sacrificed and tracheas excised at 4 weeks for histomorphometric and immunohistochemical (IHC) analysis. Collagen accumulation was analyzed by Masson's trichrome staining and expression of TGF-β pathway surrogate markers (α-SMA myofibroblasts, CTGF and p-Smad2/3) by immunohistochemistry. Quantitative data were compared by Mann-Whitney U-test and correlation analysis by Spearman's rank test. p-value less than 0.05 was considered significant.

Results: Histological examination of human and rabbit stenotic tracheas showed an extensive submucosal fibrotic, collagen stained area, as well as inflammatory cell infiltration and epithelial hyperplasia. We observed a significant increase in the density of $\alpha\text{-SMA}^+$ myofibroblasts and $CTGF^+$ cells in both cases compared to control tracheas. In human stenotic tracheal tissues, this was accompanied by increased nuclear p-Smad2/3 expression compared to healthy tissues. In rabbit stenotic lesions, p17 treatment significantly reduced the fibrotic thickness ($p=0.0006$) and the densities of $\alpha\text{-SMA}^+$ myofibroblasts and $CTGF^+$ cells per mm^2 ($p=0.0084$ and $p=0.001$ respectively). However, we did not observe a significant increase in the luminal stenotic area in p17 compared to saline-treated group. Correlation between the tracheal luminal area and collagen thickness was non-significant ($r=0.29$, $p=0.17$).

Conclusion: Tracheal stenosis is characterized by an important fibrotic component and by the activation of the TGF-β pro-fibrotic pathway. The animal model reproduces similar features and therefore, it provides a valid preclinical model. Local treatment with TGF-β1 antagonist demonstrates its ability to reduce the fibrotic but not the stenotic component, suggesting that fibrosis is only a partial contributor to the reduction of the tracheal lumen in ATS

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: RP is a common symptom of CTD. Nailfold capillary microscopy (NCM) has previously been shown to be associated with disease severity and internal organ involvement in relatively small non-consecutive cohorts. NCM may help in early recognition and awareness of (SSc like) internal organ involvement. It is unclear to which extent NCM abnormalities occur in several CTDs and whether these are associated with organ involvement. We evaluated consecutive patients visiting the vascular lab for NCM.

Methods: NCM was retrospectively assessed in consecutive patients with suspected RP (n=961) between 2008 and 2013 according to standardized procedures at our center. In 25 patients NCM was not assessable, in 177 RP was not present after careful chart review. Patients were classified as primary RP (normal NCM and ANA <1:80, n=235) or secondary RP, comprising very early diagnosis of SSc (VEDOSS, n=203), SSc according to ACR/EULAR criteria (n=39), SS according to American European Consensus Group criteria (n=37), *SLE* according to SLICC criteria (n=22), MCTD based on criteria defined by Kasuwaka (n=7) or when not meeting criteria as no classifiable disease (n=216). NCM was classified as normal, non-specific (≥3 dilated capillaries per finger) or SSc pattern: early, active or late. Giant capillaries were abnormal per definition, capillary loss was defined <20 capillaries per 3 mm. Pulmonary involvement was defined as forced vital capacity or diffusion capacity <70%, interstitial lung disease on HRCT and/or pulmonary arterial hypertension. Gastro-intestinal involvement was defined as scintigraphically (Tc-99M colloid) abnormal oesophagus motility.

Results: SSc pattern was observed in 32% of patients with SS , 31% SLE and 85% MCTD (table 1). Organ involvement was more frequent in secondary RP patients with a SSc pattern (figure 1). When analyzing patients fulfilling criteria for CTD separately this relation still existed (pulmonary 21 versus 8%; oesophageal 17 versus 9%), even after exclusion of VEDOSS and SSc patients. Also, in patients with giant capillaries pulmonary and oesophageal involvement was more frequent, while no relation was found for dilated capillaries. Capillary loss was associated with oesophageal involvement only.

Conclusion: SSc-like NCM pattern is common in CTD patients and appears to be associated with a greater prevalence of organ involvement, even in the absence of VEDOSS and SSc. Although this was a retrospective cohort, these data underline the importance of assessing NCM in RP patients to evaluate the risk for organ involvement in CTD other than SSc, already in early stages of the disease.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is characterized by significant disability due to musculoskeletal involvement. Physical and occupational therapy (PT/OT) have been suggested to improve hand function, speaking and eating ability. However, the rate of PT/OT use has been shown to be low amongst SSc patients. We aim to identify

demographic, disease-specific and psychological variables associated with PT/OT use in SSc.

Methods: Subjects were adult patients with SSc enrolled in the Scleroderma Patient-centered Intervention Network (SPIN) Cohort, recruited from Canada, the USA and Europe. Medical variables were provided by enrolling physicians. Subjects completed demographic variables, including information on PT/OT use in the 3 months prior to enrollment, and questionnaires to evaluate disability, hand dysfunction, pain, fatigue, symptoms of anxiety and depression, body image distress, and self-efficacy. Demographic, medical, and psychological variables were compared between patients who had used PT/OT services and those who did not using chi-square and independent samples t-tests (or non-parametric equivalents) as appropriate. Multivariable binary logistic regression was then used to identify factors associated with PT/OT use in the 3 months prior to enrollment.

Results: Analysis included 993 subjects with mean age of 55.2 ± 12.1 years and mean disease duration of 11.6 ± 8.8 years. 87% were females and 57% had limited SSc. 19% of subjects used PT/OT in the 3 months prior to enrollment, with hands being the most common indication (54%). PT/OT users had shorter disease duration, higher skin scores, and were more likely to have tendon friction rubs and joint contractures compared to non-users (Table 1). They had higher disability, lower rates of employment and self-efficacy, more pain, fatigue, and symptoms of depression, anxiety, and body image distress. Adjusting for other factors, PT/OT use was associated with being on disability (odds ratio [OR] 3.22, 95% confidence interval [CI] 1.81-5.71), more education (OR 1.10, 95% CI 1.04-1.17), early (≤ 3 years) SSc (OR 1.71, 95% CI 1.01-2.87), moderately severe small joint contractures (OR 1.78, 95% CI 1.11-2.86), and severe large joint contractures (OR 4.51, 95% CI 1.69-12.03) (Table 2).

Conclusion: Fewer than 20% of SSc patients in a large international cohort use PT/OT services. These patients had earlier disease, more severe musculoskeletal manifestations and higher disability. Additional studies are needed to further explore the impact of psychological distress and other factors including health insurance on PT/OT use.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is characterized by high disfigurement, morbidity, and mortality. It carries significant psychosocial impact including depression, anxiety and body image distress. However, no previous studies evaluated mental health services (MHS) utilization in SSc. Our aim was to determine the rate and source of mental healthcare for patients with SSc, and explore factors associated with MHS use.

Methods: Subjects were adult patients with SSc enrolled in the Scleroderma Patient-centered Intervention Network (SPIN) Cohort, recruited from Canada, the USA and Europe. Medical variables were provided by enrolling physicians. Subjects completed demographic variables, including questions on MHS use in the 3 months prior to enrollment, and questionnaires evaluating symptoms of depression, anxiety, fatigue, sleep disturbance, body image distress, and pain. Demographic, medical, and psychological variables were compared between patients who had used MHS and those who did not using chi-square and independent samples t-tests (or non-parametric equivalents) as appropriate. Multivariable logistic regression was then used to identify potential factors predictive of MHS use in the last 3 months.

Results: Of the included 1000 subjects, 87% were females and 57% had limited SSc. Mean age was 55.2 ± 12.1 years and mean disease duration was 11.6 ± 8.9 years. 20% used MHS in the 3 months prior to enrollment. General practitioners were the most common providers of MHS (59%), followed by psychologists (21%) and psychiatrists (13%). MHS users had shorter disease duration, more pain and were more likely to report gastrointestinal (GI) symptoms compared to non-users (Table 1). They were more likely to smoke, live in the city, be divorced and disabled, and have more symptoms of depression, anxiety, fatigue, and body image distress. Adjusting for all other factors, MHS use was associated with being on disability (odds ratio [OR] 2.50, 95% confidence interval [CI] 1.33-4.69), having shorter disease duration (OR 0.97, 95% CI 0.95-0.99), esophageal symptoms (OR 2.40, 95% CI 1.14-5.06), and higher depression (OR 1.05, 95% CI 1.00-1.10) and anxiety (OR 1.05, 95% CI 1.02-1.08) symptom scores (Table 2).

Conclusion: 20% of patients in the SPIN Cohort received mental health care in the 3 months prior to enrollment, of whom only 34% received care from a mental health specialist. Patients receiving MHS had earlier disease, more GI symptoms, higher disability, and more psychological distress. Additional studies are needed to evaluate the mental health needs of SSc patients and determine barriers to MHS use including cultural and health insurance factors.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SSc-cardiomyopathy associated conduction abnormalities carry a poor prognosis, but their pathogenesis is unclear. Early detection to prevent complications is essential. ILRs are well-established in cardiology practice. In patients (pts) with SSc and no known cardiac disease, we aimed to test feasibility of the REVEAL® ILR, the spectrum of cardiac conduction abnormalities (CCA) detected & association with CMR abnormality.

Methods: 20 pts with (ACR/EULAR criteria) SSc, with no diabetes &/or more than 1 cardiovascular (CV) risk factor, were assessed for SSc/CV profile & comprehensive CV assessment performed, inc. 3T delayed enhancement-CMR (reported by CMR-cardiologists) & ILR insertion. ILR data was downloaded 3 monthly +/- at pt request if symptomatic. Baseline CMR compared to 30 healthy controls (HC) and 1-year ILR data is reported with CMR. CK/troponin data available by time of ACR.

Results: ILR data was available for 19 pts; 63% female, 84% Caucasian; mean (SD) age 53 (12)years, median (IQR) time from 1st non-RP symptom 7.5(1.8, 19.5)years; 32% dcSSc, 32% ACA+ve, 21% Scl70+ve, 47% palpitations hx, 42% known ILD, 11% DU hx, 0% pulmonary hypertension. CMR data was available for 15 SSc pts (DE in 14; 1 pt claustrophobic, no IV access in 2, 1 CMR abandoned due to PPM insertion for CHB). Extracellular volume (ECV) was higher in SSc pts vs. HC; mean difference (diff.) 4.9 (3.2, 6.6)% p<0.001 $R^2$0.568, adj. for age/sex; with greater late gadolinium enhancement detection in SSc (36% vs. 3% in HC, p=0.009) (both markers of fibrosis), with lower LVmass/EDV (p=0.006) & trend for lower LV mass in SSc. Eleven (58%) patients had ILR findings: 7 (37%) supraventricular ectopics (SVE), 2 (11%) ventricular ectopics (VE), 3 (16%) bigeminy, 1 (5%) couplet, 1 (5%) salvo, & 5 (26%) arrhythmias of which 1 atrial flutter, 1 atrial flutter leading to atrial fibrillation, 1 SVT and 2 serious arrhythmias of 1 VT & 1 complete heart block (CHB). Of the 5 pts with arrhythmias, 4 were asymptomatic at time of arrhythmia (pt with VT had palpitations), 3 had dcSSc (inc. both serious arrhythmias), 2 ACA+ve, 1 Scl70, 2 known ILD, 2 DU hx. Trend towards greater ECV & distensibility (ie lower arterial stiffness) seen in pts with arrhythmias. Trend for higher ECV in those with SVE [unadj. mean diff. (95%CI) 1.1 (-2.5, 4.7)% p0.513], VE [0.7 (-4.9, 6.3)% p0.789] & arrhythmias [1.8 (-3.7, 7.3)%]. Table 1: CMR measures in SSc pts with/without arrhythmias (values=mean(SD) *n(%))

CMR variable	No arrhythmia N (%)=12 (80)	Arrhythmia N (%)=3 (20)	Unadjusted mean difference (95% CI), p value	Mean difference (95% CI), p value adjusted for age & sex
LVEF, %	60.11 (4.97)	60.12 (2.16)	0.01 (-6.48, 6.50), 0.997	0.30 (-5.52, 6.12), 0.912
LVmass/BSA, g/m^2	44.90 (11.66)	44.33 (5.80)	-0.57 (-15.86, 14.71), 0.937	-0.12 (-13.43, 13.18), 0.984
LV mass/EDV, g/ml	0.54 (0.08)	0.52 (0.05)	-0.03 (-0.13, 0.08), 0.592	-0.03 (-0.15, 0.09), 0.612
RVEF, %	57.30 (19.18)	59.23 (5.35)	1.94 (-22.84, 26.71), 0.869	0.18 (-18.28, 18.65), 0.983
Torsion, degrees	12.57 (5.78) (n=10)	14.36 (0.98)	1.79 (-2.45, 6.03), 0.615	1.64 (-6.31, 9.58), 0.652
ECV, %	29.55 (3.31) (n=11)	32.32 (2.0)	2.77 (-1.67, 7.20), 0.199	2.82 (-1.99, 7.63), 0.220
Presence of LGE	5 (41.7)*	0 (0.0)*	p=0.258	-
Distensibility, $10^{-3}mmHg^{-1}$	3.69 (2.25) (n=11)	5.73 (4.46)	2.04 (-8.17, 12.24), 0.277	1.96 (-1.84, 5.75), 0.277

Conclusion: This first ILR in SSc study demonstrates its feasibility and utility in the incidental detection of CCA, including serious cardiac arrhythmias & suggests associated CMR abnormalities. These data support the need for identification of pts at risk that would benefit from ILR & provide insights into the pathogenesis of SSc-cardiomyopathy.

Predicting Vascular Complications in Systemic Sclerosis: A Prospective Cohort Study

Christopher A. Mecoli[1], Ami A. Shah[2], Francesco Boin[3], Fredrick M. Wigley[4] and Laura K. Hummers[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [3]Rheumatology, University California San Francisco, San Francisco, CA, [4]Rheum Div/Mason F Lord, Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Vascular disease is of fundamental importance in the pathogenesis of scleroderma. Two major vascular complications in scleroderma patients that cause substantial morbidity and mortality are digital ulcerations (DU) and pulmonary hypertension (PH). The ability to predict which patients will develop these complications is poor in current clinical practice.

Methods: We conducted a prospective observational cohort study of 300 patients who were subsequently followed for at least a five-year period. Adult patients were included that met American College of Rheumatology criteria for scleroderma

or have at least 3 of 5 features of the CREST syndrome. At baseline patients lacked evidence of pulmonary hypertension (PH) and were without current DU. At each visit the patient was examined for signs and symptoms of development of PH and DU. The primary outcomes were (1) pulmonary hypertension defined as a mean pulmonary artery pressure greater than or equal to 25 mm Hg obtained by right heart cardiac catheterization and (2) DU were defined as new onset of severe vascular compromise as evidenced by development of ischemic digital ulcerations, gangrene or digital loss. All classes of PH were modeled together in the primary analysis (pulmonary arterial hypertension (PAH), interstitial lung disease-associated PH) as these classes are not pathogenically mutually exclusive.

Results: The majority of the patients in the cohort (N=300) were middle-aged Caucasian females, with 13% of patients being male and 14% being African American. 58% of the patients had limited disease with an average disease duration of 10 ± 8.4 years from 1st non-RP symptom at study entry. Tables 1 & 2 show demographic data and baseline values for clinical tests by each of the individual outcomes. Patients who developed PH were more likely to have diffuse disease compared to patients without PH. Interestingly, baseline DLCO was lower in patients who develop both DU and PH. There was no difference in DU incidence in PH compared to non-PH groups (Fisher exact p=0.38).

Conclusion: We hypothesized that baseline echocardiographic and pulmonary function study parameters would be predictive of vascular outcomes. Our study demonstrates that the diffuse subtype and the distance walked at the baseline 6-minute walk test are predictive of developing PH, but not DU. We speculate that there may be unique pathophysiology that contributes to developing different vascular outcomes.

Session Time: 9:00AM-11:00AM

THE EFFECT OF CYCLOPHOSPHAMIDE ON PULMONARY FUNCTION AND DEPENDENCE ON DISEASE ACTIVITY OF INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS

W. M. T. Van Den Hombergh[1], E. Teesselink[1], H. K. A. Knaapen-Hans[1], S. O. Simons[2], F. H. J. van den Hoogen[1], J. Fransen[1], M. C. Vonk[1] [1]Department of Rheumatology, [2]Department of Respiratory Medicine, Radboud University Medical Centre, Nijmegen, Netherlands

Background/Purpose: The pathogenesis of interstitial lung disease associated with systemic sclerosis (SSc-ILD) is not completely elucidated, although it is believed that chronic alveolar inflammation leads to increasing fibrosis. Treatment strategies using cyclophosphamide (CYC) have been focusing on the inflammatory pathway of SSc-ILD. We hypothesized that CYC is more effective in patients that are in the early, inflammatory phase. The objectives of this study are analyze the effects of intravenously CYC pulses (750mg/m^2) on pulmonary function (FVC, DLCO) in SSc-ILD after 12, 24 and 36 months, and whether this effect is dependent on the extent of ILD, the proportion of ground glass compared to fibrosis, SSc disease duration or baseline DLCO <60%.

Methods: Patients with SSc-ILD receiving CYC pulses between 2003 and 2015 were classified by the Goh (2008) criteria in either limited or extensive ILD, using HRCT at baseline independently judged by two raters. Pulmonary function tests were performed at 0, 6, 12, 24 and 36 months. Missing outcome data due to drop-out were replaced by last observation carried forward, except in case of death.

Results: Seventy-five patients were included, 33 with limited ILD, 42 with extensive ILD. There were no baseline differences in age, gender, SSc subtype classification, disease duration or autoantibody status. FVC and DLCO were stable after 12, 24 and 36 months of follow-up (table 1).

Table 1. Pulmonary function test during follow-up

		Baseline	Follow-up	Mean difference with 95%-CI	P-value
Δ baseline vs. 12 months	FVC	85 (72 – 97)	87 (77 – 101)	2.5 (0.3 - 5.3)	0.08
	DLCO	43 (33 – 57)	46 (36 – 59)	-0.3 (-2.7 - 2.2)	0.83
Δ baseline vs. 24 months	FVC	85 (72 – 97)	91 (71 – 104)	2.8 (-1.3 - 7.0)	0.18
	DLCO	43 (33 – 57)	43 (35 – 59)	0.8 (-2.6 - 4.1)	0.66
Δ baseline vs. 36 months	FVC	85 (72 – 97)	90 (73 – 103)	2.2 (-4.3 - 8.7)	0.49
	DLCO	43 (33 – 57)	43 (36 – 62)	2.5 (-1.7 - 6.7)	0.25

Analysis with last observation carried forward and per protocol analysis showed similar results
FVC and DLCO baseline and follow-up values are % of predicted

There was no effect in the degree of change in FVC and DLCO for the different effect modifiers (table 2): the extent of ILD, proportion of ground glass compared to fibrosis, short SSc disease duration or baseline DLCO <60%.

Table 2. Linear regression analysis				
		Δ 0-12 months		
		B	SE (B)	p-value
FVC	Constant	0.3	4.9	0.95
	Limited vs. extensive	1.3	3.3	0.69
	Constant	1.6	5.8	0.79
	GGO > fibrosis	0.4	3.4	0.91
	Constant	8.2	4.8	0.1
	Disease duration <3 yr	-4.8	3.6	0.2
	Constant	1.0	5.1	0.84
	Baseline DLCO <60%	1.3	4.0	0.76
DLCO	Constant	0.1	4.3	0.99
	Limited vs. extensive	0.6	2.8	0.83
	Constant	-0.4	5.1	0.9
	GGO > fibrosis	0.8	2.9	0.78
	Constant	-0.3	4.3	0.94
	Disease duration <3 yr	1.0	3.2	0.75
	Constant	2.6	4.4	0.56
	Baseline DLCO <60%	-1.1	3.4	0.76

FVC and DLCO values are % of predicted

Conclusion: Pulmonary function in SSc-related ILD was stable during 36 months of follow-up after cyclophosphamide pulse therapy. The extent of ILD, proportion of ground glass, SSc disease duration and baseline DLCO <60% did not influence the effect of CYC on pulmonary function. It could not be shown that CYC is more effective in the early phase of SSc-ILD.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The modified Rodnan skin score (mRSS) is a clinical evaluation score of the extent of cutaneous fibrosis in systemic sclerosis (SSc). mRSS has been associated with morbi-mortality in several studies. This study aimed to delineate different trajectories of mRSS changes overtime in a large database of patients and to compare patients' characteristics in clusters of patients identified. In this report, the results for non-treated patients are presented.

Methods: From a large French multi-center database of 2098 SSc patients, we included patients fulfilling the 1980 ACR criteria with at least two available records of mRSS. Treatment status was defined as steroids or immunosuppressive intake. Group-based modelling was used to cluster similar mRSS patterns into trajectories. Then variables of clusters obtained were compared using the SAS software.

Results: 818 patients were included: 306 had never received treatment, 403 had been treated and treatment status was unavailable for 109. Treated patients were more severe than non-treated patients with a higher frequency of diffuse cutaneous (dc) SSc, anti-topoisomerase I antibodies, muscular and joint involvements, interstitial lung disease ($p<0.0001$), and mortality ($p=0.003$). Two subgroups of similar trajectory among untreated patients were identified ($p<0.001$, figure 1). The analysis of tendencies showed that patients in cluster 1 had a low baseline mRSS (mean mRSS: 4.15±3.66) that did not change significantly during the follow-up (mean mRSS: 4.11±4.00, mean follow-up: 3.50±2.78 years; $p=0.78$). Patients in cluster 2 had a higher mRSS at baseline (mean mRSS: 21.23±6.96) with a significant decrease during the follow-up (mean mRSS: 17.62±8.5, mean follow-up: 2.98±3.04 years; $p<0.0001$). Patients in cluster 2 had a higher frequency of dcSSc (77% vs. 7%, $p<0.0001$), anti-topoisomerase I antibodies (52% vs. 17%, $p<0.0001$), muscle involvements (23% vs. 6%, $p=0.008$), digital ulcers (56% vs. 34%, $p=0.026$), gastrointestinal tract involvements (42% vs. 20%, $p=0.0079$) and interstitial lung disease (25% vs. 1%, $p<0.0001$). There was no significant difference between the two clusters concerning heart involvement, pulmonary arterial hypertension and mortality.

Conclusion: This work led to the identification of two different clusters among non-treated patients from a French multicenter database, based on similar mRSS trajectories. Interestingly, mRSS of cluster 2 significantly decreased overtime whereas the patients received no immunosuppressive treatment. Nevertheless, they remained exposed to more severe complications than cluster 1. The analysis of the entire database and comparisons between treated and untreated patients might provide new insights into the natural history of this disease. *EL and VS have contributed equally to this work.*

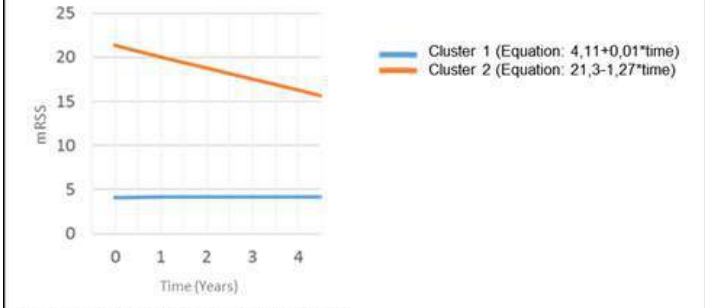

Figure 1: Main results of group-based modelling.

Cluster 1: First subgroup with low mRSS at baseline (mean mRSS: 4.15±3.66) unchanged during the follow-up (mean mRSS: 4.11±4.00, mean follow-up: 3.50±2.78 years, p=0.78). N=278.

Cluster 2: Second subgroup with high mRSS at baseline (mean mRSS : 21.23±6.96) decreasing during the follow-up (mean mRSS: 17.62±8.5, mean follow-up: 2.98±3.04 years; p<0.0001). N=26.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Raynaud's phenomenon is common but can progress to definite connective tissue disease. We have observed long term follow up of an unselected consecutive cohort of isolated RP to define frequency of progression and negative predictive value of nailfold capillaroscopy (NC) and ANA testing. Cases attending a dedicated Raynaud's clinic were stratified according to baseline assessment and observed serially. Frequency of SSc or connective tissue diagnosis at presentation and progression of nailfold capillary abnormality or development of positive ANA was determined during routine follow up.

Methods: Cases of suspected RP were referred from primary care to a dedicated Raynaud's clinic. In addition to clinical management of Raynaud's symptoms all cases had baseline ANA testing and nailfold capillaroscopy (NC) for stratification and diagnosis. There were also clinically evaluated for presence of connective tissue disease (CTD). Those with a SSc specific ANA were referred for evaluation comprehensive assessment in a specialized CTD clinic. In cases of isolated RP without evidence of CTD but considered at risk of progression annual review was performed. The number of cases with significant evolution was determined.

Results: Patients with definite symptoms of RP were assessed by clinical examination, autoantibody testing and capillaroscopy (n=457). Of these, 119 cases were assessed as potential secondary RP and were reviewed at least once. Mean (SD) follow up of RP cases was 2.0 (1.8) years with a range of 1 to 12 years. A total of 350/457 (76.7%) had negative ANA, an additional 3/119 (2.5%) became ANA positive during follow-up. NC confirmed 335/457 (73.3%) had normal capillaries and 7/119 (5.9%) developed abnormal NVC during follow up, none with ANA evolution. At first assessment 23/457 (5%) had SSc specific ANA positivity (centromere, Scl-70, RNApol3, U3-RNP reactivity) and these were referred to the CTD clinic for evaluation and review. Of these, 12/23 (52.2%) had abnormal NVC and 8/23 (34.8%) had clinical evidence of connective tissue disease. 4 fulfilled classification criteria for SSc (2 limited and 2 diffuse SSc). No SSc pattern ANA was observed in other patients during follow up. No cases developed defined CTD within the follow up period (ANA+/NC+). 28 ANA positive cases were reviewed and none developed NC progression to abnormal. Thus, overall the rate of significant change in these tests was low and no patients with negative ANA and normal NC progressed.

Conclusion: Feasibility and utility of systematic baseline assessment of cases presenting with isolated RP is confirmed. Routine assessment of ANA and NC is known to be useful in identifying cases of RP with SSc specific ANA, including new SSc diagnosis, and those at risk of long term progression. However, these tests are often normal and then the rate of progression is very low. In this cohort cases with negative tests did not show any clinical progression confirming that these tests have a robust negative predictive value.

Physical Activity in Patients with Systemic Sclerosis Liem SIE, Meessen JMTA, Wolterbeek R, Ajmone Marsan N, Ninaber MK, Vliet Vlieland TPM, de Vries-Bouwstra JK

Background/Purpose **:** Systemic sclerosis (SSc) is a condition with major consequences on many aspects of patient's functioning. Whereas its impact on exercise capabilities and daily activities has been well described, the association between the disease and its severity and physical activity (PA) is largely unknown. The aim of this study was to compare PA levels of Dutch SSc patients to the Dutch population and study factors associated with PA levels and determine needs and preferences of SSc patients regarding PA.

Methods: 59 SSc patients referred to a multidisciplinary care pathway and fulfilling the ACR 1980[1] or LeRoy criteria[2] for SSc completed the Short QUestionnaire to ASess Health-Enhancing PA[3]. The proportion of patients meeting the Dutch recommendation for PA (=moderate intensity PA for 30 minutes on > or = 5 days/week) and the total minutes of PA per week were calculated. Data were compared with aggregated data of the Dutch population (Central Bureau of Statistics; N=5789) and compared by means of t-tests. The following characteristics were extracted from the medical record: Body Mass Index, disease duration, modified Rodnan skin score, current or past immunosuppressive therapy, left ventricular ejection fraction, six minute walking distance, diffuse capacity for carbon monoxide, presence of anti-Scl-70-/ anti-centromere-antibodies, interstitial lung disease, proximal muscular weakness, synovitis, joint contractures or atrophy. The needs and preferences of SSc patients regarding PA were assessed by means of a self-developed questionnaire. Patients' characteristics and needs and preferences were multivariately compared between patients with low and patients with high levels of PA (less or more than the average minutes/week of the Dutch population).

Results: Of the 59 included patients 52 (88%) were women. The median age was 65 years and 14 (24%) SSc patients were aged 55 years and below. Stratified for age (<55 or ≥55 years) and gender, the proportion of SSc patients meeting the Dutch recommendation for PA was not significantly different from the Dutch population. However, the total minutes of PA per week was significantly lower among SSc patients as compared with the Dutch population (1729 vs. 2614, Table 1). Multivariable analyses showed that male gender and joint/muscle involvement were associated with lower PA levels (p=0.044; p=0.013). Patients not meeting the Dutch recommendations more often reported pain during exercise and a lack of energy interfering with exercise (p=0.049; p=0.002). 39 (67%) patients stated to need more information about PA.

Conclusion: In SSc patients, the total number of minutes of physical activity per week is significantly lower as compared to the general population. Pain, lack of energy, male gender and joint/muscle involvement seem to interfere with exercise, underlining the need for proper guidance of systemic sclerosis patients by health care providers. ***References:*** [1]Arthritis Rheum 1980 May;23(5):581–90. Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Prevalence of Anti-RNA Polymerase III IgG Antibody in a Cohort of Patients with Delayed Wound Healing

Background/Purpose: Anti-RNA polymerase III IgG antibody (Pol3) is associated with diffuse cutaneous scleroderma. Depending on the population studied, Pol3 prevalence in scleroderma patients ranges from 9-20% whereas its reported prevalence is less than 1% in healthy individuals. Pol3 is therefore considered highly specific for scleroderma. Emerging

data suggests that this antibody is also associated with co-temporal development of malignancy in the scleroderma population. The purpose of this study was to determine the prevalence of Pol3 in patients with delayed wound healing.

Methods: The Wound Etiology and Healing (WE-HEAL) Study is an IRB approved biospecimen and data repository designed to investigate the immunologic features of delayed wound healing. A proportion of WE-HEAL patients undergo autoimmune serologic profiling (including Pol3) as part of their ongoing clinical care due to either skin graft failure, planned surgical intervention or prior to initiation of immunosuppressants. Testing for Pol3 was performed by RDL Reference Laboratory (Los Angeles, CA) with a result of >20 units considered positive. In patients with positive Pol3 results we investigated the percentage of scleroderma and other autoimmune diseases.

Results: Of the 568 patients enrolled in the WE-HEAL study at the time of data lock, Pol3 was positive in 9 out of 167 patients (5.4%) who had the test performed. There was no significant difference in baseline characteristics or wound outcome between Pol3 positive patients and Pol3 negative patients. (Table 1). Only 1 of the 9 patients with positive Pol3 had scleroderma (11.1%). This patient had longstanding diffuse scleroderma and was also diagnosed with metastatic breast cancer at the same time that her wounds developed. Of the other 8 patients one patient had a history of cervical cancer but 7 had no active or prior malignancy. In this cohort Pol3 was associated with other immune mediated skin disorders with a prevalence of 4.7% in Hidradenitis Suppurativa, 20% in patients with Sjogren's Syndrome and 11.7% in patients with Rheumatoid Arthritis.

Conclusion: In this longitudinal cohort of patients with delayed wound healing Pol3 antibody was positive in 5% of patients tested which is higher than expected based on prevalence of this autoantibody in the general population. We postulate that Pol3 may not be unique to scleroderma and that other autoimmune mediated skin conditions such as vasculitic leg ulcers and hidradenitis may also be associated with Pol3 positivity. The findings suggest that patients with immune mediated wound issues have a higher than expected Pol3 positivity rate, a finding which further investigation in this ongoing longitudinal study.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Satisfaction with Appearance Scale (SWAP) has been used to assess dissatisfaction with appearance and social discomfort relative to disfigurement in systemic sclerosis (scleroderma, SSc); however, it has not been validated across sexes, different racial/ethnic groups, and varying disease subtypes. The study objectives were to evaluate the established two-factor structure of the SWAP; and examine the metric equivalences of the SWAP among male and female patients, Black and White patients, and patients with diffuse and limited SSc subtypes.

Methods: SSc patients were sampled from 21 centers within the international Scleroderma Patient-centered Intervention Network (SPIN) Cohort. Confirmatory factor analysis (CFA) was used to evaluate the established SWAP two-factor structure (Dissatisfaction with Appearance and Social Discomfort). The Multiple-Indicator Multiple-Cause (MIMIC) model was utilized to assess differential item functioning (DIF).

Results: The SWAP was completed by 748 SSc patients, including 651 female patients, 700 White patients, and 455 with limited SSc. Results from the CFA revealed that the two-factor model (Dissatisfaction with Appearance and Social Discomfort) demonstrated good fit based on the CFI and TLI indices, and slightly less than acceptable fit based on the RMSEA, $x^2(75)=742.33$, $p<.001$, CFI=0.98, TLI=0.97, RMSEA=0.11. Statistically significant, but small-magnitude DIF was found for six SWAP items across socio-demographic or disease characteristics; however, the overall estimates in SWAP scores were not influenced substantively by DIF.

Conclusion: SWAP scores from male and female SSc patients, Black and White patients, and patients with diffuse and limited SSc can be compared and pooled without concern that measurement differences may substantially influence results. Replications of the current study with larger samples of male patients as well as Black and other/racial ethnic minority groups are needed.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by microvascular damage and excessive fibrosis in the skin and internal organs. Myocardial fibrosis which contributes to either right or left ventricular diastolic dysfunction by reducing the ventricular compliance, is associated with poor prognosis. The aim of this study was to evaluate left ventricular (LV) dysfunction in patients with subclinical cardiac involvement by 2-dimensional speckle tracking echocardiography (2D STE)

Methods: Forty-seven patients (52±12 years, 89.4% women) and 36 gender and age-matched healthy subjects underwent transthoracic 2D STE. We evaluated global LV and RV strains, diastolic variables, cardiac biomarkers, inflammatory and metabolic parameters.

Results: The longitudinal peak systolic strains (PSS)—2CH, longitudinal PSS—APLAX , longitudinal PSS—4CH and global longitudinal PSS of the left ventricle were significantly lower in the SSc group compared with controls (-18,2±3,2% vs. -20± 2,7% p=0.02; -17,8±3,5 vs. -20,3±3,3% p=0,001; -23±3 vs.-21,8±3% p=0,000; -17,5±5,7% vs. -20,6±2,7 % p=0,000 respectively). Although early (E) and late (A) diastolic peak velocity were decreased in SSc group, E/A ratio was similar in both groups. No differences in right ventricle (RV) strain and tricuspid annular plane systolic excursion (TAPSE) were found. B-type natriuretic peptide (BNP), CRP and ESR were significantly higher in patients with SSc (198±250 mg/dl vs.122,5±161 mg/dl p=0,01; 0,5±0,4mg/dl vs. 0,3±0,3 mg/dl p=0,012; 21,7±15 mm/h vs. 11±8,5 mm/h p=0,000 respectively). Although there was no difference between the weights, patients with SSc were shorter than healthy subjects and BMI was significantly higher (28,5±5 vs 25,9±2 kg/m²). The homeostatic model assessment (HOMA) and fasting insulin were also higher in SSc group 1,9±1,3 vs 1,3±0,6 p=0,02; 8±4,9 vs 5,6 ±2,4 IU/mL p=0,008) (Table).

Conclusion: The use of 2D STE can be a sensitive method for detecting subclinic LV dysfunction in SSc patients with preserved left ventricular ejection fraction (LVEF) and pulmonary arterial pressure (PAP). Metabolic and inflammatory parameters should be considered as risk factors for development of overt cardiac disease.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Oxidized low-density lipoprotein (LDL), especially malondialdehyde modified LDL (MDA-LDL) has attracted attention as a predictive serum marker for the secondary development of atherosclerotic lesions. Although increased levels of MDA-LDL have been found in patients with rheumatoid arthritis and systemic lupus erythematosus, few studies have described MDA-LDL levels in patients with systemic sclerosis (SSc). The aim of this study was to investigate the correlation between MDA-LDL and clinical symptoms in patients with SSc.

Methods: The study involved 58 patients with SSc consisting of 10 male and 48 female patients with a mean age of 63.1 ± 14.0 years. The serum of 10 patients with SLE was used as controls. Of 58 patients, 16 patients had diffuse cutaneous systemic sclerosis (dcSSc) and 42 had limited cutaneous systemic sclerosis (lcSSc). The oxidized LDL levels were measured using the oxidized-LDL ELISA kit (Sekisui Medical Co., Ltd., Japan) according to the manufacturer's protocol.

Results: Increased levels of oxidized LDL were found in patients with dcSSc when compared with patients with SLE. The MDA-LDL/LDL-C ratio was higher in patients with dcSSc and lcSSc than in those with SLE. A significant negative correlation was observed between the %DLco and MDA-LDL levels as well as between %DLco and MDA-LDL/LDL-C. The MDA-LDL/LDL-C ratio strongly correlated with %DLco, more so than did the MDA-LDL levels. Right ventricular systolic pressure measured by echocardiography, immunoglobulin G (IgG), KL-6, and surfactant protein D showed positive correlations to oxidized LDL/LDL-C. When we defined patients with increased MDA-LDL levels by using the standard values mentioned above, and analyzed associations with clinical signs, significantly more patients in the increased MDA-LDL group had complications with lung pulmonary hypertension, and the positivity rate for anti-centromere antibodies was higher in the increased MDA-LDL group.

Conclusion: Many patients with SSc had increased levels of oxidized LDL, which may be a reflection of increased atherosclerosis lesions in patients with SSc. A positive correlation between decreased levels of %DLco, KL-6, and SP-D and oxidized LDL/LDL-C was observed and this may indicate that oxidized LDL is involved in the progression of interstitial pulmonary lesions in patients with SSc. Little is known about abnormal lipid metabolism in patients with SSc when compared with that of patients with RA and SLE. However, the frequency of complications in lipid metabolism is high in patients with SSc and the pathology of SSc remains unclear.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a multi-organ system disease manifested by fibrosis, vascular damage and dysregulation of the immune system. The leading causes of death are interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH). ILD is present in up to 80% of patients with SSc and clinically significant ILD affects approximately 25% of patients with SSc. Our objective was to evaluate the presence of pulmonary hypertension (PH) in a cohort of patients with early onset SSc-associated ILD (SSc-ILD).

Methods: Subjects with a diagnosis of SSc based on 2013 ACR/EULAR classification criteria and ILD based on high-resolution computed tomography were included in our prospective observational cohort. Subjects with disease duration of ≤ 7 years, based on inclusion criteria for ongoing controlled trials in SSc-ILD, were also identified. Subjects with PH were identified based on right heart catheterization (RHC) and were classified into PH groups 1, 2, and 3 (Table 1).

Results: Ninety-four subjects with SSc-ILD were included in this analysis. Seventy-seven percent of patients were female, the mean age was approximately 52 years old, the mean disease duration was 2.8 years after initial non-Raynaud's Phenomenon (RP) symptom, approximately 61% had diffuse cutaneous SSc, ANA was positive in 91%, anti-Scl-70 antibody was positive in 28%, and anti-centromere antibody was positive in 8% of subjects. Of those 94 subjects, 25 subjects had a diagnosis of PH based on RHC and 20 of those subjects had early onset SSc (Table 1).

Conclusion: In a large SSc-ILD cohort, with many subjects of earlier disease duration, a significant proportion of patients have co-existing PH. These are novel findings that should be entertained when designing trials for SSc-ILD and should be validated in other cohorts of SSc-ILD.

Table 1. PH in SSc-ILD

	Any Length of Disease Duration After Initial Non-RP Symptom (n=94)	Disease Duration ≤7 Years After Initial Non-RP Symptom (n=81)
FVC (% Predicted) Mean± SD (n=)	75.6 ± 16.0 (93)	74.9 ± 15.3 (81)
DLco (% Predicted) Mean± SD (n=)	54.1 ± 22.7 (83)	53.5 ± 20.6 (73)
No PH* % (n =)	73.4% (69)	75.3% (61)
PH* (Group 1, 2 and 3 PH) % (n =)	26.6 % (25)	24.7% (20)
Group 1 PH* % (n =)	6.4 % (6)	7.4% (6)
Group 2 PH* % (n =)	4.3% (4)	2.5% (2)
Group 3 PH* % (n =)	15.9% (15)	14.8% (12)

*PH Classification
Non-PH: mPAP < 25.
Group 1 PH (PAH): mPAP ≥ 25; PCWP ≤ 15.
Group 2 PH (left heart disease): mPAP≥25 ; PCWP>15.
Group 3 PH (lung disease/ hypoxia): mPAP≥25; PCWP≤15 ; FVC < 60% or moderate/severe ILD.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Oncostatin M (OSM) is a pleiotropic member of the gp130/IL-6 cytokine family involved in pathological processes of fibrosis, inflammation and vasculopathy. Diffuse cutaneous systemic sclerosis (DcSSc) subjects have increased OSM serum levels and OSM/OSM-related genes are upregulated in DcSSc skin biopsies (Feeney 2016). A previous monoclonal antibody developed for the treatment of RA was discontinued due to lack of efficacy likely associated to poor binding affinity (Choy 2013). A novel IgG1 Mab (GSK2330811), with approximately (~) >10 fold increased binding affinity in-vitro, is being developed for the treatment of DcSSc. We aimed to assess target engagement in the target tissue (skin) and to determine the antibody in-vivo affinity using physiology-based pharmacokinetic modelling (PBPK) in a first time in human study (Study 201246).

Methods: Healthy males and females of non-child bearing potential aged 18 to 65 received single ascending subcutaneous doses of GSK2330811 (0.1-6mg/kg) or placebo. Skin suction blisters were raised on the volar surface of the forearm by applying suction for 4 hours followed by collection of the blister fluid. Validated immunoassays were used to measure target engagement (free and total OSM) and GSK2330811 concentrations in blood and skin. A combined PBPK and target mediated drug disposition model (TMDD) was developed to assess in-vivo affinity of GSK2330811 (Cao, 2014).

Results: 30 Subjects received GSK2330811 and 10 placebo. GSK2330811 showed a favourable safety and tolerability profile compared to placebo. Skin suction blisters were well tolerated. The PK of GSK2330811 was consistent with IgG1 Mab against a soluble target. The typical apparent distribution volume was 11.5 l (95% CI: 10.2-13.1) and the typical apparent systemic clearance was 14.1 ml/hr (95% CI: 12.7-15.6). The mean terminal half-life was ~3 weeks. GSK2330811 ratio between skin and plasma concentration was ~ 20-30%. Estimated in-vivo affinity was ~ 0.6 nM. A rapid (~ 30 min) OSM target turnover was estimated based on total OSM data. Free OSM levels were below the limit of quantitation after drug administration in both serum and blister fluid indicating substantial OSM inhibition. At the top dose level ~ 90% of target engagement is predicted in serum, while slightly lower values (~70-80%) are predicted in the skin blister fluid.

Conclusion: This study demonstrates that GSK2330811 has sufficient affinity to achieve high target engagement in systemic circulation and target tissue. Skin blister analysis provided valuable data to inform the mechanistic target engagement model. These data support progression of GSK2330811. A proof of mechanism study in subjects with DcSSc is being developed. **References**: Feeney M, et al. Arthritis Rheumatol 2015;67(suppl 10) Choy EH, et al. SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Eosinophilic fasciitis (EF) is a rare scleroderma-like disorder described in 1974 by Shulman. It is characterized by the acute onset of edema and induration of the skin and the subcutaneous tissue associated with peripheral blood eosinophilia. Deep skin biopsy shows characteristic alterations in the muscle fascia. There is no consensus regarding the treatment of the EF. Oral or intravenous glucocorticoids (GC) are usually the initial treatment with significant improvement in most cases. Immunosuppressive drugs may be associated when the response is insufficient and the most used is methotrexate (MTX). The response to MTX is usually favorable, especially in cases with concomitant morphea lesions[1]. In this study we investigated which demographic, clinical and laboratory baseline features are associated with remission during MTX treatment in patients with EF.

Methods: We performed an observational, retrospective (1983–2014) and multicentric study of patients with EF from 5 Spanish university hospitals. Inclusion criteria: 1) characteristic cutaneous manifestations; 2) deep biopsy with consistent changes in muscle fascia, and 3) treatment with MTX. Response to treatment was divided into: 1) complete remission (absence of symptoms and disappearance of lesions); 2) partial response (patients who develop limitation despite treatment); and 3) lack of response (persistence of symptoms and findings on examination)[1]. Statistical non-parametric tests were used for the data analysis, Kruskal Wallis for continuous variables and χ^2 for categorical variables.

Results: 33 patients were included, 18 women (54.5%), with a mean age of 54.6 years (range 22–81) and median duration of disease until diagnosis of 4 months (range: 1–25). Most of these patients (97%) had previously been treated with GC with insufficient response, 8 (24.2%) had previously received other immunomodulatory drugs (hydroxychloroquine, azathioprine, cyclosporine) and 5 (15.2%) photochemotherapy (PUVA). MTX median dose was 15 mg/week (range: 10–25); 16 cases (48.5%) achieved complete remission, 15 (45.5%) partial response and 2 (6%) lack of response. Patients who achieved complete remission had a mean age at diagnosis slightly higher (64), presented more frequently induration ≥ 50% of body surface, myalgia and associated malignancies but C-reactive protein (CRP) levels were lower. Of all the variables analyzed, only low CRP level was significantly associated with complete remission (P=0.004). Two patients in remission relapsed after discontinuation of MTX, with a favourable response to re-treatment with GC.

Conclusion: The only variable that seems to be associated with remission during treatment with MTX in our series is the absence of elevated CRP. All other variables showed no significant differences, although the statistical power may be small due to the limited sample size.

	Complete remission (N=16)	Partial response (N=15)	Lack of response (n=2)	P value
Age at diagnosis	64 (40-73)	49,5 (42-57)	54 (42-69)	0.640
Female gender	8 (44%)	8 (44%)	2 (11%)	0.405
Smoking	3 (25%)	8 (67%)	1 (8.3%)	0.204
Time to diagnosis (months)	4,0 (2-7)	4,0 (2.5-7.5)	6,5 (3-10)	0.867

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Exercise is associated with improved health in many medical conditions. Little is known about the exercise habits of people with systemic sclerosis (SSc, or scleroderma). This study assessed the proportion of individuals with SSc who exercise and associations of demographic and disease variables with exercise. Additionally, the weekly amount of time spent exercising and the types of exercise performed were assessed among patients exercising.

Methods: The sample consisted of adult participants with SSc enrolled in the Scleroderma Patient-centered Intervention Network (SPIN) Cohort who completed baseline questionnaires from March 2014 through August 2015. Baseline questionnaires included questions on exercise habits, physician-reported medical characteristics, self-report demographic characteristics, the Health Assessment Questionnaire – Disability Index (HAQ-DI), Patient Health Questionnaire-9, and PROMIS-29.

Results: Of 752 patients, 389 (51.7%) reported presently engaging in exercise, and these patients exercised on average 4.7 hours (SD=2.8) per week. Among patients who reported exercising, walking was most commonly reported (n=295, 75.8%). In bivariate analyses, present exercise was associated with more education, lower body mass index, some (versus no) alcohol consumption, non-smoking, limited/sine disease subtype, absence of skin thickening, lower disability, higher physical function, lower symptoms of anxiety and depression, less fatigue, lower sleep disturbance, higher ability to participate in social roles and activities, and less pain.

Conclusion: Approximately half of SSc patients reported that they are currently exercising with walking being the most common form of exercise. Understanding exercise patterns and factors associated with exercise will help better inform intervention programs to support exercise for patients with SSc.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in systemic sclerosis (SSc). Esophageal dysfunction and aspiration may play a role in SSc-ILD. We showed that esophageal dilation on high-resolution computed tomography (HRCT) scans correlated positively with radiographic ILD and negatively with forced vital capacity (FVC)[1]. We also showed that a widest esophageal diameter (WED) >=19mm on HRCT had the highest combined sensitivity and specificity for associated ILD[2]. The purpose of this retrospective, longitudinal study was to determine if a larger WED is a risk factor for SSc-ILD incidence and progression.

Methods: Subjects that fulfilled American College of Rheumatology 2013 SSc criteria with >= one HRCT and two pulmonary function tests were included. The first available HRCT was defined as the baseline exam. WED was measured. ILD was quantified by published methods[3]. In subjects without radiographic ILD and with baseline FVC >=70% predicted, incident restrictive lung disease was defined as new FVC <70% predicted. Change in FVC % predicted was used as a surrogate for ILD progression.

Results: In total, 249 subjects were included with a median follow up of 2.9 years (0.02-13.4y). Twenty-five subjects died. At baseline, 88 (82%) with a WED >=19mm had radiographic ILD compared with 94 (66%) with a WED <19mm (p=0.005; Table 1). Three of 55 without baseline ILD developed incident restrictive lung disease. At baseline, those with WED >=19mm had an 8.38 lower FVC % predicted than those with WED<19mm. In total, there was no clinically significant decline (i.e. >5% change) in FVC % predicted (Fig. 1). There was no significant difference in change in FVC % predicted between those with WED >=19 vs. <19mm (beta=0.2663; 95% CI -0.2256, 0.7583).

Conclusion: SSc-ILD often occurs before referral to a tertiary center. Those with a larger WED had an FVC % predicted at baseline that was clinically and statistically significantly lower than those with a smaller WED. Despite this, a larger WED at baseline was not associated with more rapid decline in FVC % predicted. References: 1. Richardson et al. Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Nailfold videocapillaroscopy (VCP) has become an established method to assess the microcirculation in patients with Raynaud's phenomenon and connective tissue diseases. The 2013 Systemic Sclerosis (SSc) criteria included capillaroscopy as a necessary tool for SSc classification. Adequate training for identification of Systemic Sclerosis capillaroscopic patterns is relevant for all Rheumatologists. To date, there is little evidence of the reliability of VCP findings amongst different readers. We evaluated inter- and intra-reader agreement of 13 Rheumatologists to identify SSc capillaroscopy patterns ("early", "active" and "late") proposed by Cutolo et al (ref 1).

Methods: Thirteen rheumatologists (7 without experience and 6 with more than 2 years of experience in the routine performance and reading of capillaroscopic images) received a 20 min training regarding the identification of SSc capillarosocpy patterns to standardize reading criteria. Then, they individually rated 60 videocapillaroscopy images (12 from healthy subjects, 48 from SSc patients) at baseline, and 4 weeks after the first reading using an electronic platform in order to perform the intra-reader exercise. The reading of an expert with more than 15 years of experience in capillaroscopy was considered the gold standard. Data was analyzed using Cohen´s kappa for concordance, Student´s t test and ANOVA were used to compare kappa means for inter-reader, intra-reader and inter-pattern readings.

Results: Mean inter-reader and intra-reader kappa were 0.45 and 0.49, respectively, reflecting moderate agreement. Mean kappa scores were significantly higher among experienced readers when compared with unexperienced readers (inter-reader kappa: 0.58 vs 0.34, p=0.001, intra-reader kappa: 0.65 vs 0.37, p=0.01). Agreement was substantial (kappa =0.61) for the identification of normal vs abnormal capillaroscopy, and higher than the overall agreement (p=0.009). Agreement was higher for the identification of "active" (0.48, p=0.009) and "late" SSc patterns (0.56, p=0.008) than for the identification of "early" SSc pattern (0.35, p=0.003) when compared to overall agreement in all participants. Agreement for "early" and "active" patterns was higher in experienced vs not experienced readers ("early" pattern kappa=0.45 vs 0.26, p=0.01, "active" pattern kappa= 0.62 vs 0.35, p=0.006, "late" pattern kappa=0.66 vs 0.48, p=0.12).

Conclusion: There is moderate agreement among rheumatologists for the identification of SSc videocapillaroscopy patterns, while there is substantial agreement among rheumatologists regardless their experience in videocapillaroscopy, in the identification of normal and abnormal capillaroscopic images. Agreement for the identification of "active" and "late" patterns is higher than for "early" capillaroscopic pattern. The identification of "early" capillaroscopic changes may require more experience in the performance and interpretation of this technique. Ref 1. Cutolo M et al. J Rheumatol 2000;27:155-60.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have suggested that right ventricular (RV) adaptation in patients with scleroderma-associated pulmonary arterial hypertension (SSc-PAH) is worse than in patients with idiopathic pulmonary arterial hypertension (IPAH). This has been proposed as one of the explanations for increased mortality in SSc-PAH. However, few studies have compared incident groups of treatment naive SSc-PAH and IPAH patients. The objective of this study is to compare RV remodeling and load-adaptability metrics in patients with SSc-PAH versus IPAH at the time of diagnostic right heart catheterization (RHC) at our institution and at 1 year follow up.

Methods: A retrospective review of adults with SSc-PAH and IPAH who underwent RHC at Stanford Medical Center between 2002-2016 was performed. Inclusion criteria were as follows: mean pulmonary artery pressure (mPAP) greater than or equal to 25 mmHg, baseline echocardiogram within 3 months of RHC, absence of left heart disease (pulmonary capillary wedge pressure less than or equal to 15 mmHg), and absence of severe ILD (FVC and/or TLC < 70%). Baseline characteristics, RHC parameters, and standard echocardiographic measurements including right ventricular fractional area change (RVFAC), tricuspid annular plane systolic excursion (TAPSE), and RV global longitudinal strain (RV GLS) were obtained. Load-adaptability metrics, including the ratio of cardiac index to mean pulmonary artery pressure (CI/mPAP), right atrial pressure to pulmonary pulse pressure (RAP/PP), and RV global longitudinal strain to pulmonary vascular resistance (RV GLS/PVR) were compared between the SSc-PAH and IPAH groups. We used non-parametric Mann Whitney U-test for continuous variables and Fischers Exact Test for categorical variables. Change in RV function was examined by follow up echo (1 year post-RHC) in a subset of patients matched on PH-directed therapy.

Results: Twenty-four PVR matched SSc-PAH and IPAH subjects with newly diagnosed PAH were included in the study. Average duration of SSc was 3 years and median PVR was 12 (3-25 Wood units). There was no significant difference between the two groups in age, sex, baseline NT-proBNP, or degree of treatment at 1 year. At baseline there was no difference in resting right ventricular metrics, including RV FAC, RV GLS, TAPSE, or right atrial size (Table 1). With regards to load-adaptability, there was no difference in RAP/PP, CI/MPAP, or the RV load-adaptability metrics allometrically adjusted for PVR in each group. Overall there was improvement in RVFAC, RV GLS, and TAPSE at 1 year in both groups, though notably we did not observe a significant difference in the degree of response in RV function to therapy between Ssc-PAH and IPAH.

Conclusion: In well-matched SSc-PAH and IPAH patients without ILD or left heart disease, we did not observe a difference in baseline RV function or response to treatment.

Baseline characteristics, baseline RV metrics, and change in RV function from baseline to 1 year in Ssc-PAH and IPAH groups. Differences in continuous variables were measured using Wilcoxon rank-sum test and categorical variables using Fischer's exact test. Median values for RV metrics and change in RV function are reported. RV FAC = right ventricular fractional area change, RV GLS = right ventricular global longitudinal strain, TAPSE = tricuspid annular plane systolic excursion, RAP = right atrial pressure, PP = pulmonary pulse pressure, CI= cardiac index, MPAP = mean pulmonary artery pressure. Oral therapies include endothelin receptor antagonist, phosphodiesterase-5 inhibitor, and calcium-channel blocker. *All 4 SSc patients on baseline therapy were on PDE-5 inhibitor for Raynaud's phenomenon.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Several factors has been described as responsible for the association between olfactory impairment and brain regions. In systemic sclerosis (SSc) the olfactory interaction has been little explored. To evaluate the interaction between olfactory impairment, neuropychiatric manifestations, clinical, laboratorial and treatment features in SSc**.**

Methods: We screened consecutive SSc patients followed in a longitudinal cohort from 2011 to 2015 and age and sex matched controls. We excluded patients with overlapping rheumatic diseases. Cognitive evaluation was performed using the Montreal Cognitive Assessment (MoCA). Individual with scores≤26 were considered impaired. Mood disorders were determined through Beck´s Depression and Beck´s Anxiety Inventories. SSc patients were further assessed for clinical and laboratory SSc manifestations, disease activity (Valentini Activity Index), severity activity (Medsger Severity Index). Total dose of corticosteroids and other immunosuppressant medications used since the onset of the disease were calculated. MRI scans were performed in a 3T Phillips® scanner. Sagittal T1 weighted images were used for FreeSurfer automatic volumetric measurements. Olfactory functions was evaluated through Sniffin' Sticks kit (Burghart Medizintechnik, Wedel, Germany). Sniffin' Sticks kit consists of three stages: odor threshold, discrimination, and identification. The maximum score in each stage was 16 points, with a total score of 48 points. Subjects with a score < 30 were considered impaired [hyposmia (score between 15–30) and anosmia (scores of <15). Data were compared by non-parametric tests.

Results: We included 63 SSc patients [55 (87.3%) women; mean age of 51.01 ±11.32 years; range 20 – 82] with mean disease duration of 10.56 ±4.55 years. The control group consisted of 65 healthy volunteers [52 (80%) women p=0.418 with a mean age of 49.05±7.24; p=0.317]. Olfactory impairment were significantly higher in SSc patients [38 (60.3%)] when compared to controls [29 (44.6%)] (p=0.048). Regarding the three different stage SSc patients had significant abnormalities in the threshold [score media 6.3 vs 7.9 (p=0.016)], discrimination [score media 10.17 vs 11.5 (p=0.008)], score total [media 27.4 vs 31.24 (p=0.001)] when compared to controls. Comparing SSc patients with and without olfactory functions we observed in SSc with olfactory impairment had significant decrease in right and left hippocampus (9.5 cm^3 vs 11.3 cm^3; p=0.010) and right and left thalamic (6.05 cm^3 vs 7.2 cm^3; p=0.025) volume. Cognitive impairment was observed in 10 patients (24%) SSc and associated with decreased in discrimination (p=0.023) and identification scores (p=0.002). Significantly decreased of identification scores was associated with increase depression symptoms (p=0.032). We did not observe association between olfactory impairment and clinical, laboratory and treatment manifestations.

Conclusion: Olfactory impairment was frequently observed in SSc and associated with decreased volumes of hippocampus and thalamus. Cognitive impairment and mood disorders were the only clinical manifestations associated with olfactory function.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hand involvement is observed in almost all patients with Systemic Sclerosis (SSc), and is due in various proportions to skin and tendon fibrosis, arthritis and microvascular impairment, sometimes complicated with digital ulcers (DUs). The Duruoz's Hand Index (DHI) (or Cochin hand functional disability scale), is a reliable tool for hand function assessment in diseases like rheumatoid arthritis and SSc. A short form of the DHI comprising of 6 items (DHI-6) has been recently developed and validated. The purpose of this study was to assess the reliability, validity and sensitivity to change of the new DHI-6 in a cohort of patients with SSc.

Methods: 70 consecutive patients with SSc, examined in our EUSTAR center, satisfying the 2013 ACR/EULAR classification criteria, were included. Patients completed the DHI, the Scleroderma Health Assessment Questionnaire (SHAQ) questionnaires and the Hand Mobility in Scleroderma (HAMIS) test. Three anthropometric measures to assess finger range of motion were also measured: the finger extension (FE), finger-to-palm distance (FTP) and Δ FTP (FE - FTP). **Step 1**: In 38 patients the test-retest reliability, using intra-class correlation coefficients (ICC), and the internal consistency (Cronbach's alpha test) were examined. **Step 2**: In all 70 patients, the criterion validity by correlation coefficients with SHAQ, HAMIS and the anthropometric measures, and the discriminative capacity between different subsets of patients by Mann-Whitney U-test were examined. Moreover, the DHI-6 was correlated with DHI. **Step 3**: 35 consecutive patients had a second evaluation at an interval of (mean± SD) 8.1±30. months; among them, 8 patients had progressive early diffuse SSc. Sensitivity to change was assessed in these patients using the effect size (ES) (Cohen's d) and the standardized response mean (SRM).

Results: The study included 63 females/7 males with SSc, age 50.9±13.0 years, disease duration 5.8±5.6 years; 27 with diffuse cutaneous SSc (dcSSc) and 43 with limited cutaneous SSc (lcSSc). The DHI-6 had a score of 6.7±6.5, range 0-25 (possible range 0-30) at baseline, and 8.3±7.0, range 0-24 at follow-up. The DHI-6 presented an excellent test-retest reliability (ICC 0.98), and a good internal consistency (Cronbach's alpha 0.89). Criterion validity of the DHI-6 was proved by moderate to strong correlations with HAMIS, FE, FTP, Δ FTP and the SHAQ disability index (Spearman's rho 0.48-0.82, $p<001$). Correlation of the DHI-6 with the DHI was excellent, with a Spearman's rho of 0.96, $p<0.001$. The discriminative capacity of the DHI-6 was proven by statistically significant differences between patients with and without: synovitis, flexion contractures of the fingers, and history of DUs. The sensitivity to change (ES of 0.57 and SRM of 1.11) was very good for detecting a minimally important difference.

Conclusion: The simplified DHI is a brief, valid and reliable instrument for measuring hand disability in SSc. These results suggest that the DHI-6 could be used both in day-to-day practice and in clinical trials, reducing patient burden and increasing research capacity. However, more studies are needed to confirm these results.

Predictors of Acro-Osteolysis in Systemic Sclerosis

Ashraf Raslan[1] and Vivien Hsu[2], [1]Medicine, Rutgers-RWJ Medical School, Jersey City, NJ, [2]Rheumatology, RWJ Med Schl Scleroderma Prog, New Brunswick, NJ

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Acro-osteolysis (AO) is the bony resorption on the distal tufts of the digits, a characteristic radiological finding in Systemic Sclerosis (SSc) with estimated prevalence of 20-25% [1][2]. Some studies have suggested an association of digital ischemia and SSc specific auto-antibodies with AO [1][3][4], but the pathogenesis of AO remains poorly understood. Our goal is to better understand the factors associated with development of AO in SSc.

Methods: We evaluated 168 outpatients who met criteria for SSc [5] and were seen between 2010 and 2015. We collected relevant clinical information, including laboratory and hand x-ray assessments, obtained within 5 years of this analysis. Patients were grouped by presence or absence of AO based on hand x-rays. Associations between potential risk factors and AO were assessed with unconditional logistic regression models to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for presence of AO.

Results: Of the 168 SSc patients studied, a total of 43 (26%) had AO. In univariate analysis, anti-topoisomerase I antibody (anti-topo I) and digital tip ulcers (DTUs) had the strongest association with AO (Table-1). In multivariate model, after adjusting for Anti-Topo I and DTUs (prior and current DTUs), AO was positively associated with Anti-Topo I (OR=4.3, 95% CI: 1.8-9.9), prior DTUs (OR=5.6, 95% CI: 2.2-14.2), current DTUs (OR=4.2, 95% CI: 1.9-9.4), and hand contractures (OR=3.3, 95% CI: 1.4-7.8), whereas AO was inversely associated with age of disease onset (OR=0.97, 95% CI: 0.94-0.99). Although not statistically significant, the Anti-centromere antibody was also inversely associated with AO (OR=0.4, 95% CI: 0.14-1.08). We found no associations of AO with current skin score, synovitis, tendon friction rubs, or RNA polymerase III antibody.

Conclusion: Our findings suggest that both digital ischemia and anti-topo I are strongly and independently associated with AO. Additionally, AO was strongly associated with hand contractures and younger age of disease onset. Prospective studies are needed to confirm if more aggressive treatment of digital ischemia in this subset of patients will lead to lower risk of AO and hand contractures. **References:**

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) can greatly impact the patients' quality of life due to its multisystem manifestations. The health assessment questionnaire (HAQ) is one of the most commonly used measures of disability in musculoskeletal disorders and was extended to form the scleroderma HAQ (SHAQ), a more disease-specific disability scale that incorporates the HAQ and 5 visual analogue scales (VAS) into one score. This cross-sectional study aims to identify contributors of disability in SSc by means of the SHAQ.

Methods: Adult patients from the prospective DeSScipher cohort were included in the analysis if they had one complete SHAQ recorded (range 0-3) and fulfilled either the 1980 ACR or the 2013 ACR/EULAR criteria for SSc. Multiple linear regression analysis was used to assess the combined effect of factors defined *a priori* and possibly associated with a lower SHAQ.

Results: Between June 2013 and January 2016, 813 patients had one complete SHAQ recorded (34% of all patients followed in the DeSScipher cohort). The mean SHAQ score was 0.86 (standard deviation [SD] 0.65) and the mean HAQ score was 0.92 (SD 0.77). 60% of patients were in the "mild to moderate difficulty" SHAQ category (score of 0-1), 34% in the "moderate to severe disability" category (score of 1-2) and 6% in the "severe to very severe disability" category (score of 2-3). In order of magnitude, the means of the five VASs included in the SHAQ were: Overall disease severity (30, IQR 10-51), Raynaud's phenomenon (21, IQR 3-50), pulmonary symptoms (10, IQR 1-40), gastrointestinal symptoms (6, IQR 1-31) and digital ulcers (2, IQR 1-30). In multiple linear regression, the main contributor to functional disability was dyspnea. The SHAQ scores reported by patients with NYHA class 4, 3 or 2 were on average 0.65 units (95% confidence interval

[CI] 0.30-1.01), 0.58 units (95%CI 0.41-0.75) and 0.19 units (95%CI 0.10-0.27) higher than that of patients with NYHA class 1. The presence of fibromyalgia (0.41 units, 95%CI 0.21-0.62) as well as muscle weakness (0.25 units, 95%CI 0.14-0.36) were also associated with higher levels of disability (Figure). Patients reporting esophageal, gastric and intestinal symptoms simultaneously had, on average, a SHAQ score of 0.45 units (95% CI 0.33-0.58) higher than patients reporting no gastrointestinal symptoms. Patients with symptoms in two gastrointestinal regions had a SHAQ score of 0.28 units (95%CI 0.17-0.39) and in one region of 0.13 units (95% CI 0.04-0.23) higher than patients with no symptoms. The contributing factors to an impaired functional ability were similar in patients with diffuse SSc and patients with limited SSc.

Conclusion: Patients perceive dyspnea, pain, muscle weakness and gastrointestinal symptoms as the main factors driving their level of disability. **Acknowledgement:** The DeSScipher project was funded by the European Community's Framework Programme 7 under grant agreement N° 305495.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Nailfold capillaroscopy (NFC) is essential in the evaluation and classification of systemic sclerosis (SSc). Semiquantitative capillaroscopy scoring is a promising tool for assessing disease activity, severity and change in SSc, however there is no consensus yet over which capillaroscopy abnormalities should be analyzed and how. We aimed to investigate the reliability of the qualitative and semiquantitative scoring of NFC assessment between two raters and test-retest for each rater in a SSc cohort.

Methods: This is a pilot study from one EUSTAR centre, where 2 raters assessed the NFC images of 48 consecutive patients with SSc. Data were analyzed in 3 ways: step **1.** qualitatively by 'normal' / 'abnormal' category, step **2.** 'early', 'active', 'late' scleroderma patterns and unclassifiable in any pattern, and step **3.**semiquantitatively by calculating the mean score for capillary loss, disorganization of the microvasculat array, giant capillaries, microhaemorrhages and capillary ramifications; combinations of giant capillaries and microhaemorrhages (as a surrogate for vascular activity) and disorganization and ramifications (surrogate for vascular damage) were also assessed. Variables for all steps were calculated for all fingers and for each finger. Inter-rater/intrarater agreement was assessed by Cohen's kappa coefficients for qualitative variables and by intraclass correlation coefficients (ICC) for mean score values of abnormalities. Differences in scores between patients with digital ulcers (DUs) history and Bosentan treatment were analyzed by logistic regression.

Results: Interrater reliability ranged from good to excellent agreement for mean score values of abnormalities in all fingers (ICC coefficients 0.745 to 0.897) and was excellent for activity (ICC coefficient of 0.923) and damage combinations (ICC coefficient of 0.918). Assessment of abnormalities in a qualitative manner (normal/abnormal or with capillaroscopy patterns) showed weaker interrater agreement than the semiquantitative assessment (k coefficient <0.7). When scores were assessed in each finger, interrater reliability was good to excellent for mean scores of abnormalities and activity and damage combinations (ICC coefficients 0.781 to 0.867 for mean abnormalities scores and 0.713 to 0.856 for combinations), whereas for qualitative assessments interrater reliability was much weaker (k coefficients <0.7). Intrarater variability was good to excellent for mean score values of abnormalities and activity and damage combinations in all fingers and separate fingers for both raters; for qualitative assessment only one of the raters had good test-retest reliability. There was no difference in scores between patients with/without DUs history or Bosentan treatment.

Conclusion: Reliability of NFC assessment is essential in SSc trials/clinical practice to ensure quality of data. This pilot study demonstrates very good reliability between raters of the semiquantitative NFC assessment in a SSc cohort. Combinations of capillaroscopy abnormalities had very good reliability and might be preferred because they are less time consuming. A longitudinal assessment and confirmation of our results in other cohorts is needed.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease (CTD) characterized by fibrosis, vascular complications, and inflammation affecting both skin and internal organs. Diagnosis of SSc is difficult due to the complexity of manifestations and overlap with other autoimmune (AI) diseases. Clinical classification criteria including SSc-specific autoantibodies have been developed, but disease manifestations are often advanced once patients fulfill these criteria. In addition, heterogeneity in clinical presentation, internal organ involvement, and rate of disease progression make counseling and management of each individual patient challenging. The Immuno*Signature*(IMS) Technology has shown promise as a new diagnostic platform for both chronic and infectious diseases. The goal of this study was to identify specific antibody signatures that differentiate SSc patients from healthy individuals and those with other AI, as well as those SSc patients with and without particular internal organ complications.

Methods: Plasma samples from a study population of 876 subjects were evaluated; the cohort was comprised of SSc (n=301), dermatomyositis (DM) (396), mixed and undifferentiated CTD (31), polymyositis (14), systemic lupus erythematosus (8), other AI (42), and healthy controls (84). All met validated classification criteria for each specific disease. An IMS assay was used to detect plasma antibodies bound to an array of ~126,000 unique peptides. Peptide sequences were designed to broadly sample chemical space thus providing a library of diverse epitope mimetics for antibodies to selectively bind. Features most discriminating SSc contrasts were identified using a t-test. Support vector machine classifiers were trained and assessed by 100 iterations of 5-fold cross validation.

Results: Cross-validated estimates of classification performance are provided in Table 1. One classifier distinguished SSc patients from healthy donors. Additional classifiers differentiated SSc from other AI diseases or from DM in particular. Finally, SSc patients that suffered from interstitial lung disease (ILD), renal crisis, or gastric antral vascular ectasia (GAVE) within a year of their blood draw could be distinguished from those SSc patients who did not. Up to 10,000 peptides whose antibody-binding characteristics differentiated health status groups were used as inputs to these classifiers.

Conclusion: Reproducible binding patterns produced by peripheral-blood antibody repertoires on a mimetic-peptide microarray can differentiate SSc from healthy donors and from other AI diseases. In addition, distinctive signatures were established for SSc patients with internal organ complications including ILD, renal crisis, and GAVE. This suggests that the IMS technology may be instrumental in the development of both new diagnostic and prognostic tests for SSc.

Table 1. Classification Performance Estimates of IMS for SSc Diagnosis and Prognosis				
Contrast	**AUC**	**Sens. @ 90% Spec.**	**Spec. @ 90% Sens.**	**Accuracy @ Sens. = Spec.**
SSc vs Healthy	0.96 (0.95-0.97)	90% (86-94%)	91% (86-93%)	90% (88-92%)
SSc vs Other AI	0.77 (0.75-0.79)	42% (35-47%)	40% (32-47%)	70% (68-73%)
SSc vs DM	0.77 (0.74-0.8)	40% (33-48%)	41% (33-48%)	70% (67-73%)
ILD+ vs ILD-	0.68 (0.64-0.72)	23% (13-33%)	31% (21-41%)	63% (59-68%)
Renal Crisis+ vs Crisis-	0.72 (0.60-0.82)	27% (3-53%)	42% (12-62%)	65% (55-76%)
GAVE+ vs GAVE-	0.77 (0.64-0.84)	28% (8-46%)	49% (10-67%)	69% (62-77%)

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid antibodies (aPL) can be present in the sera of systemic sclerosis (SSc) patients. Important variations of their prevalence are observed in the literature. Their clinical associations remain largely unknown. The aim of this study was to perform a systematic review of published reports and a meta-analysis to estimate the prevalence of aPL in SSc.

Methods: A systematic review of the literature was carried out in PubMed and Embase between May 1975 and November 2015 by 3 of the authors (AL, VS and DL). We used combinations of the terms "systemic sclerosis", "antiphospholipid

antibodies", "antiphospholipid syndrome", "anticardiolipin antibodies", "lupus anticoagulant", "anti-β2GP1", "anti-phosphatidylethanolamine", "thrombosis", "pulmonary embolism", "deep vein thrombosis", "stroke", "myocardial infarct", "pregnancy". We adapted the search strategy to the specificities of each database. After screening the titles and abstracts, studies were selected after a full-length review. Inclusion criteria were: French or English-language publication, adult patients with SSc, and at least 30 patients with SSc tested for lupus anticoagulant (LA), or/and anticardiolipin (aCL) or/and anti- β2Glycoprotein 1 (anti-β2GP1) antibodies. Meta-analysis was performed using number of aPL positive (at least one of the three antibodies positive) and negative patients.

Results: 1291 references were retrieved as result of search, 79 articles were included for full text review after reading the titles and abstracts. Of these articles, 31 were assessed for eligibility. Finally, 23 studies were included in the meta-analysis, representing a total population of 2937 SSc patients. Prevalence of aPL positivity (one or more) in SSc in literature ranged from 0 to 58%. The overall pooled prevalence of aPL in SSc was 16% (95%CI [10-22]). LA was found in 0 to 16% of patients; aCL in 0 to 34% and anti-β2GpI in 0 to 50%. The prevalence of aCL was 11% (95%CI [7-15]), and prevalence of anti-β2GP1 was 9% (95%CI [3-19]). Clinical manifestations associated with aPL positivity were more frequently pulmonary arterial hypertension (PAH) or digital ulcer (DU). Six studies out of 11 found an association between aPL and PAH (aCL in 5, one or more aPL in 1). Two studies out of 8 found an association between aPL (aCL) and DU and 2 studies found a trend.

Conclusion: The prevalence of aPL in SSc was highly variable (range 0-58%). The overall pooled prevalence was 16% (95%CI [10-22]). The most frequent clinical manifestation associated with aPL positivity was PAH. AL and VS have contributed equally to this work.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Skeletal myopathy in systemic sclerosis (SSc) is associated with poor outcomes such as disability. The spectrum of muscle histopathology of weak SSc patients is heterogeneous. The purpose of this study was to determine the clinical phenotype and outcome of those with predominant fibrosis on muscle biopsy and compare them to those with inflammatory and/or necrotizing muscle biopsies.

Methods: This retrospective, cross-sectional study included SSc patients with muscle weakness and muscle biopsies available for review. Biopsies were assessed for individual pathologic features including inflammation, necrosis, and fibrosis as previously described (1). Biopsies were assigned a histopathologic category of “inflammatory myopathy” if they

had inflammation and/or necrosis with or without fibrosis. Biopsies with predominant fibrosis and no inflammation or necrosis were designated as "fibrosing myopathy". Clinical data including SSc subtype, disease duration, serum creatine kinase (CK) levels, electromyography (EMG), autoantibody profile, and survival (including Kaplan Meier curves) were compared between the two groups.

Results: 47 biopsies from weak SSc patients were available for review; 8 had fibrosing myopathy, 28 had inflammatory myopathy, and 11 could not be classified as either of these. Survival analyses demonstrated that patients with fibrosing myopathy had a statistically significant higher death rate (5 of 8; 62.5%) compared to those with inflammatory myopathy (4 of 28; 14.3%; p=0.01) (Figure 1). The mean time to death from muscle biopsy was 0.28 ± 0.19 years in those with fibrosing myopathy compared to 2.50 ± 1.6 years with inflammatory myopathy (p=0.01). Although not reaching statistical significance, compared to those with inflammatory myopathy, SSc patients with fibrosing myopathy were more likely to have the diffuse SSc subtype (87% vs. 64%, p=0.21), African-American race (62.5% vs. 35.7%; p=0.17), shorter disease duration since first non-Raynaud's symptoms (2.31 + 1.97 years vs. 2.86 ± 3.4 years; p=0.58), and lower FVC (55.5 ± 31.9 vs. 66.4 ± 17.6; p=0.23). There was also a trend for patients with fibrosing myopathy to have lower CK values (516 ± 391 vs. 2477 ± 3511, p=0.13) and more frequent non-irritable myopathy on EMG (57.1% vs. 34.7%, p=0.27). Anti-Scl-70 antibodies were found in 25% (2 of 8) of patients with fibrosing myopathy and only 4% (1 of 28) of those with inflammatory myopathy (p=0.14).

Conclusion: SSc patients with muscle weakness and a fibrosing myopathy have markedly increased mortality compared to those with inflammatory myopathy.

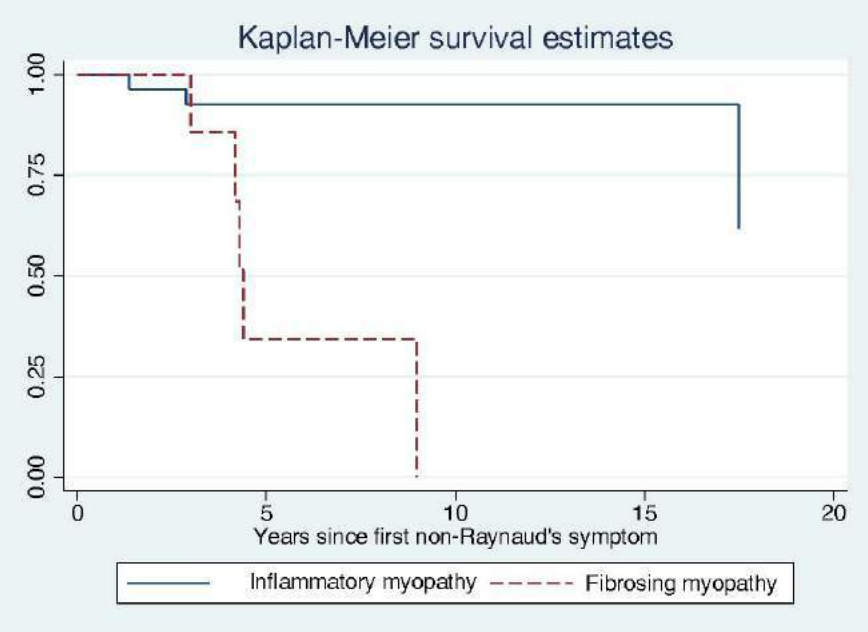

Figure 1: Kaplan-Meier survival estimates comparing SSc patients with fibrosing myopathy vs. inflammatory myopathy

Session Time: 9:00AM-11:00AM

Background/Purpose: Platelet factor 4 (PF4), also called CXLC4 is a chemokine that is found in higher levels in systemic sclerosis (SSc) patients and is in particular associated with lung involvement and early diffuse disease, conditions which are correlated with certain SSc auto antibody types. PF4 is also the antigenic target, when combined with heparin complexes, involved in heparin induced thrombocytopenia (HIT). Anti-PF4 antibodies, both heparin dependant and independent, are more prevalent in systemic lupus erythematous (SLE) patients and murine models suggest increased anti heparin antibodies in SSc(1). Our aim was to examine whether certain SSc patients then also had an associated increase in heparin dependant anti PF4-heparin antibodies.

Methods: 102 patients' sera from our SSc patient bank, recruited from consenting adult patients with a diagnosis of SSc established between 1988 and 1995, were randomly selected, each with a particular SSc related antibody (anti centromere (ACA), anti topoisomerase I antibody (ATA), RNA polymerase III (RNAP), anti Th/To). Each patient serum was tested for the presence of anti PF4-heparin antibodies using ELISA technique. A second group of SLE patients were also tested and acted as controls. Patient files were reviewed for comorbidities, type of SSc, and the presence of interstitial lung disease.

Results: A total of 102 SSc patients, split as follows: 20 with ATA antibodies, 20 with anti Th/To, 31 with ACA and 31 with RNAP. There was no significant differences in the presence of anti PF4-heparin between each SSc antibody subgroup, at 5%, 5%, 6.4% and 0% respectively. 26 patients (25.5%) had ILD, in particular 65% of ATA patients. 3.8% compared to 3.9% (p=1) of patients with and without ILD had anti PF4-heparin antibodies respectively. No patient with diffuse cutaneous SSc had anti PF4-heparin antibodies compared to 4.9% of patients with limited cutaneous disease (p=0.58). Of the 21 lupus patients, 14% of patients had anti PF4-heparin compared to 3.9% of 102 of SSc patients (p=0.095). None of these patients had any documented HIT.

Conclusion: Despite previously demonstrated increased PF4 or CXCL4 levels, there does not seem to be an associated increase in anti PF4-heparin antibodies in SSc patients, either with or without ILD. There is no indication that these patients will accrue false positives on HIT screening, which are based on anti PF4-heparin detection, and there are no direct antigenic arguments for an increased risk of HIT itself. This may provide insight into the antigenicity of CXCL4, although it may be interesting to examine the presence of heparin independent PF4 antibodies.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Survival of patients with pulmonary arterial hypertension (PAH) associated with connective tissue disease (CTD), especially systemic sclerosis (SSc), is poorer than that of patients with idiopathic PAH. Notably, combination therapy using PAH-specific drugs has been recently shown to improve survival of patients with idiopathic PAH, In the present study, we evaluated survival of patients with PAH associated with SSc and other CTDs under PAH-specific drugs combination therapy.

Methods: We performed a retrospective-cohort study of 117 patients with PAH associated with CTD, including 54 SSc, 29 MCTD, 24 SLE and 10 other CTD patients, who were followed up between January 1980 and March 2016 in our hospital. PAH was diagnosed based on heart catheterization. Our combination therapy strategy for PAH intended to achieve the following goals: 1) improvement in WHO-functional class and 2) reduction of serum BNP level of less than 100 pg/ml, based on our previous study as well as on the results demonstrated by Hoeper et. al, (Eur Respir J 2005; 26: 858–863). The PAH-specific drugs, including bosentan, ambrisentan, macitentan, sildenafil, tadalafil, riociguat, epoprostenol, and beraprost (an oral prostacyclin analog that is only available in Japan), were switched from drug to drug or adopted in combination so as to achieve these predetermined therapeutic goals once a month. We performed Cox's proportional hazard analysis for survival measured from the date of the diagnosis of PAH using propensity score (PS) methods. PS for combination therapy was estimated from a variety of factors and condition at the initial treatment for PAH using logistic regression.

Results: Sixty patients, including in 26 patients with SSc, were treated under our combination therapy strategy. The PAH-specific medications in this group at the last observation are shown in Table 1. Multivariate study demonstrated that combination therapy significantly reduced the risk for death (HR 0.316, 95%CI: 0.161-0.593) in patients with PAH associated with CTD. As shown in Table 2, stratified analysis revealed that combination therapy appeared to improve survival in PAH patients with SSc, although the efficacy was inferior to that in PAH patients with other CTDs.

Conclusion: The results demonstrate that combination therapy using PAH-specific drugs improved survival of PAH patients with ~~both~~ SSc and other CTDs. The data also confirm that the prognosis of PAH associated with SSc is worse than that of PAH associated with other CTDs. Further efforts are required for treatment of PAH associated with SSc.

SESSION INFORMATION

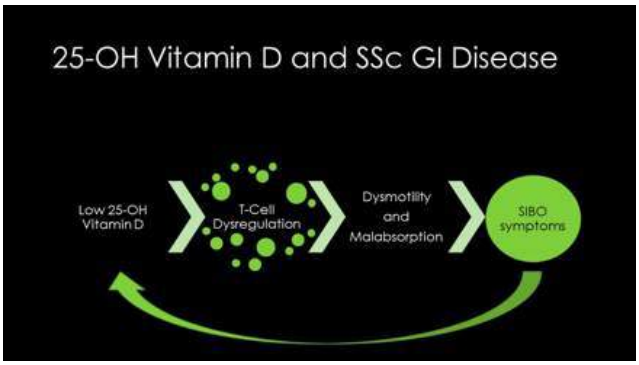
Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The GI tract is one of the most commonly affected systems in SSc patients. GI disease in SSc patients is thought to be multifactorial and its pathogenesis remains elusive. Researchers suggest that malabsorption of vitamin D might impair enteric T-cell mediated immune response and affect the myenteric plexus leading to gastroparesis. Also, delayed GI motility has been associated with the development of bacterial overgrowth in SSc. Taken together, one can envision a system in which low levels of vitamin D, through its effect on cell dysregulation, may lead to decreased GI motility and small intestinal bacterial overgrowth (SIBO). This has been the basis of our hypothesis associating low levels of Vitamin D with GI manifestations and disease in SSc patients. Our objective in this study is to evaluate the methodology for assessing SIBO by means of Lactulose vs. Hydrogen Breath testing (LBT vs. HBT). To investigate SIBO and 25-OH Vitamin D levels in relation to other clinical markers of SSc activity. Finally, to examine the relationship between SIBO (by means of LBT) and 25-OH Vitamin D levels in SSc patients.



Methods: Retrospective analysis of all SSc patients from the *UCLA SSc program* and the UCLA- database. Those meeting the 2013 ACR/EULAR SSc classification criteria, and having 25- OH Vit. D with or without LBT and/or SIBO clinical diagnosis were included in this evaluation. All patients with non-SSc diagnoses and those lacking Vitamin D levels were excluded. Logistic regression comparing LBT and hydrogen breath tests was used. A Chi-square test was used to test for difference in proportion of patients with low vitamin D among subjects who had a positive LBT compared to subjects who had a negative LBT.

Results: Of 2700 patients in the database, 608 met our inclusion criteria of having either Vitamin D levels or LBT. 163 did not have 25-OH Vitamin D, leaving 445 who were analyzed in this study. Subjects were between the ages of 48-69, with comparable female representation in both groups at 89 vs. 90% in LBT+ vs. LBT negative groups , respectively. We found a *statistically significant difference* in proportion of subjects who had low vitamin D in patients with positive LBT compared to those with negative LBT ($p<0.001$). We found a statistically significant difference in the false negative rate of the hydrogen test and the false negative rate of the methane test ($p<0.001$) indicating that *Hydrogen Breath Testing* is an adequate mode of testing for detecting SIBO in SSc. Analysis of normal/high vitamin D, with LBT positivity, by means of logistic regression model, showed no association between both factors and either SSc type, or the presence of ILD or PAH.

Conclusion: Our preliminary data suggest a ***strong association between LBT positivity and low vitamin D level.*** Decreased gut motility may be at the core of the pathogenic pathways bridging hypovitaminosis D and SIBO.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies suggest that proton pump inhibitor (PPI) use is variably associated with risk of osteoporosis. The aim of this study was to investigate the relationship between PPI use and development of osteoporosis in Scleroderma (SSc) patients. This association however has not been well characterized in a large cohort of patients.

Methods: We reviewed the records of patients followed up in our centre over a period of 10 years. Those who have had at least one bone densitometry (DEXA) performed were included in the study. Demographic and basic clinical characteristics were recorded for all patients, including results of the DEXA scans and PPI treatment prior to DEXA (none, standard dose PPIs or high dose PPIs). In addition, data on potential confounding factors, such as smoking history, steroid or bisphosphonate treatment, were also collected. Ordinal logistic regression was used to assess the effects of these factors on the DEXA results.

Results: In this study 199 SSc patients were included. Of those 91% (n=182) were female, 31% (n=61) had diffuse disease. Mean age at first DEXA scan was 57 years (range 18 to 84 years). Mean disease duration at first DEXA was 12.7 years (interquartile range 5.8 to 18.5). Bone density was normal in 21% (n=41), 40% (n=80) had osteopenia and 39% (n=78) had osteoporosis. By univariable analysis there was no significant association between prior PPI treatment and DEXA scan results (p=0.205). Among those who had normal DEXA 22% have not had treatment with PPIs, 49% have had standard dose and 29% have had high doses of PPIs. Among those with osteopenia, 12.5% had not been treated with PPIs, while 47.5% and 40% had received standard or high doses of PPIs respectively. Among subjects with osteoporosis, 27% had not had PPI treatment, while 41% and 32% have had standard and higher than standard doses of PPIs. We found no association between gender, disease subset or antibody specificity and bone density. Body mass index (BMI) was negatively associated with development of osteoporosis (OR 0.89; 95% CI 0.84, 0.94; p<0.001), while age showed a strong positive association (OR 1.07; 95% CI 1.04, 1.1; p<0.001). Presence of calcinosis showed a mild, borderline significant association with development of osteoporosis (OR 1.67, 95% CI 0.91, 3.06; p=0.096). Interestingly, there was a strong association between calcinosis and PPI use; among patients who had not received PPIs, calcinosis was present in 12.5%, among those on standard dose PPIs, 20% had calcinosis and among those on high doses of PPIs, calcinosis was present in 39%, p=0.003. Multivariable analysis of the effect of PPIs on bone density was fitted. After adjusting for age, BMI, steroid and bisphosphonate treatment, there was no association between PPI treatment and development of osteopenia or osteoporosis.

Conclusion: Our data do not support an association between prior PPI treatment and development of osteoporosis. However, the association of calcinosis with prior PPI treatment and trend of association of calcinosis with osteoporosis is noteworthy and warrants further study in other cohorts. Our results suggest that addressing coexisting risk factors for osteoporosis is required for SSc patients on PPI.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gastrointestinal involvement is recognized as a major cause of morbidity and mortality in systemic sclerosis (SSc). The pathophysiology is still unclear and includes impairment of motility, digestion, absorption and excretion. Few data on composition and function of gut micro-environment in SSc are reported in literature but there is a growing body of evidences supporting the hypothesis of a relation between gut microbiota, the host immune system and metabolic/nutritional status. The goal of this study was to characterize the gut microbiota in SSc patients compared to healthy subjects to investigate whether specific microbial species may be responsible of dysbiosis in SSc patients with gastrointestinal involvement. Furthermore, we investigated the composition of microbiota in different subsets of SSc according to patient's nutritional status to verify if microbiota characteristics may be used as a biomarker for malnutrition and poor prognosis in patients with SSc.

Methods: A total of 66 SSc patients were enrolled: 66.7% presented a normal BMI, 15.1% were underweight, while 18.2% were overweight. Gastrointestinal involvement was evaluated through UCLA-GIT 2.0 questionnaire while nutritional status was assessed through the MUST and selected blood biomarkers (albumin, Vitamin D, Vitamin B12, folate, Ferritin, cholesterol). Faecal samples were obtained from SSc patients and healthy controls. The composition of microbiota was determined through 16S-rRNA pirosequencing performed using the GS Titanium technology (Roche 454). Dedicated statistic (LEfSe) was used to identify taxa that showed differential expression between the groups; α- and β-diversity and Firmicutes/Bacteroidetes ratio were determined.

Results: In our cohort of patients the mean total UCLA GIT 2.0 score was 0.4±0.3. The values representing species richness were significantly different in the SSc group compared to controls (p=0.009 for Shannon index mean values). Noticeably, this difference was mostly accountable to BMI>25 subgroup. Firmicutes/Bacteroidetes ratio was inverted (>1) in the SSc group compared to controls, as already reported in literature for obese patients. At genus level SSc patients showed a differential expression in 21 taxa compared to controls with higher levels of genera such as Ruminococcus, Roseburia, Lactobacillus and Faecalibacterium and a decrease of genera such as Clostridium, Odoribacter, Veillonella and Prevotella. The differences in microbiota composition between SSc patients and controls were supported also by principal coordinate analysis (PCoA) of the values representing phylogenetic distance of microbial communities between specimens. Conversely, there were no substantial differences among subgroups of SSc patients according to BMI and according with the any specific gastrointestinal tract symptoms reported in the questionnaires.

Conclusion: Our analysis demonstrates an altered and distinct composition of gut microbiota in SSc patients compared to healthy controls. This may be the result of the complex pathophysiology of the disease and, at the same time, it may perpetuate immunologic aberrations and contribute to its clinical features. Though in the overweight SSc patients there seems to exist an overlap with the distinctive microbiota of obese patients, no definitive data are available to explain the relation between the nutritional status and gut microbiota in SSc patients.

Anti-Topoisomerase Positive Systemic Sclerosis – Prognosis Infaust?

Maaike Boonstra[1], Gaia A. Beerends[2], Hans U. Scherer[2], Tom W.J. Huizinga[1] and Jeska K. de Vries-Bouwstra[1], [1]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]Rheumatology, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-topoisomerase antibodies (ATA) in systemic sclerosis have been associated with poorer prognosis including diffuse skin involvement, pulmonary fibrosis, cardiac involvement and increased mortality. However, 30-60% of ATA-positive SSc patients demonstrate only limited skin involvement and some have only mild disease course. In SSc, optimal risk stratification is of utmost importance for tailored clinical management at the patient level. Therefore, we aimed to determine the prevalence of mild disease among ATA positive patients and to investigate which readily available clinical parameters best identify patients with highest disease severity.

Methods: Data from baseline visits of all subjects in the Leiden Systemic Sclerosis cohort were extracted. Patients fulfilling ACR 2013 criteria and ATA positive were included. Descriptive statistics were used to summarize sociodemographic, clinical and serological features. Patients with grade 3 or 4 disease on general, peripheral vascular, skin, lung or kidney Medsger severity scale were considered to be severely diseased. We compared presence of diffuse cutaneous involvement, Raynaud's, pitting scars, calcinosis, proximal muscle weakness, >10% weight loss, interstitial lung disease and pro-BNP between the severity groups and corrected for confounding by disease duration (time since non-Raynaud) by stratifying into quartiles.

Results: Of 422 SSc patients in the database, 344 patients had SSc meeting ACR criteria. 89 patients were exclusively ATA-positive, of which n=42 with mild disease and n=47 with severe disease. Patients with severe disease appeared to be younger, more often non-caucasian, with a longer time-since non-Raynaud and more often had diffuse skin involvement (dcSSc), calcinosis and weight loss (Table 1). Stratification by disease duration, however, showed that age and skin involvement were similar between patients with mild and severe disease. Only age at onset of first non-Raynaud, percentage of non-caucasians and percentage of patients with >10% weight loss was consistently different for patients with severe disease (Table 2).

Conclusion: In our cohort, 47% of ATA-positive patients presented with mild systemic sclerosis, which could not be explained by disease duration. This suggests that solely the presence of ATA is of limited clinical relevance. Readily available sociodemographic and clinical parameters including type of skin involvement seem to have only limited value in

identifying ATA patients with more severe SSc. More complex serological findings as antibody titers and fine-specifity of ATA should be defined for optimal serological subsetting.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Screening for pulmonary arterial hypertension (PAH) in systemic sclerosis (SSc) improves outcome. The DETECT screening algorithm (DETECT-algorithm) is recommended in a high-risk SSc subgroup. The aim of this study is to compare the positive predictive value (PPV) of screening using the 2009 European Society of Cardiology/European Respiratory Society guidelines (ESC/ERS-guidelines) and the DETECT-algorithm and comparing their cost-effectiveness in an unselected day-to-day SSc population.

Methods: 195 consecutive SSc patients, included in the Ghent University hospital systemic sclerosis unit, having their yearly SSc-specific visit between February 2015 and February 2016 were prospectively screened using both algorithms and the cost-effectiveness was calculated.

Results: In 63 (32%) of the 195 included patients (11%/71%/18% limited/limited cutaneous/diffuse cutaneous SSc), a right heart catheterization (RHC) was recommended (46/4/13 using DETECT-algorithm alone/ESC/ERS-guidelines alone/both algorithms). A RHC was performed in 53 patients: (36 [78%]/4 [100%]/13 [100%] where recommended by DETECT-algorithm alone/ESC/ERS-guidelines alone/both). PAH was diagnosed in 3 patients (incidence 1.5%/year, 95%CI:0.5-4.4%), in whom both algorithms recommended a RHC. The PPV was 23%,95%CI:8-50% (3/13) for both algorithms, 18%,95%CI:6-41% (3/17) for the ESC/ERS-guidelines and 6%,95%CI:2-17% (3/49) for the DETECT-algorithm. The average cost for screening was 80 and 227 euro using the ESC/ERS-guidelines and the DETECT-algorithm respectively.

Conclusion: In an unselected SSc population, the PPV is 23% when both algorithms recommend RHC. Interestingly, with only one algorithm used, the PPV drops to 18% for the ESC/ERS-guidelines and 6% for the DETECT-algorithm. Based upon this comparison and on cost-effectiveness, echocardiography may remain an important first step screening tool for PAH in SSc.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Raynaud phenomenon (RP) is known to precede other disease manifestations of systemic sclerosis (SSc), and classically viewed as reversible vasospasm due to functional changes in the digital arteries of the hands. However, progressive structural changes were found in the small blood vessels in many patients with SSc. Pulmonary arterial hypertension (PAH) is also prominent as a vascular involvement in SSc, which remains a leading cause of death in spite of current best treatments. As the pulmonary vascular disease (PVD) can be well compensated for, more than a half of the pulmonary circulation is impaired before early PAH is detected. Recently, it has been reported that stress testing with exercise Doppler echocardiography (DE) may facilitate early diagnosis of PVD. In this study, we tried to detect the specific changes at the stage of subclinical PVD of SSc in patients with RP

Methods: Total of 46 cases without PAH symptoms (NYHA I) with RP were investigated. To detect the involvement of pulmonary vessels, mean pulmonary artery pressure-cardiac output (mPpa-Q) response was estimated by exercise DE with Master's two-step stress, which reflects the elasticity of pulmonary artery. Then, the expressed genes in peripheral blood were explored with using next-generation sequencing. The differences between SSc-related autoantibody negative (R group=19) and positive group (S group) consisting of with (S1 group; n=22) and without (S2 group; n=7) scleroderma were investigated. The SSc-related autoantibodies include anti-RNP (n=4), topoisomerase-1 (n=1), centromere (n=23) and RNA polymerase III antibodies (n=0).

Results: The estimated mPpa-Q (mmHg•min/L) by exercise DE was significantly elevated in S group as compared with R group (6.54±5.31 vs. 4.49±2.39, $p<0.05$). In the S group, the average of estimated mPpa-Q in S1 group was higher than that in S2 group (6.70±5.97 vs. 6.01±2.60). Based on the differences in gene expression between S group and R group by ANOVA, 30 differentially expressed genes (DEGs) were selected, and then subjected to a hierarchical clustering with assessment of the statistical robustness. The hierarchical clustering showed major 2 clusters, and one of them consisted of only cases in S group, which included one case in S2 group. When we focused on 117 genes reported to be directly implicated in the development of PAH

(Parikh VN et al., Circulation. 2012;125:1520-1532.), it is noteworthy that 11 of them were differentially expressed in S2 group ($p<0.05$ by Student's t-test) as compared with R group.

Conclusion: Although detection of early PVD in SSc patients remains a major challenge, we have shown that estimated mPpa-Q which reflects elasticity of pulmonary arteries were significantly increased in S group. As S2 group is considered as very early SSc, it is notable that the average of mPpa-Q in S2 group was located between established SSc (S1) and Raynaud only (R) group. Moreover, some of genes involved in PAH development were differentially expressed in S2 group as compared with R group. It means that the changes toward PVD had already started at the very early stage of SSc. In order to detect crucial factors for PAH development, it is very important to follow up the clinical courses of these cases.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Localized scleroderma (LS) is characterized by skin sclerosis, producing devastating impairment in those affected. It was previously thought to "burn out" within 5 years, but recent studies have challenged this notion. However, no studies have prospectively examined LS disease activity over time. Understanding the course of LS is necessary to determine how to counsel and evaluate patients and to plan outcome and interventional studies. The aim of the present study was to determine the disease course of LS using a validated clinical outcome measures in a prospective cohort of patients.

Methods: Prospective cohort study of 131 participants from the Morphea in Adults and Children (MAC) cohort with at least two years of follow-up and modified LS skin severity scores (mLoSSI) scores recorded. Study visits were conducted at six to twelve month intervals. Disease activity was defined as mLoSSI score greater than 0. Time to recurrence of disease activity from the first visit with inactive disease was compared between the linear and generalized subtype using survival analysis with the log-rank (Mantel-Cox) test. All statistical analysis was performed using GraphPad Prism 6.0.

Results: 131 participants (670 study visits) were included. Fifty had at least 5 years of follow-up. Mean total follow-up was 4.3±1.7 years. The majority of participants were Caucasian (72%), female (77%), and had either a linear (55%) or generalized (31%) subtype. Median baseline mLoSSI score was 5. The mean time to first recurrence of disease activity after initial resolution of activity was 1.1 years for generalized LS and 2.3 years for linear LS. Overall, 44% of those with generalized LS had a recurrence of disease activity compared to 21% of those with the linear subtype (Hazard ratio 2.79, 95% CI 1.48-7.94). Of the 50 participants with at least five years of follow-up, 56% had a recurrence of disease activity. All but three subjects had similar or milder disease activity than the initial presentation.

Conclusion: Disease activity improves in the majority of LS patients over time. Some patients with LS have a monophasic disease course in which activity resolves. However, a substantial number of patients have a relapsing remitting course over many years. Specifically, those with the generalized subtype appear to be at a higher risk for future disease flares. Patients with LS warrant monitoring for disease flares for extended periods of time.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Accumulating data showed that Glucocorticoid-induced Tumor Necrosis Factor Receptor Family-related Protein (GITR), with its ligand (GITRL), plays an important role in promoting T-cell-mediated immunity and exacerbating autoimmunity in animal models. But its pathogenesis role in primary sjögren syndrome (pSS) remains unclear. Our study aimed to evaluate whether GITRL is related to disease severity and organ involvement in pSS patients and explore the possible mechanisms.

Methods: 78 pSS patients and 44 healthy controls were recruited, and the serum level of GITRL was measured by ELISA, and the serum levels of interleukin (IL) -17A, IL-17E, IL-17F, IL-6, IL-22 and IL-23 were determined by multiplex cytokine assays. $CD4^+$ T lymphocytes were isolated from PBMCs of 5 healthy donors by $CD4^+$ T Cell isolation kit and cultured in TexMACS™ GMP medium with anti-CD3 monoantibody (mAb), anti-CD28

mAb and rhIL-2. For Th1/Th17 cell differentiation and the pathway exploration of pS6 and pSTAT5, $CD4^+$T cells were treated either with recombinant human GITRL protein or with the medium control for 5 days. Surface marker, intracellular cytokine and phosphorylated signal protein were evaluated by flow cytometry. Clinical and laboratory data were collected and the clinical relevance of GITRL in pSS was analyzed

Results: *S*erum levels of GITRL were significantly higher in pSS patients than those in HC. There is a negative correlation between elevated levels of serum GITRL and WBC, Neutrophils, PLT, C_3 and C_4, and a positive correlation with Lymphocytes, IgG and RF. Interestingly, pSS patients with overt hypothyroidism showed higher level of serum GITRL comparing to pSS patients with subclinical hypothyroidism and normal thyroid function. Patients with pulmonary involvement had higher serum GITRL level, and pSS patients of moderate to high disease activity (ESSDAI≥5) showed higher serum level of GITRL. Moreover, *S*erum GITRL level was positively correlated with the Th17 related cytokine profile including IL-17A, IL-17E, IL-17F, IL-1β, IL-22 and IL-23, some of which had been shown to be the causal agents increasing autoimmunity and organ involvement in pSS. After GITRL treatment, we found the expansion of Th1, Th17 and Th1/17cells in vitro and there was a dose-dependent effect. We also found that the increased activaton of mTOR (S6 and STAT3) signaling in Th cells after GITRL ligation.

Conclusion: Our results identified the clinical significance of GITRL in exacerbating disease activity in pSS patients, and its pathogenic roles in enhancing the differentiation of Th1, Th17 and Th1/17 cells and the possible involved signaling pathways.

Therapeutic Targeting of JAK/STAT Pathway Inhibits Follicular Helper T Cell Maturation and Function

Flora Sagez and Jacques-Eric Gottenberg, Department of Rheumatology, Strasbourg University Hospital, Strasbourg, France

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: T follicular helper (Tfh) cells represent a $CD4^+$T cell subset specialized to provide help to B cells and to induce memory B cell and plasma cell differentiation. Proportion of blood Tfh cells are increased in patients with systemic lupus erythematosus, Sjogren's syndrome and rheumatoid arthritis (RA)[1]. The study of STAT3-deficient patients showed that JAK/STAT pathway play a crucial role in human Tfh development and function[2]. Tofacitinib is a pan JAK inhibitor with potent inhibition of JAK3 and 1 and to a

minor degree JAK2. The main reported mechanism of action of this drug, already approved for RA in many countries is the inhibition of numerous proinflammatory cytokines. JAK/STAT inhibitors are known to induce a decrease in $CD4^+$T cells but their effect on T-cell subpopulations is not known. We therefore investigated whether therapeutic targeting of JAK/STAT pathway could also result in the inhibition of Tfh differentiation and function.

Methods: Mononuclear cells were isolated from peripheral blood of healthy human donors. After selection, naive $CD4^+$T cells were cultured in the presence of cytokines known to induce Tfh differentiation. Tofacitinib, was added at 2 different times: first concomitantly to IL12 and anti-human CD3/CD28 beads required to promote Tfh differentiation in order to evaluate the effect of tofacitinib (at concentrations from 0 to 3 µM) on Tfh differentiation; second after 3 days of in vitro Tfh cell-differentiation to assess the effect of tofacitinib on Tfh function after 14, 24, 48 and 72 hours of tofacitinib exposure. The differentiation of naive $CD4^+$T cells into Tfh was analyzed using flow cytometry (positive staining for CXCR5, ICOS, PD1). Differentiation into Th1 and Th17 cells was analyzed using flow cytometry. The function of Tfh was assessed by intracellular staining of IL21 using flow cytometry. Cell viability was assessed using flow cytometry.

Results: Induction of Tfh differentiation in vitro. We first confirmed that the protocol used to differentiate naive $CD4^+$T cells into Tfh was efficacious: IL12 and anti-CD3/CD28 allowed to induce the differentiation of 33% (from 6 to 53%, n=6) of Tfh. Expression of Bcl-6, the specific transcription factor of Tfh, was significantly higher in Tfh than in non Tfh cells. Inhibition of Tfh differentiation. First, adding tofacitinib concomitantly to IL12 and beads dramatically decreased Tfh differentiation in a dose dependent manner (52% without tofacitinib vs 5% with tofacitinib, maximal inhibition of 90%). JAK/STAT inhibition also demonstrated an inhibition of Th1 and Th17. Tofactinib did not induce T-cell mortality, as demonstrated by viability test. Inhibition of Tfh function. Second, the addition of tofacitinib after Tfh-cell commitment induced a reduction of IL21. Maximal reduction was obtained after an exposure to tofacitinib during 48hours.

Conclusion: We demonstrate that JAK/STAT pathway inhibition impairs Tfh differentiation and function in vitro in healthy controls. We are currently extending our analyses to blood samples from patients with RA and other autoimmune diseases. These results highlight an additional mechanism of action of JAK/STAT inhibitors in autoimmune diseases. [1] Ueno. J Clin Immunol, 2016; [2] Ma et al. Blood, 2012

Session Date: Monday, November 14, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmune diseases are driven by a combination of predisposing genetic and environmental factors resulting in self-perpetuating chronic inflammation and tissue damage. In granulomatosis with polyangiitis (GPA), impaired regulatory T-cell function and an expansion of circulating effector memory T-cell subsets has been reported. While expansion of circulating effector memory T-cells has been linked to disease pathogenesis and progression, the causes driving alterations of the peripheral T-cell compartment have remained poorly understood so far. To investigate mechanisms driving alterations of the peripheral T-cell compartment in GPA, we performed combined approach using phenotyping, transcriptome and functional analyses of T-cell populations.

Methods: Sorted CD4+ and CD8+ single-positive and CD4+CD8+ double-positive T-cells were subject to transcriptomic profiling in GPA and healthy controls (each n=3). To characterize functional consequences of transcriptional alterations in T cell subpopulation from GPA-patients, differentially expressed genes from GPA-patients were investigated by gene ontology (GO) analysis. The frequency of circulating antigen-specific T-cells and phenotype of T-cells from 20 HLA-A2-positive patients with GPA and 20 healthy controls was assessed by flow cytometry. Antigen-specificity was detected using peptide/MHC class I dextramers in HLA-A2-positive subjects.

Results: Transcriptome signatures from GPA-patients presented significantly GO enriched signaling pathways for nuclear factor-kB (NF-kB), toll-like receptors (TLR), cytokine/cytokine receptor interaction (interleukins IL-1b and IL-18), and chemokine cell signaling pathways. Notably, significant enrichment of pathways consistent with immune responses triggered by various pathogens and infections was found including *Staphylococcus aureus* and Epstein Barr virus (EBV). Grouping of patients according to presence or absence of T-cell specificity for cytomegalovirus (CMV) and EBV showed that concomitant cellular CMV- and EBV-positivity was associated with a significant increase in the percentage of CD28- T-cells in GPA whereas sole or absent CMV- or EBV-positivity was not. T-cell specificity for other viruses (influenza A virus, metapneumovirus, respiratory syncytial virus) and PR3 was infrequently detected in GPA. Notably, antigen-specific T-cells were not specifically enriched within any of the T-cell subsets.

Conclusion: On genetic and cellular basis, here we show that , environmental factors including concomitant CMV- and EBV-infection and inflammation impact on alterations of the T-cell compartment in autoimmune disease. We identified cellular cytokine signatures (IL-1b, IL-18) on the transcriptomic level, which could represent novel targets for anti-cytokine-based induction therapies. Our data support antiviral therapy as another supplemental disease-modifying approach to be further evaluated in autoimmune disease such as GPA. Thus, our study provides novel insights into mechanisms driving autoimmune disease and on potential therapeutic targets.

T-Bet Regulates Ahr-Mediated Th-17 Differentiation Independently of IFNγ

Masahiro Yokosawa, Yuya Kondo, Shunta Kaneko, Seiji Segawa, Hiroto Tsuboi, Isao Matsumoto and Takayuki Sumida, Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Our previous reports showed that the development of collagen-induced arthritis was suppressed in T-bet transgenic (T-bet Tg) mice. The regulatory mechanism might relate to dysfunction of Th-17 cell differentiation by the overexpression of T-bet gene. The purpose of this study is to clarify the effect of T-bet overexpression on Th-17 cell differentiation.

Methods: T-bet overexpressing IFNγ deficient (T-bet Tg/IFNγ$^{-/-}$) mice were generated by crossing T-bet Tg mice under the promoter of CD2 gene with IFNγ deficient (IFNγ$^{-/-}$) mice. CD4^{+} T cells from C57BL/6 (WT), T-bet Tg, or T-bet Tg/IFNγ$^{-/-}$ mice were cultured for Th-17 differentiation, and the cytokine production (IFNγ, IL-17) and the expression of transcription factors (T-bet, RORγt) was analyzed. We examined the expression of IL-6 receptor (IL-6R) constituted by CD126 and CD130 and the phosphorylation of STAT3 by IL-6 stimulation of CD4^{+} T cells. The mRNA expression of transcription factors (*tbx21, rorc, stat3, stat1, runx1, irf4, nfkbiz, and ahr*) associated with the Th-17 differentiation were examined in the Th-17 condition. We transduced retrovirus expressing T-bet gene into naïve CD4^{+} T cells of WT or IFNγ$^{-/-}$ mice, and investigated cytokines and transcription factors expression. Moreover, we examined the expression of aryl hydrocarbon receptor (AHR) in Th-17 condition by flow cytometry in both T-bet Tg mice and retroviral transduction of T-bet gene. We investigated the facilitation of Th-17 differentiation by the addition of AHR ligand, 6-formylindolo [3,2-b] carbazole (FICZ), and analyzed the mRNA expression of *cyp1a1*, which was the AHR target gene.

Results: In both T-bet Tg and T-bet Tg/IFNγ$^{-/-}$ mice, RORγt expression and IL-17 production were inhibited in Th-17 condition, and IL-6R expression and STAT3 phosphorylation of CD4^{+} T cells were decreased. We also observed the inhibition of IL-17 production in CD4^{+} T cells of WT and IFNγ$^{-/-}$ mice transduced with T-bet, whereas T-bet transduction in vitro had no effects on IL-6 receptor expression and STAT3 phosphorylation. The mRNA expression of *nfkbiz* was up-regulated, but *rorc* and *ahr* were down-regulated with T-bet overexpression in both T-bet Tg mice and T-bet gene transduction under the Th-17 condition. FACS analyses revealed that the expression of AHR was significantly decreased not only in T-bet Tg and T-bet Tg/IFNγ$^{-/-}$ mice but also in T-bet gene transduced cells from both WT and IFNγ$^{-/-}$ mice. IL-17 production and the expression of *cyp1a1* by T-bet overexpression were not promoted by the addition of FICZ.

Conclusion: T-bet overexpression in CD4+ T cells repressed Th-17 differentiation by suppression of IL-17 production, RORgt expression, and AHR expression. Our findings support the possibility that regulatory mechanisms of Th-17 differentiation by T-bet overexpression might be due to the IFNγ-independent suppression of AHR.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have demonstrated that $CD4^+$ T cells from peripheral blood of anti-histidyl-tRNA synthetase (anti-His-tRNA) also known as anti-Jo-1 positive patients proliferate in response to stimulation with full-length His-tRNA and a N-terminal fragment comprising residues 1-60. Our group has already characterized a specific $CD4^+$T cell response towards the full length His-tRNA-synthetase and a peptide in the N-terminal fragment in blood and broncho-alveolar lavage of myositis patients. In this study we are presenting a novel epitope that identifies patients with moderate-severe interstitial lung disease (ILD).

Methods: Sixteen anti-Jo-1 positive patients with antisynthetase syndrome followed at the Karolinska University Hospital were enrolled. As controls we included HLA-DRB1*03-positive healthy individual (HCs, n=8). Peripheral blood mononuclear cells were isolated by Ficoll-Hypaque density centrifugation and *in vitro*stimulated with: a) full length His-tRNA protein; b) a novel HLA-DR*03:01 binding peptide from native

His-tRNA; c) an altered peptide ligand (APL) variant of His-tRNA, designed to prevent recognition by HLA-DR3/His-tRNA-specific TCRs. T cell activation was assessed by CD40L up-regulation and expression of pro-inflammatory cytokines (IFN-g, IL-2 and IL-17A) by flow cytometry. Clinical and laboratory data were documented: myositis-specific and associated autoantibodies, manual muscle test (MMT-8), health assessment questionnaire (HAQ) and interstitial lung disease (ILD). Descriptive statistics are shown with mean and standard deviation or median and IQR. Student's T test or Mann-Withney U-test were used to analyze differences between groups.

Results: At the time of blood sampling the patients had a mean age of 58 years (48-83 years), with a median disease duration of 50 months (11-70 months), MMT8 score 80 (79-80), HAQ 0.25 (0-13-0.75). Eighty-four percent were female, 13/16 patients had ILD and 13/16 had muscle weakness. T cell activation towards the novel His-tRNA peptide was observed in two of the 16 anti-Jo-1 positive patients. When stimulating with the APL version of His-tRNA, no T cell activation was observed in one of the patients that was reactive for the peptide. For evaluation of pro-inflammatory features, the His-tRNA-specific T cells displayed significant up-regulated levels of IFN-g ($p<0.05$) compared to HC ($p<0.05$). Additionally one out of eight healthy donors displayed a modest response to both the novel His-tRNA peptide and the full length His-tRNA protein. In this context only IL-2, and no other pro-inflammatory cytokine production was observed. The patients that showed an upregulation of CD40L in $CD4^+$T cells to the novel His-tRNA peptide had a moderate-severe clinical progression of ILD that required aggressive immunosuppressive treatment.

Conclusion: In this study, we demonstrate the presence of His-tRNA-reactive $CD4^+$ T cells in peripheral blood from anti-Jo-1 positive patients and a novel His-tRNA peptide, characterized by the expression of IFN-g. This phenotype seemed to correlate to a moderate-severe clinical progression of ILD.

The Transcription Factor Fra2 Is Playing a Key Role in Treg Development and Autoimmunity

Florian Renoux[1], Mara Stellato[2], Daniela Impellizzieri[3], Riyun Huang[4], Arun Subramaniam[5], Clara Dees[6], Jeorg HW Distler[6], Gabriela Kania[2], Onur Boyman[3] and Oliver Distler[2], [1]Depertment of Rheumatology, University Hospital Zurich, Schlieren, Switzerland, [2]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [3]Division of Clinical Immunology, University Hospital Zurich, Zurich, Switzerland, [4]Immune Mediated Diseases, Sanofi-Genzyme, Framingham, MA, [5]Sanofi-Genzyme, Framingham, MA, [6]Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany

Session Date: Monday, November 14, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Decreased numbers or altered functions of regulatory T cells (Tregs) have been reported in many inflammatory rheumatic diseases, and Tregs are considered promising therapeutic targets for autoimmune diseases. It is thus of high importance to delineate the pathways controlling Tregs biology and the onset of autoimmunity. Fos-related antigen 2 (Fra2) is a transcription factor belonging to the Fos family proteins which is part of the AP-1 transcription complex. Our aim is to characterize the potential role of Fra2 in controlling Tregs and autoimmunity.

Methods: Fra2 transgenic (tg) mice were generated, in which the Fra2 transcription factor is ubiquitously overexpressed. T lymphocyte populations were analyzed by flow cytometry, and pathological manifestations in multiple organs by histology. Bone marrow cells were transferred into lethally irradiated recipients to create Fra2-wt chimeric mice. Purified CD4 T cells were transferred into $Rag2^{-/-}$mice lacking T and B cells.

Results: At 3 weeks of age, Fra2 mice showed a striking decrease of the Treg population ($CD4^+CD25^+FoxP3^+$ in wt and Fra2 littermates spleens: 11.35 and 5.75% of $CD4^+$, respectively, p=0.0005, n=6). The strong decrease in Tregs was stable over time and also observed in $CD4^+$ single positive thymocytes, indicating that Fra2 mice have a defect in natural Treg development. Interestingly, from 7 weeks on, we could also detect the appearance of activated T cells ($CD4^+$ and $CD8^+$, with $CD62L^{high}CD44^{high}CD127^{low}$profile) which represented up to 60% of total T cells by 16 weeks of age. While the phenotype of young mice was limited to decreased Tregs, macroscopic and histological observations in 16 week-old mice showed the presence of an extensive multi-organ autoimmune phenotype: Perivascular inflammatory infiltrates, containing T cells, B cells and numerous granulocytes were observed in the lung and liver with fibrosis and vasculopthy. Extensive inflammation and fibrosis were observed in the thymus. Spleens were also enlarged with pronounced extramedullary haematopoiesis. Fra2 tg mice also developed dermatitis on eyelids and back-skin, with an increase in dermal and epidermal thickness. Finally, duodenum was enlarged due to acute inflammation and reactive hyperplasia. To understand whether the effect of Fra2 is T cell intrinsic or extrinsic, we also performed bone marrow transfer experiments in which irradiated wt recipient mice received Fra2 tg bone marrow. Interestingly, chimera mice displayed a decreased percentage of Tregs confirming an intrinsic role of Fra2 in Treg development. Finally we could show that transfer of purified CD4 T cells from Fra2 tg mice into lymphopenic host ($Rag2^{-/-}$) was sufficient to transfer the phenotype, demonstrating the ability of CD4 T cells to induce the phenotype.

Conclusion: These data suggest that Fra2 overexpression inhibits natural Treg development, resulting in **1:** diminished Tregs, **2:** activation of effector T cells and **3:**development of inflammation in multiple organs. This is the first evidence for a role of Fra2 in controlling Treg development and autoimmunity. This murine model also provides a unique opportunity to delineate the function of the Fra2 pathway in T cells and Tregs and its impact on autoimmunity.

IL-21 Inhibits Treg Differentiation and Function in SLE By Modulating GATA-3 and CTLA-4

Hiroshi Kato[1] and Andras Perl[2], [1]Division of Rheumatology/Internal Medicine, SUNY Upstate Medical University, Syracuse, NY, [2]Department of Medicine, SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Studies indicate quantitative and qualitative Treg insufficiencies underlying the dysregulated immune response in SLE. However, it is unknown what mechanisms drive the Treg dysfunction in SLE. GATA-3 is critical in differentiation and functions of murine Treg. IL-21 is upregulated in SLE and tips the balance from Treg to Th17 differentiation in mice. We sought to identify a mechanism that would link IL-21 and GATA-3 to understand the altered differentiation and function of SLE Tregs.

Methods: $CD3^+$ T cells were isolated from matched SLE and healthy control (HC) subjects. The cells were cultured in the presence of anti-CD3/CD28 with or without rapamycin, after which IL-21 was measured in the supernatant by LUMINEX assay. Naïve $CD4^+$ T cells from matched SLE and HC subjects were cultured for 3 days in the presence of anti-CD3/CD28, TGF-β, and IL-2 with or without IL-21. Frequency of $CD4^+CD25^+FOXP3^+$ Tregs and expression of GATA-3 and CTLA-4 in the Treg were determined by flow cytometry. Total STAT3 and its phosphorylation at tyrosine 705 ($pSTAT3^{Y705}$) were examined by immunoblotting. Next, $CD4^+CD25^-$ responder T cells (Tresp cells) and autologous $CD4^+CD25^+$ Tregs were magnetically isolated. Treg function was determined in the presence or absence of IL-21 by assessing the % suppression of proliferation of CFSE-stained Tresp cells cultured for 5 days in the presence of anti-CD3 and irradiated autologous PBMCs. FOXP3, GATA-3, and CTLA-4 expression in the Treg were determined upon coculture. In some experiments, Tregs were expanded *in vitro* for 4 weeks with or without rapamycin before coculture. Statistical analyses were done using Student's t-test.

Results: IL-21 inhibited SLE Treg differentiation (% $CD4^+CD25^+FOXP3^+$ cells with and without IL-21: 40.78±3.26%, 64.75±3.16%; p=0.0002). Suppressive function of SLE Tregs was diminished (SLE: 30.25±4.48%, HC: 46.63±4.90%, p=0.03) and further inhibited by IL-21 (18.99±4.95%, p=0.042), while IL-21 did not promote the Tresp cell proliferation. pSTAT3 was upregulated in SLE $CD4^+$ T cells, which was further promoted by IL-21 under Treg-polarizing conditions. GATA-3 (Relative MFI: 0.81±0.09, p=0.032) and CTLA-4 were downregulated in freshly isolated $CD4^+CD25^+FOXP3^+$ cells in SLE (% $CTLA\text{-}4^+$ cells, SLE: 5.11±0.75%, HC: 6.96±0.79%; p=0.034). IL-21 inhibited GATA-3 expression in $CD4^+CD25^+FOXP3^+$ cells in SLE (% $GATA\text{-}3^+$ cells with and without IL-21: 35.29±5.87%, 67.72±7.37%; p=0.0002). IL-21 suppressed CTLA-4 expression in SLE Tregs (% $FOXP3^+CTLA\text{-}4^+$cells with and without IL-21: 8.62±1.35%, 29.46±5.31%; p=0.001). In turn, rapamycin blocked T-cell IL-21 secretion, while it promoted FOXP3, GATA-3, and CTLA-4 expression and suppressive function of SLE Tregs.

Conclusion: IL-21inhibits Treg differentiation and function in SLE potentially by downregulating GATA-3 and

CTLA-4, whereas rapamycin promotes Treg differentiation and function in part by suppressing IL-21.

Session Date: Monday, November 14, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tyk2 is a member of the JAK family kinases and is a key mediator of IL-12, IL-23, and type I interferon signaling. These cytokines have been implicated in the pathogenesis of multiple inflammatory and autoimmune diseases such as lupus, psoriasis and inflammatory bowel diseases (IBD). Supported by compelling data from human genetic association studies, Tyk2 inhibition is an attractive therapeutic strategy for autoimmune diseases.

Methods: We utilized cutting edge proprietary structure-based drug design tools to identify highly selective Tyk2 inhibitors. These inhibitors were characterized for their potency and selectivity in enzyme and cell-based assays, and in mouse models of IBD and psoriasis.

Results: We have identified NDI-031407, a small molecule inhibitor of Tyk2, with potent enzyme and cellular activity, and excellent selectivity against other JAK family kinases and panels of receptors, transporters, ion channels, CYP enzymes and the hERG channel. This compound inhibits Tyk2 in a biochemical assay with a Ki of 0.2 nM, and is 218-, 148-, and 20-fold selective against JAK1, JAK2, and JAK3, respectively. Cell-based potency and selectivity of NDI-031407 was demonstrated in human PBMC assays by blockade of IL-12 induced phospho-STAT4, GM-CSF induced phospho-STAT5, and IL-2 induced phospho-STAT5, with IC_{50} of 0.10 μM, 3.9 μM and 0.24 μM, respectively. In addition, NDI-031407 inhibited IL-12 induced IFNγ with IC_{50} of 0.7 μM and 3.8 μM in human and mouse whole blood, respectively. We investigated the *in vivo* efficacy of NDI-031407 in mouse models of psoriasis and IBD. In an IL-23-induced mouse psoriasis model, NDI-031407 dose-dependently reduced disease with up to 74% inhibition of ear swelling and 96% inhibition of tissue levels of IL-17A at 100 mg/kg, highlighting the crucial role of Tyk2 inhibition in Th17 pathogenesis mediated by IL-23. In addition, NDI-031407 was highly efficacious in an imiquimod-induced mouse psoriasis model. NDI-031407 at 100 mg/kg achieved the same efficacy as dexamethasone in reduction of psoriasis score without body weight reduction. NDI-031407 treated mice had improved skin histology and dose-dependent reduction of spleen weight. To investigate the role of Tyk2 inhibition in Th1-driven pathogenesis, we tested NDI-031407 in a

$CD4^+CD45RA^+$ adoptive transfer model that resembles the pathology of human Crohn's disease. NDI-031407 treatment improved disease outcomes by reduction of body weight loss and colonic weight/length ratio, and improved colon histology. 100 mg/kg of NDI-031407 treatment also reduced colon myeloperoxidase levels to those of disease-free control mice, demonstrating the remarkable anti-inflammatory efficacy of Tyk2 inhibitors in this disease model.

Conclusion: Utilizing unique and innovative structure-based drug design technologies, we rapidly designed highly selective and potent Tyk2 inhibitors with suitable pharmaceutical properties as potential therapeutics in inflammatory disorders. We validated the vital role of Tyk2 in disease pathogenesis of psoriasis and IBD in preclinical mouse models.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lipids function as essential components of biological membranes, as signaling molecules, and as energy storage molecules. Glycerol-based phospholipids, called glycerophospholipids (GPL), are the most abundant membrane lipids. Their glycerol backbone is esterified to phosphoric acid, resulting in the formation of phosphatidic acid (PA), from which all other GPLs are formed by the addition of a polar headgroup like choline, ethanolamine, glycerol, inositol, and serine, producing the main phospholipids in the cell, namely phosphatidylcholine (PC), phosphatidylethanolamine (PE), phosphatidylglycerol (PG), phosphatidylinositol (PI) and phosphatidylserine (PS), respectively. GPLs such as PA, PC, PE, PI, and PS, have been eluted and identified by mass spectrometry as natural human CD1d ligands, and PC and PE have been eluted from murine CD1d. However, the functions of T cells that recognize abundant self GPLs are not known. Here, we identified these T cells in various lymphoid organs in normal and autoimmune-prone mice, investigated cell-cell interactions, and determined their role in animal models of autoimmune disease.

Methods: CD1d tetramers were loaded with various GPL antigens, and cells analyzed by flow cytometry. Cell-

cell interactions between GPL-reactive T cells and other immune cells were analyzed using *in vivo* and *in vitro* assays. *In vivo*effects of GPLs were tested in autoimmune animal models.

Results: CD1d tetramers loaded with GPLs, namely PA, PC, PE, PI, PS and BMP, identify 0.4–4% T cells in the lymphoid organs of normal and autoimmune-prone NZB/NZW and NZM.2328 mice. GPL-reactive T cells don't recognize glycolipid-loaded tetramers and don't respond to glycolipid αGalCer, suggesting that GPL-reactive T cells are distinct from other CD1d-restricted, invariant natural killer T cells. GPL-reactive T-cells expand, express CD69, and produce cytokines upon *in vivo* priming. However, all self-GPL antigens tested potently inhibited the proliferation and cytokine production by invariant natural killer T-cells via mobilization and migration of monocytic myeloid-derived suppressor cells into peripheral organs. These myeloid-derived suppressor cells inhibited invariant natural killer T-cells via interleukin-10. Treatment with a GPL antigen ameliorated autoimmune hepatitis, reduced pro-inflammatory cytokines and granulocyte accumulation, but recruited interleukin-10 producing myeloid derived suppressor cells that upon adoptive transfer protected against autoimmune disease in an animal model.

Conclusion: Normal immune repertoire contains T cells reactive to self GPLs, which ameliorate autoimmune disease via mobilization and migration of a subset of myeloid-derived suppressor cells. These novel observations have important implications for conditions with altered lipid metabolism and inflammation such as atherosclerosis and autoimmune disease. Session Date: Monday, November 14, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In anti-neutrophil cytoplasmic antibodies associated vasculitis (AAV), several clues suggest that the efficacy of B cell depletion therapy lies beyond the suppression of ANCA-producing cells and may involve the suppression of B-T cell crosstalk. However, little if any data are available regarding the impact of rituximab on CD4, regulatory T and CD8 T cells in this setting.

Methods: Using polychromatic flow cytometry we performed a thorough immunophenotypic analysis of CD4, regulatory T and CD8 cells of 53 patients with AAV in order to compare the effect of conventional immunosuppressants (CIS) and rituximab (RTX) on these 3 T cells compartments. Cytokine/chemokine production of *in vitro* stimulated CD8 T cells was assessed using a multiplex Luminex immunoassay

Results: Among CD4 T cells, we found that frequency of naïve and memory subsets and the expression of CCR5, CCR4 and CD161 were not influenced by maintenance treatment type. Similarly, total Treg frequency and Treg subsets including $CD161^{+}$, $Helios^{+}$, resting ($CD45RA^{+}$) and memory ($CD45RA^{-}FoxP3^{hi}$) Tregs were comparable among RTX and CIS treated patients. By contrast, the type of maintenance treatment markedly influenced the CD8+ T cell compartment. Indeed, RTX inhibited late differentiated effector memory (TEMRA; $CD45RA^{+}CCR7^{-}$) CD8 cell expansion whereas CIS had the opposite effect, particularly in CMV positive individuals. Furthermore, we found that unlike CIS, B cell depletion therapy effectively inhibited the pro-inflammatory cytokine/chemokine production of *in vitro* stimulated CD8 T cells.

Conclusion: B cell depletion therapy has a profound impact on the CD8 T cell compartment. This observation raises the question whether the disruption of B cell help to CD8 T cells could contribute to the dramatic efficacy of RTX. Whether B cell depletion therapy promotes CD8 T cell exhaustion and/or inhibits immunosenescence deserves further investigations.

Session Date: Monday, November 14, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease leading to the inflammatory destruction of synovial joints. Anti-citrullinated protein antibodies (ACPA) are frequently detected in the serum of RA patients and may contribute to the pathogenesis of RA. Citrullination, which may involve several endogenous (self) proteins, is a post-translational modification of arginine residues in the protein backbone. Previous studies identified a citrullinated epitope in cartilage proteoglycan (PG) aggrecan, which elicited pro-inflammatory cytokine production by RA T cells in vitro. Moreover, we have recently reported the presence of ACPA-reactive (citrullinated) PG in RA cartilage. The purpose of the present study was to identify novel citrullinated epitopes in human PG that are recognized by T cells and/or antibodies from RA patients.

Methods: We used spleen cells from mice with PG-induced arthritis (PGIA) as screening tools to select citrulline (Cit)-containing PG peptides that were more immunogenic than their arginine (R)-containing counterparts. The Cit-R pairs of selected peptides were then tested for induction of pro-inflammatory T-cell cytokine production in RA and healthy control peripheral blood mononuclear cell (PBMC) cultures using cytokine ELISA and flow cytometry methods. Anti-Cit and anti-R peptide antibodies in mouse serum or human plasma were detected by ELISA.

Results: Spleen cells from mice with PGIA exhibited greater T-cell cytokine secretion in response to the Cit than the R version of PG peptide 49 (P49) and anti-P49 antibodies were detected in PGIA serum. PBMC from RA patients, but not PBMC from healthy controls responded to the citrullinated form of P49 (designated Cit49) with robust cytokine production in vitro. Importantly, high levels of anti-Cit49 antibodies were found in the plasma of ACPA-positive RA patients (n = 32). However, there was no correlation between the levels of Cit49-induced T-cell cytokines and anti-Cit49 antibodies in ACPA-positive RA. Another PG peptide (Cit13) similar to the previously described T-cell epitope induced greater cytokine responses than R13 by healthy control (but not RA) PBMC, however, anti-Cit13 antibodies were rarely detected in human plasma.

Conclusion: We have identified a novel citrullinated human PG epitope (Cit49), which is highly immunogenic both in mice with PGIA and patients with RA. The lack of correlation between T-cell and antibody reactivity with Cit49 in the ACPA-positive RA group suggests that this peptide is recognized as either a strong T-cell epitope or a strong B-cell epitope in different subsets of ACPA-positive patients. As citrullinated PG may be present in RA articular cartilage, Cit PG epitope-induced T-cell activation or deposition of Cit PG epitope-specific antibodies can occur in the joints of ACPA-positive RA patients, potentially contributing to cartilage destruction.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: High-throughput sequencing of intestinal microbiota recently revealed that the composition of intestinal microbiota is perturbed in patients with new onset untreated rheumatoid arthritis (RA). In mice, both germ-free condition and administration of oral antibiotics before the onset of arthritis modulate T cell differentiation and attenuate the disease. However, it is not known whether and how modulation of intestinal microbiota after the onset of arthritis may influence the disease. Here, we investigated the involvement of commensal intestinal microbiota in the progression of established arthritis in both T cell-dependent and -independent mouse models.

Methods: Mice with established collagen-induced arthritis (CIA) as the most widely-used T cell-dependent model of RA, as well as mice with K/BxN serum-transfer arthritis as a T cell-independent model were treated orally with a cocktail of metronidazole, neomycin, ampicillin (1 g/l each) and vancomycin (0.5 g/l) for one week to partially eliminate intestinal microbiota. Arthritis was assessed macroscopically and by histologic analysis. Differentiation of Th1, Th17 and regulatory T (Treg) cells and production of their prototypic cytokines in intestinal lamina propria and joint-draining lymph nodes were assessed by flow cytometry and Luminex array. Development of anti-collagen type II antibodies was assessed in serum of CIA mice using ELISA. Intestinal and synovial expression of cytokines and serum amyloid A (SAA) isotypes was measured by qPCR.

Results: Elimination of intestinal microbiota in mice with ongoing CIA specifically suppressed intestinal Th17 cell differentiation without affecting Th1 and Treg cells. Accordingly, production of interleukin-17 (IL-17), but not interferon γ, IL-4 and IL-10, by lamina propria lymphocytes was significantly diminished in antibiotic-treated mice. Furthermore, intestinal expression of SAA isoforms and IL-22, known to promote lamina propria Th17 cell differentiation, was suppressed in antibiotic-treated CIA mice. Importantly, elimination of intestinal microbiota resulted in suppressed Th17 cell differentiation and IL-17 production in joint-draining lymph nodes and reduced the severity of established CIA. In contrast, antibiotic treatment did not influence disease severity in the T cell-independent K/BxN serum-transfer arthritis. Intriguingly, the abundance of intestinal Th17 cells strongly correlated with the severity of arthritis in the CIA mice. However, elimination of intestinal microbiota after disease onset did not affect the development of anti-collagen type II autoantibodies.

Conclusion : These observations suggest that modulation of commensal intestinal microbiota during established arthritis specifically suppress Th17 differentiation and dampen T cell-mediated arthritic processes. While our study does not advocate the use of antibiotics as a treatment for RA, it supports the notion that inflammatory signals provided by the gut microbiota continue to promote arthritis after its onset. Understanding the exact mechanisms linking the intestinal T cell response with arthritis may help identifying novel therapeutic strategies for RA.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mucosal associated invariant T (MAIT) cells are an innate-like lymphocyte population predominant at mucosal sites, which express a semi-invariant T cell receptor restricted to the MHC class I-like molecule, MR1. MR1 presents ligands derived from the riboflavin synthesis pathway, common to a range of bacteria and yeast. There is evidence in rheumatoid arthritis (RA) and ankylosing spondylitis (AS) for oral and/or gastrointestinal microbial dysbiosis. However the mechanisms underlying these disease associations are unclear. We analyzed how the response of MAIT cells to MR1 ligand might influence the development of dysbiosis.

Methods: We compared the frequency of $CD3^{+}CD4^{-}CD161^{hi}TRAV1\text{-}2^{+}$ PB MAIT cells in 45 RA, 10 AS patients, and 38 healthy controls (HC). We investigated the frequency of 5-OP-RU-specific MAIT cells using

MR1-tetramers and analyzed cellular activation of MAIT cells in arthritis patients and HC after stimulation with 5-OP-RU ligand. We identified compositional variations in the oral microbiome of RA patients, and assessed whether these variations are reflected in riboflavin biosynthesis pathways

Results: Bacterial species capable of riboflavin synthesis and thus MAIT cell ligand production, including *Streptococcus infantilis*, *Rothia dentocarisosa*, *Rothia mucilaginosa* and *Prevotella melaninogenica* were more abundant in the oral microbiome of RA patients than HC. We observed no difference in MAIT cell frequencies when comparing HC, RA and AS patient groups matched for age and sex. However, the proportion of PB MAIT cells declined with age in all groups and accordingly, was significantly lower in patients with late- rather than early-onset RA. PB MAIT cells were constitutively more activated than conventional T cells. The frequency of 5-OP-RU-specific PB MAIT cells ranged from 0.8-8%. When stimulated ex vivo with the riboflavin metabolite 5-OP-RU, PB MAIT cells upregulated CD69. In response to 5-OP-RU, approximately 50% of MAIT cells secreted TNF and 10% secreted IFN-g, while less than 1% secreted IL-17. The ligand was highly specific, as conventional T cells in the same culture were not activated. When compared to HC MAIT cells, MAIT cells from arthritis patients were more susceptible to apoptosis in response to 5-OP-RU, and residual live cells expressed lower levels of CD69 or TNF than HC.

Conclusion: PB MAIT cells decline with age in arthritis patients similar to HC. MAIT cells of arthritis patients have greater susceptibility to MR1 ligand-induced cell death in vitro and the surviving cells have lower capacity for cytokine production. Certain bacterial species enriched at the RA mucosal sites are capable of riboflavin biosynthesis, and presumptively, the formation and release of MR1 ligands, which could impact control of dysbiosis by MAIT cells.

Session Date: Monday, November 14, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Programmed death-1 (PD-1) is a central marker of T cell exhaustion. Exhausted T cells are present in inflammatory conditions, where they fail to eliminate the disease, and contribute to development of chronicity. They are suggested associated with a favorable prognosis in rheumatoid arthritis (RA), yet this is not fully elucidated [1]. Extracellular vesicles (EVs) carrying proteins and microRNAs (miRNAs), among other constituents have been recognized as an important route of communication in the microenvironment.

Methods: Plasma and synovial fluid from RA patients were examined for the presence of EVs by capturing EVs on CD63 coated beads. EVs were furthermore isolated from supernatants from synovial fluid mononuclear cell (SFMC) and peripheral blood mononuclear cell (PBMC) cultures and characterized. The presence of PD-1 in EVs was examined by immuno-gold electron microscopy (EM), ELISA and western blotting. EVs purified from RA and healthy control (HC) PBMC cultures were co-cultured with lymphocytes and U937 cells (a cell line negative for PD-1), and EVs from WT mice were co-cultured with cells from PD-$1^{-/-}$ mice. PD-1 expression and cell proliferation of the exposed cells were analyzed. Finally, miRNA expression in EVs from cultured RA and HC cells was investigated by sequencing.

Results: PD-1 was detected in EVs in plasma and synovial fluid from RA patients. The presence of PD-1^{+} EVs in RA and HC cell culture supernatants was confirmed with immuno-gold EM and western blotting. Co-culturing these EVs with other cells induced PD-1 on the surface of lymphocytes and U937 cells. PD-1 was furthermore induced on PD-$1^{-/-}$ cells, when these were co-cultured with EVs from WT mice. EVs from RA PBMCs increased recipient cell proliferation, compared with both EVs from HC PBMCs and cells without EVs. This was not changed by addition of recombinant PD-L1. MicroRNAs repressing expression of the co-inhibitory receptors PD-1, TIM-3 and CTLA-4, all associated with an exhausted T cell profile, were up-regulated in EVs from stimulated PBMC cultures, however not in EVs from RA SFMCs. In EVs from non-stimulated RA PBMC cultures, miRNAs repressing the exhausted T cell pathway were down-regulated compared to EVs from HC cultures, suggesting that RA PBMCs in a steady-state aim to transfer information maintaining an exhausted T cell profile.

Conclusion: EVs from RA PBMCs carry and transfer PD-1 and incorporate less miRNAs repressing the PD-1 pathway and other markers of T cell exhaustion. Despite this, EVs from RA PBMCs increase proliferation of recipient cells *in vitro*. In addition, EVs from RA synovial cells express low levels of miRNA that regulate PD-1, TIM-3 and CTLA-4, facilitating continuous T-cell exhaustion. In conclusion this suggests that EVs are pro-inflammatory in RA, and contribute substantially to the development of chronicity. 1. McKinney, E. F., et al. *Nature* **523,** 612–616 (2015).

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: $CD4^+$ T cells are important contributors to the pathogenesis of Rheumatoid Arthritis (RA). The presence of activated T cells in the inflamed synovium, strong associations with HLA-DR4, ptpn22, ctla4 and cd28 implicate their contribution, while the success of T cell targeted CTLA-4-Ig therapeutic provide more direct evidence. Yet it remains unclear when and where $CD4^+$ T cells mediate this pathogenic effect and whether the specificity of the cells is important.

Methods: A variation of antigen-induced arthritis using ovalbumin (OVA) as the inciting challenge was used to model articular inflammation. Th1 polarised OVA specific fluorescent (DsRed) OT-II TcR transgenic T cells were adoptively transferred and expanded *in vivo* by challenge with OVA/CFA. This allowed subsequent analysis and tracking of antigen-specific T cells as they were recruited to the ankle joint following periarticular injection of heat aggregated OVA (HAO). Flow cytometry allowed phenotyping of cells recruited to the inflamed articular environment. The T cell receptor (TcR) diversity of infiltrating endogenous T cells was assessed by PCR of Vβ genes. Dynamic interactions of responding DsRed T cell populations with joint residing CD11c YFP dendritic cells were visualized using intravital multiphoton laser scanning microscopy.

Results: Low numbers of the inciting OVA specific $CD4^+$ T cells could be found in the joint tissue. However, a large influx of endogenous $CD4^+$ T cells of unknown antigen specificity was also found. In comparison with the $CD4^+$ T cells in the draining lymph node, this recruited T cell population expressed surface activation markers, produced TNFa and IFNg upon *ex vivo* restimulation and exhibited a narrower range of T cell receptor Vb usage. In addition, intravital imaging of the inflamed joint revealed that a sub-population of this infiltrate demonstrated slower motility speeds and longer periods of contact with articular dendritic cells, while others rapidly migrated throughout the tissue.

Conclusion: We present data demonstrating that while the numbers of inciting antigen-specific T cells to the joint tissue is small, it is associated with a subsequent influx of a large endogenous population of unknown antigen specificity that had acquired the ability to secrete pro-inflammtory cytokines. Oligoclonal TcR Vβ gene expression by the $CD4^+$ T cells in the inflamed joint suggests some degree of antigen-specificity in recruitment while intravital imaging reveals that some of this infiltrate exhibits behaviour consistent with recognition of cognate peptide-MHCII.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by peripheral polyarthritis. The importance of CD4+ T cell in the pathophysiology of RA is well-known and it has been reported that the diversity of T cell receptor (TCR) of CD4+ T cells is decreased in rheumatoid arthritis. However, the relationship between the decrease of TCR repertoire diversity of CD4+ T cells and RA pathophysiology remains unclear. To investigate the significance of this phenomenon in RA pathophysiology, we analyzed TCR repertoire and its association with disease activity and other parameters related to RA.

Methods: Peripheral blood CD4+ memory (CD3+CD4+CD45RA-) and naïve (CD3+CD4+CD45RA+) T cells from 18 RA patients and 21 age and sex-matched healthy donors were obtained. All RA patients satisfied the 2010 ACR/EULAR classification criteria for RA. cDNAs of TCR-beta were synthesized and amplified by 5'-race method. Sequencing was performed by Miseq. Concentrations of serum cytokines were assessed with Multiplex ELAISA. Renyi entropy was used to comprehensively assess TCR repertoire diversity, and correlation with disease activity, concentrations of serum cytokines, the number of shared epitope alleles and other clinical parameters was examined.

Results: TCR repertoire diversity of both memory and naïve CD4+ T cells was significantly reduced in RA patients with high disease activity compared to healthy donors. It is generally thought that the reduction of TCR diversity of CD4+ T cells reflects the existence of antigen specific immune responses in RA, and this immune response may be associated with antigens presented on HLA class II. Our results showed a positive correlation between the dosage of shared epitope and reduction of TCR repertoire diversity in CD4+ T cells. Also, there was a negative correlation between TCR repertoire diversity of CD4+ T cells and disease activity indices, such as Disease Activity Score (DAS) 28-CRP, DAS28-ESR, and Clinical Disease Activity Index (CDAI). On the other hand, concentrations of serum cytokines, including pro-inflammatory cytokines, did not show significant correlation with TCR repertoire diversity of CD4+ T cells. These phenomenon were found not only in CD4+ memory T cells but also in CD4+ naïve T cells.

Conclusion: Our results suggest that antigen specific immune responses of CD4+ T cells to self-antigens

presented on HLA class II with shared epitope may contribute to the pathophysiology of rheumatoid arthritis in a different manner from inflammatory cytokines. These antigen specific responses, not only in CD4+ memory T cells subset, but also in CD4+ naïve T cells subset, may be related to RA pathophysiology and may suggest the importance of homeostatic expansion in RA.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The active vitamin D metabolite $1,25(OH)_2D_3$ suppresses various experimental autoimmune diseases. In addition, serum vitamin D levels, vitamin D intake and polymorphisms in the vitamin D receptor (VDR) are associated with disease incidence and severity in human autoimmune diseases such as rheumatoid arthritis (RA). However, the mechanism behind these immunosuppressive effects is currently unknown. Previously we have demonstrated that $1,25(OH)_2D_3$ directly inhibits pathogenicity of $CCR6^+$ T helper (Th) cells. These cells, which include Th17 and Th17.1 cells, are thought to play an important role in the pathogenesis of autoimmune diseases such as rheumatoid arthritis (RA). They produce cytokines like IL-17A and TNFα and activate synovial fibroblasts to induce a pro-inflammatory feedback loop. This interaction may underlie the chronic joint inflammation in RA. Therefore $CCR6^+$ Th cells are an interesting therapeutic target in this disease. Here we further investigated the effect of $1,25(OH)_2D_3$ on $CCR6^+$ Th cells to understand how

$1,25(OH)_2D_3$ suppresses the inflammatory responses in autoimmune diseases.

Methods: We cultured $CCR6^+$ Th cells from treatment-naïve early RA patients with or without $1,25(OH)_2D_3$ and generated gene-expression profiles. These profiles were validated using RT-PCR, ELISA and flow cytometry. Functional effects were evaluated via co-culture with RA synovial fibroblasts (RASF) and Boyden chamber-based migration assays.

Results: Gene-expression profiles from $CCR6^+$ Th cells confirmed that $1,25(OH)_2D_3$ treatment downregulated pro-inflammatory cytokines like IL-17A, IL-17F and IL-22, but also genes important for the pathogenic Th17 phenotype like RORC and IL-23R. In contrast, $1,25(OH)_2D_3$ induced the anti-inflammatory cytokine IL-10, but not the classical Treg transcription factor FoxP3. Instead, upregulation of genes like LAG3, c-MAF, CTLA4, and IRF8 suggests the induction of a Tr1-like phenotype. Interestingly, these $CCR6^+$ Th cells cultured with $1,25(OH)_2D_3$ were less capable of inducing the pro-inflammatory loop upon interaction with RASF. This suggests that the modulated $CCR6^+$ Th cells could contribute to regulating synovial inflammation. However, for this they need to be capable of migration towards inflammatory sites. Therefore we investigated the migration of $CCR6^+$ Th cells treated with $1,25(OH)_2D_3$ towards synovial inflammation as modeled by the $CCR6^+$ Th – RASF co-culture. Indeed, the $1,25(OH)_2D_3$-treated $CCR6^+$ Th cells migrate faster towards the site of inflammation than untreated cells.

Conclusion: $1,25(OH)_2D_3$ inhibits the pathogenic Th17 phenotype in $CCR6^+$ Th cells, while inducing a regulatory Tr1-like phenotype. These cells will then migrate towards the site of inflammation, where they are less potent activators of RASF. This effect of $1,25(OH)_2D_3$ on $CCR6^+$ Th cells may underlie the suppression of RA by vitamin D.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: *Prevotella copri*, an intestinal commensal microbe, may be prominent in stool samples of patients with new-onset rheumatoid arthritis (NORA). However, it has been unclear whether the organism is immune-relevant in RA pathogenesis.

Methods: HLA-DR-presented peptides were identified directly from RA patients' synovial tissue or peripheral blood mononuclear cells (PBMC) by tandem mass spectrometry. *P. copri* peptides or source proteins were then tested for T cell reactivity by IFN-γ ELISpot assay and for antibody responses by ELISA using cells and sera from DMARD-naive NORA patients, chronic RA (CRA) patients, and controls. For comparison, humoral responses to *P. gingivalis*, *B. fragilis,*and *E. coli* were also tested. Serum samples were analyzed for innate, Th1, and Th17 mediators by Luminex. Moreover, available serum and synovial fluid (SF) samples were tested for the presence of *P. copri* 16S rDNA by nested PCR. All RA patients met the 2010 ACR/EULAR criteria for RA.

Results: We identified an HLA-DR-presented peptide from a 27-kD protein of *P. copri* (*Pc*-p27), which stimulated Th1 responses in 17 of 40 NORA patients (42%), but not in Lyme arthritis patients (P=0.0007) or healthy controls (P<0.0001). We then found that 17 of 78 NORA patients (22%) and 16 of 49 CRA patients (33%) had IgG or IgA antibody responses to *Pc*-p27, but rarely to both. Similar results were obtained when testing was done with the whole *P. copri* organism. Three types of comparison groups suggested that *P. copri* antibody responses are specific for RA. First, *P. copri* antibodies were rarely found in patients with other rheumatic diseases or in healthy controls. Second, antibody levels to 2 other gut commensals, *B. fragilis* and *E. coli*, were similar or less in RA patients than those in patients with other type of arthritis or in healthy controls. Third, although IgG and often IgA antibodies to the oral periodontal pathogen, *P. gingivalis*, were detected in 25% of the 127 RA patients, there was little overlap between this group and those with *P. copri* antibodies. In patients with *P. copri* IgA antibodies, these responses correlated with Th17 cytokines and most had anti-citrullinated protein antibodies (ACPA). In contrast, serum *P. copri* IgG levels correlated with the Th1 cytokine CXCL10, and with significantly less frequent ACPA (P=0.01). Of 18 patients in whom both serum and SF were available, 3 of 5 patients with IgG *P. copri* antibodies had 16S DNA for *Prevotella* detected in SF compared with none of the patients with IgA *P. copri* antibodies or no *P. copri*antibodies (P=0.01).

Conclusion: Subgroups of RA patients have differential immune responses to *P. copri*. IgA antibody responses to *P. copri* correlated with Th17 cytokine responses and frequent ACPA, which may signify localized interactions between microbes and host immune cells in the gut mucosa. In contrast, IgG *P. copri* antibody responses were associated with *Prevotella* 16S DNA in SF, Th1 immune responses, and infrequent ACPA, which may result from systemic spread of the organism, presumably carried to joints within cells. These observations suggest that *P. copri* is an immune-relevant bacterium in subgroups of patients with RA, supporting a new paradigm in RA pathogenesis.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Vδ2T cells, a subpopulation of γδ T cells with inflammatory features, play a vital role in inflammation, tumor immunology, infectious disease and autoimmunity. However, the role of Vδ2 T cells in the pathogenesis of rheumatoid arthritis remains elusive.

Methods: 68 patients with rheumatoid arthritis, 21 patients with osteoarthritis and 21 healthy controls were enrolled in the study. All RA patients fulfilling the 2010 ACR/EULAR criteria for RA. Peripheral Vδ2T population, apoptosis, proliferation, chemokine receptor expression and pro-inflammatory cytokine secretion were quantified by flow cytometry. The infiltration of Vδ2 T cells within synovium was examined by immunohistochemistry and flow cytometry. The effect of TNF-α and IL-6 on Vδ2 T migration was determined by flow cytometry and transwell migration assay.

Results: The percentage of peripheral Vδ2T cells of active RA were significantly decreased compared with healthy controls (1.80±1.76% vs 5.68±2.72%), which were negatively correlated with the disease activity indexes including DAS28($r=-0.6341$, $p<0.01$), CRP($r=-0.4352$, $p<0.01$) and ESR($r=-0.4364$, $p<0.01$). However, the Vδ2T cells infiltrated in the synovium of RA were increased compared with OA ($p<0.05$). Comparing with OA Vδ2T cells, both peripheral and synovium Vδ2T cells of RA produced higher level of IFN-γ and IL-17 ($p<0.05$). The chemokine receptor CCR5 and CXCR3 expressed on Vδ2T cells in RA were significantly higher than HC and OA patients ($p<0.05$), which were induced by TNF-α and IL-6. TNF-α antagonist therapy restored the peripheral Vδ2 T cell in RA.

Conclusion: Elevated TNF-α and IL-6 in RA patients induced high expression of CCR5 and CXCR3 on Vδ2T cells, which subsequently promote Vδ2 T cells infiltrate into synovium and play an important role in the pathogenesis of RA. Vδ2 T cell is a promising potential biomarker and therapeutic target of RA.

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a group of systemic vasculitides associated with ANCA specific for myeloperoxidase (MPO) or proteinase-3 (PR3), and includes microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA), and eosinophilic granulomatosis with polyangiitis (EGPA). A high prevalence of venous thromboembolism has been reported in several cohort studies of patients with AAV, not only during active disease but also when patients are in remission. Recently, it has also been suggested that patients with AAV in the active stage are in a hypercoagulable state. However, the clinical significance of the increased incidence of venous thromboembolism among patients with AAV has not been fully recognized. Here we examined the relationship between markers for hypercoagulability and disease activity including inflammatory markers and kidney functions, and assessed the implication of abnormal coagulation status in patients with AAV.

Methods: Fifty-five patients who had been referred to Niigata University Hospital and diagnosed as having AAV (MPA (n=29), GPA (n=23), EGPA (n=3)) between 2009 and 2015 were recruited. Plasma fibrin degradation products (FDP), D-dimer, and activated thromboplastin time (APTT) were measured, and the APTT ratio was calculated and standardized using data from control plasma. Disease activity was assessed at the same time in accordance with the Birmingham Vasculitis Activity Score (BVAS). Other laboratory data including kidney function parameters and serum C-reactive protein (CRP) were also examined, and analyzed using Spearman's rank correlation coefficient and stepwise multiple regression analysis to determine their relationship with coagulation parameters. A P value of <0.05 was taken to denote statistical significance.

Results: The mean value of FDP was elevated at 11.4 μg/ml (normal <9μg/ml), the mean D-dimer value was also elevated at 4.5 μg/ml (normal <1 μg/ml), and the mean APTT ratio was 1.15. In 44 patients, the APTT ratio was >1.01. Spearman's rank correlation coefficient analysis showed that FDP and D-dimer were positively associated with CRP, daily urinary protein excretion, and BVAS, and negatively correlated with the estimated glomerular filtration rate (eGFR), whereas the APTT ratio was positively associated with BVAS. Although stepwise multiple regression analysis revealed no factor that significantly affected FDP or D-dimer, BVAS was selected as a positive independent variable affecting the APTT ratio (rho=0.3401, p=0.01186). In addition, the mean BVAS was significantly higher in patients with an APTT ratio of ≥1.01 (n=44), compared to patients with an APTT ratio of ≤1.0 (n=11) (16.1 ± 5.4 versus 11.2±5.9, p=0.0114).

Conclusion: Prolongation of APTT reflects AAV disease activity and is considered to be a possible biomarker in affected patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) usually occurs in elderly patients, but only a few studies regarding clinical features in elderly onset AAV have been reported. So far, there was no report describing clinical features of elderly onset AAV patients in Japan. The purpose of this study is to compare clinical features and outcome between elderly onset (≥75 years old) and younger Japanese AAV patients (<75 years old).

Methods: AAV patients who met the criteria for granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomaosis with polyangiitis (EGPA) were included in this study. AAV patients initially treated at Fukushima Medical University Hospital (Fukushima, Japan) from April 2004 to March 2016 were retrospectively reviewed. These patients were divided into 2 groups: elderly, age ≥ 75 (N = 10) and younger, age < 75 (N = 26). We compared the following clinical features between the 2 groups: age at diagnosis, sex, Birmingham Vasculitis Activity Score (BVAS), clinical symptoms, laboratory data, therapy and outcome.

Results: Thirty six AAV patients (9 GPA, 24 MPA and 3 EGPA) were included in this study. General clinical features showed similar between the two groups except for female rates and body weight in the elderly, compared to younger patients (80% vs. 42.3% and 43.6 vs. 58.9kg, respectively). In clinical symptoms, elderly AAV patients showed significantly higher rates of kidney involvement than younger AAV (90% vs. 50%, p = 0.03). Laboratory data showed significantly lower RBC and ferritin levels in the elderly than younger AAV (241 vs. 438 ng/mL, p = 0.021). As to therapy, significantly lower PSL doses were administered in elderly AAV patients (34 vs. 45.3 mg/day, p = 0.038). Overall survival analysis (Kaplan-Meier curve) showed significantly lower survival in elderly AAV (58.3% vs. 96.2%, p = 0.008). Five MPA patients died; the number of patients and causes of death were as follows: 4 in elderly AAV (alveolar hemorrhage, renal failure, bacterial pneumonia and pneumocystis pneumonia), and 1 in younger AAV (alveolar hemorrhage). We further analyzed correlation between serum ferritin levels and clinical items. Serum ferritin levels positively correlated with serum ALT (rs 0.47, p = 0.013) and C3 levels (rs 0.4, p = 0.045) but not with Hb, RBC, Cr, age at diagnosis, and BVAS scores.

Conclusion: Elderly AAV patients showed similar clinical features except for increased rate of females, kidney manifestations and lighter body weight. Lower serum ferritin levels in the elderly may show milder inflammatory state than younger AAV at initial manifestation. Serum ferritin, an acute phase protein, are produced in inflammatory state (macrophage activation) and considered as a biomarker of disease activity in several

autoimmune diseases. Serum ferritin levels in this study positively correlated with ALT and C3 levels, which can be considered as a possible biomarker of disease activity in AAV patients. The causes of death in elderly AAV can be explained with vasculitis progression itself (especially MPA patients), infection, and treatment using lower PSL doses. Proper management and monitoring of adverse events should be performed in patients with elderly AAV.

Interest of Procalcitonin for the Follow-up of ANCA-Associated Vasculitis: Data from a Cohort of 99 Patients

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The prognosis of the ANCA associated vasculitis (AAV) has improved with the new immunosuppressive treatments but infectious complications remain frequent. Procalcitonin (PCT) is used for a quick diagnosis of bacterial infection. The aim of this study was to assess the diagnostic accuracy of PCT for the differential diagnoses of a bacterial infection from a vasculitis flare.

Methods: All patients with a granulomatosis with polyangiitis (GPA), a eosinophilic granulomatosis with polyangiitis (EGPA) or a microscopic polyangiitis (MPA) followed in our internal medicine department were included. PCT was determined by KRYPTOR assay (Thermo Fisher BRAHMS). All bacterial infections or flares up of the vasculitis were recorded. The diagnosis of flare up was based on increase of the BVAS or the BVAS WEG. Infections were confirmed by a positive microbial test or an evidence of infection on imaging. For the cases without evidence of positive microbial test, the diagnosis was established when two out of three practitioners of the unit gave the same opinion.

Results: The cohort consisted of 99 AAV (GPA = 73; EGPA = 21; MPA = 5). The follow up was of 5 years [1,8 ; 9,2]. 53 patients experienced 96 flare ups. Those were GPA in 70% of cases. 57 patients developed 74 bacterial infections. 11 were excluded because of a lack of proof. 27 had a positive microbial test. The value of

PCT was found for 55,4% of the registered events. PCT was higher in cases of bacterial infection than flare up (0,3 µg/l [0,11 ; 1,9] vs 0,08 µg/l [0,05 ; 0,13], p<0,0001). The same results were found for the bacterial infection with a proof by positive microbial test (0,55 µg/l [0,13 ; 3] vs 0,08 [0,05 ; 0,13], p=0,0021). For a threshold in 0,11µg/l, the sensibility and the specificity of the PCT were of 75% and 73,5% respectively. For a threshold of 48mg/l, the sensibility of the CRP was 71,4% and the specificity was 62,8%.

Conclusion: Five retrospective studies were carried on this subject. For two studies, the result seems to show an increase of procalcitonin during active vasculitis. But this result is inconstant and uncertain. Three studies found results similar to ours; during bacterial infections, the PCT increase more than during flares. Therefore, a modification of the discriminant threshold could allow the using of this marker to distinguish a flare up of infection. One study that used the same assay to determine the PCT, showed that a threshold of 0,1 µg/l was effective. The accuracy of PCT for the diagnosis of bacterial infection in patients with AAV is better than CRP. PCT seems to be useful to distinguish a flare up from a bacterial infection although PCT rises too in flare up.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-neutrophil cytoplasmic antibodies (ANCA) are a hallmark of a subset of small vasculitides collectively termed ANCA-associated vasculitis (AAV). With widespread availability of ANCA testing, interpreting positive results has become increasingly challenging. Here, we conducted a retrospective study to evaluate indications for testing and diagnosis of patients with positive ANCA.

Methods: We searched The Ottawa Hospital biochemistry database and reviewed the records of patients with positive ANCA (defined as elevated myeloperoxidase [MPO] or proteinase 3 [PR3] titers) tested between April 1, 2014 and March 31, 2015. Indications for ordering ANCA and final diagnosis were determined.

Results: 1889 ANCA tests were performed in the study year. 112 patients had at least 1 positive ANCA in the

study year and 169 total tests were positive. *Indications and diagnosis of patients with first-time positive ANCA testing:* 69 patients had first-time positive ANCA in the study year, with 35 (51%) anti-MPO positive, 31 (45%) anti-PR3 positive, and 3 (4%) doubly positive. The indications for testing were suspicion for AAV in 20 patients (29%), suspicion for unspecified vasculitis in 20 (29%), suspicion for an inflammatory condition in 25 (36%), and unknown in 4 (6%). Overall, 27 patients (39% of first time positives) were diagnosed with AAV corresponding to 80%, 40%, 12%, and 0% of patients tested for these indications, respectively. Thirty-one (45%) patients had other inflammatory or infectious etiologies (most commonly inflammatory bowel disease (n=5), lupus (n=4), and inflammatory eye diseases (n=3)), and non-inflammatory diagnoses accounted for the remaining 11 (16%). Patients with AAV had significantly higher mean maximum PR3 and MPO titers than those with non-AAV diagnoses (1138 vs. 145 and 323 vs. 119 respectively, $p<0.05$ by Student's t-test). *Indications and outcomes of repeat ANCA testing:* 68 patients had repeat ANCA testing in the study year, 43 of which were first tested prior to the study year. In total, 120 repeat ANCAs were performed; 84 of these were done on 44 patients with AAV and 36 on 24 patients with other diagnoses. Altogether, 80% of patients with AAV were re-tested in the study year (between 1 and 6 times, median 2 tests) vs. 42% of those with non-AAV conditions (between 1 and 5 times, median 1 test). Routine monitoring (as opposed to testing for changed clinical status) accounted for 72% of all repeat tests (n=86). Management was changed in response to serial ANCA testing in 11 AAV patients, 10 of whom were tested at time of changed clinical status. Overall, management was changed in 9% of all patients with repeat ANCA, 34% of all re-tests performed for changed clinical status and 1% of re-tests conducted routinely.

Conclusion: Despite widespread ANCA testing, few patients who start with low clinical suspicion for AAV and have positive ANCA are subsequently diagnosed with AAV. Serial ANCA testing is a common practice but is not supported by clear evidence, and few ANCA re-tests subsequently lead to change in management. Clarification of guidelines on effective ANCA ordering may limit unnecessary hospital laboratory costs and patient bother.

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Despite progress in induction and maintenance therapy in ANCA-associated vasculitis (AAV), relapses remain the main challenge in this disease with a rate above 50%. Few data exist on the clinical features of those relapses. Our goal was to investigate the severity of relapse events (RE) and their mode of presentation in patients with AAV.

Methods: Patients from a single center diagnosed with AAV – granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA) and microscopic polyangiitis (MPA) – between 1990 and 2014, and experiencing at least one relapse according to Hellmich and al (Ann Rheum Dis 2007; 66: 605-17), were retrospectively investigated. The different organ involvements were registered during each relapse. Presentation at onset and RE were compared for each patient. The BVAS was used to assess the activity of each relapse. Statistical analysis was performed using SAS v9.4. Chi-square test of McNemar and Student test were used on paired time series to compare the proportions, and to compare mean values between initial onset and relapses respectively.

Results: Ninety-nine patients with AAV were followed in our centre: 53 patients (30 male/23 female, mean age at diagnosis 58,2 years old [49-70]) experiencing at least one relapse during their follow-up were included – 38 GPA patients (72%), 3 MPA (6%), 12 EGPA (22%) – with a total of 96 RE. The rate of RE in our series was 53% with a median time of follow-up of 81.5 months (36-130). The mean time to first RE after initial onset was 25 months. The distribution of patients was as followed: thirty patients experienced one single RE, 14 had 2, 5 had 3, 2 had 4 and 2 had respectively 7 and 8. Fifty-five percent of relapse events had the same initial organ as initial onset. Compared to initial onset, some clinical manifestations were less present: general symptoms (30% vs 69%, $p<0.0001$) including fever and weight loss; ear-throat-nose (ETN) (53% vs 81%, $p<0.0001$) including sinusitis, chondritis and conductive hearing loss; lung involvement (59% vs 74%, $p=0.0071$), with nodules (28% vs 44%, $p=0.00071$), interstitial infiltrates (13% vs 32%, $p=0.004$), pleural effusion (3% vs 12%, $p=0.014$) and alveolar hemorrhage (7% vs 27%, p=0,0002); peripheral neuropathies (7% vs 18%) and cranial nerves involvement (5% vs 20%) (p=0,0007); joints with arthritis or arthralgia alone. Moreover, some organs involvement known as being associated with a worse prognosis at initial onset were significantly less present: kidney with hematuria, proteinuria and acute kidney injury; heart but mostly related to pericarditis (1% vs 22%, $p<0.0001$), myocarditis being rare (2% vs 3%). Skin, eye and bowel manifestations were not significantly less involved during relapse events, as well as nasal crusting and ulcers, and bloody nasal discharge. The mean BVAS at initial onset was 9,47 (6-11) and 5,09 (3-6) at relapse ($p<0,0001$). Among the 96 relapse events, 44 (45.8%) had a new organ involvement compared to initial onset. None of these new manifestations were life-threatening.

Conclusion: Our study suggests that global activity of RE in AAV patients is significantly lower than on initial onset. Fewer organs seem to be involved in relapses, as shown by the decrease of the BVAS between diagnosis of the AAV and the RE. This probably reflects the effect of the follow-up visits. RE turn out to begin with the same manifestations as initial onset in most of cases which could facilitate early recognition of relapses.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-neutrophil cytoplasmic antibody associated vasculitis (AAV) are a group of disorders predominantly affecting older patients and frequently presenting with acute kidney injury. Despite the improvements made in treating these disorders, appropriate treatment strategies in the very elderly (above the age of 80) remain undefined, as the majority of clinical trials have excluded this age group and therefore it is still unclear whether the benefits of immunosuppression outweigh the risks.

Methods: We retrospectively examined 31 cases who presented with AAV and acute kidney injury in individuals aged >80 between 2006 to 2015 with a mean follow up of 39 months

Results: 32% were PR3 positive, 58% MPO positive and 10% negative. Mean creatinine at presentation was 367 mmol/L and 48% required acute dialysis on presentation. 68% of patients were treated with Cyclophosphamide as induction therapy while 16% received Azathioprine and steroids. Infection was documented in 33% of patients. Survival rate at one year was 76% and the incidence of end-stage kidney disease was 52%.

Number	31
Age	83 ± 2.7
Female	66.7%
Ethnicity: White Asians	94% 6%
Mean creatinine at presentation (µmol/l)	367
Dialysis at presentation	48%
Plasma exchange	22%
Induction Cyclophosphamide and steroids Azathioprine and steroids None	68% 16% 16%
Maintenance: Azathioprine and Steroids Mycophenolate Mofetil and steroids Steroids only None	32% 12% 26% 30%
Patient survival 1 year	76%
Renal Survival 1 year	52%

Conclusion: The results of this study show that a significant percentage of the very elderly patients can benefit from immunosuppresion therapy for AAV, despite the higher risks of adverse effects from these medications. However the precise details of what to give and for how long remains unclear.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCAs are used as diagnostic markers in patients with autoimmune vasculitis such as Granulomatosis with polyangitis (GPA), Microscopic polyangitis (MPA), and Eosinophilic granulomatosis with polyangitis (EGPA). Technique in laboratory testing for ANCAs differs among different centers. The purpose of this study is to compare two different techniques of IIF with enzyme immunoassay (EIA) and disease phenotype, specifically GPA.

Methods: Patient charts from a single tertiary medical center between August 2014 to August 2015 were retrospectively reviewed to identify occurrences in which two different methods of ANCA's by IIF (method A and B) were completed as well as ANCA by EIA on the same day. Method A: IIF first screens samples on two slides, one with ethanol-fixed human neutrophils, and one with formalin-fixed human neutrophils, before determining the titer by ethanol fixation. Method B first performs automated EIA testing for MPO and PR3 antibodies (Abs) with a reflex to IIF if the MPO or PR3 Abs is equivocal or positive (> 0.4 U). Detection of ANCA is performed by IIF using slides coated with ethanol-fixed human neutrophils. Disease phenotype correlations were limited to GPA since c-ANCA and PR3 Abs are relatively specific for this disease. Correlations were determined by phi coefficient (Φ) and measures of significance determined by Fisher's Exact Test.

Results: Fifty two patients had ANCA IIF testing done by two different established methods, A and B, on the same day. The correlation of c-ANCA by Method A IIF to PR3 Abs by EIA resulted in Φ of 0.609 ($p = <0.0001$) compared to Φ of 0.7025 ($p<0.0001$) when comparing Method B. The correlation of p-ANCA by method A IIF to MPO Abs by EIA resulted in Φ of 0.3578 ($p=0.0166$) compared to Φ of 0.4548 ($p=0.0019$) when comparing Method B. Correlation of c-ANCA by method A IIF to GPA disease phenotype resulted in a Φ of 0.2807 ($p= 0.0945$) compared with Φ of 0.3933 ($p= 0.0101$) when comparing Method B.

Conclusion: When comparing two different ANCA testing methods, Method B, in which IIF is done only after a positive EIA and only with ethanol fixation, appears to have a stronger concordance with PR3 and MPO Abs as determined by EIA as well as disease phenotype. Limitations of this study included the small number of patients, and the technician dependent nature of IIF technique. A follow up study may consider using a larger number of patients.

Session Date: Monday, November 14, 2016
Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Factors associated with cumulative glucocorticoid exposure in granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) have not previously been described. We examined the association between baseline characteristics and cumulative glucocorticoid dose in the Rituximab in ANCA-Associated Vasculitis (RAVE) trial comparing rituximab (RTX) with cyclophosphamide (CYC) followed by azathioprine for severe ANCA-associated vasculitis.

Methods: All patients received at least one 1000 mg dose of intravenous methylprednisolone prior to the initiation of prednisone at 1 mg/kg. Prednisone was reduced to 40 mg/day by 1 month and tapered off by month 6 but could be restarted or increased in response to persistent or increased disease activity. For this analysis, cumulative glucocorticoid doses were calculated monthly during induction (months 0-6) and maintenance (months 7-18). Prednisone and intravenous methylprednisolone were considered separately and when combined. The associations between baseline characteristics and cumulative dose were examined using generalized estimating equations to estimate mean differences and 95% confidence intervals (CI) over time after adjusting for potential confounders. Logistic regression was used to estimate odds ratios for achievement of glucocorticoid-free maintenance, defined as the absence of any glucocorticoid received from month 6 until study discontinuation.

Results: Mean ± SD cumulative prednisone dose was 3458 ± 806 mg at month 6 and 3771 ± 1044 mg at month 18. 89 patients (45%) achieved glucocorticoid-free maintenance. During the maintenance phase, relapsing disease (adjusted mean difference +324 mg over 12 months versus new diagnosis, 95% CI 56 to 592) and overweight or obese body mass index (BMI) (+397 mg, 95% CI 137 to 659) were associated with increased cumulative prednisone dose. In multivariate logistic regression, anti-proteinase 3 (PR3) antibody positivity (OR 0.50, 95% CI 0.26 to 0.97) was associated with decreased odds for achievement of glucocorticoid-free maintenance. Treatment with RTX was associated with decreased cumulative prednisone dose in comparison with CYC during induction (adjusted mean difference -251 mg over 6 months, 95% CI -411 to -91) but not during maintenance (+107 mg over 12 months, 95% CI -189 to +402).

Conclusion: In this clinical trial of GPA or MPA with protocol-defined glucocorticoid tapering, relapsing disease and increased BMI were associated with increased glucocorticoid exposure following induction of remission. PR3 positivity was associated with decreased likelihood of achieving glucocorticoid-free remission. Induction treatment with RTX was associated with a minimal mean decrease in prednisone exposure during induction only. These findings may allow for the prospective identification of patients with GPA or MPA at increased risk for chronic glucocorticoid exposure and toxicity.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The frequency of CNS involvement in granulomatosis with polyangiitis (GPA) is uncommon (4-18%). Among them, pachymeningitis (PM) has been reported in 0.6-8%. Improvement of these complications has been reported with conventional therapy (CS + CYC), and recently with rituximab, but many patients have recurrences. Data on related factors, outcome and quality of life is scarce. We preliminarily describe CNS involvement as investigated with MRI, PM presence in symptomatic and asymptomatic patients with GPA, and its implications for quality of life.

Methods: Forty consecutive GPA patients fullfiling the ACR criteria and/or the 2012 Chapel Hill Consensus Conference definition were studied. After informed consent, gadolinium-enhanced brain MRI in search of PM, irrespective of CNS symptoms, was done. The presence of diffuse or focal meningeal enhancement was necessary for PM diagnosis. Main subgroups for analysis were formed according to two main criteria: PM on MRI, and CNS symptoms presence or absence. They were compared regarding clinical, serological, neuroimaging and treatment-related findings. Functional status was assessed with the Short Form 36 (SF-36) health survey and Karnofsky Performance Scale Index. Univariate analysis was used to establish proportions with means ± SD and medians calculated; bivariate analysis was used to compare groups, Student's t test for continuous variables and X^2 test with Yates correction for categorical variables. Significance was established when $p<0.05$.

Results: Ten patients had generalised disease, the rest localised. Age range was 8-72 years old. Main differences regarding PM and CNS symptomatology as related to MRI findings are shown in the table.

Significant differences according to presence of CNS symptoms			
Variable	Symptomatic (n-20)	Asymptomatic (n-20)	p value
Cranial nerve palsy	5/20	0/20	<0.009
PM	13/20	6/20	0.05
Severely active disease *	9/20	0/20	0.001
Remission (at time of MRI)	3/20	17/20	0.001
Visual analogue scale (VAS) ♯	3.61 ± 2.3	0.6 ± 1.2	<0.009
Significant differences according to PM in MRI			
Variable	PM present (n-19)	PM absent (n-21)	p value
Cranial nerve palsy	5/19	0/21	0.02
Myalgias	4/19	0/21	0.04
Severely active disease	9/19	0/21	<0.009
Remission	4/19	15/21	0.003
BVAS-WG ♯	2.7 ± 2.7	0.1 ± 0.5	0.002
SF-36 §	21.5 (0-65)	50 (43-60)	0.001
Subglottic stenosis (SGS)	3/19	14/21	0.002

* Defined as that compromising life or vital organ function; ♯ mean values ± SD; § median values (intervals)

Conclusion: We found PM in 19/40 cases (47.5%) and irrespective of symptoms it was present in 1/3 of cases. Its cause (active disease or chronic inflammation, possibly due to fibrosis) is difficult to discern. Therefore, optimal therapeutic measures are unknown. Although the majority of patients had localised -predominant upper airway and ocular- disease, SGS had developed in a minority of patients with PM. This may suggest that operative mechanisms differ in both locations, and although scarring has been considered to play a role in PM in GPA, it might not be exclusive. Certain features relate straightforwardly to better health status, but in those asymptomatic PM patients, we found lower SF-36 scores, implying impaired quality of life. That PM occurs frequently in localised disease does not mean less severity than generalised malady. Although limited by the small sample size, CNS involvement detection in GPA, even in absence of symptoms, could be useful as impairment in quality of life may occur. Further research on this issue is warranted, with proper placement of early neuroimaging.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A few isolated case reports of precapillary pulmonary hypertension (PH) in ANCA-associated vasculitides, mostly granulomatosis with polyangiitis (GPA), have been published. The characteristics and outcomes of PH–GPA patients entered in the FVSG database were analyzed.

Methods: GPA patients with precapillary PH were included from this series. GPA diagnosis was based on ACR classification criteria or the revised Chapel Hill Conference Consensus (CHCC) nomenclature. Patients with connective tissue disease or undergoing hemodialysis were excluded. Chronic thromboembolic pulmonary hypertension required appropriate investigations to be excluded. Precapillary PH was defined as mean pulmonary arterial pressure (mPAP) ≥25 mm Hg at rest, with mean pulmonary capillary wedge pressure (PCWP) ≤15 mm Hg, measured during right heart catheterization (RHC).

Results: Among the 1065 GPA patients entered in the database, 3 male (0.3%) had precapillary PH; mean age, 43.1 years. All had systemic GPA according to the revised CHCC nomenclature and ACR criteria. Precapillary PH was diagnosed 4 years before GPA in 1 patient and after an average of 1.8 years for the others. All patients had NYHA III dyspnea and confirmed precapillary PH at RHC. In 1 patient, lung biopsy showed histological evidence of granulomatous vasculitis, and arteriolar and venous involvement; a ventilation–perfusion scan detected multiple perfusion defects consistent with thromboembolic disease that was ruled out by pulmonary angiography showing poor peripheral perfusion with a typical “dead tree” aspect, likely due to small-vessel vasculitis. At PH diagnosis, in combination with high-dose glucocorticoids, cyclophosphamide or rituximab was continued in 1 patient each. PH treatment was prescribed only in the patient with preexisting PH who received continuous epoprostenol infusions. Repeat RHC showed significant clinical and hemodynamic improvement in the 3 patients; their mean mPAP decreased from 51.6 (range, 41–70) to 33.0 mm Hg (range, 29–42). The patient with preexisting PH died of sepsis during GPA induction therapy. After treatment, in the patient with multiple ventilation–perfusion-scan defects, no change was observed. With median follow-up post-PH diagnosis of 4.2 years, the 2 other patients are alive, with NYHA class II dyspnea and in complete GPA remission, with median daily prednisone dose at 2.5 mg.

Conclusion: The data from this first series indicated that GPA can be a rare cause of precapillary PH. Lung small-vessel vasculitis is likely to be causative. GPA-caused precapillary PH may respond to combined high dose glucocorticoids and cyclophosphamide or rituximab.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophages may present two main phenotypes indicated as M1 and M2 under different stimuli. M1- and M2-macrophages have divergent functions that range from enhancement of inflammation for M1- to tissue repair and remodeling for M2-macrophages. The balance between tissue M1- or M2-macrophages is variable in different diseases, depending on the pathophysiological process. Granulamatosis with polyangiitis (GPA) is an antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis that mainly affects the respiratory tract and kidneys. Necrotizing granulomatous inflammation is the hallmark of airways involvement in GPA. The objective of this study is to evaluate the distribution of M1- and M2-macrophage phenotypes in biopsies from the airways of patients with active GPA and to analyze their associations with T- and B cells in those biopsies as well as with nasal carriage of *Staphylococcus aureus*, disease parameters and therapy.

Methods: Thirty-five consecutive patients with GPA and active disease involving the airways who underwent a biopsy from the respiratory tract were included in this cross-sectional study. Immunohistochemistry was performed to assess the distribution of macrophages, T- and B cells using the markers CD68, CD3 and CD20, respectively. CD86 was used as M1 marker and CD163 as M2 marker. All slides were scanned and the expression of all markers was quantified in percentage by the positive pixel count algorithm.

Results are expressed as median percentage and interquartile range or as mean percentage and standard deviation. At the time of the biopsy, GPA patients were assessed for nasal carriage of *Staphylococcus aureus* and treatment. Results: Percentages of macrophages and T cells were significantly higher than that of B cells in the respiratory tract from GPA patients [8.9% (6.4-17.4) vs. 7.4% (5.2-12.4) vs. 4.3 (2.4-8.4); $p < 0.0001$]. M2 macrophages were more frequent than M1 macrophages [18.2% (9.2-30.5) vs. 32.4 (21.3-41.9); $p = 0.0007$]. Percentages of T cells were higher in nose biopsies than in biopsies from other sites [8.3% (6.0-15.1) vs. 5.2 (3.0-6.5); $p = 0.021$] whereas macrophages were more predominant in biopsy sites other than the nose [20.7% (7.2-29.6) vs. 8.4% (6.3-13.6) $p = 0.039$]. Carriage of *Staphylococcus aureus* was associated with higher T cell scores [10.5% (6.6-15.4) vs. 5.9% (4.8-7.4) $p = 0.014$]. The frequency of macrophages, especially M2 macrophages, was higher in GPA patients treated with immunosuppressive agents [44.4% ± 18.3 vs. 29.8% ± 13.2; $p = 0.010$), whereas daily prednisolone dose was positively correlated with all macrophage markers as follows: CD68 (rho = 0.858; $p = 0.001$), CD86 (rho = 0.753; $p = 0.012$) and CD163 (rho = 0.759; $p = 0.011$). However, in multivariate analysis no independent associations were found between disease parameters or

therapy and macrophages or T cells.

Conclusion: In GPA patients, M2 is the predominant macrophage phenotype in the respiratory tract. Although some associations were observed between macrophages and T cells with therapy and nasal carriage of *Staphylococcus aureus*, they were not independent from other factors in multivariate analysis.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The cutaneous manifestations of anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV), including granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA), are varied and have not been well characterized. This study aimed to describe the spectrum and extent of dermatologic features of AAV.

Methods: A large, cross-sectional study describing, comparing, and contrasting the cutaneous manifestations of GPA, MPA, and EGPA was performed using data from the Diagnostic and Classification Criteria in Vasculitis (DCVAS) study. The DCVAS study is a large, international, collaborative effort to collect comprehensive clinical data on a large cohort of patients with vasculitis with a goal of developing new classification and diagnostic criteria.

Results: Data from 1274 patients with AAV from 130 centers worldwide were available for this study: 702 (55%) with GPA, 331 (26%) with MPA, and 241 (19%) with EGPA. Cutaneous findings were common in patients with AAV (Table 1), affecting 239 (34%) patients with GPA, 97 (29%) patients with MPA, and 113 (47%) patients with EGPA. The most frequent cutaneous manifestations in each type of AAV were as follows: GPA: petechiae or purpura (N=113; 16%), painful skin lesions of any type (N=66; 9.4%), and maculopapular rash (N=47; 6.7%); MPA: petechiae or purpura (N=33; 10%), livedo reticularis or racemosa (N=25; 7.6%), and maculopapular rash (N=20; 6.0%); and EGPA: petechiae or purpura (N=50; 21%), maculopapular rash (N=36;

15%), pruritus (N=30; 13%), and urticaria (N=19; 7.9%).

Conclusion: This is the largest study of cutaneous manifestations of AAV ever conducted. Utilizing data collected comprehensively via a standard protocol, it demonstrates that skin lesions are quite common and varied in GPA, MPA, and EGPA. Future analyses will focus on examining the association of specific cutaneous manifestations of AAV with other organ system involvement and laboratory findings. Table 1. Hypertrophic Pachymeningitis in a Population with Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis: A Retrospective Study in a Single Japanese Institution

Yasuhiro Shimojima, Dai Kishida, Akiyo Hineno, Masahide Yazaki, Yoshiki Sekijima and Shu-ichi Ikeda, Department of Medicine (Neurology and Rheumatology), Shinshu University School of Medicine, Matsumoto, Japan

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hypertrophic pachymeningitis (HP) is an inflammatory disorder causing focal and diffuse thickening of the dura mater. It is realized that anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) contributes to the development of HP, whereas the epidemiologic and clinical characteristics of patients with HP in the whole population of AAV are still uncertain. In this study, we demonstrated the characteristics of patients with HP compared with those of patients without HP in AAV.

Methods: We retrospectively investigated the clinical records of 39 Japanese patients with AAV (18 men and 21 women). Among them, patients with associated HP were detected. To determine the characteristics of HP in AAV, the epidemiological and clinical data from patients with HP were statistically compared with those from patients without HP.

Results: Of 39 patients with AAV, 7 (17.9%) had associated HP. All patients with HP were classified as having granulomatosis with polyangiitis (GPA), whereas only 5 of 32 patients without HP were diagnosed as having GPA ($P < 0.0001$) (Table 1). The frequencies of myeloperoxidase (MPO)-ANCA and proteinase 3-ANCA positivity in patients with HP were equivalent, while MPO-ANCA positivity was obviously dominant in patients without HP. HP occurred as the initial clinical episode of AAV in 3 patients (7.7% of all AAV). Frequent significant characteristics of patients with HP were headache, cranial neuropathy, and paranasal involvement ($P < 0.05$), and histopathological findings from paranasal involvement were useful for the diagnosis of GPA in some patients with HP. Combination therapy of corticosteroid and an immunosuppressant, such as methotrexate, cyclophosphamide, or rituximab, was effective for achieving remission and improving radiographic findings of HP.

Conclusion: To our knowledge, this is the first study that has described the epidemiological analyses of HP in the whole population of AAV. We conclude that the epidemiological features of AAV patients with HP are different from those of patients without HP. The geographical studies of AAV indicated that the predominance of microscopic polyangiitis and MPO-ANCA positivity as epidemiologically specific to Japan, whereas GPA and PR3-ANCA positivity are dominant in European countries. However, the epidemiology of patients with HP is similar to that of patients in European countries. In addition, HP impacts the diagnosis of AAV because it could be an initial clinical sign of disease as well as associated with frequent existence of granulomatous lesions in the respiratory tract.

Clinical Characteristics of Inflammatory Eye Disease in Patients with Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis: A Retrospective Cohort Study

Background/Purpose: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a systemic small vessel vasculitis characterized by presence of cytoplasmic-ANCA or perinuclear-ANCA, that can virtually affect any organ system. Inflammatory eye disease (IED) is a well-recognized manifestation of AAV though the data on its clinical characteristics and outcome are limited.

Methods: Medical records of 501 patients with AAV seen at our institution were reviewed. Data on demographics, ophthalmologic manifestation, laboratory investigations, treatment (ocular and systemic), disease activity, systemic organ involvement, and outcomes were abstracted. Descriptive statistics were used to summarize the data.

Results: 77 patients (mean age 50.1 years; 52% female; 96% Caucasian) with median follow-up of 6.1 years had IED. Proteinase-3 (PR-3) serology was positive in 39 patients (51%); myeloperoxidase (MPO) serology was positive in 24 patients (31%) and ANCA serology was negative in 14 patients (28%). IED was one of the initial manifestations leading to diagnosis of AAV in the majority of patients (68%) with median time from IED to diagnosis of AAV of 1.6 months. IED occurred after the diagnosis of AAV in about one-third of patients with median time from diagnosis of AAV to IED of 41.2 months. Mean Birmingham Vasculitis Activity Score (BVAS) during active IED was 6.0. Mean erythrocyte sedimentation rate during active IED was 41.8 mm/hr. Episcleritis was the most common type of IED (17%) followed by scleritis (14%), orbital inflammation (orbital pseudotumor/orbital myositis) (12%), cranial nerve III, IV or VI palsy (12%), conjunctivitis (9%), optic neuritis

(8%), amaurosis fugax (8%), uveitis (5%), lacrimal duct stenosis (5%), peripheral ulcerative keratitis (4%), retinal vasculitis (4%) and dacryoadenitis (4%). The most common manifestation of IED was redness (49%) followed by eye pain (35%), visual acuity loss (27%; gradual visual acuity loss 17% and sudden visual acuity loss 10%), diplopia (19%), and photophobia (13%). IED occurred bilaterally in 52% of patients. Oral glucocorticoids were used to treat IED in the majority of patients (91%) while topical glucocorticoids were used in 31%. Cyclophosphamide was the most frequently used immunosuppressive agent (53%) followed by methotrexate (34%), rituximab (26%), azathioprine (26%), mycophenolate (9%) and intra-orbital glucocorticoid injection (6%) in patients with orbital pseudotumor/orbital myositis. Complete remission was achieved in 94% of patients. However, relapse was common (18%). The median number of relapses was 1 during the period of observation.

Conclusion: IED occurs in about 15% of patients with AAV. Episcleritis, scleritis, orbital inflammation and cranial nerve palsy were the most common subtypes of IED. Inflammation from IED responded well to treatment although relapse was common.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA, formerly called Churg-Strauss syndrome) belongs to ANCA-associated vasculitis and is characterized by late onset asthma, blood and tissue eosinophilia and systemic symptoms. Studies on pathophysiology of EGPA are scarce, explaining the lack of specific targeted therapy. In the present study, we analyzed the implication of innate and adaptive immunity in

EGPA through a systematic phenotyping of T and B cells, type 2 innate lymphoid cell (ILC2) as well as cytokine profile in active and remission EGPA.

Methods: We included 15 patients with active EGPA, 8 patients in remission and 20 healthy controls (HC). B and T cells and type 2 innate lymphoid cells (ILC2) in peripheral blood were studied using flow cytometry. Cytokines and chemokines were assessed in sera from active EGPA (n=20), remission EGPA (n=25) and healthy controls (n=35), using Luminex® and ELISA.

Results: Compared to HC, overall EGPA patients had a significant increase of Th2 polarized (IL-4^+) $CD4^+$ T cells (3.6±3.8% *vs.* 1.1±1.3%, p=0.002) and a trend for increase of Th9 (IL-9^+) cells (0.81±0.86% *vs.* 0.40±0.52%, p=0.1) and Th17 (IL-17^+) $CD4^+$ T cells (1.5±1.1% *vs.*0.9±0.5%, p=0.056), no differences were observed between active and remission patients in these groups. T follicular helpers (TFH) were increased in patients (7.3±3.1% vs 4.5±1.5%, p=0.001) whereas regulatory CD4 T cells were decreased (0.75±0.4% vs 1.5±0.8%, p=0.02). B cells from EGPA patients displayed an activated profile compared to HC with a significant increase of CD95 expression (56±13% vs 27±2%, p<0.0001), CD86 (28±14% vs 12±12%, p<0.001) and CD69 (11±11% vs 1.9±1.8%, p<0.0001). B cells inhibition markers expression, i.e. CD72 and CD22, was lower in EGPA than in controls (60±23% vs 81±8% for CD72, p<0.01, and 74±22% vs 87±9% for CD22, p<0.01). Circulating ILC2 were significantly decreased in EGPA patients compared to controls (317±336 vs 563±284 cells/ml, p<0.05) and in active EGPA compared to remission (143±53 vs 491±415 cells/ml, p<0.05). Regarding serum cytokine profile, levels of soluble ST2 (469 ± 268 vs 288±102 pg/ml, p=0.002), IL-25 (302±405 vs 107±99 pg/ml, p=0.04), TSLP (5.6±5.9 vs 1.4±1.3 pg/ml, p=0.001) and TARC/CCL17 (1143±710 vs 709±287 pg/ml, p=0.05) were increased in EGPA compared to controls. Th2 cytokines were also more elevated in EGPA than in HC, including IL-5 (2.8±6 vs 0.53±0.11 pg/ml, p<0.0001) and IL-9 (1.6±2 vs 0.58±0.2 pg/ml, p=0.03). Th1-related cytokine IFN-γ was also elevated (2.1±0.8 vs 1.6±0.2 pg/ml, p=0.02) as well as Th17-related cytokine IL-17 (10.2±22 vs 1.3±0.4 pg/ml, p=0.03). In contrast, no differences were noted for serum IL-33.

Conclusion: EGPA patients are characterized by a Th2 polarization of T cell response and a trend for Th9 and Th17 polarization in peripheral blood, an activation of B cells and a dramatic decrease of blood ILC2 during active disease. This decrease could be explained by a recruitment of these cells within involved tissues. Increase of IL-25, TSLP and TARC as well as Th2-related cytokines in serum could illustrate the cross-talk between innate and adaptive immunity in this disease, in which ILC2 could play a central role.

Bronchiectasis Are Highly Prevalent in Anti-MPO ANCA-Associated Vasculitis and Associate with a Distinct Disease Phenotype

Antoine Néel[1], Alexandra Espitia[1], Pierre Paul Arrigoni[2], Christelle Volteau[3], Agathe Masseau[1], Marie Rimbert[4], Christian Agard[1], Fadi Fakhouri[5], Renan Liberge[2] and Mohamed Hamidou[6], [1]Internal Medicine Department, Nantes University Hospital, Nantes, France, [2]Radiology Department, Nantes University Hospital, Nantes, France, [3]Clinical Research Department, Nantes University Hospital, Nantes, France, [4]Immunology

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

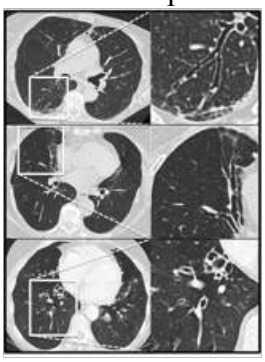
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the prevalence of bronchiectasis in a western cohort of ANCA positive GPA or MPA and its correlations with disease phenotype and outcome.

Methods: Retrospective study of AAV patients followed at Nantes University Hospital (2005-2015). Clinical, biological and follow-up data were collected through chart review. Chest High-Resolution CTs were interpreted by 2 experienced radiologists blinded to the clinical data, using Feischner Society criteria.

Results: Fifty eight patients were included, 30 patients had MPA (51,7%) and 28 patients had GPA (48,3%). Anti-MPO-ANCA and anti-PR3-ANCA were present in 39 (67,2%) had 19 (32,8%) patients, respectively. Overall, bronchiectasis were found in 22 patients (37,9%), all of whom had anti-MPO ANCA. Representative images from 3 patients are shown in Figure 1. In multivariate analysis, bronchiectasis were independently associated with anti-MPO-ANCA, female gender and age at AAV diagnosis. Further, anti-MPO ANCA patients with bronchiectasis had more frequent peripheral nerve involvement (54,5 vs 17,6%, p=0.019) and less frequent renal involvement than those without bronchiectasis (40,9% vs 82,3%, p=0,009). Disease course, survival and risk of severe pulmonary infection was similar in patients with/without bronchiectasis on chest CT.



Conclusion: Bronchiectasis is an underestimated pre-existing respiratory condition in Caucasian patients with anti-MPO AAV. This subset of patients exhibits a distinct phenotype but similar outcomes. Further studies are needed to confirm our findings and enlighten the clinical implications of this association. Whether the respiratory tract could be the site of initiation of anti-MPO auto-immunity remains to be investigated.

Immunologic, Clinical and Demographic Correlates in 51 Cocaine Users with Serum Anti-Neutrophil Cytoplasmic Antibodies

Grant Hughes[1] and **Meredith Barnes**[2], [1]University of Washington, Seattle, WA, [2]Medicine, University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Exposure to illicit cocaine and its frequent adulterant, levamisole, is associated with the development of serum anti-neutrophil cytoplasmic autoantibodies (ANCA) and a variety of hematologic, renal and skin abnormalities (e.g., thrombotic purpura). The mechanisms of cocaine/levamisole-associated autoimmunity (CLAA) are unknown but may involve drug-induced neutrophil activation. Most reports of CLAA have examined small cohorts (< 20 subjects) or have focused on select clinical abnormalities. In order to gain a fuller picture of CLAA and generate new hypotheses regarding pathogenesis, we analyzed a cohort of 51 CLAA subjects identified in a large, academic healthcare system between 2000 and 2015.

Methods: We queried an electronic database and rheumatology referral records for individuals with positive ANCA testing results (ANCA+) and evidence of cocaine exposure by urine toxicology (cocaine+). Individuals were excluded if they had biopsy-proven ANCA-associated vasculitis. Clinical and immunologic parameters were extracted from the electronic medical record. We compared rates of certain parameters with rates within the cocaine+ (n = 6,233) or ANCA+ (n = 310) populations in a de-identified clinical data repository (DCDR) using univariate (Chi square, Fisher's exact) and multivariate (logistic regression) analyses.

Results: Hematologic abnormalities were almost universal (94.1%), with anemia (84.3%), leukopenia (64.7%) and neutropenia (47.1%) the most frequently reported. Renal (74.5%), skin (58.8%) and musculoskeletal (37.3%) abnormalities were also common. When compared to the cocaine+ population, the CLAA group showed similar estimated age at first positive cocaine result (46.6 vs. 47.7 years), but it was more female (56.9% vs. 38.8%, $p = 0.0016$) and less African-American (19.6% vs. 37.5%, $p = 0.0130$). Among those tested, the CLAA group showed higher rates of anti-phospholipid Abs (ACLAs) (69% vs. 29.1%, $p < 0.0001$) and lupus inhibitor (LI) (80% vs. 34.9%, $p = 0.0002$) but not ANA (22.4% vs. 19.4%) or active HCV infection (46% vs. 52.7%). ANCA in CLAA subjects were generally high titer (often > 1:2048) and of P-ANCA pattern (60.8%). Compared to the ANCA+ population, the CLAA population had significantly higher rates of MPO/PR3 double-positivity (31.4% vs. 2.6%, $p < 0.0001$). Finally, multivariate logistic regression analysis identified a significant association in the CLAA population between anti-phospholipid Abs and skin abnormalities (OR 7.1, 95%CI 1.3 – 49.2).

Conclusion: CLAA subjects showed a variety of previously reported hematologic, skin and MSK abnormalities. However, results from our demographic analysis suggest that, in cocaine users, the development of ANCA and/or clinical abnormalities prompting ANCA testing are influenced by sex and race. Moreover, exposure to cocaine in this population may also lead to development of LI and APLAs, which could contribute to skin abnormalities such as thrombotic purpura. Finally, high-titer P-ANCA with double-positivity may help clinicians differentiate CLAA from other forms of ANCA-associated disease.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To establish EGPA/Churg Strauss inflammatory heart disease prevalence and develop an algorithm for heart disease screening in EGPA patients.

Methods: An audit of all EGPA patients attending Addenbrooke's was performed. Clinical presentation, cardiac studies, disease outcome measures and clinical course was noted. Values are given as percentages and median (IQR). Mann Whitney U was used.

Results: 131 EGPA patients (47% men) were followed of whom 96 (73%) underwent cardiac evaluation. Median age was 50 years (38 - 58), 37% were ANCA +ve and asthma preceded diagnosis in most by a median of 97 months (36 - 240). 41 of those screened (43%) were symptomatic for heart disease with: dyspnoea (47%), chest pain (29%), limb oedema (24%), palpitations (13%), syncope (4%), abdominal discomfort (2%) and shock (2%). 27/96 (28%) patients had EGPA-related heart disease in 20 of whom this was present at EGPA diagnosis, 5 developed it at time of EGPA flare and it preceeded EGPA diagnosis in two,. 59% (24) of those who were symptomatic and 5% (3) of those who did not have cardiac symptoms had EGPA heart disease. 15% patients had myocarditis, 6% pericarditis, 5% myopericarditis and 1 coronary vasospasm. One patient with pericarditis also had periaortitis. Cardiac abnormalities of any sort were found in 52% patients. Patients who had EGPA heart disease were younger (46 [28 - 52] V 50 [41 - 59]; p = 0.04), more frequently ANCA-negative (85% V 69%; NS), had higher BVAS scores (3 [1 - 4] V 1 [0.75 - 2]; p = 0.005), had higher eosinophil counts (5.60 [1.44 - 11,57] V 1.60 [0.75 - 4.00] x10^9/L; p = 0.029) and higher CRP levels (52 [30 - 100] V 15 [5 - 81] mg/L; p = 0.017). Troponin I was determined in 33 patients and was elevated in 75% patients with EGPA inflammatory heart disease V 14% without (p = 0.001). Table 1 shows the percentage of cardiac abnormalities.

Conclusion: Twenty seven percent of EGPA patients have heart disease with 60% of those symptomatic for heart disease and 5% of those asymptomatic for it being affected. Our multiple comparisons suggest that EGPA patients with inflammatory heart disease have more aggressive systemic disease associated with higher markers of inflammation. All EGPA patients should have ECG, troponin and echocardiography as screening investigations with progression to cMRI for patients with heightened suspicion for cardiac disease. Table 1: Incidence of heart abnormalities in EGPA patients symptomatic and asymptomatic for heart disease. (n=100; 4 patients originally screened in the asymptomatic group later became symptomatic and were again tested)

	Evaluated patients (n=100)	Asymptomatic patients (n=55)	Symptomatic patients (n=45)	p

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV) - granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) have heterogenous clinic and biologic phenotypes. Sporadic reports indicate that some AAV patients may have other autoimmune diseases but the frequency of the association is unknown. Our purpose was to assess the frequency of other autoimmune diseases or autoantibodies in a well-defined cohort of AAV patients.

Methods: Retrospective survey of a cohort of patients regularly controlled at outpatient facility of an Autoimmune Disease Department in a 5-year period (2011-2016). Clinical and immunologic data were retrieved from electronic records. All patients were diagnosed and treated by the authors.

Results: We included 110 AAV patients – 36 (32.7%) GPA, 45 (40.9%) MPA and 29 (26.4%) EGPA. Manifestations with higher prevalence were: chest, ear-nose-throat (ENT), mucous membranes/eyes in GPA; renal in MPA, and chest, ENT, abdominal in EGPA. Regarding to ANCA specificity – 23 (20.9%) against proteinase 3 (PR3)-ANCA, 68 (61.8%) against myeloperoxidase (MPO)-ANCA and 19 (17.3%) were ANCA negative. An additional autoimmune disease (usually organ-specific) was identified in 52 patients (47.3%), 17 (32.7%) had more than one. Associated autoimmune diseases included hypothyroidism (19,17.3%), vitamin B12 deficiency (16,13.8%), Sjögren syndrome (8,7.3%), interstitial lung disease (4,3.6%), hyperthyroidism (3,2.7%), primary biliar cholangitis (3,2.7%), celiac disease (3,2.7%), autoimmune hepatitis (2,1.8%), autoimmune thrombocytopenia (2,1.8%), myositis (2,1.8%), cryoglobulinemia (2,1.8%), anti-GBM disease (1,0.9%), and vitiligo (1,0.9%). Autoantibodies detected with higher prevalence were: ASMA (65,59.1%), ANAs (54,49.1%), anti-parietal cells (26,23.6%), anti-peroxidase (14,12.8%), anti-thyroglobulin (7,6.4%), anti-SSa/Ro (5,4.5%), anti-SSb/La (3,2.7%) and anti-dsDNA (2,1.8%). Prevalence of organ-specific autoimmune disease was higher in MPA (29,64.4%,p=0.001). Vitamin B12 deficiency was also more prevalent in MPA (25.6%,p=0.008) and in MPO-ANCA (19.1%,p=0.005). Sjögren syndrome was more prevalent in MPA (11.1%,p=0.022). Some autoantibodies were detected with higher prevalence in MPA – ANAs (68.9%,p<0.001), anti-parietal cells (31.1%,p=0.005), anti-thyroglobulin (13.3%,p=0.044), anti-SSa/Ro (8.9%,p=0.015), anti-SSb/La (4.4%,p=0.044), anti-DNAds (4.4%,p=0.003); and in anti MPO carriers - ANAs (55.9%,p=0.039), anti-SSa/Ro

(7.4%,p=0.010), anti-SSb/La (4.4%,p=0.020), anti-DNAds (2.9%,p=0.046).

Conclusion: A substantial percentage of AAV patients, particularly MPA and anti MPO carriers, have associated autoimmune diseases and autoantibodies. The limitations of our study (retrospective assessment and lack of comparator) do not allow accurate estimation of prevalence. The severity of AAV and difficulties in management, may lead to overlooking of associated autoimmune diseases which appear to be frequent. Associated autoimmune disease may contribute to additional burden in AAV patients. (Supported by SAF 2014 57708-R).

Session Time: 9:00AM-11:00AM

Title: Presentation and Clinical Features of ANCA-associated Vasculitis in US African Americans: Experience From a Single Center

Background/Purpose: Little is known about the presentation, clinical features, and prognosis of ANCA-associated vasculitis (AAV)in non-Caucasian populations. More specifically, there is a paucity of studies in US African-Americans (AAs). Some studies have described that AA race as a predictor of resistance to treatment and relapse. Little else is known about how AAs present when affected by AAV. The objective of this study is to describe the clinical characteristics of AAV in AAs in comparison to Caucasians.

Methods: Retrospective cohort analysis of patients with AAV diagnosis vasculitis per ICD-9 codes (446.0, 446.4, 447.6) during a 12-year period (2003-2015). Variables analyzed included: sex, age, duration of symptoms, time to diagnosis, ANCA antibodies, serum creatinine and organ involvement based on BVAS score. Disease severity was assessed European Vasculitis Study Group definitions. Treatment agents (steroids, DMARDs, biologics) and requirement of renal replacement therapy were recorded. Caucasians controls were chosen randomly with a 2:1 ratio with AA individuals. Fisher's exact and Wilcoxon two-sample test were used

for the analysis categorical and continuous variables, respectively.

Results: 29 cases of AAV in AAs were confirmed. AAs were younger at the time of diagnosis (44.3 [31.0-55.0] vs 56.0 [50.0-68.0], p= 0.002). There were no differences in frequencies of AAV disease subsets, ANCA antibodies, disease severity, or most organ involvements between AAs and Caucasians (Tables 1-3). AAs with GPA had less disease severity as measured by the BVAS score (9.5 ±6.3 vs 14.5 ±7.5 p=0.03)

Conclusion: Few differences were found between US AAs and Caucasians with AAV. These included younger age at presentation and less disease severity in AAs with GPA. Even though generalizability of these results is limited by the small size and retrospective nature of this cohort, this is the first study that describes differences in AAV in AA individuals.

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To identify associations between patients' clinical and biological characteristics at diagnosis of antineutrophil cytoplasmic antibody-associated vasculitides (AAVs), and their relapse during follow-up.

Methods: Long-term follow-up data from 5 FVSG prospective trials (CHUSPAN I, CHUSPAN II, CORTAGE, MAINRITSAN and WEGENT) were pooled. Relapses were defined as the recurrence and/or appearance of ≥1 new vasculitis manifestation(s) after remission lasting ≥3 months. For eosinophilic granulomatosis with polyangiitis (EGPA), relapses were defined as new appearance, recurrence or worsening of clinical EGPA manifestation(s) (excluding asthma and/or ENT), requiring the addition, change or dose increase of glucocorticoids and/or other immunosuppressants. Patient and disease characteristics at enrollment were entered into a competing-risks model (1), with relapse as the event of interest and death the competing event. Times to relapse and/or death were calculated from treatment onset and analyses were stratified for the randomization group in each trial. Univariate and multivariate analyses were computed.

Results: Patients with PAN (n=108) and those included during a relapse of a formerly diagnosed AAV (n=23) were excluded. Finally, the characteristics of 610 patients (183 EGPA, 203 granulomatosis with polyangiitis [GPA] and 224 microscopic polyangiitis [MPA]) were included in the analyses. Mean±SD follow-up was 74.6±50.5 months. At diagnosis, mean±SD age was 59.6±15.2 years and mean creatinine 154±164 µmol/L. Anti-proteinase–3 (PR3) and anti-myeloperoxidase (MPO) ANCA were detected in 170 (28%) and 244 (40%) patients, respectively; ANCA or ELISA were negative for 195 (32%) patients and unavailable for 1 MPA patient. During follow-up, 267 (43.8%) patients relapsed and 106 (17.3%) died, 67 of them without prior relapse. A higher relapse risk was independently associated with arthralgias/myalgias (subhazard ratio [sHR]=1.41; *P*=0.017), anti-PR3 ANCA (sHR=1.91; *P*=0.010) or anti-MPO (sHR=1.49; *P*=0.022) ANCA, but the relapse risk was lower for age >70 years (sHR=0.68; *P*=0.025) or creatinine >200 µmol/L (sHR=0.60; *P*=0.010) at disease diagnosis.

Conclusion: For GPA, MPA and EGPA patients, relapse risk was lower for age >70 years or creatinine >200 µmol/L at disease onset, but higher for arthralgias/myalgias, anti-MPO ANCA or especially anti-PR3 ANCA. These results should enable us to develop a score predictive of AAV relapse that could help clinicians determine the best adapted maintenance treatment for each patient. **Reference** 1. SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) treatment includes high dose glucocorticoids (GCs), which are associated with increased body-mass index (BMI), a complication abhorred by patients and associated with increased risk of metabolic and cardiovascular complications. A prior study found increased BMI to be independent of GC exposure for AAV (Arthritis Care Res 2008;59:746). The ability to classify BMI change as an adverse event related to GC exposure or a positive outcome reflecting improved disease activity is critical in studies investigating steroid-sparing strategies. We evaluated this further by investigating the complex relationship between BMI, GC exposure, and disease activity.

Methods: We analyzed patients enrolled in the Rituximab in ANCA-Associated Vasculitis (RAVE) trial. First, we replicated the methods used by the prior study by performing a multivariate linear regression to investigate the relationship between GC exposure (prednisone equivalent) and BMI changes while adjusting for age, sex, baseline BMI and creatinine, GC exposure prior to baseline, disease status (new diagnosis versus flaring), ANCA subtype (PR3- or MPO-ANCA+), randomization arm, and flare during the study. Second, we used mixed effects regression models to determine the time-varying relationship between the cumulative moving average of disease activity and BMI as well as cumulative GC exposure during induction treatment (the first 6 months of the trial) when accounting for confounders. Third, we used the same methods to assess the relationship between BMI and quality of life (QOL), as measured by SF36 scores.

Results: In RAVE (N=197), 99 (50%) patients were male, the mean age was 52.8 (±15.5) years, and the mean

baseline BVAS/WG was 8.0 (±3.1). The majority were PR3-ANCA+ (67%). The baseline BMI was 28.8 (±6.3) and the largest BMI change occurred during induction (+1.1 (±2.2) kg/m^2, P<0.0001). During RAVE, the mean cumulative GC dose was 5,038mg (±2,638), most administered in the first 6 months. In fully adjusted multivariate linear regression models, there was no association between GC exposure and change in BMI at 6, 12, and 18 months (P>0.3 for all analyses). However, in fully adjusted mixed-effects models, both cumulative GC exposure and moving averages of BVAS/WG were associated with BMI change in opposing directions [+0.2kg/m^2 per 1gm GC (±0.04) and -0.1 per BVAS/WG point (±0.02), both P<0.001]; randomization to rituximab was associated with increased BMI [+0.7 (±0.2) P<0.0001]. Increasing BMI was associated with worse QOL in every SF 36 domain (P<0.03 for all analyses).

Conclusion: During AAV induction, increased BMI was associated with increased GC exposure but also improved disease control and randomization to rituximab. These observations raises important questions regarding whether increased BMI should be classified as an adverse event related to GC therapy as BMI increases may actually indicate effective disease control whereas decreased BMI may augur poorly for long-term disease control. The observed association between rituximab and increased BMI deserves additional evaluation.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a group of vasculitides that consists of granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (Churg-Strauss; EGPA), and microscopic polyangiitis (MPA). Large-vessel vasculitis (LVV) includes Takayasu's arteritis (TAK) and giant cell arteritis (GCA). Validated algorithms are needed to accurately identify patients with AAV and LVV in administrative databases. This study sought to evaluate and validate case-finding algorithms for AAV and LVV in 3 large health administrative databases.

Methods: To develop the algorithms, 125 patients per disease and per healthcare system (System 1 and System 2) were randomly selected using the International Classification of Diseases version 9 (ICD9) codes for GPA: 446.4, EGPA: 446.4, MPA: 446.0, TAK: 446.7, and GCA: 446.5. 16 case-finding algorithms were constructed using a combination of ICD9 code, encounter type (1 inpatient ICD9 code on 3 consecutive days or 2 outpatient ICD9 codes 3 months apart), physician specialty, use of immunosuppressive medications, ANCA pattern (for AAV), and age (< 50 and ≥ 50 years) for LVV algorithms. The diagnosis was confirmed by chart review using the modified ACR classification criteria or the Chapel Hill Consensus Conference definitions for each disease. The positive predictive value (PPV) of each algorithm was calculated. For validation, algorithms with the highest average PPV from both Systems 1 and 2 with at least sensitivity > 50% were validated in the third healthcare system (System 3).

Results: A total of 1,250 patients were included in the study. Figures 1 and 2 show the average PPV and sensitivity of the 16 algorithms for AAV and LVV tested in Systems 1 and 2. The ICD9 code alone had a low PPV. Most algorithms with the highest average PPV had the encounter and/or specialty variables as part of the algorithm. Adding the ANCA pattern increased PPV in AAV algorithms. Table 1 shows the PPV of algorithms with the highest average PPV validated in System 3.

Conclusion: Case-finding algorithms can accurately identify patients with AAV and LVV. These algorithms can be used to assemble population-based cohorts of patients with AAV and LVV and facilitate future research in healthcare use, outcomes, and comparative effectiveness.

Average positive predictive (PPV) and sensitivity of algorithms for granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA), and microscopic polyangiitis (MPA) at healthcare systems 1 and 2. Algorithms are arranged by the lowest to the highest PPV. Highlighted on the right is the algorithm with the highest average PPV not including the ANCA pattern.

PPV: Positive predictive value.

ICD9: ICD9: 446.4 for GPA/EGPA and 446.0 for MPA. Given that GPA and EGPA share the same ICD9 code, patients who ever had ICD9 codes 283.3 (eosinophilia) *or* 493.X (asthma) were excluded when testing algorithms for GPA and those who ever had ICD9 codes 283.3 (eosinophilia) *and* 493.X (asthma) were included when testing for EGPA.

Encounter: 1 inpatient ICD9 code on 3 consecutive days or 2 ICD9 codes 3 months apart.

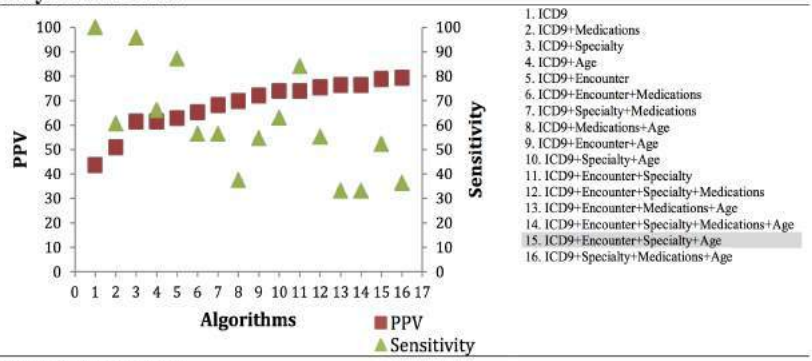
Specialty: Rheumatologist, Allergist/Immunologist, Nephrologist, Pulmonologist, or Otorhinolaryngologist involved in the care of the patient.

Medications: Glucocorticoids, disease-modifying anti-rheumatic drugs, and biologics.

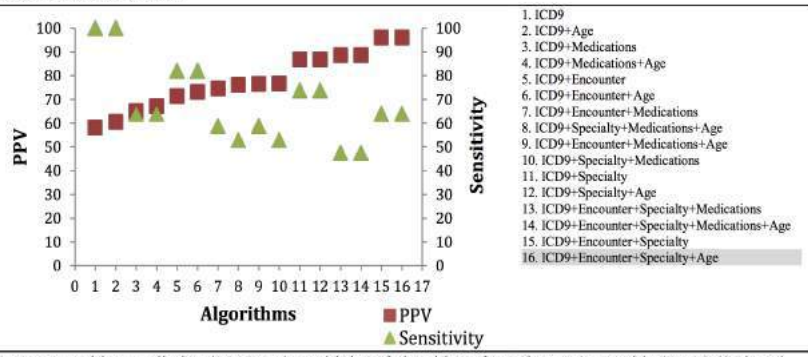
ANCA: Positive test for cytoplasmic pattern (cANCA) or perinuclear pattern (pANCA) of anti-neutrophil cytoplasmic antibody.

Figure 2. Average positive predictive (PPV) and sensitivity of algorithms for Takayasu's arteritis and giant cell arteritis

Takayasu's arteritis



Giant cell arteritis



Average positive predictive (PPV) and sensitivity of algorithms for Takayasu's arteritis (TAK) (**2A**) and giant cell arteritis (GCA) (**2B**) at healthcare systems 1 and 2. Algorithms are arranged by the lowest to the highest PPV. Highlighted on the right is the algorithm with the highest average PPV.

PPV: Positive predictive value.

ICD9: ICD9 code 446.5 for TAK and 446.7 for GCA.

Encounter: 1 inpatient ICD9 code on 3 consecutive days or 2 ICD9 codes 3 months apart.

Specialty: Rheumatologist, Cardiologist, or Vascular Surgeon involved in the care of the patient.

Medications: Glucocorticoids, disease-modifying anti-rheumatic drugs, and biologics.

Age: Current age less than 50 years for TAK and more or equal than 50 years for GCA.

Table 1. Positive predictive value of the algorithms with the highest average positive predictive value developed from Systems 1 and 2, and validated in System 3			
	Algorithm	PPV %	95% CI
GPA	**ICD9+Encounter+Specialty**	92.5	87.0 - 97.9
	ICD9+Encounter+Specialty+cANCA*	100.0	99.1 - 100.0
EGPA	**ICD9+Specialty**	100.0	73.5 - 100.0
	ICD9+Specialty+ pANCA*	100.0	47.8 - 100.0
MPA	**ICD9+Encounter+Specialty+Medications**	76.2	60.4 - 91.9
	ICD9+Encounter+Specialty+Medications+pANCA*	100.0	82.5 - 100.0
TAK	**ICD9+Encounter+Specialty+Age**	78.8	68.1 - 89.4
GCA	**ICD9+Encounter+Specialty+Age**	95.9	91.7 - 100.0

***Given that the anti-neutrophil cytoplasmic antibody (ANCA) test is not readily searchable in many healthcare systems we sought to validate algorithms with and without the ANCA pattern. PPV: Positive predictive value; CI: Confidence interval. GPA: Granulomatosis with polyangiitis; EGPA: Eosinophilic granulomatosis with polyangiitis; MPA: Microscopic polyangiitis; TAK: Takayasu's arteritis; GCA: Giant cell arteritis. ICD9: 446.4 for GPA/EGPA; 446.0 for MPA; 446.5 for TAK; 446.7 for GCA. Encounter: 1 inpatient ICD9 code on 3 consecutive days or 2 ICD9 codes 3 months apart. Specialty: Rheumatologist, Allergist/Immunologist, Nephrologist, Pulmonologist, or Otorhinolaryngologist involved in the care of the patients with GPA, EGPA, or MPA. Rheumatologist, Cardiologist, or Vascular Surgeon involved in the care of the patients with TAK or GCA. ANCA: Positive test for cytoplasmic pattern (cANCA) and perinuclear pattern (pANCA) of anti-neutrophil cytoplasmic antibody. Medications: Glucocorticoids, disease-modifying anti-rheumatic drugs, and biologics. Age: Current age less than 50 years for TAK and more or equal than 50 years for GCA.**

Antineutrophil Cytoplasmic Antibody (ANCA) Type and Body Mass Index in ANCA-Associated Vasculitis (AAV)

Background/Purpose: Phenotypic, genetic, and treatment differences distinguish PR3- and MPO-ANCA+ ANCA-associated vasculitis (AAV) patients and suggest that these serotypes represent distinct conditions which might have different risk factors. Being overweight or obese is a risk factor in some autoimmune conditions (e.g., rheumatoid arthritis) but differences in body mass index (BMI) between the PR3- and MPO-ANCA+ AAV subtypes have not been investigated. Such differences could suggest novel genetic or environmental risk factors and have implications for treatment response, as in psoriatic arthritis, and the risk of cardiovascular disease which is a common cause of death in AAV. We evaluated whether BMI differences exist between patients with PR3-ANCA+ and MPO-ANCA+ AAV.

Methods: We analyzed AAV patients from the Rituximab in ANCA-Associated Vasculitis (RAVE) trial. In univariate analyses, we compared the BMI of PR3- and MPO-ANCA+ AAV patients at enrollment; in a multivariate linear regression, we adjusted for age, gender, glucocorticoids prior to enrollment, relapsing disease at baseline, and baseline disease activity. We used an analysis of response profile to evaluate trends in BMI, adjusted for the above confounders as well as glucocorticoid exposure and flares during the trial.

Results: The majority of patients in RAVE (N=197, Table 1) were PR3+ (131, 67%). PR3-ANCA+ patients had a higher baseline BMI (29.6±6.6 vs. 27.2 ± 5.3; P=0.01) and were more often obese (42% vs. 24%, P=0.04). When analyzing only those with a new diagnosis at enrollment (N=96), PR3-ANCA+ patients still had a significantly higher BMI (29.2 ± 6.2 vs. 26.8 ± 4.9, P=0.04). In multivariate regression analyses, these differences (PR3-ANCA+ BMI 2.1 kg/m^2 (±1.1) higher than MPO-ANCA+ patients) remained (P=0.047). To address the potential impact of disease duration on BMI, we investigated the temporal trend in BMI between AAV subtypes over the course of the trial (18 months) and found a constant difference in BMI (Figure 1; P=0.3).

Conclusion: PR3-ANCA+ patients have a significantly higher BMI than MPO-ANCA+ patients, even after adjustment for important potential confounders. Several possibilities may explain findings. First, an elevated BMI may predispose to PR3-ANCA+ AAV. Second, the activity of hormones associated with metabolism (e.g., leptin) may differ in AAV subtypes. Third, BMI differences could be related to variations in shared genetic risk factors. **Table 1: RAVE Trial Cohort**

Variable	**PR3-ANCA+**	**MPO-ANCA+**	**P-Value**
Number (N, %)	131 (66.5%)	66 (33.5%)	
Age	49.6 (±14.8)	59 (±15)	<0.001
Male (N, %)	75 (57.3%)	24 (36.4%)	0.007
Baseline BVAS-WG	8.3 (±3.2)	8.5 (±3.1)	0.8
New Diagnosis at Enrollment	50 (38.2%)	46 (70%)	<0.0001
Disease Category			
Granulomatosis with polyangiitis (N, %)	127 (97%)	20 (30%)	<0.0001
Microscopic polyangiitis (N, %)	4 (3%)	44 (66.7%)	
Indeterminant (N, %)	0 (0%)	2 (3%)	
Weight and BMI			
Baseline weight (kg)	89.3 (±22.0)	77.2 (±16.0)	<0.0001
Baseline BMI (kg/m^2)	29.6 (±6.6)	27.2 (± 5.3)	<0.0001
Obese (N, %)	55 (42%)	16 (24%)	0.04
Glucocorticoid Dosing			
GC prior to baseline (mg)	1263 (±1492)	1130 (±1408)	0.6
GC over the course of study (mg)	4838.2 (±2001)	4817.7 (±3433.1)	0.96

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ocular involvement in ANCA-associated vasculitis (AAV) can cause substantial morbidity. We aimed to characterize patterns of ocular involvement in AAV and their response to treatment.

Methods: We analyzed data from two large randomized controlled trials of AAV – the Rituximab in ANCA-Associated Vasculitis (RAVE) trial and Wegener's Granulomatosis Etanercept Trial (WGET). Ocular involvement was assessed at baseline and patients were followed until the common close-out dates. Pooled post-hoc analysis was performed of initial and overall prevalences of ocular involvement. Clinical features associated with ocular involvement, time to remission, and relapse were assessed by Cox proportional hazards and logistic regression models.

Results: 377 patients were included (Table 1). 64 patients (17.0%) had ocular involvement at study entry; conjunctivitis/episcleritis was the most common subtype, while uveitis and retinal involvement were the rarest (Table 2). Over a median follow-up time of 35.4 months, 24 patients (6.4%) developed new ocular involvement. Non-white race was associated with higher odds of having retroorbital mass/proptosis (OR 4.51; P = 0.014). Female sex (OR 2.70; P = 0.032) and PR3 ANCA positive status (OR 4.48; P = 0.048) were associated with higher odds of having scleritis. Among patients with ocular disease at study entry, median times to remission were 1.3 months for conjunctivitis/episcleritis, 1.4 months for retroorbital mass/proptosis, 0.2 months for scleritis, and 0.3 months for retinal exudates/hemorrhage. Treatment with rituximab trended toward association with decreased time to remission of retroorbital mass/proptosis (HR 10.0; P = 0.060). Relapses of ocular disease occurred in 5 patients (12.5%) with conjunctivitis/episcleritis, 3 patients (25.0%) with retroorbital mass/proptosis, and 6 patients (37.5%) with scleritis. No patient treated with rituximab developed a relapse of conjunctivitis/episcleritis or proptosis.

Conclusion: Conjunctivitis/episcleritis, scleritis, and retroorbital mass/proptosis were the most common ocular manifestations of AAV. Race and sex may be associated with certain subtypes of ocular involvement. The relative efficacies of cyclophosphamide and rituximab in the treatment of retroorbital mass/proptosis deserve further study.

Table 1. Study population baseline characteristics (N=377)

Age (years), mean (SD)	51.4 (15.5)
Sex, male, n (%)	208 (55.2)
Race, white, n (%)	350 (92.8)
New diagnosis, n (%)	176 (46.7)
Limited disease, n (%)	52 (13.8)
WG diagnosis, n (%)	327 (87.0)
PR3 ANCA positive, n (%)	277 (74.5)
MPO ANCA positive, n (%)	70 (18.8)
RAVE trial participant, n (%)	197 (52.3)
Treatment with rituximab, n (%)	99 (26.3)
WGET trial participant, n (%)	180 (47.7)
Treatment with etanercept, n (%)	89 (23.6)

Table 2. Prevalence of AAV ocular involvement

	Baseline prevalence	Overall prevalence
Conjunctivitis/episcleritis, n (%)	41 (10.9)	62 (16.4)
Retroorbital mass/proptosis, n (%)	12 (3.2)	17 (4.5)
Uveitis, n (%)	0 (0.0)	2 (0.5)
Scleritis, n (%)	16 (4.2)	22 (5.8)
Retinal exudates/hemorrhage, n (%)	1 (0.3)	1 (0.3)

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA, Wegener´s) patients are more exposed to traditional cardiovascular risk factor, including obesity. In rheumatic diseases, inflammation has been associated with abnormal body composition (BC). Visceral adipose tissue (VAT) is a metabolically active tissue and is a source of humoral and cellular inflammation. It has been demonstrated that VAT is associated with incidence metabolic risk beyond its contribution to overall adiposity. Therefore, the objective of this study is to compare BC parameters, with emphasis in body fat and VAT, in GPA patients versus healthy controls and to explore the association of these parameters with disease activity and inflammatory markers.

Methods: This cross-sectional study was conducted in 32 GPA patients and 32 healthy controls matched by sex, age and body mass index (BMI). Disease activity was assessed by Birmingham Vasculitis Activity Score (BVAS) and ANCA. Damage was assessed by Vasculitis Damage Index (VDI). C-reactive protein (CRP, normal: < 5mg/L) and Erythrocyte sedimentation rate (ESR, normal < 15mm/1st hour for men and < 20mm/1st hour for women) were measured. BC was analyzed using dual-energy X-ray absorptiometry (DXA). Fat mass parameters evaluated were: total fat mass (FM), adiposity (percentage of body fat), fat mass index (FMI: fat mass/ht^2) and VAT (g, cm^3, cm^2).

Results: Compared GPA patients with healthy controls, a significantly greater VAT (696.00 ± 284.96 *vs.* 574.34 ± 243.82 g, p=0.03; 752.34 ± 313.01 *vs.* 621 ± 263.60 cm^3, p=0.03 and 144.34 ± 60.02 *vs.* 119.11 ± 50.54 cm^2, p=0.03) were observed in patients. GPA patients with BVAS > 1 demonstrated higher adiposity (38.71 ± 12.16 *vs.* 31.47 ± 9.29%, p=0.04) and FMI (13.78 ± 6.43 *vs.* 9.66 ± 4.39 Kg/m^2, p=0.02), compared to patients with BVAS ≤ 1. ANCA and VDI were not associated with any fat mass parameters. Elevated CRP and ESR were observed in GPA patients with higher FMI (13.54 ± 6.45 vs. 9.72 ± 4.45 Kg/m^2 p=0.04 and 13.68 ±

6.81 vs. 9.68 ± 4.27 Kg/m^2 p=0.03, respectively). No correlation was observed between fat mass parameters (FM, adiposity, FMI and VAT) and prednisone cumulative dose (p>0.05).

Conclusion: Our data suggest that GPA patients have abnormal BC, mainly in fat mass parameters and these variables are associated with inflammation and disease activity suggesting that BC should be evaluated in GPA patients to understand and prevent comorbidities in these subjects.

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cutaneous involvement is frequent during ANCA-associated vasculitis (AAV) and can reveal the disease. However, no large study on presentation and clinical-pathological correlations is available. In the present study, we aimed to analyze the spectrum and impact of cutaneous manifestations (CM) during AAV, including granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA), and to perform clinical-pathological correlations.

Methods: We conducted a French multicenter retrospective study on patients with AAV included in the French Vasculitis Study Group database. Clinical and biological presentation, and relapse-free and overall survival

have been analyzed in patients with and without CM. Clinical-pathological correlations of 38 biopsies from 32 patients were performed by 3 pathologists in a blind manner.

Results: 1553 patients were included: GPA (n=743), EGPA (n=436) and MPA (n=374). Cutaneous manifestations were more frequent in EGPA (53%) and MPA (52%) compared to GPA (35%) ($p<0.0001$), and palpable purpura was the most frequent reported CM (21%). Oral ulcers were more frequent in GPA than in MPA and EGPA (4.6% vs. 0.3% and 2.5%, $p<0.001$). Pitting edema and livedo were more frequent in MPA than in GPA and EGPA (19.5% vs. 4.3% and 13%, $p<0.001$, and 12.4% vs. 2.6% and 0.5%, $p<0.001$, respectively). Urticarial lesions were more frequent in EGPA than in GPA and MPA (11.5% vs. 2% and 3.5%, $p<0.001$), such as nodules ($p<0.0001$) and purpura ($p=0.0004$). Pyoderma gangrenosum (1.1%) and gingival hyperplasia (0.9%) were only observed in GPA. GPA patients with CM had more frequent vasculitis manifestations (i.e., alveolar hemorrhage, renal and gastrointestinal involvement) than granulomatosis manifestations (pulmonary nodules, pachymeningitis). Finally, relapse-free survival [HR 1.29, $p=0.03$] and overall survival [HR 1.89, $p=0.005$] were poorer in GPA patients with CM, but not in MPA and EGPA. For clinical-pathological correlations, CM biopsy specimen included purpura (n=13), nodules (n=10), papules (n=5), urticaria (n=4) and unspecified lesions (n=6). Pathological analysis showed vasculitis (68%), granulomatous infiltrates (72%), and both (50%). Vasculitis was mainly observed in purpura and nodules (86 and 80%). Granulomatous infiltrates were variable and observed regardless of the type of AAV: granulomatous vasculitis was noted in half of purpura and nodules, whereas interstitial granulomatous dermatitis was mainly noted in urticaria and papules in 75 and 60%, respectively. Neutrophils were predominant in 63%, and eosinophils seemed to be more frequent in EGPA than GPA.

Conclusion: Cutaneous manifestations are common in AAV, and more frequently observed in EGPA and MPA than GPA. Some CM are quite specific to the type of AAV. Cutaneous involvement is associated with more severe disease and poorer outcome in GPA. Clinical-pathological correlations revealed that no histological feature was specific to the type of AAV, but granulomatous infiltrates differs according to the type of lesions.

Session Date: Monday, November 14, 2016
Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Atypical manifestations have been described in patients with antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitides (AAV), such as periaortic fibrosis, pachymeningitis and orbital mass. Because these manifestations have been frequently described in the spectrum of IgG4-related disease (IgG4-RD), we hypothesized that both diseases could overlap.

Methods: We conducted a European retrospective multicenter observational study, including patients with AAV fulfilling 1990 ACR criteria and/or EMA algorithm and/or the definitions from the 2012 Chapel Hill Consensus Conference, and IgG4-RD fulfilling Umehara criteria. Such criteria defined IgG4-RD as possible, probable or definite. Data were collected using a standardized form by physicians in charge of patients.

Results: Eighteen patients were included (mean age 56.8 years, 13 men and 5 women). AAV and IgG4-RD diagnoses were made concomitantly in 12/18 patients (67%). AAV diagnosis preceded IgG4-RD diagnosis in 4/18 (22%) with a mean interval of 90 months (24-156), and IgG4-RD preceded AAV in 2/18 (11%). AAV diagnosis included granulomatosis with polyangiitis (GPA) in 14 (78%), microscopic polyangiitis (MPA) in 2 (12%), eosinophilic granulomatosis and polyangiitis (EGPA) in 1 (5%) and renal-limited AAV in 1 (5%). ANCA were positive in 15 patients (83%), including PR3-ANCA in 9 cases and MPO-ANCA in 5 cases. At diagnosis, mean BVAS was 16 (4-36). IgG4-RD diagnosis included definite IgG4-RD in 5 cases (28%), probable IgG4-RD in 5 (28%) and possible IgG4-RD in 8 (44%). IgG4-RD involvement were chronic periaortitis (i.e., retroperitoneal fibrosis, periaortitis and/or aortic aneurysm) in 9/18 patients (50%), orbital mass and tubulointerstitial nephritis in 4 cases each (22%), prevertebral fibrosis in 3 (16,7%), pachymeningitis and autoimmune pancreatitis in 2 cases each (11%), and salivary gland involvement, dacryoadenitis, mesenteric fibrosis, interstitial lung disease and myocardial involvement in 1 case each (5%). Medium serum IgG4 level was 2.3 g/L (range <0.07-4.85). Nineteen biopsies were performed and were contributive in 16/18 (84%) patients. Overall, 9/18 had histological evidence of vasculitis and 10/18 evidence of IgG4-RD. Histological features of IgG4-RD included dense lymphoplasmacytic infiltrate in 100% and dense fibrosis in 80%, but no obliterative phlebitis. IgG4/IgG ratio >40% was obtained in 50% and a number of IgG4-positive plasma cells >10 per high-power field in 80%. Patients required a median number of 2 (range 0-4) lines of immunosuppressants in association with corticosteroids. During a mean follow-up was 65.6 months (range 4-156), AAV relapsed in 9/18 (50%) whereas IgG4-RD relapsed in 3/18 (17%). One patient died because of diverticular peritonitis.

Conclusion: This study illustrates that AAV and IgG4-RD may overlap, suggesting that they could represent

various expressions of similar Th2 dominant imbalance of T cell responses. Identification of manifestations suggesting IgG4-RD in AAV patients could be useful, in particular in case of IgG4-RD manifestations mimicking refractory granulomatous lesions.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are both anti-neutrophil cytoplasm antibodies (ANCA)-associated vasculitides (AAV), but differ in clinical presentation. Anti-myeloperoxydase (MPO)-ANCA were demonstrated to be pathogenic in mice, whereas proteinase 3 (PR3) itself is responsible for disruption of immune silencing in GPA rather than anti-PR3-ANCA. Perturbations in lymphocyte homeostasis associated with these abnormalities could differ between both conditions.

Methods: We analyzed the phenotypic characteristics of lymphocyte subsets in peripheral blood of 32 consecutive GPA patients and 8 MPA patients with active disease and 22 healthy controls (HC). Using flow cytometry we studied the expression of activation and inhibitory markers, cytokine receptors and inflammatory

cytokines in B cells, and main effector (i.e. Th1, Th2, Th9 and Th17 cells) and regulatory T cell (Tregs) subsets.

Results: B cell analyses revealed that B cell subsets were similar between GPA and HC. In contrast, MPA patients had significantly more $IgD^{+}/CD27^{-}$ naive B cells (69.1% vs. 50.7%, P=0.04) and less $IgD^{-}/CD27^{+}$ class-switched memory B cells (3.8% vs. 8.7%, P=0.05) than HC. No difference between GPA and MPA patients vs. HC was noted for the expression of the activation markers (CD86 and CD95) or for the inhibitory receptors (CD22, CD32, CD72 and FCRL5) within B cells. Percentage of B-cell expressing CD69 was significantly higher in GPA (3.0% vs. 1.5%, P=0.02) and MPA (5.2% vs. 1.5%, P=0.019) compared to HC, respectively, as well as CD40 expression in GPA compared to HC (MFI ratio 20.57 vs 48.59, P=0.038). Expression of BAFF-R was strikingly lower in GPA and MPA compared to HC (MFI ratio 11.5 vs. 45.2, P<0.001 for GPA, and 14.0 vs. 45.2, P=0.003 for MPA). Finally, we found significantly more IL-6-producing B cells in GPA than in HC (25.7% vs. 14.9%, P<0.001), whereas IL-6-producing B cells were decreased in MPA compared to HC (4.6% vs. 14.9%, P=0.0049). In contrast, the frequency of TNFα-producing B cells were lower in GPA and MPA patients than in HC (15.9% and 8.4% vs. 30.0%, P=0.008 and P=0.006, respectively). T cell analyses found more Th2 (1.76% vs. 1.0%, P=0.028), Th9 (1.0% vs. 0.2%, P<0.001) and Th17 (1.44% vs 0.90%, P=0.03) cells in GPA compared to HC, whereas no difference was noted between MPA and HC. The percentage of Tregs was similar between GPA and MPA vs. HC. However, the $FoxP3^{low}/CD25^{+}$ T cell subset, that includes both naive Tregs and non-regulatory effector T cells, was significantly higher in GPA (6.4% vs. 4.1%, P=0.016) than in HC. No difference between groups was noted regarding the proportion of follicular helper T cells.

Conclusion: Main phenotypic characteristics of lymphocytes in GPA and MPA patients are an increased expression CD69 and CD40 activation markers and decreased expression of BAFF-R on B cells, suggesting a role of this cytokine. In addition, IL-6-producing B cells were increased in GPA whereas TNF-α-producing B cells were decreased, raising the question of the potential benefit of anti-IL-6. GPA patients differed from MPA patient by a skewed distribution of Th2, Th9 and Th17 cells.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA) patients are often treated with immunesuppressives or B cell depleting therapy. While B cells are involved in GPA pathogenesis as precursors of anti-neutrophil cytoplasmic antibody (ANCA) producing plasma cells, they can also exert cytokine dependent pro-inflammatory and regulatory functions. In GPA, treatment strategies could be improved by selective targeting of the effector function of B cells. Here, we investigated the effect of the Kv1.3 channel blocker dalazatide (formerly ShK-186) on effector and regulatory B cell function.

Methods: The distribution of B cell subsets was determined in peripheral blood samples of 33 GPA patients and 17 matched healthy controls (HC). Peripheral blood mononuclear cells (PBMC) from GPA patients and HC were stimulated *in vitro* with CpG-ODN or a combination of CpG, B cell activating factor (BAFF) and interleukin(IL)-21 in the presence and absence of dalazatide. The production levels of total IgG and PR3-ANCA IgG in culture supernatants were analysed by ELISA and Phadia EliA, respectively. In addition, the effect of dalazatide on B cell proliferation and cytokine production was determined by flow cytometry.

Results: Circulating switched and unswitched memory B cells were relatively decreased in GPA patients as compared to HC. Treating stimulated PBMCs with dalazatide resulted in decreased production of both total and PR3-ANCA IgG. Proliferation of B cells was not affected by dalazatide. A strong decrease in production of the pro-inflammatory cytokines TNFα, IL2 and IFNγ was observed with dalazatide treatment. While IL10 production was also decreased with dalazatide treatment in GPA patient samples, this effect was less pronounced. As such, dalazatide modulated the TNFα/IL10 ratio among the B cells, resulting in a relative increase in the regulatory B cell pool.

Conclusion: Dalazatide clearly modulates the effector function of B cells *in vitro,* by decreasing autoantibody production and the release of pro-inflammatory cytokines. Kv1.3 channel blockade may hold promise as a novel therapeutic strategy in GPA and other B cell mediated autoimmune disorders.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Most data on management and outcomes of ANCA-associated vasculitis (AAV) come from highly selected populations in tertiary referral centres, or clinical trials. These results may not be generalizable to clinical practice across all hospitals.

Methods: Rheumatology and Renal units in all hospitals within one of four health regions in England were invited to undertake a retrospective case note audit of all patients newly diagnosed with AAV during April 2013-December 2014. Data were collected on specialty of attending physician, patient demographics, place of diagnosis, date of symptom onset, admission or first clinic appointment, and diagnosis, BVAS organ systems involved, details of remission induction, and outcomes including hospitalisation for infection and death. The odds ratio (OR) for infection was estimated using logistic regression, and the hazard ratio (HR) for death was estimated using cox regression; both were adjusted for confounders age and renal involvement.

Results: Cases were contributed by 19 (56%) of 34 invited units. 126 newly diagnosed cases were included, 59% from Rheumatology and 41% from Renal units. 69 (54.8%) were diagnosed as inpatients, and 57 (45.2%) as outpatients. Cyclophosphamide (CYC) was the most common remission agent used in 95 (75%), Rituximab in 6 (5%), and other agents in 25 (20%). Frequency of organ involvement at diagnosis is shown in table 1. Diagnostic delay from first symptoms to diagnosis was median 2.6 (interquartile range 1.2-6.1) months. It was shorter in the sicker patients (defined as inpatients) 1.8(0.9-3.7) compared to outpatients, 4.1(2.0-12.6). Among inpatients, delay from admission to diagnosis ranged from 0-53 days (median 6, IQR 3-10.5). Of the 95 newly diagnosed patients treated with CYC, 70 (74%) received IV and 25 (26%) oral. 22 (23%) had infections requiring hospitalisation during or within 6 months of CYC treatment, and 14 (15%) died during follow up (table 1). Compared to IV, the crude OR for infection with oral CYC was 2.9 (1.1-7.7) and HR for death was 2.1 (0.7-6.4). Once adjusted for age and renal involvement, OR for infection remained elevated at 2.3 (0.8-6.9) and HR for death was 1.8(0.5-5.9).

Conclusion: There are potential opportunities to reduce the delay between admission and diagnosis amongst hospitalised patients. The need to improve care is highlighted by the significant mortality and infection rate in this unselected group. Although this analysis is limited by lack of power, and like all observational comparison of treatments at risk of confounding by indication, it raises the hypothesis that in contrast to the more selected CYCLOPS trial population, the routine use of oral CYC may be associated with an increased risk of death and infection requiring hospitalization.

Table 1: Frequency of organ systems affected at diagnosis, and infection & mortality after cyclophosphamide.

BVAS organ system affected		% affected

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Vasculitis - Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The published Indian data on Granulomatosis with Polyangiitis (GPA) is sparse and only in the form of few small case series. The purpose of this study was to describe the clinical features, treatment and long term outcome of 105 patients with GPA from a tertiary care centre in north India and compare them with

published single center experiences from Europe and America.

Methods: Clinical data of all patients diagnosed to have GPA between April 2005 and April 2016 were retrieved. Clinical details including the clinical presentation, laboratory data, treatment received and outcomes of 105 patients of GPA were obtained. The disease activity at presentation was assessed with Briminghams Vasculitis Activity Score (BVAS v3) and the patients were classified according to EUVAS categories into localized, early systemic, generalized, severe and refractory categories. Our results were compared with published single center experiences from Europe and USA.

Results: A total of 105 patients (60 females and 45 males) were diagnosed to have GPA at a mean age of 40.31 years. The duration of follow up ranged from 0 months to 136 months with a mean duration of follow up of 37.21 months. Ninety four (89.52%) patients had ANCA positivity by either IIF or ELISA and 11 (10.48%) were ANCA negative. Upper respiratory tract involvement was seen in 76.19% of patients. Renal and lung involvement was seen in 51.43% and 67.62% of patients respectively. Cavitating lung lesions were seen in 21.9% of patients and subglottic stenosis was noted in 3 patients. Ocular, ear, CNS, peripheral nervous system, heart, gastrointestinal and skin involvement was seen in 40.95%, 18.1%, 28.57%, 11.43%, 5.71%, 12.38% and 29.52% respectively. Constitutional symptoms were noted in 62.86% of patients and joint symptoms were present in 43.81% of patients. The mean BVAS v3 score was 17.78. Among the EUVAS categories, localized disease was seen in 3 patients, early systemic disease in 44 patients, generalized disease in 38 patients. Seventeen patients had severe disease and one patient had refractory disease. All the patients were treated with steroids at presentation and cyclophosphamide (either oral or intravenous) was used in 90 patients. Rituximab was used as primary remission induction in 6 patients while 25 patients received it as secondary remission induction agent. Plasma exchange was performed in 6 patients and 3 patients received intravenous immunoglobulins. Total 17 patients expired out of which 9 patients expired at first admission and 4 patients expired within 1 year of diagnosis. The cause of death was attributed to disease activity in 11 patients, disease activity plus sepsis in 3 patients and sepsis alone in 3 patients. Twenty six patients experienced relapses during the follow up period which were managed appropriately. Comparison of our findings with single center experiences from Europe and USA is shown in table 1.

Conclusion: Indian population seems to get effected by GPA at an earlier age compared to the western population and also has a lesser renal involvement. The other organ involvement, response to therapy, relapse rates and mortality appear to be similar between the Indian and western population. Table 1: Comparison of clinical features of GPA among European, American and Indian patients

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Plenary Session II: Discovery 2016

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: The previously reported prospective, randomizedÐcontrolled MAINRITSAN trial compared rituximab (RTX) to azathioprine (AZA) for maintenance of ANCA-associated vasculitis (AAV) remissions obtained with a combined cyclophosphamide and glucocorticoid (GC) induction regimen. Patients were randomly assigned to receive 500-mg RTX infusions on D1, D15 and 5.5 months later, then every 6 months until 18 months, or AZA for 22 months (initial dose: 2 mg/kg/d). Trial results demonstrated that RTX was superior to AZA at maintaining AAV remission during the planned 28 months of follow-up. We now report the pre-specified long-term outcomes at 60 months of MAINRITSAN trial patients.

Methods: SurvivorsÕ outcomes were ascertained prospectively. Data on survival, relapse, cancers, cardiovascular morbidity and other adverse events were collected from physicians. All patients were analyzed according to randomization group. Quality-adjusted time-without-symptoms-and-toxicity (Q-TWiST) analysis was computed, with the aim of better discerning the therapeutic impact and tradeoffs between treatment toxicity (severe adverse events, SAEs) and disease activity (relapse).

Results: Data from 60 months of follow-up were available for 110 (96%) of the 115 randomized participants. For the RTX- and AZA-treated groups, respectively: 0 and 4 died; 60-month overall survival rates were 100% and 93.0% [95% CI 86.7Ð99.9%] (P=0.045); all-relapseÐfree survival rates were 57.9% [95% CI 46.4Ð72.2%] and 37.2% [95% CI 26.5Ð52.2%] (P=0.012); and major relapse-free survival rates were 71.9% [95% CI 61.2Ð84.6%)] and 49.4% [95% CI 38.0Ð64.3%] (P=0.003). In contrast, no between-group differences were observed for survival without SAEs (P=0.95) and the cumulative GC dose (P=0.11) at 60 months.

For RTX-treated patients, PR3-ANCA positivity or ANCA persistence 12 months after starting maintenance therapy were associated with higher major relapse rates. During the 60-month follow-up, RTX- and AZA-arm patients had similar amounts of time spent with SAEs (P=0.21), whereas the former, compared to the latter, spent 9.7 months less with major relapses (P<0.001) and 12.6 months more without relapse or toxicity (P<0.001). The threshold utility analysis at 60 months showed that the Q-TWiST period was significantly longer for RTX- than AZA-arm patients (55.2 vs. 47.95 months, respectively, P<0.001) (Figure).

Conclusion: This long-term analysis showed that, despite late relapses after the 28-month initial follow-up period, maintenance therapy with RTX remained significantly superior to AZA to maintain remission at 60 months and was associated with better survival. ANCA monitoring seems to be relevant to guide treatment duration.

Session Date: Monday, November 14, 2016
Session Title: Plenary Session II: Discovery 2016
Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose: Over the last decade, the disease modifying effects of Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) and Tumor Necrosis Factor inhibitors (TNFi) have resulted in conflicting studies. No study has examined their relationship longitudinally addressing both NSAID and TNFi use. The objective of this study was to explore the direct and interactive effects of NSAIDs and TNFi on radiographic progression in Ankylosing Spondylitis (AS).

Methods: We included 527 patients meeting the modified New York criteria in a prospective cohort with at least 2 years of clinical and radiologic follow up. Progression was defined longitudinally, with >=2 modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) unit increase in 24 months. To avoid ceiling effects, patients with high mSASSS scores were censored when they could not meet the definition of progression over the next follow up period. We used a longitudinal mixed-effects multivariable logistic regression model to determine the associations of TNFi use and NSAID use with radiographic progression.

Results: Of the 527 patients, 75.7% were male with a baseline mean (SD) age and disease duration of 42.5(13.28) and 18.45(13.13) years respectively. The baseline median mSASSS was 5.36 [IQR 0.00, 28.00] and patients were followed for a mean of 4.29(2.5) years. NSAIDs and TNFi were used in 78.0% and 58.4% of patients respectively. Of 1413 visits included in this analysis, 38%, 29% and 23% had an NSAID index of 0, >0 & =<50, and >50 respectively. Multivariable results showed significant interaction between TNFi and NSAIDs (p=0.034) indicating lower progression for only those using TNFi and high dose NSAIDs [index >50]; (OR=0.17, 95%CI 0.05, 0.55, p=0.003).

Conclusion: Use of NSAIDs and TNFi in AS patients has a synergic effect in slowing radiographic progression with the greatest effect in those using both high-dose NSAIDs and TNFi.

Table 1. Longitudinal association of NSAID and TNFi use with radiographic progression, taking into account interaction, and controlling for potential confounding

Covariate	Adjusted Odds Ratio (95% CI)	p-value
TNFi use * NSAID use interaction effect		***0. 0340***
TNFi use vs. no TNFi use *for NSAID index>50*	**0.17 (0.05, 0.55)**	**0.0033**
TNFi use vs. no TNFi use *for 0< NSAID index*	**0.89 (0.32, 2.51)**	**0.8278**
TNFi use vs. no TNFi use *for no NSAID use≤50*	**0.94 (0.38, 2.33)**	**0.8867**
Baseline mSASSS ≥4	7.00 (3.68, 13.3)	<0.0001

Session Date: Monday, November 14, 2016

Session Title: Plenary Session II: Discovery 2016

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Chronic kidney disease (CKD) is a cause and consequence of hyperuricemia. While clinicians are often cautious about using allopurinol in patients with CKD, there is emerging evidence that urate-lowering therapy (ULT) may be beneficial in subjects with renal dysfunction. Whether patients with gout may experience less CKD with allopurinol is not clear.

Methods: We conducted a cohort study in The Health Improvement Network (THIN), which is a general practitioner electronic medical records database representative of the UK general population. We included subjects aged 18-89 with incident gout between 01/01/2000-12/31/2014 who had had at least 1 GP contact in the year prior to study entry. We excluded individuals with CKD stage ≥3 prior to gout diagnosis. We identified allopurinol initiators after their incident gout diagnosis. We computed propensity scores (PS) to minimize effects of confounding by indication using logistic regression, with incident allopurinol use as the dependent variable and potential confounders that reflect indication for allopurinol use and/or risk of CKD (table) as the independent variables. Each incident allopurinol user was matched 1:1 with an unexposed subject with greedy matching using the PS within 1-year cohort accrual blocks. Follow-up started from the index date (date of 1stallopurinol prescription for the exposed, and randomly assigned date for the unexposed within the one-year accrual block), and continued until CKD stage ≥3, death, or end of study. The relation of incident allopurinol use among subjects with incident gout to development of CKD ≥3 was assessed using Cox proportional hazard models. Since allopurinol initiators may stop using allopurinol or non-users may start using allopurinol during the follow-up period, we performed a sensitivity analysis in which subjects were censored if their exposure status changed.

Results: There were 13,727 allopurinol initiators who were PS-matched with 13,727 non-users, among whom 1401 and 1319, respectively, developed CKD stage ≥3, with mean follow-up time of 4 years for both groups. Overall, covariates were well-balanced in the two groups, with mean age of 58 years and mean BMI of 30 kg/m^2. Allopurinol use was not associated with an increased risk of developing CKD ≥3 compared with non-users, with a hazards ratio (HR) of 1.05 (95% CI 0.97-1.13). When additionally adjusted for the potential confounders included in the original PS model, the effect estimate remained unchanged (table). In the sensitivity analysis the adjusted HR did not change materially (HR=1.04, 95% CI 0.96-1.14).

Table. Risk of progression to CKD 3-5 among subjects with incident gout and incident allopurinol use.		
	Incident allopurinol user (N=13,727)	**Non-allopurinol user (N=13,727)**
Incident CKD ≥3, N	1401	1319
Mean follow-up time, years	4.04	3.96
Crude incidence rate (CKD ≥3) per 1000 person-years	25.26	24.28
Crude HR (95% CI)	1.05 (0.97-1.13)	
Adjusted* HR (95% CI)	1.05 (0.98,1.14)	
Sensitivity analysis Adjusted* HR (95% CI)	1.04 (0.96-1.14)	
* Variables included in the propensity-score model and included in the adjusted HR model: 1) gout duration; 2) baseline serum urate; 3) baseline kidney function and albuminuria; 4) general (age, gender, body mass index); 5) comorbidities (cardiovascular disease, diabetes mellitus, heart failure, hypertension); 6) hospitalization; 7) medication use (angiotensin-converting-enzyme inhibitor, aspirin, colchicine, diuretics, insulin, other drugs for diabetes mellitus, losartan, other angiotensin II receptor blockers, nonsteroidal anti-inflammatory drugs). CKD: chronic kidney disease; HR: hazard ratio; CI: confidence interval.		

Conclusion: In this large cohort, the prescription of allopurinol was not associated with increased risk of renal function deterioration. This is an important message for health care providers, highlighting that therapy for gout with allopurinol should not have a harmful effect on renal function.

Effect of Poverty Status in 2009, % of Years in Poverty Between 2003 and 2009, and Exiting Poverty Permanently By 2009 on SLE Damage in 2015

Edward H. Yelin[1], Jinoos Yazdany[2] and Laura Trupin[3], [1]Medicine/Rheumatology, UC San Francisco, San Francisco, CA, [2]Rheumatology, University of California, San Francisco, San Francisco, CA, [3]Medicine/Rheumatology, University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Plenary Session II: Discovery 2016

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose : The relationship between poverty and SLE damage has been observed in several cross-sectional studies. The aim of the present study was to use longitudinal data to examine the effects of poverty status, dose of poverty, and exiting poverty on subsequent disease damage.

Methods: Data are from the UCSF Lupus Outcomes Study. Study participants were recruited from diverse sources in 2003 and followed through 2015 through annual structured surveys. SLE diagnoses were confirmed by medical record review. In each year we characterized the respondents' poverty status in the surveys based on household income and family size. Beginning in 2009, the survey included a validated measure of disease damage, the Brief Index of Lupus Damage. We used ordinary least squares regression to estimate the impact of 1) poverty in 2009, 2) the dose of poverty defined as the percentage of years in poverty between 2003 and 2009, and 3) the effect of permanently leaving poverty by 2009 on change in damage between 2009 and 2015, with and without adjustment for potential confounding variables (demographics, education, SLE duration, characteristics of health care, and health behaviors). To account for attrition and missing variables, multiple imputation was used.

Results: In 2009, there were 783 respondents to the Lupus Outcomes Study annual survey, of whom 94% were female, 35% non-white, and 15% were in poverty. They were 49.8(SD12.3) years of age and had had SLE for 16.9(SD8.3) years. Damage scores averaged 1.9(SD2.0, range 0-12). Table 1 shows the effect of poverty in 2009, dose of poverty between 2003 and 2009, and exiting poverty permanently by 2009 on change in damage, with and without adjustment. Those in poverty had greater increases in damage as did those continuously poor vs. poor some years vs. never poor. Exiting poverty was associated with change in damage scores closer to that among those who were never poor with the passage of as little as a year and smaller than those who remained poor. In all analyses, adjustment had minimal effect on results, indicating that the effect of confounding variables was minimal.

Conclusion: Persons with SLE who were poor in all years experience greater accrual of damage than those who were poor only some years and those who were never poor, but exiting poverty is associated with a decreased accrual of damage. Income support policies may be critical to reducing damage in SLE.

Table 1. Effect of Poverty, Percent of Years in Poverty, and Exiting Poverty on Change in BILD Damage Scores, 2009-2015

	Poverty Status in 2009		Percent of Years in Poverty, 2003-2009			
	Poor	Not Poor	All Years	≥50% of Yrs.	<50% of Yrs.	Never Poor
Unadjusted	2.02	1.33	2.52	159	1.54	1.32
Adjusted	1.97	1.34	2.45	1.45	1.49	1.34
		Exited Poverty Permanently by 2009				
	Stayed Poor	**1 Yr. Ago**	**2-3 Yrs. Ago**	**5-11 Yrs. Ago**	**Total**	**Never Poor**
Unadjusted	2.08	1.47	1.43	1.17	1.40	1.33
Adjusted	1.98	1.24	1.44	1.08	1.30	1.36

Cells are change in damage scores. Adjusted models include demographics, duration, health care characteristics and health behaviors. Change in damage scores differs significantly by poverty status, percent of years in poverty, and exiting poverty, with and without adjustment ($p < .05$).

How Do Bone Marrow Lesions Cause Osteoarthritis Pain? a Structural and Functional Tissue-Based Study

Nidhi Sofat[1], Lena Assi[2], Anasuya Kuttapitiya[3], Alan Boyde[4], Vivian Ejindu[5] and Christine Heron[5], [1]Basic Medical Sciences, St. George's, University of London, London, United Kingdom, [2]St George's University of London, Institute for Infection & Immunity, London, United Kingdom, [3]St George's, University of London, Institute for Infection & Immunity, London, United Kingdom, [4]Queen Mary University of London, London, United Kingdom, [5]Department of Radiology, St George's Hospital, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Plenary Session II: Discovery 2016
Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose: Bone marrow lesions (BML) are well described in osteoarthritis (OA) and associate with pain, but little is known about histological and functional features of BMLs. We evaluated BMLs using novel tissue analysis tools to understand how they mediate pain.

Methods: Subjects fulfilling ACR criteria for knee OA were recruited with early and advanced OA with matched controls (n=96). Advanced OA subjects had a total knee replacement (TKR)(n=72). Early knee OA subjects had pain but did not require surgery (n=12). Controls (n=12) were recruited for pain measures and tissue comparisons from non-OA knee surgery. All subjects were assessed by Western Ontario and MacMaster Universities Osteoarthritis Index (WOMAC). Participants had knee MRI to define BML characteristics and tissue damage. Tissue was harvested at TKR for BML analysis using scanning electron microscopy (SEM) and tissue microarray using Illumina. For SEM, tissue blocks were embedded in poly (methylmethacrylate) to give intact tissue and analysed to obtain 3 Dimensional SEM. For microarray, RNA was isolated and reverse transcribed using the Qiagen system and subjected to microarray.

Results: The mean (SD) total WOMAC scores in the groups were: advanced OA 1436.2 (471.6), early OA 797.4 (549.6) and controls 10.5 (12.6), demonstrating that the advanced OA group had severe pain ($p<0.0001$). MRI scoring in the advanced OA group showed all had tibial and femoral BMLs. SEM found most normal bone marrow was adipocytic with adipocytes the major bone lining cells, making and moulding trabecular excrescences. Bone volume fraction was starkly reduced in BMLs, with marrow replaced by dense fibrous connective tissue, hyaline cartilage and fibrocartilage. Aggressive resorption was found at the periphery of BML patches and areas of calcified cartilage deep in the bone, arising by mineralisation of cartilage formed within the bone organ (Figure 1). Microarray of 24 samples from the knee OA BMLs and controls showed 218 genes were differentially regulated compared with control samples ($p<0.05$). Gene groups demonstrating highest levels of regulation included extracellular matrix proteins, thrombospondin 4, chondrocyte-expressed matrix metalloproteinases (MMP-13), neuro-epithelial and axonal development proteins, pro-inflammatory cytokines and catenin signalling.

Conclusion: Our work is the first to employ SEM and microarray in one study to interrogate OA BMLs. We have

found that BMLs demonstrate areas of high metabolic activity, expressing cartilage proteins and enzymes in addition to neuronal differentiation proteins which could explain why they are strongly associated with pain.

2015 ACR/ARHP Workforce Study in the U.S.: The Role of Graduate Medical Education (GME) in Adult Rheumatology

Background/Purpose: The 2015 ACR/ARHP Workforce Study provides a projection of the supply and demand for rheumatology care 2015-2030. GME plays a critical role, through training, to provide the flow of new rheumatologists into our field and is thus essential for addressing the gap of excess demand for adult rheumatology services.

Methods: ACR member data, state licensure registries, ABIM certificates, AAMC, ACGME, and National Resident Matching Program data, and an online survey of ACR members, were used to provide practitioner demographics, work settings, full/part-time status, retirement planning and numbers of fellows in training (FIT). Projections were made of the future supply of adult rheumatologists based on the current workforce, fellowship graduation rates, succession planning, workload, practice settings and generational changes. Factors used in demand projections included patient demographics, healthcare usage, practice trends, disease prevalence, U.S. population growth, and per capita income. We assumed one clinical practice full time equivalent (FTE) to be 1.0 FTE for private practitioners and 0.5 FTE for academic practitioners.

Results: The current supply of rheumatologists is 4,497 FTE but by 2030 is projected to fall by 31% to 3,455. The current demand for rheumatologists is 5615 FTE, 1,118 (36%) more than the supply. By 2030, excess demand will be 4,729 (138%) more than supply. There are 113 adult rheumatology programs with 431 available positions. If all positions fill, 215 fellows are expected to graduate each year (42 more fellows/year than the 2005 workforce study). Assuming a 100% position fill rate/year and no changes in the number of fellow positions offered, the average number of Clinical FTE of adult fellows projected to enter the workforce yearly is less than 215, at 107, based on the projected number of female millennials who plan to work part-time and the almost 20% of international medical graduates (IMG) who plan to practice outside the U.S. Adding to the workforce deficit, about 50% of the rheumatology workforce is projected to retire over the next 15 years with over 80% of those retiring planning to reduce their patient load by > 25% in the near term (Figure 1).

Conclusion: The current U.S. adult rheumatology workforce is in jeopardy of an accelerated decline due to decreased productivity and accelerated attrition. While it remains critical to recruit medical students and residents to pursue training in rheumatology, this will not provide ample numbers of rheumatologists to meet the

deficit in supply. Efforts to close this gap are essential and should include incentives for pursuing rheumatology training such as loan repayment, innovative mechanisms for GME funding, enhanced use of nurse practitioners and physician assistants in clinical practice, and novel strategies to improve patient access to care.

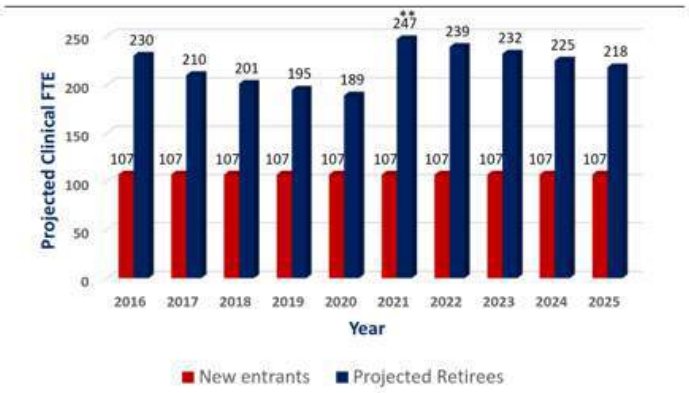

Figure 1. Comparison of Clinical FTE of New Entrants vs. Projected Retirees of Adult Rheumatologists 2016 to 2025; **Workforce modeling saw a jump in 2021 due to increased retirement projections coupled with increased projected patient load reduction in 2020.

Session Title: Antiphospholipid Syndrome
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Antiphospholipid syndrome (APS) is an autoimmune disease with incompletely understood etiology, characterized by recurrent thrombosis and pregnancy complications. We conducted this study to understand the genetic basis of primary APS.

Methods: We studied two independent cohorts of primary APS patients of European descent, consisting of 89 patients and 3072 healthy controls from Spain, and 133 patients and 1560 healthy controls from Italy. Genotyping of ~200,000 variants was performed using the HumanImmuno v1 BeadChip. Genetic association analysis was performed following rigorous quality control measures. A meta-analysis between the two cohorts was performed to identify susceptibility loci for primary APS. Additional genetic variants within loci of suggestive genetic association were imputed up to the 1000 Genomes Project density and then included in the analysis.

Results: We identified a novel genetic susceptibility locus for primary APS in *PLEK*, encoding pleckstrin, which plays an important role in hemostasis and platelet function (odds ratio= 1.71, P=7.89 x 10-6). Importantly, expression quantitative trait loci (eQTL) analysis revealed that the disease risk allele in *PLEK* is associated with significant reduction in *PLEK* mRNA expression (P=2.6 x 10-6), and is located within an active enhancer region identified by histone H3K27 acetylation and DNase hypersensitivity. Our data also confirmed the genetic association between APS and *STAT4* (odds ratio= 1.66, P=4.67 x 10-6). The association within the HLA was the most significant genetic association detected for APS in our study, with the most robust effect within HLA class II upstream of *HLA-DQA1* (OR 1.87, P=2.45 x 10-8).

Conclusion: This is the first genome-wide association study in primary APS. Our findings suggest a novel putative functional genetic susceptibility locus for primary APS in *PLEK*, and identify genetic susceptibility loci within the HLA class II locus and the common autoimmunity locus in *STAT4*. *MAR and AS equally contributed to this work

Session Title: Antiphospholipid Syndrome

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Treatment of the thrombotic manifestations of antiphospholipid syndrome (APS) primarily focuses on inhibiting clotting pathways. In an effort to identify upstream inflammatory targets that might launch these pathways, we investigated APS patient neutrophils.

Methods: We isolated neutrophils from the peripheral blood of 9 primary APS patients (as defined by Sydney criteria) and 9 healthy controls matched for age, sex, and ethnicity. A comprehensive transcriptome analysis was performed using paired-end 100bp mRNA sequencing reads generated on an Illumina HiSeq 2000 instrument. RNA sequencing data were normalized and analyzed using the EdgeR software package in the R programming environment. Differential gene expression between patients and controls was defined using a fold difference of >2 and a false discovery rate <0.01. Gene ontology, pathway, and functional enrichment analyses were performed. To model APS-associated venous thrombosis in mice, IgG fractions were prepared from either healthy volunteers or patients with primary APS, who had high-titer IgG anti-β_2GPI. C57BL/6 wild-type mice were treated with control or APS IgG by intraperitoneal injection. A laparotomy was then performed, and a ligature was fastened around the inferior vena cava (IVC) to cause an 80-90% reduction in IVC blood flow. Thrombus formation in the IVC was assessed 6 hours after the procedure. Mechanistic details were further elucidated using P-selectin glycoprotein ligand 1 (PSGL-1) knockout mice, adoptive transfer of neutrophils, and an inhibitory anti-PSGL-1 antibody.

Results: RNA sequencing analysis identified 593 overexpressed and 769 underexpressed genes in neutrophils from primary APS patients compared to age, sex, and ethnicity matched healthy controls. APS neutrophils demonstrate a pro-inflammatory phenotype with prominent transcriptional overexpression of interferon-regulated genes, the Toll-like receptor signaling pathway, Fc-gamma receptors, and adhesion molecules, including the leukocyte selectin ligand PSGL-1. The expression of neutrophil PSGL-1 was further characterized in an independent cohort of 15 primary APS patients, again revealing upregulation as compared to matched controls. In a flow-restriction model of IVC thrombosis, the introduction of APS IgG (as compared to control IgG) increases both thrombus size and thrombosis frequency in wild-type mice. While APS IgG does *not* accelerate thrombosis in PSGL-1 knockout mice, the phenotype can be rescued with infusion of wild-type neutrophils into PSGL-1 knockout mice. As proof of therapeutic potential, an anti-PSGL-1 monoclonal antibody inhibits APS IgG-mediated thrombosis in wild-type mice.

Conclusion: APS neutrophils demonstrate a baseline activated phenotype, which includes the upregulation of adhesion molecules. In a model of venous thrombosis, neutrophil PSGL-1 is required for APS IgG-mediated acceleration of thrombosis. PSGL-1 represents a potential therapeutic target in APS.

Thrombospondin-1 Is Elevated in the Plasma of Patients with

Antiphospholipid Syndrome and Is Correlated with Free Active TGF-b1 Levels, IL-1b and IL-17A

Markos Patsouras, Athanasios G. Tzioufas and Panayiotis G Vlachoyiannopoulos, School of Medicine, Pathophysiology Department, National and Kapodistrian University of Athens, Athens, Greece

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Antiphospholipid Syndrome

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Antiphospholipid syndrome (APS) is an acquired thombophillia characterized by recurrent thromboembolism and pregnancy morbidity. Thrombospondin (TSP-1) is a matricellular glycoprotein secreted by platelets upon activation with proinflammatory, antiangiogenic and pro-apoptotic properties. TSP-1 activates TGF-β_1 and has been shown to be involved in TH-17 response. We aimed to investigate the role of Thrombospondin-1 in APS.

Methods: The study involved 90 patients with APS, 46 healthy controls (HC) and 26 SLE patients. Plasma, serum, and total IgG were isolated from all groups. Monocytes and CD4+ T-cells were isolated from 4 HC. Human Umbilical Vein Endothelial Cells were isolated from 2 APS patients and 5 HC and cultured with plasma or total IgG from HC or APS patients. Monocytes were stimulated with total IgG and these supernatants were used to stimulate CD4+ T-cells. Plasma and cell culture supernatant were analyzed for the presence of: TSP-1, IL-1b, IL-17A and free active TGF-b_1 levels using an ELISA.

Results: APS patients had higher plasma levels of TSP-1 than HCs and SLE patients (APS: mean 390ng/ml vs HC: 144.3 vs SLE: 153.0 $p<0.0001$) Patient plasma free active TGF-b1 levels were higher and strongly correlated with TSP-1 ($r =0.827$ and $p<0.0001$). Among the APS patients those with TSP-1 levels >600ng/ml had detectable IL-1b and IL-17A in their plasma. APS HUVECs cultured under standard conditions and HC HUVECs cultured with APS plasma expressed higher levels of TSP-1 than HC HUVECs cultured with HC plasma. (APS=139.4ng/ml vs HC=22.8ng/ml $p=0.0009$). Monocytes stimulated with APS total IgG produced higher levels of IL-1b and TSP-1 compared to the ones stimulated with HC IgG (700pg/ml vs 50pg/ml and 500ng/ml vs 200ng/ml respectively). APS stimulated supernatants induced the expression of IL-17A from healthy donor T-cells (250pg/ml) whereas the HC had no effect. Patients with APS and pregnancy morbidity alone expressed lower TSP-1 levels (130.1ng/ml) than APS patients with miscarriages and thrombosis (403.2ng\ml).

Conclusion: Preliminary results suggest that APS patients have higher TSP-1 plasma levels which correlate with free active TGF-b1. Monocytes and HUVECs treated with APS plasma and APS IgG produce higher levels of TSP-1 and IL-1b and these supernatants induce the expression of IL-17A from naïve T-cells. All these suggest a possible involvement of TSP-1 in thrombus formation, inflammation and inhibition of angiogenesis that needs further study.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Antiphospholipid Syndrome
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: APS ACTION International Clinical Database and Repository was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL)-positive patients with/without other systemic autoimmune diseases (SAIDx). Although, IgA aCL and IgA aβ_2GPI were included in the new SLICC systemic lupus erythematosus (SLE) classification criteria, the prevalence and clinical significance of IgA isotype have been controversial. Thus our objective was to better define the prevalence and clinical significance of IgA aCL and aβ_2GPI in aPL-positive patients with/without SLE.

Methods: A web-based data capture system is used to store patient demographics, aPL-related history, and medications. The inclusion criteria are positive aPL based on the Updated Sapporo classification criteria at least twice within one year prior to enrolment. Patients are followed every 12±3 months with clinical data and blood collection. The baseline samples are analysed in the APS ACTION core laboratories to confirm aPL-positivity. For this cross sectional study, using chi square test, we compared the demographic and clinical characteristics of aPL-positive patients with/without SLE based on different aCL/aβ_2GPI isotypes.

Results: As of April 2016, 638 aPL-positive patients recruited from 24 centers; 489 (77%) had core laboratory assessments of IgG/M/A aCL/aβ_2GPI. Forty-two patients were excluded due to the diagnosis of a SAIDx other than aPL/APS and/or SLE. Thus, 320 (72%) aPL-positive patients without SLE (258 [81%] with APS) and 127 (28%) with SLE (96 [76%] with APS) were analyzed. The frequency of aCL and aβ_2GPI IgG/M/A positivity (defined as > 20U) was not different between the two groups except the IgG isotype, which was more common in aPL-positive patients without SLE (53% vs 42% [p: 0.03] for aCL and 38% vs 21% [p: 0.03] for aβ_2GPI). However, the frequency of IgA aβ_2GPI positivity was 3-fold higher than IgA aCL positivity (33% vs 11% [p<0.001] in those with SLE, and 32% vs 12% in those without SLE [p<0.001]). The demographics and aPL-related clinical manifestations were not different among aCL/aβ_2GPI IgG, IgM, and IgA isotypes (Table). The results were similar when the aCL/aβ_2GPI ELISA cut-off was set to 40U. Of note, the frequency (%) of isolated aCL IgG/M/A- and aβ_2GPI IgG/M/A-positive patients (independent of the LA status) were 22/19/1 and 11/11/8,

respectively (when the ELISA cut-off was set to 20U); isolated aβ_2GPI IgA positivity was significantly higher in aPL-positive patients with SLE, compared to those without SLE (p: 0.006).

Conclusion: Although IgA aβ_2GPI positivity is more common than IgA aCL positivity, especially in SLE, the aCL/aβ_2GPI IgA isotype does not distinguish between aPL-positive patients: a) with/without SLE; and b) with different aPL-related clinical events.

Table: Clinical features of All IgG, IgM and IgA aPL positive patients, cut-off aPL ELISA ≥20u.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Antiphospholipid Syndrome
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: APS ACTION Registry was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL)-positive patients. Previously, based on five new thrombotic events, we reported the one-year first and recurrent thrombosis risk in persistently aPL-positive patients as 0% and 1.7%, respectively (Erkan et al. *Arthritis Rheumatol*. 2015; 67 [suppl 10]). The objective was to report additional thrombotic events based on one-, two-, and three-year follow-up visits.

Methods: A web-based data capture system is used to store patient demographics, aPL-related history, and medications. The inclusion criteria are positive aPL based on the Updated Sapporo Classification Criteria at least twice within one year prior to enrollment. Patients are followed every 12±3 months; they also receive advice on cardiovascular disease and thrombosis prevention at each visit. We report the new events in a descriptive fashion.

Results: As of April 2016, 627 patients included in the APS ACTION Registry (aPL/APS without any other autoimmune disease: 410, and aPL/APS associated with another autoimmune disease: 217). Of 627 patients, 432 (67.7%), 244 (38.2%), and 43 (6.7%) completed their one-, two-, and three-year follow-up visits, respectively. Mean follow up times were 1.67 years (505 patient-years) and 1.65 years (215 patient-years) for those with and without a history of thrombosis, respectively. Based on a total of 12 recurrent (7 events during the 1st year; 3 during the 2nd year; and 2 during the 3rd year) and four initial (2 events during the 1st year; 1 during the 2nd year; and 1 during the 3rd year) events since the inception of the registry (Table), the incident thrombosis risk was 2.37 and 1.86 per 100 patient-years in patients with and without history of thrombosis, respectively. The annual thrombosis risk was 2.38% and 1.86% in patients with and without history of thrombosis, respectively.

Conclusion: The incident thrombosis risk is relatively low and commonly associated with lupus anticoagulant and/or triple aPL-positivity as well as non-aPL thrombosis risk factors in our multi-center international cohort. Annual and risk stratified analysis of APS ACTION registry will better determine the risk of thrombosis in persistently aPL-positive patients based on different risk profiles.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Antiphospholipid Syndrome
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The domain reactivity of antibodies against b2 glycoprotein I (anti-b2GPI) has been investigated in patients with thrombotic anti-phospholipid syndrome (APS), leading to the identification of antibodies targeting domain 1 of the molecule (anti-D1) as the most relevant autoantibody subpopulation. Scarce attention has been paid to the domain profiling of patients with pregnancy morbidity (PM). The aim of this study was to characterize the relevance of the fine epitope reactivity of anti-b2GPI antibodies in anti-phospholipid antibody (aPL)-associated PM.

Methods: Women with persistent positivity for anti-b2GPI IgG antibodies at medium-high titers, with at least one pregnancy and without systemic autoimmune disease were included. Anti-D1 and anti-D4/5 antibodies were tested using a chemiluminescent immunoassay and a research ELISA assay, respectively (QUANTA Flash b2GPI IgG and QUANTA Lite, Inova Diagnostics). Statistical analysis was performed using R package.

Results: 138 women fulfilling the inclusion criteria were retrospectively recruited at 3 referral centres. 49 patients (35%) had obstetric APS, 18 (13%) thrombotic APS, 37 (27%) thrombotic and obstetric APS while 34 women (25%) were asymptomatic aPL carriers. 81 women (60%) displayed triple aPL positivity, 32 (23%) had two positive aPL test and 23 (17%) carried a single aPL positivity. 110 patients had at least one untreated pregnancy, culminating in a live birth in 31 cases (28%). 89 women underwent a pregnancy course while receiving treatment, with 71 women (80%) having a live birth. A significant difference in the distribution of positive anti-D1 antibodies emerged between women with or without PM and with or without thrombosis ($p=0.05$, $c^2=2.710$ and $p<0.001$, $c^2=12.174$, respectively); no significant difference was observed for anti-D4/5 antibodies (**Table 1**). In a multivariate logistic regression model also encompassing treatment, positive anti-D1 antibodies, but not anti-D4/5, were significantly associated with obstetric complications, conferring an odds ratio (OR) of 2.32 ($p=0.040$ and $p=0.724$, respectively). Triple aPL positivity corrected by treatment significantly predicted PM ($p=0.015$, OR=2.78).

Conclusion: Our data suggest that anti-D1 antibodies are significantly associated not only with thrombosis but also with obstetric morbidity while positive anti-D4/5 antibodies are not predictive of PM. **Table 1. Different combinations of reactivity against D1 and D4/5 in women with or without pregnancy morbidity (PM) according to the updated classification Criteria for APS and in women with or without thrombosis.**

	No PM (%)	PM (%)	No thrombosis (%)	Thrombosis (%)
Anti-D1+/anti-D4/5-	15 (29%)	43 (50%)	27 (33%)	31 (56%)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: African American (AA) people with Systemic Lupus Erythematosus (SLE) are at high risk for severe disease and depression, and often require complex medication regimes. Prior data suggest that AA patients with SLE have poor medication adherence; however little is known about the leading patient-centered factors. We sought to examine the effect of depression, medication satisfaction, and self-confidence to manage lupus on treatment adherence in an AA population with SLE.

Methods: The Georgians Organized Against Lupus (GOAL) is a longitudinal cohort of patients with SLE living in Atlanta, predominantly derived from the population-based Georgia Lupus Registry. Since 2011, participants are surveyed annually on multiple exposures and outcomes. For this study, we selected all AA participants who completed the Morisky Medication Adherence Scale (MMAS-8) in 2015. MMAS-8 scores range from 0-8 and a cutpoint <6 has been validated as indicator of low adherence. Depressive symptoms were assessed with the Patient Health Questionnaire (PHQ-9) and categorized as minimal, mild/moderate, and moderately severe/severe depressive symptoms using clinically validated cutpoints. Self-confidence was assessed with the Stanford Self-efficacy 6-item Scale, and medication satisfaction with an ad-hoc 4-point Likert scale question (How satisfied are you with your current lupus medication options?). The association between patient centered-factors and low adherence (MMAS-8 <6) were examined with multiple logistic regression. Self-reported disease activity, organ damage, and demographic factors were tested as covariates.

Results: We examined 632 AA participants (93% females; 44% living below the poverty level; 43% under- or uninsured). Mean age, disease duration and education at survey were 48, 15 and 14 years, respectively. Mild to severe depressive symptoms were endorsed by 392 (63%) and low adherence by 329 (54%) participants. Multivariate analysis revealed that the odds of low adherence were significantly higher in those with mild/moderate (OR= 2.3) and moderately severe/severe (OR= 2.4) depressive symptoms, compared to those with none/minimal symptoms. While women and younger participants were more likely to be low-adherent, disease activity, organ damage and other patient-centered factors were not associated with treatment adherence.

Table 1. Factors associated with Low Treatment Adherence* in AA patients with SLE

Factor	OR (95% CI)	P value
Depressive symptoms (ref: none/minimal)		
Mild/Moderate	2.28 (1.45-3.58)	0.0003
Moderately severe/Severe	2.41 (1.25-4.66)	0.0007
Female gender	2.83 (1.35-5.96)	0.0061
Age at Survey (per 5 years ↓)	1.10 (1.02-1.18)	0.017
Education (per 3 years ↑)	1.16 (0.95-1.43)	0.15
Disease activity score (per 1 unit ↑ SLAQ score)	1.02 (0.99-1.05)	0.11
Confidence of manage lupus (per 1 point ↑)	0.96 (0.88-1.05)	0.35
Severe organ damage (SA-BILD score ≥3; ref: 0-2)	0.92 (0.63-1.34)	0.66
Under or uninsured	1.02 (0.69-1.51)	0.93
Unsatisfied/Somewhat unsatisfied with medications	1.35 (0.74-2.46)	0.33

*Low adherence defined as MMAS-8 <6; SLAQ: Systemic Lupus Activity Questionnaire; SA-BILD: self-administered Brief Index Lupus Damage.

Conclusion: Over half of AA patients with SLE are low adherent to their medications, and over 60% have depressive symptoms ranging from mild to severe. Women, those of younger age, and those with depressive symptoms are at high risk of low adherence. Notably, satisfaction with treatment and self-confidence were not associated with adherence. Our findings point to the need for wide-scale depression screening and effective depression management interventions as means to potentially improve treatment adherence in AA populations with SLE.

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Adverse childhood experiences such as extreme deprivation, neglect, abuse, parental separation or incarceration, have been associated with adult health status, including onset of rheumatic diseases.

It has been hypothesized that cumulative trauma may have long term effects on immune regulation, putting children at greater risk for autoimmune disease as adults. However, there has been no research on the association of adverse experiences in childhood with outcomes of rheumatic diseases. In this analysis, we examine the association of adverse experiences in childhood with disease activity and damage, depression, and quality of life among adults with systemic lupus erythematosus (SLE).

Methods: Data were derived from the California Lupus Epidemiology Study (CLUES), a population based, multi-ethnic cohort of patients with SLE begun in 2015. Participants completed an extensive interview including validated self-report measures of SLE activity (Systemic Lupus Activity Questionnaire; SLAQ) and damage (Brief Index of Lupus Damage; BILD), quality of life (SF-36), depression (Patient Health Questionnaire; PHQ-8) and sociodemographic measures. They also completed the Adverse Childhood Experiences (ACE) questionnaire, a validated 8-item scale included in the Behavioral Risk Factor Surveillance System, covering parental separation, mental illness or suicide, incarceration, dysfunction due to drugs or alcohol, and verbal, physical or sexual abuse prior to age 18. Each endorsed item is given one point, and the scores were categorized as 0, 1, 2-3, and ≥4. We compared SLE outcomes by ACE score categories using ANOVA.

Results: To date, 126 CLUES participants have completed the ACE questionnaire. Participants were mostly women (88%) and racially diverse (30% white, 23% Hispanic, 15% African American, 30% Asian American). Mean age was 44±14; mean age at diagnosis 27±12. Among the individual ACE items, parental separation or divorce was most commonly reported (34%), but nearly all the items were endorsed by at least 10% of participants. Median ACE score was 1, and 20 (16%) had a score of 4 or higher. ACE scores ≥4 were more common in Hispanic (24%) and African American (37%) participants, and in participants with poverty level income (50%). Scores did not differ by age at study entry or diagnosis. Higher ACE scores were associated with greater SLE activity and damage, poorer quality of life, and higher levels of depressive symptoms (Table).

Conclusion: Adverse childhood experiences are reported frequently among individuals with SLE and appear to be associated with poor SLE outcomes. As the cohort expands, we will compare ACE scores in the cohort to the general population and examine the associations between childhood experiences and SLE outcomes in a multivariable context that takes into account sociodemographic differences.

ACE Score categories					
Outcomes	0 (n=52)	1 (n=26)	2-3 (n=28)	≥4 (n=20)	p-value
SLE activity (SLAQ)	5.4 (5.3)	6.3 (5.4)	12.9 (7.5)	12.6 (8.8)	<0.001
SLE damage (BILD)	1.9 (2.1)	1.5 (1.6)	1.9 (2.3)	3.3 (3.1)	0.05
Quality of life (SF36 PCS)	45.6 (10.6)	44.8 (9.0)	38.8 (11.0)	27.4 (8.9)	<0.001
Depressive symptoms (PHQ-8)	4.4 (4.1)	4.1 (3.7)	8.5 (5.2)	8.3 (4.2)	<0.001
Table values are mean (sd) of outcome measure.

Peer Approaches to Lupus Self-Management (PALS): A Novel Lupus Peer Mentorship Intervention

Edith M. Williams[1], Leonard Egede[2], Jim Oates[3], Delia Voronca[2] and Mulugeta Gebregziabher[2], [1]Public Health Sciences, Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, SC, [3]Medicine/Rheumatology & Immunology, Medical University of South Carolina, Charleston, SC
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Healthcare Disparities in Rheumatology
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that is associated with increased morbidity, mortality, health care costs and decreased quality of life. In the United States, African Americans have three to four times greater burden of lupus compared with Caucasians, with the highest rates experienced by African American women. While evidence-based self-management interventions that incorporate social support and health education have reduced pain, improved function, and delayed disability among lupus patients, persistent disparities may be due to the non-responsiveness of existing programs to the unique needs of African Americans and/or women with lupus. Peer mentoring interventions are effective in other chronic conditions that disproportionately affect minorities, such as diabetes, HIV, and kidney disease, but there is currently no empirically tested peer mentoring intervention developed for SLE patients.

Methods: A literature review, needs assessment, and patient interviews guided the development of a peer mentoring training manual and intervention. The intervention was piloted with African American women with lupus participating in the SLE database at the Medical University of South Carolina. Seven mentors were trained and paired with 21 mentees to encourage mentees to engage in activities that promote the learning of disease self-management skills and to support the mentees' practice of these learned skills by telephone for at least 60 minutes every week for 12 weeks. Mentee outcomes of self-management, disease progression (including disease activity, damage, and cytokine balance) were obtained at baseline, mid-intervention (6 weeks from baseline), and immediately post-intervention (12 weeks from baseline), using validated tools. All participants met at least four components of the 1997 ACR revised criteria for SLE. Descriptive statistics and effect sizes will be calculated to determine clinically important (>0.3) changes.

Results: Preliminary data from the PALS pilot study suggest that the peer mentoring intervention is credible, acceptable and likely to be effective at improving self-management, decreasing disease activity and improving quality of life in women with SLE. Between baseline and 6 weeks (mid-intervention), mentees (n=20) reported increased social support; improved physical functioning, general health, social functioning, vitality, and patient activation; and decreased physical limitation, bodily pain, and emotional limitation. Observed changes exceeded the clinically meaningful level of 0.3, suggesting that the intervention will likely be effective at 12 weeks. At 6 weeks, both mentees (n=20) and mentors (n=7) gave high ratings for perception and credibility of the intervention. Post-intervention (12 week) data is currently being analyzed and will be shared.

Conclusion: Given the success of the peer mentoring approach, and its responsiveness to the needs of this unique population, this intervention could result in health improvements that have not been attainable with other interventions. This could lead to significant reductions in disparities and have considerable public health impact.

Disparities in Access to Specialist Care at the Time of Diagnosis of Systemic Lupus Erythematosus

Lisa Gaynon[1], Patricia P. Katz[2], Maria Dall'Era[3], Laura Trupin[2], Lindsey A. Criswell[4], Cristina Lanata[4], Charles Hemlick[5] and Jinoos Yazdany[2], [1]Internal Medicine, California Pacific Medical Center, San Francisco, CA, [2]Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA, [3]Division of Rheumatology, University of California, San Francisco, San Francisco, CA, [4]Division of Rheumatology, UCSF, San Francisco, CA, [5]Centers for Disease Control and Prevention, Atlanta, GA

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Healthcare Disparities in Rheumatology
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Disparities in outcomes among racial/ethnic minorities and individuals with low socioeconomic status with systemic lupus erythematosus (SLE) have been well reported. The degree to which these populations have delayed access to specialists, particularly at the time of diagnosis, is less well described and was the focus of this study.

Methods: Data were derived from the California Lupus Epidemiology Study (CLUES), a population-based, longitudinal, multi-ethnic cohort of patients with SLE. Data were collected via annual telephone interviews as well as in-person clinical visits. Questions on access to care included time from onset of symptoms to diagnosis of SLE, the specialty of the diagnosing physician, the time until first visit with a specialist (rheumatologist or nephrologist) if not diagnosed by one, and the specialty of the physician currently managing SLE. The significance of the relationships between these variables and race, poverty level, education level and health literacy was determined through chi-squared tests.

Results: This study included 196 patients, with a mean age of 45 (SD 15) years. Thirteen percent had an education level ≤ high school, 34% had limited health literacy and 13% were below 125% of the federal poverty level. The racial/ethnic distribution was 30% Caucasian, 22% Hispanic, 14% African-American and 33% Asian. The time from symptom onset to receiving a diagnosis of SLE varied, with 32% diagnosed in ≤3 months, 22% in 3-6 months, 15% in 6-12 months and 32% in >12 months. There were no significant differences for this outcome by race, education, literacy or poverty level. Of the 84 (43%) patients who received their initial diagnosis from a physician other than a rheumatologist or nephrologist, 64 (76%) were referred to a rheumatologist or nephrologist within 3 months but 20 (24%) experienced a delay >3 months. There was a significant difference in the time to referral to a specialist by race and education level: 64% of African-Americans and 66% of Asians saw a specialist within 3 months of diagnosis, compared with 92% and 85% for Caucasians and Hispanics respectively ($p=0.02$). For those with an education level ≤ high school, 45% were referred within the first 3 months compared with 81% of those with a higher level of education ($p=0.01$).

Conclusion: The time from symptom onset to diagnosis of SLE varied greatly within this population, with up to 32% waiting over 1 year for a diagnosis. Roughly a quarter of SLE patients not initially diagnosed by a

rheumatologist or nephrologist experienced a delay in access to specialty care at the time of diagnosis. Of these patients, African-Americans and Asians, as well as those with a lower level of education had the longest delays in accessing specialists.

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Disparities in access to care to pediatric rheumatologists have been described in JIA, but little has been published in regards to pediatric lupus. We aimed to examine demographic and clinical features of pediatric lupus patients in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry with delays to first encounter with a pediatric rheumatologist and to investigate associations between delays and disease outcomes.

Methods: CARRA registry data for participants meeting ACR classification criteria for lupus were analyzed. Delays of one month, 3 months, and one year from symptom onset to first encounter with a pediatric rheumatologist were examined. Predictors of delay, associations between levels of delay, and associations between delays and disease outcomes, including patient reported outcomes of pain and health-related quality of life, were investigated.

Results: Data from 598 participants were analyzed. The median time to first encounter with a pediatric rheumatologist was 1.4 months; 24% of participants had delays between 1-3 months, 23% between 3 months to one year, and 9% had delays of one year or more. The percentage of participants with a family history of SLE (p-trend=0.004) and percentage of participants from a low income household (p-trend=0.01) increased significantly with each level of delay, while younger ages of onset were observed with increasing delays (p-trend=0.001). In

multivariate regression models, presence of neurologic disease, absence of discoid rash, and location in a state with a low density of pediatric rheumatologists predicted delays of one month or greater. Younger age of onset, absence of proliferative lupus nephritis, and low density of pediatric rheumatologists predicted delays of 3 months or greater. Predictors for one year or greater were younger age of onset and low household income. Poor and very poor quality of life, disability by ACR functional class, moderate to severe pain, and worse patient/parent global wellness scores were associated with delays of 3 months or more when assessed on follow up. All of these effects were significant after controlling for baseline outcome status, age of onset, sex, and race/ethnicity except disability by ACR functional class. When accounting for low income in these models, delays of 3 months remained a significant predictor for only health related quality of life with OR 5.00 (CI 1.46, 17.18).

Conclusion: Severe delays of one year or more from symptom onset to first encounter with a pediatric rheumatologist exist in a notable minority of CARRA registry participants. Increasing delays in care are seen disproportionately in those who are younger, have a family history of SLE, and are from low income households. While location in an area with a low density of pediatric rheumatologists predicted delays of 1 month or greater and delays of 3 months or greater, no differences in the proportion of participants from these areas were seen between levels of delay. Delays of 3 months or more are associated with poorer outcomes, and worse health related quality of life even after accounting for confounding socio-demographic features.

Creatine Kinase in the United States Population: Impact of Demographics, Comorbidities and Body Composition on the Normal Range

Neilia-Kay McGill, Joshua F. Baker and Michael D. George, Rheumatology, University of Pennsylvania, Philadelphia, PA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The accurate interpretation of creatine kinase (CK) values is critical as this laboratory measure guides the workup of suspected myopathies. Incidentally discovered CK elevation is a common reason for rheumatology referral. This study comprehensively evaluated clinical factors associated with CK levels among a nationally representative sample and determined the distribution of CK levels in race-ethnicity subgroups.

Methods: Data was analyzed from the cross-sectional National Health and Nutrition Examination Survey (NHANES) 2011-2014, which interviews and examines a representative sample of the U.S. population. Included

subjects were non-pregnant adults ≥ 20 years old. Race-ethnicity was based on self-report. In analyses stratified by sex, linear and logistic regression was used to identified clinical variables associated with CK levels and the likelihood of an individual being outside of sex-specific reference ranges. To assess the role of muscle mass on race-ethnicity differences in CK, linear models were adjusted for body mass index (BMI), arm circumference, and waist circumference. In order to inform the appropriate upper limit of normal reference range, 95th percentiles of CK in sex/race-ethnicity subgroups were calculated, excluding patients with strenuous exercise in the past 3 days.

Results: A total of 10,096 subjects were included: 4119 non-Hispanic white, 2256 non-Hispanic black, 2159 Hispanic and 1270 Asian subjects. In linear and logistic regression, race-ethnicity was most strongly associated with CK among men and women. Compared to white subjects, CK was more likely to be abnormal in black men (OR 8.39, 95% CI 6.11 to 11.52) and in black women (OR 5.08, 95% CI 3.65 to 7.08). Greater BMI, chronic kidney disease, recent exercise, and physical activity were modestly associated with elevated CK, while men ≥ 70 were less likely to have an elevated CK (Table). Race-ethnicity differences in CK remained after adjustment for BMI, waist circumference, and arm circumference. The 95th percentile of CK was 312 (95% CI 268 to 356) in white men, 712 (95% CI 530 to 894) in black men, 188 (95% CI 122 to 254) in white women, and 323 (95% CI 218 to 428) in black women (Figure).

Conclusion: Creatine kinase values in the general population are substantially higher in black patients particularly among men. These racial differences are not explained by differences in body composition. Proposed reference ranges for race-specific subgroups in this study are markedly higher than current reference ranges and provide a practical guide for clinicians when interpreting CK values.

Table: Multivariable logistic regression of odds of having creatine kinase above the upper limit of normal (334 IU/L in males, 199 IU/L in females)

Session Title: Imaging of Rheumatic Diseases II: Ultrasound in Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The aim of this study was to compare the efficacy of intramuscular versus ultrasound (US)-guided peritendinous glucocorticoid injection in providing disease control after 2, 4 and 12 weeks in rheumatoid arthritis(RA) patients with tenosynovitis.

Methods: Fifty RA patients with tenosynovitis were randomised into two double-blind groups: A. “intramuscular group”, receiving intramuscular injection of betamethasone and US-guided peritendinous isotonic saline injection and B. “peritendinous group” receiving saline intramuscularly and US-guided peritendinous betamethasone injection. All patients were in stable disease-modifying anti-rheumatic drug treatment prior to and during the study. Patients were excluded, and considered non-responders, if any treatments were altered during the follow-up period. “US tenosynovitis remission”, defined as US tenosynovitis grey-scale score ≤1 and colour Doppler score=0, was assessed at week 4 (primary outcome), and weeks 2 and 12, using non-responder imputation for missing data. The tenosynovitis was assessed at baseline, 2, 4 and 12 weeks using the semi-quantitative scoring system for GS (0-3) and CD(0-3) as proposed by the OMERACT US group, clinical assessment and a patient reported pain tenosynovitis visual analogue scale (VAS tenosynovitis) from 0-100

Results: US tenosynovitis remission at week 4 was achieved in 25% (6/24) [95% confidence limits: 8%; 42%] in the “intramuscular group”, versus 64% (16/25) [45%; 83%] in the “peritendinous group” (Fisher exact test; $p<0.01$). Corresponding values for the “intramuscular group” versus the “peritendinous group” at 2 and 12 weeks were 21% [5%; 37%] versus 48% [28%; 68%] ($p=0.07$) and 8% (0%; 19%) versus 44% (24%; 63%) ($p<0.01$). Most US and clinical/patient-reported scores improved more in the “peritendinous group” at all follow up visits (see table 1).

Conclusion: In this randomised double-blind clinical trial, RA patients with tenosynovitis responded significantly better to US guided peritendinous glucocorticoid injection than to intramuscular glucocorticoid injection, both at 4 and 12 weeks follow up.

Table 1 Tenosynovitis outcome values: At baseline,changes within patients receiving the intramuscular BM injection group ("im group") and patients receiving US-guided peritendinous BM injection ("peritendinous group"), and differences between groups.

Session Title: Imaging of Rheumatic Diseases II: Ultrasound in Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Several studies have shown the presence of subclinical inflammation by ultrasound (US) in rheumatoid arthritis (RA) patients despite clinical remission according to clinical composite scores. However, no agreement exists on which joints to assess when monitoring RA patients in remission to reveal potential subclinical inflammation. The present objective was to evaluate if US examination of the hands is sufficient for this purpose.

Methods: A total of 209 patients with RA (mean (SD) age 53 (13) years, disease duration 10 (9) years, 81% women, 79% anti-CCP positive) were included when initiating bDMARDs, with 182 patients continuing at 6

months and 152 patients at 12 months. The patients were assessed at baseline and after 6 and 12 months with patient's global disease activity VAS, clinical examination (assessor's disease activity VAS, tender and swollen joint counts performed by a study nurse) and ESR. DAS28(ESR), CDAI, SDAI and ACR/EULAR Boolean remission were calculated. All US examinations (semi-quantitative scoring (0-3)) of GS and PD (PIP 2-3, MCP 1-5, wrist (RC, IC, RU), elbow, knee, tibiotalar, MTP 1-5 and extensor carpi ulnaris (ECU)/tibialis posterior (TP) tendons bilaterally) were performed by one rheumatologist (HBH) with high intra-reader reliability (using Siemens Acuson Antares, excellence version, 5-13 MHz probe, optimized for PD with no upgrading during the study). In all the calculations only GS ≥2 and PD≥1 were regarded as US pathology. To explore if bilateral examinations of the hands (wrist, MCP/PIP joints, ECU tendon) could represent overall US pathology, the percentages of patients with US pathology present only in other sites than the hands (i.e. elbow, knee, ankle, MTP joints, TP tendons) at 6 and 12 months were calculated.

Results: At 6 months, depending on the different composite scores, 20.7%-40.8% were in clinical remission, but in these patients, US pathology was commonly present (75.7% - 86.1% for GS and 67.6% - 77.2% for PD). At 12 months, 23.0%-38.8% of the patients were in clinical remission, still having GS and PD pathology in 60.0% - 78.0% and 57.1% - 72.5%, respectively (table 1 shows the percentage US pathology depending on joint regions). In patients in remission, there was a low frequency of patients with US pathology only in joints other than the hands (GS found in 13.2 - 17.1% and PD in 2.4- 8.1 % at 6 months and 12 months) (table 2).

Conclusion: A majority of patients in remission according to clinical composite scores still had US pathology (especially in wrist, finger and MTP joints). PD activity has been shown to be associated to radiologic damage, and presently a very low percentage of patients had PD activity not detected by examination only of the hands. Thus, a feasible US examination including only the hands seems to reveal most of the patients with subclinical inflammation.

	Percentages of GS/PD pathology in spite of clinical remission according to composite scores							
	6 months				12 months

Session Title: Imaging of Rheumatic Diseases II: Ultrasound in Rheumatoid Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Morning stiffness has long been recognized by both patients and rheumatologists as a characteristic feature of rheumatoid arthritis (RA). However, morning stiffness is no more included in 2010 ACR/EULAR Classification Criteria for RA or in major instruments for evaluating disease activity of RA such as Disease Activity Score (DAS), ACR Core Set, Simplified Disease Activity Index (SDAI), and 2011 ACR/EULAR Provisional Definition of Remission for the lack of solid evidence for its independent value. In this study, we aimed to clarify the associations between morning stiffness and synovial inflammation and determine the independent value and the optimal measurement of morning stiffness in patients with RA.

Methods: We enrolled 76 consecutive RA patients who underwent musculoskeletal ultrasound and agreed to participate in the study. In addition to asking the duration of morning stiffness, we asked patients to complete a diagram which represents the time course of their morning stiffness in the dominant hand. We also determined the activity of synovitis in 11 joints and tenosynovitis in 8 tendons/tendon compartments in the same hand by using power Doppler (PD) ultrasound with a semiquantitative score (0-3).

Results: Study patients were predominated by women (78.9%) with a mean age of 58.4 (SD 14.6) years and a median disease duration of 24 (IQR 8-63.75) months. Rheumatoid factor (RF) and anti-citrullinated protein antibody (ACPA) had been positive in 84.2% and 77.6%, respectively. For synovitis, swollen/tender joint counts more strongly correlated with total PD scores ($r = 0.379$-0.561, $p \leq 0.001$) than did any parameters of morning stiffness ($r = 0.217$-0.314, $p = 0.006$-0.021) (Table 1). For tenosynovitis, however, the severity on awakening and the improvement of morning stiffness more strongly correlated with total PD scores ($r = 0.503$-0.561, $p < 0.001$) than did swollen/tender joint counts ($r = 0.276$-0.388, $p = 0.001$-0.016) (Table 1). Multivariate analyses identified the severity on awakening and the improvement but not the duration of morning stiffness as factors that independently associate with the total tenosynovial PD score.

Table 1. Correlations between clinical manifestations and ultrasound scores in dominant hand

	Joint count		Morning stiffness				
	Swollen joint	Tender joint	Duration	Severity VAS on awakening	Improvement of VAS at 1/4	Improvement of VAS at 1/2	Improvement of VAS at bedtime
Intra-articular synovial power Doppler score							
ρ *	0.561	0.379	0.265	0.314	0.217	0.266	0.306
p value *	< 0.001	0.001	0.021	0.006	0.060	0.020	0.007
Tenosynovial power Doppler score							
ρ *	0.388	0.276	0.280	0.503	0.505	0.561	0.538
p value *	0.001	0.016	0.014	< 0.001	< 0.001	< 0.001	< 0.001

* Spearman's correlation coefficient

VAS, visual analogue scale

Conclusion: Our data demonstrate a pathophysiological link between morning stiffness and tenosynovitis and also give an insight into the optimal measurement of morning stiffness. Our data support an independent value of evaluating morning stiffness in the management of RA.

Session Title: Imaging of Rheumatic Diseases II: Ultrasound in Rheumatoid Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: To further decrease the burden of RA we need to identify patients early, preferably in absence of clinical apparent synovitis. Recent studies in US suggest that earlier detection is possible. We aim to identify arthralgia patients developing clinical apparent inflammatory arthritis (IA) within a year using US to detect subclinical synovitis at first consultation.

Methods: We followed arthralgia patients with at least two painful joints of hands, feet or shoulders without clinical apparent synovitis over one year in a multi-centre cohort study. Their symptoms needed to be present <1 year and were not explained by other conditions (e.g. fibromyalgia). We collected data at baseline, 6 months and 12 months follow-up including physical examination, laboratory variables (ESR, CRP, auto-antibodies), diagnosis and medication. At baseline we also examined 26 joints (bilateral MCP2-5, PIP2-5, wrist, MTP2-5) by US and images were scored semi-quantitatively on greyscale (GS; 0-3) and power Doppler (PD; 0-3). US synovitis was defined as GS grade 2 or 3 and/or presence of PD. One-year incident IA was defined as clinical soft tissue swelling. Univariate logistic regression was used to analyse the association between demographic characteristics, clinical characteristics, and US findings and the incidence of IA for all patients. This was then further explored selecting the strongest variables ($p<0.157$) in a multivariate logistic regression. Missing values in independent variables were imputed using STATA (multiple imputation by chained equations (m=5)).

Results: In total, 196 patients were included of whom 160 completed the 12 months follow-up. At baseline 71 (37%) arthralgia patients had US synovitis and in 29 (15%) patients PD signal was detected. Incident IA was present in 37 (19%) patients (Table 1: baseline characteristics) of whom 22 patients initiated DMARD treatment during the one-year follow-up. Strongest associations in the univariate analysis were found for RF (OR 2.4), morning stiffness >30 minutes (OR 2.9), ACPA (OR 3.8), US synovitis (OR 2.1) and PD signal (OR 4.8). In the

multivariate logistic regression the presence of morning stiffness >30 minutes (OR 3.7: 95%CI 1.4-9.5), ACPA (OR 4.0: 95%CI 1.5-10.6) and PD signal (OR 4.3: 95%CI 1.7-10.9) were associated with incident IA (Table 2).

Conclusion: One-year incident IA was present in 19% of the early arthralgia patients of which 53% showed US synovitis at baseline. The presence of PD signal, morning stiffness >30 minutes and ACPA were significantly associated with the development of IA after one year.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases II: Ultrasound in Rheumatoid Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Remission or low disease activity is the therapeutic target for rheumatoid arthritis (RA). There is a consistent body of evidence supporting the value of ultrasound in the diagnosis, disease activity and treatment monitoring of RA patients. In spite of these pieces of information, the impact of ultrasound in treatment decisions in RA patients from real clinical setting has not yet sufficiently studied. Purpose: To explore the impact of ultrasound findings, in terms of the proportion of patients in whom treatment recommendation differed after the ultrasound examination in RA outpatients. We also tested the variations of ultrasound impact according to the level of patient´s disease activity or the physician´s experience.

Methods: 85 consecutive RA outpatients were included. In the 1st step a senior rheumatologist (SR) and a trainee in rheumatology (TR), blinded to each other evaluation performed a clinical assesment that included DAS28; then, they independently proposed a treatment recommendation. In a 2nd step, all patients underwent an ultrasound examination using the 7-joints score (US-7,[2]) by an experienced rheumatologist blinded to clinical evaluation; US-7 assessed gray scale sinovitis (GS), power doppler sinovitis (PD) and accordingly determined disease activity. In the final step, all the patients returned to both, the SR and the TR, who integrated the US-7 findings to their previous evaluation and reviewed their prescription. TR and SR changes of treatment (pre- and post-US-7) were recorded on standardized formats. Patients received final recommendation only from the SR. US-7 usefulness was separately evaluated by the SR and the TR according to a Likert scale (0= not useful at all, 10= very useful). Patients signed informed consent.

Results: Patients were mainly female (91.4%), with (mean±SD) 45.13 ± 12.4 years of age and disease duration of 7.45±3.9 years. Sixty one (71.8%) patients were in DAS28-remission (<2.6), meanwhile 24 (28.2%) had some level of disease activity according to DAS28. US-7 evaluations showed that 98.8% of the patients had at least some degree of GS sinovitis and 22.6% had PD. In 34 (20%) out of the 170 clinical evaluations (85 patients concomitantly evaluated by SR and TR), US-7 modified treatment and it was most frequently increased. Interestingly, 24 out of these 34 evaluations were performed by TR vs. 10 performed by the SR: 70.5% vs. 29.5%, p=0.01. Also, US-7 usefulness was scored higher by TR than by the SR, 4.9±2.5 mm vs. 4.1±1.8, p= 0.02. Disease activity did not affect the impact of US-7 on treatment recomendation.

Conclusion: US-7 findings impacted treatment in up to 20% of RA patients assessed in routine clinical practice; this impact was greater in TR than in SR. References: 1. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases II: Ultrasound in Rheumatoid Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Musculoskeletal ultrasound (MSUS) can enhance the clinical assessment of the pediatric enthesis. Doppler signals in particular are considered a sign of pathology but may not be specific for enthesitis. The normal pediatric enthesis can exhibit Doppler. The aim was to obtain data of knee and ankle entheses in healthy children at the peak of linear growth as a reference for patients.

Methods: 42 males and females, 11-14 years old, free of musculoskeletal (MSK) symptoms, conditions or medication affecting the MSK system, no MSK injuries in the past 3 months and no participation in sports more than 3 times per week took part. The Quadriceps insertion, proximal and distal patella tendon insertion and Achilles enthesis were examined in Power and Colour Doppler using an Esaote Mylab 70 XVG Gold with a linear probe 6 to 18 MHz. Doppler settings were optimized individually to obtain maximum sensitivity. Extremities were assessed in neutral and 30 degrees flexion. Images were acquired by one examiner and read by two. 10 volunteers were reassessed 2 days later. Presence of Doppler signals was assessed directly at the bone/cartilage interface as well as within 2mm, 5mm and 10mm using a scoring system 0=no Doppler signals via 1a=single signal, 1b=single confluent signal up to 3 b=3 and more confluent signals. Signals at the enthesis were differentiated from peri-tendinous and intra-cartilage signals. A marginal logistic regression model with generalized estimating equation for associations between ultrasound signal detection and distance, Doppler mode, position, location, and side of measurement was used. Agreement between observers and scan days was determined using prevalence- and bias-adjusted Kappa.

Results: Doppler signals were hardly ever present directly at the tendon bone junction but did show the highest prevalence within 2 mm of the enthesis with an Odds ratio (OR) of 4.58 (95 % CI 2.71-7.72), $p<0.001$, and 5 mm, OR 4.24 (95 % CI 2.18-8.25), $p<0.001$. Doppler signals were significantly less likely to be present in the proximal patella and Achilles tendon insertion compared with the Quadriceps and distal patella tendon insertion ($p<0.001$ each). There was no significant difference between right and left as well as the two degrees of flexion in the logistic regression model. The mean(range) for kappas between the first and second assessment at the various distances and entheses was 0.82 (0.45-1). The mean(range) for kappas regarding agreement between the

two readers at the various distances and entheses was 0.87 (0.46-1).

Conclusion: We found Doppler signals especially within 2 and 5 mm of the enthesis of the Quadriceps and distal Patella tendon. Contrary to results in adults with Spondylarthritis, Doppler signals were not consistently more prevalent in the flexed or extended position. Results showed good agreement between the right and the left extremity and were stable over time. Our results indicate the need to differentiate various entheses in MSUS. Doppler signals may be more specific for pathology in the proximal Patella tendon and Achilles tendon than in the Quadriceps or distal Patella tendon insertion. The exam should be performed in various positions of the joint.

Session Title: Pain – Basic and Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Total knee arthroplasty (TKA) is a common elective surgery to treat pain and functional limitation due to refractory arthritis. Post-operative pain is commonly underestimated and undertreated, which can prolong hospital stay, and interfere with engagement in rehabilitation exercises and lead to poorer health-related quality of life (HRQOL). Our **objective**was to examine if immediate post-arthroplasty pain trajectory (pain scores plotted from pre-operative to all time-points post-operative) is associated with long-term pain outcome after total knee arthroplasty (TKA), and assess important correlates of pain trajectories.

Methods: We used the data from the pain sub-study of the FORCE-TJR study, a nationally representative cohort of U.S. patients (n =28,000) undergoing TKA (or hip arthroplasty) from more than 150 surgeons in 22 states. In a sub-study, patients evaluated pain severity at 2- and 8-weeks after index TKA using a validated survey; pain was assessed on a 0-10 numeric rating scale (NRS). We used group-based trajectory models to determine the number and shape of short-term pain (baseline, 2 weeks, and 8 weeks post-op) trajectories. We then examined the predictive ability of these short-term pain trajectory for longer-term pain outcomes at 6 and 12 months, using

multiple linear regression analyses with logit function. Outcomes were Knee injury and Osteoarthritis Outcome Score (KOOS) pain at 6 and 12-months (higher score, worse pain). Multivariable logistic regression adjusted for age, gender, body mass index (BMI), race, Charlson Comorbidity count, and pre-operative health-related quality of life as measured by the SF-36 physical health (PCS) and mental health (MCS) scores.

Results: 659 TKA patients provided 2-week and 8-week pain survey data. The majority of respondents were female (64.5%) and at least 65 years old (66.5%). Among respondents two pain trajectories were evident, with majority being pain responders (72%); i.e. pain decreased in a meaningful way after TKA compared to pre-operative pain) and a smaller proportion were pain non-responders (28%). Early pain trajectory was highly significantly associated with 6- and 12-month pain outcome on KOOS. Additional factors significantly associated at 6 and 12 months were, Charlson Comorbidity count 3, and pre-operative PCS and MCS. African American/other race was significantly associated with pain outcome at 6 months, but not 12 months. Gender, age, and BMI were not significantly associated with pain trajectory at either 6- or 12-months.

Conclusion: We found that pain trajectory up to 8-weeks post-TKA surgery independently predicted longer-term pain outcome. Interventions to modify early post-operative pain experience may lead to better pain outcome (and other patient-reported outcomes) after TKA. Table 1. Predictors of 6- and 12-month KOOSpain scale after TKA among members of FORCE-TJR

Session Title: Pain – Basic and Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with knee osteoarthritis (OA) often start with acute intermittent, activity-related pain, which evolves to additionally experiencing chronic, persistent pain; why this transition happens is not known. It is possible that peripheral and central sensitization, which is associated with knee pain severity in knee OA, contributes to the transition from solely acute intermittent pain to chronic, persistent pain. We assessed whether a marker of sensitization, pressure pain threshold (PPT), was associated with change from intermittent to chronic, persistent pain over time in a large cohort of older adults with or at risk of knee OA.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded cohort longitudinal cohort of persons with or at high risk of knee OA. Subjects had a standardized somatosensory evaluation of mechanical pressure pain thresholds (PPT) at the wrist and patella and completed pain questionnaires at baseline and two years later. PPT was assessed with an algometer ($1cm^2$ tip, 0.5 Kg/sec) as the point at which the subject felt the pressure change to slight pain. The average of 3 PPT trials was categorized into sex-specific tertiles. Lower PPT indicates more sensitization/pain sensitivity; at a site of disease (e.g., knee), it indicates peripheral sensitization, while at a site without disease (e.g., wrist), it indicates central sensitization. The Intermittent and Constant OA Pain (ICOAP) instrument assesses presence and severity of intermittent and constant pain, and for intermittent pain, its frequency (5-point Likert scale for each). Using the knee-specific ICOAP, pain patterns were defined as: 1) no intermittent or constant pain; 2) intermittent pain only (of at least mild severity occurring at least sometimes); and 3) constant pain (of at least mild severity) with or without intermittent pain. Among subjects with either no pain or intermittent pain only at baseline, we evaluated the relation of baseline PPT to incidence of constant pain using logistic regression. We compared the two highest PPT tertiles with the lowest tertile as there appeared to be a threshold effect. All analyses were adjusted for age, sex, BMI, depressive symptoms, catastrophizing, and clinic site.

Results: There were 1951 subjects included (mean age 68, 60% female, mean BMI 31), of whom ~8% developed constant pain over two years. A low level of peripheral sensitization, as reflected by medium and high knee PPT tertiles, was associated with a lower risk of developing incident constant pain [OR: 0.64 (0.40-1.00, p= 0.05)]. Similarly, a low level of central sensitization as measured by wrist PPT was also associated with a lower risk of incident constant pain [OR: 0.52 (0.32-0.86, p=0.01)].

Conclusion: Lower levels of peripheral and central pain sensitization are associated with lower rates of evolution or progression of the pain pattern from intermittent or no pain to constant pain over time. These

findings support the hypothesis that sensitization plays an important role in changing a patient's pattern and severity of OA-related pain. These findings have implications for understanding the transition from acute to chronic pain.

Session Title: Pain – Basic and Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Although significant advances have been made in treating inflammation in RA, little is known about central nervous system (CNS) pain pathways in inflammatory arthritis. Recognizing this gap in knowledge, the ACR Pain Management Task Force emphasized the need for quantitative, non-invasive biomarkers of pain and the application of these measures to the study of pain. Our objective was to use pulsed arterial spin labeling (pASL), a type of functional MRI, to evaluate the neural correlates of clinical pain in RA and to characterize changes in CNS pain pathways in response to DMARD treatment.

Methods: This pilot study included 2 stages: 1) a cross-sectional analysis of 15 RA patients with active disease compared to 16 age- and sex-matched controls, and 2) a prospective analysis of 10 RA patients followed for 12-weeks after starting DMARD treatment. To be included, RA patients had to have chronic pain with an average of at least 3/10 in intensity at the MCPs and be starting a DMARD for active disease. Controls could not have current pain or have a history of chronic pain conditions or systemic inflammatory disease. All subjects underwent 6-min pulsed arterial spin labeling scans (voxel size = 3.515*3.515*6.25 mm, number of slices = 16) to assess regional cerebral blood flow (rCBF) using a 3T Siemens MAGNETOM Skyra, with a 32-channel head

coil. Scans were obtained under the following conditions: resting state and pressure at the left MCP joints. The experimental stimulus was applied using a blood pressure cuff inflated to achieve 40/100 pain in the patients and using the same pressure for the matched controls. RA patients were followed for 12-weeks after starting a DMARD and scanned again at the end of the treatment using the same parameters.

Results: The pressure stimulus was more painful in RA patients (median 50.0; interquartile range (IQR) 36.5-65.0) than in controls (median 3.5; IQR 0-11.3; p = 0.0001). Accordingly, a significant stimulus-induced increase in rCBF in the middle anterior and pregenual anterior cingulate cortices (aMCC/pgACC) was observed only in RA patients (Figure).The group x condition interaction trended for significance in a region-of-interest analysis (p = 0.065). After 12-weeks of treatment with a DMARD, normalized rCBF in the aMCC/pgACC decreased from a mean ± SD of 0.92 ± 0.08 to 0.87 ± 0.10 (one-sided p = 0.10), becoming similar to control values (0.87 ± 0.10).

Conclusion: These preliminary results suggest that: a) pASL may be able to identify CNS pathways involved in the regulation of pain in RA, and b) activity in these pathways may change in response to DMARD treatment. The aMCC and pgACC are brain regions that have been implicated in the cognitive modulation of pain affect in chronic, non-inflammatory pain states. Larger studies are needed to determine if rCBF in these regions will be useful as as an objective biomarker of pain in future studies evaluating the efficacy of pain interventions in RA.

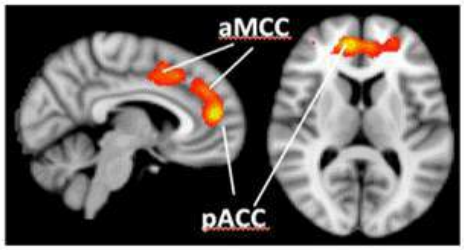

Figure. Pain-induced differences in regional cerebral blood flow in the middle anterior cingulate cortex (aMCC) and pregenual anterior cingulate cortex (pACC) in RA patients (N = 15) compared to controls (N = 16).

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Pain – Basic and Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The use of opioid analgesics for non-cancer, primarily musculoskeletal pain, in the U.S. has increased markedly and has been accompanied by an increase in deaths and hospitalizations due to opioid toxicity. Opioids likely vary with regard to these risks. There are particular concerns about transdermal fentanyl and long-acting oxycodone. Transdermal fentanyl has variable absorption and prolonged effects. There was an increase in opioid-related mortality after the addition of long-acting oxycodone to formularies and reports that oxycodone was involved in approximately one in three cases of opioid-related deaths. Thus, it is important to define the comparative safety of long-acting opioids, particularly transdermal fentanyl and oxycodone. We aimed to compare the risk of death in patients with chronic non-cancer pain receiving transdermal fentanyl, oxycodone slow release (SR), and morphine SR.

Methods: We conducted a retrospective cohort study in 50,658 patients enrolled in Tennessee Medicaid who filled prescriptions for: transdermal fentanyl (n=8,717), oxycodone SR (n=14,118), or morphine SR (n=27,823) between 1/1/1999 through 12/31/2011. Individuals with cancer or other serious diagnoses were excluded. The primary outcome was out-of-hospital mortality. Relative risk was estimated with the use of Cox proportional hazard models; propensity scores were used to adjust for multiple potential confounders, using a time-dependent analysis.

Results: Long-acting opioids were used primarily for musculoskeletal pain, which accounted for more than 90% of the prescriptions. There were 689 deaths during 44,385 person-years of follow-up; the all-cause mortality rate was 155/10,000 patient-years. All-cause mortality was not significantly different in patients using transdermal fentanyl compared to morphine SR (adjusted HR=0.96, 95% C.I.: 0.77-1.21). However, patients taking oxycodone SR had 21% lower mortality risk (adjusted HR=0.79, 95% C.I. 0.66-0.95) than those receiving morphine SR. Sensitivity analyses, including propensity score–matched cohorts and follow-up restricted to the first year of evaluation yielded similar results.

Conclusion: Patients taking long-acting opioids for non-cancer pain, primarily musculoskeletal pain, have a high mortality risk. Our findings suggest that there is a significant decreased risk of death in patients taking oxycodone SR compared to those taking morphine SR.

Pain and Sensitization in Women with Aromatase Inhibitor-Associated Arthralgias

Monica Crespo-Bosque[1], Carrie Brown[2], Brenda Cartmel[3], Maura Harrigan[4], Melinda Irwin[3] and Tuhina Neogi[5], [1]Internal Medicine, Boston Medical Center, Boston, MA, [2]Boston University School of Public Health, Boston, MA, [3]Yale School of Public Health, New Haven, CT, [4]Cancer Center, Yale School of Public Health, New Haven, CT, [5]Clinical Epidemiology, Boston University School of Medicine, Boston, MA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Pain – Basic and Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Aromatase inhibitors (AIs) are the preferred treatment for estrogen receptor positive breast cancer in postmenopausal women, but are frequently associated with arthralgias, which can decrease adherence. While the syndrome of AI-associated arthralgias has been well-recognized, the mechanism by which AIs induce arthralgias is not clear. Estrogen may be anti-nociceptive, and therefore with estrogen deprivation, it is possible pain sensitization develops. Further, whether exercise, which decreases AI-associated arthralgia pain, mediates its effects through improving pain sensitization is not known. Pressure pain threshold (PPT) provides one means of assessing pain sensitization. We therefore examined the relation of PPT to pain in AI-associated arthralgias, and also evaluated the effect of exercise on pain and PPT.

Methods: The HOPE (Hormones and Physical Exercise) study randomized 121 postmenopausal women with history of breast cancer treated with AIs for at least 6 months and also had arthralgias to an exercise intervention versus usual care. Exclusion criteria included pre-existing rheumatologic conditions. The exercise group had supervised resistance training twice a week and 150 minutes of aerobic exercise weekly. The usual care group did not have any specific exercise support. Self-reported pain severity (WOMAC for lower extremity symptoms; QuickDash for upper extremity symptoms), pain location and an assessment of pain sensitization measured by PPT evaluations at the knee and wrist using a hand-held algometer were obtained. We evaluated the relationship between pain severity, number of painful sites and PPT using linear regression.

Results: Of the 121 subjects enrolled in the trial, 99 subjects had pain and PPT data available at 6-months. Their mean age was 62 and mean BMI was 30. Higher number of joints with pain were associated with higher baseline pain severity scores on WOMAC (42.6±5.2 for 7-10 sites vs. 9.4±3.7 with 0-3 sites, $p<.0001$) and on QuickDash (29.2±3.4 for 7-10 sites vs. 12.0±2.3 with 0-3 sites, $p<.0001$), and with lower PPT at baseline (PPT 1.94±0.47 for 7-10 sites and 3.31±0.32 with 0-3 sites, p 0.02) (**Table 1**). While pain severity improved more in the exercise arm than the usual care arm, there was no significant change in PPT over time (**Table 2**).

Conclusion: The severity of AI-associated arthralgias by WOMAC and QuickDash were associated with number of painful joints and PPT. While pain severity improved with exercise, this improvement was unrelated to improvement in PPT, suggesting that pain improvement through exercise must occur through mechanisms other than improvements in pain sensitization.

Table 1: Relation of Number of Painful Sites to Pain Severity (WOMAC, QuickDash) and to PPT

	# of Patients	Pain sites	Baseline Mean ± SE	Overall p-value	p-value
QuickDash	26	0-3	12.0 ± 2.3	0.0001	
	26	4-6	22.4 ± 2.3		0.002
	12	7-10	29.2 ± 3.5		<.0001
WOMAC	26	0-3	9.4 ± 3.7	<.0001	
	26	4-6	17.6 ± 3.6		0.1
	12	7-10	42.6 ± 5.2		<.0001
PPT wrist	26	0-3	3.3 ± 0.3	0.06	
	26	4-6	3.1 ± 0.3		0.6
	12	7-10	1.9 ± 0.5		0.02
PPT knee	26	0-3	3.3 ± 0.3	0.07	
	26	4-6	2.6 ± 0.3		0.1
	12	7-10	1.9 ± 0.5		0.03

Table 2: Change in Pain Severity and PPT over 12 months by Intervention Group

	Exercise		Usual Care		
Change over 12 months	Mean	95% CI	Mean	95% CI	p-value
WOMAC	-9.4	-14.2 to -4.6	9.9	2.8 to 16.9	<.001
QuickDash	-6.7	-10.0 to -3.4	1.3	-2.3 to 4.9	0.002

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Pain – Basic and Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The correlates of localized knee pain (KP) and multi-site pain (MSP) have been clearly

demonstrated; however, whether these factors also contribute to intermittent or persistent knee pain or MSP remains unclear. Furthermore, which peripheral structural pathology leads to persistent knee pain or MSP is yet available, there may be different mechanisms underlying their pathogenesis. Therefore, this study aimed to describe the risk factors for persistent knee pain and persistent MSP, and to investigate the associations of MRI-defined knee structural pathology with these different types of pain.

Methods: 1099 participants (mean age 63 years; range 51-81 years) from the population-based Tasmanian Older Adult Cohort study were recruited at baseline. 875, 768 and 563 participants attended years 2.6, 5.1 and 10.7 follow-up, respectively. Demographic, psychological, lifestyle and comorbidities data were obtained at baseline. T1-weighted or T2-weighted fat saturated MRI of the right knee was performed to measure knee structural pathology--cartilage defects, bone marrow lesions (BMLs) and effusion-synovitis at baseline. Presence of pain (yes/no) at the neck, back, hands, shoulders, hips, knees and feet was assessed by questionnaire at each time-point. Participants were classified as never (N), persistent (P) and intermittent (I) pain, respectively, if they had knee pain or MSP (≥2 sites) at: no assessment, four consecutive assessments from baseline with all others considered intermittent pain. Multi-nominal logistic regression was used to analyse the data with adjustment for potential confounders.

Results: A total of 563 patients (50% female, mean BMI 27.6 kg/m^2) were included. Of these, 33%, 50% and 17% were NKP, IKP and PKP, and 11%, 41% and 48% were NMSP, IMSP and PMSP, respectively. In multivariable analyses, IKP and PKP were significantly associated with baseline BMI, emotional problems, and musculoskeletal diseases. Female gender was also associated with increased odds of IMSP and PMSP. There were no associations of age, physical activity, education level, occupation and other comorbidities with either KP or MSP. Furthermore, PKP but not IKP was associated with cartilage defects (OR 2.55, 95% CI 1.38 to 4.72), BMLs (OR 1.93, 95% CI 1.07 to 3.47) and effusion-synovitis (OR 1.89, 95% CI 1.08 to 3.31) after adjustment for age, sex, BMI, other potential confounders. However, no significant associations of these lesions with IMSP or PMSP were observed.

Conclusion: Higher BMI, psychological problems and musculoskeletal diseases are associated with both intermittent and persistent KP and MSP, suggesting that factors contributing to pain may be shared in the pathogenesis of regional and generalised pain, but gender may have a different role in regional pain and generalized pain. Knee structural lesions predict PKP but not IKP, IMSP and PMSP, indicating that peripheral pathology is most important for ongoing localized pain, but it might be a trigger in contributing to generalised pain. Further research is needed to understand the underlying mechanisms of structural pathology differences in regional pain and generalised pain.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Macrophage Activation Syndrome (MAS) is a life-threatening sepsis-like condition complicating many systemic JIA (sJIA) and Adult-Onset Stills Disease (AOSD) patients. We recently identified that gain-of-function mutations in inflammasome component *NLRC4* cause an inflammasomopathy of early-onset enterocolitis, life-threatening MAS, and extraordinary serum IL-18. Similar serum IL-18 levels are also present in sJIA/AOSD patients with a history of MAS.

Methods: We used plate-bound ELISA and custom bead-based multiplex cytokine arrays to characterize IL-18 and related cytokines in a uniquely broad cohort of autoinflammatory patients with and without a history of MAS. We genome-edited a gain-of-function mutation in *Nlrc4* into the mouse germline and assessed IL-18 levels in *Nlrc4*/wildtype bone marrow chimeras.

Results: Extraordinary elevations of serum IL-18, but not its endogenous antagonist IL-18 Binding Protein (IL-18BP) or other related cytokines, uniquely marked patients with a history of MAS but not other inflammasomopathies or IL-1-mediated diseases. Patients with monophasic disease show a slow normalization of serum IL-18 long after normalization of other cytokines and acute phase proteins while patients with early-onset or relapsing disease, including those bearing *NLRC4* mutations, showed persistence of extraordinary IL-18. IL-18 in some patients measured serially over several years showed persistence of an abnormally high "set point" even with completely inactive disease (Fig.1). Mice bearing an *Nlrc4*-T337S point mutation displayed no spontaneous inflammation, but demonstrated chronic elevation of serum IL-18. Elevated IL-18 was present as early as 3 weeks of age and was unaffected by administration of broad-spectrum antibiotics. Elevated IL-18 was dependent on the inflammasome adaptor ASC, suggesting canonical inflammasome activation and cleavage of IL-18. Surprisingly, bone marrow chimeras made from Nlrc4-T337S mice demonstrated that IL-18 hyperproduction derived from non-hematopoietic cells (Fig.2).

Conclusion: Extraordinary high serum IL-18 levels are uniquely associated with the clinical presentation of recurrent MAS and may be a promising diagnostic biomarker and therapeutic target. The main source of IL-18 in Nlrc4-T337S mice is non-hematopoietic and suggests that the serum IL-18 "set point" observed in MAS patients, particularly those with *NLRC4* mutations, would be resistant to bone marrow transplantation. This research was supported by the Intramural Research Programs of NIAMS and NIAID of the NIH.

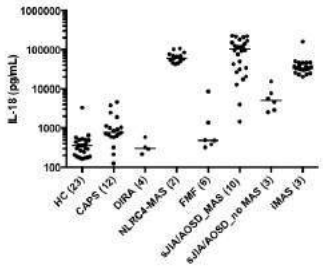

Figure 1: Serum IL-18 in patients with inflammmasomopathies (CAPS-Cryopyrin-Associated Periodic Syndromes and FMF- Familial Mediterranean Fever) and the IL-1 mediated disease DIRA-Deficiency of IL-1 Receptor Antagonist. Diagnosis (number of pts) HC-healthy controls; iMAS-Idiopathic MAS.

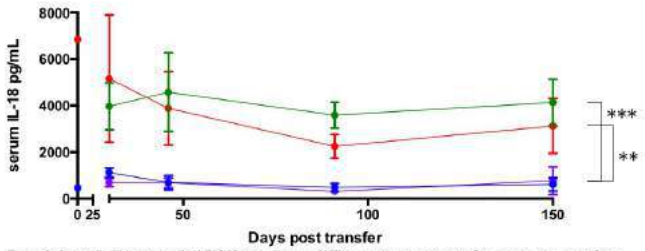

Figure 2: Serum IL-18 levels in *Nlrc4*-T337S and wild-type (WT) bone marrow chimeras. Day 0 indicates serum from donor mice. Blue = WT immune cells, WT host; Purple = *Nlrc4*-T337S immune cells, WT host; Green = WT immune cells, *Nlrc4*-T337S host; Red = *Nlrc4*-T337S immune cells, *Nlrc4*-T337S host. **p<0.01, ***p<0.005, Repeated Measures ANOVA with Tukey's post-test.

Session Time: 2:30PM-4:00PM

Background/Purpose: There are 75,000 children affected by JIA in the United States. Despite recent therapeutic advances, treatment often requires chronic therapy and is associated with considerable cost and morbidity, yet is still not curative as episodic flares are common. However, the pathophysiology of these flares is not well understood. There is a common observation that arthritis flares exhibit a strong tendency to recur in the same joints. This fixed pattern of joint involvement is highly individualized and persists for decades. To study this phenomenon, we established a murine model of recurrent, joint-specific inflammation.

Methods: Methylated bovine serum albumin (meBSA) or ovalbumin (OVA) is injected into the wrist, knee and ankle joints of B6 mice. The contralateral side was injected with vehicle as a negative control. For the OVA conditions, 5x10^6 CD3+ cells collected from peripheral lymph nodes of OT-I mice were transferred IV into the mice 1 day prior to intra-articular OVA injection. Interleukin-1 was concurrently injected into the footpad of the mice to stimulate the immune response. Arthritis flare was triggered by i.p. meBSA or OVA re-stimulation. At days 7 (acute inflammation), 28 (remission) and 31 (flare), the joints were analyzed for inflammation by measuring joint thickness, histological evaluation, and flow cytometry analysis of disaggregated synovium.

Results: 7 days after injection, there is measureable swelling and histological evidence of synovitis, specifically in the joints exposed to the antigen. In the synovium, there is a corresponding increase in CD4 and CD8 T cell populations. At 28 days after injection, inflammation subsides with normalization of both joint size and resolution of synovitis. During this post-inflammatory remission, we found a persistent population of antigen-specific cells with resident memory T cell (TRM) phenotype (CD45.2+CD3+CD8+CD44+CD62L-CD69hi). These TRM cells are preferentially increased in the synovium of the joint exposed to antigen. Upon intraperitoneal challenge with antigen, there is a recurrent inflammation specifically in the joints previously exposed to antigen, and a corresponding expansion of antigen-specific CD8+ TRM cells in the synovium is also seen.

Conclusion: Here, we created an inducible model of recurrent, joint-specific inflammation. Our data suggests synovial resident memory T cells may represent the basis for joint-specific memory in inflammatory arthritis.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Chronic recurrent multifocal osteomyelitis (CRMO) is a rare, pediatric, autoinflammatory disease characterized by bone pain due to sterile osteomyelitis, and is often accompanied by psoriasis or inflammatory bowel disease. There is evidence for a genetic basis in several syndromic forms of the disease including the Deficiency of the Interleukin-1 Receptor Antagonist (DIRA; due to mutations in *IL1RN*), Majeed syndrome (due to mutations in *LPIN2*) and murine chronic multifocal osteomyelitis (due to mutations in *Pstpip2*). However, for the majority of cases of CRMO, the genetic basis remains unknown.

Methods: We used whole exome and Sanger sequencing, gene expression microarray and Luciferease assays to identify additional CRMO susceptibility genes.

Results: Via whole-exome sequencing, we detected a homozygous mutation in the filamin-binding domain of *FBLIM1* in an affected child with consanguineous parents. Microarray analysis of bone marrow macrophages from the CRMO murine model (cmo mouse) determined that the *Fblim1* ortholog is the most differentially expressed gene, further implicating it in disease pathogenesis. In addition, studies suggest FBLIM1/FBLP1 is an anti-inflammatory molecule regulated by STAT3, and one involved in bone remodeling via ERK1/2 phosphorylation and the subsequent regulation of RANKL activation. We sequenced *FBLIM1* in 96 CRMO subjects and found a second proband with compound heterozygous mutations in *FBLIM1* composed of a novel frameshift mutation in exon 6 and a rare regulatory variant. The enhancer contains binding sites for STAT3 and NR4A2. Enhancer activity of a 1-kb region around the mutation was validated by luciferase assays in fluoride-treated SaOS2 cells, as was the effect of the mutation on regulatory activity. In SaOS2 cells, overexpressing the regulatory mutation showed the flanking region acts as an enhancer, and the mutation ablates enhancer activity.

Conclusion: Our data implicate *FBLIM1* in the pathogenesis of CRMO and autoinflammatory disease.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Oral pathogens that cause periodontitis have been implicated as triggers for rheumatoid arthritis (RA), via antibodies to citrullinated proteins. Gingivitis is common in children and is a chronic inflammatory precursor to periodontitis. Patients with juvenile idiopathic arthritis (JIA) rarely produce anti-citrullinated peptide antibodies (ACPA). The children with polyarticular JIA who carry ACPA tend to have more aggressive arthritis, similar to adult RA patients. We hypothesized that gingival inflammation is associated with JIA, and that ACPA may represent a link between JIA and oral health. Our objectives were to: (a) Test for increased frequency of gingivitis in children with JIA compared to controls and (b) Test for correlations between ACPA and dental clinical outcomes.

Methods: This was a cross-sectional study of 85 patients with JIA and 62 dental clinic patients at a children's hospital. A second control group was derived from 11 healthy child volunteers. Serum from an additional historic cohort of 30 healthy children was used to study ACPA. Dental indices were compared between groups using linear regression adjusting for demographic characteristics. ACPA were detected with a commercial CCP3 assay and also to 29 citrullinated full-length peptides using a custom multiplex autoantibody assay. Elevated levels for antibodies to each peptide were defined as values larger than the maximum value for the historical controls. Positive ACPA was defined as elevated levels of antibodies specific for more than 4 of the citrullinated proteins. The prevalence of positive ACPA was compared across groups using the Fisher's exact test.

Results: Although JIA patients overall had better oral health than dental controls they had significantly more bleeding on probing of the gingiva, the most specific sign of active inflammation ($p = 0.007$). There was no correlation between JIA disease activity or immunosuppression with dental indices. TMJ arthritis was

associated with a higher gingival index. Patient smoking (only present in dental group) and household smoking exposure in JIA group correlated with a worse 'decay, missing, filling teeth' index (DMFT) score. By commercial CCP3 assay ACPA were detected in only four JIA patients (all poly-JIA), but elevated levels were detected by the custom array in 15/41 (37%) of poly JIA, 14/36 (39%) of oligo JIA, and 19/58 (33%) of dental controls. Antibodies to more than 4 citrullinated peptides were most common in poly JIA 9/41 (22%) compared with 1/36 (3%) for oligo JIA, and 2/58 (3.4%) for dental controls, (p=0.002). We found no associations between ACPA status and any dental index.

Conclusion: Gingival inflammation was associated with JIA, suggesting that a systemic immune response could be triggered by oral bacteria involved in both oral and synovial inflammation, and cannot be attributed to poor dental hygiene secondary to JIA disability. Microbial analysis of plaque will help understand this relationship further. No association was found between ACPA and gingival inflammation; however more sensitive and specific tests for ACPA may lead to improved prognosis and understanding of the triggers for arthritis in children.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The transcription factor signal transducer and activator of transcription 3 (STAT3) mediates cytokine-induced changes in gene expression. STAT3 is classically activated by phosphorylation followed by homodimerization, nuclear translocation and DNA binding. STAT3 is downstream of numerous cytokines, including interleukin-6 (IL-6). IL-6 is a pro-inflammatory cytokine and therapeutic blockade of the IL-6 receptor using tocilizumab is approved for the treatment of rheumatoid arthritis and juvenile idiopathic arthritis. Germline, gain-of-function (GOF) mutations in STAT3 have been shown to cause multi-organ autoimmunity, including juvenile-onset polyarthritis. Patients with STAT3 GOF also have short stature and decreased T regulatory cells. Specific mechanisms by which STAT3 GOF mutations impact the roles of STAT3 have not been determined.

Methods: We investigated STAT3 activation using flow cytometry and Western blot in STAT3-deficient cells and cells engineered with heterozygous (het) and homozygous (homo) mutations in the STAT3 DNA binding domain (G421R), modeling a variant discovered in a GOF patient with polyarthritis, autoimmune hemolytic anemia, autoimmune hepatitis and scleroderma-like skin. Constructs containing STAT3 cDNA were modified and used in transfection experiments with a luciferase reporter. DNA binding was determined using an ELISA based assay. G421R STAT3 GOF mice were created using genetic engineering. Phenotypic characteristics were noted and the T cell compartments were analyzed by flow cytometry *ex vivo*and after polarization.

Results: De-phosphorylation of G421R is delayed in a dose-dependent manner (homo>het>WT) in response to multiple cytokines, similar to primary patient cells. However, co-transfection of WT with G421R results in reduced transcriptional activity compared to G421R alone, suggesting G421R is not dominant. Cellular fractionation experiments reveal the prolonged phospho-G421R is retained in the nucleus. This was consistent with the finding that G421R displayed stronger DNA binding. After IL-6 stimulation, un-phosphorylated G421R increases compared to WT. Unlike WT, un-phosphorylated G421R is also found in the nucleus in the resting state. Further, un-phosphorylated G421R retains transcriptional activity, unlike un-phosphorylated WT. Interestingly, STAT3 GOF mice recapitulate the small size noted in STAT3 GOF patients, and in a dose-dependent fashion. After polarizing conditions, CD4 T cells from STAT3 GOF were less likely to develop into CD25+Foxp3+ regulatory cells, but produced increased IL-17 expressing cells.

Conclusion: Our data suggests that G421R enhances STAT3 activity through increased DNA binding and enhanced transcriptional capacity of un-phosphorylated molecules. Initial characterization of STAT3 GOF mice suggests this model recapitulates the human disease. Future work will further characterize these mice, as well as investigate the mechanisms of other STAT3 GOF mutations. These studies will provide valuable information on the role of STAT3 in autoimmunity and arthritis, particularly given the potential impact of therapeutic inhibition of STAT3 in human disease.

Session Title: Rheumatoid Arthritis – Clinical Aspects II: Risk and Impact of Comorbidity
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Cardiovascular (CV) disease is a prevalent comorbidity in patients with rheumatoid arthritis (RA). However, recent cohort studies with long term follow up studying this risk are scarce. We report the results of a 15 year observational cohort study comparing the risk of CV events in patients with RA to the general population and participants with type 2 diabetes (DM).

Methods: The CARRÉ study is a prospective cohort study with the purpose of investigating CV disease and its risk factors in a random sample of 353 patients with longstanding RA. CV endpoints were assessed at baseline, 3, 10 and 15 years of follow up and compared to the Hoorn Study population (n=2540), a cohort representative of the general population designed to analyze glucose metabolism and CV risk factors over 15 years. Incidence rates per 100 person-years were calculated and Cox regression analyses were performed to investigate CV risk in these persons.

Results: 96 patients with RA developed a CV event during 2703 person-years of follow up resulting in an incidence rate of 3.6 per 100 person-years. In the Hoorn Study population, 298 individuals developed a CV event, of which 41 had DM, during a follow up of 25335 person-years, resulting in an incidence rate of 1.4 per 100 person-years in the general population. Age and sex adjusted hazard rates (HR) for CV events were increased for RA (2.14 [95% CI 1.65-2.78, P<0.01]) and DM (1.63 [95% CI 1.17 – 2.27, P<0.01]) compared to the general population (figure 1). HR was significantly increased in RA (1.73 [95% CI 1.27 – 2.35, P<0.01]) and reached borderline significance in DM (1.42 [95% CI 1.00 – 2.00, P=0.047]) after additional adjustment for traditional CV risk factors (figure 2). Exclusion of prevalent CV disease resulted in increased HR for RA (2.16 [95% CI 1.53 – 3.04, P<0.01]) and not for DM (1.28 [95% CI 0.83 – 1.98, P=0.27]) compared to the general population after adjustment for traditional CV risk factors.

Conclusion: The incidence rate of CV events was 3.6 per 100 person-years in patients with established RA which is more than double that of the general population. RA patients have an increased risk of CV endpoints comparable to type 2 DM. This increased risk remains for RA patients even after adjustment for traditional CV risk factors, indicating that the (ongoing) systemic inflammation of RA is an independent contributor to CV risk.

Risk of Incident Diabetes Mellitus and Its Association with Disease-Modifying Antirheumatic Drugs and Statins in Rheumatoid Arthritis

Gulsen Ozen[1,2], Sofia Pedro[3], Marie Holmqvist[4], Frederick Wolfe[3] and **Kaleb Michaud**[2,3], [1]Rheumatology, Marmara University Faculty of Medicine, Istanbul, Turkey, [2]Rheumatology, University of Nebraska Medical Center, Omaha, NE, [3]National Data Bank for Rheumatic Diseases, Wichita, KS, [4]Dept of Medicine, Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects II: Risk and Impact of Comorbidity

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Diabetes mellitus (DM) is an important cardiovascular risk factor in RA. Although a few prior studies reported DM risk reduction with hydroxychloroquine (HCQ) and TNF inhibitors in RA, at present the impact of newer biologics and statins, the timing, dosing and the sustainability of the HCQ effect are unknown. In this study, we examined the incident DM rate and the impact of DMARDs and statins in RA patients.

Methods: We studied patients with RA and ≥1 year participation in the National Data Bank for Rheumatic Diseases without baseline DM from 2000 through 2015. DM was determined by self-report or initiating DM medication. DMARDs were categorized into 4 mutually exclusive groups: (1) MTX monotherapy (reference) (2) any abatacept (ABA) with or without MTX (3) any other DMARD with MTX (4) all other DMARDs without MTX; along with separate statin, glucocorticoids (GC), and HCQ (yes/no) variables. Time-varying Cox proportional hazard models were used to adjust for sociodemographics, comorbidities, BMI, and RA severity measures.

Results: A total of 1,139 incident DM cases were observed during median (IQR) 4.6 (2.5-8.8) years of followup in 13,669 RA patients. The incidence rate in RA patients found to be increased (age and sex-adjusted SIR 1.37 [1.29-1.45]) compared to that of in US adult population (*Table 1*). Adjusted HR (95% CI) for DM were 0.67 (0.57, 0.80) for HCQ, 0.52 (0.31, 0.89) for ABA, 1.31 (1.15, 1.49) for GC, and 1.56 (1.36, 1.78) for statins. Other synthetic/biologic DMARDs were not associated with any risk change (*Table 2*). DM risk reduction started after 2 years of HCQ treatment, HR 0.76 (0.58-1.00), and continued to decrease with longer duration, >4 years HR 0.69 (0.59-0.81). HCQ doses of <400mg/day (HR 0.71, 0.52-0.96) and ≥400mg/day (HR 0.66, 0.55-0.81) were both associated with DM risk reduction. Patients who initiated and then discontinued HCQ (N=342) had a nonsignificant risk reduction up to 6 months compared to HCQ never-used patients: HR 0.65 (0.21-2.0) for ≥ 3 months, 0.88 (0.28-2.75) for ≥ 6 months, and 1.27 (0.31-5.10) for ≥ 1 year off-HCQ. Concomitant use of HCQ either with GC (HR 0.69, 0.51-0.93) or statins (HR 0.92, 0.68-1.25) abolished risk increase associated with both drugs.

Conclusion: Incidence of DM in RA patients is increased. HCQ and ABA were associated with decreased risk of DM, and GC and statins with increased risk. HCQ confers a sustainable, dose and treatment duration-dependent DM risk reduction, and also attenuates the increased risk associated with GC or statins. Careful monitoring for DM should be considered in RA patients especially who were on GC or statins.

Table 1. Crude incidence rates (95% CI) and standardized incidence ratios (95% CI) of diabetes in rheumatoid arthritis by treatment compared with US population

	No. of DM	Person-years	Incidence rate (95% CI) per 100 person-years	SIR* (95% CI)

Session Title: Rheumatoid Arthritis – Clinical Aspects II: Risk and Impact of Comorbidity

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Increased insulin resistance and impaired β-cell function have been demonstrated in pts with rheumatoid arthritis (RA). The aim of our study was to investigate these metabolic disturbances in RA pts compared to controls and analyze its association with disease activity.

Methods: The study population included 127 non-diabetic subjects: 90 RA pts (mean age 52.4±9.9 yrs, disease duration 9 yrs, range 4-13) and 37 matched controls (mean age 49.0±7.5 yrs). All pts were on disease modifying anti-rheumatic drugs (methotrexate 93.3%, steroids 65.6% (5 mg/day, range 5-10, none on steroids >10 mg/day), biologic therapy 27.8%). Clinical work-up included determination of the body mass index (BMI), waist circumference (WC), blood pressure (BP), disease activity (mDAS28-SE), inflammation markers, lipids, glucose, specific insulin, and C peptide. The updated-computer Homeostasis Model Assessment was used to calculate insulin resistance (HOMA2-IR) and β-cell function (HOMA2-%B). HOMA2-IR>1 was defined as increased insulin resistance. Lack of compensatory rise of HOMA2-%B implied impaired β-cell function.

Results: Increased insulin resistance (logHOMA2-IR>1) was detected in 74.4% of RA pts and in 54.2% controls, p=0.025. RA pts also had higher values of logHOMA2-IR than controls 1.4 (range 1.0-2.3) vs. 1.2 (range 0.8-1.4); p=0.008; followed with impaired β cell function: HOMA2-%B 148 (116-190) vs.141 (114-158) p=0.186. Univariate regression revealed association of logHOMA2-IR with all insulin resistance risk factors: age, BMI, WC, BP, and triglycerides, while multivariate analysis demonstrated that beside BMI and triglycerides, RA itself was an independent risk factors for logHOMA2-IR (β 0.065, 95% CI 0.019-0.112, p=0.006). Increased insulin resistance was more frequent in pts with DAS28-SE≥5.1 than DAS28-SE<5.1 (84.0% vs. 63.6%, p=0.021). Importantly, these groups were comparable regarding all insulin resistance risk factors and anti-inflammatory treatment including glycocorticoids. Pts with high disease activity also had higher levels of logHOMA2-IR (1.7 (1.2-2.5) vs. 1.3 (0.9-1.9) (p=0.003) while HOMA2-%B was not different 150 (118-195) vs.133 (115-184) p=0.446. In comparison with controls, both RA groups were not different regarding insulin resistance risk factors (Table 1). Parameters of glucose metabolism were comparable between controls and pts with DAS28-SE<5.1. Significant difference of logHOMA2-IR and logHOMA2-IR>1 was found between controls and pts with DAS-SE≥5.1. This was not followed with increase of HOMA2-%B.

Conclusion: RA pts had higher logHOMA2-IR than controls which was followed with impaired β cell function. More significant difference was demonstrated in pts with high disease activity compared to controls. RA itself was an independent risk factor for increased insulin resistance

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects II: Risk and Impact of Comorbidity

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk for infections, hospitalizations and cardiovascular (CV) events. The association of serious adverse events (SAE) with the risk of developing a stroke is unclear. We aimed to examine the cumulative incidence of strokes depending on precedent SAEs and the effect of CV treatment.

Methods: We performed a nested case-control study within the German biologics register RABBIT. Since May 2001, RA patients have been enrolled at start of a conventional synthetic (cs) or biologic (b) DMARD after ≥1 csDMARD failure. Rheumatologists report patient characteristics, comorbidities and their therapy at baseline as well as clinical status, disease activity, RA treatment and SAEs every 6 months. We considered all incident non-haemorrhagic strokes reported until October 2015 as cases. Two controls were matched to each case (Table); all but three cases could be matched. In addition, we considered all hospitalized SAEs reported before the event of stroke (index date in matched controls). We calculated the cumulative incidence of stroke depending on precedent SAEs and applied multi-state proportional hazard models.

Results: Compared to the remaining cohort, cases and controls were older and had more CV risk factors. Cases and controls were similar in treatment of RA, comorbid osteoporosis, and diabetes but CV diseases were significantly less frequently treated in cases (Table). In an adjusted model, patients with treated CV diseases had a moderately elevated risk for stroke (hazard ratio (HR): 1.41 [95% CI: 0.66, 3.01]) (Ref: patients with no CV disease). In contrast, patients with untreated CV disease had a highly increased risk (HR: 3.10 [1.41, 6.79]). Treatment with TNF inhibitors or other bDMARDs was not associated with the stroke risk (HR: 0.9 [0.6, 1.4] and 0.7 [0.4, 1.2], Ref: csDMARDs). The cumulative incidence of stroke was 2.5-fold higher in patients with precedent hospitalized SAEs than in patients without (Figure). Immediately after SAEs the risk was most pronounced.

Conclusion: The risk of stroke in RA patients may be driven by precedent SAEs requiring hospitalization. In addition, untreated CV disease was a significant risk factor for a future stroke. These results strengthen the need for a better CV management in RA patients. Table: Baseline characteristics of the cohort, controls and cases.

Session Title: Rheumatoid Arthritis – Clinical Aspects II: Risk and Impact of Comorbidity

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: While the impact of interstitial lung disease (ILD) on mortality in RA has been demonstrated, less is known about the influence of other lung diseases either in isolation or in the context of other comorbidity. Thus, we assessed the associations of chronic lung disease (CLD) comorbidity with RA disease characteristics, DMARD use, all-cause mortality, and compared the impact of CLD and cardiovascular disease (CVD) comorbidity on survival.

Methods: Participants were enrollees in a longitudinal observational cohort of US veterans with RA. We characterized comorbidity using the Healthcare Cost and Utilization Project Clinical Classification Software (CLD: categories 127, 128, 130-133; CVD: categories 96-117) from national administrative data over the 12 months preceding enrollment. Analyses were also conducted using ICD-9 codes for ILD and chronic obstructive pulmonary disease (COPD) documented by treating physicians at enrollment. Vital status was determined by the National Death Index. We constructed multivariable logistic and linear regression models to assess associations of CLD comorbidity with RA disease characteristics and medications; multivariable Cox proportional hazards regression models were used to assess the associations with all-cause mortality. Finally, we compared the relative and combined impact of CLD and CVD comorbidity on survival with Kaplan-Meier (KM) curves and Cox regression models.

Results: A total of 2,053 participants were included with mean age of 64 (SD 11) years, RA duration 12 (11) years, 90% male, 87% RF or CCP positive, and 80% current or former smokers. CLD comorbidity was present in 34% (18% COPD, 4% asthma, 2% pleural, 1% external agent/chronic failure, 23% other lung [includes ILD]). CLD comorbidity was associated with higher ESR, CRP, and DAS28 and lower odds of obtaining DAS28 remission (OR 0.76, 95% CI 0.62-0.92). CLD comorbidity was associated with lower odds of ever methotrexate use (OR 0.67, 95% CI 0.55-0.82) and higher odds of ever azathioprine (OR 1.67, 95% CI 1.04-2.67), leflunomide (OR 1.50, 95% CI 1.20-1.87), and prednisone (OR 1.44, 95% CI 1.19-1.76) use. No association was observed with ever biologic use (OR 1.10, 95% CI 0.91-1.34). CLD was associated with 50% increased mortality (95% CI 1.28-1.75), driven by COPD (HR 1.59, 95% CI 1.30-1.94) and other lung disease (HR 1.33, 95% CI 1.24-1.44). Physician classification performed similarly for COPD (HR 1.49, 95% CI 1.18-1.88) but demonstrated increased mortality risk specifically for ILD (HR 1.92, 95% CI 1.26-2.94). KM curves and HRs for CLD and CVD comorbidity are shown in Figure 1.

Conclusion: Chronic lung comorbidity is associated with higher RA disease activity, altered DMARD selection, and increased mortality. Reduced survival is similar, and additive, to that of CVD. Identification and aggressive treatment of chronic lung disease in RA should not be limited to ILD.

Smoking Is Associated with Unfavorable Flare/ Remission Pattern in Patients with Rheumatoid Arthritis

Shafay Raheel[1], Cynthia S. Crowson[2], Eric L. Matteson[1] and Elena Myasoedova[1], [1]Rheumatology, Mayo

Clinic, Rochester, MN, [2]Health Sciences Research, Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects II: Risk and Impact of Comorbidity
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Smoking is well recognized as a risk factor for rheumatoid arthritis (RA), and determinant of RA disease activity, severity, response to therapy, and possibly mortality. However, long-term data on flare rates in RA among patients with smoking history are lacking. The purpose of this study was to assess trends in the occurrence of flares and remissions in RA among smokers and non-smokers.

Methods: A population-based cohort of patients with RA (age≥18 years; 1987 ACR criteria met in 1988-2007) was used to perform this retrospective medical records review of each clinical visit to estimate flare and remission status. RA flare was defined as any worsening of RA activity leading to initiation/change/increase of therapy (OMERACT 9). Remission was defined as the absence of disease activity (i.e. tender joint count [TJC] = 0 + swollen joint count [SJC] = 0 + ESR ≤ 10 mm/hr) (OMERACT 7). All subjects were followed until death, migration or July 1, 2012. Binomial regression models with random effects to account for multiple visits per subject were used to assess the association between smoking status and flare/remission rates adjusting for age, sex, and calendar year. Smoothing splines were used to allow for non-linear effects. Two way interactions between RA disease duration and smoking status were examined.

Results: The study included 650 RA patients (mean age 55.8 years; 69% female) with mean follow up of 10.3 years. Flare/ remission status was collected for a total of 17,323 clinical visits. Patients were flaring in 2887 (17%) visits and were in remission in 1747 (10%) visits. Current smokers had higher flare rates than non-smokers (p=0.047) and former smokers were not different from non-smokers (p=0.87; Figure 1). A borderline interaction between smoking status and RA disease duration indicated there were no differences in flare rates by smoking status during the first few years of RA disease duration, but subsequently current smokers had higher flare rates as compared to non-smokers (p=0.072). The pattern of RA disease flares over the follow up time was similar among former smokers and non-smokers (p=0.16). The overall rate of remission by baseline smoking status was significantly lower in current smokers than non-smokers (p=0.034; Figure 2). There was no difference in remission rates for former smokers compared to non-smokers (p=0.24), and no indication that remission rates differed over the disease course for current smokers (interaction p=0.42) or former smokers (interaction p=0.93) compared to non-smokers.

Conclusion: In this long term followup study, current smokers have higher rates of flares compared to non-smokers. Concordantly, remission rates were lower in smokers compared to the non-smokers. Smoking adversely affects RA flare/ remission. These findings should be helpful in counseling patients with RA who smoke.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Safety and Cost Effectiveness

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: According to national guidelines issued in 2015, a non-medical switch from originator infliximab (IFX) (Remicade) to biosimilar Remsima was conducted in all Danish patients with inflammatory rheumatic diseases treated in routine care. We aimed to investigate 1) effects of the switch on serum (s) IFX and presence of anti-drug antibodies (ADA) in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axial SpA), 2) association between sIFX and ADA at the time of switch and adherence to Remsima treatment.

Methods: We included Remicade-treated patients, who switched to and were treated with Remsima. Blood samples were drawn at baseline (immediately before switching) and during follow-up (after ~3, 6, 12 months, immediately before IFX infusion to ensure trough levels). sIFX and ADA were analyzed using automated in-house assays at OUS-Radiumhospitalet. Trough sIFX<3mg/l was considered low and ≤1mg/l very low. If sIFX<5mg/l, ADA was measured. ADA≤30AU/l was considered low and ADA>30AU/l median-high. Clinical characteristics and outcomes were registered in the DANBIO registry. Remission was defined by disease activity composite scores (DAS28<2.6 (RA, PsA) and ASDAS<1.3 (axial SpA)). Medians (IQR) or percentages are shown. Comparisons were performed using Mann Whitney U test (unpaired) and Wilcoxon signed rank test (paired). The impact of baseline sIFX and ADA on treatment adherence was studied by Kaplan-Meier drug survival curves and Cox regression analyses.

Results: 231 pts with available baseline samples from 9 departments were included (age 52 (46-65) years, 51% women). Previous IFX treatment duration was 7.1 (4.5-9.7) years. Observation time after switch was 345 (275-361) days. Trough sIFX levels increased from 2.5 mg/L at switch to 2.9 mg/L 3 months after (Table). 18 of 108 pts (17%) with low baseline sIFX had high sIFX at 3 months, and 6 of 82 pts (7%) with high baseline sIFX had low sIFX at 3 months. Presence of medium-high ADA was unchanged over time (Table) and 94% of patients had similar ADA levels at baseline and at 3 months. Concomitant methotrexate (yes/no) was not associated with baseline sIFX or ADA (both p>0.05, Mann Whitney). Patients with low sIFX (<3mg/L) received lower IFX doses than pts with sIFX≥3mg/l (i.e. 260 (200-320)mg vs. 300 (252-400)mg, p=0.005) and with longer intervals (8 (8-9)weeks vs. 7 (6-8)weeks, p<0.001). Being in remission at baseline (61%/58%/18% of RA/PsA/axial SpA patients) or at 3 months (56%/68%/19%) was not associated with sIFX (all p>0.05). A total of 37 pts (16%) stopped Remsima treatment during follow-up (lack of effect (17 pts), adverse events (11 pts), other reasons (9 pts)), median treatment duration was 126 (85-210) days. In these patients, 13/37 (35%) had low

baseline s-IFX and 5 pts had ADA at baseline. ADA levels in individual patients were unchanged at the time of withdrawal of Remsima treatment. Treatment adherence was higher in patients with low baseline sIFX (<3mg/L) vs. ≥3 mg/L (Figure), also when stratified by diagnosis (RA, PsA, axial SpA. Data not shown). Presence of ADA had no impact on treatment adherence (Log rank, P=0.8).

Conclusion: In this highly selected group of patients treated with Remicade for >5 years, a non-medical switch to biosimilar Remsima had no negative impact on drug concentration or presence of ADA at 3 and 6 months following switch. At baseline, 53% of patients had low sIFX, but few patients had ADA, perhaps indicating low immunogenicity of IFX in these patients. The poorer treatment adherence among patients with high sIFX at the time of switch warrants further investigation.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Safety and Cost Effectiveness

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Three non-TNF targeted biologics – rituximab, abatacept, and tocilizumab – are widely used, notably in TNF-IR patients. We aimed to compare the efficacy and safety of the drugs in common practice.

Methods:

This was a multicenter open-label observational study of patients with RA according to 1987 American College of Rheumatology criteria who were initiating rituximab, abatacept, or tocilizumab treatment and enrolled in three French Society of Rheumatology prospective registries (AIR for rituximab, ORA for abatacept, and REGATE for tocilizumab). Severe adverse events (death, serious infection, major adverse cardiovascular events, and cancer) were validated by chart review by three experts. The primary outcome was drug retention without failure at month 24. Failure was defined as all-cause death; rituximab, abatacept, or tocilizumab discontinuation; initiation of a new biologic or a combination of conventional DMARDs; or increase in corticosteroid dose greater than 10 mg/day compared to baseline at two successive visits. We used a propensity-score approach to adjust for differences in observed factors that might affect both treatment assignment and outcome.

Results:

In total, 4,498 patients (abatacept: 1,016, rituximab: 1,984, and tocilizumab: 1,498) were enrolled in the registries, with a follow-up of 18,898 patient-years (abatacept: 4,912, rituximab: 10,545, and tocilizumab: 3,441). Among the 4498 enrolled patients (median disease duration: 11 [5-18] years, 83.3% of patients previously treated with a biologic, median number of prior of anti-TNF 2 [1; 3]), 3,507 patients had a follow-up at month 24. At month 24, 64.6% of patients [95% confidence interval (95% CI): 61.1; 68·5] were still receiving rituximab without failure, 40.0% [95% CI: 36·0; 45·0] abatacept, and 61.3% [95% CI; 54·9; 68·8] tocilizumab (Figure 1). Drug retention without failure was significantly greater with rituximab and tocilizumab than abatacept (hazard ratio 2·00 [95% CI: 1·65; 2·43]; p<0·001, and 1·82 [95% CI: 1·37; 2·41], p<0·001, respectively), with no difference between rituximab and tocilizumab. Concordant results were observed in six sensitivity analyses. At month 60, drug retention without failure was significantly greater with rituximab than abatacept (48.1% [95% CI: 44.3; 52.5] and 21.0% [95% CI: 18.1; 24.6], respectively, HR 2.06 [95% CI: 1.78; 2.39]; p<0·001).

At month 24, 513 patients (6.7/100 patient-years) had experienced at least one of the adverse events of specific

interest including serious infection, MACE, cancer, or death: 255 in the rituximab registry (7.3/100 patient-years), 116 in the abatacept registry (6.4/100 patient-years), and 142 in the tocilizumab registry (6.0/100 patient/years) (IRR abatacept versus rituximab: 0.79 [0.56;1.12], p=0.19; IRR tocilizumab versus rituximab: 0.87 [0.58;1.32], p=0.52; IRR abatacept versus tocilizumab 0.91 [0.57;1.47], p=0.71).

Conclusion:

Among patients followed up in common practice with long-standing RA, mostly refractory to at least one previous biologic, the effectiveness at two years seems lower for abatacept than rituximab and tocilizumab. Safety of the three drugs seems similar.

Figure 1. Drug survival without failure in RA patients treated with abatacept, rituximab and tocilizumab

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Safety and Cost Effectiveness

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) who have an inadequate response to a tumor necrosis factor inhibitor (TNFi) can switch to another targeted disease-modifying antirheumatic drug (DMARD), either by changing to another TNFi ("cycling") or by switching to a new mechanism of action ("new MOA switching"). Given potential differences in outcomes conditional on choosing either of these strategies, this study examined the cost per effectively treated patient in the first year after TNFi cycling or new MOA switching.

Methods: This claims-based analysis included a cohort of patients with RA in the Truven Health Analytics MarketScan Commercial database who either cycled from a TNFi (adalimumab, certolizumab pegol, etanercept, golimumab, or infliximab) to another TNFi or switched to a new MOA biologic (abatacept or tocilizumab) or targeted oral DMARD (tofacitinib) between January 2010 and December 2014. A validated claims-based algorithm was applied to estimate treatment effectiveness for the 12-month post-switch period based on six criteria: 1) adherence ≥80%; 2) no dose increase; 3) no addition of a synthetic DMARD (leflunomide, methotrexate, sulfasalazine, or hydroxychloroquine); 4) no switch to another targeted DMARD; 5) no new/increased oral glucocorticoid; and 6) intra-articular injections on <2 days. Costs were calculated from healthcare claims based on the paid amount for targeted DMARDs, adjusted for inflation according to price changes for the individual medications during the study period. Cost per effectively treated patient was defined as the average 12-month post-switching cost per patient for targeted DMARDs divided by the proportion of patients categorized by the algorithm as effectively treated. Bivariate analysis was conducted to compare treatment effectiveness and costs between TNFi cyclers and new MOA switchers.

Results: A total of 8,517 patients were analyzed (5,997 TNFi cyclers and 2,520 new MOA switchers). TNFi cyclers and new MOA switchers had similar age (mean±SD, 49.7±9.6 vs 51.0±9.3 years), sex (female, 81.2% vs 83.9%), and comorbidity (mean±SD Deyo-Charlson index score, 1.4±0.8 vs 1.5±1.0). Costs and treatment effectiveness favored new MOA switchers over TNFi cyclers, resulting in higher cost per effectively treated patient for TNFi cycling vs new MOA switching. Differences in adherence, subsequent treatment switches, and dose increases were major drivers of cost effectiveness (Table).

Outcomes in 12-Month Post-Switch Period	TNFi Cyclers (N=5,997)	New MOA Switchers (N=2,520)	Difference*	*P**
Average targeted DMARD costs	$38,456	$33,008	-$5,448	<0.001
Effectiveness, per claims-based algorithm				
Overall (all six criteria)	23.3%	26.0%	2.7%	0.008
Adherence	39.1%	39.8%	0.7%	0.560
No dose increase	88.0%	93.9%	5.9%	<0.001
No new conventional synthetic DMARD	85.0%	85.7%	0.8%	0.371
No switch to another targeted DMARD	64.2%	69.6%	5.4%	<0.001
No increased/new glucocorticoids	85.9%	85.3%	-0.6%	0.451
Intra-articular injections on <2 days	90.6%	90.6%	0.0%	0.973
Drug cost per effectively treated patient				
Overall (all six criteria)	$165,200	$126,991	–$38,208	
Adherence	$98,387	$83,013	–$15,373	
No dose increase	$43,694	$35,156	–$8,538	
No new conventional synthetic DMARD	$45,264	$38,509	–$6,755	
No switch to another targeted DMARD	$59,917	$47,423	–$12,494	
No increased/new glucocorticoids	$44,746	$38,688	–$6,058	
Intra-articular injections on <2 days	$42,456	$36,450	–$6,005	
* New MOA switchers vs TNFi cyclers; *P*-value from Chi-square test for categorical variables and t-test for continuous variables.				

Conclusion: After prior exposure to TNFi, switching to a new MOA rather than cycling to another TNFi was associated with better treatment effectiveness and lower drug costs, resulting in lower cost per effectively treated patient.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Safety and Cost Effectiveness

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with a history of cancer were excluded from pivotal clinical trials evaluating biologics. Therefore, only registries can inform us on the incidence of cancers in such patients treated with a biologic.

Methods: Registries of the French Society of Rheumatology AIR and ORA included 1986 and 1024 patients to study tolerance and efficacy of rituximab (RTX) and abatacept (ABA) in common practice, respectively. Cancers and serious infections were validated by analysis of the charts of patients.

Results: Treatment with rituximab 270 patients had a history of cancer and 1656 patients did not have a history of cancer before RTX (60 missing data). The 1656 patients without a history of cancer had a mean follow-up of 5.4 years (8942 patient-years) and 83 cancers occurred (*0.9 cancers/100 patient-years*). Among the 270 patients with a history of cancer, mean follow-up was 5.2 years (1404 patient-years) and 48 incident cancers (*3.4 cancers/100 patient-years*), including 19 new cancers (1.3 cancers/100 patient-years) and 29 relapses of past cancers (2.1 cancers/100 patient-years). Cancers occurred after a median period of 32.2 (18.5 ; 53.9) months and 37.7 (21.7 ; 57.8) months after RTX initiation in patients with and without a history of cancer, respectively. Cancers occurred after a median number of 2 (1 ; 4) and 2 (1 ; 4) cycles, in patients with and without a history of cancer, respectively. Treatment with abatacept 55 patients had a history of cancer and 961 patients did not have a history of cancer before abatacept (8 missing data). The 961 patients had a mean follow-up of 4.8 years (4613 patient-years) and 61 cancers occurred (*1.3 cancers/100 patient-years*). The 55 patients with a history of cancer had a mean follow-up of 4.6 years (253 patient-years). Five incident cancers occurred (*2.0 cancers/100 patient-years*) including 3 new cancers (1.2 cancers/100 patient-years) and 2 relapses of past cancers (0.8 cancers/100 patient-years). Cancers occurred after a median period of 8.0 (6.4 ; 24.3) months and 34.8 (19.4 ; 46.1) months after ABA initiation in patients with and without a history of cancer, respectively.

Conclusion: The incidence of cancers in patients with a history of cancer treated with abatacept and rituximab, approximately two to three-fold that of patients without a history of cancer, is in the range of what is expected in these patients at higher risk of cancer.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Safety and Cost Effectiveness

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The aim of the study is to assess whether the risk of post-operative infectious complications in rheumatoid arthritis (RA) patients undergoing surgical procedures is greater in patients continuing therapy with different disease-modifying anti-rheumatic drugs (DMARDs) and/or biologic agents (BA) compared with patients who stop their medications prior to surgery.

Methods: Using the United States Department of Veterans Affairs (VA) administrative databases & surgical quality registry, we identified surgical procedures in RA patients, who were on at least one DMARD or one BA in the perioperative period, between October 1, 1999 and September 30, 2009. We used the VA pharmacy database and a previously validated method to determine whether the medication had been stopped prior to or continued through surgery. Surgeries among RA patients were divided into the following treatment groups: methotrexate (MTX) alone, hydroxychloroquine (HCQ) alone, leflunomide (LEF) alone, and MTX plus TNFα - inhibitor (TNFi). Primary endpoints were total infectious complications and wound infection. Unconditional multivariable logistic regression models were used to calculate odds ratios and compare infection risk of infection between groups. Statistical significance is defined with $p<0.05$.

Results: We identified a total of 9362 surgeries among 5544 RA patients during this period. In the MTX monotherapy group, a total of 2601 surgeries were identified. MTX was continued in 1961 surgeries. Continuing MTX during surgeries was not associated with post-operative infection (OR=0.79, *p*=0.11) and post- operative wound infection (OR=0.77, *p*=0.10). In the HCQ monotherapy group, a total of 2012 surgeries were identified. HCQ was continued in 1496 surgeries. Continuing HCQ during surgeries was not associated with post- operative infections (OR= 0.93, *p*=0.67) or wound infection (OR 0.86, *p*=0.42). In the LEF monotherapy group, a total of 652 surgeries were identified. LEF was continued in 508 surgeries. Continuing LEF during surgeries was not associated with post- operative infections (OR=0.78, *p*=0.34) or wound infections (OR 0.87, *p*=0.63). In the MTX plus TNFi group, a total of 386 surgeries were identified. Both drugs were continued in 196 surgeries. MTX was stopped and TNFi continued in 59 surgeries. MTX was continued and TNFi was stopped in 72 surgeries. Both MTX and TNFi were stopped in 59 surgeries. With stopping both MTX and TNFi before surgery as reference, continuing [i] only MTX (OR=0.80, *p*=0.77) or [ii] only TNFi (OR=0.15, *p*=0.12) or [iii] both drugs (OR=0.35, *p*=0.15) were not associated with post- operative infections. Continuing [i] only MTX (OR=1.18, *p*=0.86) or [ii] only TNFi (OR=0.19, *p*=0.23) or [iii] both drugs (OR=0.38, *p*=0.32) were not associated with post- operative wound infections, either.

Conclusion: Our results suggest that the continuation of DMARD monotherapy such as MTX, HCQ, LEF, or the combination of MTX and TNFi therapy for RA in the perioperative setting is not associated with increased rates of overall post- operative infectious complications and wound infections. This is a retrospective study evaluating all surgeries. Further sub-group analyses for specific surgeries will be analyzed in our future studies.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III: Axial Spondyloarthritis – Clinical

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: To compare the clinical features of spondyloarthritis in first degree relatives (FDRs) of patients with ankylosing spondylitis (AS) with chronic back pain (CBP) with those participants in a nationally representative sample of US adults examined in 2009-2010 US National Health and Nutrition Examination Survey (NHANES) who also had CBP.

Methods: Non-Hispanic White FDRs of AS patients, without a prior diagnosis of AS, between the ages of 20-69 were included in a prospective cohort study. A questionnaire was used to obtain demographic and clinical data focusing on features of spondyloarthritis. We compared demographic and clinical features between FDR and NHANES cohorts using both univariable and multivariable regression analyses, controlling for age and gender. We focused on non-Hispanic whites because of the limited number of nonwhite FDRs available from the family study. Excluded from the analysis were 20 FDRs and 12 participants in the 2009-2010 NHANES study with CBP who carried a diagnosis of AS.

Results: This study of non-Hispanic White FDRs with chronic back pain without a prior AS diagnosis between 20-69 years of age, including 67 FDRs from 60 families from a total of 499 FDRs examined and 722 with chronic back pain of the 2244 white participants in the 2009-2010 NHANES cohort. Significant results are shown in Table 1. FDRs of AS patients were more likely to have neck, buttock and hip pain. They were also more likely to have alternating buttock pain, pain that improves with activity and worsens with rest as well as pain that awakens them at night and morning stiffness of >30 minutes. Of particular interest was a higher frequency of heel pain and ulcerative colitis and marginal increases in uveitis and psoriasis. Of note, there were no significant differences in the frequencies of upper, mid or low back pain (data not shown). Also, although FDRs of AS patients were more likely to use non-steroidal anti-inflammatory drugs (NSAIDs) for their back pain, there were no differences in response to NSAIDs compared to the US population (data not shown).

Table 1. Comparison of AS-FDR and NHANES Non-Hispanic Whites Aged 20-69 Years with Chronic Back Pain Based on Univariable/Multivariable Regression Models

Variable	FDR's n=67	NHANES n=772	Univariable P value	Multivariable P value
Male, %	43.3	45.9	0.685	0.683
Age (±SD in years)	45.2 (± 13.5)	45.1 (± 13.6)	0.933	0.934
Age Onset (±SD in years)	26.1 (± 12.3)	32.6 (± 14.1)	<0.0001	<0.0001
Neck pain, %	52.2	36.1	0.009	0.011
buttock pain, %	49.3	30.7	0.001	0.002
hip pain, %	43.3	15.9	0.0006	0.001
Alternating buttock pain, %	57.4	32.5	<0.0001	<0.0001
Pain improves with activity,%	86.9	65.4	0.002	0.003
Pain worsens with rest,%	31.8	23.6	<0.0001	0.0002
Pain awakens from sleep,%	61.9	48.1	0.036	0.046
Morning stiffness >30 minutes,%	74.6	48.6	0.0003	0.001
Heel pain not due to trauma,%	49.2	19.6	<0.0001	<0.0001
Uveitis, %	3.1	0.65	0.039	0.068
Ulcerative colitis,%	4.6	1.0	0.015	0.030
Crohn's disease,%	0	0.4	0.615	0.989
Psoriasis,%	11.1	5.3	0.057	0.065

Conclusion: Chronic back pain in FDRs of non-Hispanic White AS patients not carrying a diagnosis of AS shares significantly more features of axial spondyloarthritis than chronic back pain in the general population. The

clinician should have a high index of suspicion of axial spondyloarthritis in the clinical evaluation and treatment of chronic back pain in this group.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III: Axial Spondyloarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The ASAS Health Index (ASAS HI) was developed to measure functioning and health in patients with spondyloarthritis (SpA) aiming to better define the impact of disease in these patients. The 17 questions of the questionnaire (range 0-17, with a lower score indicating a better health status) have now been translated into 18 languages worldwide. Face validity and feasibility (time of completion) have already been assessed in a field test. The objective of the present study was test construct validity, discrimination across relevant health states, reliability and responsiveness of the original English version and the 16 translations of the ASAS HI in 23 countries

Methods: A convenient sample of SpA patients fullfilling the ASAS classification criteria for either axial (axSpA) or peripheral SpA (pSpA) were included into the study from 33 centers of 22 countries worldwide. Data were collected by the local rheumatologist. Construct validity against other health outcomes was evaluated by Spearman correlation. Discrimination across patient reported health states was decribed. Test-retest reliability was assessed by intraclass correlation coefficient (ICC) in patients without treatment changes (stable disease state, interval 4-7 days). In those patients who required a therapeutic change because of high disease activity, responsiveness was tested (standardized response mean (SRM)) after 2-24 weeks depending on the type of medication.

Results: 1548 patients were included: 64.9% male, mean (SD) age 42.0 (13.4) years, mean (SD) BASDAI 4.1

(2.5). There were 1299 patients with axSpA (375 nr-axSpA and 924 AS patients) and 256 patients with pSpA. The total score of the ASAS HI was 6.7 ± 4.3 (mean ± SD). Floor or ceiling effects were limited (0.8 and 6.9%, respectively). Convergent validity ranged as hypothesized with Spearman correlations from low (age: 0.10) to good (BASDAI: 0.70). ASAS HI scores showed<span" roman"="Roman"" new="New"> a high internal consistency with a Cronbachs-α of 0.93. The ASAS HI discriminated well between patients with different stages of disease activity and function irrespective of the tool applied (ASDAS, BASDAI and BASFI) (table). The groups with greater disease activity and more impaired functioning had higher mean ASAS HI scores (indicating impaired functioning) than those with lower disease activity. Reliability (tested in 578 patients) was good (ICC: 0.87 (95%CI 0.84 to 0.89), p<0.01) and comparable across all disease subtypes. Sensitivity to change (tested in 246 patients) showed a moderate SRM of -0.44 for NSAIDs (n= 75 patients), 0.69 for DMARDs (n=41) and -0.85 for TNFi (n=127). The smallest detectable change in this cohort was 3.0.

Conclusion: The ASAS HI is a valid, reliable and responsive measure of disease severity in people affected by SpA. It should be used in clinical trials to evaluate the impact of SpA and its treatment on overall functioning and health. Table: Discriminative ability of the ASAS HI stratified by disease activity

ASDAS status groups

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III: Axial Spondyloarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Disease activity has an important impact on work productivity in patients with Ankylosing Spondylitis (AS). However, if and to what extent this is the case in early axial Spondyloarthritis (axSpA) and if it is similar in subgroups of patients e.g. male vs. female patients. The aim is to investigate if the impact of disease activity, assessed by ASDAS (AS Disease Activity Score, CRP based), on work productivity is similar according to gender, age, medication use, profession, HLA-B27 status and duration of back pain at baseline in early axSpA patients.

Methods: The SPACE-cohort includes patients (chronic back pain ≥3 months, ≤2 years, onset <45 years) from 5 European centers. Patients who fulfilled the ASAS criteria for axSpA were included in the analysis. Work Productivity and Activity Impairment questionnaire (WPAI) was completed by patients at baseline to assess Work Productivity Loss (WPL; i.e. total work impairment due to disease), presenteeism (i.e. decreased work functionality due to disease) and absenteeism (i.e. absence at work due to disease) in the past 7 days. Higher scores indicate greater impairment (range 0-100). ASDAS was used to assess disease activity. Gender, age, medication use, profession and duration of back pain were tested for effect modification ($p<0.20$) one by one in a linear regression model. Continuous variables were split by the median.

Results: 124 axSpA patients working at baseline were included; 73 fulfilled the clinical arm, 51 patients the imaging arm of the ASAS axSpA criteria. Patients were on average 31.1 years old (SD 7.7), 50.8% were male and had a mean duration of back pain of 13.7 months (SD 7.8). They worked on average 28.0 (SD 15.7) hours and missed 3.3 (SD 8.8) hours per week at work due to axSpA. Mean WPL, presenteeism, and absenteeism (SD) were 35.7% (29.4), 33.2% (27.0) and 9.3% (22.6) respectively. Patients had a mean ASDAS of 2.4 (SD 0.9). In the univariable model (Table 1), 1 point increase in ASDAS resulted in an increase of 18.5%, 16.9%, 9.6% in WPL, presenteeism and absenteeism, respectively. Fulfilment of the clinical or imaging arm was not an effect modifier (WPL $p=0.69$; presenteeism $p=0.66$; absenteeism $p=0.58$). Gender was an effect modifier in the associations between ASDAS and WPL ($p=0.22$, borderline significant) and presenteeism ($p=0.15$). The use of NSAIDs ($p=0.16$), age, and gender (two-way interaction $p=0.06$) were effect modifiers of absenteeism. The associations remained statistically significant in all stratified models, except in several models of absenteeism.

Conclusion: In early axSpA, higher disease activity is associated with increased work productivity loss including presenteeism and absenteeism. The same level of disease activity appears to have more adverse impact on work productivity in women than in men. Disease activity was associated with higher absenteeism in patients using NSAIDs, younger men and older women.

Table 1: Association between ASDAS and Work Productivity Loss, presenteeism, absenteeism and stratified for its related effect modifiers at baseline among axial Spondyloarthritis patients who performed paid work in the SPACE cohort (n=124)

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III: Axial Spondyloarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: To evaluate drug-free sustained clinical remission and clinical relapse after induction therapy with golimumab in patients with active peripheral Spondyloarthritis (pSpA) in a very early stage of the disease. The hypothesis would be that treatment with a TNF-blocker at this early ("immature") stage of the disease would result in a significant higher number of patients in clinical remission compared to placebo.

Methods: CRESPA (Clinical REmission in peripheral SPondyloArthritis) is an ongoing monocentric study of golimumab treatment in pSpA patients. Eligible patients were ≥18 years and fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for pSpA. All patients had a symptom duration of less than 3 months. Patients were randomized 2:1 to receive golimumab 50 mg every 4 weeks or matching placebo for 24 weeks. The primary endpoint was the percentage of patients achieving clinical remission at week 24. Clinical remission was defined as the absence of arthritis, enthesitis and dactylitis on clinical examination. If patient were in clinical remission at two major consecutive visits planned at week 12 and 24, treatment was stopped. These patients were prospectively followed to assess the percentage of patients in drug-free sustained clinical remission or having a clinical relapse of arthritis, dactylitis and enthesitis. In case of clinical relapse patients were retreated with open-label golimumab in the extension part of this trial.

Results: In total 60 patients were randomized of whom 20 received placebo and 40 golimumab. Baseline demographics and disease characteristics were generally similar between the 2 groups. At week 24 a significantly higher percentage of patients receiving golimumab achieved clinical remission compared to patients receiving placebo (75% (30/40) versus 20% (4/20); P<0.001). At week 12 similar results were observed (70% (28/40) versus 15% (3/20) ; P<0.001). Sustained clinical remission (both at week 12 and 24) was observed in 67.5% (27/40) of golimumab treated patients, compared to only 15% (3/20) in the placebo group; in these patients treatment was stopped. All patients had at least a follow up of 6 months after discontinuation of treatment with a maximum of 52 months. 60% (18/30) of these patients are still in drug-free sustained clinical remission and 40% (12/30) had a clinical relapse. In the 12 patients with relapse after withdrawal of treatment, 10 patients (83.3%) already experienced this flare within 6 months of discontinuation.

Conclusion: In patients with active, very early peripheral spondyloarthritis, treatment with golimumab led to high percentages of clinical remission at week 12 and 24. A high percentage of patients stayed in sustained drug-free clinical remission after induction therapy with golimumab the first 24 weeks.

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III: Axial Spondyloarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at a well-documented increased risk of tuberculosis (TB) compared to the general population, both with and without treatment with tumor necrosis factor inhibitors (TNFi). Whether or to what extent these increased risks apply also to patients with ankylosing spondylitis (AS), psoriatic arthritis (PsA), or other types of spondyloarthropathies (SpA), whose age, gender and disease characteristics differ from RA, is much less known. We therefore investigated TB risks in these conditions, in relation to biological treatment and risks in the general population.

Methods: Through linkages including the Swedish national Patient, Population, TB and Rheumatology registers, we identified all individuals in Sweden registered with AS, PsA or SpA, and matched general population comparators, who were followed for TB from 2002 through 2013. Incidence rates were estimated for biological-naïve and biological-exposed patients and their comparators. We calculated hazard ratios (HR) and 95% confidence intervals (CI) for the whole period and stratified by calendar period. HRs were adjusted for age, sex and country of birth.

Results: 38,702 patients with AS, PsA or SpA, and 200,417 population comparators were included. Thirteen percent of patients used a biological drug during the study period, of which 99% was a TNFi. The average age of patients was approximately 10 years lower than the RA patients of the previous study. During the study period, 11 TB cases were identified among the patients, corresponding to an incidence rate (per 100,000) of 2.7 (95% CI 1.3 to 5.6) for biological-naïve patients, 22 (95%CI 8.3 to 59.2) for biological-exposed patients, and 2.4 (95% CI 1.8 to 3.3) for the general population. The HR comparing biological-naïve to biological-exposed patients was 7.5 (95% CI 1.9 to 29), and 1.2 (95% CI 0.5 to 2.7) comparing biological-naïve patients compared to the general population.

Conclusion: Biological-naïve AS, PsA and SpA patients have a similar risk of TB as the general population, and hence lower incidences than those previously reported in RA. However, these patients had a 7.5-fold higher risk of TB when treated with TNFi. Although the absolute risk of TB is low, and the most cases occurred in the biological-naïve group, the risk of TB increased after treatment with TNFi. **Table:** Incidence rates and 95% confidence intervals of tuberculosis (TB) in the general population and patients with AS, PsA or SpA with and without biologic therapy. Hazard ratios for TB comparing biological-naïve to biological-exposed, overall and stratified by calendar time of follow-up.

	General population		Biological-naïve AS, PsA or SpA		Biological-exposed AS, PsA or SpA		
	No. of TB cases	Incidence rate (95% CI)	No. of TB cases	Incidence rate (95% CI)	No. of TB cases	Incidence rate (95% CI)	Hazard ratio (95% CI)
Overall	58	2.4 (1.8 to 3.3)	7	2.7 (1.3 to 5.6)	4	22 (8.3 to 59)	7.5 (1.9 to 29)
2002-2006	12	2.8 (1.5 to 4.1)	3	3.2 (1.0 to 9.9)	0	-	-
2007-2015	26	2.4 (1.6 to 3.4)	4	2.4 (0.9 to 6.3)	4	25 (9.5 to 66)	8.6 (2.0 to 37)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III: Axial Spondyloarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Making the diagnosis of axial spondyloarthritis (axSpA) may be difficult. Antibodies against CD74 have been shown to be present in 2/3 of patients with long established axial SpA. InterSpA is an international multicenter study, conducted to compare the sensitivity and specificity of anti-CD74 and HLA-B27 in patients with axSpA of recent onset.

Methods: Patients between 18 and 45 years suffering from inflammatory back pain (IBP) for maximally 2 years were recruited. The presence of ankylosing spondylitis, additional inflammatory rheumatic disorders and biologic therapy were exclusion criteria. MRI of the sacroiliac joint was performed in all patients; HLA-B27 was detected by genotyping and anti-CD74 using a CE certified kit of Aesku Diagnostics (Wendelsheim, Germany). The sensitivity of anti-CD74 and HLA-B27 were calculated in patients fulfilling the imaging arm of ASAS criteria, in all patients fulfilling ASAS criteria and in 100 blood donors. Both the MRI reading as well as the laboratory procedures were performed blinded.

Results: 205 patients suffering from IBP were recruited. There were 40 recruiting failures, and complete data sets are currently available of 122 patients (mean age 29 years, mean duration of IBP 13 months, 56% male). Sacroiliitis was diagnosed by the expert reader in 67 % and HLA-B27 was positive in 69 % of the patients. 23 patients fulfilled the ASAS criteria of axSpA by the imaging arm only, 59 by both the imaging and clinical arm and 22 by the clinical arm only. The sensitivities of IgA anti-CD74, IgG anti-CD74 and HLA-B27 were 64.6%, 24.4% and 75% in the axSpA patients fulfilling the imaging arm, 65.4%, 23.1% and 80.7% in the patients fulfilling ASAS criteria, and 3%, 5% and 8% in the blood donors. The likelihood ratios are 21.5 (IgA anti-CD74), 4.9 (IgG anti-CD74) and 9.4 (HLA-B27) when considering the patients fulfilling the imaging arm, and 21.8 (IgA anti-CD74), 4.6 (IgG anti-CD74) and 10.1 (HLA-B27) when considering all patients fulfilling ASAS criteria.

Conclusion: In view of the high likelihood ratio, IgA anti-CD74 is a useful addition to our diagnostic tools for axSpA.

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Novel and Current Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The rationale for this prospective, biomarker-driven, open-label clinical trial of rapamycin (ClinicalTrials.gov Identifier: NCT00779194) has been based on growing evidence for involvement of the mechanistic target of rapamycin (mTOR) in abnormal T-cell activation and preliminary results of clinical efficacy in mice (Arthritis Rheum. 37:289-97) and patients with SLE (Arthritis Rheum. 54:2983-8; J Immunol.191:2236-46).

Methods: 40 SLE patients meeting eligibility criteria were started on 2 mg of rapamycin (sirolimus) with the dose adjusted to tolerance and trough levels of 6-15 ng/ml. British Isles Lupus Assessment Group (BILAG; Rheumatology 44:902-6) scores, SLE disease activity index (SLEDAI; Arthritis Rheum. 35:630-40), and routine laboratory and immunological assessments were performed before 1st rapamycin dose and 1 month, 3 months, 6 months, 9 months, and 12 months after initiation of treatment. At each study visit, blood samples were obtained from healthy controls matched for patients' age, gender, and ethnicity for parallel analyses 665 flow cytometry biomarkers. Patients having active disease with SLEDAI of 10.2±0.8 (mean±SEM), prednisone dose of 23.7±4.9 mg/day, and proteinuria <0.5 g/day, who were unresponsive or intolerant to conventional immunosuppressants, were enrolled. Prednisone dose was titrated to control disease activity during the study.

Results: Therapeutic rapamycin plasma levels were achieved between months 1 (6.9 ng/ml) through 12 (7.8 ng/ml). 11 patients dropped out due to non-compliance. Among safety outcomes, fasting lipid profile, liver function, platelet and lymphocyte counts were unchanged, while neutrophil counts (from 5,100/µl to 3,900/µl) and haemoglobin (from 13.5 to 12.9 g/dl) were moderately reduced in 12 months. As primary clinical efficacy endpoint, reduction of SLEDAI (≥4) and BILAG disease activity scores (≥2) over 12 months was met in 16 of 29 patients (55%). Among 29 patients, 19 achieved ≥4-point drop of SLEDAI, no BILAG A flare and only one BILAG B flare, indicating a 65.5% SLE Responder Index (Arthritis Care Res. 61:1143-51). SLEDAI was

reduced from baseline of 10.2±0.8 to 7.5±0.9 at 1 month (p=0.04) and 4.8±0.8 at 12 months (p=0.00002). Within the SLEDAI components, arthritis, rash, and hypocomplementemia were significantly improved after 12 months. BILAG was reduced from baseline of 28.9±1.9 to 23.8±2.2 at 1 month (p=0.005) and 17.4±1.9 at 12 months (p=0.00003).Within BILAG components, fatigue, cardiopulmonary, musculoskeletal and mucocutaneous organ-domain scores were significantly reduced after 12 months. Daily prednisone use was reduced from 23.7±4.9 mg to 7.2±2.3 mg after 12 months (p=0.02). Rapamycin blocked the activity of mTOR complex 1 in all T cells, expanded $CD4^+CD25^+FoxP3^+$ regulatory, $CD4^+$ central-memory ($CD62L^+CD197^+$), and $CD8^+$ effector-memory ($CD62L^-CD197^-$) T cells and inhibited the pro-inflammatory necrosis and IL-4 production of $CD4^-CD8^-$ double-negative T cells after 12 months.

Conclusion: Rapamycin elicits rapid, progressive, and sustained improvement of disease activity via correcting abnormal T-cell lineage specification in patients with active SLE.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Novel and Current Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The Phase IIb MUSE study (NCT01438489) of intravenous anifrolumab in 305 patients with moderate to severely active SLE (300 or 1,000 mg vs. placebo, every 4 weeks for 48 weeks) demonstrated efficacy in multiple composite endpoints, with many favoring the 300 mg dose at Day 365.

Methods: This exploratory analysis compares the impact of anifrolumab on common individual manifestations of SLE including: rash, alopecia, and arthritis using the categorical descriptors of SLEDAI–2K and continuous outcome measures of cutaneous activity (rates of ≥50% improvement in the Cutaneous Lupus Erythematosus

Disease Area and Severity Index [CLASI] activity score) and arthritis (change from baseline in swollen and tender joint counts).

Results: At Day 365, placebo response was minimal for SLEDAI–2K rash (Table), distinguishing a substantial treatment effect of anifrolumab, with 300 mg response rates markedly greater than 1,000 mg. More patients treated with anifrolumab compared with placebo also achieved ≥50% improvement in CLASI, but with minimal distinction between doses. The placebo group demonstrated response rates to alopecia and arthritis on SLEDAI–2K of 26% and 42%, respectively. A significantly greater response in alopecia and arthritis manifestations was achieved with 300 mg anifrolumab, with only modest drop-off in efficacy rates with 1,000 mg. Compared with placebo, decreased tender and swollen joint counts were greater in patients treated with anifrolumab, with no difference between doses. Anifrolumab effects on SLEDAI–2K improvement for each manifestation, were primarily seen in patients with a high type I interferon gene signature at baseline (IFN high), driven by lower placebo response rates in this subpopulation.

Conclusion: Anifrolumab demonstrated greater rates of improvement than placebo in rash, alopecia and joint manifestations, with greatest effects achieved by 300 mg anifrolumab in IFN-high patients. An apparent inverse dose response favoring the 300 mg (lower) dose, previously reported for several composite outcomes, characterized the SLEDAI–2K rash response which requires complete resolution of the rash, but was less pronounced in arthritis and alopecia categories or when using quantitative measures. These data contribute understanding of the impact of anifrolumab on individual lupus features, and suggests benefits of continuous variables, as demonstrated by the CLASI and joint counts, in outcome measures to inform interpretable trial designs.

Table: Improvement in individual manifestations of SLE at Day 365

	Placebo	Anifrolumab 300 mg*	*P*-Value	Anifrolumab 1,000 mg*	*P*-Value
Improvement at Day 365					
Skin, n (%)					
Rash (SLEDAI–2K)	13/88 (14.8)	39/88 (44.3)	<0.001	23/82 (28.0)	0.033
Alopecia (SLEDAI–2K)	19/74 (25.7)	32/75 (42.7)	0.026	33/82 (40.2)	0.064
≥50% improvement in CLASI#	34/101 (33.7)	58/99 (58.6)	<0.001	51/102 (50.0)	0.018

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Novel and Current Therapies

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Non-adherence to treatment, a major cause of continued lupus activity and flares, may be difficult to recognize. In this international prospective study, we evaluated adherence to hydroxychloroquine (HCQ) in systemic lupus erythematosus (SLE) patients with flares (ClinicalTrials.gov: NCT01509989).

Methods:

This study included 305 SLE patients (who all met the SLICC criteria) from 19 centers in 10 countries, all of whom had been prescribed HCQ for at least 2 months and were having a disease flare according to the SELENA-SLEDAI Flare Index. Adherence to HCQ was assessed by (1) blood concentrations of HCQ and its main metabolite desethylchloroquine ([HCQ] <200ng/ml and/or undetectable [DCQ] defining severe non-adherence by dosage), (2) self-questionnaires (MASRI<80% and/or Morisky<6 defining non-adherence by questionnaires), and (3) physician's assessments (on a VAS 0-100).

Results:

305 patients (288 women; mean age 38±12ys) met the inclusion criteria. Fifty-six patients (18.4%) were severely non-adherent by dosage (1 missing data point): 44 patients (14.5%) had [HCQ] <200ng/ml and 12 additional patients (3.9%) had an undetectable concentration of DCQ indicating a very recent resumption of treatment. Comparison between non adherent and adherent patients is summarized in table 1. These 56 non-adherent patients by dosage were younger at SLE diagnosis (28±11 vs 23±9; p=0.0025), more likely to be unemployed (46.3% vs 30.9%; p=0.03), and less likely treated with steroids (60.7% vs 79.8%; p=0.0050), whereas their exposure to immunosuppressive drugs was not different. Drug level assessment at inclusion was most often their first drug measurement (84% vs 71%, p=0.046). Their anxiety and depression scores (on the HADS questionnaire) were not different from those of the other patients. Even if their median MASRI and Morisky scores were statistically significantly lower, 24 non adherent patients (43%) would still have been defined as adherent by at least one questionnaire. Moreover, even if the median [Q1-Q3] physician's adherence rating was statistically significantly lower in these 56 patients (75 [43-90] vs 87 [70-95], p<0.0001), their expert physicians considered that 42 patients (75%) took at least half of their treatment and even that 24 (43%) took at least 80% of their treatment.

Among the 305 patients, 121 (39.9%) were non adherent by self-questionnaires. The total non-adherence (dosage + self-questionnaires) was 47%, with only 7% of the patients being classified as non-adherent by both methods.

Conclusion:

These data show that blood HCQ and DCQ measurements objectively identify significant non-adherence in nearly 20% of SLE patients who are flaring. Non-adherence can be missed by the physician and underreported by the patient strongly suggesting the usefulness of blood assays in this setting and the value of using different methods to increase the likelihood of diagnose of non adherence.

Table 1: Characteristics of 304 patients according to their adherence defined by blood drug levels.

	Non-adherent patients by dosage (n=56)	Other patients (n = 248)*	p
Mean Age (± SD) (yr)	35.4 (10.8)	38.2 (11.7)	0.09
Sex, female (%)	55 (98.2)	232 (93.5)	0.09
Ethnicity - White - Black - Asian - Other	 23 (41.1) 21 (37.5) 4 (7.1) 8 (14.3)	 129 (52.0) 62 (25.0) 32 (12.9) 25 (10.1)	0.13
Highest educational level (n=295) - Before high school - High school level - After high school	 8 (14.8) 14 (25.9) 32 (59.3)	 38 (15.8) 64 (26.6) 139 (57.7)	0.97
Employment status (n=297) - Unemployed - Employed - In formation	 25 (46.3) 24 (44.4) 5 (9.3)	 75 (30.9) 154 (63.4) 14 (5.8)	0.03
Active smokers (%) (n=302)	10 (18.2)	34 (13.8)	0.64
Mean age at diagnosis (± SD) (yr)	23.1 (8.9)	28.0 (11.3)	0.0025
Median disease duration [Q1-Q3] (yr)	11 [7 - 17]	9 [5 - 14]	0.06
Median duration of HCQ use [Q1-Q3] (yr) (n=303)	6.1 [3.9 - 11.0]	7.9 [3.3 - 12.3]	0.50
Previous blood HCQ level determination (%) (n=303)	9 (16.1)	72 (29.1)	0.046
Median BMI [Q1-Q3] (n=294)	24 [22 - 30]	23 [21 - 28]	0.06
Median Serum Creatinine (µmol/L) (n=296)	60 [53 - 70]	64 [54 - 79]	0.94
Current use of steroids (%)	34 (60.7)	198 (79.8)	0.005
Current use of immunosuppressive drug or biotherapy (%)	23 (41.1)	117 (47.2)	0.46
Median PGA [Q1-Q3]	1.6 [1.0 - 2.0]	1.5 [1.1 - 2.0]	0.61
Median SELENA-SLEDAI score [Q1-Q3]	8.0 [6.0 - 10.0]	8.0 [6.0 - 10.0]	0.60
Severe Lupus flare (%)	20 (35.7)	112 (45.2)	0.20
Median HADS anxiety score on a 0-21 scale [Q1-Q3] (n=298)	8.0 [3.0 - 10.5]	8.0 [5.0 - 11.0]	0.30
Median HADS depression score on a 0-21scale [Q1-Q3](n=292)	5.5 [4.0 - 9.0]	6.0 [3.0 - 8.0]	0.38
Median MASRI HCQ score on a 0-100 scale [Q1-Q3] (n=298)	74.0 [50.0 - 90.0]	98.0 [90.0 - 100.0]	<0.0001
Median Morisky HCQ score on a 0-8 scale [Q1-Q3] (n=300)	4.6 [2.5 - 6.0]	7.0 [5.8 - 8.0]	<0.0001
Median HCQ adherence by physician on a 0-100 scale [Q1-Q3]	75 [43 - 90]	87 [70 - 95]	< 0.0001

Legends: HCQ Hydroxychloroquine; DCQ: desetylhydroxychloroquine; SD: standard deviation; Q1: quartile 1; SELENA-SLEDAI: SLE Disease Activity Index; PGA: physician's global-assessment visual-analogue scale.
MASRI is a self-questionnaire assessing adherence from the patient's point of view.
Non-adherence was defined by [HCQ] <200ng/ml and/or undetectable concentration of DCQ.
"Others" included patients perfectly adherent as well as less adherent patients with a blood level of HCQ >200 ng/ml and a measurable DCQ.
*: 1 missing data regarding [HCQ] and [DCQ].
PS: The multivariate analysis of the predictive factors is ongoing.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Novel and Current Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Treatment of non-renal manifestations in systemic lupus erythematosus (SLE) remains challenging. To date, available data on the efficacy, safety and steroid-sparing effects of non-biological therapies is limited and provided mainly by small open-label studies and few randomized controlled trials (RCTs). The aim of the study is to assess the efficacy and safety of enteric-coated mycophenolate sodium (EC-MPs) compared with azathioprine (AZA) for active non-renal SLE.

Methods: This is a 24-month randomized, superiority, open-label, multicenter study (ClinicalTrials.gov: NCT01112215). Adults age ≥18 years with moderate-to-severe active SLE disease were recruited from 13 Hospitals in Spain. Patients were stratified by centre and SLEDAI-2k score (6-9 *vs.* ≥10) and randomized (1:1) to receive oral EC-MPs (target dose: 1440 mg/day) or azathioprine (target dose: 2 mg/Kg, according to TPMT levels when available), in addition to background therapy with oral prednisone and antimalarial agents. To have a ≥80% statistical power to detect a ~20% difference in clinical response between the 2 study groups, assuming a clinical response in the AZA group at 2 years of 40-50% we calculated we needed 120 patients in each group with a two-sided significance level of 0.05. Statistical analysis was by intention-to-treat. Rates of complete remission (CR) at 3 and 24 months were the primary endpoints. Secondary endpoints included time to CR, rate and time to BILAG A/B or BILAG A flares, reduction of corticosteroids and adverse events.

Results: A total of 240 patients were included. More patients in the EC-MPs group than in the azathioprine group achieved CR at 3 (32.5% vs. 19.2%, p=0.027) and 24 months (71.2% vs. 48.3%, p=0.0005). Time to CR was shorter in the EC-MPs group (hazard ratio, 1.43; 95% CI, 1.07 to 1.91; P=0.017). BILAG A/B flares were observed in 86 (71.7%) AZA-treated and 60 (50%) EC-MPs-treated patients (p=0.001). Time to first flare was longer with EC-MFs (hazard ratio, 1.81; 95% CI, 1.3 to 2.56; p=0.0004). New BILAG A flares occurred in 26 (21.7%) AZA-treated and 10 (8.3%) EC-MPs-treated patients (p=0.004). Time to severe flare was longer in the

EC-MPs group (hazard ratio, 2.84; 95% CI, 1.37 to 5.89; p=0.0029). Steroid reduction was superior in the EC-MPS group (p=0.024). Adverse events did not differ between groups except for leukopenia in the AZA group.

Conclusion: EC-MPs was superior to AZA for treating active disease and preventing relapse in non-renal SLE patients.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Novel and Current Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

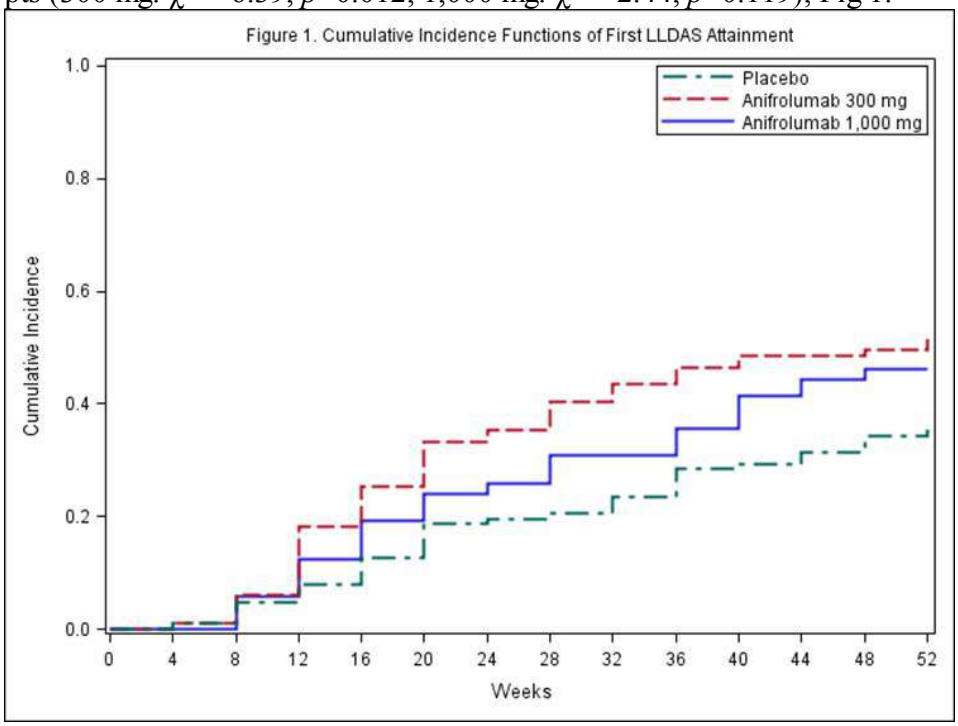
Background/Purpose: Preliminary validation of a Lupus Low Disease Activity State (LLDAS) definition has demonstrated that LLDAS attainment is associated with reduced damage accrual in patients (pts) with SLE.[1] However, it has not been evaluated in randomized controlled trials (RCTs). We present a *post-hoc* analysis evaluating LLDAS in the MUSE trial of anifrolumab in pts with moderate to severe SLE.[2]

Methods: LLDAS requires all of the following: SLEDAI–2K <4 without major organ activity, no new disease activity, Physician's Global Assessment (0–3) <1, prednisolone <7.5 mg/day, and tolerance of standard immunosuppressant dosages.[1] LLDAS criteria were assessed at each study visit. The utility of LLDAS, its association with other endpoints, and the difference in attaining LLDAS between pts treated with anifrolumab and placebo, were explored using descriptive statistics, logistic regression, and Gray's test.

Results: During the 52-week study period of MUSE, pts received intravenous placebo (n=102), anifrolumab 300 mg (n=99), or anifrolumab 1,000 mg (n=104), in addition to standard of care, every 4 weeks for 48 weeks. LLDAS criteria were met, at least once, by 35%, 52%, and 46% of pts, respectively (odds ratio [OR] vs. placebo; 300 mg: 1.97, 90% CI 1.19, 3.25; *p*=0.027; 1,000 mg: 1.63, 90% CI 1.00, 2.68; *p*=0.103). Positive associations were observed between LLDAS and both the SLE Responder Index (SRI[4]) and BILAG-based

Composite Lupus Assessment (BICLA) at 52 weeks, irrespective of treatment; 87% and 74% of pts meeting LLDAS criteria at 52 weeks also fulfilled the SRI(4) and BICLA criteria, respectively (χ^2 = 57.61 and 55.18; p<0.0001 in each case). However, LLDAS was more stringent, with 47% of SRI(4) and 51% of BICLA responders reaching LLDAS.

Compared with placebo, anifrolumab 300 mg and 1,000 mg treatments were associated with increases in LLDAS attainment from Week 12 and Week 28, respectively, with ORs ranging between 1.7 and 3.6 (300 mg), and 1.7 and 2.5 (1,000 mg) at subsequent visits. At Week 52, LLDAS was achieved more frequently in the anifrolumab groups (OR vs. placebo; 300 mg: 3.41, 90% CI 1.93, 6.06, p=0.001; 1,000 mg: 2.03, 90% CI 1.13, 3.64, p=0.046). ORs for spending ≥50% of observed time in LLDAS were 3.04 (90% CI 1.53, 6.06; p=0.008) and 2.17 (90% CI 1.07, 4.39; p=0.072), respectively. Anifrolumab-treated pts reached LLDAS earlier than placebo pts (300 mg: χ^2 = 6.39, p=0.012; 1,000 mg: χ^2 = 2.44, p=0.119), Fig 1.



Conclusion: In the MUSE study, LLDAS correlated with clinically relevant definitions of treatment response and discriminated responders from non-responders. Treatment with anifrolumab 300 mg was associated with up to 3.6-fold increase in odds of LLDAS attainment. LLDAS should be considered as an outcome measure in SLE RCTs.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Novel and Current Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Type I interferons (IFN-I) are implicated in the pathogenesis of systemic lupus erythematosus (SLE). BDCA2 is a plasmacytoid dendritic cell (pDC)-specific receptor that, upon engagement, inhibits the production of IFN-I and other inflammatory mediators produced by human pDCs. Targeting BDCA2, therefore, represents an attractive therapeutic strategy for inhibiting pDC-driven inflammation that is such a prominent feature of SLE. BIIB059 is an investigational humanized anti-BDCA2 monoclonal antibody. This first-in-patient study aimed to assess the safety, tolerability, pharmacokinetics (PK), pharmacodynamic (PD) effects and clinical activity of BIIB059 in adult SLE patients with active cutaneous disease following administration of a single BIIB059 dose.

Methods: A phase 1b randomized, double-blinded, placebo-controlled, multicenter clinical trial was conducted in 12 adult SLE subjects (meeting 1997 ACR criteria) with active cutaneous manifestations [including acute, sub-acute and/or chronic cutaneous forms of cutaneous lupus erythematosus (CLE)]. Subjects received a single IV administration of either BIIB059 20 mg/kg (n=8) or placebo (n=4). A panel of IFN-responsive genes (IRG) was assessed from whole blood by qPCR at baseline and several post-dose time points. Skin biopsies from active lesions were obtained and evaluated at baseline and week 4 for IFN-regulated proteins, including MxA using quantitative immunohistochemistry. CLE disease activity was determined using the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI™), and safety data, including adverse events (AEs) and laboratory tests, were also collected.

Results: Most SLE subjects had high IRG signatures in the blood and/or skin biopsies demonstrating features of inflammation consistent with active CLE, including elevated expression of MxA and other IFN-regulated proteins. A single dose of BIIB059 led to reversible inhibition of IRG in the blood. A marked decrease in skin expression of MxA at week 4 was observed in 5 of the 6 subjects treated with BIIB059 who had elevated MxA at baseline compared to less pronounced effects in the 4 placebo subjects (all with elevated baseline MxA). In addition, CLASI-activity at week 12 was also notably decreased in 6 of 8 BIIB059-treated subjects compared to the 4 placebo subjects (2/4 non-responders, 1/4 lost to follow-up and 1/4 treated with IV steroids for SLE flare). BIIB059 was generally well tolerated; the incidence of AEs was similar between BIIB059- and placebo-treated SLE subjects, and most AEs were mild or moderate in severity. There were no withdrawals due to AEs.

Conclusion: A single dose of BIIB059 resulted in inhibition of the IRG in peripheral blood and MxA expression in lesional skin of SLE subjects, consistent with BIIB059's proposed mechanism of action. The clinical and biomarker data together confirm the role of human pDCs in SLE skin pathology, and support further development of BIIB059 in SLE.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose : Systemic sclerosis (SSc), a connective tissue disease, is associated with high mortality rates. The main causes and risk factors for death are only poorly known. Our aim was to better determine causes and predictors for mortality by using two complementary strategies.

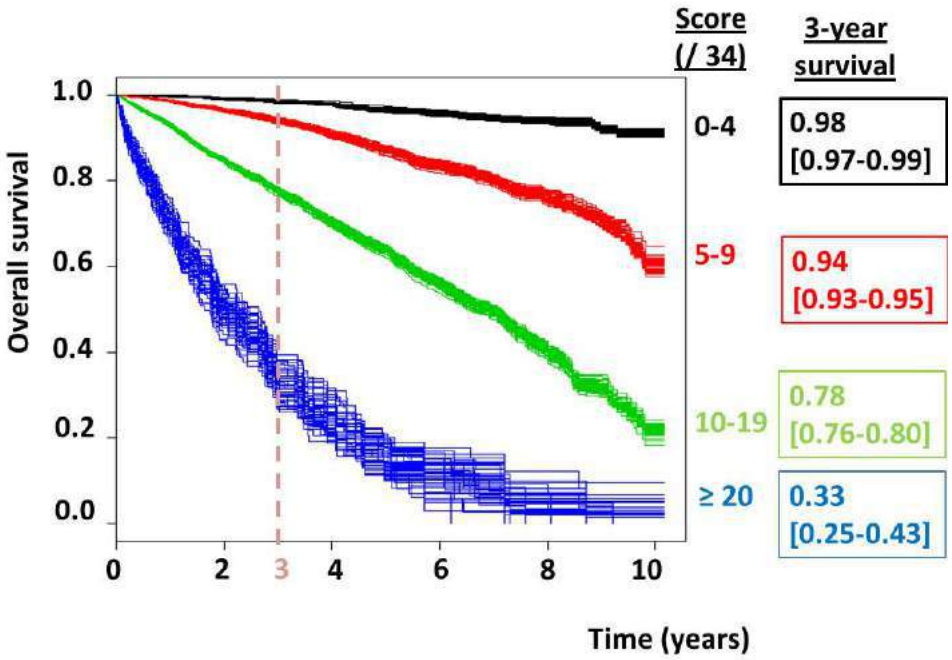
Methods : We first studied causes and predictors of death among the international multicenter EUSTAR cohort; overall survival was estimated by the Kaplan-Meier method, prognostic factors were identified by multivariate cox analysis with imputations for missing data. A risk score for 3-years mortality was established and internally validated by bootstrapping. We then examined standardized mortality rates, its trends over time and the causes of death in SSc-patients from the exhaustive analysis of all death certificates in France from 2000 to 2011.

Results : In Eustar cohort, a total of 11,193 SSc-patients were included: 86% of women, 31% of diffuse cutaneous forms, and mean disease duration: 8.1 years. During a median follow-up of 2.3 years, 1072 (9.6%) patients died. Multivariate analysis identified 14 independent predictors for death (age, male sex, CRP elevation, dyspnea, lung fibrosis and decrease in DLCO and FVC, proteinuria, and scleroderma renal crisis, heart failure,

Rodnan skin score, digital ulcers, and joint involvement) leading to establishment of a prognostic score. This score had better discrimination to predict survival at 3-years than previous mortality score ($p<0.0001$). Furthermore, it allowed accurate stratification of patients in four distinct groups of disease severity (Fig. 1). Death certificates identified 2719 deaths related to SSc: the causes of death strengthened those observed using the EUSTAR cohort highlighting the major contribution of the cardiovascular system (Fig. 2). The overall O:E ratio demonstrated an increased risk of death by infection (5.61), respiratory (2.99) and cardiovascular diseases (1.39) (particularly before 60 years (3.14)) in SSc-patients. Death certificates also revealed a decrease in standardized mortality rates during the time (1 per 10^5 patients in 2000 to 0.6 per 10^5 patients in 2011).

Conclusion : Using two complementary sources of information, which allowed working on the unreached number of 3700 deaths, we provide insight into the causes of deaths and emphasis on the contribution of the cardiopulmonary system. In addition, we have established a robust mortality score to estimate the 3-year survival of SSc-patients. The Scope score allows risk-stratification and will support future studies to improve the management in the perspective of extending survival in SSc.

Figure 1 Overall survival



according to simplified score categories. Curves are plotted for each of the 50 imputed dataset.

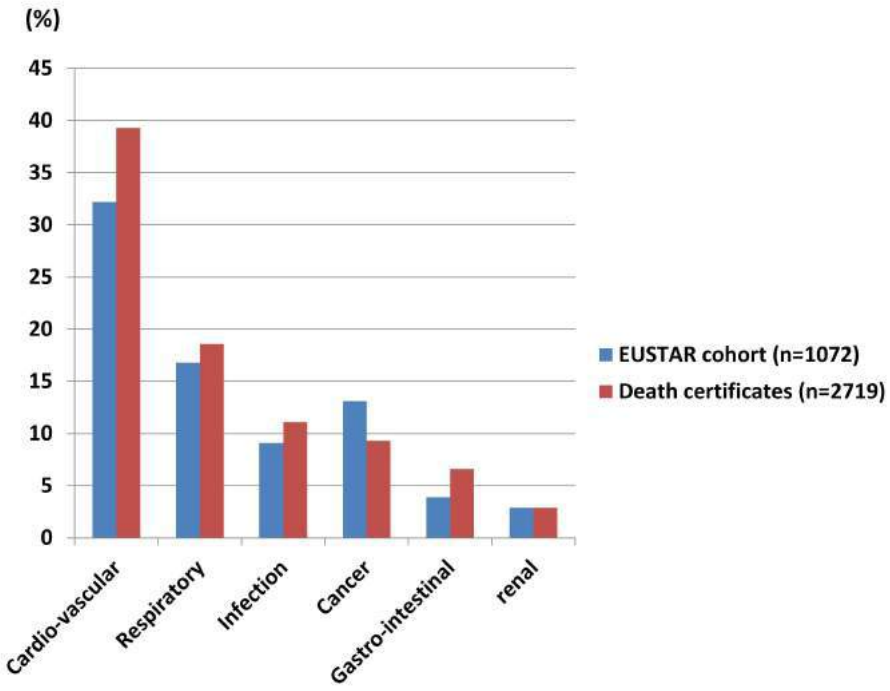


Figure 2: Causes of death in EUSTAR cohort and in French death certificates

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics II

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: A single center study demonstrated that systemic sclerosis (SSc) patients have a distinct colonic microbial consortium (based on lavage specimens) compared with healthy controls and that these ecological changes are associated with SSc-gastrointestinal tract (GIT) symptoms.[1] The purpose of the present study was to compare the fecal microbial composition in SSc patients from 2 independent cohorts and to determine whether certain microbial genera are associated with SSc-GIT symptoms.

Methods: Adults SSc patients from UCLA and Oslo University Hospital were eligible to participate. Healthy controls were also recruited (1:1). SSc patients completed the GIT 2.0 questionnaire to assess GIT symptom severity at the time of the stool collection. The microbiota from these samples were determined by Illumina HiSeq 2500 16S rRNA sequencing at UCLA, and operational taxonomic units were selected using the Greengenes database at 97% identity. Linear discriminant analysis effect size was used to identify the genera that showed differential expression in the two cohorts. Differential expression analysis for sequence count data was used to identify specific genera associated with GIT symptoms.

Results: 17 UCLA SSc patients (88% Female; Median age 52.1 years), 17 Oslo SSc patients (71% Female; Median age 60.5 years), and 17 healthy controls (60% Female; Median age 29.0 years) were enrolled. The mean (SD) total GIT 2.0 score was 0.7 (0.6) and 0.6 (0.5), and the median (IR) disease duration was 6.6 (2.5, 16.4) and 7.0 (1.0, 19.2) for the UCLA and Oslo cohorts, respectively. Principal coordinate analysis illustrated significant microbial community differences between the UCLA SSc and control cohorts (p=0.001) and between the Oslo SSc and control cohorts (p=0.002). At the genus level, SSc patients had significantly lower levels of protective commensal genera, such as *Bacteroides* (UCLA and Oslo), *Faecalibacterium* (UCLA), *Clostridium* (Oslo); and significantly higher levels of pathobiont genera, such as *Fusobacterium* (UCLA), compared with controls (Figure 1). SSc patients with none/mild GIT symptoms had higher levels of commensal genera, such as *Clostridium*, compared with patients with moderate/severe GIT symptoms.

Conclusion: Consistent with the results of our prior study[1], the present analysis detected specific aberrations in the lower GIT microbiota of patients with SSc from two geographically and ethnically distinct cohorts. These findings suggest that GIT dysbiosis may be a pathological feature of the SSc disease state. **References**:

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics II
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic sclerosis (SSc) associated gastroesophageal reflux disease (GERD) can cause symptoms of dysphagia and heartburn, and is associated with esophagitis, stricture, Barrett's esophagus, and esophageal adenocarcinoma. A genealogic resource, the Utah Population Database (UPDB) has successfully identified systemic sclerosis (SSc) pedigrees and comparable hereditable risk for this disease. We hypothesized that these pedigrees could be used to assess for the hereditability of esophageal disease in order to risk stratify SSc patients with esophageal symptoms and inform their monitoring needs.

Methods: SSc (ICD-9 710.1 and ICD-10 M34.0, M34.1, and M34.9), GERD (ICD-9 530.1 and ICD-10 K21.9), dysphagia (ICD-9 787.20), esophageal stricture (ICD9 530.3 and ICD10 K 22.2), Barrett's esophagus (ICD-9 530.85 and ICD-10 K22.7), and esophageal adenocarcinoma (ICD-9 150.9 and ICD-10 C15.9) was identified from statewide discharge data, the University of Utah Health Science Center Enterprise Data Warehouse, and death certificates and were linked to the UPDB for analysis. SSc probands that had pedigree information for first, second, and third degree relatives were analyzed for the presence of each of the aforementioned diagnostic codes. Inheritance was evaluated by familial standardized incidence ratio and relative risks (RR) to first, second, third, fourth degree relatives and spouses for cases of SSc. Five matched controls were selected from the statewide UPDB population file without replacement in a Monte Carlo method to simulate random sampling in this low penetrate disease. The controls were matched on gender, birth year, and whether they were born in Utah.

Results: A software kinship analysis tool analyzed 2227 unique SSc patients and 11136 controls. In this study, 15% of the SSc from the Utah population is familial based on calculated population attributable risk. The SSc proband had a significant presence of esophageal symptoms and disease: GERD (RR: 3.28), dysphagia (RR 5.58), esophageal stricture (RR: 5.16), esophagitis (RR: 4.86), and Barrett's (RR: 4.52 (all $p<2e-16$) as expected. In a first-degree relative of a SSc proband GERD (RR: 1.14, $p=6.85e-05$), dysphagia (RR: 1.22 $p=0.002$), and esophagitis (RR: 1.37, $p=2.10e-06$) were significantly seen in SSc first degree relatives (parents and children). Esophagitis and dysphagia was significantly seen in first cousins (RR: 1.09, $p=0.03$) and spouses (RR; 1.37, $p=0.02$), suggesting that both genetics and similar exposures (ie, diet) may play a role in pathogenesis. Esophageal stricture and Barrett's esophagus do not appear to be hereditable and were also not seen in spouses. None of the SSc cases had esophageal adenocarcinoma.

Conclusion: The UPDB is a resource that allows for meaningful inheritance analysis. These data suggest that independent of GERD, esophagitis in SSc patients and their relatives may have both a hereditable and environmental etiology. Importantly, there does not seem to be a heritable component to Barrett's esophagus in this population suggesting that modulation of reflux may play an important role in prevention.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics II
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The modified Rodnan skin score (mRSS) is used as a primary outcome measure in clinical trials of dcSSc. EUSTAR analysis has proposed that a lower mRSS and earlier disease duration are associated with progressive disease, as defined by worsening mRSS [1]. Our objective was to find an optimal cut off for worsening mRSS in 4 cohorts of dcSSc.

Methods: We used 4 cohorts with early dcSSc (defined as ≤60 months from 1st non-RP sign or symptom) – 2 US cohorts [Combined Response Index in Systemic Sclerosis [CRISS] and Prospective Registry in Early Systemic Sclerosis [PRESS]], the UK Royal Free Hospital [RFH] cohort, and the Australian Scleroderma Interest Group [ASIG] cohort. Inclusion criteria included dcSSc diagnosed by a scleroderma physician, mRSS data at 2 time points (12±3 months apart), and availability of disease duration (defined as 1st non Raynaud phenomenon sign or symptom). Worsening of skin fibrosis was defined as increase in mRSS >5 points and ≥25% from baseline to 2nd visit. To identify the optimal cut point of baseline MRSS that yields the highest sensitivity for worsening disease, we developed the ROC curves. For worsening of mRSS, we fitted logistic regression model with worsening as outcome variable and a binary variable of baseline mRSS cut point as predictor.

Results: There were 231 patients with early dcSSc included in the analysis. Mean (SD) disease duration was 26.7 (14.6) months, median=23.67 months. We evaluated 3 cut points for disease duration based on inclusion criterion from recent clinical trials: ≤24, 36, and 60 months. For all disease durations, approximately 10% of patients had mRSS worsening at 1-year period. A mRSS cut off of ≤28 had the highest probability of worsening (Table). mRSS of ≤28 was able to enrich worsening mRSS from 10% to approximately 14% for different cut points but excluded 26-27% of patients with early dcSSc. **Worsening in mRSS for the Whole Cohort vs. Cut Point of ≤28**

*increase in mRSS>5 points and ≥25% from baseline to second visit

*decrease in mRSS>5 points and ≥25% from baseline to second visit

Conclusion: In this preliminary analysis, a mRSS≤28 was the optimal cut point for worsening disease in 4 cohorts with dcSSc. This threshold gained an additional 4% of patients who worsened but excluded 26-27% of patients with early dcSSc. Further criteria are needed for enrichment of patients with dcSSc so large proportion of patients are not excluded from participating in RCTs . **References:** Maurer B Ann Rheum Dis 2015

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic sclerosis (SSc) is a rapidly evolving field with multiple potential therapeutic agents under development and several active clinical trials focused on treating diffuse cutaneous SSc. When weighing management decisions for therapy and considering clinical trial involvement, estimating the likelihood of skin thickness progression over the next year will be helpful. **Objectives:** To derive a clinical risk prediction tool to predict skin thickness progression over one year.

Methods: We used a US single-center cohort of prospectively followed early diffuse SSc patients seen for an initial visit from Jan. 1, 1980 to Dec. 31, 2014. To reflect current early diffuse SSc clinical trial design, early was defined as <3 years after the first non-Raynaud symptoms and diffuse skin as proximal to the elbows or knees. Eligible patients had ≥ 2 modified Rodnan skin scores (mRSS) within one year of the first SSc center visit, for ≥ 3 mRSS over one year. The outcome was mRSS progression at any time over one year of follow-up, defined as an increase of ≥5 points and a 25% increase in the mRSS from baseline. SSc autoantibodies were confirmed by the gold standard methods of immunodiffusion or immunoprecipitation. Skin change was assessed in multiple ways, including Receiver Operating Curve (ROC) analysis to determine a risk cut-off point for mRSS. Multivariable logistic regression modeling was used. Beta-estimates were rounded to the nearest 0.5, summed and ROC analysis performed.

Results: Among 317 eligible patients the mean age was 50.8 ± 13.5 years, 74% female and 92% Caucasian. The median disease duration from first SSc symptom was 0.90 years (IQR 0.63, 1.46). The mean first visit mRSS was 23±11. 25% (n=79) were scl-70 positive, 56% (n=178) RNA-polymerase III positive (RNAP) positive, 54 (17%) other SSc-associated antibody and 2% (n=6) missing. In total, 163 patients (51%) developed skin progression over one year. The mean time to peak mRSS among progressors was 0.51±0.23 years from the first visit. ROC analysis showed mRSS ≤27 to best predict skin progression. A 4-variable model was developed to predict skin progression over one year (Table 1) with a AUC = 0.81 (95% CI 0.75, 0.88). When β-estimates were rounded and summed as in Table 1, a 3-level risk stratification model was created with rate of skin progression depicted in Table 2. The AUC for this model remained excellent at 0.80 (0.75, 0.85).

Conclusion: We have derived an accurate 3-level clinical risk stratification tool for skin thickness progression over one year of follow-up in early diffuse SSc patients.

Table 1: Multivariable Logistic Regression Model

	β	**Odds Ratio (95% Confidence Interval)**	**p-value**	**Points Assigned**
Disease duration< 1 year	1.33	3.79 (1.74, 8.23)	0.0008	1.5
Pulmonary fibrosis on chest imaging	-1.35	0.26 (0.11, 0.62)	0.002	-1.5
SSc antibody **RNAP** **Scl-70** **Other SSc antibody**	-1.53	0.22 (0.08, 0.60)	0.003	0 0 -1.5
Baseline mRSS ≤27	2.39	10.96 (4.31. 27.84)	<0.0001	2.5
				Sum Score

Table 2: 3-level risk stratification tool for predicting skin progression		
	Sum Score	**% of diffuse SSc patients with skin thickness progression**
Low risk	-0.5 and below	10%
Moderate risk	0 to 1.5	28%
High risk	2.5 and above	72%
AUC = 0.80 (0.64, 0.73)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Prognostication in scleroderma has historically depended on using static measures such as antibody status and extent of skin involvement to stratify risk of mortality and major organ complications. These static measures are intrinsically unable to inform the difference between disease activity and disease damage in scleroderma, which is a critical for clinicians considering the timing of potentially toxic treatment. We hypothesized that serial changes in a clinical outcome of interest--in this case the forced vital capacity (FVC)Ñcould itself be used to classify patients with a common disease course and comparable mortality.

Methods: We retrospectively applied a form of latent subtype analysis called probabilistic subtype modeling (PSM) to serial lung function data from patients followed at an academic scleroderma referral center, to identify shared trajectories of FVC among individuals over time. We then examined mortality across each of these shared trajectories using Kaplan Meier curves and adjustment for demographics with Cox proportional hazards models.

Results: Serial FVC from 1615 patients defined 10 trajectories by PSM, which were collapsed by the authors into 5 clinically similar patterns of FVC change over time (Figure 1). Mortality separated largely into 3 groups (Figure 2), with a protective hazard in subgroups with intact lung function (HR of 0.36 [95%CI=0.30Ñ0.44] and 0.60 [0.44Ñ0.82]) in Groups A and B, respectively, an intermediate mortality in the subgroup with variable FVC (Group C HR 0.98 [0.80Ñ1.21]), and a high mortality among patients with depressed and declining FVC (HR 2.14 [1.77Ñ2.59] and 2.81 [2.33Ñ3.41] in Groups D and E, respectively). Major antibody, skin extent, race, gender, disease onset after age 55, and the presence of calcinosis most frequently helped distinguish among the FVC trajectory subtypes. However, the highest prevalence of any single characteristic within a subtypeÑfor example, diffuse skin (68%) or centromere antibody (37%)Ñwere not sufficiently associated with an FVC trajectory to serve as the only distinguishing feature among subtypes.

Conclusion: Grouping patients by longitudinal change in FVC identifies patients with similar risk of mortality, illustrating the potential utility of incorporating serial clinical metrics into the risk assessment of patients with scleroderma. If identifiable early within an individualÕs course, clinical trajectories may be powerful tool to inform treatment decisions.

Making the Case for Self-Management Education: Marketing Lessons Learned from Qualitative Research

Teresa J. Brady[1], Bithiah Lafontant[2], Tai Baker[3] and Rebecca Ledsky[4], [1]Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA, [2]FHI 360, Washington, DC, [3]Centers for Disease Control and Prevention, Atlanta, GA, [4]Social Marketing and Communication, FHI 360, Washington, DC
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: ARHP III: Education and Community Programs
Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Self-management education (SME) uses educational and behavioral strategies to help people with arthritis (PWA) and other chronic conditions (CC) develop healthy behaviors and gain confidence in their ability to manage their condition. Approximately 11% of PWA report attending a SME program. Past audience research suggested that a primary reason PWA do not attend SME programs is that they do not know the programs exist. Past research also suggested that arthritis frequently is a lower priority if a PWA also has another CC, and approximately 47% of PWA also have another condition. PWA can learn key self-management skills (i.e. problem-solving, goal-setting, and self-monitoring) by attending generic SME programs, or programs for their higher priority CC even if they are not motivated to attend for arthritis. This research developed and tested messages and creative executions to motivate people with CC, including PWA, to learn more about SME programs.

Methods: 20 focus groups were conducted (6 for feasibility testing, 6 for concept testing, 8 for materials testing) in 8 cities in the East, Midwest, West and South United States in 2013-2015. Gender-stratified groups were held with people aged 45–75 years old who had one or more CC. All groups were conducted using a structured moderator's guide, and results were summarized across groups using thematic analysis. Participants discussed their views and preferences about SME-related terminology, messages, and ad concepts and executions.

Results: A total of 156 people participated. The sample was 51% male; 49% white, 30% black, and 22% Hispanic; 69% had less than college degree, 56% had incomes <$40,000; and 23% were age 65-75.Over half of the sample had arthritis (56%) and more than one CC (57%).Although unfamiliar with SME terminology, most participants grasped and valued the concept. Messages that explained benefits (e.g., increased energy, reduced stress, feel better) and program components (goal-setting, self-monitoring) were the most important factors in motivating this audience to seek additional information about SME. Although most referred to themselves as having a chronic disease, "ongoing health problem" was preferred to "chronic disease" or "chronic illness" terminology. The terms "strategies and techniques" were favored over "skills and tools." Other important message characteristics included having a personal and positive tone, using empowering language, and

describing benefits without overpromising. Participants preferred a website rather than phone number for more information.

Conclusion: Consumers, including PWA, are receptive to SME although they were not previously aware of the term. Lack of familiarity with SME necessitates informational messages and outreach tools. Concepts seen as personal, believable, and credible which also provided information about processes and benefits of SME were preferred. It is possible to craft messages that appeal to people with a variety of CC, including arthritis. The findings from this research are being used to develop the *Learn More. Feel Better.*broad SME awareness campaign designed to motivate people with CC, including PWA, to seek out SME.

Development of an Item Bank on Disease and Treatment Associated Knowledge of Rheumatoid Arthritis to Improve Patient Engagement in Care

Marieke J. de Jonge[1], Martijn A.H. Oude Voshaar[2], Anita M.P. Huis[1], Mart A.F.J. van de Laar[2], Marlies E.J.L. Hulscher[1] and Piet L.C.M. van Riel[1,3], [1]Radboud university medical center, Radboud Institute for Health Sciences, IQ healthcare, Nijmegen, Netherlands, [2]University of Twente, Department of Psychology, Health and Technology, Enschede, Netherlands, [3]Bernhoven, Department of Rheumatology, Uden, Netherlands

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: ARHP III: Education and Community Programs
Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Patient involvement and personalization of healthcare have become increasingly important in managing chronic diseases. Knowledge about their disease and its treatment is an important precondition for patients to be able to be involved in their own care. Therefore many healthcare professionals offer patients with Rheumatoid Arthritis (RA) education about RA and its treatment. An instrument to assess patients' knowledge about their disease and its treatment provides health professionals as well as researchers with a tool to identify and target patients' information needs. Also, it can be used to evaluate the effect if educational efforts and to monitor progress. Currently available patient knowledge questionnaires were developed before the introduction of biologicals as well as treat to target strategies in rheumatoid arthritis (RA). In fact a general limitation of static questionnaires is that their content may become outdated over time. Therefore we developed the Disease and treatment Associated Knowledge in RA item bank (DataK-RA). This Item Response Theory (IRT) based item bank can be kept up to date by adding or removing items, without changing the common scale. Moreover, the scoring procedure also provides the flexibility to use any subset of items, while retaining comparability with other applications of the item bank.

Methods: An initial item pool was developed from a systematic review of existing knowledge questionnaires, supplemented by an elaborate qualitative approach in cooperation with health professionals and patients. Consensus was reached on relevant content through a RAND modified Delphi scoring procedure by rheumatology nurses (n=6) and rheumatologists (n=6), and a consensus meeting with rheumatology nurses (n=6) and rheumatologists (n=4). Subsequently, a focus group among RA patients (n=9) was organized to identify additional content areas. Patients and health professionals also rated readability, feasibility and comprehensiveness of the resulting items. Item pool reduction and initial validation of the item pool (n=62) were performed using a cross-sectional sample of 473 patients with RA.

Results: Twenty items were discarded based on a corrected item-total point biserial correlation <0.30. Confirmatory factor analysis with weighted least squares estimation on the polychoric correlation matrix suggested acceptable fit for a unidimensional model for the remaining 42 items (CFI .97 TLI=.97, RMSEA=0.02, WRMR=0.97), supporting the proposed scoring procedure for the item bank. Scores were highly reliable and normally distributed with minimal ceiling (1.8%) and no floor effects (0.0%).

Conclusion: The DataK-RA item bank of 42 items was developed to comprehensively measure knowledge on all relevant aspects of RA and its treatment. The results of this study suggest it is a promising measure of factual disease related knowledge in RA. Work directed at developing tailored short-forms and a computerized adaptive testing algorithm is currently ongoing. Acknowledgements*:* We thank all rheumatology nurses, rheumatologists and patients who have helped in the development or validation of the item bank.

Developing a Gout Needs Assessment Incorporating Patient Perspective on Self-Management, Self-Efficacy and Disease Specific Knowledge, to Inform a Patient Education Initiative

Adam Rifaat[1], Adena Batterman[2], Roberta Horton[2] and Theodore R. Fields[1], [1]Rheumatology, Hospital for Special Surgery, New York, NY, [2]Social Work Programs, Hospital for Special Surgery, New York, NY
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: ARHP III: Education and Community Programs
Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Gout is the most common inflammatory arthritis in adults, with great impact on quality of life. Despite excellent therapeutic options, outcomes remain suboptimal. Research supports the need for patient-centered education interventions as an integral part of effective gout management. While studies have

demonstrated that provider-created knowledge assessments can be a first-step in designing patient education interventions, they have not typically included patient identified needs. This is especially important since gout patients need assistance in diet and lifestyle change in addition to urate management. We developed a needs assessment which inquired about patient perspective and self-efficacy re: gout self-management. Our purpose was to identify disease–specific knowledge gaps and patient-identified concerns, to ensure their inclusion in a patient education initiative for gout patients.

Methods: We developed a 26-item needs assessment, including Likert & open-ended questions to assess patient self-efficacy around essential gout-related knowledge and patient-identified needs to enhance self-management. Knowledge-based questions were derived from evidence-based clinical guidelines re: gout treatment and lifestyle changes and data from our concurrent gout patient education study. Potential participants (357) were treated for gout by rheumatologists in an ambulatory clinic or private office and approached either in person or by mail.

Results: One hundred questionnaires were completed, with a return rate of 42/294 (14%) by mail and 58/63 (92%) in-person. Mean yrs since diagnosis: 10.8; M74%, F26%; mean age: 64 yrs; Race/Ethnicity: White 78% Asian 12% African American 7% Latino 2%. Completed college or above: 79%. In the preceding 6 months 13.4% had >3 flares; of these, 33% felt their gout was “under control.” Fifty-four % of respondents did not know “how often to have uric acid checked”; in patients with >3 flares in past 6 months , 77% did not know; 29% did not know their uric acid goal; 51% of all respondents did not know “how to manage side-effects of medications.” When asked about purpose of bridge therapy, 60% were unsure or did not answer; 55% did not answer or didn’t know when they should discontinue bridge therapy. When asked about “information of most interest [to them]”, most frequent response was diet guidelines; 83% wanted to hear from an MD; 61% from a nutritionist.

Conclusion: Even in a highly educated sample of rheumatologist-treated gout patients with a mean diagnosis of 10.8y, we found major patient knowledge gaps in essential gout-related self-management skills. Core findings include gaps related to: uric acid goals, frequency of testing, bridge therapy and outcome expectations. In open-ended questions, patients stated a desire for more information about diet guidelines, and input from a nutritionist. Our results are consistent with prior studies showing large gaps in critical gout patient knowledge, which are likely associated with widely reported poor gout patient outcomes. Our data informed the content of an educational symposium for gout patients and may be of use to others involved in enhancing self-management and improving outcomes for gout patients.

Patient Barriers to Osteoporosis Screening in a Medical Clinic: Why Underserved Patients Who Follow Recommendations for Colonoscopy and Mammography Fail to Get Their DXA Scans

Suzana John[1], Sonam Kiwalkar[2], Hamdy Mohamed Abdelaziz Ahmed[1] and Walter Polashenski[3], [1]Internal Medicine, Rochester General Hospital, Rochester, NY, [2]internal medicine, Rochester general hospital, Rochester, NY, [3]Internal medicine, Rochester general hospital, rochester, NY

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: ARHP III: Education and Community Programs

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Osteoporosis is a silent disease until it is complicated by fractures. Fractures are common; they place an enormous medical and personal burden on the elderly and take a major economic toll on the nation. Despite this fact, screening for osteoporosis by DXA scan remains inadequate mainly because most patients are unaware of its importance. We found that the rate of DXA scan completion by patients who visited our hospital's outpatient medical clinic was only 23.6% of all eligible women ≥65 years. The objective of this study was to identify specific patient barriers that prevent patients from completing a DXA test ordered during a clinic visit.

Methods: Between December 2014 and March 2015 DXA scans were appropriately ordered for 133 women ≥65 years who had visited the Rochester General Hospital medicine clinic; 75 completed the recommended DXA scan and 58 patients did not. A retrospective chart review of the 58 non-compliers showed that 13 of them had completed DXA at a much later date, 3 had died, 4 switched PCP to outside practice; these patients were excluded. We conducted a structured telephonic interview of the remaining 38 patients with the help of a barrier related questionnaire: • Are you aware you have DXA scan ordered? • If yes, did you schedule the appointment? • Do you use wheelchair, cane or walker for ambulation? • Do you have transportation issues? • Do you have problems with child care / elder care? • Are you working / retired? All patients were counseled on the importance of osteoporosis screening at the end of the interview Of the 38 patients we attempted to call, 3 refused to continue the conversation, 2 were hospitalized for critical illness, 3 Nepali speakers could not answer the questions, even with the help of an interpreter, 3 did not answer despite >2 phone calls. That left us with 25 effective calls. Of the 25 patients with completed surveys (none of whom had completed a recommended DXA scan), 72% (18/25) were up to date with mammography and 68% (17/25) had completed colonoscopy testing. 80%(20/25) were insured by medicare/medicaid and 84%(21/25) were retired

Results: Based on the structured questionnaire we were able to identify several patient barriers to osteoporosis screening: • 72% (18/25) of patients reported lack of awareness that a DXA test was ordered. • 24% (6/25) reported lack of transportation to go for the test • 20%(5/25) cited health issues • 4%(1/25) had to care for an elderly family member • 36%(9/25) used a cane/wheelchair/walker for ambulation.

Conclusion: The main patient related barrier to osteoporosis screening is patients' lack of awareness about osteoporosis, the reason for screening and the consequences of osteoporosis if left untreated. Patients are usually asymptomatic and believe that weak bones are a part of ageing naturally. There is also lack of effective physician patient communication and counseling on osteoporosis. The fact that most patients who failed to complete their DXA scan are up to date with other screening tests such as colonoscopy and mammography suggest that non-compliance is not the only reason for poor rates of osteoporosis screening

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: ARHP III: Education and Community Programs
Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: A needs assessment was conducted on an evidenced-based, national lupus telephone peer counseling service, ongoing since 1988, with 30,000+ client contacts to date. We have reported on the evolution of this hospital-based program at previous ACR/ARHP annual meetings. Trained peer volunteers have proven to be skilled providers of psychosocial support for SLE & other chronic illnesses. Findings from staff & veteran peer counselors trained in 1988 & 1994 using an 8-week, 20-hour curriculum on peer counseling skills & impacts of lupus, pointed to the need to update the training program. Recommendations included more hands-on learning opportunities, increased preparation for the initial call, integration of new technology to enhance communication & shortening the length of training.

Methods: The training was revised to a 6-week, 18-hour program. The core curriculum components were maintained & included updated materials, a culture/diversity module, counseling tools, enhanced resource guide & a workbook-style trainee manual. After a comprehensive recruitment process, 8 women from diverse backgrounds, mean age 47, were selected & participated in the new training. Two instruments were utilized pre & post training to assess trainees: the Applied Knowledge Assessment (AKA), a validated 30-item multiple choice test that measures knowledge of SLE & counseling skills, & the Communications Exercise (CE), a 21-item test with rating scale & open-ended questions to assess communication skills. Paired t-tests (α=.05) were conducted to examine differences in mean scores.

Results: AKA results indicated that most trainees (75%) showed an increase in overall scores. The mean pre & post test scores (59 & 68 respectively) were significantly different, $t(7) = 3.457$, p=011. The relative change from pre to post was 16%. Types of questions were categorized into two groups: peer counseling skills & medical impacts of SLE. Stratified results showed that most trainees (88%) showed an improvement in counseling skills, with one trainee improving by 50%. Similarly, 75% trainees showed an increase in medical knowledge, with one trainee improving by 75%. For the CE, most trainees (88%) showed improvement in overall scores after the training. The mean pre & post test scores (60 & 83 respectively) were significantly different, $t(7) = 2.808$, p=026. The relative change from pre to post was 38%, with one trainee improving by 200%. Open-ended responses assessing trainee's ability to respond to hypothetical callers underscore improved effective communication, including increases in empathy, reflecting feelings, summarizing & utilization of open-ended questions. Decreases in premature problem-solving, advice-giving & closed-ended questions were also noted.

Conclusion: Despite limitations due to a small sample size, our results highlight overall improvement in counseling skills, medical knowledge of SLE & communication skills. Results indicate that we were able to successfully enhance the training while retaining the core elements of the original curriculum. Furthermore, this training program continues to be a relevant model to effectively prepare peers to support patients with chronic

illness, supporting previous findings.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: ARHP III: Education and Community Programs

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Primary and emergency care providers may have received 45 minutes of lupus education in medical school. Providers may fail in recognizing lupus because symptoms are often vague, delaying referrals and diagnosis for 2-6 years. Delay can lead to accrual of organ damage and death, which is more prevalent in minority populations. Many patients are referred to rheumatology not meeting assessment criteria for lupus, creating barriers to rheumatology care for urgent patients. The goal of LEAP is to increase lupus knowledge and improve lupus assessment and referral procedures among primary and emergency providers within the healthcare system.

Methods : LEAP enlisted rheumatology fellows to serve as educators to deliver a 1 Continuing Medical Education credit seminar. Four sites were selected based on commitment from Rheumatology Fellowship Program Directors or previous experience with the Teaching Fellows in Lupus Project, after which LEAP was modeled. Sites identified a problem in lupus referrals and included ways to address the problem in the seminar. Examples of problems in referrals that were addressed in the seminar include 1) ANA titer not included in the referral; 2) patients referred with only a positive ANA and no relevant clinical symptoms included; 3) consults with rheumatology conducted prior to issuing a formal referral. Rates will be analyzed to assess if the seminar changed behavior. Voluntary, anonymous pre/post assessments were used to evaluate changes in knowledge and behavior and collect qualitative data. A t-test was used to analyze independent group means.

Results: Preliminary data from 427 assessments were analyzed on a 9-point scale. Total mean score increased 2.10 immediately post seminar and 2.88 points at 4-6 weeks post seminar ($p<.01$). Over 85% reported the 1) activity improved medical or practice knowledge and 2) they would make changes that will benefit patient care. Respondents are considering lupus more at 4-6 weeks post seminar.

Conclusion: Rheumatology fellows can increase knowledge and promote behavior change in lupus assessment and referral among primary and emergency providers. LEAP may be an effective strategy to reduce health disparities in lupus.

Table 1. Knowledge Change Pre/Post/4-6 Weeks Post Seminar

Assessment (Group Data)	N	Mean Score (SD)	Mean Score Change from Pre Assessment	P-Value
Pre Seminar	208	5.07 (2.38)	n/a	<.01
Post Seminar	199	7.17 (1.45)	2.10	<.01
4-6 Weeks Post Seminar	20	7.95 (1.90)	2.88	<.01

Table 2. Sustained Behavior Changes Matched Assessments Pre to 4-6 Weeks Post **N=15**

Question	Pre %	4-6 Weeks Post %
1) You consider lupus in your differential diagnosis during an exam?		
Very Often	0 (0.0)	11 (73.3)
Somewhat Often	3 (20.0)	3 (20.0)
Not Very Often	1 (6.7)	1 (6.7)
Not At All	11 (73.3)	0 (0.0)
2) You refer patients to the rheumatologist for suspected lupus?		
Extensively	1 (6.7)	12 (80.0)
Significantly	0 (0.0)	1 (6.7)
Occasionally	3 (20.0)	1 (6.7)
Seldom	0 (0.0)	1 (6.7)
Never	11 (73.3)	0 (0.0)
3) You refer patients to lupus educational material or other educational resources?

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Obesity and foot problems are common in older adults and associated with many negative health outcomes. Better understanding of the consequences of patterns of weight change may lead to better prediction and dealing with foot pain and foot disorders. This study identified longitudinal trajectories of weight in a population-based study and examined the association of these groups with current foot problems.

Methods: We used 28 measures of weight over 57 years to identify trajectories of weight in 2445 members of the Framingham Foot Study using k-means longitudinal cluster analysis. Foot examinations (2002-2008) recorded presence of foot pain, hallux valgus, claw toes, hammer toes and overlapping toes on each foot. Associations between weight group membership and foot problems at time of foot exam, adjusted for age and sex, were examined using logistic regression with generalized estimating equation correction for two feet per subject. The reference group used for analysis was the group with the lowest weight trajectory ("E").

Results: We found 5 trajectories of weight, representing relatively constant patterns over time, with weight increasing from groups E to A. Those in group "E" were more likely to be older, while the youngest were in group "A" group (Table 1). "E" had the lowest prevalence of foot pain (14%) while group "A" had the highest (22%). Similarly, group "A" had the lowest prevalence of hallux valgus, while group "E" had the highest (36%). Compared to group "E", other groups were more likely to have foot pain (ORs 1.57-3.50, Table 2) and less likely to have hallux valgus (ORs 0.73-0.99). For claw toes, all but one group were more likely to have claw toes compared to group "E". Groups "A" and "D" were more likely to have hammer toes (ORs 2.40 and 1.35, respectively) compared to group "E". We found no associations between overlapping toes and group membership.

Conclusion: Trajectories with higher weight over a lifetime had increased odds of foot pain and claw toes, and decreased odds of hallux valgus later in life. These results provide evidence that having lower weight over one's lifetime can reduce the likelihood of foot problems later in life.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Regular engagement in physical activity reduces the risk adverse health outcomes such as cardiovascular diseases, functional limitation, and depression in people with knee osteoarthritis (OA). While walking is the most common form of physical activity for older adults, the relative health benefits of walking at a light intensity and at a moderate-to-vigorous intensity are unclear. The primary purpose of this study was to investigate the association of replacing 'no-walking' with different intensities of walking, with risk of developing adverse health outcomes over two years among people with or at high risk of knee OA.

Methods: The Multicenter Osteoarthritis Study (MOST) is a NIH-funded longitudinal cohort of older adults who have or are at high risk of knee OA. Steps/day over 7 days were objectively measured with a StepWatch monitor at the 60-month MOST study visit. Walking was classified in minutes per day (min/day) of no-walking (<1 step/minute), very-light walking (1 – 50 steps/min), moderately-light walking (51 – 100 steps/min) and moderate-to-vigorous walking (>100 steps/min). Incident outcomes were slow gait speed during a 20-meter walk (<1 metre/second), comorbidity (Charlson index ≥1), depressive symptoms (CES-D ≥16) and low balance confidence (Activities-specific Balance Confidence scale <67) assessed 2 years post 60-month MOST study visit (i.e., 84-month MOST study visit). Isotemporal substitution analysis was conducted to evaluate the effect of replacing 10 minutes of 'no-walking' with 10 minutes of walking at very-light, moderately-light and moderate-to-vigorous intensities, with study outcomes. All models were adjusted for age, sex, BMI, study site, race, education, marital status and lower limb pain.

Results: Of the 1782 subjects who wore the StepWatch for ≥3 days (Age 67.3 ± 7.7, 60% women, BMI 30.7 ± 5.9), incidence of poor health outcomes ranged from 5.6% for depressive symptoms (82/1460) to 16.6% for slow gait speed (251/1514). Replacing 10 minutes of no-walking with 10 minutes of moderate-to-vigorous walking per/day was associated with modest reductions in the risk of slow gate speed and low balance confidence (RR = 0.75 and 0.81, respectively), though low balance confidence bordered on significance (p =.05) (Table 1). Replacing 10 minutes of no-walking with 10 minutes of very-light walking per/day was associated with a small reduction in risk of comorbidity (RR = 0.97).

Conclusion: Findings indicate the presence of a dose-response relationship with regards to walking intensity and pertinent health outcomes in people with, or at high risk of OA. Specifcally, replacing no-walking with just 10 minutes of walking at increasing intensities each day may hold positive consequences for preserving functional gate speed, sustaining confidence with regards to functional capacity (i.e., balance confidence), and reducing risk of comorbidity. *Table 1.*Adjusted risk ratios

	Risk of Incident Slow Gait Speed at 2 years (< 1.0 m/s) *N = 1514*		*Risk of Depressive symptoms at 2 years (CES-D > 16)* *N = 1460*		*Risk of Comorbidity at 2 years (Charlson > 1)* *N = 1238*		Risk of Low Balance Confidence (ABC < 67) N = 1578

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Limb length inequality (LLI) is a condition in which one limb is longer than the other. Previous reports of a link between LLI and knee radiographic osteoarthritis (rOA) are limited by short follow-up durations. This longitudinal analysis examined the hazard of incident and progressive rOA and symptoms of the knee and hip by LLI in a large community-based cohort over a median 10-year follow-up period.

Methods: Participants were African American and Caucasian men and women 45+ years old enrolled from 1991-1997 (original cohort) or 2003-2004 (enrichment cohort), and follow up data were collected during 1999-2004, 2006-2010, or 2012-2015 (median follow-up time = 10 years, range= 4-22 years). Lower extremity lengths were measured with a tape measure from anterior superior iliac spine to distal medial malleolus with the participant supine; LLI was defined as ≥ 2 cm difference between limbs. Radiographs (anteroposterior [AP] standing knee and AP supine pelvic) were read for Kellgren-Lawrence grade (KLG). Incident rOA was defined as KLG <2 at baseline that becomes KLG ≥2 at follow-up. Progressive OA was defined as ≥ 1 KLG increase with baseline KL=1. Incident symptoms were defined as new symptoms (pain, aching, or stiffness on most days) at follow-up among joints without symptoms at baseline. Progressive symptoms were defined as joints with mild or moderate baseline symptoms that increased ≥1 level of severity (to moderate or severe) at follow-up. Separate parametric Weibull time-to-event models estimated hazard ratios of the association of LLI and knee and hip outcomes, adjusting for cohort (original or enrichment), time of LLI assessment (1991-1997 or 1999-2004), age, sex, race, and body mass index (BMI). In models where symptoms were the outcome, rOA was included as a covariate. Interactions between LLI and covariates were examined ($p<0.10$ considered statistically significant).

Results: At baseline, complete LLI with knee and hip radiograph data were available for 2872 and 2669 participants with at least one follow-up, respectively. Characteristics of the pooled sample were: mean ± standard deviation (SD) baseline age 61 ± 9.8 years; 2/3 women; 1/3 African American; mean ± SD baseline BMI 30 ± 6.4 kg/m^2, and 7% with a LLI. The hazards of incident or progressive knee or hip rOA and symptoms by LLI were not statistically different (Table). There was a statistically significant interaction between LLI and

BMI for progressive knee rOA; thus, results were stratified by BMI (<30 and ≥30 kg/m^2). Among participants with BMI≥30, the adjusted hazard for progressive knee rOA was 76% higher among those with LLI vs. no LLI (adjusted hazard ratio 1.76, 95% confidence interval 1.12, 2.75).

Conclusion : Among obese participants, LLI was associated with progressive knee rOA. These results suggest that obese individuals with knee rOA and LLI may benefit from interventions to limit rOA progression.

Table. Adjusted* Hazard Ratio (aHR) and 95% Confidence Interval (CI) of Baseline Limb Length Inequality (LLI) and Knee and Hip Incident and Progressive Radiographic Osteoarthritis (rOA) and Joint Symptoms Outcomes.

Joint	Outcome	n	aHR (95% CI)
Knee	Incident rOA	1783	0.88 (0.61, 1.29)
	Progressive rOA	976	1.16 (0.81, 1.67)
	Incident symptoms**	1332	1.12 (0.77, 1.64)
	Progressive symptoms**	874	1.19 (0.78, 1.81)
Hip	Incident rOA	1519	0.92 (0.59, 1.44)
	Progressive rOA	1608	1.28 (0.88, 1.88)
	Incident symptoms**	1419	1.08 (0.73, 1.62)
	Progressive symptoms**	649	1.00 (0.58, 1.74)

*Adjusted for cohort (original vs. enrichment), time of baseline LLI assessment, age, sex, race, body mass index.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

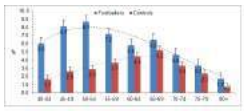
Background/Purpose: To determine the prevalence of knee pain (KP), radiographic knee osteoarthritis (RKOA) and total knee replacements (TKR) in ex-professional footballers compared to general population controls and to determine the associated risk factors.

Methods: 1207 ex-footballers and 4085 controls were recruited in the United Kingdom from professional football associations and the general population in East Midlands respectively. Current KP was defined as pain in or around the knees or most days of the last month. RKOA was examined in a subset of 470 ex-footballers and 491 controls, irrespective of pain status. RKOA was assessed using the Nottingham Line Drawing Atlas (NLDA) scores and the Kellgren Lawrence (KL) grading with a cutoff for OA of ≥3. All known risk factors such as age, body mass index (BMI), knee injury, high risk occupation, 2D4D digit ratio, self-reported constitutional knee alignment and nodal OA were assessed and included in a univariate analysis to identify their significance to knee pain/OA. Values were adjusted for use in a generalised linear model (GLM) with Poisson distribution to determine the relative risk (RR) and 95% confidence interval (CI) of KP and KOA in ex-footballers compared to controls.

Results : The mean age of ex-footballers was 59 years (SD ± 11.7) and that of the controls 62.8 years (SD +10.4) ($p<0.01$). They were gender matched (all men) with no difference on BMI ($p=0.135$). However, ex-footballers had more nodal OA, type 3 finger ratio (2D<4D), pain elsewhere and knee malalignment, knee injuries (65.7% v 24%) but less comorbidities than controls ($p<0.001$). Ex-footballers are almost twice as likely to present with KP [RR 1.84, 95%CI 1.71-2.00, $P<0.001$] and RKOA compared to the controls once adjusting for risk factors [RR 1.69, 95%CI 1.44-1.98 (r/knee) RR 1.69, 95% CI 1.44-1.97 (l/knee), $p<0.001$]. Ex-footballers report more KP across all age-groups and report onset of KP almost 15-20 years earlier (aged 50-54 years) compared to controls (aged 60-69 years; Figure 1). Ex-footballers reported RKOA (20 years) and TKR (5 years) earlier than controls. They were also almost three times more likely to have a TKR (either unilateral or bilateral) [RR 2.79, 95%CI 2.42-3.23, $p<0.001$] and a physician diagnosis of OA [RR 2.62, 95% CI 2.32-2.96, $p<0.001$) and twice as likely to have radiographic chondrocalcinosis [RR 1.78, 95%CI 1.56-2.02, $p<0.001$].

Figure 1 ***Prevalence of KP by age in the football and control population***

Conclusion: The prevalence of KP, RKOA and TKR are 2-3 times higher and the peak ages of onset are 5-20 earlier in ex-footballers compared to the general population in the UK. The higher prevalence of knee injuries and presumed repetive microtrauma of professional football are likely to be the major attributable factors. Employers and the Industrial Injuries Advisory Council should consider this risk and whether KOA is an



industrial compensatable disease.

Difference in Risk Factor Profile Between Medial and Lateral Compartment Involvement in Tibiofemoral Knee Osteoarthritis

Na Lu[1], Jingbo Niu[1], Hyon Choi[2] and Yuqing Zhang[3], [1]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, [2]Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, [3]Clinical Epidemiology and Training Unit, Boston University School of Medicine, Boston, MA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Tibiofemoral radiographic osteoarthritis (TFROA) can occur in medial, lateral, or both compartments. While several risk factors have been found to be associated with the risk of TFROA, no study has formally examined if the risk factor profile (or magnitude of association) differs among the subtype of TFROA (i.e., medial and lateral TFROA). Elucidation of the relationship between the putative risk factors and the occurrence of each subtype of TFROA can improve our understanding of its causality, thereby guiding the development of precision medicine and strategies.

Methods: Among participants in the Osteoarthritis Initiative, we identified subjects without compartment-specific ROA in either knee at baseline (i.e., joint space narrowing =0 in both medial and lateral tibiofemoral compartments). Subjects were followed for up to 72 months with annual bilateral knee X-rays. Medial or lateral TFROA was defined by Kellgren and Lawrence grade ≥2 and joint space narrowing ≥1 in the respective compartments. We examined traditional risk factors (i.e., sex, age, body mass index [BMI], race, knee injury) on the risk of TFROA subtypes (i.e., medial vs. lateral TFROA) and tested the heterogeneity of TFROA subtypes using the duplication method for nominal polytomous logistic regression.

Results: Of 2874 subjects (5748 knees) without TFROA in either compartment at baseline (mean age=59.9, 58.9% women, mean BMI=27.8 kg/m^2, 29.0% with a history of knee injury), 306 knees (5.3%) developed medial, 84 (1.5%) developed lateral, and 5 (0.1%) developed bilateral compartment TFROA. Women had a 3.7 times higher risk of developing lateral compartment TFROA than men (RR=3.70, 95% CI: 2.08-6.57), whereas no such association existed on the risk of medial compartment TFROA, suggesting a different impact of sex on the risk of TFROA between the two subtypes (P for heterogeneity < 0.001) **(Table)**. A higher BMI tended to have a larger association with the risk of medial compartment TFROA than with lateral compartment TFROA (P for heterogeneity=0.06). Furthermore, non-Whites appeared to be at a higher risk for lateral compartment TFROA than Whites, but not for medical compartment TFROA (P for heterogeneity=0.09). Associations with age and a history of knee injury did not differ between medial and lateral compartment involvement **(Table)**.

Conclusion: The risk factor profile for medial compartment TFROA may differ from that for lateral disease. Wide hips among women might explain high risk of lateral compartment TFROA whereas weight gravity falling more on the medial side might explain high risk of medial compartment TFROA. These findings suggest that personalized preventive and treatment strategies may be feasible for individuals with differential susceptibility to a specific subtype of TFROA.

Table. Risk factors in relation to risk of compartment-specific TFROA and subtype heterogeneity						
Risk Factor	No. knees	Medial TFROA		Lateral TFROA		P value for heterogeneity

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Although some individual foods and nutrients have been associated with knee osteoarthritis (OA) progression, the association between overall diet and OA progression is unknown. We aimed to examine the prospective association of major dietary patterns characterized by principal component analysis (PCA) with radiographic progression of knee OA.

Methods: In the Osteoarthritis Initiative (OAI), 2741 participants (4302 knees) with modest to moderate radiographic knee OA in at least one knee (Kellgren and Lawrence [KL] grade of 1, 2 or 3) who had dietary data at baseline were followed 12, 24, 36 and 48 months. We defined radiographic knee OA progression for a specific knee as at least one full score increase of KL grade characterized by joint space narrowing and/or osteophytes from baseline to 48 months. Dietary intake was assessed with a Block Brief Food Frequency Questionnaire completed at baseline. Two dietary patterns were identified by PCA: the Prudent pattern characterized by high intakes of fruit/vegetables, legumes, whole grains, and fish; the Western pattern characterized by high intakes of red / processed meats, refined grains, and French fries. The Cox proportional hazards models using a discrete likelihood method were developed to calculate hazard ratios (HR) after adjusting for age, sex, race, body mass index (BMI), baseline KL, injury/surgery, NSAIDs use, physical activity, and total calorie intake. We also used quantitative loss in joint space width (JSW) over time between the medial femur and tibia of the knee based on plain radiographs as the secondary measure of knee OA progression. Linear mixed models for repeated measures were used to assess the association between dietary patterns and JSW loss over time.

Results: Among 2741 participants (4302 knees) with OA at baseline, 721 knees had structural progression over 48 months. In multivariable adjusted models, a higher score for the Prudent dietary pattern was associated with a reduced risk of knee OA progression (p trend <0.01), while a higher score for the Western pattern was associated with an increased risk of progression (p trend <0.01) (Table). In addition, we observed a significant dose-response relationship between each dietary pattern score and adjusted mean JSW loss (Table). The observed associations attenuated after additionally adjusting for BMI.

Conclusion: Following the Prudent dietary pattern may reduce the risk of knee OA progression, whereas following the Western pattern may be associated with an increased risk of progression. The associations were partially mediated by BMI. Replication of these novel findings in other prospective studies demonstrating that improvement of dietary quality leads to delay in knee OA progression are needed. **Key words: Dietary pattern, osteoarthritis progression, joint space width.**

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Genetics, Genomics and Proteomics I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common childhood rheumatic disease, affecting approximately 1 in 1,000 children. JIA is a complex genetic trait and encompasses a wide spectrum of clinical heterogeneity. To date, genetic association studies in JIA had limited sample sizes, used heterogeneous patient populations containing all disease subtypes, or included only candidate regions (e.g. Immunochip). In this study, we focused on oligoarticular and rheumatoid factor negative (RF^-) polyarticular subtypes of JIA because they are clinically similar and the most prevalent forms of disease. This study employed large cohorts and imputed SNP data in a genome-wide association study (GWAS) to catalog novel genetic risk factors.

Methods: Three cohorts totaling 2,751 oligoarticular or RF^- polyarticular JIA cases and 15,864 controls, all of European ancestry, were genotyped using two platforms. Cohort 1 (814 cases and 3,055 controls) and cohort 2 (1,057 cases and 11,824 controls) were genotyped on the Affymetrix Genome-Wide Human SNP 6.0 Array, while cohort 3 (880 cases and 985 controls) was genotyped on the Illumina HumanCoreExome-12+ Array. Imputation was performed using 1000 Genomes Project data, followed by a meta-analysis of all 3 cohorts.

Results: Meta-analysis resulted in suggestive evidence of association ($P<1x10^{-6}$) at 10 regions along the genome: JAK1 (rs10889504: OR=0.78, $P=4.18x10^{-7}$), PRR9_LOR (rs873234: OR=1.43, $P=5.12x10^{-8}$), PTH1R (rs1138518: OR=1.23, $P=1.87x10^{-7}$), ILDR1_CD86 (rs1138518: OR=1.45, $P=6.73x10^{-8}$), FLJ41649 (rs10807228: OR=1.42, $P=5.80x10^{-7}$), AHI1_LINC00271 (rs9321502: OR=1.18, $P=3.48x10^{-7}$), HBP1 (rs111865019: OR=0.84, $P=7.29x10^{-7}$), ASAP1 (rs34962169: OR=1.43, $P=6.36x10^{-7}$), WDFY4 (rs1904603: OR=1.27, $P=1.79x10^{-7}$), and RNF215 (rs5753109: OR=1.19, $P=3.09x10^{-7}$). Among these regions, association studies in other autoimmune diseases provided additional evidence of support for JAK1 (Celiac Disease: rs12409333 - $r^2=0.898$, $P=3.80x10^{-5}$, Multiple Sclerosis: rs12409333 - $r^2=0.898$, $P=2.70x10^{-4}$), ILDR1_CD86 (Celiac Disease: rs2061197 - $r^2=0.407$, $P=8.55x10^{-6}$), AHI1_LINC00271 (Autoimmune Thyroid Disease: rs2179781 - $r^2=0.757$, $P=4.84x10^{-4}$, Celiac Disease: rs12206850 - $r^2=0.701$, $P=6.89x10^{-4}$, Multiple Sclerosis: rs11154801 - $r^2=0.740$, $P=1.00x10^{-13}$, Type 1 Diabetes: rs11154801 -$r^2=0.740$, $P=2.55x10^{-5}$) and WDFY4 (Systemic Lupus Erythematosus: rs877819 - $r^2=0.473$, $P=8.00x10^{-9}$). Furthermore, *cis* expression quantitative trait loci were shown for PTH1R (rs2242116), AHI1 (rs2614276), HBP1 (rs7790080, rs2301801, and rs2237659), WDFY4 (rs2940707), and RNF215 (rs2242116). Histone modifications of JAK1 (rs6588107: H3K4Me1, H3K27Ac and rs72922282: H3K4Me3, H3K27Ac), AHI_LINC00271 (rs6935146: H3K4Me1), and ASAP1 (rs67434056: H3K4Me1) showed additional regulation of gene expression.

Conclusion: These genome-wide genetic association results are supported by findings in other autoimmune diseases and/or relate to gene expression levels. Thus, they are likely to represent novel regions potentially contributing to the disease pathology of oligoarticular and RF^- polyarticular JIA.

A Multi-Dimensional Genomic Map for Polyarticular Juvenile Idiopathic Arthritis

Session Title: Genetics, Genomics and Proteomics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Polyarticular juvenile idiopathic arthritis (JIA) is a complex trait characterized by gene-environment interactions. While we are beginning to identify multiple genomic regions associated with disease risk in JIA, most of that risk is located within non-coding regions of the genome. Thus, to develop a mechanistic understanding of how genetic variance contributes to JIA, we require a detailed understanding of the non-coding genome and the functional elements located within these regions.

Methods: We created a multidimensional genomic map in JIA. Using genome-wide methylation sequencing, RNA sequencing, and chromatin immunoprecipitation-sequencing for informative histone marks (H3K4me1 and H3K27ac) in neutrophils, as well as whole genome sequencing on the Illumina 10x platform, we provide new insights into the interaction between genetic variation, the epigenome, and gene expression in the context of a common human disease.

Results: The epigenomes of JIA neutrophils display numerous differences from those from healthy children. DNA methylation changes, however, had only a weak effect on gene expression. In contrast, H3K4me and H3K27ac marks, commonly associated with enhancer functions, strongly correlated with gene expression. Furthermore, although some unique/novel enhancer marks were associated with insertion-deletion events (indels) identified on whole genome sequencing, genetic variation could account for no more than 30% of the JIA-specific epigenome. Treatment with methotrexate was associated with a re-ordering of transcription associated with changes in both methylation and histone marks, including histone and methylation marks located within indels. This finding demonstrates the plasticity of the epigenome in this setting. Alterations in histone marks most strongly associated with the transcriptional changes that accompanied the initiation of therapy.

Conclusion: JIA represents a complex genetic-epigenetic trait characterized by aberrant transcription in pathologically relevant cells. Initiation of effective therapy is associated with significant re-ordering of the epigenome, even in genomic regions where there is underlying genetic variance.

Session Title: Genetics, Genomics and Proteomics I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Recent genetic studies have identified multiple susceptibility loci for Behçet's disease. However, these genetic factors do not fully explain the apparent disease heritability.The purpose of this study was to densely genotype loci associated with immune-related diseases to identify novel susceptibility loci for Behçet's disease.

Methods: 1900 Turkish Behçet's disease patients and 1779 controls were genotyped using the Immunochip. For novel loci with association test $P<5\times10^{-5}$, additional SNPs in the region were genotyped or imputed using 1000 Genomes Project data as a reference. For replication, the lead genotyped SNP in each novel locus with $P<5\times10^{-5}$ in the Turkish population was genotyped in 982 cases and 826 controls from Iran. We also replicated disease associations with imputed previous GWAS data from 608 Japanese cases and 737 controls. $P<5\times10^{-8}$was considered the threshold for genome-wide significance.

Results: *HLA-B*51* was the strongest associated marker and rs1050502 the strongest associated SNP. rs1050502 is located in exon 2 of *HLA-B* and the risk allele T is a tag SNP for *HLA-B*51*. Outside of the MHC region, we identified 4 novel loci, *IL1A-IL1B*, *ADO-EGR2*, *IRF8,* and *CEBPB-PTPN1*, which exceeded genome-wide significance in Turks. Genotyping Iranian samples and meta-analysis with Turkish data replicated associations of three loci, *ADO-EGR2*, *IRF8* and *CEBPB-PTPN1*. Comprehensive meta-analysis of the regional imputed genotype data of Turks and Japanese replicated two loci, *ADO-EGR2* and *IRF8*, and revealed two additional novel loci, *RIPK2* and *LACC1*. The disease associated allele of rs4402765, the lead marker of the *IL1A-IL1B* locus, was associated with both decreased interleukin-1α and increased interleukin-1β protein production. Ancestry specific *FUT2*non-secretor genotypes, homozygous rs601338 (p.Trp143Ter) in Turks and Iranians and rs1047781 (p.Ile129Phe) in Japanese, showed strong disease association. The non-secretor genotype has been associated with Crohn's disease and gut microbiome composition.

Conclusion: Here, we conducted an Immunochip study in the largest Behçet's disease discovery cohort ever with multiple populations for replication. This study identified 6 novel loci (*IL1A-IL1B*, *RIPK2*, *ADO-EGR2*, *LACC1*, *IRF8*, and *CEBPB-PTPN1*) with genome-wide significance for Behçet's disease. Our findings that the disease-associated allele of *IL1A* is associated with dysregulated IL-1 biology, with less IL-1alpha and more IL-1beta production, and that functionally defective structural *FUT2* variants are associated with disease risk suggest that an impaired host response to microbes, including those of the microbiome, may contribute to Behçet's disease susceptibility.

Background/Purpose: Despite the progress in human leukocyte antigen (HLA) causal variant mapping, independent localization of major histocompatibility complex (MHC) risk from classical HLA genes is challenging.

Methods: We conducted a large-scale MHC fine-mapping analysis of rheumatoid arthritis (RA), an autoimmune disease with chronic destruction of synovial joints in Japanese (6,244 RA cases and 23,731 controls). We applied the HLA imputation method using the reference panel of the Japanese population (n = 908). We further conducted a multi-ethnic validation study by assessing the MHC fine-mapping analyses of RA in east Asians and Europeans (n = 7,097 and 23,149, respectively).

Results: Our study identified a risk of a synonymous mutation at *HLA-DOA*, a non-classical HLA gene, on anti-citrullinated-protein-autoantibody (ACPA)-positive RA risk (rs378352, odds ratio [OR] = 1.20, $P = 1.4 \times 10^{-9}$), independently from the risk classical HLA genes (*HLA-DRB1*, *HLA-DPB1*, and *HLA-B*). The *HLA-DOA* risk variant demonstrated a cis-expression quantitative trait loci (cis-eQTL) effect on *HLA-DOA* expression levels, demonstrating its dosage expression effect on RA risk. Independent risk of the *HLA-DOA* variant was further validated in east Asians (OR = 1.15, $P = 0.0040$) and Europeans (OR = 1.06, $P = 0.031$). Trans-ethnic comparison revealed different linkage disequilibrium (LD) patterns between *HLA-DOA* and *HLA-DRB1*, which explains the observed *HLA-DOA* variant risk heterogeneity among ethnicities; which was most evident in Japanese but not in Europeans.

Conclusion: Whilst the previous HLA fine-mapping studies have identified amino acid polymorphisms of the classical HLA genes as driving genetic susceptibility of the diseases, our study additionally identifies the dosage contribution of a non-classical HLA gene to disease etiology. Our study contributes to understanding of HLA

immunology in human diseases, and suggests the value of incorporating additional ancestry in MHC fine-mapping.

Session Title: Genetics, Genomics and Proteomics I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystemic autoimmune disorder with different genetic and environmental factors playing role in its pathogenesis. Early onset SLE, familial SLE, and syndromic SLE are rare situations which may lead to identification of monogenic defects responsible for the disease. Identification of monogenic causes through these cases can help us to understand the pathogenic mechanisms in SLE. We aimed to discover monogenic defects causing SLE by performing whole exome sequencing (WES) in familial or early-onset SLE cases.

Methods: We enrolled 12 pediatric SLE cases (from 7 different families) who had disease onset before 5 years of age and a family history consistent with an autosomal recessive inheritance (affected siblings or parenteral consanguinity). Whole exome sequencing and bioinformatic analyses were performed in six index cases and the suspected mutations were confirmed by Sanger sequencing. Only *C1Q* gene was analyzed by Sanger sequencing in patient 4 since he had similar features with the first three cases.

Results: There was consanguinity in all families. The characteristics of index SLE cases are presented in Table 1. We have demonstrated a homozygous nonsense mutation (c.622C>T/p.Gln208Ter) in *C1QA* gene in 2 patients; homozygous nonsense mutation (c.79C>T/p.Gln27Ter) in *C1QC* gene in 1; homozygous missense mutation (c.100G>A/p.Gly34Arg) in *C1QC* gene in 1; homozygous stop codon mutation (c.1945G>C/p.Ala649Pro) in *C1S* gene in 1; homozygous frameshift mutation (c.290_291delCA/p.Thr97Ilefs*2) in *DNASE1L3* gene in 1 patient. There was a candidate novel gene in 1 patient and functional studies on this gene are ongoing.

Conclusion: Five of our patients had homozygous mutations in the genes coding for early complement proteins. The risk to develop pediatric SLE is estimated to be 93% for C1q and 66% for C1s/r defects. There are around 100 published cases with homozygous C1q deficiency. The clinical presentations are variable; however, they usually had cutaneous involvement, normal C3, C4 levels and negative anti-dsDNA which was the case in our patients. C1s deficiency is much rarer. The nonsense mutation in C1S gene of our patients was novel. *DNASE1L3*

gene encodes for DNase1 enzyme which functions as an endonuclease cleaving DNA. Deletion in *DNASE1L3* gene has been previously reported to be associated with SLE in the study on 7 SLE families where it was shown that protein encoded by the mutant *DNASE1L3* completely lacked DNase activity. We suggest that monogenic causes/associations should be sought for an early-onset SLE.

Table1. Characteristics of pediatric patients with early-onset systemic lupus erythematosus

Characteristics	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Patient 6	Patient 7
Lupus in sibling	+	+	-	-	+	-	+
Mutant genes	C1QA	C1QC	C1QC	C1QA	C1S	DNASE1L3	Candidate novel gene
Malar/discoid rash/photosensitivity	+	+	+	+	+	+	-

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Genetics, Genomics and Proteomics I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Hypomorphic mutations in the *TRNT1* gene result in a syndrome of sideroblastic anemia, immunodeficiency, periodic fevers and developmental delay (SIFD). The TRNT1 enzyme is essential for tRNA maturation and regulation, aminoacylation and protein synthesis. Complete deficiency is incompatible with life.

Methods: Genetic studies included whole exome sequencing and candidate gene screening. Patient cells were used for deep RNA and tRNA sequencing, cytokine profiling, immunophenotyping, immunoblotting and electron microscopy (EM).

Results: We have identified 9 patients with biallelic missense mutations in *TRNT1*. 5 out of 9 mutations have not been reported. Patients suffered from recurrent fevers, variable degrees of immunodeficiency and a combination of inflammatory and degenerative disease. Inflammatory cytokines, mainly IL-6, IFN-g and IFN-induced cytokines were found elevated in the serum and in stimulated cells ex vivo. Deep tRNA sequencing of patients' fibroblasts showed that more than two third of patient's mature tRNAs were decreased compared to controls. EM microscopy of bone marrow and skin biopsy tissues showed striking abnormalities across all cell types, including pyknotic nuclei, disorganized cytoskeleton, extranuclear DNA, and abnormal mitochondria. We observed a mix of necroptotic and normal appearing cells in all tissues. Autophagosomal vesicles were observed intracellularly and in the serum. Intriguingly, the patient with the most severe inflammatory phenotype had evidence by EM of different, coexisting, types of cell death, proteinaceous substance and cellular debris in the bone marrow stroma. In agreement, gene expression profiling from patients' fibroblasts and whole blood, showed that the top differentially expressed genes belonged to pathways involving DNA damage control, protein trafficking, acute phase response, and extracellular tissue homeostasis. By immunoprecipitation, we further determined that patients' fibroblasts have malfunction in the maintenance of proteostasis as evidenced by dysregulation in proteasome and autophagy function, and accumulation of ubiquitinated proteins. No effective treatment has been described for this syndrome so far. Preliminary experience in our cohort suggests that treatment with a TNF-a inhibitor is beneficial for suppressing inflammation, stabilizing anemia and improving growth.

Conclusion: Mutations of TRNT1 enzyme lead to a severe and often fatal syndrome, linking protein homeostasis and autoinflammation. Future study of this disease will likely give new insights at cellular level about the role of protein homeostasis in immune cell development and susceptibility to inflammation in general. It might also provide more insights for targeted therapies of inflammatory diseases linked to protein degradation.

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) is a growing multi-center network organized on a learning health system model designed to improve outcomes of care for children with juvenile idiopathic arthritis (JIA). Since 2011, data from JIA clinical encounters have been entered into a shared registry to track performance on process and outcome quality measures (QMs) to drive improved outcomes. Currently, 17 centers learn established quality improvement methodology to conduct quality improvement work and share best practices at biannual face-to-face learning sessions and monthly webinars.

Methods: Statistical process control methods are used to determine if there are changes in performance on the

QMs. A centerline (the mean of the first 12 months of data) and control limits (±3 SD) are calculated, and control charts are monitored for special causes. Site specific and aggregate control charts are displayed monthly. If it is determined that a sustainable change has occurred, a new centerline and new control limits are calculated. Process QMs include measurement of: arthritis-related pain, physician global assessment of disease activity (PGA), joint counts, health related quality of life, physical function, medication counseling, as well as adherence to guidelines for uveitis screening, medication toxicity monitoring, and tuberculosis screening. Outcome QMs include: proportion of patients with clinical inactive disease (CID), mild to no pain, and optimal physical function; mean clinical Juvenile Arthritis Disease Activity Score 10 (cJADAS10); and percent of polyarthritis or oligoarthritis patients with inactive or low disease activity by cJADAS10.

Results: As of May 2016, 3716 JIA patients are enrolled, with over 20,000 visits recorded in the registry. Performance improvements have been achieved in process QMs, including percent of patients on Disease Modifying Anti Rheumatic Drug (DMARD) who had appropriate toxicity lab monitoring (from 56 to 82%) and documented medication counseling with DMARD initiation (from 59 to 93%). In addition, PR-COIN sites reliably perform complete joint counts (99%), PGA (96%), measurement of arthritis-related pain (94%), and tuberculosis screening for patients newly prescribed biologic drugs (99%). Forty-two percent of all PR-COIN patients have CID, with marked center-to-center variability (range 25% to 59%) and statistical improvement in a subset of centers. Seventy-five percent of patients have mild to no pain, and 60% have optimal physical function. PR-COIN has shown improved outcomes in mean cJADAS10 scores (from 4.4 to 3.8) and percentage of patients with inactive or low disease activity by cJADAS10 (from 49 to 54%) from 2011 to present.

Conclusion: PR-COIN has demonstrated success in improving processes of care for management of JIA. There is, however, variability in performance across centers. The dichotomous outcome measure “clinical inactive disease” has been slow to show statistical improvement in aggregate. By adopting a continuous outcome measure, the cJADAS10, PR-COIN has been able to demonstrate incremental improvements in outcomes for patients with JIA.

Abstract Number: 2039

Assessing Barriers to Uveitis Screening in Patients with JIA: A Qualitative Study

Laura Ballenger[1], Kyla Driest[2] and Stacy P. Ardoin[3], [1]Nationwide Children's Hospital, Columbus, OH, [2]Rheumatology, Nationwide Children's Hospital, Columbus, OH, [3]Pediatric & Adult Rheumatology, Ohio State University, Columbus, OH

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Uveitis is a major complication in patients with juvenile idiopathic arthritis (JIA) can be completely asymptomatic until vision loss develops. In order to prevent ocular complications, it is important to adhere to the recommended screening guidelines which range from every 3 to 12 months depending on JIA subtype, age of onset, duration of diagnosis and ANA status. However, this schedule may be difficulty for patients to adhere to. Little literature exists regarding compliance with uveitis screening in patients with JIA and we do not fully understand the barriers to obtaining screening eye exams. The specific aim of this quality improvement study as to assess barriers to obtaining screening eye exams in patients with JIA.

Methods: Patients with JIA were identified by ICD-9 code in our electronic medical record (EMR) prior to scheduled follow up appointments. They were then identified a adherent or non-adherent with established uveitis screening guidelines based on documentation of eye exams in the EMR. The guardians of those patients that were non-adherent were called the week prior to their scheduled appointments and a semi-structured interview was conducted. The interview included questions regarding the patient's most recent eye exam, knowledge about the screening frequency, and barriers to completing the eye exams. The results were then analyzed qualitatively to determine any categorical variables present and the relative importance of each variable.

Results: 92 patients, ages 3-22 years, were identified as non-adherent to screening exam guidelines out of a possible 246 total patients with JIA with upcoming appointments. 45 guardians of these patients or patients older than 18 years were interviewed by phone. Responses were categorized into system problems, access to care, and knowledge. System problems (57.8%) represented the largest category. These problems included the most recent eye exam not being in the EMR, the wrong provider was identified in the EMR, or difficulty with scheduling an appointment. 48.9% of patients who were identified by review of EMR record as non-adherent with screening exams had parent/guardian reports of more recent eye exams. Lack of appropriate parent knowledge regarding uveitis screening was also identified as a key barrier with 26.7% unaware of how often screening exams should be performed. Access to care was the least cited category with 20% of those interviewed identifying a barrier such as transportation or insurance.

Conclusion: This qualitative study identified system problems as the greatest barrier to obtaining screening eye exams in this patient population. The most common system problem was the most recent eye exam not being in the EMR. Lack of knowledge also appears to contribute. These results will be helpful in planning the next steps in improving compliance with uveitis screening.

Responsiveness of Patient Reported Outcomes Measurement Information System Measures in RA Patients Starting or Switching a DMARD

Alyssa Wohlfahrt[1], Clifton Bingham III[2], Zhi Zhang[1], Marcy Bolster[3], Larry W. Moreland[4], Tuhina Neogi[5], Kristine Phillips[6] and Yvonne C. Lee[7], [1]Rheumatology, Immunology and Allergy, Brigham and Women's

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Quality Measures and Quality of Care I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The Patient Reported Outcome Measurement Information System (PROMIS) is an NIH-developed metric for assessing multidimensional aspects of health across different conditions. Prior RA studies have reported cross-sectional results from PROMIS measures but were limited by small numbers of patients with active inflammatory disease. The purpose of this study was to evaluate the performance of multiple PROMIS measures in active RA patients initiating DMARDs.

Methods: Subjects were the first 148 RA patients enrolled in an ongoing multi-site, prospective observational study. Inclusion required active disease necessitating a start/switch to a new DMARD based on physician assessment. Subjects were evaluated before and 12-24 weeks after DMARD initiation. Subjects completed the PROMIS Global Health v1.1 short form and the following PROMIS computer adapted tests (CATs): Pain Interference, Pain Behavior, Sleep Disturbance, Sleep Related Impairment, Fatigue, Anxiety, and Depression. Scores were T-scores standardized to a general population mean of 50 ± 10. Higher scores indicate more of the concept measured. We performed linear regression models to identify cross-sectional associations between baseline PROMIS measures and disease activity measured using the CDAI; paired t-tests to evaluate responsiveness in subjects with follow-up data; and Pearson correlations to identify associations between changes in PROMIS measures and changes in CDAI.

Results: 85% of the cohort was female. Mean RA duration was 10.1 ± 12.8 years. At baseline, the mean CDAI was 25.3 ± 14.4. In multivariable linear regression models adjusted for age, sex, race, disease duration, and seropositive status, higher CDAI categories were significantly associated with higher PROMIS scores of pain, sleep, fatigue, and anxiety and lower PROMIS scores of physical and mental health ($P \leq 0.05$). Among 89 patients with pre/post data, paired t-tests showed statistically significant decreases in PROMIS domain measures ($P \leq 0.01$), ranging from -3.3 ± 8.2 to -5.5 ± 7.5 (Table). PROMIS Global Profile physical scores increased by 4.6 ± 7.3 ($P < 0.0001$), and PROMIS Global Profile mental scores increased by 2.0 ± 7.4 ($P = 0.01$). Changes were significantly correlated with changes in CDAI for all measures (absolute rho's = 0.21-0.33) except for the Global Profiles and Depression.

Conclusion: These data confirm the ability of PROMIS measures to distinguish RA patient groups based on levels of disease activity. Although minimal clinically important improvements have not been defined, our data suggest that PROMIS instruments are responsive to changes in therapy. We conclude that PROMIS measures may be useful tools for assessing RA symptoms in research studies and in routine clinical care, before and after starting a new DMARD.

Table. Mean (±SD) PROMIS Scores for RA patients before and 12-24 weeks after starting a DMARD (N = 89).				
	Mean Baseline Score	**Mean Follow-Up Score**	**Mean Change**	**P Value***
Physical Global Health Profile	41.7 (±7.5)	46.3 (±8.3)	4.6 (±7.3)	<0.0001
Mental Global Health Profile	48.3 (±8.6)	50.3 (±9.1)	2.0 (±7.4)	0.01
Pain Interference CAT	59.8 (±8.4)	54.5 (±8.0)	-5.5 (±7.5)	<0.0001
Pain Behavior CAT	58.9 (±5.1)	54.3 (±8.1)	-4.6 (±8.9)	<0.0001

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The measurement of patient reported outcomes (PROs) is a growing priority for performance improvement in clinical care of chronic conditions such as SLE. Measuring PROs at the point of care requires validated instruments with minimal responder burden. PROMIS¨ Global Health Short Form (GHSF) is a 10 question generic PRO instrument measuring global physical and mental health domains with T-scores normalized to the general population (mean score = 50). The validity and reliability of the PROMIS GHSF have not been demonstrated in SLE. The aims of this study were to evaluate: 1) validity and 2) test-retest reliability of PROMIS GHSF in adults with SLE.

Methods: Adult outpatients meeting 1997 ACR SLE classification criteria were recruited from a SLE Center of Excellence. Subjects completed the SF-36, LupusQoL-US, selected PROMIS CATs, and PROMIS GHSF. PROMIS GHSF global physical and mental health scores were compared with PROMIS CATs and legacy instruments using Spearman correlations. Test-retest reliability was evaluated among subjects reporting stable SLE activity at two assessments a week apart using intraclass correlation coefficients (ICC).

Results: PROMIS GHSF demonstrated face validity with SLE patients scoring worse than the general population in global physical health (mean T-score 41.6 +/- SD 8.8; range 19.9 - 67.7) and global mental health (mean T-score 43.7 +/- SD 8.7; range 25.1 - 67.6). PROMIS GHSF physical health scores correlated strongly with physical function, pain, and social health domains in the PROMIS CATs, SF-36, and LupusQoL, while PROMIS GHSF mental health scores correlated strongly with the PROMIS depression CAT and the LupusQoL emotional health domain (table 1). Correlation between PROMIS GHSF physical health and the SF-36 physical component scores (PCS) was weak, while correlation between PROMIS GHSF mental health and the SF-36 mental component scores (MCS) was moderate (table 1). Test-retest reliability for both PROMIS GHSF physical and mental health scores was high with ICCs of 0.89 and 0.85 respectively. Median time to complete the short form was less than 2 minutes.

Conclusion: This study is the first to demonstrate the validity and reliability of PROMIS GHSF in adults with SLE. PROMIS GHSF can be used to quickly, accurately, and reliably screen for impaired physical function, pain, and depression and could be an important tool in the measurement of patient centered outcomes and improvement of quality of care in SLE.

Session Title: Quality Measures and Quality of Care I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The risk of developing invasive pneumococcal pneumonia is 13 times higher in Lupus patients in comparison with general population. CDC anticipates 7.6 Million-Dollar medical cost reduction by providing pneumococcal vaccination per guidelines. Improving overall pneumococcal vaccination rate in lupus patients at our clinic through a multifaceted quality improvement initiative.

Methods: Eligibility: All lupus patients should receive pneumococcal vaccination. With help of quality improvement tools (interview with stakeholders {fig a}, process mapping) we analyzed the underlying barriers in providing vaccination and prepared a cause & effect diagram {fig b}. Following interventions were implemented, based on above analysis: **Staff** was responsible to confirm previous Pneumococcal vaccination, administer vaccines and update immunization history. **Physicians** were responsible to review daily reminders and place correct vaccination orders. **Patients** were given information handouts and education regarding Pneumococcal vaccines. After implementation of project, we calculated following rates (per week): Pneumococcal Vaccination (PCV 13, PCV 23 & vaccination complete) rates (percentage of pneumococcal vaccination given), documentation error rate (percentage of charts with immunization schedule not updated), historical error rate (percentage of patients not given pneumococcal vaccination due to unknown previous vaccination history) and vaccination refusal rate (percentage of patients refusing pneumococcal vaccination). Weekly progress was plotted on graph and discussed with the team members which helped us in modifying the interventions iteratively for achieving better rates.

Results: In 2 months {fig c}, overall vaccination improved from 8% to 28.2%, PCV 13 vaccination rate improved from 5% to 27.8%, PCV 23 vaccination rate improved from 8% to 50% and pneumococcal vaccination complete rate increased from 2% to 50%. Patient refusal rate decreased from 25% to 14%. 40% of patients are still not receiving immunization because of other reasons (forgetfulness, insufficient time).

Conclusion: Integrated workflow and performance data sharing helped in improving vaccination rates. Ongoing efforts are focused to overcome remaining barriers and achieve better rates.

Session Title: Quality Measures and Quality of Care I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Physician payments in the U.S. are shifting from fee-for-service to a value-based system, which will require quality measures to be extracted automatically from the electronic health record (EHR). However, the feasibility and accuracy of such "e-specification" of quality measures has not been widely reported. In this study, we compared the accuracy of automated electronic vs. manual chart review abstraction for a sample patient safety quality measure.

Methods: We developed electronic specifications for the following measure – "If a patient receives rituximab, then s/he should be screened for prior Hepatitis B infection with Hepatitis B surface antigen and Hepatitis B core antibody tests prior to rituximab initiation, because Hepatitis B reactivation is a potentially fatal (and preventable) adverse event in this population." We used EHR data derived from a tertiary care university center that has almost one million outpatient visits per year. Patients were included if they had at least 2 encounters during the 12 months before and at least one encounter 30 days after their first rituximab dose during the study period (June 2012-January 2016). We queried EHR structured data to define a denominator population of rituximab users and to classify the receipt of adequate Hepatitis B screening at any time prior to starting rituximab treatment. Two physicians performed chart reviews, including reviewing all clinical notes and scanned documents, to validate these data.

Results: The EHR query of structured data identified 1,167 users of rituximab in the denominator for this measure. Physician chart review found that this was an overestimate (321 patients did not receive the medication or had a historical reference to the medication). The automated query identified 618 (out of 1,167) patients in the numerator for this measure. Physician chart review found that this was an underestimate of actual testing, as 11% of the 926 patients in the denominator had additional lab results described in clinical narratives. The use of chart review in addition to electronic queries of EHR data increased the performance on this patient safety measure from 53% to 61%, representing a 15% increase.

Conclusion: Relying solely on the extraction of structured data from the EHR resulted in an overestimate of the denominator population and an underestimate of the numerator of Hepatitis B screening for this patient safety quality measure. Such misclassifications may threaten the validity of e-measurement and potentially undermine physicians' incentives to participate in a value-based payment system. As the number of e-Measures expands, accurate reporting will need to rely on additional strategies, including natural language processing for extraction of unstructured data from clinical notes, as well as changes to provider workflows to collect critical data elements in structured fields.

Table: Performance of patient safety measure using automated and manual data extraction.			
	EHR Query Using Structured Data N	Chart Review Findings N	EHR Query Using Structured Data & Chart Review Findings N
Denominator			
Patients taking rituximab after EMR go-live date	1,167	Of the 1,167 • 179 where rituximab was not completed or discontinued • 142 where rituximab was historical use	926
Numerator			
Receipt of Hepatitis B surface antigen (HepBsAg) and core (HepBCab) antibody labs prior to starting rituximab	Of the 1,167: • 618 had HepBsAg and HepBCab test results in a structured EHR table	Of the 926: • 561 received HepBsAg and HepBCab tests per structured EHR data table • 13 also had a lab value of "see text" where text was valid • 44 had no Hepatitis B test data but did have a test result mentioned in a clinical note, of which 4 received HepBsAg and HepBCab tests	565
Proportion of patients at risk receiving adequate testing	53%		61%

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: There are conflicting results about the effect pregnancy has on the health of systemic lupus erythematosus (SLE) women. The objective of the current analysis was to estimate the effect of pregnancy on disease flares in SLE using a stratified Cox model.

Methods: Data were prospectively collected in a university-based cohort from 1987-2015. Patients met ACR or SLICC criteria for SLE. All women aged 14-45 years with >1 measurement of disease activity were included, regardless of pregnancy status. Visits were classified into one of three exposure categories: pregnant, 1-year postpartum period, or non-pregnant/non-postpartum period (unexposed). Patients were allowed to switch from

one category of exposure to another between any two clinic visits based on pregnancy status. At each visit, disease activity was measured by Physician Global Assessment (PGA) and SELENA-SLEDAI. Flares during follow-up were defined as: 1) change in PGA ≥1 from previous visit and 2) change in SELENA-SLEDAI ≥4 from previous visit. Patients with a >1-year gap in study visits were considered lost to follow-up, but were allowed to re-enter the cohort. Hazard ratios (HR) between 1) pregnant and unexposed periods and 2) postpartum and unexposed periods were estimated with a stratified Cox model, a model that adjusts baseline hazards based on the number of previous flares. Hydroxychloroquine (HCQ) was explored as a time-varying covariate, with effect measure modification defined by likelihood ratio test (α=0.20).

Results: There were 1349 patients, including 398 pregnancies in 304 patients. Median age at cohort entry was 31 years, and median follow-up was 4 years. The crude incidence of flares based on the PGA definition was 60.7 per 100 person-years (PY) during pregnancy compared to 40.2 per 100 PY during non-pregnant/non-postpartum periods (Table 1). Stratified Cox models estimated an increased rate of flare during pregnancy (HR: 1.59; 95% CI: 1.27, 1.96), with no evidence of an increased rate during the postpartum period. There was effect modification by HCQ use. Among periods of no HCQ use, the HR of flares in pregnancy compared to non-pregnant/non-postpartum periods was estimated to be 1.83 (95% CI: 1.34, 2.45) compared to 1.26 (95% CI: 0.88, 1.69) among periods with HCQ use (likelihood ratio p-value: 0.04). When flares were defined by SELENA-SLEDAI, results were similar, with an increased rate of flare during pregnancy but no observed increased rate of flare postpartum compared to non-pregnant/non-postpartum periods. No evidence of effect modification by HCQ use was found when flares were defined by SELENA-SLEDAI.

Conclusion: Our study supports and extends previous findings that the incidence of flare is increased during pregnancy. Continuing HCQ in pregnancy, however, appeared to mitigate the risk of flare during pregnancy. We did not find evidence of an increased rate of flare postpartum.

Table 1. Crude incidence, crude incidence rate ratio, and hazard ratio of flares during pregnancy and postpartum periods compared to non-pregnant/non-postpartum periods (n=1349)

	Crude incidence per 100 person-years	Hazard Ratio (95% CI)

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Reproductive Issues in Rheumatic Disorders
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Early preeclampsia is a serious pregnancy complication characterized by abnormal placentation and diffuse maternal endothelial cell dysfunction, and requires emergent delivery which may be very premature. SLE has been shown to increase the risk of preeclampsia, but little is known about the risks of early onset preeclampsia – a pregnancy morbidity associated with stroke, placental abruptions, and perinatal death.

Methods: Using national population-based Swedish registers we identified women with SLE (≥2 visits with corresponding ICD codes) and without SLE who gave birth to singleton infants 2001-2012 in the Swedish Medical Birth Register. Comparators without SLE were drawn from the general population. Preeclampsia was defined using date of first corresponding diagnosis during pregnancy to define early onset (<34 weeks). The association between early preeclampsia and maternal SLE was estimated by multivariable-adjusted modified Poisson models for first, subsequent, and all births. BMI, age, smoking, and pregestational hypertension and diabetes were included as potential confounders. We used ICD-10- coded visit and heparin dispensing during pregnancy from the Prescribed Drug Register (2006-2012) as a proxy for antiphospholipid syndrome (APS).Preeclampsia history was adjusted for in analyses of subsequent and all births. We investigated effect modification by pregestational hypertension, examined residual confounding by APS and misclassification of preeclampsia due to lupus nephritis.

Results: There were 742 births to women with SLE (343 first births) and 10484 births to women from the general population (4443 first births). Compared to the general population, SLE was associated with a significantly increased risk of early preeclampsia for all, first, and subsequent births [RR=7.3, (95% CI=4.5, 11.9), mvar-adj, all births]. Adjustment for APS proxy attenuated the association (RR=3.7, 95% CI=1.7, 7.9), but SLE remained significantly associated with early preeclampsia. Findings were similar among women without pregestational hypertension, a strong risk factor for early preeclampsia, as well as in the absence of recent nephrology care. RRs for early preeclampsia were smaller, but significant, for subsequent births compared to first and all births [RR=2.8, (95% CI=1.2, 6.4) subsequent].

Conclusion: Women with SLE are at increased risk of preeclampsia before 34 weeks gestation, and importantly, this increased risk may be independent of pregestational hypertension, APS, BMI, or smoking. Traditional risk factors alone may not explain the increased risk of early preeclampsia among women with SLE for first, subsequent, or any birth. Women with SLE during pregnancy should continue to be monitored carefully for early preeclampsia and future research is needed to identify what non-traditional preeclampsia factors might be causing this serious outcome.

The Low-Dose Intravenous Cyclophosphamide Euro-Lupus Regimen Does Not Impact the Ovarian Reserve of Lupus Patients, As Measured By Serum Anti-Mullerian Hormone Levels

Séverine Nieuwland[1], Farah Tamirou[1], Damien Gruson[2], Frédéric Debière[3], Bernard R. Lauwerys[1] and **Frédéric A. Houssiau**[1], [1]Rheumatology Department, Cliniques universitaires Saint-Luc, Brussels, Belgium, [2]Clinical Chemistry Department, Cliniques universitaires Saint-Luc, Brussels, Belgium, [3]Obstetrics Department, Cliniques universitaires Saint-Luc, Brussels, Belgium

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The low-dose intravenous (IV) cyclophosphamide (CY) Euro-Lupus (EL) regimen (cumulative dose 3g) has been developped to reduce gonadal toxicity. Although no case of premature menopause has been reported, uncertainty persists regarding a marginal effect on the ovarian reserve. To address this issue, we measured serum titers of anti-Mullerian hormone (AMH) in patients suffering from systemic lupus erythematosus (SLE) treated with the EL regimen and compared them to those measured in SLE patients treated with higher doses of IVCY and in those never treated with IVCY.

Methods: Serum anti-Mullerian hormone (AMH) levels were measured by ELISA (Ansh Laboratories, TX, USA) in a cohort of 169 consecutive premenopausal female SLE patients fulfilling the SLICC/ACR criteria. Demographic and clinical data were collected, as well as the cumulative dose of IVCY. Patient's consent was obtained, as appropriate.

Results: Median serum AMH titers of patients given the 3g EL IVCY regimen (1.15 ng/ml ; n=31) did not differ from those measured in patients never treated with IVCY (1.42 ng/ml ; n=112). By contrast, and as anticipated, serum AMH titers were statistically lower in patients treated with >3g IVCY (median : 0.71 ng/ml; n=26 ; mean ± SD IVCY dose of 8.1 ± 3.7g ; p=0.036 by Mann-Whitney test). These results were confirmed when serum AMH values were adjusted for age (based on titers measured in the cohort of SLE patients who never received IVCY). Patients given >6g IVCY (n=15 ; mean ± SD IVCY dose : 10 ± 3.9g) have much lower median age-adjusted serum AMH values (0.09 ng/ml) compared to patients never given IVCY (p=0.008 by Mann-Whitney test). In 10 patients, paired serum samples were tested before and after EL IVCY. Median AMH values did not differ (1.54 ng/ml before and 1.39 ng/ml after : p=0.49 by Wilcoxon matched-pairs signed rank test).

Conclusion: Based on cross-sectional and longitudinal data, the EL IVCY regimen does not impact the ovarian reserve of SLE patients and can therefore be proposed as induction immunosuppressive therapy in severe patients without risk of compromising fertility.

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Histopathologic studies of cutaneous neonatal lupus erythematosus (cNLE) lesions usually show interface dermatitis. Hydroxychloroquine (HCQ) is an effective treatment for interface dermatitis seen in connective tissue diseases. It may also be effective for cNLE. Due to the transplacental passage of HCQ, fetuses of treated mothers are exposed to HCQ. The aim of this study was to asses if in utero exposure to HCQ would lower the risk of cNLE.

Methods: A multicenter case control study was performed. Inclusion criteria were: (1) infant born to a woman positive for anti-Ro ± anti-La antibodies and with a diagnosis of either systemic lupus erythematosus, Sjogren's syndrome, dermatomyositis or rheumatoid arthritis, (2) infant cNLE status documented, and (3) documentation of maternal medications during pregnancy. Children with cardiac NLE were excluded from this study. Generalized estimating equation (GEE) was used to account for within-family correlation of data. A subgroup analysis was performed including only cases with cNLE onset ≤ 4 weeks of life, as neonates are not continued on HCQ after delivery therefore HCQ levels are expected to decline after birth.

Results: A total of 545 children (10 twin pairs) were included. Cases (N=112) and controls (N=433) differed with respect to maternal characteristics (Table 1). 169 (31%) infants were exposed to HCQ. Univariable GEE

models showed that maternal diagnosis, anti-La antibody, maternal intake of HCQ and maternal intake of non-fluorinated steroids ± azathioprine were associated with cNLE (Table 2). In multivariable GEE, maternal intake of HCQ remained associated with a significant decrease in cNLE (Table 3). 41/112 infants with cNLE had onset of rash within 4 weeks after birth. When analyses were restricted to these early onset cNLE cases, results were similar to that of the entire study population (multivariable GEE, maternal intake of HCQ OR 0.2 (95% CI 0.1-0.7); p=0.009).

Conclusion: In this large multicenter study of 545 children born to women with anti-Ro ± anti-La antibodies and a connective tissue disease and/or RA, in utero HCQ exposure was associated with a decreased risk of cNLE.

Table 1. Baseline characteristics

	Patients (N)	Cases (N=112)	Controls (N=433)	p value
Maternal characteristics[1]	535			
Age at child birth, years (median (IQR))	522	31 (29-35)	32 (29-35)	0.446

Session Title: Reproductive Issues in Rheumatic Disorders
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Women with chronic inflammatory diseases, including rheumatic diseases and Crohn's disease (CD), face uncertainty regarding the safety of the use of biologics during breastfeeding. For women with RA, postpartum flare is common.[1] Currently, limited and non-validated data exist on potential transfer of anti-TNFs into breast milk. CRADLE was the first sponsored study designed to evaluate certolizumab pegol (CZP) concentrations in breast milk, and to estimate average daily infant dose of maternal CZP (the daily amount of CZP potentially ingested by infants).

Methods: CRADLE (NCT02154425) was a safety and pharmacokinetic study of lactating mothers (≥6 weeks postpartum) receiving commercial CZP for an approved indication. Decision to treat with CZP and to breastfeed was made independently of study participation. At steady-state (≥3 CZP doses), breast milk samples were collected at days 0, 2, 4, 6, 8, 10, 12, 14 (±28) from each mother across 1 dosing period (14 days for 200 mg Q2W; 28 days for 400 mg Q4W). Maternal burden was minimized through in-home visits with nurses. A highly sensitive CZP-specific ELISA was developed (validated in milk; LLQ=0.032 μg/mL, 10-fold lower than assay used in CZP pharmacokinetic studies[2]). CZP stability in milk was confirmed.

Results: 18 CZP-treated mothers were screened and 17 entered the sampling period; 16 on 200 mg Q2W; 1 on 400 mg Q4W (7 RA; 5 SpA; 5 CD; Table A). Samples from 4/17 mothers had no measurable CZP in breast milk; 13/17 had quantifiable levels at any time point (highest concentration: 0.076 μg/mL; Table B). Estimated average daily infant dose ranged 0–0.0104 mg/kg/day; median relative infant dose (calculated[3] *post hoc* by Dr Hale): 0.15%. The infants of mothers exposed to CZP had a safety profile consisting of events occurring in unexposed infants of similar age (Table C).

Conclusion: Using the highly sensitive assay, CZP was undetectable in 56% of milk samples collected. When detectable, CZP concentrations were less than 3 times LLQ (<1% of expected plasma concentration of a therapeutic dose),[2] indicating no to minimal transfer of CZP from plasma to breast milk. Relative infant dose was below 0.5% of maternal dose; <10% is considered unlikely to be of clinical concern.[3] In addition, CZP absorption by infants via breast milk is unlikely due to its Fc-free molecular structure[4] and the low bioavailability of biologics after oral administration. These findings are reassuring and imply that continuation of CZP treatment is compatible with breastfeeding. **References:** 1. de Man Y. Arthritis Rheum 2008;59:1241–8; 2. Lacroix B. 13	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ	-
14	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ	-
15	BLQ	BLQ	0.041	0.034	0.033	BLQ	0.037	BLQ	-
16	0.040	0.033	0.036	0.037	0.043	BLQ	BLQ	BLQ	-
17	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ	BLQ

Key: BLQ (<0.032 µg/mL); Less than 2×LLQ (<0.064 µg/mL); Less than 3×LLQ (<0.096 µg/mL)

Days 0 and 14 are pre-dose for mothers on CZP 200 mg Q2W dosing regimen;
Days 0 and 28 are pre-dose for the mother on CZP 400 mg Q4W dosing regimen.

BLQ: below the limit of quantification, <0.032 µg/mL; LLQ: lower limit of quantification.

For reference, the mean 12-week CZP plasma C_{trough} value, ie. the trough concentration at steady-state, reported from patients with rheumatoid arthritis receiving CZP 200 mg Q2W in the RAPID2 trial was 15.7 µg/mL (95% CI: 14.0, 17.7).[2]

Table C: Summary of adverse events from the Safety Set during the CRADLE study (from screening to safety follow-up)

	Mothers (n=18) n (%)	Infants (n=17) n (%)
Any adverse event	10 (55.6)	8 (47.1)
Intensity		
Mild	3 (16.7)	6 (35.3)
Moderate	6 (33.3)	2 (11.8)
Severe	1 (5.6) [a]	0

Severe	1 (5.6) [a]	0
Serious adverse events	1 (5.6) [a]	0
Discontinuations due to adverse events	1 (5.6) [b]	0
Drug-related adverse events	4 (22.2)	1 (5.9)
Herpes zoster	1 (5.6)	-
Crohn's disease flare	1 (5.6)	-
Upper respiratory tract infection	2 (11.1)	-
Pneumonia	1 (5.6)	-
Nasopharyngitis	-	1 (5.9)
Adverse events of interest [c]	0	0
Deaths	0	0

Adverse events are reported from the Safety Set, which included all mothers who received at least 1 dose of CZP, and the infants of all mothers who participated in the study. The safety follow-up period extended up to 5 weeks (±5 days) after the final sample was obtained. [a] Breast abscess during screening period, which resolved prior to sampling; [b] Herpes zoster during screening period resulting in screen failure; [c] Includes any opportunistic infections, any malignancies (including unspecified), any major adverse cardiac events, any hematopoietic cytopenias, any serious bleeding events, any hepatic events, and any injection or injection site reactions in mothers.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Tumor Necrosis Factor inhibitors (TNFi) are increasingly used during RA pregnancy.

Most of these are actively transported across the placenta, reaching higher fetal than maternal blood levels. Despite concerns that these drugs cause immunosuppression, there are no data on the risk of serious infections in exposed offspring. Thus, we evaluated serious infections in RA offspring exposed to TNFi in the preconception and/or gestational period compared to unexposed RA offspring, as well as to children from the general population.

Methods: The "PregnAncies in RA mothers and Outcomes in offspring in the United States cohort (PAROUS)" includes all women with ≥1 hospitalization for delivery after RA diagnosis, identified through MarketScan commercial databases (2011-2014). PAROUS also includes a randomly selected control group of women, matched ≥4:1 for age, year of delivery, and state of residence, without an RA diagnosis prior to or at the time of delivery. Only women continuously enrolled within MarketScan for ≥12 months prior to delivery and with available child linkage were included in PAROUS. We identified children born live to RA mothers and their matched controls, and defined TNFi exposure based on ≥1 filled prescription of adalimumab, certolizumab, etanercept, golimumab, or infliximab during pregnancy and/or the preconception period (ie 12 weeks prior to conception). We ascertained serious infections based on ≥1 hospitalization with infection as a primary diagnosis, ≤12 months of life. We performed multivariate analyses with generalized estimating equations to adjust for maternal demographics, co-morbidities, pregnancy complications, and drugs.

Results: We identified 2455 RA offspring and 11 018 matched controls. Among children born to RA women, 290 (11.8%) were exposed to TNFi during pregnancy (ie TNFi pregnancy) (including 109 in the third trimester), 109 (4.4%) were unexposed during pregnancy but exposed in the preconception period (ie TNFi preconception), and 2056 (83.7%) were unexposed both during the pregnancy and preconception periods (ie RA with no TNFi). Each group of RA offspring experienced more serious infections vs general population controls [TNFi pregnancy 3.1% (95%CI 1.5,6.0), TNFi third trimester 2.8% (95%CI 0.7,8.4), TNFi preconception 1.8% (95%CI 0.5,6.4), RA with no TNFi 2.1% (95%CI 1.6,2.9), vs controls 0.2% (95%CI 0.1,0.2)]. In multivariate analyses, children born to RA women had a substantially increased risk of serious infections vs controls [OR for TNFi pregnancy 15.4 (95%CI 6.2,38.6), OR for TNFi preconception 9.6 (95%CI 2.1,43.8), OR for RA with no TNFi 12.8 (95%CI 6.9,23.8)]. We were unable to establish an increased risk of serious infections in RA offspring exposed to TNFi during pregnancy compared to unexposed RA offspring (OR 1.2; 95%CI 0.6,2.6); results were similar when we restricted TNFi exposure to the third trimester (OR 1.0; 95%CI 0.3,3.4).

Conclusion: Compared to children from the general population, children born to RA women have a substantially increased risk of serious infections. We were unable to establish a marked excess risk for serious infections in RA offspring exposed to TNFi during pregnancy, including the third trimester, vs unexposed RA offspring.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects III: Prevention of Comorbidity
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Patients with RA are either more at risk of, or less well screened for, several comorbidities including cardiovascular (CV) risk, cancer, infections and osteoporosis.[1] In 2012, patients with established RA participated in a trial including a nurse visit for comorbidity counselling [2]. In the present follow-up study, we aimed to quantify both at study entry and 3 years after the trial ended, comorbidity screening and management in this population.

Methods: *Study design*:This was an open long term (3 years) extension of the COMEDRA 6 month randomized controlled trial in which patients with definite, stable RA were visiting a nurse for comorbidity counselling.[2] Comorbidity status was assessed and nurses provided advice on screening and management, at baseline and 3 years later. *Outcome measure:* A score was developed to quantify comorbidity screening and management: this score gives 50 points to CV risk (ie hypertension, diabetes, lipids, renal insufficiency), 20 points to cancer, 20 points to vaccination and 10 points to osteoporosis screening. Lower scores indicate better screening and management. *Statistical analysis*: The score was compared between baseline and 3-year assessment using a Wilcoxon test for paired data. For each comorbidity, the percentage of patients in conformity with screening and/or management recommendations was also assessed at both timepoints and compared using a MacNemar test for paired data.

Results: Of the 970 recruited patients, 776 (80%) were followed up at 2-4 years and 769 (79%) had available data for comorbidities at both timepoints: mean (±SD) age 58 (±11) years, mean disease duration 14 (±10) years; 614 (80%) were women and 538 (70%) were receiving a biologic with a mean DAS28 of 3.0±1.3. At baseline,

the mean comorbidity screening score was 36.6(±19.9) (range, 0-100) and it improved at 3 years to 24.3(±17.8) (p<0.0001) thus with a relative improvement of 33%. Patients in conformity with management recommendations improved most remarkably for CV risk screening, vaccination status and bone densitometry performance, whereas cancer screening improved less (Table).

Conclusion: Comorbidity screening is suboptimal but has improved notably in this study over 3 years, after a nurse-led program aiming at checking systematically for comorbidity screening and giving patient advice. Improvements were particularly important for CV screening and vaccinations. This long-term efficacy pleads in favour of nurse-led interventions to better address comorbidities in RA.

Session Title: Rheumatoid Arthritis – Clinical Aspects III: Prevention of Comorbidity
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of developing cardiovascular (CV) comorbidity compared with the general population. Contradictory results concerning CV disease prior to onset of RA have been reported. Of the known CVD risk factors, a more atherogenic lipid profile and smoking have been presented prior to RA onset. In this study, lifestyle factors, lipid levels, presence of hypertension and diabetes were evaluated in individuals prior to onset of symptoms of RA and matched population controls from northern Sweden.

Methods: A nested case-control study was based on population surveys from The Västerbotten Intervention Programme (VIP) and the WHO Multinational Monitoring of Trends and Determinants in Cardiovascular Disease (MONICA). Data were collected by a questionnaire (socioeconomic and lifestyle factors), assessments by a nurse (body mass index; BMI, waist and blood pressure), and blood sampling. The registers of patients with RA (ARA criteria) attending the Department of Rheumatology, Umeå was co-analysed with the registers from VIP and MONICA. This study included 547 pre-symptomatic individuals (median age 50.2 years; 372f/175m, median (IQR) predating time 5.0 (7.0) years), and 1641 controls (median age 50.3 years; 1116f/525m). CVD risk factors were defined as: hypertension (systolic ≥140 mmHg and/or diastolic ≥90 mmHg including hypertensive treatment), elevated ApoB/ApoA1 ratio (females ≥0.7, males ≥0.8, including lipid lowering treatment), BMI ≥25, diabetes, and ever smoker.

Results: In conditional logistic regression models elevated ApoB/ApoA1 ratio (OR 1.3 (95% CI 1.0,1.6)), smoking (OR 2.0 (95% CI 1.6,2.5)), BMI≥ 25 (OR 1.3 (95% CI 1.1,1.6)) and diabetes (OR 2.0 (95% CI 1.1,3.7)) were associated with individuals who subsequently developed RA. In women elevated ApoB/ApoA1 (OR 1.4 (95% CI 1.1-1.8)), smoking (OR 1.9 (95% CI 1.1-1.8)), and BMI ≥25 (OR 1.3 (95% CI 1.1-1.7)) were significant for being pre-symptomatic for RA, in men the risk factors were smoking (OR 2.2 (95% CI 1.5-2.5), and diabetes (OR 4.7 (95% CI 1.71-13.1)). Stratifying on the median age, the factor remaining significant for the future RA group in older individuals was smoking (OR 1.7 (95% CI 1.2,2.5)), whereas in the individuals ≤50.2 years the factors were: elevated ApoB/ApoA1 ratio (OR 1.4 (95% CI 1.0,1.9)), BMI ≥25.0 (OR 1.5 (95% CI 1.0-2.0)), and smoking (OR 2.1 (95% CI 1.5,3.0). The pre-symptomatic individuals had significantly higher frequency of risk factors, 42% had ≥3 of these compared with 30% of the matched controls (OR 2.8 (95% CI 1.8, 4.5)). Especially, ACPA positive pre-symptomatic individuals had a high OR for future RA when having ≥3 of the CV risk factors (OR 5.7 (95% CI 2.1-15.3)).

Conclusion: Several of the CV risk factors were present in individuals already years before onset of symptoms of RA. One third of the pre-symptomatic individuals had at least 3 of these factors present. The risk factors for CVD associated with future RA differ between women and men. In younger individuals as well as ACPA

positive individuals the CVD risk factors have a greater impact. These results urge an early CV prevention in patients with RA.

Session Title: Rheumatoid Arthritis – Clinical Aspects III: Prevention of Comorbidity

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Patients taking biologic DMARDs often undergo elective surgery, but data to guide if and when to hold biologics before surgery is limited. This study evaluated whether the timing of infliximab before elective hip or knee arthroplasty was associated with an increased risk of serious infection.

Methods: A retrospective cohort study using U.S. Medicare data evaluated adults with rheumatoid arthritis, inflammatory bowel disease, psoriasis, psoriatic arthritis, or ankylosing spondylitis who received infliximab within 6 months of elective inpatient primary or revision total knee or hip arthroplasty from 2007-2013. Multivariable logistic or Cox regression evaluated associations of infliximab stop time (time between most recent infusion and surgery) with 1) hospitalized infection within 30 days of surgery (excluding urinary infections given relative lack of specificity) using a validated set of discharge diagnoses and 2) rate of prosthetic joint infection (PJI, ICD9 996.66) within 1 year (including within 30 days), adjusting for confounders. Analyses considering the propensity of being in each stop time category were also performed using inverse probability weighting.

Results: Among 4288 surgeries in 3867 patients, the 30 day cumulative incidence of infection was 6.3% (n = 270), with bacteremia, skin/soft tissue infection, and pneumonia the most common infections. In adjusted analyses, infliximab stop time < 4 weeks vs 8-12 weeks was not associated with an increase in infection within 30 days [OR 0.85, 95% CI 0.58,1.25] [Table]. Risk factors for infection included oral glucocorticoid dose > 10mg, age > 80, higher Charlson comorbidity, previous hospitalized infection, more outpatient visits, and year 2007-2009 (vs 2010-2013) [Table]. Over 12 months, the rate of PJI was 2.9 per 100 person-years (n = 105

infections) and was similar for patients who stopped infliximab < 4 weeks vs ≥ 4 weeks before surgery [Figure]. After adjustment, infliximab stop time of < 4 weeks vs 8-12 weeks was not associated with increased rate of PJI [HR 1.01, 95% CI 0.56, 1.82]. Risk factors for PJI included glucocorticoid use, revision surgery, previous hospitalized infection, extra-articular RA, and year 2007-2009. Results were similar in propensity-adjusted analyses.

Conclusion: Administering infliximab within 4 weeks of elective total knee or hip arthroplasty was not associated with a higher risk of short or long-term serious infection compared to withholding infliximab for longer periods of time. In contrast, glucocorticoid use, especially > 10mg per day, was associated with an increased risk of infection. **Table:** Results of multivariable logistic regression analysis for serious infection within 30 days, based on 4283 observations among 3863 patients

Session Title: Rheumatoid Arthritis – Clinical Aspects III: Prevention of Comorbidity

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Studies have shown rheumatoid arthritis (RA) to be a risk factor for development of prosthetic joint infections (PJI) and for worse outcome from PJI compared to non-RA patients, but these findings may not be generalizable to the U.S. veterans. Thus, we aimed to evaluate the risk for recurrence of PJI in RA patients compared with non-RA patients among the veteran population.

Methods: We conducted a retrospective cohort study of all patients admitted for a *S. aureus* PJI and undergoing surgical intervention between 2003 and 2010 at 123 Veterans Affairs Medical Centers (VAMCs). RA was the exposure of interest, identified using the ICD9 code 714.0, and the outcome was recurrent PJI. Co-variates studied were age, sex, methicillin resistance status of *staphylococcal aureus*, site of PJI, time to recurrence of PJI, co-morbidities (i.e., hypertension, diabetes, renal disease, Charlson comorbidity score), steroid use and the type of surgical intervention done for the index PJI. T-test was used to compare continuous variables; Chi-square or Fisher exact test was used to compare dichotomous variables among the RA and non-RA groups. Cox proportional hazards regression model was used to compare the time to recurrent PJI for the RA versus non-RA group.

Results: Of the 731 veterans in our cohort who had a revision surgery for their first *S.aureus* PJI, 91 (12.4%) had RA. PJI patients with RA tended to be older than PJI patients without RA (mean years: 67.6 vs. 65.1, p=0.03). The two groups did not differ based on the time to their first PJI after arthroplasty. The RA patients had a significantly higher prevalence of hypertension. The prevalence of diabetes and renal disease and the Charlson Comorbidity score were similar among the two groups. RA patients tended to have a lower risk for recurrence of PJI compared with non-RA patients; however, this association was not statistically significant (HR=0.78, 95% CI 0.5-1.2, p=0.27). Infection with methicillin-resistant *S.aureus* (MRSA) carried an increased risk of recurrent PJI (HR=1.36, 95% CI 1.03-1.80) compared with MSSA. Two-stage exchange surgery was associated with a lower recurrence rate compared with debridement, antibiotics and implant retention (HR=0.35, 95% CI 0.23-0.53, p<0.001).

Conclusion: : MRSA PJI and the type of surgical intervention were the main predictors of recurrent PJI in a national cohort of veterans with *S. aureus* PJI treated with surgical modality. Our study results are in keeping with reports that two-stage prosthesis revision offers the best chance for recurrence-free 2-year outcomes following PJI. In contrast, our results did not find RA to be a risk factor for worse disease outcome or increased PJI. The strength of our study is the identification of a large cohort of veterans with *S. aureus* PJI with a validated outcome of recurrence. The small number of female patients and the possible higher co-morbidity inherent in our cohort are limitations that affect the generalizability of our findings to non-veteran populations. To summarize, prior RA diagnosis was not associated with recurrence of *S. aureus* PJI compared with non-RA patients in the veteran population.

Session Title: Rheumatoid Arthritis – Clinical Aspects III: Prevention of Comorbidity

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at a higher risk of infection due to the underlying immune dysfunction and immune suppression associated with treatment. Thus, vaccination against preventable diseases including influenza is recommended for all RA patients. Methotrexate (MTX), the mainstay of treatment in RA, has been associated with decreased response to influenza vaccination. This study was aimed to investigate whether a temporary discontinuation of MTX improves the vaccine efficacy to seasonal influenza.

Methods: In this single center, randomized, single-blind, open-label, prospective, parallel group intervention study, RA patients with stable MTX dose were randomly assigned to continue MTX (Group 1), to hold MTX for 4 weeks before vaccination (Group 2), to hold MTX for 2 weeks before and for 2 weeks after vaccination (Group 3) and to hold MTX for 4 weeks after vaccination (Group 4). We measured HI antibody titers against each antigen at baseline prior to vaccination with tri-valent seasonal influenza vaccination containing A/California/72009 (H1N1), A/Switzerland/9715293/2013 (H3N2) and B/Phuket/3073/2013 (B-Yamagata), and then again 4 weeks post-vaccination. Satisfactory vaccine response was defined as ¡Ã 4-fold increase in post-vaccination antibody titer relative to baseline. Protective antibody titer was defined as ¡Ã1:40.

Results: The per-protocol population comprised 219 patients (54, 44, 49 and 52 patients for Group 1, 2, 3 and 4, respectively). Prevaccination titer did not differ between the 4 groups. Four weeks after vaccination, Group 3 and Group 4 showed higher increase in antibody titers against H1N1 and H3N2 and B-Yamagata antigens than Group 1. The percentage of the satisfactory vaccine response against H3N2 and B-Yamagata were statistically higher in Group 3 and Group 4 than Group 1. By contrast, Group 2 were comparable to Group 1 in regard to increase in antibody titers and satisfactory vaccine response (Figure). The percentage of patients who showed protective titers for H1N1 and B-Yamagata was prominently increased in Group 3 and 4 as compared with group 1 (Figure). All groups showed high percentage of protective titers for H3N2. The influenza vaccine was well tolerated. RA flares were observed in 4 (7.4%), 6 (13.6%), 9 (18.4%) and 6 (11.5%) patients in Group 1, 2, 3 and 4, respectively, after vaccination.

Conclusion: Temporary discontinuation of MTX improves the immunogenicity of seasonal influenza vaccination

in RA patients. Further studies are needed to determine the duration of MTX discontinuation. **Trial registration:** [www.clinicaltrials.gov, protocol number NCT02748785]

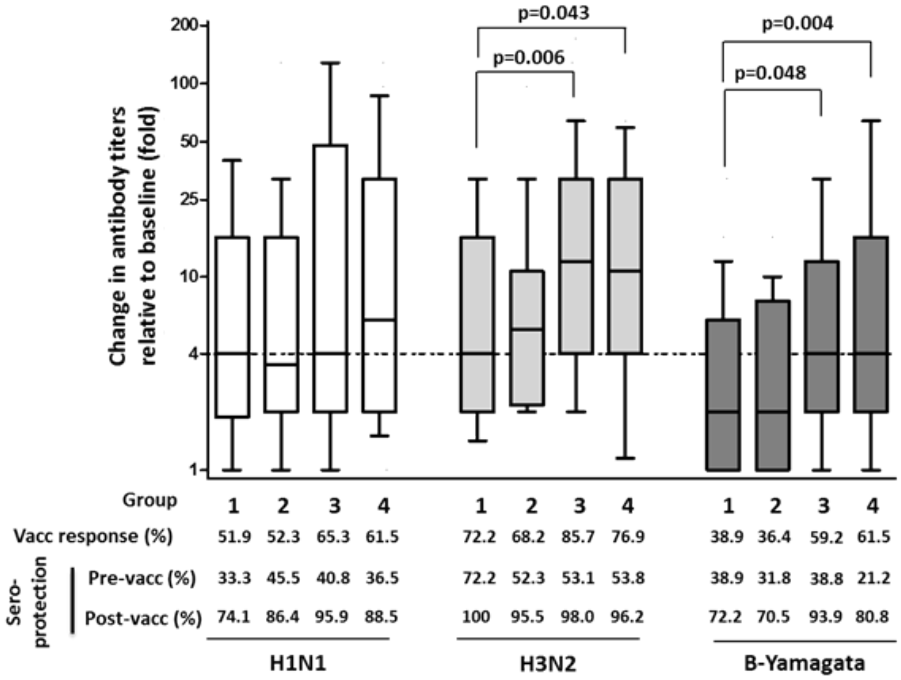

Figure. Fold change in antibody titers relative to baseline and proportion of satisfactory vaccine response. Box represents the interquartile range, the median is represented by the horizontal line. Whiskers represent 10 and 90th percentiles. Horizontal line marks 4 fold increase in antibody titers. Mann-Whitney test used to compare treatment groups. Vacc, vaccination.

Session Title: Rheumatoid Arthritis – Clinical Aspects III: Prevention of Comorbidity

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Individuals with rheumatoid arthritis (RA) have two-fold higher risk of sudden death than age- and sex-matched controls without RA. We hypothesized that myocardial abnormalities are associated with corrected QT (QTc) interval in RA. This study aimed to prospectively investigate the association of myocardial abnormalities assessed using cardiac magnetic resonance imaging (CMR) with QTc interval in patients with RA without cardiac symptoms.

Methods: Consecutive patients with RA and control subjects without cardiac symptoms were enrolled. Patients with RA and control subjects with no history and/or clinical findings of systemic hypertension, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, and dyslipidemia underwent CMR. Patients with RA were administered non-biologic disease-modifying antirheumatic drugs (nbDMARDs) or biologic DMARDs (bDMARDs). Images were assessed for myocardial late gadolinium enhancement (LGE: an indicator of myocardial fibrosis or myocarditis) and T2-weighted imaging (T2WI: indicator of active inflammation). The 440-ms QTc interval was considered prolonged in this study. We investigated the association of MR-assessed myocardial abnormalities with QTc interval.

Results: We enrolled 70 patients (mean age, 55.2±6.7 years; 88% female). nbDMARDs (26, methotrexate [MTX, 9.7±2.1 mg]; 7, other drugs) and bDMARDs (15, infliximab; 15, tocilizumab; 7, abatacept plus MTX [9.8±1.4 mg]) were administered to 33 and 37 patients with RA, respectively. Myocardial and T2WI abnormalities were seen in 27 (38%) and 7 (10%) patients with RA, respectively. A total of 20 (28%) patients with RA were LGE positive, wherein 7 showed T2WI abnormalities. Simplified disease activity index scores in the LGE-positive group were significantly higher than that in the LGE-negative group (p=0.011). All patients with RA showed normal QTc interval (412.0±20.5 ms). However, the QTc interval in the LGE-positive group was significant higher than that in the LGE-negative group (431.1±20.1 vs 408.2±10.5 ms; p=0.001). Myocardial abnormalities were associated with QTc interval (ρ=0.356, p=0.014). The QTc interval in the bDMARDs group was significantly lower than that in the nbDMARDs group (p=0.001). Other RA characteristics such as disease duration, autoantibody status, and cardiovascular risk factors were not associated with myocardial abnormalities and QTc interval. Receiver operating characteristic analysis showed that the QTc interval reliably detected myocardial abnormalities (area under the curve 0.898; 95% confidence interval, 0.830–0.900). Considering patients with RA and normal QTc interval and using 420-ms cut-off value, the sensitivity and specificity for detecting myocardial abnormalities were 91% and 70%, respectively.

Conclusion: Myocardial abnormalities may contribute to the QTc interval. We should consider the possibility of subclinical cardiac involvements in RA cases even in those with normal QTc interval.

Choroid Plexus Infiltrates in Lupus Model (MRL/lpr) Mice Represent Tertiary Lymphoid Structures, Shedding Light on the Immunological Mechanisms of Neuropsychiatric Lupus

Ariel Stock[1], Sivan Gelb[2], Ayal Ben-Zvi[2] and Chaim Putterman[3], [1]Microbiology and Immunology, Albert Einstein College of Medicine, Bronx, NY, [2]Hebrew University, Jerusalem, Israel, [3]Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: MRL/lpr mice develop an overt neuropsychiatric phenotype including depression and cognitive dysfunction, similar to diffuse neuropsychiatric manifestations of human lupus. Additionally, MRL/lpr mice display a robust infiltration of predominately lymphocytes through the choroid plexus (CP) of the central nervous system. Radiological studies and evaluation of pathological tissue has provided evidence to suggest CP involvement in human lupus as well. There has been, however, little evaluation of the functional features of these infiltrating cells, or their potential contribution to neuropsychiatric disease. Localized tertiary lymphoid structures have been described in various neoplastic and autoimmune models, including the kidneys and peritoneum of spontaneous and inducible lupus models. Given the immunoprivileged nature of the central nervous system and recent studies describing the critical role of the CP in immune surveillance, we evaluated 3D reconstructions of cellular infiltrates, and now hypothesize that the CP infiltrates in MRL/lpr mice consist of tertiary lymphoid structures (including ectopic germinal centers), induced in response to local inflammatory signals.

Methods: We evaluated MRL/lpr and control MRL/+ mice at several time points, beginning at 5 weeks of age. Expression of lymphotoxin-β and CXCL13 were evaluated by RT-qPCR at 8, 12 and 16 weeks of age. Brain tissue was immunofluorescently stained at 5, 8, 12 and 16 weeks of age to determine the phenotypical characteristics of infiltrating cells, as well as the kinetics of their infiltration. High resolution three dimensional reconstructions were generated by confocal microscopy, and both scanning and transmission electron microscopy were used to study regional compartmentalization and local intercellular interactions of infiltrating cells.

Results: We found dramatically increased lymphotoxin-β and CXCL13, key molecules in lymphoid follicle organization, in the CP of MRL/lpr mice. Lymphotoxin-β and CXCL13 were upregulated by 8 weeks of age, well before any significant cellular infiltration was present. Upon detailed examination, we found organizational and phenotypic features of lymphoid follicles, including structural reticular fibers and type I collagen cords, as well as clusters of proliferating (PCNA+) T and B cells, organized according to local chemokine gradients. Furthermore, we identified phenotypically distinct groups of B-Cells (e.g. IgM^+, $GL7^+$, $BCL6^+$) and T-Cells (e.g. $FoxP3^+$, $BCL6^+$, GL7+), as well as follicular dendritic cells. Finally, we found aggregates of $CD138^+$plasma cells, in localized regions sharply demarcated from naïve B-cells.

Conclusion: Based on the structural, organizational and phenotypical characteristics of the MRL/lpr CP

infiltrate, we conclude that the CP of MRL/lpr mice contain tertiary lymphoid structures with germinal center activity, the pathogenicity of which, including production of neuropathic autoantibodies, remains to be determined.

Session Date: Monday, November 14, 2016

Session Title: Systemic Lupus Erythematosus – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by the formation of autoantibodies, immune complex deposition, elevated production of type I interferons (IFNs), and inflammatory-mediated multi-organ damage. Lupus nephritis (LN) flares contribute to high mortality and morbidity among patients. Activation of endosomal toll-like receptor (TLR) 7 is an important trigger of LN activity. Stimulation of TLR7 leads to type I interferon (IFN) production and nuclear factor kappaB (NFkB) activation. Type I IFNs are important for TLR7-mediated immunoproliferation, but their role in TLR7-mediated nephritis has not been examined. This study explores the novel hypothesis that TLR7 promotion of lupus nephritis is independent of type I IFNs.

Methods: To address this hypothesis, we use the lupus prone NZM 2328 and iNZM (NZM2328 lacking a functional type I IFN receptor) murine models. In order to induce LN flares, we administered 100µg of R848 (TLR 7 agonist) epicutaneously to the right ear or intraperitoneally (IP) to 10-week old female NZM2328 and iNZM mice thrice weekly. Serum was collected from mice every 2 weeks and urine collected every week. Mice were harvested at 14 days or at LN onset. Double stranded DNA antibodies were quantified via ELISA. Immunofluorescence for C3 and IgG was performed on kidney tissue to examine the extent of immune complex deposition. Flow cytometry was used to characterize the immune cell populations in the kidney for both strains. Real-time qPCR was performed to examine gene expression in the kidney following R848 treatment.

Results: Lymphoproliferative response to R848 was absent in iNZM mice, consistent with previous reports. Notably, both NZM2328 and iNZM mice exhibit a decline in survival after 3 to 4 weeks of R848 treatment. This

decline was significantly more robust with epicutaneous vs. IP injection of R848. Both NZM and iNZM mice demonstrated equivalent acceleration of lupus characteristics including: rise in dsDNA antibodies, increased kidney immune complex deposition, and development of proteinuria. They also demonstrated infiltration of the kidney by macrophages and dendritic cells 2 weeks into treatment. Transcriptional changes within the kidney identified upregulation of inflammasome-associated genes as a shared response in both NZM2328 and iNZM mice after R848 treatment.

Conclusion: The development of TLR7-mediated lupus nephritis flares occurs independent of type I IFN signaling. Further investigation into the role of the inflammasome in mediating TLR7-driven lupus is key to development of novel therapies which may prevent lupus nephritis flare induction.

Ectonucleotidase-Mediated Protection of Lupus Mice from Exaggerated Immune Responses and Arterial Vasculopathy

Session Title: Systemic Lupus Erythematosus – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: CD39 and CD73 are so-called ectonucleotidases, surface enzymes expressed by leukocytes and endothelial cells that jut into the extracellular space. There, they mediate the step-wise conversion of the autocrine and paracrine danger signal ATP into anti-inflammatory adenosine. Given the established role of a cell's "purinergic halo" in maintenance of immune and vascular homeostasis, we hypothesized that ectonucleotidases might play a protective role in lupus.

Methods: Lupus can be modeled by intraperitoneal administration of pristane to mice. Cardinal features of lupus develop over 6-9 months, including anti-ribonucleoprotein (RNP) antibody production and immune-complex nephritis. In this study, we administered either pristane or saline to three groups of female C57BL/6 mice: wild-type (WT), $CD39^{-/-}$, and $CD73^{-/-}$. After 36 weeks, we characterized serum autoantibodies, splenocyte activation/polarization, neutrophil responses, proteinuria, and endothelial function.

Results: As both CD39 and CD73 have well-recognized roles in regulatory T cell function, we first assessed adaptive immune responses. In the T-cell compartment, deficiency of either ectonucleotidase led to a 3-fold expansion of autoimmune-promoting T_H17 (but not T_H1) cells. $CD39^{-/-}$ mice developed marked spenomegaly in

response to pristane. Activated B cells and plasma cells were expanded in CD73$^{-/-}$ mice. Regarding serum autoantibodies, the CD73$^{-/-}$ mice in particular showed exaggerated anti-RNP production in response to pristane (a 10-fold increase) as compared to WT. As purinergic signaling may also regulate innate immune cells, we assessed an effector function of emerging importance in lupus, neutrophil extracellular trap (NET) release. NETs are pro-inflammatory webs of chromatin extruded from neutrophils. CD73 deficiency resulted in relative neutrophilia in response to pristane, while deficiency of either ectonucleotidase led to exaggerated NET release (a 2-fold increase) as compared to WT. Further, CD73$^{-/-}$ mice demonstrated heightened levels of plasma cell-free DNA, a surrogate for circulating NETs. Both nephritis and accelerated arterial disease are major causes of morbidity in lupus. Urine protein was elevated in both pristane-treated CD39$^{-/-}$ and CD73$^{-/-}$ mice as compared to pristane-treated WT. The administration of pristane to WT mice triggered only subtle dysfunction of the arterial endothelium. In contrast, both CD39$^{-/-}$ and CD73$^{-/-}$ mice demonstrated striking dysfunction in response to pristane. This endothelial dysfunction could be rescued by treatment with superoxide dismutase, suggesting a role for oxidative stress in driving the vasculopathy.

Conclusion: These data are the first to link ectonucleotidases with lupus autoimmunity and vascular disease. In particular, they newly implicate purinergic signaling in the regulation of lupus T-cell responses and NET release, and demonstrate that ectonucleotidases protect against endothelial dysfunction in lupus by suppressing oxidative stress. New therapeutic strategies may harness purinergic signaling to limit the damage inflicted by lupus upon organs and blood vessels.

Serine/Arginine-Rich Splicing Factor 1 (SRSF1) Is a Novel Factor in T Cell Homeostasis and Its Selective Loss in T Cells Causes Autoimmunity and Lupus-like Nephritis

Vaishali R. Moulton[1], Hao Li[2], Michael W. Mosho[2], Andrew R. Gillooly[2], Meghan L. Keane[3] and George C. Session Title: Systemic Lupus Erythematosus – Animal Models
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: T cells from patients with systemic lupus erythematosus (SLE) express reduced amounts of the critical CD3 zeta signaling chain, and produce low levels of the vital cytokine interleukin (IL)-2. We used

a discovery approach namely mass spectrometry analysis of proteins “pulled-down” by a CD3 zeta mRNA-defined oligonucleotide, and identified the splicing regulator serine arginine-rich splicing factor 1 (SRSF1). We showed that SRSF1 promotes generation of a full-length CD3 zeta transcript over a short spliced unstable isoform to promote normal expression of CD3 zeta chain in human T cells. We found that SRSF1 expression levels are decreased in SLE T cells, more so in patients with worse disease. We further showed that force expression of SRSF1 into SLE T cells rescues IL-2 production. While these findings suggest that SRSF1 deficiency is important in SLE T cell dysfunction, it remains unknown whether SRSF1 contributes to immune-mediated disease. To this end, in this study, we generated mice with a T cell-restricted deletion of SRSF1 to evaluate the mechanistic role of SRSF1 in T cell dysfunction and the development of immune-mediated disease *in vivo*.

Methods: *Srsf1* “floxed” mice were crossed with *Lck.Cre* (*distal promoter)* transgenic mice to delete SRSF1 specifically in mature T cells and generate the T cell *Srsf1* conditional knockout (*Srsf1*-cko) mice. Mice were euthanized at 10-16 weeks of age, or aged to >1 year. Central (thymus) and peripheral (spleen, lymph nodes) lymphoid organs were analyzed for immune cell phenotype and function by flow cytometry, enzyme-linked immunosorbent assay (ELISA) and intracellular staining. Serum and urine were collected at monthly intervals to assess autoantibody levels and proteinuria respectively. Non-lymphoid (lung, liver, kidney) tissues were fixed, sectioned and stained with hematoxylin and eosin to evaluate histopathology.

Results: *Srsf1*-cko mice develop peripheral T cell lymphopenia, with a striking reduction in the CD8 compartment. T cells exhibit an activated phenotype and produce increased amounts of IFN-γ and IL-17 but lower amounts of IL-2 upon e*x vivo* stimulation. The *Srsf1*-cko mice develop increased levels of autoantibodies, and exhibit increased proteinuria compared to control mice. Kidney histopathology shows evidence of glomerular damage with glomerular hyperproliferation, glomerular capillary hyperplasia, and interstitial infiltration of mononuclear cells. These results indicate that lack of SRSF1 leads to an aberrant T cell homeostasis, aberrant T cell activation, with increased inflammatory cytokine production, autoantibody development and kidney damage.

Conclusion: SRSF1 is a novel regulator of T cell homeostasis and function, and its deficiency leads to autoimmunity and lupus-like nephritis. Therefore, deficiency of SRSF1 in T cells may represent a molecular defect that contributes to the pathogenesis of systemic autoimmune disease.

Session Date: Monday, November 14, 2016
Session Title: Systemic Lupus Erythematosus – Animal Models
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The Bcl-2 family guards the mitochondrial apoptotic pathway. Among numerous Bcl-2 antagonists, only the loss of Bim in mice leads to the development of SLE-like disease, suggesting Bim's unique status that exerts dominance in several pathways that are vital for the development of SLE. However, the role that Bim plays in macrophage functions and relevance to SLE is unknown.

Methods: We generated mice lacking Bim specifically in macrophages ($Cre^{LysM}Bim^{fl/fl}$) and assessed mice at 8 months of age for characterization of SLE-like disease. Macrophage turnover/proliferation and activation were examined *in vivo* using flow cytometric analyses. To better understand the role of Bim in regulating transcriptional profile in kidney macrophages, RNA-seq analysis was performed on sorted macrophages from $Cre^{LysM}Bim^{fl/fl}$ and $Bim^{fl/fl}$ mice.

Results: $Cre^{LysM}Bim^{fl/fl}$ mice displayed splenomegaly, lymphadenopathy, hyperglobulinemia, IC deposition in the kidney, proteinuria, GN, and early mortality as compared to $Bim^{fl/fl}$ and mice lacking Bim in either lymphocyte compartments. $Cre^{LysM}Bim^{fl/fl}$ mice were lack of splenic marginal zone macrophages (MZMs) and marginal zone B cells (MZ-B cells), which is also evident in lupus patients. Bim functions in macrophages are independent of its role in apoptosis as there were no differences in the rate of EdU incorporation in macrophages from $Bim^{fl/fl}$ and $Cre^{LysM}Bim^{fl/fl}$ mice. TLRs, the well-known initiators of autoimmune disease, are not required for the break in tolerance, as mice lacking MyD88 or TRIF in $Cre^{LysM}Bim^{fl/fl}$ mice ($MyD88^{fl/fl}$ $Cre^{LysM}Bim^{fl/fl}$ and $TRIF^{-/-}$ $Cre^{LysM}Bim^{fl/fl}$) developed systemic autoimmunity similar to $Cre^{LysM}Bim^{fl/fl}$ mice. However, $TRIF^{-/-}Cre^{LysM}Bim^{fl/fl}$ mice did not develop end-stage GN. Consistent with these data, $Cre^{LysM}Bim^{fl/fl}$ mice showed increased numbers of kidney macrophages, while $TRIF^{-/-}$ $Cre^{LysM}Bim^{fl/fl}$ mice exhibited significantly reduced numbers as identified by multi-parameter flow cytometry. To better understand the effect of Bim deletion in kidney macrophages *in vivo*, we utilized RNA-seq for FACSorted kidney macrophages from young and old mice. Exploratory analysis via principal component analysis (PCA) revealed that Bim deletion affected the transcriptional profile of kidney macrophages. We were able to identify unique cellular processes up-regulated in $Cre^{LysM}Bim^{fl/fl}$ kidney macrophages using pairwise GO processes analyses. We also identified that kidney macrophages from $Cre^{LysM}Bim^{fl/fl}$ mice significantly up-regulate *ifnar1*, the receptor for IFNα and IFNβ.

Conclusion: The expression of Bim in macrophages is sufficient to inhibit SLE-like pathogenesis. Bim controls macrophage functions independent of its role in apoptosis which challenges the conventional dogma that Bim's role in autoimmunity is to prevent the escape of autoreactive lymphocytes from apoptosis. We provide data to identify the role of kidney macrophages throughout SLE-like disease development in the context of Bim deficiency. The discovery of Bim-regulated transcriptome in kidney macrophages are crucial for translational studies leading to the development of new targets for SLE.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Systemic Lupus Erythematosus – Animal Models
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: , In areas where helminths infections are common, autoimmune diseases are rare. Treatment with helminthes and their ova, improved clinical findings of inflammatory bowel disease, multiple sclerosis and rheumatoid-arthritis. The immunomodulatory functions of some helminths were attributed to the phosphorylcholine (PC) moiety. We aimed to decipher the tolerogenic potential of Tuftsin-PC (TPC) compound in mice genetically prone to develop lupus when the disease was already established. In addition we analyzed the microbiota, assuming that it may be affected by TPC treatment on lupus development.

Methods: , Lupus prone NZBXW/F1 mice received subcutaneously TPC (5 mg/1 ml), 3 times a week starting at 24 weeks of age, when proteinuria showed 10 mg/dl. At this point feces were collected weekly. Autoantibodies were tested by ELISA, cytokines secretion by splenocytes in-vitro using DuoSet ELISA, T-regulatory-cells by FACS. Glomerulonephritis was addressed by detection of proteinuria, and immunoglobulin complex deposition in the mesangium of the kidneys of the mice by immunofluorescence. Stools from the mice were collected every 3 days for microbiome analyses. DNA was extracted from the stools and then sequenced using Illumina Miseq platform. Data analysis was performed using QIIME.

Results: Our results show that TPC treatment attenuated the development of glomerulonephritis in lupus prone mice, manifested by reduced proteinuria and immunoglobulin deposition in the kidney mesangium. TPC also increased the expression of IL-10 ($p < 0.001$), and inhibited the production of IFNg , IL-1b and IL-17 ($p < 0.03$). TPC significantly expanded $CD4^+CD25^+FOXP3^+$ T-regulatory cells (Tregs) phenotype in the treated mice. The microbiota analyses showed that TPC exhibited a marked depletion of *Akkermansia* (specifically muciniphila species) and higher abundance of *Odoribacter* compared to PBS treated mice, which correlated to proteinuria

levels. Generally, high protein secretions correlated with an increased abundance of four bacteria genera; *Akkermansia* AF12, S24-7, *Bacteroides*, and one bacteria order *Clostridiales*. High protein levels were correlated also with decreased levels of thirty three additional otus, with the *Odoribacter* genus among them.

Conclusion: Our data indicate that TPC treatment inhibits lupus nephritis development in genetically lupus prone mice, attenuates pro-inflammatory cytokines and enhance anti-inflammatory IL-10 expression, as well as Tregs expansion. The results propose harnessing novel natural therapy for lupus patients. In addition our results show that TPC significantly alters the microbiota composition which correlated with decreased protein levels in the urine.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: RGC (Response Gene to Complement)-32 is a cell cycle regulator widely expressed in normal tissues including brain, kidney, spleen, thymus, multiple tumors and in a variety of cell lines. RGC-32 is localized in the cytoplasm and translocates to the nucleus upon upregulation by complement activation, growth factors and cytokines. Depending on the cell type, physiological or pathological conditions, RGC-32 can stimulate cell growth through increased p34CDC2 kinase activity and Akt phosphorylation or suppress it via arrest in mitotic progression. Previous studies by our group have shown that RGC-32 is critical for murine Th17 cell differentiation in vitro and in vivo. Initially identified in rat oligodendrocytes in response to sublytic C5b-9 complex, RGC-32 is induced by TGFβ in fibroblasts and human proximal tubular epithelial cells (PTEC) and mediates TGFβ dependent profibrotic pathways that contribute to renal fibrosis. RGC-32 expression has been

described in tubules of normal human kidneys and its upregulation was reported in tubules from patients with IgA nephropathy. The expression patterns and function of RGC-32 in lupus nephritis (LN) have not yet been investigated.

Methods: In situ expression and localization of RGC-32 was assessed by immunohistochemistry in kidney biopsies from 25 lupus patients with proliferative lupus nephritis and 11 patients with other nephropathies (IgA nephropathy, minimal change disease, ANCA-associated glomerulonephritis, nephrosclerosis, acute tubular necrosis). In vitro, the expression of RGC-32 in human PTEC cells was assessed by Flow cytometry, Western blot and RT-PCR in the presence or absence of cytokines with known nephritogenic potential such as IL-1, TNFα, IFNγ and TGFβ.

Results: Consistent with the staining distribution reported in normal kidneys, RGC-32 immunostaining was predominant in proximal and distal tubules and was detected in a focal or diffuse pattern. Tubular mean staining intensity was significantly higher in SLE than in non-SLE specimens (2.0±0.23 vs 1.30±0.49; p=0.04) and was noted both in areas of normal appearing as well as damaged tubules. RGC-32 expression was also detected in glomeruli and in inflammatory cells in the interstitium of LN biopsies and colocalized with CD4+ T cells and CD68+ macrophages, respectively. Staining intensity was significantly higher in glomeruli and interstitium of LN specimens compared to disease controls (2.4±1.4 vs.1.6±0.8 and 1.8± 0.9 vs. 0.96±0.4 respectively) and correlated with the activity (r=0.4), chronicity (r=0.5) and interstitial fibrosis scores (r=0.5). In vitro, RGC- 32 mRNA and protein expression was upregulated in PTEC by nephritogenic cytokines including IL-1 (7.8 fold), TNFα (5 fold), TGFβ (3.1 fold) and to a lesser extent by IFNγ (2.1 fold).

Conclusion: RGC-32 expression is increased in glomeruli and tubulointerstitium from patients with lupus nephritis. Upregulation of RGC-32 is mediated by proinflammatory cytokines and may play pathogenetic role in organ damage in SLE by promoting manifestations of progressive renal disease such as interstitial fibrosis.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: High dose corticosteroids such as cyclophosphamide are commonly used to treat lupus nephritis (LN). Although effective in preventing end stage renal disease (ESRD) in most cases, significant long-term side effects such as infections, increased risk of malignancy, and infertility are common and are related to the duration of therapy or the cumulative dose of medications. These side effects could be mitigated via a personalized medicine approach, if an individual's response to treatment could be predicted. However there are currently no markers that can reliably determine response or refractoriness to treatment at an individual level. MicroRNAs (miRNAs), a class of small, non-coding RNAs responsible for post-transcriptional regulation, have been shown to have altered expression levels in a variety of diseases suggesting their potential use as diagnostic, prognostic, and treatment response biomarkers. We propose miRNAs can be appropriate predictive markers for response to cyclophosphamide treatment.

Methods: <span">RNA was isolated and analyzed via TaqMan® Array MicroRNA 384-well Cards, from formalin-fixed paraffin embedded (FFPE) renal biopsies of two unique cohorts of patients with LN who were subsequently treated with cyclophosphamide and had at least 2 years of follow up history. Patients who responded to cyclophosphamide based on urinalysis criteria of no active urinary sediments, no RBCs and/or WBCs in urine, and proteinuria less than 1 gram were classified as responders while those that did not fit the criteria were classified as non-responders. The first cohort was composed of 32 patients with 17 responders and 15 non-responders, while the second cohort (the validation cohort) contained 39 patients with 22 responders and 17 non-responders. Significantly differentially expressed miRNAs, determined via $2^{-\Delta\Delta Ct}$method, from the first cohort were validated by the second cohort. Potential target mRNAs for candidate miRNAs were determined through miRDB, TarBase, RNA22, and Ingenuity Pathway Analysis (IPA) databases. Predicted targets were further analyzed for disease activity and nephrotoxicity through IPA.

Results: Six significantly up-regulated miRNAs, hsa-miR-30c-2-3p, hsa-miR-29b-1-5p, hsa-miR-195-3p, hsa-miR-424-3p, hsa-miR-1260a, and hsa-miR-1248 were found in responders. Analysis of miRNA targets generated by four prediction algorithms revealed immunological disease specificity and renal involvement.

Conclusion: These miRNAs may act as prognostic markers of renal outcomes and treatment response, which can establish a more personalized treatment of lupus nephritis in the future. As our next step we will attempt further validation of these miRNAs in serum and urine of patients with lupus nephritis.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Kidney biopsy remains the gold standard for diagnosis and staging of Lupus Nephritis (LN). Although kidney biopsies are commonly performed in the clinical setting, they carry morbidity. Identification of reliable biomarkers in the blood that correlate with pathological changes in the kidney of LN patients may allow LN diagnosis and staging with only a minimally-invasive drawing of blood.. To that end, we performed a comparative transcriptomic and proteomic biomarker analysis of blood samples and kidney biopsies from LN patients compared to samples from healthy controls and non-lupus kidney disorders. We evaluated whether a molecular signature could identify LN patients versus the comparator disease states and if that signature was similar between the kidney and blood.

Methods: Paired-end strand specific RNASeq was used for gene expression profiling of blood and kidney biopsies from healthy subjects (n=12 and 5 respectively), Lupus Nephritis (10,7) and other kidney diseases such as Diabetic Nephropathy (DN) (10,5), Hypertension (HT) (11,4), Minimal Change (MC) (6,3), and Membranous (MB) (4,4) collected under informed consent. For each sample, approximately 100 million reads were sequenced for a total of ~50 million fragments. Serum collected from these subjects was profiled for autoantibody specificities using ProtoArray®.

Results: RNA-Seq analysis from blood samples revealed a signature enriched in IFN-inducible transcripts unique in the LN patients when compared to the blood transcriptomes from healthy controls or patients with DN, HT, MC, or MB. Remarkably, signatures of "kidney damage" pathways were also identifiable in the blood of LN subjects. Increased expression of the "Complement System" pathway was observed in blood across 3 of the 5 diseases tested (LN,DN,HT). RNASeq analysis of kidney biopsies showed a more homogeneous landscape across the different diseases, with a core of 50 common genes related to kidney injury pathways. Most of the LN kidney biopsy samples exhibited an upregulation of IFN signature genes, that also correlated with blood IFN signatures in the same patients. Broad autoantibody analysis of serum samples indicated that LN patients exhibited vast upregulation of autoantibodies versus healthy controls, in stark contrast to the other kidney diseases examined where autoantibodies were found to be down-modulated (DN, MC, MB).

Conclusion: In this study, we performed blood and kidney transcriptomics and broad serum autoantibody profiling comparing LN patients to patients with other kidney diseases. Pathway analysis of differentially expressed transcripts indicated a unique profile in the blood and kidney biopsies of LN patients in comparison with other kidney diseases. We were able to identify an interferon signature in both the blood and kidney biopsies from LN patients, which correlated between the two tissues. We also identified a kidney damage signature in the blood of LN patients. Further validation studies are needed to determine the utility of using whole blood biomarker testing analysis to replace conventional kidney biopsies in subjects with LN.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease characterized by heterogeneity of presentation, an undulating course, and elevated risk for premature cardiovascular disease. Platelets have been understudied as a relevant contributor. Yet, these cells, which contain transcripts and the necessary molecular machinery to conduct translation, are intercellular regulators of inflammation and immune activation and play a key role in atherothrombosis. Platelets express low affinity type 2 receptors (FcγRIIA) whose ligand is the Fc portion of IgG. A single amino acid substitution, H131R, in the extracellular ligand binding domain increases the affinity for IgG and may account for individual variation in platelet activation, specifically an increase of function. Accordingly, this study addressed the hypothesis that FcγRIIA genotype associates with preclinical atherosclerosis and platelet hyperreactivity.

Methods: Genotyping at rs1801274 (allelic discrimination, HWE P=NS) was performed in 71 SLE patients and 30 healthy controls. In 49 of the SLE patients and 30 healthy controls, carotid ultrasound for plaque (≥50% increase over background IMT in any arterial segment); levels of soluble E-selectin as a proxy of endothelial cell activation; and C3, C4 to reflect complement activation were assessed. In 22 SLE patients, monocyte-platelet (MPA) and leukocyte-platelet aggregates (LPA), and light transmission aggregometry (LTA) in response to submaximal concentrations of collagen and arachidonic acid were evaluated.

Results: Overall genotyping for FcγRIIA revealed 43 SLE patients carrying at least one copy of the variant allele and 28 patients who were homozygous for the ancestral allele. For the 49 with IMT, carotid plaque was reported in 22. A significant enrichment of carotid plaque was identified in patients with a variant compared to those who were homozygous ancestral (58% vs 25%, p=0.039). In contrast, among 30 healthy controls, the presence of carotid plaque was not associated with the variant or ancestral genotype (15% vs 15%). Soluble E-selectin (mean + 2SD, shown as dichotomous being above normal controls) was significantly increased in those

patients with the variant vs ancestral (64% vs 23%, p=0.013). Complement levels, a proxy of circulating immune complexes, were lower in patients with the variant vs ancestral (64% vs 40%). With regard to platelet reactivity, among 22 SLE subjects evaluated, there was a significant increase in MPA and LPA (above controls, mean + 2SD) in those carrying at least one variant compared to the ancestral group (86% vs 37%, p=0.02 and 46% vs 12%, p=0.05, respectively). Platelet aggregation was more robust for those patients with the variant vs ancestral in response to 160 uM arachidonic acid and 1 ug/mL collagen (47% vs 19% and 47% vs 14%, respectively).

Conclusion: These data suggest a model in which an FcγRIIA polymorphism associates with preclinical atherosclerosis and confers increased platelet activity in the setting of SLE, a disease characterized by circulating immune complexes.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The role of anti-dsDNA in the pathogenesis of the systemic lupus erythematosus (SLE) has been clearly established. However, the influence of these autoantibodies in the atherothrombotic status of SLE patients has not yet been evaluated. Aim: 1. To analyse in vivo the involvement of anti-dsDNA antibodies in the development of CVD in SLE patients. 2. To evaluate in vitro the mechanisms underlying the effects of anti-dsDNA antibodies in these processes.

Methods: The study was conducted in 50 SLE patients and 38 healthy donors. Endothelial function was assessed by measuring the post-occlusive hyperaemia using Laser-Doppler. Various markers of oxidative stress,

inflammatory cytokines, prothrombotic mediators and NETosis, were quantified in purified leukocytes and plasma from SLE patients and controls. Activation of intracellular pathways was analyzed in monocytes using pathscan intracellular signaling array. In vitro, purified neutrophils, monocytes and lymphocytes from healthy donors and endothelial cells (HUVEC) were treated separately and in a trans-well co-culture system with anti-dsDNA antibodies isolated from the serum of SLE patients. Then, markers of inflammation, thrombosis, oxidative stress and NETosis were evaluated by flow cytometry (protein) and RT-PCR (mRNA).

Results: SLE patients showed impaired micro-vascular endothelial function (reduction of hyperaemia post occlusion area) and altered expression levels of pro-inflammatory proteins (IL6, IL8, MCP-1 and PCR), prothrombotic molecules (TF), oxidative stress markers (peroxides and mitochondrial membrane potential) and netosis-related molecules (elastase, myeloperoxidase and free-DNA). Monocytes from anti-dsDNA-positive SLE patients showed activation of various intracellular pathways (ErK, STAT-3, p38, JNK and GSK). Association studies demonstrated that molecules related to inflammation and thrombosis, endothelial dysfunction, oxidative status and netosis were linked to the occurrence of thrombotic events, as well as to the presence of anti-dsDNA antibodies. In vitro treatment of purified leukocytes with anti-dsDNA antibodies promoted an increase in the production of NETosis, levels of peroxides and percentage of cells with altered mitochondrial membrane potential, as well as enlarged expression of a number of proinflammatory and prothrombotic molecules. In vitro treatment of HUVEC with anti-dsDNA antibodies promoted an increase in endothelial activation molecules (ICAM-1, VCAM-1 and E-selectin). All those effects on leukocyte subtypes and endothelial cells were even more pronounced when they were cocultured.

Conclusion: 1. Positivity for anti-dsDNA antibodies is linked to an increased pro-atherothrombotic status in SLE patients. 2. Anti-dsDNA antibodies, in vitro, promote NETosis, modulate the expression of molecules related to inflammation and thrombosis, and induce endothelial activation. Together, that data suggest the involvement of such autoantibodies on atherothrombosis development in SLE. Acknowledgements: Supported by CTS-7940, PI15/01333 Disclosure of Interest: None declared

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The premise of this study is that the impact of renal injury in lupus nephritis is widespread with consequences to resident cells in other tissue beds, such as non-sun exposed non-lesional skin. Reflection of a relevant pathway in renal tissue by a more readily accessible compartment would be an advance. Single-cell transcriptional states may provide a framework for understanding how in vivo biological function emerges from complex cell ensembles.

Methods: As an approved nested study within the SLE Accelerated Medicines Partnership (AMP), single cell RNAseq was performed on cell suspensions prepared from ~2 mm punch biopsies of non-lesional non-sun exposed skin from the buttocks of 3 SLE patients with proteinuria and known ISN/RPS Class and 3 healthy controls. Libraries were prepared on the Fluidigm C1 platform followed by sequencing on an Illumina HiSeq 2500. Differential expression was used to assign in vivo cell-type compositions through unsupervised sampling and modeling of transcriptional states in single cells. We generated 36 single-cell data sets with on average 852 genes/cell and 37% of reads mapping to the reference genome. Data are expressed as log2 transcripts per million.

Results: Based on expression of COL1A1, COL1A2, COL3A1, MFAP5 and MFAP4, assignments yielded 12 fibroblasts from 3 patients. From the one Class II subject there were 5 single cell transcriptomes. The other 2 subjects (1 Class IV,V; 1 Class III,V) yielded 7 single cell transcriptomes. From the 3 controls, there were 22 transcriptomes. In the aggregate data for controls, the top one thousand genes were used for a cluster analysis of categories in the DAVID annotation. In the controls, a prominent cluster with an enrichment score of 5.60, in the extracellular matrix category, was significantly represented in the set (P=3.77E-12). The DAVID annotation of skin transcriptomes from subjects with proliferative nephritis resembled the healthy controls; however, closer scrutiny showed differences as highlighted in Table 1 which focuses on the expression of an annotated gene set of transcripts in the extracellular matrix category (11 are shown) comparing case vs control. In dermal fibroblasts from subjects with proliferative disease the expression of anti-fibrotic genes was increased while pro-fibrotic genes were attenuated. This result suggests that an event involving localized fibrosis of renal tissue yields at distant sites (such as the skin), a fibroblast transcriptome which exerts a countermeasure to forestall fibrosis. The profile of transcripts of subjects with class II resembled controls.

Conclusion: Single-cell RNAseq is feasible and informative in cell specific transcriptome analysis of fresh non-lesional skin biopsies from SLE patients with a spectrum of active renal disease. The expression of fibroblasts and genes reflective of anti-fibrotic pathways support application of this novel approach to study readily accessible tissue.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and

Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Type 2 innate lymphoid cells (ILC2s) are identified as population of cells with lymphoid morphology lacking re-arranged antigen-specific receptors. Recently, emerging data show that ILC2s might play a key role in the pathogenic process of fibrotic diseases. However, the potential benefit of applying ILC2s as therapeutic target remains to be elucidated. We aimed to profile ILC2s in fibrotic tissues and to evaluate the functional impact of IC2s in the pathogenesis of systemic sclerosis (SSc).

Methods: Human blood samples and skin sections (sixty-nine patients with SSc and 47 healthy controls) as well as skin and lung tissue of various fibrotic mouse models were analyzed by flow cytometry and multi-color immunohistochemistry using several complementary panels of markers each. Kinetics of ILC2 accumulation during the course of fibrosis was studied and ILC2s were further profiled by transcriptome as well as secretome analysis.

Results: Significantly elevated numbers of ILC2s were detected in the skin (10-fold increase) and blood (4-fold increase) of SSc patients by two independent established sets of ILC2 markers compared to healthy controls. In contrast to circulating ILC2s, skin-resident ILC2s express various activation markers and stained positive for skin homing markers. Furthermore, our data suggest that ILC2s might be involved in the pathogenesis of fibrosis in SSc by showing multiple associations of ILC2 counts with fibrotic manifestations in SSc patients. Significantly higher frequencies were observed in diffuse cutaneous (dc)SSc patients compared to limited cutaneous SSc (lcSSc). The modified Rodnan Skin Score (mRSS) positively correlated with ILC2 counts and pulmonary involvement. In parallel, we detected significantly elevated numbers of ILC2s in the fibrotic skin of bleomycin-induced and DNA topoisomerase I-induced mice compared to control mice. Moreover, in the tight-skin (Tsk)-1model of fibrosis resembling less inflammatory stages of SSc significantly increased ILC2 counts were detected compared to control mice. Kinetic analyses revealed an early upregulation of ILC2s in experimental models of fibrosis. In contrast to lineage positive lymphocytes that peak at early inflammatory stages of fibrosis, however disappear over time, ILC2s persist also in later stages of established fibrosis. Profiling of ILC2s in the fibrotic tissue revealed exaggerated production of pro-fibrotic cytokines that in turn activate fibroblasts to produce extracellular matrix proteins.

Conclusion: Here, we provide first evidence for a role of ILC2s in the pathogenesis of SSc by demonstrating increased ILC2 counts in the skin and blood of human SSc patients. These findings were indirectly supported by elevated numbers of ILC2s in the fibrotic skin and lung sections of various mouse models for SSc, reflecting different pathophysiological aspects of the disease. The pro-fibrotic phenotype of ILC2s and their persistant upregulation in early as well as in late stages of fibrosis suggest a central role of ILC2s in the pathogenesis of fibrosis.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Dipeptidyl-peptidase-4 (DPP4) has been recently shown to identify a distinct dermal lineage with intrinsic fibrogenic potential and its targeted inhibition leads to reduced scar formation (1). Fibrotic disease may be considered as a consequence of persistent, exaggerated and uncontrolled tissue repair processes. Systemic sclerosis is the prototype of fibrotic diseases and effective antifibrotic therapies are still lacking. DPP4 inhibitors are already used in treatment of diabetes. The aim of the study was to characterize the DPP4 positive cells, investigate the expression of DPP4 in SSc skin and to evaluate the antifibrotic effect of DPP4 inhibitors in preclinical models of systemic sclerosis.

Methods: Mouse fibroblasts were isolated and DPP4 positive cells properties were assessed after cell sorting. Expression of DPP4 in human and murine skin was analyzed by immunofluorescence. DPP4 inhibitors were tested in two different concentrations administered orally (Sitagliptin 3mg/kg/d and 10mg/kg/d, Vildagliptin 1,5mg/kg/d and 15mg/kg/d) in bleomycin induced skin fibrosis and in sclerodermatous chronic graft-versus-host disease mouse model (cGvHD). The antifibrotic effect on skin was assessed by hydroxyproline assay, alpha smooth muscle cells quantification and measuring the dermal thickness. Inflammatory infiltrate was asses by CD45 immunofluorescence staining.

Results: We have demonstrated that DPP4 positive cells are a unique population of cells implicated in fibrosis. DPP4 positive fibroblasts count is increased not only in experimental fibrosis, but also in skin biopsies from SSc patients as compared to healthy volunteers. Treatment with DPP4 inhibitor reduced dermal thickness in both mouse models ($p<0.05$). The differentiation of resting myofibroblast into fibroblast was also significantly decreased ($p<0.05$) in all treatment groups. Collagen content of the skin diminished by 40% in comparison with NaCl injected mice or syngeneic transplanted mice. Moreover, DDP4 inhibitors reduced the inflammatory infiltrates in two different pathophysiological settings of fibrosis.

Conclusion: DPP4 identifies a subpopulation of fibrosis-promoting fibroblasts that plays a key role in the pathogenesis of fibrosis in SSc. Moreover, inhibitors of DPP4 show a significant antifibrotic effect in several

mouse models of established fibrosis in well tolerated doses. These results may have direct clinical implications as DPP4 inhibitors are already in clinical use for diabetes.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Long noncoding RNAs (lncRNAs) are an emerging class of large noncoding transcripts involved in the regulation of gene expression in health and disease. We have recently identified a novel lncRNA, H19X, which is strictly regulated by TGFβ in a dose and time dependent manner. Here we aim to characterize the expression of H19X in Systemic Sclerosis (SSc) and other fibrotic diseases as well as its function in fibrotic events.

Methods: Skin and lung biopsies from patients with SSc, idiopathic pulmonary fibrosis (IPF), and healthy controls (HC) were obtained from cohorts at four different expert centers. Expression of H19X was analyzed by RNA Sequencing Ilumina HiSeq2000 and quantitative (q)PCR respectively. The function of H19X was investigated in skin fibroblasts transfected with locked nucleic acid oligonucleotides (LNA GapmeRs) by using the following methods: microarray analysis, qPCR, immunofluorescence, sircol, contraction assay, ELISA and

Western blot (WB). In situ hybridization of H19X in SSc dermal fibroblast was performed using Stellaris FISH probes.

Results: H19X expression was consistently upregulated across all the four cohorts (SSc n=34, HC= 26), using different techniques. The upregulation was also consistent across different subsets of patients and between patients with different disease durations. H19X showed a similar expression profile in clinically non-fibrotic and clinically fibrotic skin biopsies indicating a role in early disease development. Moreover, H19X expression was also significantly increased in SSc interstitial lung disease patients versus HC (n=11 each, $p<0.05$). A significant H19X overexpression was also detected in IPF samples suggesting a broader role of H19X in fibrotic diseases (n=11 each, $p<0.05$). Microarray analysis after H19X silencing revealed a strong involvement in extracellular matrix production with collagens being the most downregulated genes. Accordingly, collagen catabolic process, extracellular matrix organization and extracellular matrix disassembly were among the pathways with highest number of enriched genes. Downregulation of collagen Iα1, fibronectin and α-smooth muscle actin (αSMA) after H19X knockdown was confirmed by qPCR (n=5, $p<0.05$). Sircol assay for pan-collagen production, ELISA for pro-collagen Iα1 and WB analysis for fibronectin confirmed the importance of H19X in the regulation of extracellular matrix components. Additionally, silencing of H19X significantly impaired αSMA fiber formation, stress fiber formation as well as cell contractility strongly suggesting an important role of H19X in the development of the myofibroblast phenotype (n=5-6, $p<0.05$). Cell fractionation showed that TGFβ induced expression of H19X is localized mainly into the nucleus. In situ hybridization confirmed H19X localization as mainly nuclear and within a defined spot indicating that H19X could influence gene expression by interacting directly with the chromatin (n=4).

Conclusion: This is the first study reporting a significant upregulation of H19X expression in SSc and across fibrotic organs. By focusing on this novel class of regulatory, noncoding RNAs new perspectives in the pathogenesis of fibrotic diseases are opened.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: We and others have previously reported that pulmonary fibrosis in patients with scleroderma is accompanied by pulmonary accumulation of predominantly CD8+ T lymphocytes. Earlier reports also suggested that NEU1, a sialidase that removes terminal sialic acid from glycoproteins, is associated with and may contribute to both fibrotic changes and immune disturbances in the lungs, but the mechanistic details of such contributions remain unclear.

Methods: Immunohistochemical analyses were used to analyze NEU1 expression in the lung of patients with scleroderma and healthy controls. Cell culture studies were performed in normal adult primary pulmonary fibroblasts (PF). Overexpression of human NEU1 in mouse lungs in vivo and in cultured human lung fibroblasts was performed utilizing a replication-deficient recombinant adenovirus. In PF cell cultures, the effect of NEU1 overexpression on the levels of type I collagen protein were assessed utilizing western blotting. In the in vivo experiments, total and differential bronchoalveolar lavage (BAL) cells counts, flow cytometry of BAL cells, immunohistochemistry of lung tissues, trichrome staining for collagen, and total lung collagen measurements were utilized to characterize NEU1 overexpression-induced changes.

Results: NEU1 was expressed in airway epithelial cells, endothelial cells, and parenchymal cells in all tested lung tissue samples, but the expression was more pronounced in the lungs of scleroderma patients with pulmonary fibrosis. Western blot analyses revealed a strong increase in NEU1 expression in cultured PF from patients with scleroderma compared to healthy controls. NEU1 overexpression in normal fibroblast cultures led to a significant elevation in collagen levels, without increasing TGF-β mRNA or total or active TGF-β protein. Simultaneously, overexpression of NEU1 caused autocatalytic proteolysis of MMP14, a collagen-degrading enzyme, whose desialylation state is known to accelerate self-proteolysis. Intratracheal instillation of a NEU1-encoding but not a control adenovirus in mice in vivo caused accumulation of lymphocytes in BAL and lung tissue, elevation in total pulmonary TGF-β, and increases in pulmonary collagen. The accumulating lymphocytes were predominantly T cells, with CD8+ cells exceeding CD4+ cells by nearly 2 fold.

Conclusion: NEU1 expression is elevated in the lungs of scleroderma patients with pulmonary fibrosis, contributing to collagen protein accumulation by activating autocatalytic proteolysis of the collagen-degrading enzyme MMP14. In vivo, NEU1 gene delivery causes pulmonary fibrosis and lymphocytosis with predominant accumulation of CD8+ T cells, which are also seen in patients with scleroderma lung disease. Together, these data suggest an important pathophysiological role for NEU1 in pulmonary abnormalities observed in patients with scleroderma.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic sclerosis (SSc) is a multisystem connective tissue disease characterized by autoimmunity/inflammation, vasculopathy, and tissue fibrosis. Fli1 is a member of Ets family transcription factor, the deficiency of which is a potential predisposing factor of SSc. Although the detailed mechanism explaining Fli1 downregulation still remains unknown, an epigenetic mechanism is reported at least in dermal fibroblasts, and Fli1 deficiency contributes to the induction of an SSc-like phenotype in those cells. A recent study has demonstrated that activated dermal fibroblasts regulate skin-localized transdifferentiation of regulatory T cells (Tregs) into T helper (Th) 2-like cells through the production of IL-33 in SSc, suggesting that activated dermal fibroblasts induce and/or amplify aberrant immune response characteristic of SSc. Based on these backgrounds, we conducted experiments with *Fli1*$^{+/-}$mice to elucidate the potential role of Fli1 deficiency in dermal fibroblast-dependent modification of Tregs.

Methods: The cytokine expression profile of skin-homing Tregs was assessed by Flow cytometry. Cytokine expression was examined in the skin and cultivated cells by immunostaining and/or quantitative reverse transcription PCR. Fli1 binding to the target gene promoters was assessed by chromatin immunoprecipitation. Co-culture of *Fli1*$^{+/-}$ fibroblasts and wild type Tregs was performed with or without blocking antibodies against target cytokines.

Results: The proportions of Th2- and Th17-like Tregs were increased in the lesional skin of BLM-treated *Fli1*$^{+/-}$ mice. *Fli1*$^{+/-}$ fibroblasts abundantly expressed IL-33 and IL-6, in particular IL-33, and Fli1 occupied the promoters of the *IL33* and *IL6* genes in human dermal fibroblasts. More importantly, the proportions of IL-4- and IL-17A-producing cells were higher in wild type Tregs co-cultured with *Fli1*$^{+/-}$ fibroblasts than in those co-cultured with wild type fibroblasts. To investigate the impact of IL-33 and IL-6 overexpression in *Fli1*$^{+/-}$ fibroblasts on Tregs, we next co-cultured them in the presence of neutralizing antibodies against these cytokines, which revealed that the increased proportions of IL-4- and IL-17A-producing Tregs co-cultured with *Fli1*$^{+/-}$ fibroblasts were decreased by neutralizing IL-33 and IL-6, respectively.

Conclusion: IL-33 and IL-6 overexpression in dermal fibroblasts due to Fli1 deficiency may contribute to the induction of Th2- and Th17-like Tregs in the skin, respectively, leading to the development of skin fibrosis in SSc. These data indicate a pivotal contribution of Fli1-deficienct dermal fibroblasts to the aberrant immune response in SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Prolonged endogenous activation of fibroblasts is a major hallmark of fibrosing disorders such as Systemic Sclerosis (SSc). It results in tissue fibrosis, organ failure and a high morbidity and mortality. Trimethylation of H3 at lysine residue K27 (H3K27me3) is an epigenetic mark that mediates gene repression. H3K27me3 was recently identified as an important negative regulator of fibroblast activation [1]. Demethylation of H3K27me3 is mediated by JMJD3. JMJD3 inhibitors are currently being tested as therapeutic strategies in malignant diseases. The aim of this study is to characterize the role of JMJD3 in fibroblast activation and to explore JMJD3 as a potential drug target in SSc.

Methods: The expression of JMJD3 was analyzed by qPCR, IF and Western blot in patients with SSc, healthy controls and in experimental fibrosis. siRNA mediated knockdown and pharmacologic inhibition by GSKJ4 were used to target JMJD3. *In vivo,* the effects of JMJD3-inhibiton were analyzed in the mouse model of bleomycin-induced dermal fibrosis, in the model of Topoisomerase-I-induced (TopoI) fibrosis and in a mouse model with adenoviral overexpression of a constitutively active transforming growth factor beta (TGF-β) receptor type 1 (TBR^{act}). Signaling pathways regulated by JMJD3 were analyzed *in vitro* and *in vivo* using qPCR, Western Blot and reporter assays.

Results: The expression of JMJD3 was increased in the skin of SSc patients as compared to healthy volunteers. Accumulation of JMJD3 was also observed in experimental models of SSc. TGF-β potently induced the expression of JMJD3 *in vitro* and *in vivo*. Pharmacologic inhibition and siRNA mediated knockdown of JMJD3 strongly upregulated the levels of H3K27me3 *in vitro* and *in vivo*. Inhibition of JMJD3 reverted the activated fibroblast phenotype in SSc fibroblasts and persistently decreased the expression of contractile fibers and of α-smooth muscle actin. Secretion of collagen was reduced upon inhibition of JMJD3. JMJD3- inhibition also resulted in a significant down-regulation of the profibrotic transcription factor Fra-2 *in vitro* and *in vivo*. Overexpression of Fra-2 in JMJD3-knockdown fibroblasts restored the profibrotic effect of JMJD3. *In vivo*, inhibition of JMJD3 ameliorated fibrosis in bleomycin-, TopoI- and TBR^{act}-induced experimental fibrosiswith reduced dermal thickening, hydroxyproline content and myofibroblast differentiation.

Conclusion: We present first evidence that histone methylation by JMJD3 contributes to the activated phenotype of SSc fibroblasts. JMJD3 is upregulated by TGF-β in SSc. Inhibition of JMJD3 prevents the aberrant collagen release and ameliorates the activated fibroblast phenotype in SSc fibroblasts. *In vivo* inhibition of JMJD3 has potent anti-fibrotic effects in several preclinical models of SSc. Session Title: Vasculitis II: Population Studies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Antigenic triggers initiating granulomatous inflammation in giant cell arteritis (GCA) have yet to be elucidated. Recently, histopathological studies of temporal arteries from GCA patients have identified varicella zoster virus (VZV) antigen, implicating VZV as a potential causative organism. Given the cross-sectional design of past studies, the temporal relationship between herpes zoster (HZ) infection and GCA has not been established. Furthermore, if VZV is pathogenic, it is possible that HZ vaccination or antiviral

treatments could prevent GCA. We assessed the associations of HZ, HZ treatment, and HZ vaccination with new onset GCA using two large administrative databases.

Methods: We utilized a random 5% sample of Medicare data (2006-2013) and the MarketScan Commercial Claims and Encounters database (2010-2014). Enrollees age >50 years with 365 days of continuous enrollment and without prior GCA or polymyalgia rheumatica were eligible for analysis. HZ events were identified by ICD-9 codes from hospital discharge or physician visits and classified as complicated (053.X, excluding 053.9) or uncomplicated (053.9). Antiviral treatments within 7 days of a HZ diagnosis were collected from pharmacy claims. HZ vaccination was identified through current procedural terminology and national drug codes. Incident GCA was defined by ICD-9 codes for GCA (446.5) from one hospital discharge or two physician visits 7 to 365 days apart. Using Poisson regression, we calculated GCA incidence stratified by HZ exposure. Cox proportional hazards regression was used to examine time-varying multivariable-adjusted associations of HZ, HZ treatment, and HZ vaccination with incident GCA.

Results: A total of 16,664,161 persons were included (1,250,931 Medicare; 15,413,230 MarketScan) with 8,962 GCA cases (1,777 Medicare; 7,185 MarketScan) occurring over 37,993,079 pt-yrs of follow-up. GCA incidence was highest in those with complicated HZ in both datasets. Adjusting for age and sex, complicated HZ was associated with an ~2-fold increased risk while uncomplicated HZ was associated with a ~50% increased risk of GCA (Figure 1 table). The cumulative incidence of GCA stratified by HZ and adjusted hazard ratios (HR) are shown in Figure 1. Neither antiviral therapy (Medicare HR 0.70 [95% CI 0.48-1.03], MarketScan HR 1.15 [0.86-1.53]) nor HZ vaccination (HR 0.97, 95% CI 0.89-1.04) was associated with GCA.

Conclusion: HZ events are associated with an increased risk of GCA, with the highest risk amongst those with complicated HZ (e.g. cranial nerve involvement). These findings are among the first to establish a temporal relationship of prior HZ with subsequent GCA and provide further support for a potential causal association. We did not find evidence that either HZ vaccination or antiviral treatment is protective for GCA but additional study is warranted.

Figure 1. Cumulative incidence of GCA by herpes zoster.

	MarketScan HR (95% CI)	Medicare HR (95% CI)
No Zoster	*Referent*	*Referent*
Uncomplicated Zoster	1.47 (1.25-1.73)	1.37 (1.10-1.72)
Complicated Zoster	1.93 (1.41-2.63)	2.12 (1.45-3.11)

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Vasculitis II: Population Studies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Recent studies found an high prevalence of varicella-zoster virus (VZV) infection in temporal arteries (TAs) from both temporal artery biopsy (TAB)-positive and TAB-negative giant cell arteritis (GCA) patients compared to controls, suggesting that VZV infection may trigger the inflammatory cascade that characterizes GCA (1,2). The aim of our study was to analyze VZV infection in TAs from patients with TAB-positive GCA (biopsy-proven GCA), TAB-negative GCA (patients with negative TAB and a final diagnosis of GCA) and controls (patients with negative TAB and a final diagnosis different from GCA).

Methods: 79 formalin-fixed, paraffin-embedded (FFPE) TABs performed between 2009 and 2012 from 34 TAB-positive GCA patients, 15 TAB-negative GCA patients and 30 controls were retrieved. Six 5-µm sections of all FFPE TABs were cut. The first section was analyzed by immunohistochemistry using a mouse monoclonal antiVZV glycoprotein E (gE) IgG1 antibody (Santa CruzBiotechnology, Dallas, TX) and UltraView DAB Detection Kit (Ventana, Roche, Tucson, Az.). DNA was extracted from the remaining 5 sections with the QIAamp DNA FFPE tissue kit (Qiagen) and analyzed by real-time polymerase chain reaction (PCR) for the presence of VZV with primers for the major DNA binding protein of VZV (ORF 29) using both the VZV ELITe MGB kit (CE-IVD assay) and the primers designed by Gilden et al (1,2). For 10 of the 34 TAB-positive GCA patients, a specimen of temporal artery longer than 2 mm obtained at the time of TAB and immediately stored frozen at -80°C was available. DNA was extracted from these 10 frozen specimens with the RNA/DNA/Protein purification kit (Norgen Biotek) and analyzed by PCR for the presence of VZV DNA. 30 additional 5-µm sections were cut from each of these 10 FFPE TABs for which the frozen specimens were available and analyzed by immunohistochemistry. A FFPE skin lesion from a patient with active infection with VZV was used as

positive control.

Results: Immunohistochemical analysis detected VZV antigen in 1/34 (3%) TAB-positive GCA, 0/15 TAB-negative GCA and 0/30 controls, and in none of the 300 sections cut from the 10 FFPE TABs positive for GCA for which the frozen specimens were available. Instead VZV antigen was clearly detected in the skin lesion from a patient with active infection used as positive control. DNA obtained from all TABs was amplifiable. DNA obtained from frozen TABs was more concentrated than that obtained from FFPE TABs which allowed to load a higher quantity of DNA per reaction increasing assay sensitivity. VZV DNA was not detected in any of the FFPE TABs nor in frozen TABs, but was clearly detected in the FFPE skin lesion used as positive control. The histopathologic analysis showed transmural inflammation in all sections and no skip areas were found.

Conclusion: Our data do not support a role for VZV infection in the etiopathogenesis of GCA in Italian patients.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis II: Population Studies

Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Work disability associated with rheumatic diseases accounts for an important part of the costs of these conditions. Few studies have investigated disability among patients with vasculitis and most such research was conducted before 2005 and focused on granulomatosis with polyangiitis (GPA). The purpose of this study (VascWork) was to learn about the impact of vasculitis on employment and income in patients with systemic vasculitides.

Methods: Patients enrolled in the Vasculitis Clinical Research Consortium Patient Contact Registry, living in the USA or Canada, and followed for more than 1 year since their vasculitis was diagnosed were invited via email to participate in an on-line survey-based study. Participants were asked about their disease, their employment and work status, and the financial impact of their vasculitis on their lives.

Results: Between June and December, 2015, 421 patients completed the survey: 205 with GPA, 67 with eosinophilic granulomatosis with polyangiitis, 33 with microscopic polyangiitis, 27 with Takayasu arteritis, 27 with Behçet's disease and 62 with other forms of vasculitis. 125 (30%) patients were male; mean age 54.5±13 years; 92% Caucasian; 354 (84%) living in USA. Compared to patients who continued to work after a diagnosis of vasculitis, patients who stopped working or retired early because of their vasculitis (N=111) were older (56±11 vs. 53±11 years, p=0.036) and, accounting for sex and age, were less likely to have health insurance (OR=0.36; 95% CI: 0.15–0.9) and less likely to have attained education beyond high school (OR=0.51; 95% CI: 0.26–0.99). Figure 1 summarizes the work status of patients at time of diagnosis and at last follow-up (mean of 9±6.5 years).

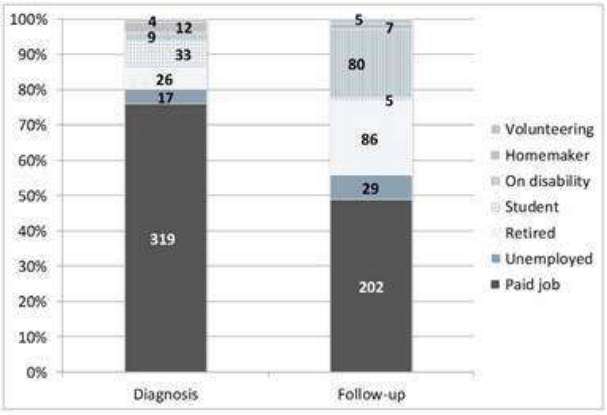

Figure 1. Work status of patients at time of diagnosis and at last follow-up. 76 patients reported income loss with an average (range) loss of 45% (2-95%). 253 patients (61%) reported having paid for some of their medications or investigations for vasculitis, leading 32 patients to not receive some prescribed treatment or testing because they could not afford the costs. Patients who were unable to pay for treatments had more often become unable to work (OR=3.12; 95% CI: 1.14–8.52).

Conclusion: This study using patient self-reported data demonstrates substantial limitations in work, productivity, and net personal income loss that patients accrue due to vasculitis. These burdens of disease are additive to the effects of vasculitis on physical functioning and directly negatively impact patients' healthcare and overall quality of life.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis II: Population Studies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Few retrospective studies in giant cell arteritis (GCA) previously reported, separately, that 1) patients with diabetes had less positive temporal artery biopsies (TAB), 2) patients on angiotensin-converting enzyme inhibitors (ACE-I) or angiotensin II receptor blockers (ARB) experienced fewer relapses and 3) patients on statins experienced the same frequency of clinical complications and relapses as non-exposed patients. This retrospective chart review study simultaneously investigated the impact of these 3 factors on a cohort of patients followed in 2 large North American centers.

Methods: Patient who were diagnosed with GCA were included in this study if they met the American College of Rheumatology's (ACR) modified classification criteria (age >50 and ≥2 of the following: new onset headache, TA abnormality, ESR >40mm, abnormal TAB and large vessel vasculitis by angiogram or biopsy). Their demographics, presenting symptoms, TAB results, disease complications and outcomes (relapses, duration of glucocorticoid use) were compared between exposed (diabetes/ACE/ARB/statin) and non-exposed patients.

Results: Of 175 charts reviewed of consecutive patients with a diagnosis of GCA (between 1993-2015) seen in the 2 study centers, 137 met the ACR modified classification criteria. 70% were female and the mean (SD) age at diagnosis was 71 (8.9) years. 17 patients had preexisting diabetes (11 developed diabetes after diagnosis), 36 were using ACE-Is (14 more after), 26 were using ARBs (6 more after) and 52 were on statins (15 more after). TAB was less often positive in patients with diabetes (RR 0.24 [95% CI: 0.069-0.81], $p < 0.02$). The cumulative probability of flaring over time was higher in both patients with pre- and post-diagnosis diabetes when compared to non-diabetic patients (log-rank, $p < 0.03$), with adjusted HRs of 0.25 [0.10-0.62] and 0.28 [0.095-0.84], respectively. There was a significant difference in the probability of successful discontinuation of prednisone for ACE-I therapy (log-rank, $p < 0.03$), but a nonsignificant trend for ARB therapy when compared to non-exposed patients, with adjusted HRs of 0.44 [0.22-0.87] and 0.60 [0.30-1.2] respectively. Clinical complications (Table 1) and relapse rates (log-rank test, $p > 0.80$, adjusted HR 0.54 (0.24-1.2)) did not significantly differ between patients on statin therapy or not.

	Diabetes	Statin therapy	ACE-I therapy	ARB therapy
Positive temporal artery biopsy	0.24* 95% CI (0.069-0.81)	0.69	0.95	0.50
Headache	1.77	1.77* 95% CI (0.96-3.26)	1.2	1.09
Temporal artery tenderness	1.0	1.5	0.79	1.3
Jaw claudication	0.80	1.03	1.5	1.1
Upper limb claudication	0.48	0.30* 95% CI (0.081-1.1)	0.67	0.88
Lower limb claudication	0.00	0.22	0.79	0.11
Anterior ischemic optic neuropathy	2.3	1.16	1.4	0.88
Visual loss	1.6	0.95	1.2	0.49
Other large vessel manifestation	0.48	0.48* 95% CI (0.23-1.0)	1.06	0.69

Table 1. Relative risk ratios of the presenting features of giant cell arteritis * $p < 0.05$

Conclusion: In this study, patients with GCA and diabetes appeared more likely to have a negative TAB, and to relapse. ACE-I therapy showed an independent association with success at discontinuing prednisone. Statin therapy did not alter the clinical presentation or course of GCA. These observed findings confirm most (but not all) of those from similar, yet separate studies which explored this topic.

Session Date: Monday, November 14, 2016

Session Title: Vasculitis II: Population Studies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: There are few data on clinical profiles of ANCA-associated vasculitis (AAV) and or ANCA specificity in different ethnic populations. This study examined differences in the clinical features of AAV between populations using the Diagnostic and Classification Criteria in Vasculitis Study (DCVAS) dataset.

Methods: DCVAS is an international, multi-center observational study recruiting in 128 sites worldwide. Rheumatology, renal, immunology, neurology, respiratory and dermatology specialties contributed to recruitment. Ethnic groups were categorized into 8 groups: Chinese, Northern & Southern European, Indian subcontinent, Japanese, Middle Eastern, White American. Other ethnic groups of <50 people were excluded. ANCA type was categorized as MPO, PR3, and ANCA-negative. The extent of organ involvement was classified by the presence of constitutional, musculoskeletal, skin, ophthalmic, ENT, respiratory, cardiovascular, gastroenterological, genitourinary, and neurological symptoms. Differences were analyzed by chi-squared test using a Bonferroni correction, and logistic regression (adjusting for age, sex, specialty of recruiting center). Northern European was the reference group.

Results: Data from 1,069 patients were included (Table 1). Recruiting specialties were not evenly distributed among ethnic groups. There were differences in ANCA type between ethnic categories ($p<0.001$). MPO was more common than PR3 in Southern European, Chinese, & Japanese; and PR3 was more common in the other ethnic categories. ANCA-negative AAV was more common in White Americans than in Northern Europeans. These effects remained after adjustment for age, sex, and recruiting specialty. There were differences in organ involvement in the crude analysis: systemic involvement was less common in Southern Europeans, renal involvement more common in Chinese and Japanese, musculoskeletal less common in Southern European, Chinese and Japanese, ophthalmic more common in Indian and less common in Japanese. Adjustment for age and sex did not alter the associations. However, recruiting specialty confounded the association between ethnicity and system involvement for all organ systems. Due to interaction, the analysis was stratified by recruiting specialty. The majority (83.7%) of patients were recruited by rheumatology. Within this group, there were no significant differences, except ophthalmic and ENT involvement were less common in Japanese people compared to Northern Europeans. The numbers in the other specialties were too small to draw conclusions.

Conclusion: This study confirms the previously-observed differential occurrence of MPO-AAV and PR3-AAV. Organ system involvement in AAV does not appear to be different among various ethnic groups, after accounting for the different likelihood of seeing and recording symptoms in different specialties.

Table 1: Demographic data, recruiting specialties, diagnoses, and ANCA type of patients with ANCA-associated vasculitis in the cohort

		n	%
Sex	Male	532	49.8%
	Female	537	50.2%

Session Date: Monday, November 14, 2016
Session Title: Vasculitis II: Population Studies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Pneumocystis Jirovecii pneumonia (PJP) is a life-threatening complication in granulomatosis with polyangiitis (GPA). Guidelines from EULAR for ANCA-associated vasculitis (AAV) recommend institution of PJP chemoprophylaxis during cyclophosphamide therapy. Rituximab has been increasingly used in AAV, however the necessity for PJP chemoprophylaxis in this group of patients is unclear. The objective of this study was to determine the incidence and risk of PJP in GPA patients who received Rituximab.

Methods: We conducted a retrospective cohort study using the 2006 to 2013 Truven Health Analytics MarketScan Commercial Claims database which contains inpatient, outpatient, and pharmacy claims from the privately-insured US population. We selected patients aged 2-60 years old and identified GPA and PJP cases using ICD-9-CM codes 466.4 and 136.3, respectively. As GPA shares the same ICD-9-CM code with eosinophilic granulomatosis with polyangiitis, patients with eosinophilia (ICD-9-CM 288.3) were excluded. From these patient records, we collected demographic data, dates of first coding for GPA, presence of PJP and dates of PJP onset, dates of Rituximab use, presence and dates of PJP chemoprophylaxis, and use of immunosuppressive drugs within 90 days of PJP onset. We performed all statistical analyses using STATA (STATA Corp, College Station, TX).

Results: We identified 4,606 patients with GPA. Only 7% of GPA cases (n=322) were children under 21 years of age. The mean age at the time of first coding for GPA was 44.5 ± 12.6 years and 54.5% were female. Less than a quarter of GPA patients received Rituximab chemotherapy during the study period (n=636 patients, 13.8 %). During the study period, 23 GPA patients (0.5%) were diagnosed with PJP. The mean age at PJP onset was 47± 13 years with slight female preponderance (65%). The annual incidence rate of PJP in GPA patients across all ages, regardless of treatment, was 2 cases per 1,000 person-years. Two of the PJP patients were diagnosed with PJP within 2 months of Rituximab initiation, resulting in an annual incidence rate of PJP in Rituximab-

treated GPA patients of 1 case per 1,000 person-years. The relative risk of PJP in Rituximab-treated patients was 0.6 (95% CI 0.14-2.53, p=0.48) compared to non-Rituximab-treated patients. Among the 636 patients who received Rituximab, 339 patients (53%) had claims for PJP chemoprophylaxis within 90 days prior to the PJP onset; only one of these developed PJP while on the PJP prophylaxis. The relative risk of developing PJP on prophylaxis medication was 1.0 (95% CI 0.99-1.01, p=0.9).

Conclusion: The overall incidence of PJP in GPA patients and in Rituximab-treated GPA patients in particular, was low. Rituximab does not appear to be associated with an increased risk of PJP in GPA patients. Chemoprophylaxis for PJP may not be indicated in the Rituximab-treated GPA patients. Further study is warranted to evaluate cost-effectiveness of PJP chemoprophylaxis in Rituximab-treated GPA population.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: ARHP IV: Clinical Practice, Patient Care and Health Services

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Fibromyalgia (FM) is a multi-symptomatic pain disorder that affects 10-15 million US adults, including 1 in 20 patients seen in primary care. As such, primary care providers are increasingly expected to recognize and diagnose these patients rather than rely on specialists such as rheumatologists. The purpose of this study was to evaluate the usefulness of 3 simple measures, that when routinely used, will alert the clinician to consider a diagnosis of FM.

Methods: A descriptive cross sectional study assessed adults being seen in 2 academic primary care clinics. Data sources included chart review, history, physical exam and patient-completed surveys.

Results: 356 patients were studied (mean age 50 ± 16.3 years, 70% female). Chart review revealed that 53 (15%) of these patients carried a diagnosis of FM in their medical record. On survey, 159 had pain of which 122 (77%) stated that their pain was present greater than three months. On physical exam, those who had FM were

tender at a lower level of sphygmomanometery-evoked pain than those without FM (128 mmHg ± 5.4 vs 181 mmHg ± 6.1, p< 0.0001). Similarly, those with FM exhibited more bilateral skin roll tenderness (upper trapezii, radii, interphalangeal joints, anterior thighs) compared to those without FM (p < 0.0001). Pinching the Achilles tendon with 4 kg over 4 seconds was the most commonly endorsed tender area in FM patients. Similarly, those with FM endorsed the question "I have a persistent deep aching pain over most of my body" more commonly than those without FM (p < 0.0001).

Conclusion: Primary care providers should schedule a visit to fully evaluate a patient for FM if the patient has any of the following: 1) sphygmomanometry-evoked allodynia, 2) pain on the Achilles tendon pinch, or 3) endorses the statement "I have a persistent deep aching over most of my body." By raising providers' index of suspicion for FM, patients may be spared years cycling through the medical system before receiving a diagnosis and beginning treatment.

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: ARHP IV: Clinical Practice, Patient Care and Health Services

Session Type: ARHP Concurrent Abstract Session

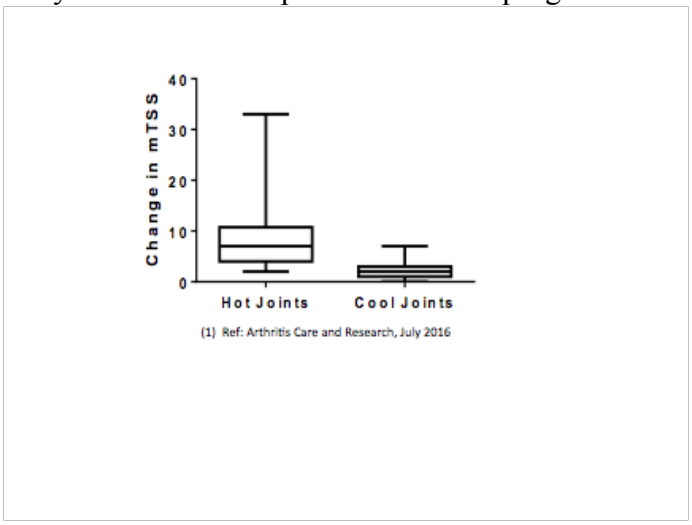
Session Time: 4:30PM-6:00PM

Background/Purpose: Nurses and rheumatology extenders can rapidly identify rheumatoid arthritis (RA) patients who flare, with high predictive value for which individual is at high risk for crippling deformity. Published literature has shown that an elevated dermal temperature Òwarm jointÓ can identify RA patients who most need disease modifying therapy (DMARD).(1) Nurses or rheumatologic extenders in clinic can assess in less than a minute which specific patient will develop radiographic damage by documenting a single dermal temperature of 97 F or greater over the left wrist.

Methods: All 297 sero-positive RA patients were on DMARD therapy in good control or remission at least 6 months. Hand/wrist xrays were obtained annually. In each case where there was a significant worsening of skeletal damage, the clinic visit record showed a dermal temperature over 97 F in the left wrist (used as the default joint for dermal assessment). None of the 297 RA patients were permitted prednisone or narcotics; stable doses of anti-inflammatory medications were permitted. Annual xray analysis was performed by a single reader, blinded and in random sequence. The minimal meaningful change in mean total Sharp score (mTSS) was ≥ 5 U.

Results: Over a three year period, there was demonstrable radiographic damage in 15 RA patients (5%) of the 297 RA patients in this trial. All 297 remained on stable DMARD therapy for the three years with control of RA disease, except for the 15 RA patients with a dermal temperature over 97F; 12 women and 3 men. There were no differences in baseline characteristics between the stable RA patients and the 15 who flared. The 15 patients flared while on stable DMARDs. Subsequent to recording a dermal temperature at least 97 F or over in the left wrist, the damage was clear on the following annual xray. The DMARD therapy in the 297 patients included methotrexate(MTX) alone (32%), MTX / TNF (35%), MTX/ abatacept (10%), MTX/ rituximab (15%), MTX/ JAK (5%), or any biologic alone without MTX (3%). The flares with subsequent xray damage occurred randomly on each of the DMARD treatment regimens.

Conclusion: Triage performed by a nurse or rheumatology extender may rapidly identify which patients most need a change in DMARD therapy. If the dermal temperature is 97F or higher, this predicts that a specific RA patient will have radiologic damage in the next years. Dermal temperature can be a prognostic indicator to guide therapy and avoid permanent joint damage.



Dermal Temperature predicts flare and radiographic damage in RA patients previously well controlled on DMARD therapy

	Less than 97F (n=282)	97F or higher (n=15)
Erosions	1.2 (0.16), no change	9.7 (6.7), 38% worse after 3 yrs
Joint space loss	1.6 (0.9), no change	12.1 (8.8), 34% worse after 3 yrs
mTSS	2.8 (1.2), no change	21.8 (14.5), 36% worse after 3 yrs

Results are presented as absolute unit change over 3 years with standard deviation (sd) and as the % change compared to baseline in these patients.

Session Date: Monday, November 14, 2016
Session Title: ARHP IV: Clinical Practice, Patient Care and Health Services
Session Type: ARHP Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: There are more than 5 million rheumatoid arthritis (RA) patients in China, but only 5,000 rheumatologists. Treat-to-target (T2T) is a widely accepted cretria as management strategy for rheumatoid arthritis (RA) to achieve defined outcomes (remission or low disease activity), but the Chinese rheumatologists can hardly provide patients with a complete assessment in the clinic due to limited time. Our previous study shows that patients in China can master the application of Smart System of Disease Management (SSDM) for accurately evaluating disease activity score in 28 joints (DAS28) and health assessment questionnaire (HAQ) after training. The purpose of this study is to describe major clinical characteristics of Chinese RA patients using SSDM and analyze the potential association among DAS28, HAQ and morning stiffness time in real world.

Methods: SSDM includes physicians' and patients' application system. The patient application system includes self-assessment (DAS28, HAQ), morning stiffness time and medication management. After data entry, patients can synchronize data to the mobile terminal of authorized rheumatologist. All patients fulfilling the 1987 ACR criteria for RA were recruited. The mean of each variable was analyzed using t-test, assuming normality for DAS28 distribution and the level of disease activity was analyzed using Pearson's statistics. One-way analysis of variance was employed to explore for difference between sub-groups.

Results: From August 2014 to May 2016, data were extracted online from the mobile terminals of 741 rheumatologists in 295 rheumatology centers across China. A total of 5,756 RA patients participated in the study. The mean age was 46.37 ±13.32 (18 to 99) years and the median disease duration was 2.58 (0 to 51.83) years. All patients performed self-assessment of DAS28, HAQ and morning stiffness time for 8,533 times. At baseline, the mean DAS28, HAQ scores and morning stiffness time were 3.75 ± 2.52 (0.21 to 9.71), 2.75 ± 4.30 (0 to 24) and 19.02 ± 30.01 (0 to 240) minutes respectively. DAS28 was positively correlated with HAQ and stiffness time independently. Both HAQ and morning stiffness time showed linear regression association with DAS28

score, the regression equation as “DAS28 = 3.40 + 0.019*morning stiffness time” and ““DAS28 = 3.41 + 0.0145*HAQ” respectively, p<0.01. According to the T2T criteria, 19.29% of patients achieved remission (Rem), 12.78% with low disease activity (LDA), 42.50% with moderate disease activity (MDA) and 25.43% with high disease activity (HDA). The most commonly used medication were small molecule DMARDs (92.7%) include leflunomide (65.33%), methotrexate (45.99%) and hdroxychloroquine (44.19%). Etanercept (2.40%) was the most common being used biological DMARDs (6.07%). The number of DMARDs being taken by patients who reach target was significantly less than who fail to reach target (2.78 ± 1.64 vs 3.05 ± 1.74), p = 0.019.

Conclusion: SSDM is an effective mobile interface to serve for RA patients performing self-management as well as to supply physicians with valuable data. DAS28 was positively correlated with HAQ and morning stiffness time independently. HAQ and morning stiffness time could surrogate reflect disease activity.

Session Date: Monday, November 14, 2016

Session Title: ARHP IV: Clinical Practice, Patient Care and Health Services

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Clinical disease activity for patients with rheumatoid arthritis requires frequent monitoring for optimal management. Patient reported outcome (PRO) tools provide information that complements physician’s assessment of changes in disease activity and response to treatment. The use of electronic data capturing (ePRO) is potentially advantageous over paper based (pPRO) in terms of reducing missing data, reducing ambiguous responses and allowing time-stamped records and analysis.

Methods: Patients were assigned randomly to either ePRO or pPRO at visit one. At visit 2, patients crossed over into the other PRO modality (both pre-treatment) and remained in that arm for subsequent visits at week 6,

12 and 36. Patient assessments included 28 swollen (SJC) and tender joint counts (TJC), Patient assessment of pain (PAAP), Patient assessment of global disease activity (PtGADA) and Bristol Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ).

Results: 52 patients with mean RA duration 11.7 years were enrolled and. Mean age was 55.7 (SD 14.3) years and 67% were female.

There was moderate to high correlation (Table 1) and agreement (Figure 1) between Nurse-Patient-Physician PRO assessments. There was no significant difference in PtGADA, PAAP and BRAF-MDQ between ePRO and pPRO assessments.

Patients reported high levels of satisfaction with both PRO arms with only 2 patients (8.3%) reporting dissatisfaction. 88-92% reported that they were either satisfied or very satisfied with either tool. 58% of those who transitioned from ePRO to pPRO had no preference for one over the other format whereas 67% of those who transitioned from pPRO to ePRO preferred the electronic tablet.

Conclusion: Both ePRO and pPRO provided consistent results and demonstrated equivalence in PRO assessment. ePRO was well embraced by patients with only a minority reporting dissatisfaction. It may be a desirable inclusion in routine RA and potentially other disease assessments for its added reliability, consistency and increased patient involvement.

Session Title: ARHP IV: Clinical Practice, Patient Care and Health Services
Session Type: ARHP Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose : Under the treat-to-target approach for patients with rheumatoid arthritis (RA), a biologic agent is considered when the target is not met despite trying disease-modifying anti-rheumatic drugs. However,

patients sometimes struggle with the decision to use these medications due to the potential side effects. We have developed a user-friendly decision aid, *ANSWER-2*, for patients who are considering biologic and small molecule agents. Patient decision aids are designed to present the potential benefits and harm of treatment options and clarify individuals' preferences. A main feature of *ANSWER-2* is the trade-off exercise designed to help patients consider value-sensitive options (e.g., the mode and frequency of medication administration). We aimed to assess the extent to which *ANSWER-2*reduces patient's decisional conflict, and improves their medication-related knowledge and self-management capacity.

Methods: We used a pre-post study design. Participants were recruited from rheumatologists' clinics, patient groups and social networking sites (e.g., Facebook). Individuals were eligible if they: 1) had a physician diagnosis of RA, 2) had been recommended to start/switch to a new biologic or small molecule agent, and 3) had internet access. Access to *ANSWER-2* was provided immediately after enrollment. Participants completed outcome measures before and within 2 days after using *ANSWER-2*. They included: 1) Decisional Conflict Scale (DCS; 0-100, scores < 25 are associated with follow-through with decisions), 2) Partners in Health Scale (PIHS; 0-88, lower = better), and 3) Medication Education Impact Questionnaire (MeiQ; 6 subscales, higher score = better). Paired t-test or Wilcoxon signed-rank test was used to assess differences pre and post intervention.

Results: 50 participants were enrolled in November 2014 – December 2015. The majority were women (n = 40) with a mean age of 49.6 years (SD: 12.2). 64% (n = 32) attended/completed university. The median disease duration was 5 years (Q1; Q3: 2; 10). The mean DCS was 45.9 (SD: 25.1) pre-intervention and 25.1 (SD: 21.8) post-intervention (change: -21.2, 95% CI: -28.1, -14.4; $p < 0.001$). Before using *ANSWER-2*, 20% of participants scored < 25, compared to 52% after the intervention. Similar results were observed in the PIHS (pre: 25.3, SD: 14.8; post: 20.4, SD: 13.0; change: -3.7, 95% CI: -6.3, -1.0; $p= 0.009$). Findings from the MeiQ were mixed, with statistically significant differences found in the self-management sub-scales (Table 1).

Table 1: Results of MeiQ Subscales

MeiQ subscale (maximum possible score)	Before (SD)	After (SD)	Difference (95% CI)	*p*
Information Quality (30)	21.9 (5.5)	22.4 (5.0)	0.3 (-0.6, 1.3)	0.490
Active Communication (24)	18.8 (4.6)	19.5 (3.7)	0.7 (-0.1, 1.4)	0.086
Coming to Terms with Diagnosis & Treatment (24)	19.4 (3.0)	19.7 (2.9)	0.3 (-0.3, 1.0)	0.299
Self-management Ability (36)	26.7 (5.3)	28.0 (4.9)	1.3 (0.0, 2.5)	0.048
Self-management Role & Responsibility (36)	31.8 (3.3)	32.6 (2.8)	0.9 (0.2, 1.6)	0.012
Self-management Support (24)	17.5 (4.4)	18.9 (3.2)	1.1 (0.2, 2.0)	0.019

Conclusion: Patients' decisional conflict and self-management capacity improved after using *ANSWER-2*. Our results show similar changes to other studies evaluating patient decision aids in chronic diseases, including RA[1]. Future research comparing *ANSWER-2*with education material on biologics will provide further insight into the value of patient decision aids in RA management. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: ARHP IV: Clinical Practice, Patient Care and Health Services

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Title: Minding the Gap: The Use of Nurse Practitioners and Physician Assistants in U.S. Rheumatology Practice to Affect Rheumatology Workforce Shortages Authors: Smith BJ[1], Bolster MB[2], Ditmyer M[3], Jones KB[4], Monrad S[5], Battafarano DF[6] [1] McIntosh Clinic, P.C. **[2]** Massachusetts General Hospital **[3]University of Nevada, Las Vegas, [4]Nationwide Children's Hospital, [5]University of Michigan, [6]San Antonio Military Medical Center**

Background/Purpose: The United States (U.S.) is facing a significant deficit of physicians and **rheumatology is subject to workforce challenges. Currently, in many areas in the U.S., persons with rheumatic disease face prolonged wait times and experience significant travel distances to a rheumatologist. Nurse Practitioners (NPs) and Physician Assistants (PAs), valuable members of the healthcare team, are utilized by about 25% of rheumatology practices.** The 2015 ACR Workforce Study sought to expand current knowledge of the rheumatology workforce which included NP/PAs.

Methods: The 2015 ACR/ARHP Workforce Study was completed using several primary and secondary data sources, including ACR member data, state licensure registries, the 2005 ACR workforce study, professional organizations, and other medical literature. These data were augmented by a web-based survey to collect information on demographics, work settings, practice patterns, and retirement planning.

Results: Thirty-two completed survey responses were received (30% response rate; 32/110 NP/PA members), of which 23% were NPs (19/82) and 46% were PAs (13/28). Self reported as female were 54% (n=26) and 12.5% (n=6) as male, representative of the gender breakdown in the NP/PA professions. On average, NPs reported working 43 hours/week, while PAs reported working 39 hours/week. Of these hours, most were in clinical care (NP Mean=30 hours; PA Mean=27) with NPs reporting an average 31 patients and PAs an average 47 patients seen/week. A small percentage (<18% combined NP/PA) reported performing and billing for ultrasounds, DXA scans, and office based infusions. Although the majority of new patient visits seen by NP/PAs are shared visits with a rheumatologist, follow-up patients are mostly managed as independent visits (Figure 1). About 27% NPs/PAs plan to retire in the next 10 years. Of those, all plan to reduce their patient load before that time by 25-50%.

Conclusion: NP/PAs have been identified as a potential means of increasing the rheumatology workforce. While NP/PAs have different formal educational training, they function similarly within a rheumatology office and are able to accomplish unique needs of the practice, within the scope of state legal requirements. NPs and PAs offer one potential solution to meet rheumatology workforce needs particularly if use of this valuable resource is expanded and optimized. As the majority of NP/PA clinical encounters are follow-up visits accomplished "independently", an opportunity to maximize the rheumatology workforce occurs when physicians, NPs and PAs function to the highest level of their licensure. Our data is limited only to NP/PA ARHP members and does not fully reflect NP/PAs in the rheumatology workforce. Recruitment and training strategies to increase the number of rheumatology NP/PAs to augment the workforce and improve access-to-care should be explored.

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid antibody syndrome (APS) is an autoimmune, hypercoagulable state which may elicit thrombosis and pregnancy loss. Although several tests exist to guide diagnosis of APS and SLE, their utilization has been highly variable among laboratories. Therefore, we have introduced a panel of nine tests and examined their sensitivity and specificity for supporting the diagnosis of APS in SLE and non-SLE patients at our Institution between 2010 and 2015.

Methods: 356 SLE and 288 non-SLE patients were evaluated for the presence of APS, as earlier defined (*J. Thromb. Haemost.* 4:295-306). SLE patients satisfied the ACR criteria for a definitive diagnosis (*Arthritis Rheum.* 25:1271-1277; *Arthritis Rheum.* 40:1725). Lupus anticoagulants were assessed in house on fresh samples within 24 h of acquisition by hexagonal phase phospholipid neutralization assay (HPPNA; delta <10 seconds; Stago, Parsippany, NJ), diluted Russell viper venom test (DRVVT; <1.2 normalized ratio; Stago), and platelet neutralization procedure (PNP; delta < 1 second) using a STA-R Evolution instrument (Stago). IgG, IgM, and IgA antibodies against β2-glycoprotein 1 (aβ2-IgG, aβ2-IgM, aβ2-IgA) and cardiolipin (aCL-IgG, aCL-IgM, aCL-IgA) were measured by Quest Diagnostics (Madison, NJ). Sensitivity and specificity for detection of APS was calculated in both SLE and non-SLE patients and compared amongst these assays by χ^2 test using GraphPad software (San Diego, CA).

Results: 77/356 SLE patients had APS when using a combination of nine tests. Table 1 shows the frequency of positive and negative test results and p value for each assay in the SLE cohort. HPPNA has provided by far the greatest sensitivity at 73% for detecting APS in SLE patients relative to all other tests. In contrast, HPPNA has lower specificity at 85% as compared to all other test. While not shown, HPPNA also exhibited the greatest sensitivity at 78% for detecting APS in 61/78 non-SLE patients. Importantly, the 2nd most sensitive test for detection of APS in non-SLE patients was DRVVT at 14.3%; which was lower than that of HPPNA (chi-square $p<0.0001$). However, DRVVT had greater specificity at 96% for detection on APS in non-SLE subjects ($p<0.0001$).

Conclusion: This study indicates that HPPNA is the most sensitive but least specific assay for detecting APS both in SLE and non-SLE subjects. While it has been underutilized in a survey of 53 North-American Coagulation Laboratories (*Am. J. Clin. Pathol.* 134:764-773), these data clearly indicate the relevance of HPPNA for the clinical diagnosis of APS in patients who need long-term anticoagulation to prevent life-threatening thrombotic events.

Table 1. Sensitivity and specificity of nine test for detection of APS in SLE patients									
TEST	HPPNA	PNP	DRVVT	aβ2-IgG	aβ2-IgM	aβ2-IgA	aCL-IgG	aCL-IgM	aCL-IgA

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In several autoimmune diseases, most notably in systemic lupus erythematosus (SLE), a type I interferon (IFN) signature has been described. This signature is thought to be related to the activation of plasmacytoid dendritic cells (pDCs) and their subsequent production of type I IFN. Whether a type I IFN

signature is also present in patients with (primary) antiphospholipid syndrome ((P)APS) and its contribution to its pathophysiology is as of yet unknown. Therefore, we assessed the presence of a type I IFN signature in monocytes of SLE, SLE+APS and PAPS patients and determined the frequency of pDCs as key producers of type I IFN.

Methods: The expression of four type I IFN inducible genes Ly6E, IFITM1, IFI44L and Serping-1 was determined by RT-qPCR in monocytes isolated from peripheral blood of healthy controls (HC, n=24), patients with SLE (n=52), SLE+APS (n=30) and PAPS (n=24). Expression levels were used to calculate a type I IFN signature score. The frequency of pDCs was determined by flow cytometry by double positive staining for BDCA2 and BDCA4. The percentage of classical, intermediate and non-classical monocyte subsets was determined by CD14 and CD16 expression using flow cytometry on isolated monocytes.

Results: The mean (±95% confidence interval) type I IFN score was 1.91 (1.52 – 2.30, $p<0.001$) in SLE patients, 1.74 (1.27 – 2.20, $p<0.001$) in SLE+APS patients and 0.97 (0.41 – 1.54, $p=0.03$) in PAPS patients as compared with 0.00 (-0.36 – 0.36) in HC. SLE patients had a statistically significant higher type I IFN score as compared with PAPS patients ($p=0.014$). The median frequency (interquartile range) of pDCs in SLE, SLE+APS and PAPS was respectively 0.22% (0.15 – 0.38, $p=0.005$), 0.24% (0.20 – 0.30, $p=0.003$) and 0.18% (0.14 – 0.35, $p=0.004$) as compared with 0.40% (0.25 – 0.49) in HC. In patients with SLE, the type I IFN score correlated with disease activity. Although not related to a clinical or serological APS phenotype or the expression of tissue factor, the type I IFN score correlated with the proportion of monocytes subsets in APS patients.

Conclusion: We confirm the presence of a type I IFN signature in monocytes of SLE patients but show for the first time the presence of this in PAPS patients as well. In line what has been reported in SLE, pDCs frequencies are reduced in the circulation of PAPS patients as well. Altogether, these observations justify further research into the role of pDCs in the pathogenesis of PAPS aside to that in SLE.

Session Date: Tuesday, November 15, 2016
Session Title: Antiphospholipid Syndrome - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Lupus anticoagulant hypoprothrombinemia syndrome (LA-HPS) is a rare condition that may predispose to both thrombosis and bleeding due to positive lupus anticoagulant (LA) and factor II (FII) deficiency. It can be seen in association with infections or systemic lupus erythematosus (SLE) and may require glucocorticoids (GC) and/or immunosuppressive medications. The purpose of this report is to describe the novel use of rituximab (RTX) as a steroid-sparing agent in three pediatric SLE cases and to systematically review the literature on pediatric cases of LA-HPS.

Methods:

Pediatric LA-HPS cases that received only RTX for LA-HPS (in addition to GC) at two institutions between January 2010 and June 2016 were analyzed descriptively. PubMed was queried for "pediatric" or "children" and "lupus anticoagulant hypoprothrombinemia", "acquired hypoprothrombinemia", "lupus anticoagulant" or "hypoprothrombinemia", retrieving all articles in English. Relevant articles and their references were checked. Pediatric LA-HPS cases (≤18 years) with bleeding or thrombotic events were included in the systematic analysis. Information obtained included demographics, presenting symptoms, diagnoses, treatments, pre/post-treatment prothrombin time (PT)/partial thromboplastin time (PTT)/LA/FII levels and outcomes.

Results:

In addition to three LA-HPS cases identified at our institutions (Table 1), as of June 2016, 35 articles reported 52 pediatric LA-HPS cases [mean age: 7.9y (10m – 17y); Female/Male: (2:1); viral illness 27 (52%), SLE 20 (38%), and other 5 (10%)]. All cases had a positive LA and FII deficiency (range: 0-40%). All cases presented with bleeding diathesis and were treated with various regimens, but there was no reported use of RTX. Of cases with viral illness, 23/27 (85%) received no or supportive treatment alone with 4/27 (15%) receiving GC and/or immunosuppressive medications. Of SLE cases, the majority 18/20 (90%) received GC [7/18 (39%) combined with immunosuppressive medications] with only 1/20 (5%) receiving supportive treatment alone. Post-treatment LA and FII were checked in 29/52 (56%) and 34/52 (65%) cases respectively. Patients had complete resolution: 25 (48%), partial/clinical resolution: 23 (44%), or no response/not available: 4 (8%) based on further bleeding diathesis/thrombotic events and post-treatment FII levels.

-

Conclusion:

Based on our experience with three pediatric SLE LA-HPS patients, RTX: a) is an effective steroid sparing agent; b) improves or normalizes FII levels; and c) does not affect LA positivity. Our systematic literature review of pediatric LA-HPS cases demonstrates that: a) viral illness-associated LA-HPS is mostly transient; b) steroid is the mainstay in the acute management of SLE-associated LA-HPS; c) there are no standardized maintenance treatments for SLE-associated LA-HPS; and d) there is no reported use of RTX in the literature.

Table 1: Rituximab and Glucocorticoid Combination Therapy in three pediatric SLE cases with LA-HPS

	Case 1	Case 2	Case 3

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is a well-characterized autoimmune and thrombotic disorder but its pathogenesis remains to be elucidated. Genomic studies have revealed the association of signal transducer and activator of transcription 4 (STAT4) and B lymphoid kinase (BLK) with APS, suggesting the involvement of T cell differentiation and B cell maturation in the development of APS. However, little information has been available on the role of T and B cells in the pathogenesis of APS. We aimed to identify the deviation of lymphocyte subset and its association with single nucleotide polymorphisms (SNPs) in APS patients.

Methods: This cross-sectional study included patients with primary APS (PAPS), APS associated with systemic lupus erythematosus (SLE/APS) and healthy controls. Peripheral blood mononuclear cells and genomic DNA were obtained from these subjects. T cells were analyzed into 12 subsets with markers as follows; CD3, CD4, CD25, CD45RA, CD127, CD45RA, CCR6, CCR7, CXCR3, CXCR5. B cells were analyzed into 6 subsets with markers as follows; CD3, CD4, CD24, CD27, CD38, IgD. In addition, a total of 28 SNPs, which had been shown to associate either with SLE or with thrombotic diseases, were analyzed by TaqMan genotyping assay.

Results: Seventeen PAPS, eight SLE/APS patients and eight healthy controls were included in this study. In T cell analysis, Th2 cells ($CD3^{+}CD4^{+}CD45RA^{-}CCR6^{-}CXCR3^{-}CXCR5^{-}$) were increased in PAPS ($p = 0.016$, Dunnett's test) and SLE/APS ($p = 0.013$) patients compared to healthy controls. Resting regulatory T cells ($CD4^{+}CD25^{int/high}CD45RA^{+}CD127^{low}$) were decreased in PAPS patients compared to healthy controls ($p = 0.017$). In B cell analysis, pre-switched memory B cells ($CD3^{-}CD19^{+}$ $CD27^{+}IgD^{+}$) and post-switched memory B cells ($CD3^{-}CD19^{+}CD27^{+}IgD^{-}$) were simultaneously decreased in PAPS patients compared to healthy controls ($p = 0.022$ and $p = 0.016$, respectively). In SNPs analysis, one of Toll-like receptor 7 gene polymorphisms (rs3853839) was associated with the decrease of post-switched memory B cells observed in PAPS patients ($p = 0.038$).

Conclusion: In APS patients, Th2 cells were increased while resting regulatory T cells, pre- and post-switched memory B cells were decreased. Furthermore, association between Toll-like receptor 7 and a decrease of memory B cells was found in APS patients. The deviation in lymphocyte subsets in patients with APS could be, in part, immunogenetically regulated, presumably contributing to the development of this syndrome.

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The antiphospholipid syndrome (APS) is an autoimmune disease characterized by the presence of antiphospholipid antibodies in serum together with clinical manifestations such as thrombosis, fetal loss, hemolytic anemia, and thrombocytopenia. Along with a crucial role of antiphospholipid antibody, proofs of the genetic predisposition of APS are not fully elucidated. The purpose of this study is to identify the novel genetic variations of primary and secondary Korean APS patient group.

Methods: Genomic DNA was isolated from 6 patients of established APS and 6 age/gender-matched healthy control's blood sample and whole-exome sequencing was performed using the Illumina HiSeq-2500 platform. Samples were submitted through analysis software where sequencing reads were mapped to the human reference genome (GRCh37, UCSC hg19 from NCBI, Feb 2009) using the Burrows-Wheeler Aligner algorithm, with removal of PCR duplicates using Picard. Local re-alignment, base quality recalibration and variant calling were performed using the Genome Analysis Toolkit. The potential effect of rare coding-sequence single nucleotide variants were predicted using predictive tools that included Polyphen-2, SIFT, and combined annotation-dependent depletion (CADD) Phred. To sort novel variation in patients group, <span">all variants observed in HapMap, dbSNP, 1000 Genome, and NHLBI ESP6500 databases w<span">ere filtered to be eliminated. Demographic, Clincal (cerebral infarction, pulmonary thromboembolism or recurrent pregnancy loss) and laboratory (lupus anticoagulant, anti-cardiolipin antibody, anti-beta2-glycoprotein1antibody) parameters were reviewed from the medical record of APS group.

Results: Overall mean target exon coverage was 96.4% of targets with at least one read at a mean depth of 185–223× in patients group. A total of 43 potentially disease-associated variants observed in APS group that were absent from the reference databases were identified. 30 of them were missense variants (*MST1L, TUBA3E, IDUA, HGC6.3, C7ORF26, MUC3A, METTL2B, RP1L1, ADAMTSL2, SUFU, TPBGL, CCDC168* etc), 11 frameshift (*HLA-DR5, CD36, ATXN3, HS3ST6, LILRB3, FAM47C* etc), and 2 stop variants (*PABPC3, CCDC154*). Notably, *CD36*gene on chromosome 7 (NM_000072.3) encodes the major glycoprotein of the platelet surface, which serves as a receptor for thrombospondin and is involved in cell adhesion /blood coagulation, shows frameshift variant in 5/12 alleles of APS group.

Conclusion: We demonstrated high-throughput profiling of the genomic and transcriptomic data in APS patient group. Several novel, potentially disease-associated variants were identified. Further investigation regarding functional relationship with APS pathogenensis, and comparison between primary and secondary APS is needed.

Antiphospholipid Syndrome Patients' Time within Therapeutic Range

of International Normalized Ratio (INR)

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Antiphospholipid Syndrome - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid Syndrome (APS) is a systemic autoimmune disease characterized by recurrent arterial or venous thrombosis and/or recurrent pregnancy morbidities, with persistently positive antiphospholipid antibodies. Patients with APS who have had a thrombosis require anticoagulation with a vitamin K antagonist (VKA), mainly warfarin, to a target international normalized ratio (INR) indefinitely. The purpose of this study was to investigate whether patients with APS are spending more or less time within therapeutic range (TTR) of INR compared to non-APS controls.

Methods: All patients within a large, multi-center university hospital system with possible APS who were also prescribed warfarin between July 2012 and July 2015 were first identified, and then chart reviewed for accuracy. True diagnosis was based on an APS diagnosis identified as the reason for anticoagulation in chart notes, or fulfillment of Sapporo criteria for diagnosis of APS while being prescribed warfarin therapy. These patients were then age- and sex-matched with controls, consisting of all non-APS patients who were on warfarin. The TTR for each patient was calculated using the percent of days in range (Roosendaal method). The APS and control patients' TTR values were compared overall, as well as in subcategories such as the type of thrombotic event, presence of lupus anticoagulant, and enrollment in a pharmacy monitoring program.

Results: Of 149 patients surveyed, there were 45 APS patients who met all inclusion criteria. These were matched with 45 control patients. There were no differences seen for any of the analyzed variables, including mean INR, when comparing controls with APS patients. As determined by logistic regression analysis, using the 50th percentile as a cut-off, an increase in 10 years of age was associated with having higher TTR [p=0.01, OR=1.91 (1.17-3.12)], though this association was only seen in APS patients, and not in the controls. Positivity for the lupus anticoagulant did not affect TTR. Patients who were enrolled in a pharmacy monitoring program had increased TTR for both controls [p=0.011, OR=5.77 (1.50-22.15)] and APS patients [p=0.011, OR=9.02 (1.64-49.58)]. When comparing TTR values for patients with the same thrombotic event type, most TTR values were similar, however, APS patients with deep vein thrombosis had a higher TTR as compared to the controls (p=0.016).

Conclusion: APS patients and controls have no significant difference in TTR values, even when analyzing specific manifestations, with the exception of venous thrombosis, which was slightly better managed in APS patients. Young APS patients, but not controls, had markedly decreased TTR, independent of disease duration. Individuals enrolled in a pharmacy monitoring program had, in general, more visits, longer duration of treatment and reached their TTR to a higher degree. Surprisingly, the presence of certain antiphospholipid antibodies also did not impact TTR. This study indicates that there is no evidence that anticoagulation with a VKA (most often warfarin) is particularly difficult, or that TTRs in patients with antiphospholipid syndrome are different in this regard than a control population.

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Primary antiphospholipid syndrome (PAPS) is characterized by thrombotic and/or obstetrical morbidity in the presence of persistent antiphospholipid antibodies (APLA) and in the absence of other autoimmune disease. APLA are necessary, but not sufficient for the clinical manifestations of APS. Triggering receptor expressed on myeloid cells-1 (TREM-1) is an innate-immune cell-surface receptor involved in amplification of TLR-4-mediated inflammatory response. Soluble TREM-1 (sTREM-1) reflects membrane TREM-1 upregulation and exerts an anti-inflammatory effect. **Aim**: To determine plasma level of sTREM-1 in .patients with PAPS

Methods: A cross-sectional, case-control study. Plasma level of sTREM-1 was analyzed by ELISA in a cohort of consecutively recruited patients diagnosed with PAPS (defined by Sapporo criteria), asymptomatic patients with persistently positive APLA, and healthy controls (HC). Patients diagnosed with other inflammatory disease, .and/or with concurrent infection, and/or malignancy as well as during pregnancy or puerperium were excluded

Results: The study groups comprised of 36 patients with PAPS (age 50.25±16.4 yrs.), 10 asymptomatic APLA-53.5±18.4 yrs.) and 21 HC (30.19±6.3 yrs.). Of the PAPS group, 30 patients (83.3%) had) positive patients thrombotic and/or obstetrical features prior to the study encounter (past PAPS), while 6 patients (16.7%) were evaluated at the time of PAPS-related thrombotic event (current thrombotic PAPS). The mean plasma sTREM-1 level was significantly greater in the PAPS group compared to HC (98.1±95.0 pg/ml, vs. 45.5±10.46 pg/ml, p=0.0013), between current thrombotic PAPS and HC (p=0.0002) and asymptomatic APLA (64.3±28.7 pg/ml, p=0.03), as well as between past PAPS and HC (p=0.02). Plasma sTREM-1 was positively correlated with older age (r=0.59, p<0.0001), higher ferritin level (r=0.44, p=0.005), higher ESR (r=0.43, p=0.003) as well as with elevated serum creatinine (r=0.64, p<0.0001) and lower eGFR (r=-0.63, p<0.0001). Plasma level of

sTREM-1 was not different in the asymptomatic APLA group compared to HC. Plasma sTREM-1 level was significantly higher in the PAPS patients who ever had MI ($p<0.001$), stroke ($p=0.02$), venous thrombophlebitis ($p=0.02$), pulmonary embolism ($p=0.001$), and arterial thrombosis ($p<0.0001$). Plasma sTREM-1 level was neither associated with anti-cardiolipin, anti-β_2 glycoprotein I (IgG/IgM/IgA) Abs' titers and/or lupus anticoagulant positivity, nor with single-, double- or triple- APLA positivity. A multivariate regression model was used to predict the sTREM-1 level by thrombotic PAPS ever, age, diabetes mellitus, hypertension and dyslipidemia found that sTREM-1 level is independently associated with thrombotic PAPS ($p = 0.001$).

Conclusion: Our data show for the first time that plasma sTREM-1 level is significantly elevated in patients with PAPS as well as during a thrombotic PAPS event. Soluble TREM-1 might be used as a biomarker for thrombosis .in patients with PAPS

Session Date: Tuesday, November 15, 2016

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with autoimmune disorders are at risk for thrombotic events and antiphospholipid antibodies (aPL) are one of known markers of increased thrombotic risk. The aims of our cross-sectional retrospective study were a) to evaluate association of different risk factors with thrombosis and b) to calculate the risk score of individual patients for experiencing thrombosis on a large cohort of unselected patients

with autoimmune diseases, treated at our secondary/tertiary medical center.

Methods: Lupus anticoagulant (LA)[1], IgG, IgM, and IgA isotypes of anti-cardiolipin antibodies (aCL)[1], anti-β2glycoprotein I (anti-β2GPI)[1] and anti-phosphatidylserine/prothrombin antibodies (aPS/PT)[1] were determined in sera of 585 consecutive patients with inflammatory rheumatic diseases and different conditions (Table 1) between January 1 and November 30, 2014. Medical records were analyzed, looking at patient age, gender, body mass index (BMI), thrombocytopenia, arterial hypertension, hyperlipidemia, diabetes, smoking, history of thrombotic or obstetric complications and current therapy including oral contraception. **Table 1: Patients' clinical characteristics**

No. of patients with	Venous Thrombosis	Arterial Thrombosis	Obstetric Complicaitons
APS (107)	52	40	39
Cerebrovascular insult (18)	3	15	1
Systemic lupus erythematosus (54)	2	0	4
Rheumatoid arthritis (14)	1	1	0
Sjogren's syndrome (34)	1	0	2
Systemic sclerosis (7)	0	0	0
Spondylo-arthritis (34)	0	0	5
Polymyalgia rheumatica (6)	2	0	0
Giant-cell arteritis (26)	1	3	1
Other Vasculitis (26)	2	2	0
Patients with different conditions (259)*	25	19	78

*Raynaud's phenomenon, migraine, depression, fibromyalgia, ischemic lesions.

Results: A univariate logistic regression revealed that BMI, hiperlipidemia, arterial hypertension, use of oral contraceptive pill and thrombocytopenia were significantly associated with thrombosis (Table 2). Among tested aPL only IgM isotype of aCL and anti-β2GPI showed no association to thrombosis. A thrombotic risk score calculation (TRS) was constructed by assigning to each of the 13 variables showing significant correlation to thrombosis, a number of points proportional to its β-regression coefficient divided by the value of the lowest β-coefficient (βx/βmin). TRS values were significantly higher in patients with thrombosis than non-thrombotic patients (median (IQR) 2 (0-7)) vs. 8 (2-13), p<0.001), showing area under ROC curve of 0.703. **Table 2: Association of risk factors to thrombosis**

Conventional risk factor for thrombosis	n	OR (95% CI)	p	β-coefficient	βx/βmin
Smoking	539	0.903 (0.589-1.383)	0.638		
Bosy mass index	488	1.561 (1.025-2.378)	0.037	0.61	1
Hiperlipidaemia	500	2.795 (1.836-4.256)	<0.001	1.51	2
Arterial hypertension	582	2.321 (1.575-3.419)	<0.001	3.85	6
Oral contraceptive pill	431	5.407 (2.039-14.340)	<0.001	13.00	21
Thrombocitopenia	569	1.907 (0.995-3.654)	0.049	2.36	4
Diabetes	529	1.471 (0.701-3.087)	0.305		
aPL association to thrombosis	**n**	**OR (95% CI)**	**p**	**β-coefficient**	**βx/βmin**
LA	358	2.8 (1.7-4.7)	<0.001	2.686	5
aCL IgG	582	2.4 (1.6-3.9)	<0.001	1.361	3
aCL IgM	582	1.4 (0.7-3.1)	0.341		
aCL IgA	582	5.3 (1.0-28.9)	0.034	0.917	2
anti-beta IgG	582	2.5 (1.5 -4.2)	<0.001	0.881	2
anti-beta IgGM	582	1.4 (0.7-2.9)	0.409		
anti-beta IgGA	582	2.6 (1.4 -5.07)	0.003	1.163	2
aPS/PT IgG	582	3.3 (1.7-5.9)	<0.001	1.686	3
aPS/PT IgM	582	2.0 (1.1 -3.5)	0.022	1.154	2
aPS/PT IgA	582	2.6 (1.2-5.3)	0.009	0.500	1

Conclusion: Our results show that, in addition to various conventional risk factors, aPS/PT (all isotypes), aCL (IgG and IgA) and anti-β2GPI (IgG and IgA) associate with thrombotic risk in patients with autoimmune diseases. Calculation of a TRS accounting for significant conventional risk factors and aPL, better assesses thrombotic risk in different patients with autoimmune diseases compared to evaluating individual or just conventional factors alone.

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Complement activation is proposed as one of the major thrombophilic mechanisms in antiphospholipid syndrome (APS). Among three complement pathways (classical, alternative and lectin), activation of classical pathway triggered by the immune complexes (IC) composed of antiphospholipid antibodies (aPL) has been considered as the mainstream of the phenomenon. However, we have reported that in APS patients, the serum IC levels were relatively low, and antibodies against C1q, the first component of the classical pathway that boost the complement activation immunologically are highly present. Recently, in vitro reports revealed that beta-2 glycoprotein I, a major target of aPL, interacts with the factor H (FH), one of the complement regulatory factors (CRF). CRF are the group of proteins that suppress the excessive activation of complement pathway mainly in the alternative pathway, of which activation spontaneously cleaves C3 and spreads activation to the late complement components thus contributes to the acceleration of inflammation. Membrane cofactor protein (MCP) and FH are the two major CRF that inhibit the C3 cleavage. The former inhibits the cleavage on cell surfaces, and the latter soluble components. We evaluated them in APS patients.

Methods: The patients with connective tissue diseases including APS that visited the Hokkaido University Hospital rheumatology clinic during 2000 and 2013 were enrolled. The solid-phase enzyme-linked immunosorbent assays (ELISA) were performed as to detect the excessive activations of different complement pathways qualitatively (Wieslab® Complement system Screen, Euro Diagnostic). Serum MCP levels (MCP ELISA kit, Cloud-Clone) and FH levels (factor H human ELISA kit, Human Innovative Research) were also tested. Autoantibodies against FH were determined by western-blotting which detects the antibodies in 10% of patients with atypical hemolytic uremic syndrome, according to the previous reports (Moore et al, Blood, 2010 etc.).

Results: Twenty-six patients with primary APS (PAPS), 45 systemic lupus erythematosus (SLE), and 56 other autoimmune diseases (control) were enrolled. Serum complement levels of PAPS as well as SLE were low compared with control (C3: 85.9±35.6, 73.0±51.5 vs 109.4±42.8 mg/dl). In PAPS, 22/26 (84.6%) showed normal serum IC levels. Excessive complement activations over 99 percentile of normal healthy controls were observed in 5/26 for the classical pathway and 4/26 for the alternative pathway. The serum levels of MCP were in normal range in all the groups. On the contrary, serum FH levels were significantly depleted in PAPS as well as SLE compared with control (median 180.1, 146.1 vs 368.5 μg/ml, $p < 0.0001$). In PAPS, serum FH levels were positively correlated with serum C3 levels ($p = 0.015$, $R^2 = 0.502$), however no significant correlation with the presence of any aPL was confirmed. Autoantibodies against FH were not detected in any of the patients.

Conclusion: Complement activation in APS patients were multifactorial partly due to activation of classical pathway with less contribution of the circulating IC and the activation of alternative pathways mainly due to depletion of FH.

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Oxidized low-density lipoprotein (oxLDL), a key molecule in atherogenesis, serves as the source of anionic charged particles that bind to beta2glycoprotein I (B_2GPI) and reinforces procoagulant activity or concomitant atherosclerosis in the presence of antiphospholipid antibodies(aPL). High density lipoprotein (HDL) is the major molecule not only blocks arteriosclerotic/procoagulant function of oxLDL but helps prevent LDL from oxidation with the assistance of HDL-associated proteins such as paraoxonase type 1 (PON-1) and apolipoprotein A-1 (ApoA-1).In antiphospholipid syndrome(APS), as well as in systemic lupus erythematosus (SLE), autoantibodies against HDL are prevalent and inversely correlate with serum HDL levels which may in turn, be associated with the production of oxLDL. In this study, we identified autoantibodies against HDL(aHDL), PON-1(aPON-1) or ApoA-1(aApoA-1) and explored their correlations with oxLDL in patients with APS.

Methods:

This study was designed as a retrospective and cross-sectional study and comprised a total of consecutive patients with primary APS (PAPS) (n=24),SLE (n= 47) and non-lupus connective tissue diseases (others)(n=19) who visited Hokkaido University Hospital Rheumatology clinic during 2009 and 2012. Blood samples of 52 healthy controls (healthy) were also investigated. Lupus anticoagulant assays and aPL ELISAs (IgG/M of anticardiolipin antibodies, anti-B_2GPI antibodies and phosphatidylserine dependent antiprothrombin antibodies) were performed in all patients.In-hose ELISA was used to detect aHDL, aApo-A1 and aPON-1 according to the previous report (Batuca *et al*, Rheumatology(Oxford), 2009). Serum oxLDL levels were measured with a commercial ELISA (MDA-oxLDL, Human, ELISA Kit,Biomedica, UK). Kruskal-Wallis test was employed to analyze the data of three or more groups

Results:

Among the patient groups, serum levels of lipoproteins (LDL, HDL) and the prevalence of statin treatment were comparable, while serum levels of oxLDL were significantly elevated in PAPS (PAPS vs. SLE vs. others (mean+/-2SD): 3.27+/-6.89 vs. 1.69+/- 4.35 vs. 0.8 +/- 3.72 mg/ml, $p<0.05$). Titers of aHDL were similar among the patient groups, while the titers of aApo-A1 and aPON-1 were significantly elevated in PAPS (aAPO-A1vs. PAPS vs. SLE vs. others vs. healthy (means +/-2SD) 0.93+/-0.63 vs. 0.63+/-0.94 vs. 0.45+/-0.50 vs. 0.42+/-0.96 mg/ml $p<0.002$) (aPON-1: PAPS vs. SLE vs. others vs. healthy(mean+/-2SD) 148+/-182 vs. 116 +/- 196 vs. 72.6 +/- 156 %positive control, $p<0.005$). In PAPS, patients with positive (over healthy control 99 percentile) aAPO-A1 and aPON-1 were significantly prevalent. Either antibody was positive in 14/24 of PAPS, whilst in SLE and others were 14/47 and 7/19, respectively ($p<0.01$). Double positivity (aApo-A1 and aPON-1) was found in 5/24 PAPS, 5/47 SLE and 1/19 in others($p<0.01$). None of the aPL or total aPL titers (aPL scores) correlated with autoantibodies related to HDL nor with oxLDL levels.

Conclusion:

Elevated oxLDL in PAPS may be one of the causal mechanisms of the disease and might be consequence of the impairment of the antioxidant function of HDL induced by the presence of aApoA-I and aPON .

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Risk of recurrence after a first episode of venous thrombo-embolism (VTE) is strongly correlated to VTE characteristics. Indefinite anticoagulation is recommended for patients with unprovoked VTE. VTE is the most frequent manifestation of antiphospholipid syndrome (APS). However a search for antiphospholipid antibodies (aPL) is not systematically performed after a provoked thrombosis. And although long-term anticoagulation is usually advised in APS, some authors have suggested stopping anticoagulation in provoked VTE. We aimed to determine the features of venous APS, according to the provoked or unprovoked nature of the first thrombotic event.

Methods: We performed a retrospective study of patients who met Sidney criteria of APS, revealed by VTE. Provoked event was defined as major if VTE occurred < 12 weeks after surgery, after ≥ 3 days strict immobilization, or after lower-limb fracture and as minor if VTE occurred during travel, immobilisation, sepsis, oestrogen treatment or pregnancy. Other VTE were considered unprovoked.

Results: The files of 57 women and 30 men, with a mean age of 36.2 +/- 16.1 years were reviewed. VTE presented as: deep vein thrombosis (DVT) n= 46/87, pulmonary embolism +/- DVT n= 41/87. Laboratory exams revealed: lupus anticoagulant n = 67/87, triple positivity n = 38/87. VTE was provoked by major factors in 9 and minor factors in 36/87 patients. Pregnancy and oestrogens were involved in 29 cases. Mean follow-up was 121.7 +/- 73.1 months: 27 patients presented with one or more further thrombosis; the 1st recurrence was venous in 22 and arterial in 5/27 patients; 11/27 occured under anticoagulation. We found no correlation between clinical features and 1st recurrence. We observed one death related to catastrophic APS, and six major haemorrhages. In bivariate analysis, the unprovoked nature of VTE was associated with a higher age, male sex, dyslipidemia and past history of VTE. In multivariate analysis, we found no correlation between the nature of VTE and clinical or biological features at diagnosis or during follow-up.

Conclusion: Provoking factors are frequent in venous APS. In this venous APS cohort with numerous high risk-profile patients, provoked nature of VTE was not correlated to clinical or biological features. A search for aPL should be advised in young patients with VTE even if thrombosis is provoked. This study does not support the

hypothesis of a lower risk-profile of APS patients with provoked VTE.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pathogen-associated transient antiphospholipid antibodies suggest a microbial trigger for antiphospholipid syndrome (APS). We hypothesized that the gut microbiota could represent a chronic stimulus in APS patients and defined the fecal microbiome and IgA-coated microbiota in APS patients over time and correlated them with autoantigen-related responses.

Methods: Anti-β_2-glycoprotein I (β_2GPI)-positive APS patients, patients with non-autoimmune thrombophilic states, and healthy donors were sampled at 3 time points (0, 4 and 8 weeks). Sixty stool samples of 22 APS patients, 13 samples of 6 controls, and 49 samples of 19 healthy donors were collected to date including dietary and medication history as well as HLA-DR53 genotype. PBMC proliferation to β_2GPI was determined by [^{3}H]-thymidine incorporation and autoantibodies against β_2GPIdomain I using a standardized kit (Inova). Stool DNA was PCR-amplified using barcoded primers targeting the V4 region of the 16S rRNA gene. Samples were sequenced using 2x250bp paired-end reads on an Illumina MiSeq instrument and analyzed using Quantitative Insights Into Microbial Ecology (QIIME) and Linear Discriminant Analysis Effect Size (LEfSe) methods.

Results: PBMCs from HLA-DR53+ APS patients responded preferentially to β_2GPI compared to controls. APS versus control fecal microbiomes showed a significant decrease in the genus *Bilophila* and an increase in the genus *Slackia* within the family of *Coriobacteriaceae* across multiple time points. 59% of APS patients but none of the control subjects were persistently positive for anti-domain I (DI) antibodies. Anti-DI IgG positivity correlated significantly with increased abundances of *Slackia* and a decrease in the butyrate-producing genus

Butyricimonas ($p<0.01$ for each taxon).

Conclusion: High-throughput sequencing of APS gut microbiomes revealed a persistent enrichment of the genus *Slackia* over time, particularly among the anti-DI IgG+ APS patients. *Slackia* is capable of producing phospholipids including cardiolipin. We speculate that gut commensal-derived cardiolipin contributes to a conformational change of β_2GPI exposing DI, thereby promoting autoreactivity against the major B cell epitope. Reduction of the butyrate producer *Butyricimonas* might associate with less regulatory T cells allowing for stronger proliferation towards β_2GPI as butyrate is known to directly induce this cell type. In summary, this ongoing microbiome study represents the first 16S rRNA community profiling in APS patients and uncovered an altered microbial community with potential implications for the pathogenesis of APS that will be tested in follow-up studies.

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Current classification criteria for definite antiphospholipid syndrome (APS) recommend the use of one or more of three positive standardized laboratory assays, including anticardiolipin antibodies, lupus anticoagulant, and antibodies directed to β(2)glycoprotein I. Several other autoantibodies have been proposed to be relevant to APS. The aim of the study was to assess the prevalence of non-criteria anti-phospholipid antibodies (APL) in patients diagnosed with systemic lupus erythematosus (SLE) and their association with APS diagnosis and its clinical manifestations.

Methods: The 449 subjects meeting SLE ACR classification criteria were evaluated. The following non-criteria APL were assessed by ELISA using standardized techniques: anti-phosphatidyl ethanolamine (aPE), anti-prothromin (aPTR), anti-phosphatidyl serine (aPS), anti-annexin V (AnV).

Results:

Non-criteria APL included aPTR in 28.1% patients, aPS in 19.7% patients , AnV in 24.2% patients, aPE in 21.1% SLE patients. In 127 patients with SLE APS was diagnosed. The diagnosis of APS was associated with the presence of aPE (OR:5.69) and aPTR (OR: 2.51). The risk of developing thrombosis occurred in patients

with presence of AnV IgG (OR 4.06), aPTR (OR 2.61) and aPS (OR 2,10).The presence of aPE IgM (OR 4.41), aPS (OR 2.27) and aPTR (OR 2.04) were risk factors for pregnancy failures. Epilepsy was significantly more common in patients with presence of aPE IgM (OR 4.75) and aPE IgG (OR 4.30).

Conclusion: Non-criteria APL are relatively common in patients with SLE and demonstrate a significant association with the diagnosis of APS, as well as its most important clinical symptoms.

Session Date: Tuesday, November 15, 2016

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: 1) To identify and characterize microRNAs linked to thrombosis and atherosclerosis development in APS; 2) To assess the effects of antiphospholipid antibodies in that epigenetic process.

Methods: Six microRNAs proven to be involved in atherothrombosis development (miR-124-a, -125a, -125b, -146a, -155, and -222), were quantified in purified leukocytes from 23 APS and 56 healthy donors. In parallel, pro-inflammatory and prothrombotic proteins and oxidative stress markers were evaluated at both, plasma and cellular levels. Proteins related to the biogenesis of miRNAs (Drosha, Dicer, Ago-1, Ago-2 and Xpo-5) were quantified by RT-PCR and Western blot. The clinical cardiovascular disease (CVD) profile was further recorded in APS patients. In vitro experiments were performed in endothelial cells (ECs), monocytes, and neutrophils, which were treated with anti-phospholipid antibodies of IgG isotype (aPL-IgG) purified from APS patients' serum, or with IgG from healthy donors (IgG-NHS).

Results: Levels of microRNAs in neutrophils were lower in APS than in healthy donors. Accordingly, gene and protein expression of miRNA biogenesis-related molecules were reduced. In monocytes, miR124a and -125a

were low, while miR-146a and miR-155 appeared elevated. The expression levels of some miRNAs differentially expressed in neutrophils and monocytes significantly correlated with parameters related to autoimmunity, thrombosis, inflammation and oxidative stress. Association studies showed that the occurrence of thrombotic events and the presence of a pathological increase in the CIMT were linked to altered levels of a number of miRNAs in neutrophils and monocytes, as well as with low levels of proteins related to miRNA biogenesis. An additional control group, including 20 patients with thrombosis but without aPL was evaluated. Thrombotic patients displayed a specific profile of miRNA expression that differed from that of APS patients, thus indicating a differential mode of regulation and activity. In vitro treatment of neutrophils, monocytes, and ECs with aPL-IgG antibodies deregulated microRNAs expression, and decreased miRNA biogenesis-related proteins. Accordingly, aPL-IgG antibodies induced upregulation of MCP-1, TF and VCAM-1, and downregulation of eNOS, relevant markers of endothelial dysfunction, and potential targets of the miRNAs evaluated. Monocyte transfections with pre-miR-124a and/or -125a validated the data obtained, causing reduction in atherothrombosis-related target molecules.

Conclusion: 1. Specific miRNAs might act as modulators of atherothrombosis in APS patients. 2. Antiphospholipid antibodies regulate CVD in APS, at least partially, by regulating the biogenesis and the expression of miRNAs. Funded by CTS7940, PI15/01333.

Session Date: Tuesday, November 15, 2016
Session Title: Antiphospholipid Syndrome - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is an autoimmune thrombophilia characterized by recurrent thromboembolism and or pregnancy morbidity in the presence of antiphospholid antibodies (aPL). Major auto antigen is B2 Glycoprotein I (B2GPI). APL form immunocomplexes with B2GPI and activate platelets leading to thrombus formation. Previous studies have shown that APS patients have higher circulating levels of platelet derived chemokines. Among them CXCL4, a proinflammatory chemokine with antiangiogenic properties, has already been proven to bind and dimerize B2GPI leading to the formation of a triple complex,

aPl-B2GPI-CXCL4, which strongly activates platelets. Therefore, we aimed to investigate the pharmaceutical disruption of the B2GPI-CXCL4 interaction.

Methods: An in vitro binding assay was developed for the study of B2GPI-CXCL4 interaction. Briefly, 1 μg/ml B2GPI was coated overnight on high binding polystyrene plates and CXCL4 was incubated in various concentrations for 2 hours. Detection of CXCL4 was performed using a biotinylated polyclonal goat anti-human antibody against CXCL4 followed by Streptavidin-HRP incubation with TMB as substrate. Next in silico molecular docking experiments using the MAESTRO and GLIDE (Schrodinger Inc.) software determined the exact interaction residues of CXCL4 and B2GPI. A number of oligopeptide CXCL4 fragments was screened according to their capacity to bind on B2GPI on the interaction interface with CXCL4. The amino acid sequence of the most promising was further modified in order to achieve high binding strength and optimal solubility properties. Finally, four oligopeptides were designed and synthesized. These oligopeptides were tested using the aforementioned assay for their ability to bind on B2GPI and consequently to inhibit B2GPI-CXCL4 interaction. B2GPI was incubated with the oligopeptides prior to the addition of 10ng/ml of CXCL4.

Results: Preincubation of B2GPI with the peptides resulted in partial inhibition of B2GPI-CXCL4 interaction in all cases. Among them one presented the highest inhibiting properties which resulted in 40% inhibition of CXCL4 binding on B2GPI.

Conclusion: Preliminary results show that the designed peptides exhibit inhibiting properties. Further experiments and possibly amino acid alterations are required to determine their exact efficiency. Once desirable inhibition and solubility properties are achieved these oligopeptides could be tested as lead compounds for potential therapeutic agents.

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Venous thrombotic events (VTE) are the most common complications in patients with persistently positive aPL antibodies (aPL+)[1] · The pathogenesis of VTE is multifactorial, and not all aPL+ individuals develop thrombosis[2]. ABO blood type, a determinant of plasma levels of von Willebrand factor (vWF), is an established VTE risk factor in the general population, but not in aPL+ patients. In the general population, non-type O blood type is associated with a higher risk of VTE. The objective of this study was to investigate the association between ABO blood type and VTE in aPL+ patients.

Methods: We included patients >18 years old followed at an urban tertiary care center between 2000 and 2015 with the serologic criteria for aPL positivity by the revised Sapporo Criteria (anticardiolipin IgG or IgM >40 IU, and/or anti-beta-2- glycoprotein1 IgG or IgM >40 IU or positive lupus anticoagulant measured twice at least 12 weeks apart)[3] and a type and screen. VTE were verified by radiological criteria and historical records. Data including age, sex, race, body mass index, smoking status (ever smoker), blood type, hypertension, diabetes, and ever use of aspirin or warfarin were ascertained from chart review. Odds ratios of VTE were estimated with logistic regression models for O vs. non-O blood type. Because there was a significant statistical interaction between sex and ABO, the results were stratified by sex. Logistic regression models were adjusted for age, sex, race, DM, HTN, and smoking status.

Results: Of the 226 study patients, 47 (21%) were men. The rates of VTE were 33% overall, 38% among men, and 32% among women. Overall, men were slightly older, more likely to smoke and to receive anticoagulation (Table 1). There was no association between blood type and VTE in the overall sample (Table 2). However, the frequency of non-O blood type was significantly higher in men with VTE than in men without VTE, 72% and 35%, respectively. The odds of VTE were significantly higher among men with non-O blood type compared to men with O blood type, adjusted OR 4.7 (1.2, 18.7), p=0.03. The association between ABO and VTE was not significant among women. There was no association between ABO blood type and arterial thrombosis.

Conclusion: The association between ABO and VTE varies by sex in aPL+ individuals. Non-O blood type is associated with a higher risk of VTE in men, but not in women. The effects of ABO blood types on vWF in aPL+ individuals may be attenuated by genetic and environmental factors that differ by sex. Understanding the relationship between sex, ABO, and aPL may elucidate thrombosis mechanisms of VTE in aPL+ individuals.

Table 1. Baseline Characteristics of aPL positive Patients by Sex

Patient Characteristics	aPL positive women n=179	aPL positive men n=47	p-value
Age at aPL measurement, median (IQR), years	43 (29, 53)	47 (38, 63)	0.02
Black race, n (%)	57 (36)	16 (36)	0.92
Hispanic ethnicity, n (%)	61 (23)	11 (43)	0.22
History of diabetes, n (%)	63 (35)	22 (46)	0.15
History of hypertension, n (%)	112 (62)	36 (75)	0.08
Ever smoked, n (%)	56 (33)	23 (49)	0.04
Low Density Lipoprotein> 100 mg/dl, n (%)*	60 (53)	9 (27)	0.01
Body Mass Index, median (IQR), kg/m2	28 (23, 34)	28 (25, 36)	0.55
Aspirin use	88 (48)	26 (54)	0.48
Anticoagulant use	72 (40)	27 (56)	0.04
Prednisone use	88 (48)	26 (54)	0.47
SLE by ACR/SLICC Criteria	61 (36)	9 (21)	0.06
Non-type O blood type	91 (48)	23 (50)	0.80

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Antiphospholipid Syndrome - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Domain(D)I is the immunodominant epitope of antiβ2-glycoproteinI(aβ2GPI) and in several studies antibodies to DI were shown to be associated with clinical manifestations of APS. Herein, we aimed to describe the prevalence, correlations and clinical associations of IgG/IgA/IgM aβ2GPI and aDI in an APS cohort of patients from Turkey.

Methods: Serum was obtained from 75 patients with: primary APS, n=31; systemic lupus erythematosus (SLE) and APS, n=44. IgG/IgA/IgM aβ2GPI, aDI and IgG anticardiolipin (aCL) were measured by ELISA. Positivity was defined as titres > 99th percentile of the mean activity of healthy control cohort. Cut-offs for positivity were: 17GPLU; 9GBU; 14GDIU for IgG aCL/aβ2GPI and aDI, 18MBU; 21MDIU for IgM aβ2 GPI and aDI, and 9ABU; 8ADIU for IgA aβ2 GPI and aDI respectively. Lupus anticoagulant (LA) was measured in the clinical laboratory of Istanbul Faculty of Medicine. Triple positivity was defined as IgG aβ2GPI/aCL and LA; double positivity as LA/IgG aCL, LA/IgG aβ2GPI or IgG aCL/aβ2GPI and single positivity as LA or IgG aCL or IgG β2GPI.

Results: 76% of the patients were female. The mean age and duration of disease were 40±11 years and 114±92 months respectively. 17 patients suffered arterial thrombosis (AT) only, 23 venous thrombosis (VT) only, 5 AT + VT, 15 pregnancy morbidity (PM) only, 13 thrombosis and PM and 2 catastrophic antiphospholipid syndrome. The prevalence and the titers of the tested antiphospholipid antibodies(aPL) are shown in tables 1 and 2. There were patients with single positivity for IgA aDI (n=2) and aβ2GP1 (n=1) and they all suffered vascular thrombosis. Comparison of the vascular thrombosis only and PM only groups revealed a significantly higher IgM aDI positivity (table1) and titer in the PM only group (mean, interquartile range; 14, 8 vs 22,15 respectively; p=0.04) There were 10 triple positives, 19 double and 49 single positives. 80% of patients with triple positivity had vascular thrombosis and all had IgG aDI antibodies. There was a positive correlation between IgG aβ2GP1 and DI ($p<0.05$). 58 % of double and 27 % of single positives had IgG aDI antibodies.

Conclusion: We found a high prevalence of IgA aβ2GP1 and aDI in this cohort. Given that some patients with thrombosis had single positivity for IgA aβ2GP1 and aDI, these tests may help to recognize a small group of patients with APS. Significantly more patients with PM only were positive for IgM aDI. Whether testing IgM aDI

may be of value in relation to PM needs to be validated. Despite lacking significance, the positivity for IgG aDI was higher in the vascular thrombosis group. IgG aDI was more frequent in triple-positives most of whom had thrombotic events. There was a positive correlation between IgG aDI and aβ2GPI which may show that DI is the major antigenic target in β2GPI and that IgG aDI antibodies can be used to identify APS patients with a high thrombotic risk. **TABLE** THE PREVALENCE OF THE TESTED aPL

	All patients (n=75)	Vascular Thrombosis only (n=45)	PM only (n=15)	P
IgG anti-β2GPI	17%	19%	14%	NS
IgA anti-β2GPI	36%	38%	43%	NS
IgM anti-β2GPI	36%	34%	36%	NS
IgG anti-DI	20%	26%	7%	NS
IgA anti-DI	36%	45%	29%	NS
IgM anti-DI	29%	21%	57%	**<0.05**
IgG aCL	29%	28%	29%	NS
LA	58%	57%	54%	NS
