Session Date: Sunday, November 13, 2016
Session Title: Quality Measures and Quality of Care - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with autoimmune conditions have higher rates of pneumococcal disease and they are often immunosuppressed. In 2014, the Advisory Committee on Immunization Practices issued new guidelines recommending vaccination with the 13-valent pneumococcal conjugate vaccine (PCV-13) for immunosuppressed patients. However, only 12% of patients on immunosuppression were vaccinated at our academic referral center. Our aim was to use the Institute for Healthcare ImprovementÕs Model for Improvement to increase the PCV-13 vaccination rate from 12% to 40%.

Methods: Plan-Do-Study-Act (PDSA) methodology was used over 3 cycles within a large rheumatology practice. Patients were eligible for vaccination if they were prescribed disease modifying antirheumatic drugs (DMARDs), biologic agents, or prednisone. Prior to the start of the intervention, vaccination rates were reviewed between 5/1/2014 and 3/1/2015. PDSA Cycles included: (1) Investigator-led educational session for providers regarding risks of pneumococcal disease and benefits of new vaccine (3/1/15 to 5/1/15); (2) Medical assistant (MA) training, utilization of the electronic medical record (EMR) by messaging patients if there was no documentation of their vaccination status prior to visit (5/1/15 to 7/1/15) (3) Creation of a paper form for MAs to complete and indicate patient eligibility followed by MAs writing electronic pended orders, if appropriate. (7/1/15-4/1/16) On a quarterly basis, vaccination rates were abstracted from the EMR (Apex and Clarity) and vaccination rates were tracked using p-charts.

Results: 9 rheumatology fellows, 11 faculty members, 1 nurse practitioner and 9 medical assistants participated in the quality improvement activity. Prior to the intervention, 12% patients had received a PCV-13 vaccination in clinic over a 10-month period. After the third PDSA cycle, over 52% of eligible patients received a PCV-13 vaccination (see Figure).

Conclusion: Targeted education for clinicians and medical assistants in conjunction with using EMR tools for patient reminders and MA-generated orders increased rates of pneumococcal vaccination from 12% to 52% in our large academic rheumatology practice. Ultimately, paper reminders for providers and pended orders by the MAs, in addition to previous interventions, resulted a sustained increase in vaccination rates over a 9-month period without further interventions. Future work will include surveying stakeholders and identifying remaining barriers to vaccination to further increase vaccination rates.

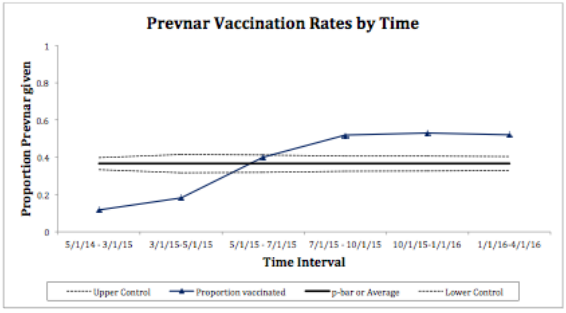

Figure 1. The dark blue triangles show the proportion of patients vaccinated with PCV13. The upper and lower control limits describe the variation of the denominator (different numbers of immunosuppressed patients were seen in each time period). The p-bar shows the average.

Herpes Zoster Vaccine: A Quality Improvement Study in Rheumatoid Arthritis Patients

Rochella A. Ostrowski and **Hina Chaudhry**, Rheumatology, Loyola University Medical Center, Maywood, IL
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Quality Measures and Quality of Care - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Herpes Zoster Vaccine: A Quality Improvement Study in Rheumatoid Arthritis Patients Chaudhry, Hina S.; Ostrowski, Rochella A. Division of Allergy, Immunology, and Rheumatology, Loyola University Medical Center, Maywood, Illinois

Background/Purpose: The ACR recommends herpes zoster (HZ) vaccination prior to use of non-biologic and biologic disease modifying anti-rheumatic drugs (DMARDs) in RA patients and for those currently on non-biologic DMARD therapy. We evaluated the success rate of HZ vaccination or a documented discussion with eligible RA patients and whether it was affected by educational intervention.

Methods: In June 2015, a lecture on indications for HZ vaccine was given to the rheumatology practice at a single academic center; a pocket guide was provided. Records of RA patients over the age of 60 on medications including those in Table 1 were reviewed. Rates of HZ vaccination or a documented recommendation for the vaccine were compared between August 2014 and August 2015 (before and after the educational lecture). Patients excluded were those with HIV/AIDS, malignancy, tuberculosis therapy, pregnancy, prednisone > 20 mg/day (>/=2 weeks), biologic or contraindicated non-biologic DMARD, or documented fever at the visit. Clinical information was compared between the 2014 and 2015 groups. Fisher's exact test was used to compare the primary outcome in each year. Logistic regression was used to adjust for potential confounders. An anonymous survey was given to identify challenges to HZ vaccination

Results: 91 RA patients met inclusion criteria, 36 in 2014 and 62 in 2015, including 7 duplicate patients (Table 1). In 2014, 25% (9 patients) had a documented discussion or received the HZ vaccine; 22.2% received the vaccine while 33.3% already received it. In 2015, the rate of vaccination or documented discussion increased to 37% (23 patients). 8.7% received the vaccine (23% already received it). The difference in rates did not reach statistical significance. In multivariate analyses, the primary outcome not significantly affected by age, gender, race, year (surrogate for educational intervention), and clinic location. Only individual physician as a factor was significant (p=0.01).

Conclusion: Compliance rates were low for HZ vaccine in eligible RA patients despite educational intervention. Based on survey results, contraindication was the top reason for not giving the vaccine (Figure 1). However, 71.6% patients met criteria for vaccination. Ways to improve compliance include innovative use of electronic medical systems, creation of specialty prevention clinics, improved availability of the HZ vaccine, and increased education for practitioners. Additional studies are warranted to explore ways to improve HZ vaccination rates in eligible RA patients. **Disclosures**: H. Chaudhry, None; R. Ostrowski, None.

Identifying Barriers to Zoster Vaccination Rates Among RA Patients in an Academic Rheumatology Practice

Ami Joglekar[1], **Ashley Blaske**[2] and Narender Annapureddy[3], [1]Department of Medicine, Division of Rheumatology, Vanderbilt University, Nashville, TN, [2]Internal Medicine/Pediatrics, Vanderbilt University, Nashville, TN, [3]Vanderbilt University, Nashville, TN

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The risk of herpes zoster (HZ) infection in patients with rheumatic disease is 1.5 to 2 times that of the general population. The 2012 ACR Treatment Guidelines for rheumatoid arthritis (RA) added HZ vaccination as a

recommendation in accordance with CDC guidelines. Studies have shown HZ vaccination rates among RA patients ranging 1%–21%. We assessed HZ vaccination rates based on documentation in an academic practice with a focus on location of primary care provider (PCP).

Methods: A retrospective chart review of 639 RA patients (one-time ICD 9 code 714.0) seen by physician rheumatology providers from December 1, 2014 to June 30, 2015 was conducted. 50% of all eligible patients per provider were randomly selected for chart review. Patients with RA age ≥ 60 were included. Exclusion criteria were: 1. age < 60 2. biologic therapy 3. prednisone ≥ 20 mg/day for ≥ 14 days; MTX > 0.4 mg/kg/wk; azathioprine > 3 mg/kg/day 4. ongoing chemotherapy or radiation OR cancer remission < 3 mos 5. immunodeficiency 6. solid organ transplantation 7. HIV patients with CD 4 count < 200 8. pregnancy. An additional 61 patients were excluded for the following reasons: wrong diagnosis, seen outside the time frame, or not seen in rheumatology clinic. The primary outcome was vaccination status and difference in vaccination rates based on location of PCP. Chi-square was used to compare categorical variables.

Results: 193 patients met inclusion criteria. 89.2% were white and 77.3% female with a mean age of 70.15 yrs. (SD = 7.54, range: 60-98). 110 (56.7%) were Medicare beneficiaries and 44 (22.68%) were privately insured. Nearly all visits (97.9%) were follow-up visits. 73.2% had inactive disease. Of the 144 with internal PCPs, 30% were vaccinated vs. 8% of 49 with external PCPs. 12.4% of patients had a documented history of herpes zoster. 72% of patients were on MTX (4 pts on ≥ 20 mg) and 54.64% on prednisone (2 pts on > 10 mg). 27 (13%) of patients were vaccinated with 11 vaccinations given within the institution. Total vaccination percentage was 13.9% with 92.6% of the vaccinations appropriately given. Vaccination was addressed by the rheumatologist in 7.7% of patients.

Conclusion: Patients with internal vs. external PCPs were about 4 times more likely to be being vaccinated based on documentation. There was no difference in vaccination status based on insurance, disease duration, age of patients, or history of HZ. Similar to prior studies, rates of vaccination in eligible RA patients continue to be low even in large academic centers. Interventions to improve vaccination rates must be further explored with focus on collaboration between PCPs and rheumatologists.

Random Forest Models Using Electronic Health Record Data Are Predictive of One-Year Outcomes in Lupus Nephritis Patients Taking Mycophenolate Mofetil Induction Therapy

Bethany J Wolf[1] and **Jim Oates**[2,3], [1]Public Health Sciences, Medical University of South Carolina, Charleston, SC, [2]Medical Service, Rheumatology Section, Ralph H. Johnson VAMC, Charleston, SC, [3]Medicine/Rheumatology & Immunology, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) outcomes are affected not only by patient biology but also by patient, provider, and system factors. One way to improve outcomes in LN is to use a systems approach to stratify all patients in a population by their risk for LN treatment failure. We have demonstrated that traditional and novel biomarkers obtained at the time of renal biopsy can be used to create random forest machine learning models of one-year treatment outcomes. However, to predict system-level outcomes for care coordination, one must leverage available electronic health record (EHR) data to model outcomes. This project was designed to determine the effectiveness of using currently available EHR data to create random forest models predictive of one-year outcomes in LN.

Methods: 212 LN patients from one academic prospective cohort and two clinical trials of lupus nephritis were selected as follows. LN was defined by International Society for Nephrology/Renal Pathology Society (ISN/RPS) renal biopsy classification within two months of baseline data collection. All patients were started on mycophenolate mofetil as induction therapy. The following data were collected at the start of induction: age, sex, race, biopsy class (ISN/RPS), C3, C4, and DNA antibody levels, UPrCr, and estimated glomerular filtration rate (eGFR, Chronic Kidney Disease Epidemiology Collaboration formula). One-year complete response outcome was calculated from baseline and one year eGFR and UPrCR using the ACR renal response criteria modified for the LN and Rituximab trial. Random forest models were created in using the baseline EHR variables above to predict a one-year outcome of complete response versus partial response or treatment failure. A separate test set from 1/3 of the data was created for reporting the receiving operator characteristics area under the curve (ROC AUC).

Results: The model predicted the outcome in the test set with an ROC AUC of 0.74.

Conclusion: These results demonstrate that treatment response in patients on mycophenolate mofetil induction therapy can be predicted with a reasonable level of accuracy using data available in the EHR. This level of accuracy is sufficient to prioritize care coordination efforts to patients most at risk. The ideal implementation of this model would calculate the risk score in near real time in the EHR. Because the ISN/RPS classification is not typically reported in discreet fields, natural language processing would be necessary to extract these data. To have impact at a population level, the risk score must be visible in population level reports or dashboards so that high risk patients can be targeted for assistance to reduce patient, provider, and system barriers to good outcomes.

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The increase in therapeutic options for our Pediatric Rheumatology patients has led to improved outcomes but has increased the number of immunocompromised (IC) patients. A reliable method of identifying IC patients is essential to their care. However, there is currently no automated method in our electronic medical record (EMR) that identifies a patient as IC. Relying on physician or staff identification of IC has the potential for human error and/or oversight, is time consuming and has not been standardized. The aim of our study was to formulate an IC operational definition to be used in an automated report via our EMR to accurately identify patients who should be classified as IC based on their current diagnoses and/or medications.

Methods: An operational definition of IC status was constructed and included 173 ICD-10 diagnostic codes and 617 immunosuppressant medications. These parameters were assembled in an EMR grouper-based report that was able to filter and flag IC patients scheduled in our clinic. Our EMR report's performance was tracked by comparing its identification accuracy to a pediatric rheumatologist and nurse evaluation. Daily reports for five consecutive weeks were

screened including a total of 448 patients scheduled. These comparisons were tracked and adjustments were made to operational definition based on EMR failures.

Results: In total, 214 patients were found to be IC during our data collection, based on multi-provider consensus. The physician and nurse continued to produce instances of human screening error, but our EMR performance steadily improved during our period of analysis. (Chart 1) The most common reason for our EMR failure to capture patients was formulation variations in our commonly utilized medications. Taking into account its cumulative improvement overtime, our EMR was able to capture 84% of the IC patients. The accuracy of the EMR is anticipated to reach 100% as we are able to obtain a complete list of all the names used for Methotrexate and Etanercept.

Conclusion: We have demonstrated that using EMR to identify IC patients is a unique and effective method that will provide level of reliability 3 (LOR#3). Automated identification of IC patients in Pediatric Rheumatology is efficient and will ultimately lead to better outcomes for our complex patient population. We believe that our EMR process of identifying IC patients is transferrable to other subspecialties and centers caring for similar at-risk patients. Once the operational definition for the EMR is perfected, we will use the EMR identification of IC to generate an automated report of Hepatitis B and Pneumococcal serologies, vaccination data, as well as Tuberculosis screening. In addition, we will be able to automatically notify other healthcare providers of IC status that will assist with potential harmful exposures such as live virus vaccines.

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In the setting of today's heroin epidemic, hepatitis B infection remains a significant public health concern, especially for patients with immunocompromising conditions. With reports of up to 25% mortality associated with hepatitis B reactivation while on immunosuppressive therapy, these patients should be thoroughly screened with hepatitis B surface antibodies (anti-HBsAb) for evidence of immunity, in addition to hepatitis B core antibodies (anti-HBcAb) and hepatitis B surface antigen (HBsAg) for evidence of acute or chronic infection. Our aim was to develop a process to reliably complete hepatitis B screenings on patients receiving intravenously infused biologic medications within the rheumatology division at Cincinnati Children's Hospital Medical Center (CCHMC).

Methods: Providers within the rheumatology division recognized common barriers to obtaining hepatitis B serology. Eligible patients included all rheumatology patients receiving intravenous biologic therapy between January 2016 and June 2016. Interventions implemented during the study included education of clinic providers and nurses, pre-visit planning resulting in ordering of serology, and the development of physician "talking points" for patients.

Results: Prior to the intervention, only 4 patients had a complete set of hepatitis B serology obtained within the past year. Anti-HBsAb, anti-HBcAb, and HBsAg serologies were pre-ordered to be drawn at the time of infusion encounters, so there were very few misses (see Figures 1 and 2). The intervention began in January 2016 by targeting patients receiving infliximab, and expanded in April 2016 to include all rheumatology patients receiving infusions of abatacept, belimumab, golimumab, rituximab, and tocilizumab. By June 2016, a total of 109 patients had updated hepatitis B serology. We were able to identify that 71% of patients had negative or indeterminate results for anti-HBsAb and will require repeat vaccination. Much to our surprise, we identified 1 patient on infliximab with a positive anti-HBcAb, presumably from transplacental transmission. This patient is now being monitored by hepatology for re-activation of chronic hepatitis B infection.

Conclusion: We were able to successfully develop a method to update hepatitis B serology for at-risk rheumatology patients on biologic therapy. Next steps will be to develop a process to reliably provide vaccines for patients identified as seronegative; expand this process to screen all patients identified as immunocompromised within rheumatology; and then expand this process to other divisions at CCHMC.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hepatitis B reactivation in the setting of rituximab use is a potentially fatal but preventable event. The rate of hepatitis B screening in patients receiving rituximab treatment is unknown. We used electronic health record (EHR) data to examine the proportion of patients who received adequate Hepatitis B screening prior to starting rituximab and also assessed patient and provider factors associated with inadequate screening.

Methods: Data derive from the EHR of a university health system, including diagnosis grouper codes, problem lists, medications, laboratory results, procedures codes, clinical encounter notes, and scanned documents. Data were extracted through back-end access to the EHR and supplemented via chart review by 2 physicians. We defined a cohort of patients who received rituximab between 6/1/2012 and 3/1/2016 (“index date”). We calculated the proportion of rituximab users who received inadequate screening for hepatitis B according to the Centers for Disease Control guidelines for detecting latent Hepatitis B infection (Hepatitis B surface antigen and Hepatitis B core antibody tests) prior to their first rituximab infusion during the study period. We used a relative risk regression model to identify independent predictors of inadequate testing. Variables included in the models were decided a priori and based on previously reported predictors of risk for Hepatitis B that may have influenced a provider’s decision to screen.

Results: 926 patients received rituximab during the study period. Mean age was 49 years; 50% were women; 51% were white. Most received rituximab for treatment of lymphoma (52%), kidney transplant rejection (10%), or multiple sclerosis (10%)– only 6% of orders were written by rheumatologists, for diagnoses such as vasculitis (4%) and rheumatoid arthritis (2%). Additional patient characteristics are shown in the Table. 565 (61%) patients had adequate screening for Hepatitis

B; 214 (23%) had no Hepatitis B test documented at all. Nephrologists treating renal transplant rejection were most likely to have adequate screening (90%). Multivariate regression showed that the strongest predictor of inadequate screening was department of the ordering provider (see Table).

Conclusion: We found wide variations in Hepatitis B screening practices among patients receiving rituximab, resulting in unnecessary risks to patient safety. Strategies including provider education, use of checklists, and clinical decision support within the EHR should be developed to improve rates of screening in this high-risk patient population.

Monitoring Hepatitis B Screening Compliance in Patients with Rheumatoid Arthritis (RA) Receiving Anti-TNF Therapy

Vedashree Panthulu[1] and John Waterman[2], [1]Rheumatology, University of Connecticut Health Center, Farmington, CT, [2]Rheumatology, Connecticut VA Healthcare System, Newington, CT

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The risk of infection in patients with RA is higher than in comparable patients but still the vaccination rates in RA patients are low. The recent 2015 American College of Rheumatology guidelines for the treatment of rheumatoid arthritis **strongly recommended serologic testing and vaccination for hepatitis B** before and during anti-TNF therapy.

Methods: Patients who were getting anti-TNF therapy at the **VA Connecticut Healthcare System Newington campus** were identified from review of pharmacy records. 52 patients were identified after reviewing the charts of which **25 patients** met the **2010 American College of Rheumatology classification criteria for RA** and were included in this study. 27 patients taking anti-TNF therapy but who did not have RA were excluded (psoriatic arthritis, psoriasis, seronegative spondyloarthropathy etc). Hepatitis B serology was reviewed using the electronic medical record lab data base.

Results: 18 patients came to the VA for medication after being started on anti-TNF therapy by their private rheumatologists while remaining 7 were started at the VA. Only 2 (8%) patients had accurate hepatitis B serology, 7 (28%) had incomplete serology namely Hepatitis B Core ab was missing (4 were co-managed by private MD) and 16 (64%) patients had no Hepatitis B serology (14 were co-managed by private MD). The 23 identified patients lacking appropriate hepatitis B serology testing were contacted and the need for hepatitis B serology and vaccination was discussed. After further lab testing - 3 patients were found to be immune for hepatitis B, 2 patients had isolated anti-HBc status who on further testing had negative PCR for Hepatitis B viral load (i.e. resolved HBV infection) & 1 patient was lost to follow up. The remaining 19 patients underwent start of successful vaccination schedule for Hepatitis B.

Conclusion:

1. In our study sample we found **very poor and incomplete compliance (92%)** to hepatitis B screening in RA patients receiving anti-TNF therapy & majority of them (72%) were being co-managed by private rheumatologist.
2. We were able to **successfully vaccinate the RA patients** against Hepatitis B.
3. This study has also brought to our attention the need to **address the critical knowledge gap for the need to check Hepatitis B core ab levels**. Incomplete screening can lead to dangerous complications of reactivation of Hepatitis B**.** We found 2 patients with resolved HBV infection who needed close monitoring to prevent reactivation of Hepatitis B while on therapy.

The Prevalence of Latent Tuberculosis and Hepatitis B Found after Systematic Screening of Patients Starting with Biological Therapy in a Low-Endemic Area

Marin de Jong[1,2], Danielle Roosen[1], Andy Peters[1], Valerie Verstraeten[3], Marieke Pierik[1] and A. van Tubergen[4], [1]Department of Internal Medicine, division of Gastroenterology, Maastricht University Medical Centre, Maastricht, Netherlands, [2]NUTRIM – School for Nutrition and Translational Research in Metabolism, Maastricht University Medical Centre, Maastricht, Netherlands, [3]Department of Dermatology, Maastricht University Medical Centre, Maastricht, Netherlands, [4]Department of Internal Medicine, Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologicals are a powerful treatment option for moderate to severe immune-mediated inflammatory diseases (IMID). Since biologicals modulate the immune system, the risk for reactivation of latent infections with a fulminant disease course, such as tuberculosis (TBC) or Hepatitis B (HBV), is increased. Guidelines therefore recommend screening for TBC and HBV before starting biological therapy. In 2012, at the Maastricht University Medical Centre+, we have introduced a central, multi-disciplinary and systematic screening of all IMID patients starting biological therapy. Prevalence data from systematic screening for latent TBC infection (LTBI) and HBV in patients prescribed biological therapy in a low-endemic area have not been reported thus far.

Methods: All IMID patients commencing biological treatment from May 2012 through July 2015, were included. Screening consisted of a detailed medical history on risk factors for LTBI (e.g. previous diagnosis of TBC, close contact with a TBC-infected person, previous living outside Europe, North-America and/or Australia) and HBV infection (occupation, history of intravenous drug abuse, sexual behaviour), a Quantiferon test (QFT), serology for HBV (HBs-Ag, anti HB-core) and a chest X-ray.

Results: In total, 547 of 549 patients (99.6%) starting biological therapy were screened. One patient (0.2%) tested positive for HBV without having reported any risk factor. Table 1 shows that 22 patients (4.0%) tested positive on QFT and were classified as LTBI patients. Of these, 14 did not report any risk factor, 18 had always lived in The Netherlands and 18 had never travelled outside of Europe, North America or Australia. Four patients had abnormalities on chest X-ray, 3 of them also tested positive on QFT and the other one turned out to have sarcoidosis, not LTBI. All LTBI patients were treated with isoniazid therapy. After a mean follow-up period of 19.8 ±8.8 months none of the patients had a reactivation of LTBI after the start of biological therapy.

	QFT Positive N=22	QFT negative N=525
Medical history, N (%) Risk factors No risk factors	8 (36.4) 14 (63.6)	37 (7.0) 488 (93.0)
Chest X-ray, N (%) Positive Negative	3 (13.6) 19 (86.4)	1 (0.2) 524 (99.8)

Table 1

Conclusion: The overall prevalence of LTBI and HBV in patients prescribed biological therapy in a low-endemic area is 4.0% and 0.2%, respectively. Systematic screening by means of QFT and HBV serology seems more reliable than history taking and chest X-rays alone. Since implementation of systematic screening of IMID patients, none of our patients showed reactivation of LTBI or HBV during biological therapy.

Nurse Scheduled Telephone Visit: The Right Rheumatology Care for the Right Patient at the Right Time

Shazdeh Butt[1], Eric Newman[2] and Natasha Smith[1], [1]Rheumatology, Geisinger Medical Center, Danville, PA, [2]Department of Rheumatology, Geisinger Medical Center, Danville, PA

First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Quality Measures and Quality of Care - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rising healthcare costs have resulted in greater patient burden, higher health insurance costs, deductibles, and copayments. Access to care is delayed and problematic. Many of our patients have well controlled disease, yet scheduled follow up is based on patterns of behavior rather than disease control or patient needs. How we can deliver the right care for the right patient at the right time?

Methods: We proposed and developed a new visit type within our electronic health record (EHR) – a Nurse Scheduled Telephone Visit (NSTV). This was a scheduled encounter with the nurse via telephone. The nurse called the patient and collected data including disease activity measurement (RAPID3), events, problems, or symptoms that occurred since the last visit (probes) and assessed need for medication refills. The assessment was assigned one of two statuses – 1) RAPID3 with low disease activity AND all probes negative AND no refills needed, or 2) ANY of these items needed attention. The encounter was routed to the patient's rheumatologist. If status = 1, the encounter could be closed. If status = 2, further action was needed by the provider. Using PDSA (plan do study act) process improvement methodology, a pilot (cycle 1) was conducted. Patient travel cost and co-pay cost savings were calculated. The patients completed a survey after the NSTV. Based on the positive results in cycle 1, cycle 2 included presenting results to other rheumatologists seeking their insight to use this visit type across a broader array of patients and providers.

Results: **Cycle 1**: 6 of the 6 completed NSTVs had status = 1 and 1 requested a call back from his physician (status = 2) (Table 1). **Cycle 2**: 70 patients were enrolled over 2 months. Out of these, 14 completed visits thus far. 13 had status =1 and only 1 requested a call back from his physician (status = 2). Patients showed similar savings by avoiding co-pays and transportation costs in both cycles (Table 2). Our survey results showed 100% patient satisfaction. By extrapolating these results to our database of RA patients where 50% (1,200 patients) are in low disease activity or remission, using NSTV will reduce 1 visit per year and open up an additional 300 hours of clinic time.

Table 1: Nurse Scheduled Telephone Visit: Survey Results

	Patients who completed visit	Was this phone call more convenient to you?	Did this phone call save you time and money?	Do you prefer this phone call over an office visit?
Cycle 1	6	6	6	6
Cycle 2	14	14	14	14

Table 2: **Nurse Scheduled Telephone Visit: Cost and Convenience Analysis**

Cost saved	Co-pay	Transportation cost	Total cost saved	Time saved
Cycle 1	$14	$28	$42	1 hour and 34 min
Cycle 2	$24	$42	$65	2 hours and 45 min

Conclusion: As healthcare moves towards a value-based system, we propose the NSTV as a solution to improve patient experience, minimize cost burden to the patient, and increase access to care. It was well accepted by the patients and providers as an efficient resource in a busy clinic setting. It improved access in the clinic and reduced cost for the patient.

It Takes Two, an Interdisciplinary Approach to Increasing Hydroxychloroquine Screening Adherence

Christina Downey[1], Tombra Govina[1] and Eric Newman[2], [1]Geisinger Medical Center, Danville, PA, [2]Department of Rheumatology, Geisinger Medical Center, Danville, PA
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a widely used rheumatologic drug that carries a risk for irreversible retinal toxicity. The incidence of adverse effect increases to greater than 1% beyond the five year mark and screening is recommended annually beyond this time. This risk is mitigated through screening exams; 10-2 visual field testing (VF) and spectral domain optical coherence tomography (SD-OCT). In our practice setting, several visits to ophthalmology are needed to complete the screening. First the patient makes an appointment for consultation with the ophthalmologist, who then orders the testing to be done at a later date and finally the results are reviewed with the ophthalmologist.

Methods: To analyze the problem, the electronic medical record (EMR) was reviewed to identify the patients who have been on HCQ for five years or more. These patients were then cross-referenced with system procedure codes for the American Academy of Ophthalmology recommended monitoring options for HCQ related retinal toxicity in addition to the 10-2 visual field testing (VF) and (SD-OCT). Letters were sent to patients with brief education and a request to schedule an appointment. The investigators collaborated with the ophthalmology department to create a work flow for HCQ screening. Schedulers were educated about methods of screening and coached to schedule the required testing without an initial ophthalmology visit. This process streamlined the usual ophthalmology scheduling process, which involves seeing the ophthalmologist initially followed by a return visit(s) for the recommended screening and a return visit for test review.

Results: Of the 183 patients on HCQ longer than 5 years, 58.4% have not been screened. Chart review unearthed 183 patients on HCQ longer than five years. 148 of these patients did not have billing codes for screening tests in the EMR. Manual chart review revealed an additional 41 screened patients. Overall, the increase in monitoring for patients within the system was increased by 41.8%.

Conclusion: The pre-intervention process for HCQ monitoring was prohibitive for patients to receive timely monitoring. When patients called the ophthalmology scheduling department they were first scheduled with an ophthalmologist to establish the goal for the appointment. This initial visit is unnecessary if the only purpose of the visit is HCQ screening, as the guidelines are very specific. Further, the wait time to see an ophthalmologist is approximately three months or longer. There is additional wait time for an appointment for the visual field and SD-OCT testing post appointment. Tests meant to be performed annually could take four to six months to schedule and complete. Patients who identify themselves as requiring an ophthalmology appointment for the sole purpose of HCQ monitoring should be scheduled immediately for VF and SD-OCT without an initial visit with an ophthalmologist. The cumbersome appointment process was unknown to rheumatologists. It was only in working in an interdisciplinary fashion that the process was able to be more patient centered and timely.

Are Providers Recommending Appropriate Screening for Hydroxychloroquine-Induced Retinal Toxicity to Their Patients?

Sarah Haserodt[1], Chris Tonner[2], Gabriela Schmajuk[3] and Jinoos Yazdany[4], [1]Internal Medicine, California Pacific Medical Center, San Francisco, CA, [2]Rheumatology, University of California, San Francisco, San Francisco, CA, [3]San Francisco VA Medical Center, University of California, San Francisco, San Francisco, CA, [4]Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although well tolerated by most patients, hydroxychloroquine (HCQ) can cause irreversible retinal damage. The American Association of Ophthalmology (AAO) 2016 Guidelines recommend a baseline eye exam and then annual exam after 5 years of HCQ use in patients without risk factors for retinopathy. In this study, we evaluated whether patients who are receiving HCQ were counseled to receive screening for HCQ-induced retinal toxicity and whether screening procedures were congruent with AAO Guidelines.

Methods: We analyzed system-wide electronic health records (EHR) from a large, academic health center to identify 704 patients with a face-to-face encounter in which HCQ was prescribed between 1/1/2014- 3/14/2016. A random sample of 200 patients was chosen for further analysis. 19 patients were excluded because they were not taking HCQ or did not have >1 visit with a rheumatology or dermatology clinician based on chart review. Baseline characteristics of the patients were identified through queries of structured EHR fields. Physician chart review was used to determine if counseling on the need for retinopathy screening was documented and if patients had seen an ophthalmologist. Chi-square tests were used to determine if there was a significant difference in recommended retinopathy screening intervals based on clinical department. Among the subset of patients seen by an ophthalmologist within our system, we determined whether tests were performed according to AAO guidelines.

Results: Of the 181 patients included in the study, 82% were female, the mean age was 40±18.7 years, 43% were Caucasian, 23% were Asian, 17% Hispanic, 5% African American, and 12% other/multiple. The mean Charlson score was 2.1±2.6 and the majority (63%) had private insurance. 152 (84%) of the patients were counseled to undergo screening for HCQ-mediated retinopathy. Table 1 lists the screening intervals recommended by clinicians, which varied significantly by department. Interestingly, of the 69 incident HCQ users, only 2 were counseled to delay annual ophthalmologic exams until 5 years of HCQ use, the recommended interval for new, low-risk users per the AAO guidelines. 115 (64%) patients saw an ophthalmologist for retinopathy screening within the study period. Of the 48 patients who were seen by ophthalmologists in our system, 25 (51%) received the more sensitive screening tests now recommended in the AAO Guidelines.

Conclusion: In our study, a majority of patients were counseled by clinicians to receive screening for HCQ-mediated retinopathy. However, very few clinicians recommended the screening interval established by the AAO 2016 Guidelines for incident users, with most suggesting yearly screening regardless of duration of use. Additionally, many patients did not receive appropriate screening for HCQ-mediated retinopathy, despite the fact that it was recommended, highlighting an area for future quality improvement efforts.

Table 1- Screening Interval for HCQ-mediated Retinopathy Recommended by Prescribing Providers in Rheumatology and Dermatology Departments

	Rheumatologists (N=21)	Dermatologists (N=18)	
	N=135 patients	N=46 patients	
Screening interval recommended by physician			P<0.001
0 months - < 1 year	9 (7)	5 (11)	
Yearly	77 (57)	14 (30)	
Retinal toxicity screening recommended, no interval specified	22 (16)	25 (54)	
No documentation of need for retinal toxicity screening	27 (20)	2 (4)

Incidence of Gastrointestinal Events and Physician Compliance of Co-Prescribing Proton Pump Inhibitors in Chronic NSAID Users with Osteoarthritis, Rheumatoid Arthritis and Ankylosing Spondylitis

Arina Garg, Rakeeba Din, Daniel Torres Leyva, Maryam Hasan, Ma Moe and Bruce Garner, NYU Lutheran Medical Center, Brooklyn, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The most common group of patients with chronic use of NSAIDs include those with rheumatic diseases such as osteoarthritis (OA), rheumatoid arthritis (RA) and ankylosing spondylitis (AS). Serious GI complications such as bleeding, perforation and obstruction occur in about 1.5% of chronic NSAID users, while about 15% of patients report dyspepsia daily. Guidelines recommend co-therapy with PPIs or misoprostol and/or the use of COX-2 selective inhibitors in chronic NSAID users at high risk for GI events. Most such patients do not receive PPI co-therapy. We investigated the incidence of new GI events and physician compliance of co-prescribing PPIs to chronic NSAID users with RA, OA and AS at a large community hospital.

Methods: We conducted a retrospective cohort study using a simple random sample of 125 patients with OA, RA, AS who were started on NSAIDs between 1/1/2014- 12/31/2014 taken from ECW. Data was collected on 89 patients after excluding for age <30, duration of NSAID use <60 days, or no information on NSAID prescription. The study was divided as: 1) Inclusion period (1/1/2014– 12/31/2014) to identify NSAID prescription and PPI co-prescription. 2) Follow-up period (1/1/2015- 12/31/2015) to assess duration of NSAID/PPI use, and new GI events. 3) History period (1/12013 – 12/31/2013) to assess GI Risk Score (1 point each for Age>65 years, previous PPI use, GI symptoms, H.Pylori/EGD, aspirin, steroids, anticoagulation). Primary outcome measured was new GI event as dyspepsia, PUD, GERD or GI bleeding. We calculated relative risks of GI events by NSAID-PPI overlap time (none, some or complete), both unadjusted and adjusted for previous NSAID use, GI symptoms, cardiac disease, h.pylori/EGD, aspirin, steroids, and anticoagulant use.

Results: 13% of patients were on a PPI throughout NSAID use, 16% were on PPI for some time and 71% had no overlap of PPI. Only 17% were either co-prescribed or were already on a PPI at the time of NSAID prescription. There was a greater risk of GI event with greater raw number of days of NSAID use (Crude RR 1.002, p=0.007). After adjusting for covariates, those on PPI only some of the time were 4.67 times more likely to have a GI event as compared to those on complete overlap (p=0.003). Physicians were 5.31 times more likely to co-prescribe a PPI for patients with 1 or more GI risk factors. (Crude RR 5.31, p=0.007). Physicians co-prescribed PPIs 27% of the time in patients with high GI risk score as compared to 5% for patients with no GI risk factors (Crude p=0.002). Physicians were 5.31 times more likely to co-prescribe a PPI for patients with 1 or more GI risk factors. (Crude RR 5.31, p=0.007).

Conclusion: PPI co-therapy appears to have a protective effect on GI risk associated with chronic NSAID use in RA, OA and AS patients. Chronic NSAID users with higher GI risk factors are more likely to receive a PPI co-prescription, indicating that physicians consider patient's GI risk level when prescribing NSAIDs. However, 63% of patients who had GI risk factors did not receive a PPI co-prescription indicating incomplete adherence to clinical practice guidelines that recommend gastro-protection for at-risk chronic NSAID users. More awareness about PPI prophylaxis is needed among physicians prescribing NSAID for chronic use.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoid (GC) use and adverse effects (AEs) are prevalent in rheumatic diseases, yet there is no standardized patient-reported outcome measure to assess benefit and risk. This study aims to determine the AEs related to GCs in two cohorts of GC users and determine the benefits and risks from the patient perspective. A secondary aim was to compare AEs amongst RA patients both exposed and unexposed to GCs.

Methods: Participants in cohort 1 attended an Australian tertiary rheumatology clinic with various rheumatic diseases and were taking an oral GC currently or within the past 12 months. Cohort 2 was from the Hospital for Special Surgery RA database (all met ACR/EULAR RA criteria) and included both GC users and non-users. The survey included a checklist of 19 known AEs and an open-ended question about presence of 'other GC side effects'. The median number of AEs experienced by each patient was compared between cohorts using poisson regression. All participants were asked to rate the three 'worst' AEs. Participants exposed to GCs were asked to indicate whether GC therapy helped 'a lot', 'a little', 'not sure' or 'not at all' and the ordinal trend between groups was compared using the Cochran Armitage exact test. GC-users were also asked whether the AEs they experienced were worse than the benefits of treatment (Yes/No/Not sure), and analyzed by chi-square.

Results: There were 55 participants from cohort 1 (71% female, median age 68, range 33-89yrs) and 124 from cohort 2 (83% female, median age 63, range 27-82). The disease range amongst cohort 1 was broad, with CTDs (14/55), RA (4/55), PMR (14/55) and GCA (5/55) most common. Amongst Cohort 2, 95 (77%) had ever used GCs (GC-users) and 29 (23%) were GC non-users. The median number of AEs was higher in cohort 1(7.7, 95% CI 7.0-8.5) compared to GC users in cohort 2, (5.3, 95% CI4.9-5.8), and both were higher than GC non-users (2.6, 95%CI 2.1-3.3). All patients in cohort 1 reported at least one GC AE compared to 86% of GC-users in Cohort 2 (p=0.002). The frequency of patient reported AEs and worst AEs are shown in Table 1. In both GC use cohorts, the majority (73%/62%) felt GCs helped their disease 'a lot', 11%/21% felt they helped 'a little', 9%/8% were 'not sure' and 2%/8% felt GCs did not help at all, with no difference between groups (ordinal p=1.0). Most participants in cohort 1(55%) and 2 (64%) reported that the benefits of treatment were greater than the AEs (p=0.67).

Conclusion: Apart from weight gain, AEs that are important from the patient perspective are poorly captured using current measures, and patients with different diagnoses may rate GC AEs and benefits differently. These hypothesis generating surveys reveal the need for further study and to develop a patient reported outcome measure for GC AEs and benefits so patients with rheumatic diseases can participate in informed treatment choices.

Table 1. Frequency of Patient Reported Adverse Events and Worst Adverse Events

Adverse Effect	Cohort N=55		Cohort 2- GC Users N=95		Cohort 2- GC Non-Users N=29	
	Number Reporting as AE	Number Reporting as worst AE	Number Reporting as AE	Number Reporting as worst AE	Number Reporting as AE	Number Reporting as worst AE
Thin skin or easy bruising	45 (82%)	9/45 (20%)	44 (46%)	7/44 (16%)	4 (14%)	0/4 (0%)
For women, vaginal thrush	26/39 (67%)	0/26 (0%)	8 /77 (10%)	1/8 (13%)	2/26 (8%)	1/2 (50%)
Weight gain	36 (65%)	9/36 (25%)	40 (42%)	13/40 (33%)	4 (14%)	0/4 (0%)

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The use of opioids in treating chronic pain can be difficult and is a common problem across multiple specialties, including rheumatology. Opioid contracts have become more common place in various outpatient practices to help standardize the way in which physicians prescribe narcotic medications and sets expectations and goals for both the provider and patient[1]. Currently, our office has no formal policy on prescribing controlled substances. This has led to lack of agreement between the expectations of health care providers and those of our patients resulting in frequent, unpredictable, and unsatisfactory number of phone calls and in-person interactions between patients and our staff related to narcotic prescriptions.

Methods: The objective of the study was to determine whether implementing a narcotic contract in the section of rheumatology will improve work flow by decreasing the number of narcotic-related EPIC phone messages. A rheumatology section meeting was held in July of 2015 regarding narcotic policy within TUH rheumatology practice and formal implementation of written narcotic contract was initiated in August 2015. Using questionnaires as a subjective measurement, we polled our staff of various positions (including physicians, nurses, medical assistant, and office personnel) on their perception of the number of narcotic prescription-related patient phone interactions both 6 months before and after initiation of the contract. Furthermore, using number of EPIC messages as our objective measurement of change, we compared the number of narcotic related phone encounters resulting in a narcotic prescription and the total number of narcotic prescriptions 6 months before and after the implementation of the contract. We also compared the total number of clinic encounters resulting in narcotic prescription 6 months before and after our intervention.

Results: Upon subjectively surveying our nurses and administrative assistants who handle the majority of incoming office

phone calls, 2/4 perceived the number of narcotic-related phone calls as increasing and 2/4 thought the number of phone calls were unchanged over the one year study period. On provider surveys, 4/11 providers had patients formally sign the written contract and 6/7 providers who did not have patients formally sign the contract, verbally referred to the new policy during office visits. Seventy three percent of providers agreed that the contract had positive effect on office work flow. The total number of EPIC messages and total number of office visits resulting in narcotic prescription decreased by 20% and 16% respectively, after implementation of the contract.

Conclusion: Although, subjective perception regarding number of narcotic phone calls encountered by office personnel did not decrease based on survey responses, there was an overall objective decrease in number of phone calls after implementation of the narcotic contract.

the Majority of Biologic Injectors Are Stored Under Suboptimal Conditions at Home

Marin de Jong[1], Marieke Pierik[1], Andy Peters[1], Mark Roemers[2], Veronique Hilhorst[3] and A. van Tubergen[4], [1]Department of Internal Medicine, division of Gastroenterology, Maastricht University Medical Centre, Maastricht, Netherlands, [2]AntTail, Utrecht, Netherlands, [3]Department of Clinical Pharmacy & Toxicology, Maastricht University Medical Centre, m, Netherlands, [4]Department of Internal Medicine, Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The introduction of biologics has significantly improved long-term outcome of immune-mediated inflammatory diseases. However, after discontinuation or switch of therapy, 26-49% of patients on subcutaneous biologics have unused injectors at home, leading to spillage of these costly drugs. When drug quality is ensured by proper storage within recommended temperature ranges (2˚C-8˚C), unused injectors could potentially be redistributed reducing spillage. The aim of this study was to assess the quality of home storage by evaluating the proportion of injectors stored within the recommended temperature range.

Methods:

All subcutaneous golimumab users at the Maastricht University Medical Centre+, irrespective of the indication, were asked to participate in this prospective study between April and October 2015. During 3 months, patients received golimumab in the original package provided in a sealed bag containing a validated temperature sensor connected to the internet. Patients were asked to store their medication as usual. Temperature was measured every 5 minutes. Deviations from the recommended range were defined as 1). > 30 minutes below 2˚C or above 8˚C and 2). any duration below 0˚C. After 3 months, patients filled out a questionnaire on their opinion about monitoring medication storage conditions at home and potential redistribution of unused injectors.

Results:

In total, 50 patients (46.3% male, mean age 52.3 ± 13.8 years) received 276 injectors with temperature sensors that generated 2,466,576 measurements. Figure 1 shows that 11.6% of the injectors were stored within the recommended temperature range. Of the remainder, 11.2% were stored more than 30 minutes below 0˚C and 19.6% were stored above

8°C for more than 48 hours. Of all patients, 95% would appreciate an alarm when the injector is not stored under the right conditions, and also 95% is willing to accept unused medication when product quality is ensured.

Conclusion:

Only a minority of injectors was stored within the recommended temperature range. This hinders not only redistribution of unused biologics, but is also alarming regarding the effectiveness of the drug in these patients. We are currently investigating how to improve biologics' home- and transport storage conditions and the criteria to be met for redistribution.

Abstract Number: 441

Improving Care and Avoiding Errors. Can Our Patients Recall Their Medications and Create an Accurate Medication List?

Carla F Gamarra-Hilburn and Salvador Vila, Department of Medicine, Division of Rheumatology, University of Puerto Rico Medical Sciences Campus, San Juan, PR

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Medications errors are common and are an important cause of morbidity and mortality. We aimed to evaluate patient accuracy in recalling current medication use, doses and reasons for taking the medications in a general rheumatology outpatient clinic.

Methods: This is a descriptive study of 100 consecutive patients who attended clinic and voluntarily accepted to fill a

single questionnaire. The questionnaire consisted of name (s) of the medication (s) the patient was taking, dose, diagnosis associated with their medications, medical record number, sex and age. Once we had this information, the medical records were reviewed to look for discrepancies. Data collected was entered in Excel Files and was analyzed in STATA version 14. The information was verified and converted to groups of interest. Data whose overall category only had 5 cases were only presented as frequencies describing the patient's characteristics but were not fit for further analysis and thus they were eliminated from the bivariate and multivariate analysis. Association of variables was determined using a p-value < 0.05. To assess our objectives, frequency distributions were made to describe the characteristics of the patients. Then chi squares analysis were done for categorical variables in order to determine if they were associated to our variables of interest. For continuous variables such as age and number of prescriptions a t-test was performed. At last a logistic regression was done when we found characteristics that were significantly associated with our variable of interest. In the logistic regression we also assessed whether or not interaction among the variables existed in order to find the best explanation to the associations found between variables.

Results: We had 85 females and 15 males. Mean age was 47.13 ± 14 years. The average number of prescriptions per patient was six. Lack of knowledge regarding reason for taking medications was seen in 35 patients; fifty five did not recall the dose of medications prescribed. Discrepancies between the patient's and the electronic medical record medication list were identified in 71, with an average of two per patient; the majority of them were patient derived. The most common medications involved in errors were antidepressants/anxiolytics (19), vitamins (18), immunosuppressants (13), NSAIDS (12), antihypertensives (12) and anti-acids (9). The most common diagnosis in our clinics were fibromyalgia (33), osteoarthritis (16), RA (17), SLE (13) and others (26). The most common prescribed medications were antihypertensives (41), antidepressants (38), prednisone (25), hydroxychloroquine (25) and immunosuppressants (22). No significant associations were found between variables of interest.

Conclusion: Although most of our patients know the medical condition associated with a medication, the majority of them cannot precisely recall a medications list. This is a very important factor that can lead to medical errors. Patients should be educated regarding the importance of keeping an accurate medication list.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Quality Measures and Quality of Care - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Subcutaneous (SC) anti-TNF agents such as Golimumab (GLM) Adalimumab (ADA), Etanercept (ETA) and Certolizumab pegol (CZP) have been used for many years for the treatment of inflammatory arthritis. It is known that across diseases, and especially with chronic diseases, adherence to therapy is an important modifiable factor that may compromises treatment outcomes. The aim of this analysis was to compare adherence and dosing interval of SC anti-TNF in the treatment of inflammatory arthritis.

Methods: We used the IMS Brogan database which combined both private (PDP) and public drug plans databases of the provinces of Ontario (OPDP) and Quebec (RAMQ). Target drugs included SC anti-TNF biologics for indication of

rheumatoid arthritis, ankylosing spondylitis, and psoriatic arthritis combined. The Index period was from January 1, 2010 - June 30, 2012 and patients were followed for 24 months through June 30, 2014. Patient selection criteria were adult patients newly prescribed a target biologic drug with at least three prescriptions and retained on therapy at 24 months. Recommended dose regimens as per the Canadian product monographs were used to compare actual vs. expected drug utilization. The compliance rate (MPR) was calculated as the estimated days' supply in the defined period divided by the number of days in the defined period. Patients who scored >80% were considered adherent. For dose-interval analysis, the average days between units was estimated by taking the total days on therapy and dividing by the number of units the patient received. A unit is a syringe or vial; the total amount of drugs dispensed (in mg) were standardized at units as per the following: GLM: 50 mg; ADA: 40 mg; ETA: 50 mg; CZP: 200 mg. P-value obtained from Chi-square and Pair-wise comparison tests for statistical differences on the proportion of adherent patients; p-value < 0.05 is considered to be statistically significantly different.

Results: There were 4,035 new patients on target biologic drugs with at least three prescriptions and retained on therapy at 24 months. The number of patients for each biologic drug used was 683, 1400, 1765 and 187 for GLM, ADA, ETA and CZP, respectively. The data source was as follow: PDP national (N=2509), RAMQ (N=634) and OPDP (N=892). In 24 months-retained patients, there was a greater proportion of GLM-treated adherent patients (n=595/683, 87%, $p<0.0001$) compared to ADA- (n=1044/1400, 75%), ETA- (n=1285/1765, 73%) or CZP-treated patients (132/187, 71%). We also investigated the number of patients receiving biologic drug at a shorter dosing interval. That proportion was similar between groups and was 5%, 6%, 12% and 4% in GLM- (≤26 days), ADA- (≤12 days), ETA- (≤6 days) and CZP-treated patients (≤12 days), respectively.

Conclusion: In this real life Canadian administrative database, GLM has better adherence compared to other SC biologics. The reason for this difference and impact on long-term outcomes are currently under investigation.

Repetitive Requisition of Antinuclear Antibody Testing (ANA) in Outpatient Multispecialty Clinics in Patients with a Known Positive ANA

Laura Amorese-O'Connell[1], Pinky Vaidya[2], Durkhani Mahboob[2], Charis Gn[3] and Stuart Schwartz[4], [1]Rheumatology, Brown University, RI hospital, Providence, RI, [2]Rheumatology, Roger Williams Medical Center, Providence, RI, [3]Internal Medicine, Rhode Island Hospital, The Warren Alpert Medical School of Brown University, Providence, RI, [4]Brown Medical School, Providence, RI

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ANA test is a commonly used initial screening for connective tissue diseases (CTD). The ultimate clinical utility of this highly sensitive test depends on the pretest diagnostic probability. It should not be a first line test for the investigation of musculoskeletal symptoms like fatigue or joint pains, unless accompanied by other clinical features to suggest autoimmune disease. It can be positive in multiple autoimmune and mixed connective tissue disorders. It can also be falsely positive in multiple other scenarios. ANA test rarely needs to be repeated. It is a diagnostic, not monitoring test. If an unexpected result is given, it is reasonable to repeat the test to confirm the finding. It is also useful to repeat if a person's illness has significantly changed. It, however, has no correlation to disease activity in SLE or other CTD. A trend of repeating ANA testing on patients with a history of positive ANA was noted in our outpatient multispecialty clinic. The purpose of this study is to review how frequently patients with known positive ANA testing undergo repeat ANA testing, the reason for it and the specialty and level of training of providers ordering it.

Methods: Retrospective chart review was performed on 598 patients who underwent ANA testing between April 1st, 2015 and March 31st, 2016. Data collected included: Age, gender, positive ANA test result, reason for ordering ANA, specialty and level of training of provider ordering ANA. Patients with a positive ANA were identified first followed by review of number of repeat ANA testing after first positive result. Data analyzed using percentage to determine frequency of events.

Results: Of the total of 598 patients undergoing ANA testing between April 1st 2015 and March 31st 2016, 196 (32.8%) patients had a positive result. All patients were older than 18 years, 140 (71.4%) were females and 56 (28.6%) were males. Repeat ANA was noted in 111 (56.6%) patients. Of those, 58 (52.2%) patients had repeat testing once, 23 (25.5%) twice, 11 (9.9%) three times, 8 (7.2) four times, 2 (1.8%) five times, and 9 (8.1%) six or more times. There were 2 patients who underwent repeat ANA test 33 and 56 times. A total of 194 (64.4%) of 301 providers ordering repeat ANA testing were identified. Rest were not available. Most were rheumatologists 76 (39.1%) and primary care physicians 67 (34.5%). Remaining included gastroenterology, pulmonary, dermatology, nephrology and emergency medicine. Majority of repeat tests wherein data was available (172 total) were ordered by attending physicians 162 (94.1%).

Conclusion: Further education and emphasis should be given on appropriate ANA testing criteria in order to decrease misuse and increase cost effectiveness.

Improvement in Knee Arthrocentesis Via Constant Compression

Tej Bhavsar[1], Wilmer Sibbitt Jr.[1], Romy Cabacungan[1], Timothy Moore[1], Luis Salayandia[1], Roderick Fields[2], Arthur Bankhurst[3], Suzanne Emil[1], Monthida Fangtham[1] and Konstantin Konstantinov[4], [1]Rheumatology, University of New Mexico, Albuquerque, NM, [2]Internal Medicine/ Rheumatology, University of New Mexico School of Medicine, Albuquerque, NM, [3]Rheumatology, University of NM Medical Center, Albuquerque, NM, [4]1 University Of New Mexico, University of New Mexico, Albuquerque, NM

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthrocentesis has emerged as a highly valuable diagnostic and therapeutic intervention for rheumatic diseases since first standardized by Hollander in the 1950's. Successful arthrocentesis of the knee, to decompress the effusive knee and provide objective material for laboratory analysis, is contingent upon obtaining sufficient synovial fluid. As a Quality Improvement process within the Division of Rheumatology, we introduced constant compression of the knee during arthrocentesis and determined whether quality measures including aspiration success and fluid volume were improved.

Methods: This Quality Improvement project was performed within the Rheumatology Division at the University of New Mexico Health Sciences Center and assessed quality improvement of intra-procedural constant compression during knee arthrocentesis in terms of overall success, outcome and quality among individual patients. All patients undergoing knee arthrocentesis for therapeutic/diagnostic reasons were sequentially included and classified prior to the procedure as to either non-effusive (dry) vs. effusive knees as per physical examination. The more effective conventional lateral knee arthrocentesis techniques alone were undertaken rather than the less effective medial approaches. Initially the patient underwent arthrocentesis with an elastomeric knee brace placed loosely around the knee with syringe exchange maneuvers performed as required to decompress large effusions if present. Upon termination of synovial fluid return using the conventional method, the elastomeric brace was securely tightened without disturbing either arthrocentesis needle or syringe and arthrocentesis was again attempted. Quality outcome measures included: 1) trace yield of synovial fluid with

initial arthrocentesis, 2) diagnostic yield of synovial fluid (defined as ≥0.25 ml) with and without compression, 3) total synovial yield in milliliters (ml) with and without compression. Pierson Chi squares two by two table analysis was performed on categorical data calculating both p values and confidence intervals. Measurement data was analyzed using the Student t-Test calculating both p values and confidence intervals as well.

Results: There were no complications encountered by the 113 patients in the cohort including, but not limited to infection, significant bruising or other hemorrhage. At least trace synovial fluid was obtained in 83.3%. However, diagnostic synovial fluid (at least 0.25 ml) was obtained in 31.9% without compression and 46.6% with compression (p=0.0001, z for 95% CI= 1.96, Pierson). Absolute volume of arthrocentesis fluid yield without compression was 3.7±6.6 ml versus 6.6±13.0 with compression (p=0.018, 95% CI -5.5881 <-2.9< -0.2119) corresponding to a mean 2.9±6.1 ml (80%) increase in synovial fluid yield. In the subset of 87 patients with a palpably dry knee at least trace synovial fluid was obtained in 79% of patients. Diagnostic synovial fluid (at least 0.25 ml) was obtained in 13.8% without compression and 42.5% with compression (p=0.0001, z for 95% CI= 1.96). In the palpably dry knee absolute volume of arthrocentesis fluid without compression was 0.3±0.9 ml versus 1.1±2.1 ml with compression (p=0.001, 95% CI -1.2801 <-0.8< -0.3199). This corresponds to a mean 0.8±1.6 ml (266%) increase in synovial fluid yield. In the subset of 26 patients with a palpably effusive knee, at least trace synovial fluid was obtained in 100% of patients. Diagnostic synovial fluid (at least 0.25 ml) was obtained in 96% without compression and 100% with compression (p=0.2, z for 95% CI= 1.96). In the palpably effusive knee absolute volume of arthrocentesis without compression was 15.4±14.1 ml versus 25.7±15.9 ml with compression (p=0.008, 95% CI --18.4686 <-10.3< -2.1314) corresponding to a mean 10.3±9.2 ml (67%) increase in synovial fluid yield.

Conclusion: The quality and success of knee arthrocentesis can be markedly improved through the application of constant compression using a circumferential knee brace. The overall success of diagnostic/therapeutic arthrocentesis can be significantly increased with markedly improved fluid yield compared to conventional arthrocentesis in both the clinically non-effusive and effusive knee. The increased synovial fluid return and arthrocentesis also provides additional value through confirmation of accurate intraarticular needle placement. As complete arthrocentesis has been demonstrated to improve subsequent intraarticular injection outcomes, constant compression with an elastomeric knee brace is a simple and economical quality improvement maneuver that can be incorporated into clinical musculoskeletal practice and injection clinics.

Session Title: Quality Measures and Quality of Care - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: NIH's PROMIS (Patient-Reported Outcomes Measurement Information System) measures have the potential to improve and expand outcomes measurement in SLE, but have not been tested on a large scale in lupus.

Methods: Data were from the California Lupus Epidemiology Study (CLUES), a population-based, multi-ethnic SLE

cohort. All subjects' diagnoses were physician-confirmed. Subjects participated in a structured interview administered by a trained interviewer. Nine PROMIS short-forms (Table 1) were administered and scored to derive T-scores scaled to population means of 50 and SD of 10. Race and ethnicity were self-reported. Score distributions were examined. Deficits in function were defined as scores 1 SD "worse" than the population mean. Means (±SDs) were calculated for the total sample and by racial/ethnic group. Correlations with self-reported disease activity (Systemic Lupus Activity Questionnaire; SLAQ) and damage (Brief Index of Lupus Damage; BILD) were examined. We expected moderate to large correlations of current functioning with SLAQ, but small correlations with BILD. Differences in mean scores by race/ethnicity were tested by ANOVA and then in multivariable regression analyses controlling for age, sex, education, and poverty.

Results: To date, data from 197 individuals are available. The sample is 31% white, 22% Hispanic, 14% African American, and 33% Asian; 89% female; mean age 46 (±10) years; 13% with education ≤high school; 13% with poverty-level income; mean SLAQ score 8.2 (±7.3); and median BILD score 1 (IQR 0, 3). With the exception of Pain Intensity, mean scores were ±3 points of the population mean (Table 1). Correlations with disease activity (SLAQ) ranged from |0.47| — |0.73|. Correlations with disease damage (BILD) were lower, ranging from |0.1| — |0.3|, except for physical function (r=-0.38). Fewer than 5% of scores were at scale floors but relatively high proportions scored at the ceiling for 6 scales. Except for Pain Intensity, 17-30% had scores one SD worse than the population mean. In bivariate analyses, significant differences existed among racial/ethnic groups, but differences disappeared after adjusting for sociodemographic characteristics.

Conclusion: These 9 PROMIS short forms appear to function well in this multi-ethnic cohort of SLE patients. Few scores were at the scale floor, but relatively high portions were at the ceiling, suggesting potential weakness of the scales in measuring higher positive levels of function. Means were not substantially different than population means, but relatively large portions of the cohort exhibited deficits in physical and social functioning. Correlations with current disease activity were moderate to large, and correlations with disease damage were small, as expected. Differences in scores among racial/ethnic groups appear to be explained by differences in socioeconomic characteristics.

Session Title: Quality Measures and Quality of Care - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) leads to a variety of health outcomes through complex disease paths. The LupusPro (LP) is a comprehensive self-report measure which assesses health and non-health related quality of life for patients with SLE. It is increasingly used in a variety of ethnicities and diverse populations, and continues to hold psychometric integrity. Research, however, is needed that examines the validity and factor structure of the LP in order to precisely understand its psychometric integrity as an outcome measure used cross-culturally. The major purpose of this research was to evaluate the performance of the LP in two divergent patient samples and to identify differences in model fit between the two samples that would illustrate the potential for adapting the LP measure in future research.

Methods: Two diverse samples including 236 patients with SLE were included one from an ethnically-diverse, urban region in Southern California, and the other from an ethnically-homogenous, rural region in Manila, Philippines. All patients met ACR classification criteria for SLE. Confirmatory factor analyses (CFA) were conducted in each sample separately and combined to provide evidence of the factorial integrity of the 12 subscales comprising the LP.

Results: Demographic analyses indicated significant differences in age, disease activity and duration, education, income, and medication use between groups. Results of the separate CFA's indicated moderate fit to the data for the hypothesized 12-factor model for both the Manila and California groups, respectively [χ^2 (794)=1283.32, p<.001, CFI=.793; χ^2 (794)=1398.44, p<.001, CFI=.858] (note: with large scales, χ^2 less than double the degrees of freedom indicated reasonable fit). The factor structures between the California and Manila groups were constrained to be equal between the two groups, and findings revealed that the factor structures of measured variables fit the two groups reasonably well (χ^2=2950.413, df =1697, p<.000; CFI=0.811) [14]. After removing seven constraints and eight correlations suggested by the Lagrange multiplier test, the model fit improved significantly [$\chi^2(15)$ = 147.165, p < .000].

Conclusion: This research provides for significant support for the subscale structure of the LP in two disparate cultural samples of SLE patients. Despite significant sociodemographic and clinical differences between the two samples, for the most part, the LP performed similarly in both samples. Table 1. Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - ARHP Poster

Session Type: ACR Poster Session A

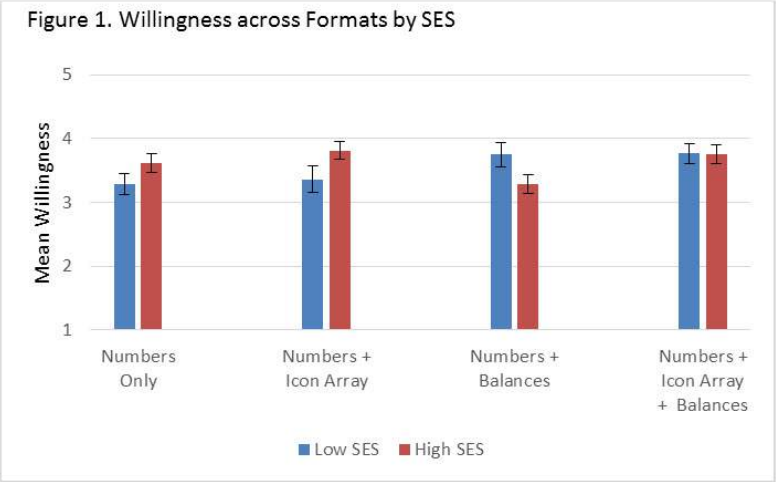
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis frequently refuse to escalate care because they overweight the probability of adverse events. Effectively communicating risk information to patients is difficult. Several approaches have been developed to facilitate comparative risks; however, recent data suggest that current approaches have a limited impact on risk perceptions and willingness to take medication. The objective of this study was to examine whether an icon array (IA), an illustration of the gist of how medications regulate the immune system (a series of balance beams), or both influence willingness to start a medication.

Methods: Patients with a rheumatic disease were mailed a survey in which they were asked to imagine that their symptoms had worsened and that their physician was recommending a new medication. We varied the probability of an adverse event (pneumonia requiring hospitalization): 2% or 0.2%, and the risk presentation format: numbers, numbers + IA, numbers + balance beams (BB), or numbers + both. Route of administration, benefit, and cost were held constant. Each subject responded to a single, randomly-assigned scenario. We controlled for socioeconomic status (SES), using a variable including both difficulty paying for medications as well as education, in a full-factorial model testing willingness to take the medication (measured on a 5-point scale).

Results: Of 1453 surveys, 465 patients completed the survey. Overall, the mean (SD) age was 59.0 (14.8); 79.7% were female; 83.2% White and 39.1% were classified as having low SES. There were no statistical differences in patient characteristics across the risk presentation formats. Willingness to start the medication was predicted by the interaction between the risk presentation format and SES ($F = 2.9$, $p = 0.03$). Willingness by SES status is described in the Figure 1. Among low SES subjects, addition of an IA did not affect willingness compared to the numbers-only format. In contrast, addition of BB (mean difference = 0.47, $p = 0.07$), or both IA and BB increased willingness (mean difference = 0.48, $p = 0.04$). Among high SES subjects, addition of an IA or BB or both did not influence willingness compared to the numbers only format. However, both formats including an IA increased willingness compared to the BB format among high SES subjects (mean difference IA vs BB= 0.53, $p =0.01$; mean difference IA vs IA + BB = 0.48, $p = 0.02$).

Conclusion: SES affects how subjects respond to risk presentation formats. IA marginally increases willingness in high SES subjects, while BB increases willingness in low SES subjects; when both IA and BB are present, SES differences disappear. BB, when not accompanied by an IA, may decrease willingness in high SES subjects. These results demonstrate the differential effects of risk presentation formats, and highlight the need to identify mechanisms underlying their effects



when implementing decision-support tools.

Session Title: Quality Measures and Quality of Care - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The computerized Animated Activity Questionnaire (AAQ) assesses activity limitations in hip and knee osteoarthritis (HKOA), and consists of video animations from which patients can choose the animation that best

matches their own performance. Application of the AAQ in international studies requires good cross-cultural validity, i.e. minimal Differential Item Functioning (DIF) across countries. The aim of this study was to evaluate cross-cultural and construct validity of the AAQ in 7 languages.

Methods: Patients in 7 European countries completed the AAQ on a computer. Ordinal logistic regression analysis was used to evaluate DIF across languages (Dutch versus 6 other languages). DIF is defined as follows: if a patient in a country has the same level of activity limitation as a patient in the Netherlands (the reference country in which the AAQ is developed), he/she should score the same on each item of the AAQ. If there is a statistical significant difference between countries, there is DIF. Construct validity was assessed by testing correlations between the AAQ and a Patient Reported Outcome Measures (PROM) and performance-based tests. Analyses were adjusted for sex, age, weight, height, and affected joint. The influence of each individual item with DIF on the total score was calculated by means of comparing the correlation between AAQ score with and without the DIF item. A Spearman's correlation of 0.95 or less was interpreted as important influence of the DIF of that item on the total AAQ score.

Results: Data of 1239 patients were available. Compared to Dutch (n=279), none of the 17 items showed DIF in English (n=202), French (n=193), 1 item showed uniform DIF in Spanish (n=99) and Norwegian (n=62), and 2 items showed uniform DIF in Danish (n=201). For Italian (n=203) versus Dutch however, 6 items showed uniform DIF, and 1 item showed non-uniform DIF, indicating some problems with the cross-cultural validity between these countries. In all the languages, the occurrence of DIF did not influence the total score with correlations of 0.98-0.99 in comparing AAQ scores with and without DIF item(s). All the translated versions remain comparable with the original Dutch version. With regard to construct validity, the correlations with PROM (0.74) and performance-based tests (0.36-0.68) were partly as expected (> 0.60).

Conclusion: The AAQ, a new construct that can be placed on the continuum between PROMs and performance-based tests showed a good overall cross-cultural validity, and seems to have great potential for international use in research and daily clinical practice in many languages.

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A newly developed and (cross-cultural) validated measurement tool, the computerized Animated

Activity Questionnaire (AAQ) for assessing activity limitations in hip and knee osteoarthritis (HKOA) patients, consists of video animations from which patients can choose the animation that best matches their own performance. For application in daily clinical practice as well as in research, the aim of this study was to determine reliability, responsiveness, and interpretability of the AAQ.

Methods: First, 238 HKOA patients mixed from hospital and rehabilitation center completed the AAQ twice with 7 days in between. Test-retest reliability (intra-class correlation coefficient (ICC)) the Standard Error of Measurement (SEM), and the Smallest Detectable Change (SDC) were calculated. Second, 92 other patients with hip or knee OA were followed for 6 months in order to assess responsiveness. Patients received conservative physical therapy treatment or joint replacement surgery and were measured before intervention and 6 months later. We hypothesized that change scores on the AAQ (score range 0-100) correlated at least 0.6 with self-report (ADL subscore of the Hip disability and Knee Injury Osteoarthritis Outcome Score,), performance based tests (Timed Up and Go test, Stair Climbing Test, and 30 seconds Chair Stand Test), and a Global Rating of Change (GRC). To estimate the Minimal Important Change (MIC) of the AAQ an anchor-based MIC distribution method was used. The Receiver Operating Characteristic (ROC) method was used to find the optimal AAQ change score that best discriminates. The MIC was compared to the SDC in order to facilitate the interpretation of change scores.

Results: ICC for test-retest reliability was 0.93 (95%CI: 0.91-0.95). SEM and SDC were 4.9 and 13.5, respectively. After 6 months the change scores of the AAQ correlated 0.67 with self-reports, 0.47-0.55 with performance based tests, and 0.43 with GRC. The ROC curve showed an area under the curve of 0.71 with a sensitivity of 62% and a specificity of 79% for the optimal MIC of 9.12 for discrimination. The MIC was smaller than the SDC meaning that the change is important but cannot be distinguished from measurement error in individual patients.

Conclusion: The AAQ showed good internal consistency, test-retest reliability, and SDC resulting in an average mean score difference of the AAQ over 14% indicating a real improvement in activity limitations in a mix of surgical and conservative HKOA patients. The AAQ is considered responsive, despite the moderate correlations with performance-based tests and GRC, which seems to be caused by the slightly different, new construct the AAQ is measuring with regard to the domain activity limitations.

Session Title: Quality Measures and Quality of Care - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: OMERACT Filter 2.0 encourages use of robust methods to develop new measures. Instrument results also should be highly relevant, easily scored and interpreted, and meaningful to stakeholders likely to use the instrument. We conducted Rasch analysis to further explore the psychometric properties OMERACT RA Flare Questionnaire (RA-FQ). We reviewed results with RA patients research partners (PRPs) to gain additional insight into the interpretability, meaningfulness, and utility of results.

Methods: People with RA in Canada (n=896), France (n=138), and the Netherlands (n=178) completed 5 items representing each of the OMERACT RA flare core domains. RUMM2030 was used to evaluate how the five items worked together, fit a unidimensional measurement continuum, and targeted the population of interest. We also evaluated reliability, response options, redundancy, local dependence, and response bias among groups (e.g., men vs. women, age categories, country/language). Ten PRPs first completed the questionnaire then reviewed individual and group findings to provide feedback.

Results: Rasch results supported use of the 5 items as a unidimensional measure of RA flare symptoms and impacts and the simply summation of items for a total score ranging from 0-50. Each item had ordered thresholds and acceptable fit. Reliability, was high (PSI =.91). Items and people covered a continuum ranging from -3.2 to +3.4 logits, and items were well-targeted to respondents. Overall model fit was excellent (χ^2 = 31.6, df=45; p=0.935). There was little evidence of differential item functioning by sex, age, or country/language. Items suggest flare symptoms and impacts increased together showing a consistent story of how individuals experience worsening RA disease activity. Among PRPs, scores ranged from 10 to 41. There was unanimous agreement from the patients that the story depicted and individual results obtained were easily understood, meaningful, and very reflective of their current state. Many patients noted that beyond clinical trials, the RA-FQ could also enhance communication between doctors and patients at routine visits. Several noted potential applicability in monitoring day-to-day status and with self management.

Conclusion: The Rasch results offer additional support for the robust psychometric properties of the RA-FQ. Feedback from RA PRPs increases confidence in the relevance, meaningfulness, and easy interpretation of RA-FQ results for clinicians, researchers, and patients.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Quality Measures and Quality of Care - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The improved Health Assessment Questionnaire (iHAQ) is a novel version of the HAQ (ACR-recommended metric of physical function for RA) based on Item Response Theory. However, there is limited evidence examining its performance in OA. Our purpose was to evaluate the cross-sectional and longitudinal construct validity of the iHAQ in knee OA.

Methods: In a randomized trial comparing Tai Chi with physical therapy among adults with symptomatic knee OA (ACR criteria), we pooled the similar treatment effect that was found and performed a cross-sectional and longitudinal analysis. Participants completed the iHAQ, Patient Global Assessment, Short Form-36, and WOMAC at baseline and after 12 weeks. We examined two iHAQ scoring methods: method A used all 20 items, method B used 16 (Range: 0-100; 100=more disability). Applying the Consensus-based Standards for the Selection of Health Measurement Instruments (COSMIN) standard to assess cross-sectional construct validity, we tested 6 *a priori* hypotheses with the expected Spearman's correlations between iHAQ scores and legacy scores at 12 weeks. After a comparison of instruments, we formulated each hypothesis with the direction, strength, and rationale for expected correlation. Longitudinal construct validity was investigated similarly but used correlations in score changes from baseline to 12 weeks. Cross-sectional or longitudinal construct validity was based on number of confirmed hypotheses: High, 5-6 of 6 (>80%); Moderate, 3-4 of 6 (80-35%); or Poor, 0-2 of 6 (<35%).

Results: In 159 participants (71% female, 57% white, mean age 61 years), the 12-week median (Interquartile Range) iHAQ scores were respectively 12.5 (3.1, 25) and 9.4 (1.6, 23) for A and B methods. The change scores from baseline were -4.7 (-15.6, 3.1) for A; and -3.1 (-12.5, 3.1) for B. All associations were in the anticipated direction **(Table 1**). Affirming high cross-sectional construct validity, all 6 respective hypotheses (100%) were confirmed for both A and B methods (**Table 2)**. Indicating high longitudinal construct validity, 5 of 6 respective hypotheses (83%) were confirmed (**Table 3)**.

Conclusion: iHAQ is able to measure its intended construct and detect changes over time among those with knee OA, which supports its consideration as a novel, recommended outcome instrument in OA.

Table 1. Spearman's Correlations between iHAQ and Legacy Measures		
Legacy Measure	**iHAQ Method A†, rho**	**iHAQ Method B†, rho**
SF-Physical Function* (Score range: 0-100)	-0.6604	-0.6729
Change SF-Physical Function	-0.4757	-0.4868
SF-Mental Health (Score range: 0-100)	-0.3812	-0.3795
Change SF-Mental Health	-0.3042	-03278
WOMAC function (Score range: 0-1700)	0.5404	0.5487
Change WOMAC function	0.4972	0.5212
SF-Role Physical (Score range: 0-100mm)	-0.4629	-0.4830
Change SF-Role Physical	-0.3734	-0.3864
Patient Global (Score range: 0-10cm)	0.4946	0.5363
Change Patient Global	0.3055	0.3299
*Cross-sectional scores were taken at 12-week follow-up. †Change iHAQ scores were correlated with change legacy measures. Change scores reflected change from baseline to 12 weeks. Note: Consensus guidelines from COSMIN do not recommend reporting *p* values of correlation coefficients for the purposes of instrument validation.		

Table 2. Hypotheses for Cross-Sectional Construct Validity of the Improved HAQ

Hypotheses	Rationale	Correlation Result(s)		Confirmed?
1. There will be a strong* (≥ 0.5) negative correlation between iHAQ and Short Form (SF)-Physical Function after intervention	iHAQ and SF-Physical Function attempt to measure similar constructs	Expect‡≥ 0.50	Method A: -0.66 Method B: -0.67	Yes
2. The positive correlation between iHAQ with SF-Physical Function will be at least 0.1 higher than the correlation between iHAQ with SF-Mental Health	iHAQ and SF-Physical Function attempt to measure similar constructs, but iHAQ and SFMH attempt to measure unrelated constructs	Expect ≥ 0.10	Method A: 0.28 Method B: 0.29	Yes
3. There will be at least a mod-strong (≥ 0.4) positive correlation between iHAQ and WOMAC Function after intervention.	iHAQ and WOMAC Function attempt to measure similar constructs, but the WOMAC function is lower limb-specific	Expect≥ 0.40	Method A: 0.54 Method B: 0.55	Yes
4. There will be at least a moderate (≥ 0.3) positive correlation between iHAQ and WOMAC Pain after intervention.	iHAQ and WOMAC Pain attempt to measure loosely-related constructs	Expect≥ 0.30	Method A: 0.49 Method B: 0.51	Yes
5. There will be at least a moderate (≥ 0.3) negative correlation between iHAQ and SF-Role Physical after intervention.	iHAQ and SF-Role Physical attempt to measure loosely-related constructs	Expect≥ 0.30	Method A: -0.46 Method B: -0.48	Yes
6. There will be at least a weak-moderate (≥ 0.2) positive correlation between iHAQ and Patient Global Assessment after intervention.	iHAQ and Patient Global Assessment attempt to measure partially related constructs,	Expect≥ 0.20	Method A: 0.49 Method B: 0.54	Yes
Cross-Sectional Construct Validity Rating: High†		**Hypotheses Confirmed: 6 of 6; 100%**		

*Correlation strength: r ≥ 0.5, Strong; 0.5 > r ≥ 0.4, Moderate-Strong; 0.4 > r ≥ 0.3, Moderate; 0.3 > r ≥ 0.2, Weak-Moderate; 0.2 > r ≥ 0.1, Weak; and 0.1 > r, Negligible. †Overall construct validity was assigned based on percent of total hypotheses confirmed: High, (5-6 of 6 (≥75%); Moderate, 3-4 of 6 (50%≤ x <75%); or Poor, 0-2 of 6 (<50%). ‡For clarity, "Expect" values are expressed as absolute values.

Table 3. Hypotheses for Longitudinal Construct Validity of the Improved HAQ				
Hypotheses	**Rationale**	**Correlation Result(s)**		**Confirmed?**
1. There will be a strong* (≥ 0.5) negative correlation between change of iHAQ and change of Short Form (SF)-Physical Function	iHAQ and SF-Physical Function attempt to measure similar constructs	Expect‡ ≥ 0.50	Method A: -0.48 Method B: -0.49	No
2. The positive correlation of change on the iHAQ with that of the SF-Physical Function will be at least 0.1 higher than the correlation of change on the iHAQ with the SF-Mental Health	iHAQ and SF-Physical Function attempt to measure similar constructs, but iHAQ and SF-Mental Health attempt to measure unrelated constructs	Expect ≥ 0.10	Method A: 0.17 Method B: 0.16	Yes
3. There will be at least a moderate-strong (≥ 0.4) positive correlation between change of iHAQ and change of WOMAC Function	iHAQ and WOMAC-Function attempt to measure similar constructs, but the WOMAC function is lower limb-specific	Expect≥ 0.40	Method A: 0.497 Method B: 0.52	Yes
4. There will be at least a moderate (≥ 0.3) positive correlation between change of iHAQ and change of WOMAC Pain	iHAQ and WOMAC Pain attempt to measure loosely-related constructs	Expect≥ 0.30	Method A: 0.43 Method B: 0.44	Yes
5. There will be at least a moderate (≥ 0.3) negative correlation between change of iHAQ and of SF Role Physical	iHAQ and SF-Role Physical attempt to measure loosely-related constructs	Expect≥ 0.30	Method A: -0.37 Method B: -0.39	Yes
6. There will be at least a weak-moderate (≥ 0.2) positive correlation between change of iHAQ and change of Patient Global Assessment	iHAQ and Patient Global Assessment attempt to measure partially related constructs	Expect≥ 0.20	Method A: 0.31 Method B: 0.33	Yes

Session Date: Sunday, November 13, 2016

Session Title: Quality Measures and Quality of Care - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are more sedentary than the general population, which can have serious health consequences. Reducing sedentary behaviour (SB) and increasing light intensity physical activity is advocated as a potentially more achievable health promotion focus in patients with chronic diseases and mobility problems. Intervention studies have shown that behavioural approaches are effective in reducing SB in healthy populations. Whether this applies to patients with RA is yet to be determined. **Objective:** To test the efficacy of a 16-week individually tailored, behavioural intervention in reducing daily sitting time, pain and fatigue and improving health-related quality of life, self-efficacy, physical function and cardio-metabolic disease risk in patients with RA.

Methods: Parallel-group, observer-blinded randomized controlled trial (N=150). RA patients >18 years of age, self-reported daily sitting time > 5 hours and Health Assessment Questionnaire (HAQ) score < 2.5 were consecutively recruited from a rheumatology outpatient clinic. The intervention group (n=75) received three individual motivational counselling sessions with a health professional and text messages aiming at improving motivation for light intensity physical activity through reduction of SB. The control group (n=75) was encouraged to maintain usual lifestyle. Primary outcome was change from baseline in daily sitting time measured objectively by ActivPAL, analyzed using ANCOVA with a factor for group and adjustment for the outcome level at baseline. Primary analyses were based on the intention-to-treat population. Secondary outcomes included patient-reported outcomes and cardio-metabolic biomarkers (blood pressure, cholesterol levels, blood glucose, body weight and waist circumference).

Results: After 16 weeks, three participants were lost to follow-up. There was a mean decrease in daily sitting time of 1.61 hours (h)/day with the intervention and an increase of 0.59 h/day in the control group; between-group difference was -2.20 h/day (95%CI: -2.72 to -1.69; p<.0001) in favor of the intervention group. Most of the secondary outcomes were also

in favor of the intervention; VAS-pain: -22.36 (-29.27 to -15.44); VAS-fatigue: -26.80 (-34.32 to -19.30), physical function (HAQ): -0.42, (-0.54 to -0.30) and total cholesterol: -0.37 (-0.50 to -0.24) mmol/l.

Conclusion: An individually tailored, behavioral intervention effectively reduced daily sitting time by on average more than two hours in patients with RA and additionally improved patient-reported clinical outcomes and cholesterol levels. The results may be important for clinical practise and physical activity recommendations for patients with RA and can most likely be generalized to other populations with chronic disease and mobility limitations.

Session Title: Quality Measures and Quality of Care - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) represents a group of heterogeneous autoimmune disorders of connective tissue characterized by progressive fibrosis of the skin and internal organs [1]. The disease spectrum ranges from localized form, which causes physical disability to more systemic forms affecting internal organs and the vasculature, which may result in life threatening crises. The SSc Quality of Life Questionnaire (SScQoL) [2] is a 29-item, needs-based tool, which measures the disease impact on health and well being of patients with SSc. The aim of this study was to adapt the English SScQoL into Spanish and to determine measurement equivalence between the two versions of the tool.

Methods: This was a cross-sectional tool validation study involving cross-cultural adaptation and cross-cultural validation phases. In the first phase, we adapted the English SScQoL into Spanish using a 5-stage process involving: forward translation, synthesis of translations, backward translation, expert committee revision and pilot testing with 30 patients [3]. This process ensured conceptual equivalence between the English and the Spanish version of the SScQoL. For the cross-cultural validation phase, we recruited adult patients with SSc who were willing and able to complete the questionnaire unaided. We collected the data from both versions of SScQoL and analysed them by comparing with the Rasch model using fit statistics. Fit to the Rasch model implies construct validity, unidimensionality, reliability and statistical sufficiency. To discount local dependency, we grouped items into the following subscales: function, emotion, sleep, social and pain and repeated Rasch analysis at a subscale level. Finally, we pooled both the UK and the Spanish data in order to test measurement equivalence between the two cultures and to calibrate the SScQoL into a logit-based interval scale.

Results: The SScQoL translated well from English into Spanish providing a conceptually equivalent version of the tool. For the validation sample comprised 121 patients from the UK (male/female = 15/106) and 106 from Spain (male/female = 16/87). Their mean (SD) age was 57.1(12.1) and 58.0 (13.9) for the UK and Spain respectively. Table 1 presents item parameters, where non-significant Chi-Square probabilities indicate that most items did not deviate from the Rasch model although local dependency was evident (data not shown). Items were grouped into the afore-mentioned 5 subscales and re-

analysed, resulting in adequate fit to Rasch model. See table 2. There was no differential item functioning by culture, thus allowing for a common scale, which can be converted into logit-based transformed scores for use in parametric analyses when required.

Conclusion: The SScQoL was adapted successfully into Spanish and satisfied the strict requirements of the Rasch measurement model, thus establishing its cross-cultural validity. The SScQoL data obtained from Spain and the UK are therefore comparable. Further research is required to determine cross-cultural validity of the SScQoL in the American Spanish populations.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: With Patient-Reported Outcomes (PROs), the patient's perspective can be assessed. Several forms can be used; Verbal Rating Scale (VRS), Numerical Rating Scale (NRS), Visual Analog Scale (VAS) and Likert-scale. Since contradictory findings exist with regard to advantages and disadvantages of these scales, the aim of this study was to assess the clinimetric properties (using OMERACT 2.0 filter) of these scales for the measurement of pain, fatigue, experienced disease activity (DA) and general well-being and to ask patients which scale they prefer most.

Methods: Patients (all fulfilling ACR criteria for RA) visiting the rheumatology outpatient clinic Bernhoven (Uden, the Netherlands) were included. They filled in a questionnaire directly after their visit, consisting of 21 items in 4 domains

using VRS, NRS, VAS and 5-point Likert scale. They were asked to fill in the same questionnaire 5 days after their visit and return it in a self-addressed envelope. DAS28(3) scores were calculated (absence of VAS global rating). Regarding truth, Pearson correlations with DAS28(3) were used for validity analysis. Regarding discrimination, Pearson correlations were used for reliability analysis and paired sample t-tests for sensitivity to change (patients in this group were treated with 120 mg methylprednisolone). Regarding feasibility, patients indicated which scale they preferred most.

Results: Two hundred fifty-seven patients (63% female) filled in the first questionnaire, of which 184 patients filled in questionnaire two. Mean DAS28(3) score was 3.16 (±1.15). Concerning truth, 211 stable patients were included for validity analysis. The highest correlation coefficient was found for NRS in the domain pain ($r = 0.41$, $p < 0.001$). On fatigue and DA VAS scored best, while Likert scored best on general well-being. With regard to discrimination, 153 patients were eligible for the reliability analysis, 31 patients for the sensitivity to change analysis. For fatigue NRS was most reliable ($r = 0.853$, $p < 0.001$). VAS was most reliable to measure pain and DA, while Likert scored best on general well-being. Regarding sensitivity to change, VAS pain was most sensitive ($t = 2.843$, $p < 0.005$), followed by Likert pain and NRS pain ($t = 2.340$ and $t = 2.151$ respectively, both $p < 0.05$). Patient indicated NRS as overall scale preference (first questionnaire 47.9%, second questionnaire 48.4%). Besides that, NRS was most preferred for every domain separately (45.1 to 50.0%) (Table1).

Conclusion: Mixed results exist with regard to the clinimetric properties of 4 scales to measure the 4 domains. The great majority of patients preferred NRS and NRS showed reasonable to good clinimetric properties for most domains. Therefore we might consider using NRS as the preferable scale for these PROs except may be for general well-being for which the Likert scale has some advantages.

Patient Engagement in Research: Understanding Patient Interest and Needs

Jennifer R. Horonjeff[1], Emily L. Creek[2] and Cindy McDaniel[3], [1]Rheumatology, Columbia University Medical Center, New York, NY, [2]Consumer Health, Arthritis Foundation, Atlanta, GA, [3]Arthritis Foundation, Atlanta, GA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Quality Measures and Quality of Care - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The goal of clinical and health-related research is to benefit the end-consumer—the patient. Since patients are the experts on their unique experiences living with their condition, they represent an important stakeholder to engage in the research process. Patient engagement in research is an expanding area, elevating patients from solely research subjects to active collaborators in research development, design and execution. Despite the recognized importance of patient engagement, little has been done to examine how to better prepare patients for inclusion. The objective of this study was to provide an informational session to patients on patient engagement in order to: 1) elicit feedback regarding what information and resources they need to feel confident in participating in research, and 2) gauge their level or interest in being involved in future research.

Methods: A learning session was conducted at the 2016 National Gathering Conference, which was hosted by Arthritis Introspective and the Arthritis Foundation and provided educational sessions to adults with rheumatic diseases and their loved ones. Individuals did not register in advance for the breakout session and all were eligible to participate. The session lasted 1.25 hours and presented: 1) the value of patient engagement in research, 2) different levels patients can be involved in the research process and 3) basic research concepts and examples, and was followed by a discussion. At its conclusion, participants were asked to complete a survey to provide feedback regarding the session, indicate their level of interest in engaging in research and identify beneficial information and resources to increase or improve their involvement.

Results: Twenty participants attended and completed the survey (n=20). Of them, 15% indicated that they had some prior research experience (eg. college research assistant, advanced research degree, research team involvement) while the remainder responded no prior experience. Forty percent responded they were unaware patients could be involved in research beyond being a research subject. Participants rated on a 5-point Likert scale (5=high) how well the session was able to accomplish certain goals: 1) improved understanding of research process (4), 2) improved understanding of how patients can be involved in research (4.2), 3) helped them feel empowered that their experiences matter (4.05) and 4) made them interested in getting involved in research at some level (4.1). After the session, 75% of participants indicated they wanted more research training. Participants expressed interest in trainings that are conducted in-person, online or via webinars. Concerns regarding involvement in research included knowledge and access to opportunities and confidence to collaborate with researchers and clinicians.

Conclusion: The results of this study suggest that patients benefit from a basic informational session on patient engagement. Future efforts should include the development and evaluation of additional trainings and resources to increase research understanding and elucidate the value of patient involvement. Improved access to opportunities for patients involvement should also be considered.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Checkpoints and mechanisms regulating the onset of rheumatoid arthritis (RA) remain largely elusive. Apart from B cells and auto-antibodies, Th17 cells were shown to critically contribute to disease development. Mice lacking IL-23, a cytokine controlling the pathogenicity of Th17 cells, are completely protected against arthritis. Yet, the exact role of the IL-23/Th17 axis during this autoantibody-driven disease remain incompletely understood.

Methods: IL23A$^{-/-}$ mice and mice receiving an IL23 blocking antibody were analyzed during active and passive arthritis models including collagen-induced arthritis (CIA), the K/BxN arthritis model, collagen-antibody induced arthritis (CAIA) and K/BxN-serum transfer arthritis. Both clinical, histological and immunological parameters of arthritis were assessed. IgG glycosylation was analyzed using the MALDI-TOF technique. IgG activity was determined by measuring the cytokine release of immune-complex-stimulated myeloid cells. To study the crosstalk between B cells and Th17 cells, co-culture experiments were performed.

Results: Here we report, that the IL-23/Th17 axis did not directly contribute to auto-antibody induced inflammation within inflamed joints, but controlled the glycosylation profile and inflammatory activity of auto-antibodies during the prodromal phase of disease. Th17 cells were found to accumulate in germinal centers auf secondary lymphatic organs prior to onset of experimental arthritis, where they suppressed the expression of b-glactoside a2,6-sialyltransferase 1 (St6gal1) in differentiating plasmablasts. The consecutive change in the immunoglobulin G (IgG) glycosylation profile provoked a shift towards a pro-inflammatory autoantibody repertoire and triggered the inflammatory phase of arthritis. Plasmablasts of RA patients similarly displayed a decreased St6gal1 activity, while IgG from these individuals showed corresponding changes in its glycosylation profile as well as an increased inflammatory activity, suggesting that related pathways might contribute to onset and progression of autoantibody-mediated diseases in humans.

Conclusion: Our current findings identify a novel IL-23/Th17-dependent checkpoint that controls autoantibody activity, unmasks a preexisting breach in humoral tolerance, and initiates the transition from a stage of asymptomatic autoimmunity into inflammatory autoimmune disease.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by an unrestrained inflammatory response in selective, anatomically distinct synovial joints. The innate immune system plays a crucial role in the pathogenesis of RA which is highlighted by the efficacy of biologicals directed against cytokines that are predominantly produced by macrophages. One family of tyrosine kinase receptors involved in an anti-inflammatory feedback mechanism are Tyro3, Axl and Mer (gene name *Mertk*; TAM). Of importance, Axl and Mer are mainly expressed on the antigen-presenting cells of the innate immune system. The plasma level of the TAM receptor ligand Growth arrest specific 6 (Gas6) is significantly reduced in RA patients suggesting this feedback mechanism is impaired in RA. We investigated the individual role of the TAM receptors Axl and Mer in an inflammatory model of arthritis that is driven by macrophages.

Methods: The KRN serum transfer model of arthritis was induced by two intraperitoneal injections of arthritic K/BxN serum in $Axl^{-/-}$, $Mertk^{-/-}$, $Axl^{-/-}Mertk^{-/-}$ and wild-type (WT) mice. Ankle joints were macroscopically scored for 7 days. At day 2 and 7, ankle joints were isolated for histology and immunohistochemistry. At day 7, knee joints were macroscopically scored and isolated for histology and immunohistochemistry.

Results: $Mertk^{-/-}$ mice had an increased macroscopic ankle score until day 4 whereas $Axl^{-/-}$ mice had an enhanced macroscopic score from day 4 until the end of the experiment at day 7. Histology of the ankle joints showed significantly more inflammation in $Mertk^{-/-}$ mice at day 2 and increased arthritis pathology in $Axl^{-/-}$ mice at day 7, reflecting the macroscopic ankle scores. Histological analysis of ankle joints of $Axl^{-/-}Mertk^{-/-}$ mice at day 7 showed enhanced inflammation and cartilage depletion compared to both $Axl^{-/-}$ and WT mice, indicating an additive effect of Axl and Mer deficiency. In contrast to the ankle joints at day 7, enhanced macroscopic score and arthritis pathology in the knee joints of $Mertk^{-/-}$ mice, compared to WT mice, was observed. No differences on arthritis pathology were detected in the knee joints of $Axl^{-/-}Mertk^{-/-}$ compared to $Mertk^{-/-}$ mice. To explain the discrepancy of Axl involvement between ankle and knee at day 7, we looked for Axl expression in synovium before the onset of arthritis. The cells in the lining layer of ankle synovium were strikingly Axl positive whereas the synovium of the knee joints was Axl negative.

Conclusion: These findings identify the TAM receptors Axl and Mer as important players in arthritis. The Mer receptor plays a protective role at the onset of arthritis whereas the Axl receptor takes over this role in established disease in ankle joints. In the knee joints, however, Mer but not Axl, plays a prominent protective role, likely due to the lack of Axl in naïve knee joints. These findings highlight differences in topographically distinct synovial joints in inflammatory arthritis.

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone destruction in rheumatoid arthritis is mediated by osteoclasts, which are derived from precursor cells of the myeloid lineage. Although there is much known about mature osteoclasts, the identity of osteoclast precursor populations during arthritis is poorly understood. Blood monocytes can be subdivided in classical inflammatory monocytes ($CD115^{+}Ly6C^{high}CCR2^{+}$) and non-classical resident monocytes ($CD115^{+}Ly6C^{-/low}CCR2^{-}$) and especially classical monocytes have been implicated in mediating tissue damage in autoimmunity.

Methods: HTNFtg mice were clinically scored once per week for grip strength and swelling. In addition, blood was collected every other week starting on week 4. Mice were sacrificed at week 10 - blood, spleen and bone marrow were collected for flow cytometry analysis. K/BxN Arthritis was induced in wild type mice, blood and spleen were collected 14 days after disease induction. HTNFtg/$CCR2^{-/-}$and hTNFtg mice were analyzed histologically. Different monocyte subsets were Facs-sorted and cultured in the presence of RANKL and MCSF to induce osteoclasts. RNA sequencing of RANKL stimulated osteoclast precursor cells was performed.

Results: Here we show that hTNFtg mice lacking CCR2, which lack circulating classical inflammatory monocytes, show enhanced local bone erosion and osteoclast generation in chronic TNF driven arthritis. When we correlated the number of the two monocyte subsets in blood with histological signs of joint destruction the number of inflammatory monocytes did not correlate at all with those parameters. In contrast, the number of non-classical monocytes in blood significantly correlated with the extent of tissue damage in both hTNFtg arthritis and also K/BxN serum transfer arthritis. Histological examination revealed that while all infiltrating monocytes express CD115, only a small fraction of these cells express Ly6C, suggesting that the synovial infiltrate predominantly consists of $Ly6C^{-/low}$ monocytes. Upon sorting resident and from blood, we demonstrate that resident $Ly6C^{-/low}$ monocytes are more potent to form osteoclasts *ex vivo* than classical $Ly6C^{high}$ monocytes. Genome-wide transcriptome profiling revealed increased expression of genes which are required for pre-osteoclast fusion in RANKL-stimulated resident $Ly6C^{-/low}$monocytes.

Conclusion: Non classical resident monocytes possess particular osteoclastogenic potential and their numbers in blood correlate with histological parameters of joint destruction in two different models of inflammatory arthritis. Therefore these cells may provide a biomarker for erosive inflammatory arthritis and even a possible target for therapeutically intervention.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Bruton's Tyrosine Kinase (BTK), a non-receptor tyrosine kinase is involved in intracellular signaling pathways downstream of several receptors, including the B cell receptor (BCR), Fcγ receptors (FcγR) and receptor activator of NF-κB (RANK). An aberrant activation of signaling pathway mediated by these receptors are reported to be associated with a progression of several autoimmune diseases such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Therefore, BTK inhibitor would be a potential therapeutic option for the treatment of RA and SLE. TAS5315 is a highly potent and selective BTK inhibitor and its inhibitory activity (IC_{50}) against anti-IgM-induced phosphorylation of BTK is 0.15 nmol/L. Here we describe the potential efficacy of TAS5315 in animal models of RA and SLE.

Methods: In vitro biochemical assay was performed using available kinase assay panels. In macrophages, the expression of inflammatory factors induced by IgG was measured with ELISA assay. To establish collagen-induced arthritis, male DBA/1 mice were injected on day-27 and-6 with an emulsion of complete Freund's adjuvant and bovine type II collagen. On day 0, mice were randomized into treatment groups. TAS5315 was administrated orally once daily for 15 consecutive days. Disease severity was evaluated by clinical score of paw swelling. In MRL/lpr lupus model, mice were randomized into treatment groups at 14 weeks. TAS5315 was administrated orally once daily from 14 to 20 weeks. At the end of treatment period, spleen and lymph nodes were extracted to measure their weights, and kidneys were extracted to analyze the histopathological changes. The serum levels of anti-dsDNA antibody and proteinuria were also measured at the end of treatment period.

Results: TAS5315 selectively inhibited the enzyme activity of BTK and had less off target inhibition against other kinases. In cell-based functional assay, TAS5315 significantly inhibited FcγR-mediated TNF-α production by macrophages in a dose dependent manner (IC_{50}= 47.2 nM). In established mouse CIA model,TAS5315 dose-dependently decreased the clinical score in arthritic mice compared with that in vehicle-treated mice. TAS5315-treated mice had a marked reduction in the levels of TNF-α, IL-1β and IL-6 in synovial fluid and MMP3 in plasma. In MRL/lpr lupus model, TAS5315-treated mice showed the improvement for several inflammatory responses, such as lymphadenopathy, splenomegaly and the incidence of glomerulonephritis. TAS5315-treated mice also showed lower serum levels of blood urea nitrogen (BUN) and anti-dsDNA antibodies than vehicle-treated mice.

Conclusion: Our study demonstrates that a novel BTK inhibitor, TAS5315, shows significant efficacy by inhibiting inflammation in both RA and SLE models. These data suggest that TAS5315 could be a promising therapeutic agent for human autoimmune disease including RA and SLE.

Involvement of CD163-Positive Macrophages in the Pathogenesis of Arthritis Via Modulation of Inflammatory Cytokine and Chemokine Expression in the Synovium of a Murine Model

Shinjiro Kaieda[1], Hiroaki Ida[2] and Tomoaki Hoshino[3], [1]Department of Medicine, *Division of Respirology, Neurology and Rheumatology, Kurume University School of Medicine, kurume, Japan, [2]Respiorogy, Neurology and Rheumatology, Kurume University School of Medicine, Kurume, Japan, [3]Department of Medicine, Division of Respirology, Neurology and Rheumatology, Kurume University School of Medicine, Kurume, Japan

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial-lining macrophages play a crucial role in the onset and maintenance of joint inflammation in arthritis. CD68 and CD163 are commonly used markers of synovial macrophages in the RA synovium. CD163 is a cell-surface glycoprotein of the group B cysteine-rich scavenger receptor family that binds to and internalizes hemoglobin-haptoglobin complexes, thereby releasing IL-10 and carbon oxide with strong anti-inflammatory effects. Serum-soluble CD163 levels are significantly elevated in long-standing RA patients. The restrictive expression of CD163 by monocytes-macrophages was confirmed in the affected joint tissues of RA patients; however, the pathogenic roles of CD163-positive macrophages in inflammatory arthritis remain unclear. We investigated the roles of CD163-positive macrophages in arthritis development in mice.

Methods: A collagen antibody-induced arthritis (CAIA) mouse model was established with a combination of monoclonal anti-type II collagen antibodies and lipopolysaccharide in C57BL/6 (B6)-background CD163 knockout (KO) mice. Arthritis was graded using a 0–16 clinical scale (0–4) per paw. Histological assessment of arthritis severity was performed on paraffin-embedded hematoxylin and eosin-stained sections, and synovial inflammation (inflammatory cell infiltration) and bone erosion were graded in a blinded fashion on an established 0–5 scale. Anti-Iba-1 and anti-NIMP-R14 antibodies were used for immunocytochemical staining to identify synovial tissue-resident macrophages and neutrophils, respectively. Anti-CD163 antibodies were used for histomorphometric quantitation of CD163-positive macrophages in the synovial tissue. Total RNA was isolated from the mouse ankle joints for gene expression analysis of pro-inflammatory cytokines IL-1β and IL-6 and the chemokine CXCL-1 before and 10 days after CAIA induction by quantitative RT-PCR.

Results: Immunohistochemistry revealed that CD163 antigens were restricted to Iba-1-positive synovial tissue-resident macrophages. The number of CD163-positive cells increased during arthritis. CD163 KO mice exhibited significant exacerbation of clinical scores during arthritis compared with control wild type (WT) B6 mice. Histomorphometric quantification of the arthritic changes in the joint tissues confirmed the clinical assessment, with significant increases in inflammation and bone erosion scores in CD163 KO mice. Recruitment of neutrophils was significantly increased in the synovial tissue of CD163 KO mice compared to that of WT mice. Correspondingly, mRNA expression of CXCL1 was significantly more up-regulated in the inflamed ankle joints obtained from CD163 KO mice than control mice. Additionally, CD163 KO mice showed significantly elevated IL-1b and IL-6 mRNA expression levels in the inflamed synovium.

Conclusion: CD163 deficiency exacerbates arthritis severity via up-regulation of synovial tissue IL-1b and IL-6. CD163-positive macrophage deficiency induced neutrophil recruitment via up-regulation of CXCL1 in the inflamed synovium. CD163-positive macrophages may play an inhibitory role in the pathogenesis of joint inflammation.

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Matrix metalloproteinase-9 (MMP9), highly expressed by infiltrating inflammatory cells, pannus tissue, and multinucleated cells in the synovium and subchondral bone tissue, including osteoclasts, participates in joint destruction, drives inflammation via activation of cytokines and chemokines, and promotes tissue destruction by degrading the basement membrane of epithelia and vasculature. MMP9 knockout mice are protected from collagen-induced arthritis (CIA) disease progression. A potent, allosteric antibody that inhibits MMP9 is currently being investigated in clinical trials{Marshall et al 2015}. The ability of a functional murine analog of this antibody to reduce disease signs and symptoms in established, chronic mouse CIA model both as a single agent and in combination with anti-TNF, was investigated.

Methods: CIA was induced in male DBA/1J mice (n=15/group) and treatments were administered after disease establishment. Efficacy was assessed via metrics of joint injury including clinical score (erythema/ paw swelling, score 0-4) in addition to histopathological assessment of destructive joint remodeling (soft tissue changes: edema, necrosis, inflammatory cell infiltration, and fibroplasia, sum score 0-16; bone changes: cartilage damage, bone erosion, periosteal bone formation, synovitis, pannus formation, and joint destruction, sum score 0-24).

Results: All animals were included in the evaluation. In all endpoints assessed, treatment with each therapeutic agent, on its own or in combination, resulted in efficacy with respect to body weight change, clinical score, and histopathological measures. The combination group provided the best overall trend for therapeutic benefit, although statistical significance as compared to each single agent alone was not met in most parameters. Body weight recovery was superior in combination as compared to single agent therapies (52% vs. 12-34%, relative to sham; $p<0.05$ combination vs. single agents). Clinical score and histopathology measures in soft tissue and bone changes were most improved in the combination therapy group, although it did not achieve statistical significance as compared to each single agent (26% vs. 17-21%; 1.5 vs. 1.5-1.8; and 7 vs. 7-9, respectively). Importantly, combination therapy resulted in a significant number of limbs with zero or mild disease as compared to single agents (no disease sign: 256% vs. 172-223%; mild disease sign: 178% vs. 138-141%). Analysis of complete blood count at the end of study revealed no abnormalities in any treatment group.

Conclusion: Selective inhibition of MMP9 was effective in reducing disease severity in CIA models of RA. The combination of anti-MMP9 with anti-TNF was well tolerated and increased the number of limbs with no or mild disease compared to anti-TNF alone. Further studies are required to examine combination therapy of selective anti-MMP9 and anti-TNF therapies in a clinical setting.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The transmembrane protein VISTA, is a member of the B7/CD28 family of immune modulator proteins and can function as a negative immune checkpoint regulator through a currently undefined molecular mechanism(s). VISTA is expressed on myeloid cells and activated T-lymphocytes. Interestingly, qPCR analyses showed VISTA mRNA (human ortholog C10orf54) is expressed abundantly in human rheumatoid synovial tissue. The importance of VISTA expression on myeloid cells was investigated in the collagen-II antibody induced arthritis (CAIA) model.

Methods: Joint targeted inflammation was initiated in the CAIA model by passive-immunization of mice with anti-type-II collagen monoclonal antibodies (5-Clone Cocktail, Chondrex, Seattle) and intraperitoneal injection of LPS, 3 days afterwards. The CAIA model does not require lymphocytes for induction of transient, immune-complex driven joint inflammation (duration 14-15 days), but does require complement activation, neutrophils and monocytes. The arthritic response was evaluated for (1) DBA/1J mice treated with anti-VISTA antibody MH5A (Biolegend) versus hamster IgG as control, and also for (2) VISTA-deficient mice versus wild type, C57/B6 mice.

Results: A sustained attenuation of paw swelling compared to controls was observed from approximately 6-13 days after initiation, for mice treated with anti-VISTA monoclonal antibody MH5A, and for VISTA-deficient mice. Histologic analysis of all major joints involved (knees, ankles, paws) indicated overall reduced joint inflammation/damage in VISTA deficient mice compared to controls. Since C5a generation is crucial to CAIA development, levels of C5a in plasma of wild type and VISTA-deficient mice were determined by ELISA 5 days after passive immunization and found to be equivalent. However, FACS analyses of phagocytic cells isolated from bone marrow as well as in peripheral blood of both arthritic and non-arthritic VISTA-deficient mice consistently displayed reduced C5a receptor expression on neutrophils and on bone marrow derived macrophages. Consistent with these findings, acute C5a receptor responses (ERK, AKT phosphorylation) and chemotaxis to C5a were also diminished in macrophages cultured from VISTA deficient mice.

Conclusion: These findings implicate VISTA in arthritic pathology for the first time, possibly due to a role in recruitment of phagocytes to joints. Antibodies reactive with VISTA may be useful therapeutic agents for autoimmune arthritis where immune-complexes drive joint damage.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Evidence suggests that periodontal infection by *Porphyromonas gingivalis*(Pg) exacerbates rheumatoid arthritis (RA); however, the underlying mechanisms remain unknown. Here, we examined the pathogenic and therapeutic correlation between periodontitis and RA in a mouse model of arthritis.

Methods: Pg strain 2561 was obtained and cultured anaerobically. Collagen-induced arthritis (CIA) mice were infected with Pg or Pg pre-incubated with an anti-FimA antibody (aFimA Ab) specific for fimbriae which are a flexible appendage on the cell surface. Fimbriae plays a pathological role in adhering Pg to gingiva, so neutralizing Pg with aFimA decreases adherence of Pg in mouse cavity. aFimA Ab was cloned and produced by our manufacturing system. Immunohistochemical analysis, microcomputed tomography analysis, confocal microscopy, immunofluorescence analysis, electron microscopy, RT-PCR, and western blot assay were done for proarthritic effect of Pg and neurtralizing anti-arthritic effect of aFimA Ab.

Results: aFimA Ab inhibits Pg induced periodontitis in CIA mice. Pg infection altered the oral microbiota, increased alveolar bone loss, and caused synovitis and joint bone destruction. However, pre-incubation with aFimA Ab led to a significant reduction in the severity of both oral disease and arthritis. aFimA Ab treated Pg fails to trigger arthritis in CIA mice. aFimA Ab treated Pg suppresses cartilage erosion and bone destruction in the joint of CIA mice. Moreover, aFimA Ab attenuated bacteria attachment and aggregation on human gingival and rheumatoid synovial fibroblasts. We discovered bacteria utilized dendritic cells, macrophages, and neutrophils to migrate to the joints of CIA mice.

Conclusion: Pg-induced periodontitis plays a significant role in RA development. Inhibiting Pg adhesion using a FimA Ab prevented RA progression. Disrupting Pg fimbriae suppresses the migration of bacteria to the joints and ameliorates RA.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) manifests in persistent synovial inflammation, cellular infiltration and pro-inflammatory cytokine production, and results in progressive joint destruction. Macrophages have been implicated in RA progression and persistence through production of degradative enzymes, cytokines, and chemokines. However, the mechanisms underlying these activities are not fully elucidated. We previously demonstrated that naïve mouse joints contain MHC II^+ and MHC II^- macrophages, the majority being MHC II^-tissue-resident macrophages that can limit initiation of an acute model of inflammatory arthritis. However, macrophages are plastic and can alternate their phenotype from an immunosuppressive to a proinflammatory phenotype depending on the microenvironment. Thus, we have optimized

a multi-parameter flow cytometry protocol to isolate synovial macrophage subsets to perform subset-specific transcriptomic and metabolic analysis.

Methods: K/BxN serum transfer-induced arthritis was initiated in 10-12 week old female C57BL/6 mice and clinical severity was assessed over a 21-day period. Flow cytometric analysis was employed to delineate macrophage subsets via expression of MHC II and CX3CR1 to obtain distinct macrophage populations. These populations were sorted throughout the course of arthritis and RNAseq was performed to obtain transcriptional profiles. In addition, flow cytometric analysis was employed to determine mitochondrial function of synovial macrophage subsets throughout the course of arthritis through the use of MitoSox Red, mBBr and JC-10 dyes.

Results: We observe that both the genetic and metabolic profiles of synovial macrophage subsets shift throughout the course of arthritis and contract back towards their steady-state phenotype during resolution of disease. PCA and clustering analysis of synovial macrophage subsets show that these populations display distinct genetic signatures and have identified gene clusters and cellular processes that dictate their function during arthritis intiation, progression and resolution. Further, synovial macrophages appear to shift towards a more metabolically active phenotype, with an increase in mitochondrial membrane potential, at the height of inflammation and contract back to normal as disease wanes.

Conclusion: We conclude that inflammation induces genetic and metabolic alterations in synovial macrophage subsets that coincide with initiation, progression and resolution phases of an acute model of inflammatory arthritis. These alterations indicate that specific macrophage subsets possess distinct genetic and metabolic profiles coinciding with designated functionality during the course of disease, thereby providing insight into potentially useful targets for therapy.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies identify gut microbiota dysbiosis as a possible contributor to rheumatoid arthritis (RA) pathogenesis. RA patients have significantly different microbiomes than healthy controls. The K/BxN mouse model of arthritis does not develop disease in germ free conditions but adding commensal bacterial triggers arthritis in these mice. Sexual dimorphism may also contribute to differences in RA incidence, severity, and mortality. We recently described sex differences in the tumor necrosis factor transgenic (TNF-Tg) mouse model of RA wherein females have a decreased lifespan (166 vs 229 days). Here, we initiated a study to elucidate the microbiomes of male and female TNF-Tg mice.

Methods: Fecal samples were collected from 5.5 month male and female TNF-Tg mice that were housed separately (C57BL/6 background, n=10), an age when females have exacerbated disease. 16s DNA sequencing was performed to identify bacterial diversity. Beta-diversity and principal coordinate analysis (PCoA), i.e. a 3D representation of the specific differences between mice, were used to estimate bacterial diversity. Least discriminant analysis (LDA) was

applied to determine significantly enriched (LDA score>2) species between sexes.

Results: Females have significantly decreased beta-diversity ($p<0.05$), and PCoA demonstrated that females have a distinctly different microbiome based on a clear spatial separation (Fig. 1 A and B). LDA determined that females were significantly enriched in Bacteroidetes and males in Firmicutes (Fig. 2).

Conclusion: Dysbiotic microbiota, loss of bacterial diversity, and sex differences separately have been associated with several autoimmune and inflammatory diseases. Here we show for the first time that female TNF-Tg mice with advanced arthritis have significantly less microbial diversity than males. Furthermore, the female microbiome differs in part due to enrichment of the pathobiont Bacteroidetes whereas males display enrichment of Firmicutes. Others have reported that an altered ratio of Bacteroidetes/Firmicutes influences autoimmune and inflammatory disease progression. This initial study assessed sexually dimorphic microbiota in TNF-Tg mice, and analyses of wild-type littermates are underway. Since the published microbiomes of male and female C57BL/6 mice do not differ in beta-diversity or specific species enrichment, we hypothesize that the loss of diversity and enrichment in Bacteroidetes significantly contributes to the disease progression in female TNF-Tg mice.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: IL-21 is a T cell-derived cytokine whose receptor is expressed on variety of cells in immune system. IL-21was reported to be involved in the development of Th17 cells and follicular helper T cells, as well as in antibody production of B cells, all of which could be involved in the development of autoimmune diseases. Therefore, IL-21 might be involved in the pathogenesis of RA possibly via induction of pathogenic T cell responses and/or autoantibody production. However, these remains to be determined and might be analyzed in animal models of arthritis. The purpose of this study is to clarify the roles of IL-21 signaling in the pathogenesis of autoimmune arthritis

Methods: In order to declare the phathogenesis of IL-21 signaling for animal models of arthritis, we investigated the development of collagen-induced arthritis (CIA) in IL-21 receptor (IL-21R)-deficient mice. IL-21R-deificient or wild type (WT) C57BL/6 mice were immunized with chicken type II collagen (CII) emulsified in CFA on day 0 and were given boost injection with CII on day 21. Analyses of lymphcytes in regional lymph nodes by flow cytemeter and antigen(CII)-specific antibodys in serum were done. Lymphocytes of regional lymph nodes were restimurated by CII *in vitro* and then were analyzed by flow cytometer. Culture supernatants were also analyzed by ELISA. RAG-deficient mice which transfered T and B cells from WT or IL-21 R-deficient mice were induced CIA, because of comfirming which cells demand IL-21 signaling for developing arthritis *in vivo*.

Results: We found that IL-21R-deficient mice were resistant to the development of CIA. CII-specific antibody production was severely impaired in IL-21R-deficitent mice, which is consistent with the reduction of germinal center B cells. On the other hand, development of Th17 and Tfh cells was largely unaffected by the absence of IL-21 signaling. In addition, RAG-deficient mice were transferred WT CD4 T cells with WT or IL-21R-deficient B cells, and soon were induced CIA. We found that RAG-deficient mice transferred IL-21R-deficient B cells were resistant to the development of CIA, although which transferred WT B cells were susceptible.

Conclusion: Thus, IL-21 signaling is critically involved in the development of CIA mainly by inducing pathogenic autoantibody production of B cells.

Angiotensin II Exacerbates Bone Destruction in TNF-Transgenic Arthritis Mice

Takafumi Mito[1], Tomoyuki Mukai[2], Shunichi Fujita[2], Akiko Nagasu[2], Hiroyasu Hirano[2], Teruki Sone[3] and Yoshitaka Morita[2], [1]rheumatology, Kawasaki medical school, Okayama, Japan, [2]Rheumatology, Kawasaki medical school, Okayama, Japan, [3]Nuclear Medicine, Kawasaki medical school, Okayama, Japan

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Angiotensin II (Ang II) is known to function on various organs including kidneys, adrenal glands as well as the nervous and cardiovascular systems. In addition, recent studies have revealed that Ang II affects the skeletal system as well. The presence and up-regulation of receptors for Ang II and angiotensin converting enzyme, a key enzyme for the formation of Ang II, have been previously described in the synovial tissue in patients with rheumatoid arthritis (RA), suggesting the potential involvement of Ang II in the disease process. However, the details are not yet clear. The purpose of this study was to determine whether hypertensive stimulus Ang II further exacerbates TNF-induced bone destruction and systemic bone loss in a murine arthritis model.

Methods: To evaluate the role of Ang II in osteoclastogenesis, we conducted primary bone marrow-derived macrophages (BMMs) culture and co-culture with primary osteoblasts. In the BMMs culture, cells were treated with Ang II in the presence of RANKL. In the co-culture, cells were treated with Ang II in the presence of prostaglandin E2 and vitamin D. The formation of osteoclasts was examined by tartrate-resistant acid phosphatase (TRAP) staining. To investigate in vivo effect of Ang II, Ang II (1 μg/kg/min) was infused by osmotic pumps from 12 to 16 weeks of age in wild-type and TNF-transgenic (TNF-tg) mice. As controls, saline was infused by osmotic pumps in wild-type and TNF-tg mice. The swelling of the paws was graded as arthritis score once per week until 16 weeks of age. The bone property of talus and tibia was analyzed by micro-computed tomography (CT) to assess the extent of bone loss.

Results: In the BMMs culture, the number of TRAP-positive osteoclasts was not affected by Ang II stimulation, whereas, in the co-culture with osteoblasts, the number of osteoclasts was increased by Ang II treatment in a concentration-dependent manner. This result suggests that Ang II augments osteoclastogenesis through acting on osteoblastic cells not directly on BMMs. In vivo administration of Ang II significantly raised the systolic blood pressure in both wild-type and TNF-tg mice. Arthritis scores in TNF-tg mice were not altered by the Ang II infusion. Micro-CT analysis revealed that erosive bone destruction on the talus was significantly more severe in Ang II-infused TNF-tg mice compared to saline-infused TNF-tg mice. Bone volume per total volume in the trabecular bone of proximal tibia was significantly lower in TNF-tg mice than in wild-type mice, and further diminished by the Ang II infusion.

Conclusion: Ang II infusion exacerbated bone destruction and systemic bone loss without significant alteration in the severity of arthritis. These findings suggest that Ang II attributes to the bone destructive mechanisms mainly by increasing osteoclastogenesis with the minor effect on the inflammation in the murine arthritis model. Ang II could be a therapeutic target to protect the inflammatory bone destruction in patients with RA.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease with an unknown cause. Observations of dysbiosis and mucosal inflammation in patients with RA has raised interest in studying microbial-mucosal interactions as a potential trigger of RA. Using the murine collagen-induced arthritis (CIA) model, we hypothesized that microbiota and mucosal inflammation are required for the development of autoimmune arthritis.

Methods: 4-6 DBA1j mice were treated with or without broad-spectrum antibiotics in the drinking water 7 days preceding and throughout the induction of CIA, by immunization of bovine type II collagen (CII) in Complete Freund's Adjuvant (CFA) on days 0 and 21. Fecal pellets and sera were collected every 7 days during the study for microbiome analysis and autoantibody development. Mice were euthanized on days 21 or 35 for tissue analyses for cytokines and autoantibodies by ELISA. Microbiome analyses were performed on fecal pellets by 16S sequencing of the bacterial rRNA.

Results: During the preclinical phase of CIA (without antibiotics), we find remarkable changes in the intestinal microbiome, specifically increased *Clostridia* and decreased *Lactobacillus* and *Bacteroides*. In parallel, intestinal permeability and cytokines IL-12 and IL-1β increased significantly (P value < 0.05). Furthermore, anti-CII autoantibodies were increased within the intestine, suggesting a developing mucosal immune response. In microbiota-depleted mice (antibiotic treated), CIA severity was reduced by 50% as assessed by clinical scores (P value < 0.01). Correspondingly, tissue cytokines and both serum and fecal anti-type II collagen antibody levels were reduced.

Conclusion: Taken together, these data suggest a model in which intestinal dysbiosis and mucosal immune responses drive the development of autoimmune arthritis. Future studies are aimed at elucidating the pathway by which microbiota and mucosal immune responses stimulate systemic autoantibody production that is necessary for the development of CIA.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Various citrullinated proteins and anti-citrullinated protein antibodies (ACPA) are increased in patients with rheumatoid arthritis (RA). ACPA have high specificity for RA, and are the predictive factor of joint radiographic progression. It is considered that citrullinated proteins and ACPA may contribute to the development and progression of RA. However, the relevance in the course of arthritis development remains uncertain. In this study, we explored the pathogenic relevance of citrullinated proteins and ACPA in peptide glucose-6-phosphate isomerase (pGPI)-induced arthritis (pGIA) mice.

Methods: 1) The titers of anti-pGPI antibodies and ACPA in sera from pGIA mice were analyzed by ELISA.

2) Citrullinated protein expressions in joints, skins and lungs were examined by immunohistochemistry. The protein expressions in sera were examined by Western blot analysis.

3) Cl-amidine, the inhibitor of protein arginine deiminase (PAD), was injected intraperitoneally to pGIA mice. Clinical score, the titers of ACPA, citrullinated protein expressions, T cell response and the level of proinflammatory cytokines in sera were assessed.

Results: 1) The titers of anti-pGPI antibodies and ACPA in sera from pGIA mice were elevated from day14, and were significantly higher than those from control mice.

2) In immunohistochemistry, citrullinated proteins were detected in joints on day 14 and in skins on day 7 from pGIA mice, whereas not detected from control mice. In joints, citrullinated proteins were expressed in areas of synovial hyperplasia. In skins, these proteins were expressed in infiltrating inflammatory cells surrounding injected areas in subcutaneous tissues. In lungs, citrullinated proteins were not detected from pGIA or control mice. In sera, citrullinated protein was detected at approximately 120 kD on day 14 from pGIA mice, and significantly increased than control mice.

3) Cl-amidine treatment significantly decreased clinical and synovitis score. The titers of anti-pGPI antibodies and ACPA in sera were not significantly different, but tended to lower by Cl-amidine treatment. Citrullinated proteins in joints, skins and sera from treated mice were clearly decreased. The level of IL-6 in sera on day 14 was significantly decreased in Cl-amidine injected mice as compared with control mice, but pGPI-specific CD4+ T cell response was not changed.

Conclusion:

Citrullinated proteins and ACPA were increased in pGIA mice. Additionally, the inhibition of PAD decreased the expression of citrullinated proteins and the production of proinflammatory cytokines, resulting in the suppression of arthritis. These results suggested that PAD was involved in the pathogenesis and maintenance of autoimmune arthritis.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Humanized nonobese diabetic/Shi-scid/γc^{null} (NOG) mice, which are reconstituted with human hematoimmune system by transplantation with human $CD34^+$ hematopoietic stem cells (termed as humanization), have been shown to reproduce key aspects of human Epstain-Barr virus (EBV) infection. We previously demonstrated that EBV-infected humanized NOG (hu-NOG) mice developed erosive arthritis similar to that in Rheumatoid arthritis (RA). Furthermore we showed that human osteoclasts were present in the bone erosion sites and that human osteoclasts actually differentiated in vitro from osteoclast progenitors settled in the bone marrow of EBV-infected hu-NOG mice. However, the mechanisms for the development of human osteoclasts in the EBV-infected hu-NOG mice including cells supplying human receptor activator nuclear factor-κB ligand (RANKL), an essential molecule for osteoclast differentiation, have not been elucidated yet. In this study, we investigated the roles of EBV in RANKL expression responsible for osteoclastogenesis in EBV-infected hu-NOG mice.

Methods: Humanization of NOG mice and inoculation of hu-NOG mice with 5 to 20 × 10^2 TD_{50} (50% transforming dose) of EBV (B95-8) were performed as described in our previous study. After 8 to 10 weeks of the EBV inoculation, when erosive arthritis can be observed at a high rate, peripheral blood cells (PBCs) collected from the mice were stained with monoclonal antibodies (Abs) specific to human RANKL, CD19 and CD20 by multicolor immunofluorescence technique and analyzed by flow cytometry. To examine the effects of EBV on RANKL expression, not only EBV-free cord blood mononuclear cells (CBMCs) obtained after informed consent but also Ramos cells, an EBV-negative B-cell lymphoma cell line, were incubated with culture medium containing EBV (5 to 20 × 10^2 TD_{50}). Then, both cell types were stained with those Abs as mentioned above and analyzed by flow cytometry. Quantification of EBV DNA was performed by a real-time PCR assay.

Results: $RANKL^+$ cells were found in PBCs of the EBV-infected hu-NOG mice, most of which cells showed positivity for the B-cell markers, CD19 and CD20. In contrast, almost no $RANKL^+$ cells were detected in that of un-infected hu-NOG mice. Inoculation of CBMCs with the EBV in vitro induced RANKL on $CD19^+CD20^+$ B cells. The positivity for RANKL on B cells increased dramatically, reaching nearly 90% after 3 to 4 weeks of EBV inoculation. Real-time PCR assay showed a high level of EBV DNA (5 × 10^4 copies/μg of DNA) in these cells, indicating that the cells were actually infected with EBV. The experiments with Ramos cells showed that inoculation with the same dose of EBV as that with CBMCs markedly induced RANKL on the Ramos cells around 3 weeks after the EBV inoculation, whereas the cells without EBV inoculation remained negative for RANKL. EBV DNA was detected (1 × 10^4 copies/μg of DNA) in the EBV-inoculated Ramos cells.

Conclusion: Our present study demonstrates that EBV infection induces RANKL expression on B cells and that B cells, the primary target of EBV, are the predominant $RANKL^+$ population in the PBCs of EBV-infected hu-NOG mice, suggesting that EBV-induced $RANKL^+$ B cells play roles in osteoclastogenesis causing bone erosion in these mice.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease, characterized by synovial infiltration of various inflammatory cells. Chemokines are involved in controlling the recruitment of different cell types into the synovial membrane. Increased production of MIP-3-a and accumulation of CCR6 expressing mononuclear cells can be found in joints of RA patients. CCR6 expression has also been reported on $CD4^+$ T cells, in particular regulatory as well as Th17 cells. Recent data suggest that $CD25^-Foxp3^+$ T cells upregulate CCR6 and promote arthritis. In this study, we investigated the role of CCR6 in the pathogenesis of arthritis using different arthritis models.

Methods: Clinical as well as histological signs of arthritis were investigated in the collagen-induced arthritis (CIA), K/BxN serum transfer arthritis and in the human tumor necrosis factor (hTNFtg) arthritis model, comparing *wt* and *CCR6-/-* mice. We analyzed the phenotype of lymph node cells by flow cytometry and cytokine concentrations in serum. Anti-collagen antibodies and cytokines were measured by enzyme-linked immunosorbent assay.

Results: Since CCR6 is an important component of the innate immune system we compared the development of arthritis in *CCR6-/-* mice in 2 different arthritis models known to be T cell independent, the K/BxN serum transfer arthritis and hTNFtg arthritis. In both models, we did not detect any significant differences in clinical signs of inflammation or histological severity of arthritis between wt and CCR6-/- mice. In additon, we could not detect differences in bone density between *wt* and *CCR6-/-* mice. To investigate the role of CCR6 as part of the adaptive immune system in the development of arthritis we induced CIA in *wt* and *CCR6-/-* mice. *CCR6-/-* mice were almost completely protected from CIA. Analyses of T cell subsets by flow cytometry revealed a significant reduction of $CD25^-Foxp3^+$ T cells.

Conclusion: These data suggest that CCR6 is not crucially involved in innate immunity driven arthritis, but is necessary for the development of autoimmune arthritis. Importantly, CCR6 is necessary for the generation of pathogenic $CD25^-Foxp3^+$ T cells in CIA, suggesting an important function of CCR6 on T cells in the development of autoimmune arthritis.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the migration, colonization and distribution of bone marrow mesenchymal stem cells (BM-MSCs) traced by green fluorescent protein (GFP) in the immune organs and joints of CIA rats, and study the mechanism of MSCs in repairing damage.

Methods: 1.MSCs labeled with GFP was cultured, amplified and identified in vitro. 2.Injected with mixture of II type collagen and complete Freund's adjuvant into Wistar rats space at 14 days to establish the rat model of collagen induced arthritis (CIA): (1) It was randomly divided into five groups, including early intervention group (n=20), late intervention group (n=20), CIA early control group (n=12), late control group (n=12) and normal control group (n=12).(2) MSCs were injected from tail veins according to the number of 1×10^7/kg,and the control groups were given equal volume of normal saline. (3) Observe the changes of arthritis index, arthritis swelling degree,and appearance of imageology and pathology. 3.Observe the migration of transplanted stem cells by means of small animal in vivo imaging system. 4.The spleen, thymus, lymph nodes and joint tissues of the rats were made into pathological sections when transplanted at 3, 11, 30 and 42 days.The migration and distribution of the transplanted cells in the immune organs and the inflammatory joints were detected by immunohistochemistry.

Results: 1.(1)The arthritis index and degree of joint swelling in early and later intervention groups were decreased significantly than that of CIA control groups($P< 0.05$). (2)The early intervention group had lower arthritis index and the degree of joint swelling than the later intervention group ($P < 0.05$). 2.The small animal in vivo imaging system could not monitor the migration of MSCs transplanted into CIA rats in vivo , and the fluorescence interference of the animal itself was obvious. 3.The positive results of GFP was successfully detected by immunohistochemical method in the immune organs and joints of CIA rats, and sustainable for at least 42 days.

Conclusion: 1.MSCs transplanted through tail vein can migrate to the spleen, lymph nodes and thymus and joints,and can be long-term(42 days)colonization in these organizations. 2.GFP was not suitable for the detection of MSCs in the immune organs and joints of rats. 3.The intervention of MSCs for CIA rats was effective , and early intervention effect was better than advanced intervention.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Cognitive dysfunction including depression-like symptoms is a frequent comorbidity of rheumatoid arthritis (RA)[1]. Mechanisms that have been linked to cognitive impairments in the general population such as endothelial dysfunction, systemic inflammation or functional limitations have particular relevance for RA. Brain-derived neurotrophic factor (BDNF) is abundantly expressed by endothelial cells and neurons in the brain, where it plays a crucial role in cognition. Surprisingly, the impact of RA on BDNF is poorly documented. Available studies reported higher circulating BDNF levels in RA patients than controls[2]. In order to gain further insights into the interplay between RA, cognitive dysfunction and BDNF, we explored brain and circulating BDNF levels in a rat model of RA.

Methods:

Adjuvant-induced arthritis (AIA) was used as a rat model of RA. Using Western blot analysis, BDNF expression were measured in two brain regions involved in cognition (frontal cortex and hippocampus) and in the microvasculature isolated from the whole cortex. BDNF levels were measured in serum and peripheral blood mononuclear cells (PBMC) and serum TNFα and IL-1β levels were measured in serum using ELISA and the Magpix® Luminex kit, respectively. Disease activity was assessed from the arthritis score, depression-like symptoms from the sugar preference test and physical limitations from mobility in activity chambers. All the parameters were evaluated on day 29-32 post-immunization (n=40) and in corresponding non-AIA control rats (n=28). Data were analyzed using non parametric tests. $P<0.05$ was considered statistically significant.

Results:

AIA resulted in physical limitations and depression-like symptoms. These alterations coincided with a significant decrease in BDNF levels in the frontal cortex (- 70%) and hippocampus (-50%) as well as in the cerebrovasculature (-40%). Conversely, BDNF levels in serum and in PBMC were higher in AIA than in controls (+30% and +75%, respectively). Serum but not brain BDNF levels were positively associated with the arthritis score and circulating TNF alpha levels. No association was observed with IL-1β.

Conclusion: The present results support the involvement of brain BDNF depletion in AIA-induced impaired cognition and identify TNFα as a potential actor in AIA-induced rise in circulating BDNF levels. From a clinical perspective, our data refute serum BDNF level as a reliable marker of brain BDNF levels or impaired cognition in RA. Given the evidence of low cerebrovascular BDNF levels in AIA interactions between cerebral endothelial dysfunction, cerebrovascular BDNF and cognition should be explored further. References:

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: N-3 polyunsaturated fatty acids (PUFA) have anti-inflammatory effects and were considered useful for the treatment of rheumatoid arthritis (RA), however the mechanism is still unclear. Interleukin 17 (IL-17) is a pro-inflammatory cytokine produced by T helper 17 (Th17) cells which cause tissue inflammation and bone erosion. In contrast, regulatory T (Treg) cells down-regulate various immune responses by suppression of naïve T cells. The

imbalance between Th17 cells and Treg cell is important for the pathogenesis of RA. We investigated whether n-3 PUFAs attenuate collagen antibody-induced arthritis (CAIA) using fat-1 transgenic mice which contain the fat-1 gene from *Caenorhabditis elegans in which* n-6 PUFAs are converted into n-3 PUFAs in vivo.

Methods: To induce arthritis, the AthritoMab^{TM}CllmAb cocktail (4 mg/mouse, MD bioscience GmbH, Zurich, Switzerland) was injected intravenously. Three days after antibody administration, 100 μg LPS (*Escherichria coli* 055:B5; MD Biosciences) was injected intra-peritoneally. The severity of arthritis was assessed by clinical arthritis score and hind paw thickness. On day 9, the mice were sacrificed and joint tissues were harvested from each animal for end point histology. IL-6, IL-17 and IL-23 levels in whole blood were determined using Milliplex¢ç MAP kit (KomaBiotech, Korea). Flow cytometry analysis was conducted for Treg analysis.

Results: Clinical score was significantly attenuated in fat-1 mice compared to wild type on day 7 (1.6¡¾1.8, p=0.012) and day 9 (1.5¡¾1.6, p=0.003). Ankle thickness was also decreased significantly in fat-1 mice compared to WT (1.82¡¾0.11, p=0.008) (Fig 1). The pathologic finding showed that inflamed cell infiltration and bone destruction were reduced in fat-1 mice compared to WT ($p<0.05$) (Fig 2). The expression levels of IL-17 and related cytokines including IL-6 and IL-23 decreased in the spleen and ankle joint tissue of fat-1 mice. Furthermore, Treg cells were expanded in the spleen of fat-1 mice and Treg cell differentiation was higher in fat-1 mice than in wild type ($p<0.033$) (Fig 3).

Conclusion: These data suggest that n-3 PUFAs attenuate arthritis through increasing the number of Tregs and reducing IL-17 production. Therefore, dietary supplementation of n-3 PUFAs may be a promising therapeutic potential for the treatment of RA.

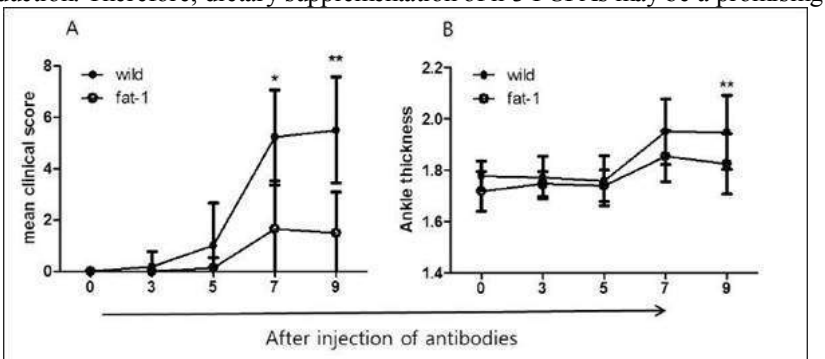

Figure 1. Clinical disease scores and ankle thickness in anti-collagen antibody induced WT and fat-1 mice. Arthritis was induced with 4mg collagen antibodies in WT and fat-1 mice. Clinical scores (A) and ankle thickness (B) were monitored every other day until day 9. Values are the mean±SD (n=5 mice/group). (*p<0.05, **p<0.01) WT: wild type

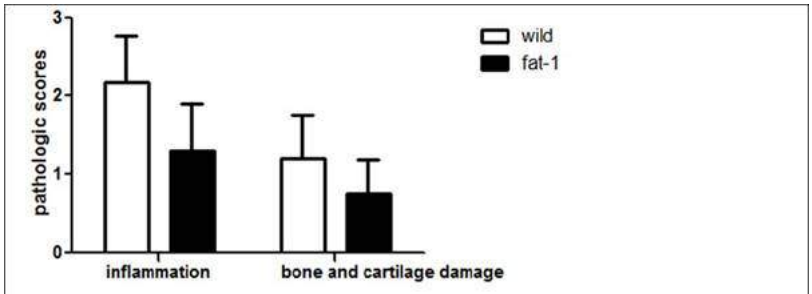

Figure 2. N-3 PUFAs inhibits ankle joint inflammation and bone and cartilage damage in CAIA mice. Ankle joints were collected on day 9, sectioned and stained with H&E in WT and fat-1 mice. This graph is a histopathological scores of the joint tissues. Pathologic scores were determined as described in the Materials and Methods. Values are the mean±SD (n=5 mice/group). (*p<0.05, **p<0.01)

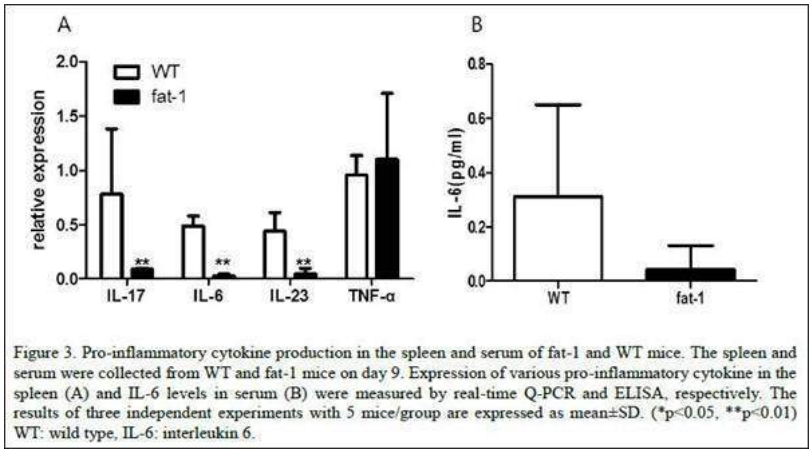

Figure 3. Pro-inflammatory cytokine production in the spleen and serum of fat-1 and WT mice. The spleen and serum were collected from WT and fat-1 mice on day 9. Expression of various pro-inflammatory cytokine in the spleen (A) and IL-6 levels in serum (B) were measured by real-time Q-PCR and ELISA, respectively. The results of three independent experiments with 5 mice/group are expressed as mean±SD. (*p<0.05, **p<0.01) WT: wild type, IL-6: interleukin 6.

Conventional Non-Steroidal Anti-Inflammatory Drugs, but Not COX2 Selective Inhibitors, Are Beneficial on Vascular Function in Arthritis: A Study in Adjuvant Induced Arthritis

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is associated with an increase in cardiovascular (CV) risk explained in part by an accelerated atherosclerosis as a consequence of endothelial dysfunction. Non-steroidal anti-inflammatory drugs (NSAID) are widely prescribed in RA patients in case of acute pain. Surprisingly, despite the commonly held belief that NSAID worsen CV risk, data concerning their impact on endothelial function in RA are lacking. The present study investigated the effect of naproxene (COX non-selective inhibitor), diclofenac (COX-1 preferential inhibitor) and celecoxib (COX-2 selective inhibitor) on vascular function in arthritic rats and identified the underlying mechanisms.

Methods: Adjuvant-induced arthritis (AIA) was induced in 6 weeks old male Lewis rats by injection of *Mycobacterium butyricum* in adjuvant at the basis of the tail. At the onset of arthritis, rats were daily treated (i.p) with naproxene (10

mg/kg/d), or diclofenac (5mg/kg twice a day), or celecoxib (3 mg/kg/d) or saline (Vehicle) for 21 days. Arthritis score and tarsus diameter were daily monitored. At the end of treatment, thoracic aortas were harvested to measure the relaxation to acetylcholine on pre-constricted aortic rings in the presence or not of inhibitor of nitric oxide (NO) synthase (L-NAME), arginase (nor-NOHA), EDHF (Apamin/Charybdotoxin), or a superoxide dismutase analog (Tempol). The relaxing effect of a NO donor (sodium nitroprussiate, SNP) was studied on endothelium-denuded aortic rings. Blood pressure and heart rate were also assessed.

Results: Compared to "Vehicle", AIA "Naproxene", AIA "Diclofenac" and "AIA Celecoxib" exhibited reduced ($p<0.05$) arthritic score and paw diameters. Diclofenac was responsible for an elevation of the blood pressure. Naproxene and diclofenac significantly ($p<0.05$) improved Ach-induced relaxation through distinct mechanisms. Naproxene increased NO synthase activity and EDHF production ($p<0.05$), decreased arginase activity ($p<0.05$) and decreased superoxide anions production ($p<0.05$). Diclofenac increased EDHF production ($p<0.05$), decreased arginase activity ($p<0.05$) and decreased superoxide anions production ($p<0.05$) but had no effect on NO synthase activity. By contrast, celecoxib did not modify Ach-induced relaxation but only increased NO synthase activity and EDHF production ($p<0.05$). The response of rings to the NO donor was unchanged after treatment whatever the treatment.

Conclusion: Our study demonstrates for the first time that naproxene and diclofenac are beneficial for endothelial function in case of arthritis, even though diclofenac enhanced blood pressure. Conversely, despite the same effect on the inflammatory symptoms, the COX-2 selective NSAID (celecoxib) did not improve endothelial function. From a clinical perspective, these results raise the question of the restriction of the use of COX-2 selective inhibitors in patients with inflammatory rheumatisms. In case of arthritis, the use of a non-selective COX inhibitor could be a preferential choice due to beneficial effects for the vascular function without changes in blood pressure.

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Polyglutamate metabolites of methotrexate (MTX) are believed to represent the pharmacologically active form of the drug and have been proposed as a biomarker to guide therapy in autoimmune arthritis. This work seeks to investigate the relationships between the formation of MTX polyglutamates and MTX efficacy in the collagen-induced arthritis (CIA) mouse model.

Methods: Arthritis was induced in male DBA/1 mice at 7-9 weeks of age by intradermal injection of chicken-collagen in complete Freund's adjuvant (Day 0) with a booster injection at Day 19 (n=25) and compared to healthy controls (n=5). Subcutaneous MTX injections of 0, 2, 10, 20, and 50 mg/kg were given weekly beginning at Day 14 for a total of 6 weeks. Animal weight and arthritis disease activity were routinely assessed by paw volume measurements and a 16-point clinical disease score. Mice were sacrificed at Day 54 and tissue samples were collected. Joint and liver tissues were submitted

for histopathologic scoring on a 16-point scale. Erythrocyte and liver samples were evaluated for MTX and its glutamate metabolites and plasma was analyzed for aspartate (AST) and alanine (ALT) aminotransferase activity.

Results: The disease induction protocol resulted in 100% incidence of arthritis by Day 30 and an average ± SEM clinical disease score of 13.8 ± 1.3, a 69 ± 4% increase in paw volume, and a 10 ± 2 joint histology score in the positive control group by the end of the study. MTX treatment resulted in a dose-dependent reduction in disease activity. Maximum response was observed with the 20 mg/kg dose resulting in a reduced clinical disease score of 4 ± 4 ($p<0.05$), a reduction in paw volume expansion to only 12 ± 7% ($p<0.001$), and a reduced joint histology score of 1 ± 1 ($p=0.02$). Changes in animal weight were proportionate to disease activity, not MTX dose, and no hepatic toxicity was observed by Roenigk histological scoring or by AST/ALT evaluation. Erythrocyte concentrations of MTX were proportional to dose and ranged from 87 ± 2 nM at the 2 mg/kg dose to 303 ± 33 nM at the 50 mg/kg dose. In contrast, MTX concentrations in the liver were independent of dose and averaged 483 ± 21 nmol/mg of tissue. In contrast to human studies, significant accumulation of MTX polyglutamates was not observed in erythrocytes or liver tissue. Without regard to dose, the non-polyglutamated parent form of MTX accounted for 91 ± 0.4 % and 80 ± 1.5 % of total MTX in erythrocytes and liver tissue, respectively.

Conclusion: Once weekly subcutaneous MTX was effective in reducing the severity of collagen-induced arthritis in mice despite negligible tissue accumulation of MTX polyglutamates, and resulted in no measurable hepatotoxicity.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Mast cells have long been recognized to increase strikingly in number in the synovial membrane of rheumatoid arthritis（RA），accounting for 5% of the surface synovial membrane cells. Type II collagen has the longest half-life in cartilage matrix. The main cells which might affect articular cartilage in RA are synovial fibroblasts, synovial macrophages and mast cells. The latter two could express cathepsin S. We aimed to find the cells which have the biggest influence on type II collagen secreted from articular chondrocytes and the possible mechanisms in RA mice.

Methods:

Four types of cells from collagen-induced arthritis model-established C57BL/6 mice were primary cultured，including synovial fibroblasts，peritoneal macrophages，bone marrow-derived mast cells and articular chondrocytes. The first three were co-cultured with articular chondrocytes separately. LHVS, a specific inhibitor of cathepsin S, and E64, a broad-spectrum inhibitor of cysteine protease, were added into the cocultures of macrophages and articular chondrocytes separately. Also, C48/80, an activator of mast cells, LHVS, and E64 were added into the cocultures of mast cells and articular chondrocytes separately. The culture supernatant fluid was collected. The concentration of cathepsin S and type II collagen were measured by ELISA. The expression of type II collagen mRNA in each group was detected with RTPCR.

Results:

Macrophages and mast cells expressed cathepsin S, while synovial fibroblasts did not express cathepsin S. Synovial fibroblasts had little effect on the expression of type II collagen from articular chondrocytes. When articular chondrocytes were co-cultured with macrophages，the expression of type II collagen decreased(8.79±2.79ng/ml),compared with the control group (17.75±7.84ng/ml). The secretion of type II collagen could return to normal by the inhibitors of cathepsin S, both LHVS(16.15±8.05 ng/ml) and E64 (12.55±6.64 ng/ml). When articular chondrocytes were co-cultured with mast cells, the type II collagen could be restrained by C48/80 (9.82±0.42ng/ml), compared with the control group(26.09±9.34ng/ml).Similarly，the secretion of type II collagen could return to normal by LHVS and E64（16.15±8.05 ng/ml，12.55±6.64 ng/ml，respectively）. There was no significant difference in the expression of type II collagen mRNA between different groups. It showed that the type II collagen was not suppressed at the transcription level, but was mainly destroyed by cathepsin S after secretion.

Conclusion:

Macrophages and mast cells are the major sources of cathepsin S, which might be the main factor that destroys type II collagen secreted from articular chondrocytes in RA mice.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cryotherapy is widely and empirically used in an adjuvant and symptomatic setting in inflammatory rheumatic diseases, with a low level of evidence [1]. The aim of this work was to evaluate local and systemic anti-inflammatory effects of local cryotherapy (LC) in adjuvant-induced arthritis (AIA), comparing 2 techniques (ice and cold gas spray). We considered clinical (arthritis score and ankle diameter) and biological effects on IL-6, IL-17A, IL-1β, TNF-α local and systemic levels.

Methods: Arthritis was induced by a single Mycobacterium butyricum injection in male Lewis rat tails (day 0). At the onset of arthritis (day 11), rats were treated either by 30 minute-ice applications on hind paws (in cages lined with ice pops – n=10) or by 2 minute-cold gas pulverizations on both hind paws (n=9) twice a day for 14 consecutive days. Ten non-treated AIA rats were used as controls. At day 24 (the day after the last cold application), hind paws were grinded in order to measure cytokine gene expression levels by Q-RT-PCR. Plasmatic levels of the same cytokines were also measured in plasma by cytometry (Multiplex Magpix® ebioscience). IL-6 plasma levels were measured by ELISA (rat IL6 platinum ELISA, BMS625®, ebioscience).

Results: Ice application significantly reduced the mean arthritis score and ankle diameter from day 6 to day 14 ($p<0.001$) and globally throughout the 14 day treatment period (2-way ANOVA: $p<0.001$) compared to non-treated AIA controls. Cold gas first aggravated arthritis at days 11-12 ($p<0.01$) then improved clinical inflammation at days 21-24 ($p<0.001$). Skin temperature after LC didn't differ between treatment groups. Both techniques significantly reduced IL-6, IL-1β, IL-17A gene expression levels in hind paws at day 24 compared to non-treated AIA (by 60%, 87% and 50% respectively, $p<0.001$,$p<0.001$ and $p<0.05$). Cytokine gene expression levels correlated positively with hind paw arthritis score and ankle diameter. Conversely, LC had no effect on TNF-α gene expression in hind paws. LC also significantly reduced IL-17A plasmatic protein levels at day 24 (Ice : 47+/-3pg/ml versus 132+/-15pg/ml;n=9;p<00001 – cold gas : 89+/-12pg/ml versus 132+/-15pg/ml;$p<0.02$) and IL-17A plasmatic levels correlated positively with arthritis score, ankle diameter and negatively with weight gain. Ice also reduced IL-6 plasmatic levels (118+/-20pg/ml versus 197+/-60pg/ml;$p<0.05$) and IL-6 plasmatic levels correlated positively with ankle diameter. By contrast, LC had no effect on TNF-α nor IL-1β plasmatic levels.

Conclusion: These results demonstrate in vivo previously unknown therapeutic and anti-inflammatory effects of 14 day-LC in AIA. We observed both local (at the gene level in treated hind paws) and systemic (at the protein level in plasma) down-regulation of key cytokine pathways critically involved in the pathogenesis and severity of inflammatory rheumatic diseases. LC local and systemic anti-inflammatory effects were mainly IL-6 / IL-17A-driven and TNF-α-independent in this model. [1] Guillot X, et al. Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have shown that cellular metabolism plays an important role in regulating immune cell function. In the process of cell differentiation, both interleukin-17-producing helper T (Th17) cells and dendritic cells (DCs) show increase of glycolytic activity by upregulating glycolytic enzymes, such as hexokinase-2 (HK2). Blocking glycolysis by 2-deoxyglucose has recently been demonstrated to inhibits Th17 cell differentiation while promotes

regulatory T (Treg) cell generation, and then ameliorates experimental autoimmune encephalitis model. In addition, inhibition of glycolysis by 2-deoxyglucose has been reported to suppress activation of DCs. The aim of this study is to verify the effect of 3-bromopyruvate (BrPA), a specific inhibitor of HK2, on the differentiation and function of immune cells and on experimental arthritis in SKG mice.

Methods: Synovium from rheumatoid arthritis (RA) patients was stained by anti-HK2 antibody. Arthritis was induced in SKG mice by Zymosan A (ZyA) injection. BrPA (5mg/kg) was administered subcutaneously once daily. CD4+ T cells from spleens of unimmunized SKG mice were cultured with anti-CD3/anti-CD28, anti-IFN-γ, anti-IL-4, IL-6, TGF-β, IL-2, with and without BrPA for 5 days, and then analyzed by flow cytometry. Bone marrow (BM) cells from unimmunized SKG mice were cultured with GM-CSF and IL-4 (for 3 days), and with lipopolysaccharide (for 1 day) with and without BrPA, and then analyzed by flow cytometry.

Results: Immunohistochemistry revealed that HK2 expressing lymphocytes were increased in RA synovium. Treatment with BrPA significantly ameliorated arthritis of SKG mice (Figure). Histological scores of arthritis in BrPA-treated mice significantly were decreased compared to those of the control mice. Significant increase of Treg cells, decrease of Th17 cells, and decrease of CD40+CD86+CD11b+CD11c+ (activated) DCs were observed in the spleens from BrPA-treated SKG mice. *In vitro*, BrPA facilitated the differentiation of Treg cells, while it inhibited the development of Th17 cells. In addition, treatment of BM cells with BrPA reduced the proportion of activated DCs and inhibited the production of TNF-α, IL-6.

Conclusion: BrPA ameliorates autoimmune arthritis in SKG mice by facilitating the differentiation of Treg cells, and inhibiting the development of Th17 cells and activation of DCs.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilars are created to be essentially the same as their reference marketed biopharmaceuticals which have lost exclusivity, and they aim to offer more affordable treatment. Development of the proposed adalimumab biosimilar GP2017 involved extensive characterization of the originator adalimumab followed by a step-wise target-directed and re-iterative technical development program involving state-of-the-art physicochemical and functional characterization methods. The nonclinical pharmacological characterization was designed to demonstrate similarity to the originator adalimumab at multiple stages. These included assessment of target molecular interactions, functional assays reflecting the mechanisms of action of adalimumab, pharmacokinetics (PK) and assessment of efficacy in an established human TNFα transgenic murine model of polyarthritis.

Methods: *In vitro* functional characterization of GP2017 to confirm similarity with the originator consisted of

comparative assays addressing binding to TNFα, complement component C1q, FcγR and FcRn and cell-based TNFα neutralization, antibody dependent cell mediated cytotoxicity (ADCC) and complement dependent cytotoxicity (CDC) potency assays. *In vivo*, GP2017 was evaluated in comparative rabbit PK studies and in the Tg197 human TNFα transgenic mouse model of polyarthritis. Shortly after the onset of disease, mice were treated twice weekly from 6 weeks until the age of 10 weeks, with either placebo, or 3 mg/kg GP2017 vs. originator adalimumab which is a most sensitive sub-therapeutic dose or saturating dose (30 mg/kg) of originator adalimumab. All the animals were sacrificed 3 days after the last treatment. Histological analysis of the joints and circulating TNFα and IL-6 levels were analyzed as pharmacodynamics (PD) endpoints. Swelling of ankles, hind limb distortion, impaired movement and body weight were also assessed.

Results: High degree of similarity was observed in target binding affinity and functional activity for TNFα, Fc-receptors and C1q binding for both GP2017 and the originator adalimumab. Also, bioassays for TNFα neutralization and for Fc dependent effector functions (ADCC and CDC) showed that GP2017 is similar to the originator adalimumab. Similar *in vivo* PK, efficacy and PD effects were shown for GP2017 and the originator adalimumab. In the murine model of polyarthritis, at 3 mg/kg dose level, a superimposable time-course profile could be demonstrated. GP2017 showed similar increase in body weight, same effect on in life arthritic symptoms and histopathological examination of the underlying lesions in the arthritic joints compared to the originator. Total TNFα and IL-6 levels were similar between the treatment groups at 3 mg/kg dose level. Consistent correlations were observed between total TNFα, IL-6, clinical and histopathology scores.

Conclusion: Similarity of GP2017 and the originator adalimumab was demonstrated based on *in vitro* pharmacology, *in vivo* PK, efficacy and safety in human TNFα transgenic murine models of polyarthritis at nonclinical level.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The management of the chronic inflammatory rheumatisms has dramatically evolved in the last decade with a concept of “treat to target”. The theory of a window of opportunity with more beneficial effects of an early intensive treatment is supported by several evidences. The positive impact of an early treatment with a TNFα blocker is expected but the place and the interest of non-steroidal anti-inflammatory treatments (NSAIDs) and glucocorticoids is not clear. The aim of this study was to evaluate the radiological outcomes after an early treatment during 21 days by Etanercept, or Naproxene, or Celecoxib, or Prednisone, or Diclofenac or Methotrexate in adjuvant induced arthritis in rats.

Methods: Adjuvant-induced arthritis (AIA) was induced in 6 weeks old male Lewis rats by injection of *Mycobacterium*

butyricum in adjuvant at the basis of the tail. At the onset of arthritis, rats were daily treated with Naproxene (10 mg/kg/d i.p), or Diclofenac (5mg/kg i.p twice a day), or Celecoxib (3 mg/kg/d i.p) or Prednisone (10 mg/kg/d i.p), or Etanercept (10 mg/kg/3 days, s.c.), or Methotrexate (1mg/kg/3 days, s.c.), or saline solution (Vehicle), for 21 days. Arthritic score was daily monitored. At the end of treatment, paws' radiological exam was performed with a BMA High Resolution Digital X Ray (40mV, 10mA). A score of 0 to 20 was determined for each paw using a grading scale modified from Ackerman *et al (1979)*.

Results: Compared to the Vehicle, all treatments significantly reduced($p<0.001$) arthritic score with a reduction of the arthritic score evaluated between 40% (for methotrexate) and 70% (for diclofenac). Compared to the vehicle, the radiographic score was improved by Naproxene, Diclofenac, Celecoxib, Glucocorticoids, Etanercept ($p<0.001$) but not by methotrexate. Compared to Etanercept, Naproxene and diclofenac showed less radiological structural changes ($p<0.01$).

Conclusion: Our study demonstrates for the first time that an early treatment with NSAIDs, excluding COX2 selective inhibitor, is more beneficial than Etanercept on the radiological damages in adjuvant induced arthritis. The close efficacy of all drugs on the arthritis score suggests that the beneficial impact of NSAID is not only driven by their impact on the systemic inflammation. NSAIDs should be used during the window of opportunity.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Bruton's Tyrosine Kinase (BTK) mediates signaling in hematopoietic cells important for the initiation and progression of rheumatoid arthritis (RA). GS-4059 is an oral, selective, irreversible BTK inhibitor being developed in RA. JAK inhibitors have demonstrated clinical efficacy in RA and exert their biological activity principally by blockade of proinflammatory cytokine signaling. Here we demonstrate that 1) the single agent activity of GS-4059 is efficacious in two different rat models of collagen-induced arthritis (CIA); 2) the combination of GS-4059 with a JAK inhibitor increases efficacy in a chronic CIA model; and 3) the activities of targeting BTK or JAK as single agents can be functionally differentiated.

Methods: The in vivo efficacy of GS-4059 and a JAK inhibitor were tested alone or in combination in rat CIA model. In the chronic model, dosing was initiated at the peak of disease and continued into the chronic phase; making the test more indicative of late treatment effects in the highly destructive macrophage-mediated phase, rather than in the acute, early, neutrophil mediated phase of this model. Efficacy evaluations were based on animal body weights, daily ankle caliper measurements, ankle diameter (expressed as area under the curve), terminal hind paw weights, and histopathologic evaluation of ankles and knees. Anti-type II collagen antibody levels in terminal serum were analyzed, and PK was collected to evaluate the relationship to efficacy. Joint tissue RNA and protein were analyzed for transcriptional and protein modulation.

Results: GS-4059 demonstrated dose-responsive efficacy in two rat CIA models. In the chronic model, administration of either GS-4059 or a JAK inhibitor showed efficacy on the clinical and histopathologic parameters. Combination therapy with GS-4059 and a JAK inhibitor showed significantly greater effects on paw weights, ankle swelling, and ankle histopathology scores than the single agents. Body weight loss was significantly inhibited in the combination therapy group, and weight was increased compared to the monotherapy arms, suggesting the combination treatment was more effective. Serum anti-type II collagen antibody (IgG) levels were significantly reduced in rats treated with the combination of GS-4059 and a JAK inhibitor. Knee ED-1 immunopositive osteoclast counts were significantly reduced in the animals treated with GS-4059 or the combination, but not in the single agent JAK inhibitor group, highlighting functionally distinct effects of BTK or JAK inhibition. PK analysis of GS-4059 and the JAK inhibitor showed serum exposure levels similar to those achieved in human studies.

Conclusion: GS-4059 is a novel BTK inhibitor that displayed in vivo therapeutic efficacy in the acute and chronic rat CIA models. Combining GS-4059 with a JAK inhibitor significantly improved clinical and histopathology scores, and reduced body weight loss in the rat CIA model, at exposures achieved in humans. These data suggest that simultaneously targeting BTK and JAK can provide an efficacious therapy for inflammatory diseases.

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although rheumatoid arthritis (RA) tends to occur earlier and with increased severity in females, the underling etiology of this sexual dimorphism is unknown. We have investigated the behavior of draining lymph nodes in murine models of inflammatory-erosive arthritis as a potential translational biomarker of arthritic initiation and flare. We have shown in tumor necrosis factor-transgenic (TNF-Tg) mice that ankle arthritis commences with enlargement of the popliteal lymph node (PLN) that continues to expand until the volume suddenly and stochastically collapses, coinciding with arthritic flare in the ipsilateral knee. To assess if this biomarker of disease onset and progression recapitulates the sexual dimorphism observed in clinical RA, we performed a longitudinal power Doppler ultrasound (PD-US) study of PLN in male and female TNF-Tg mice.

Methods: PD-US was performed on the PLN and knee of each leg in male (n=3 mice; 5 PLN/knees) and female (n=6 mice; 12 PLN/knees) TNF-Tg mice at 2, 3, 4, 5, and 5.5 months of age. PLNs were phenotyped as expanding if the normalized PD (NPDV) signal exceeded the 75th percentile, or collapsed if it dropped below the 25th percentile after an expanding classification, as previously described (1). Each PLN/knee was evaluated independently, and percentiles were computed for each sex separately. The frequencies of expanded or collapsed PLN over time were compared using Fisher's exact test; and knee NPDV comparisons used RM-ANOVA.

Results: There were more expanded nodes at 3 months in female TNF-Tg mice (Figure 1a) compared to males (Figure 1b) (6 vs 0, $p<0.01$), but at 5.5-months, male animals had significantly more expanding nodes (5 vs 0, $p<0.01$). The transition to collapsed nodes occurred in 5 females during the study period compared to 0 collapsed in males. Even more strikingly, all of the females with collapsed nodes before 4 months of age died before the final 5.5 month time point. There were no significant differences between sexes in knee NPDV at any time point, however both female and male displayed significantly increased NPDV at 5.5 vs. 5 months of age (0.19 ± 0.10, 0.24 ± 0.04 vs 0.04 ± 0.04, 0.11 ± 0.10, $p<0.05$).

Conclusion: This is the first demonstration that PLN collapse occurs earlier in female TNF-Tg mice. Interestingly, knee NPDV increases, indicative of inflammatory-erosive arthritis, occur at the same time in both sexes. Taken together, this data supports the hypothesis that the mechanisms of RA are sex dependent, confirming this animal model as representative of the sexual dimorphism seen in patients. Further work is needed to elucidate the mechanism for early PLN collapse and mortality of female TNF-Tg mice. 1. Bouta EM, Ju Y, Rahimi H, de Mesy-Bentley KL, Wood RW, Xing L, et al. Power Doppler Ultrasound Phenotyping of Expanding versus Collapsed Popliteal Lymph Nodes in Murine Inflammatory Arthritis. PLoS One. 2013;8(9):e73766.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Chikungunya virus (CHIKV) is an arthritogenic alphavirus that invades the joints and causes chronic arthritis in up to 60% of infected individuals. Over the last two years, approximately 2 million people have been infected with CHIKV in the Western Hemisphere. The symptoms and immunological features of CHIKV arthritis mimic phenotypes observed in patients with untreated rheumatoid arthritis. Interferon regulatory factors (IRF) including IRF5 contribute to anti-viral immunity, but polymorphisms leading to over-expression of IRF5 increase the risk of developing rheumatologic disease. Thus, we reasoned that IRF5 expression may modulate the pathogenesis of CHIKV infection including the risk of developing severe CHIKV arthritis.

Methods: IRF5 knockout mice and wild-type control animals were infected with a highly pathogenic La Reunion strain of CHIKV and then monitored for virus replication, spread, and clinical features of disease including joint swelling, cytokine production, and leukocyte infiltration.

Results: We found that expression of IRF5 restricts CHIKV dissemination to distal joints, but at the expense of triggering more severe acute CHIKV arthritis. IRF5 expression was associated with enhanced cytokine production and leukocyte infiltration into the joints of infected animals.

Conclusion: IRF5 restricts CHIKV dissemination and promotes acute arthritis in mice. These findings suggest that over-expression of IRF5 in humans may limit the spread of arthritogenic alphaviruses to distal joints, but at the cost of promoting more severe clinical disease during the acute phase of infection.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Multiple biomarker disease activity (MBDA) cytokine panels identify RA subsets with continuing inflammation despite fulfilling clinical and acute phase reactants (APR) parameters of low disease activity or remission. However, the characteristics of MDBA in the RA subset of discordant disease, (clinically active, normal APR), are yet to be defined. Herein, we compared clinical characteristics and cytokine assays in RA concordant and discordant disease subsets.

Methods: RA patients enrolled in a longitudinal observational registry (VARA) were studied and clinical and disease status characteristics documented. Patients with high joint counts (TJC + SJC>3) and APR (ESR ≥ 28 + CRP ≥ 1.5) were categorized as Concordant (C1), those with TJC+SJC ≤3 and normal APR (ESR < 28 + CRP < 1.5) were C2, while those with TJC+SJC>3, but with ESR < 28 and CRP < 1.5 were categorized as Discordant (D). Discordant patients were further stratified into Low, Medium, High disease activity (DL, DM, DH), based on TJC+SJC of 4 or 5, 6-8, 9 or higher, respectively. Cytokines and chemokines (IL-1β, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12 (p70), IL-13, IL-17, GCSF, GM-CSF), IFN-γ, MCP-1, MIP-1β, TNF-α) were measured via bead-based multiplex assay and a cytokine score calculated (weighted average). Chi-square tests compared categorical measures by concordance status, t-, Wilcoxon rank sum and Kruskal-Wallis tests, ANOVA models, ordinary least squares regressions compared continuous measures.

Results: 1467, predominantly male, VARA patients had cytokine assays. Compared to C1 patients (n=434), D patients (n=174) were younger (62[11] vs 66[11] years), less frequently seropositive (RF [75% vs 91%], ACPA [72% vs 86%), with lower TJC (8.1 [7.1] vs. 10.0 [8.0] , SJC (6.1 [5.4] vs. 9.5 [6.9]) and DAS28-3v scores (3.8 [1.1] vs. 5.5 [1.1]. p<0.001). Cytokine scores at all levels of discordance were significantly lower than in C1 patients (p<0.001) (Table). DL, DM and DH subsets were not significantly different in cytokine scores, and were similar to C2 (n=356) patients. In multivariable analyses comparing C1 vs D patients, log CK Score was associated with RF status (p=0.037) and DAS28-3v scores (p=0.012). In the OLS model including C2 patients (mean log cytokine score = 1.99), there was significant association with RF (p=0.042), ACPA (p=0.031), but only a trend towards DAS28-3v scores (p=0.066).

Conclusion: In our RA discordant subset, cytokine scores were congruent with APR levels and disease status suggesting this particular MBDA at a single time point was not useful in delineating active disease. Prospective studies assessing disease outcomes in this RA subset may argue for less aggressive DMARD therapies.

Table: Associations of TJC+SJC >3 with cytokine assays/quartiles in RA patients with

Elevated and Normal Acute phase reactants

Group	Group Abbreviation	N	Cytokine Score Median (IQR)
TJC+SJC>3, ESR>28, CRP>1.5 (Concordant)	C1	174	11 (6-27)
TJC+ SJC >3 - <6, ESR<28, CRP<1.5 (Discordant, low activity)	DL	77	6 (4-11)
TJC+ SJC ≥6 - <9, ESR<28, CRP<1.5 (Discordant, moderate activity)	DM	91	6 (4-15)
TJC+ SJC ≥9, ESR<28, CRP<1.5 (Discordant, high activity)	DH	267	7 (4-20)

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The etiology of rheumatoid arthritis (RA) is multi-factorial, with expression of HLA-DRB1 shared epitope (SE), smoking and socioeconomic status (SES) exerting influence. Prior studies have evaluated the associations of air pollutant (AP) exposure with RA incidence, but not RA seropositivity or titers. We evaluated the associations of AP exposure with RA autoantibody status independent of SES, SE expression and tobacco exposure.

Methods: Patients from 7 sites of the Veterans Affairs Rheumatoid Arthritis (VARA) registry were included in the analysis. Socio-demographic, HLADRB1 SE status, tobacco exposure and RA seropositivity parameters (rheumatoid factor [RF], anti-cyclic citrullinated peptide [ACPA]) were available. Mean exposure levels for AP (NO_2, SO_2, Particulate matter {$PM_{2.5}$, PM_{10}} and Ozone) were obtained from local air quality monitoring stations based on the patient's zip code for the year prior to VARA enrollment. Mean standardized scores of individual pollutants were used to calculate a global pollution score and patients were further grouped into pollution quartiles. For SES, the mean standardized score of a composite based on zip code was used, which included percent in labor force, percent unemployed, median household income, and percent below the poverty line, while years of education served as a surrogate. Generalized estimating equations (GEE), using the log of RF and ACPA titers with nested models based on VA location were used to determine independent associations of AP on RF and ACPA positivity and titers.

Results: There were 1078 Veterans (91.1% male, 80.4% Caucasian), with mean age of 69.4 +/- 10.4 years and disease

duration of 12.5 +/- 11.7 years. HLADRB1 SE was positive in 73%, while 80.6% and 75.1% were RF and ACPA positive, respectively. Univariate analyses of the individual AP scores revealed no association with either RF or ACPA positivity. In multivariate GEE models, former and current smoking ($p<0.0001$), HLA-DR SE positivity ($p <0.0001$), and lower education status ($p<0.0001$, $p=0.027$) were predictive of higher RF and ACPA titers, respectively. In the same model, while patients in quartile 2 and 4 of AP exposure had lower ACPA levels ($p= 0.03$, $p< 0.0002$), there were inconsistent associations of AP quartiles with RF (Table 1). Analyses of individual pollutants revealed higher $PM_{2.5}$ levels to be associated with higher RF and ACPA titers ($p=0.0005$, $p=0.0092$).

Conclusion: In a predominantly male RA population with long standing disease, while confirmation of the association of HLADRB1 SE and smoking with autoantibody seropositivity was found, there was an inverse relationship between higher levels of air pollutant exposure and ACPA. Only small particulate matter exposure ($PM_{2.5}$) was linked to higher RF and ACPA titers. The overall effect of air pollutants on RA autoantibody status appears to be a varied and complex relationship.

Table 1: Nested GEE multivariate model of association of global air pollution (quartiles) with RF and ACPA titers

	RF (Units/ml)				ACPA (Units/ml)			
Mean Pollution (quartile)	Adjusted mean	Lower 95% CI	Upper 95% CI	P value	Adjusted mean	Lower 95% CI	Upper 95% CI	p value

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

ACR ABSTRACT 2016 Early detection of inflammatory arthritis: the role of musculoskeletal symptoms, infections and rheumatoid arthritis-related comorbidities in primary care ***Background/Purpose:*** Rheumatoid arthritis is characterized by clinically apparent inflammatory arthritis (IA). A preclinical phase has been recognized in which symptoms arise and ambulatory care utilization increases. However, information on location and timing of symptoms before IA diagnosis is still largely lacking. The present study was undertaken to identify pathogenetic clues to the development of IA and to assist early identification of future IA patients with a focus on musculoskeletal symptoms, infections and chronic comorbidities.

Methods: We conducted a nested case-control study using data from electronic medical records of general practitioners, participating in NIVEL Primary Care Database, to evaluate timing and numbers of visits for 192 symptoms and diseases up to nine years before diagnosis of IA. To this end we used the International Classification of Primary Care (ICPC-1) coding system. 2772 patients who received a new diagnosis of IA between 2012 and 2014 were matched (ratio 1:2) with controls on age, gender, general practice and retrospective duration of follow-up. The frequency of primary care visits between the IA patients and controls were compared using logistic regression in different time periods before diagnosis.

Results: The consultation rate for musculoskeletal symptoms was increased in IA patients in the last 1.5 years before diagnosis with odds ratios (ORs) of 1.8 (confidence interval; CI: 1.6-2.1, p-value<0.05), 1.4 (CI 1.2-1.6, p<0,05) and 1.3 (CI 1.1-1.5, p<0.05), respectively, at 6, 12 and 18 months before diagnosis. For infections, the consultation rate was significantly higher 6 and 18 months prior to diagnosis (OR=1.2; both CI: 1.1-1.4, p-value<0.05). Finally, for IA-related disease and other chronic diseases a significant difference was observed only 3 months before diagnosis with ORs of 1.2 (CI 1.02-1.3, p<0.05) and 1.3 (CI 1.1-1.5, p<0.05) respectively. All ORs are corrected for age and gender. Important contributors to the above mentioned significance levels were presence of shoulder complaints (16.1% in the IA-patients versus 9.6% in the controls; chi2 73.9, p<0.001), hand/finger complaints syndrome (12.2% versus 5.6%; chi2 112.5, p<0.001), carpal tunnel syndrome (5% versus 2.5%; chi2 37.1, p<0.001) and foot/toe complaints (15.2% versus 9.2%; chi2 67.0, p<0.001).

Conclusion: We found significantly increased consultation rates in general practice for musculoskeletal symptoms and infectious diseases prior to the diagnosis of IA. This diverging trend started 4-6 years before diagnosis, but becomes statistically significant around 1.5 years preceding diagnosis. Possibly, these symptoms can be used to develop methods for earlier detection of IA in general practice.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Persons at risk of rheumatoid arthritis (RA) may experience a variety of symptoms[1,2]. However, information on location, timing, severity and predictive value of these symptoms is largely lacking. The Symptoms in Persons At Risk of Rheumatoid Arthritis (SPARRA) questionnaire has been developed with support of EULAR to provide more insight into these symptoms. Aim of the study is to report the symptoms and symptom complexes using the SPARRA questionnaire in an international group of arthralgia patients at risk of developing RA.

Methods: The SPARRA questionnaire contains questions on presence, severity, impact and location of 13 symptoms derived from a qualitative study in seropositive arthralgia patients[1]. The items are: joint pain or swelling, joint stiffness, burning and tingling sensations, numbness, changes in skin colour, muscle cramps, weakness, fatigue, emotional distress, concentration difficulties and sleep problems. Answers are given on an ordinal scale. If present, number of days with a symptom per month (0, 1-5, 6-15, 16-30 days), severity (none, mild, moderate and severe) and influence (no, small, moderate or high impact) were recorded. Secondly, we recorded the location of joint pain. Finally, patients were asked to describe the pattern of symptom development over time. Patients were included in the Netherlands (N=68), United Kingdom (N=16), Sweden (N=15), Austria (N=11) and Switzerland (N=21). Validation of the questionnaire is ongoing.

Results: Of 131 arthralgia patients included, 85 were positive for anti-citrullinated protein antibodies (ACPA), 29 were positive for rheumatoid factor only, and 17 were seronegative with clinically suspect arthralgia. Most symptoms were present in a high percentage of patients, with pain as the most often experienced symptom and change of skin color rarely reported. When a symptom was present, it was usually experienced as moderate to severe, and with moderate impact by half of the patients (Table 1). The mean presence of symptoms was similar in the ACPA positive and negative groups, however, ACPA positive patients more often had severe symptoms (mean 61% versus 54%, NS) with higher impact (48% versus 41%, NS). Joint pain was most frequently located in the fingers. The most frequently reported pattern of symptoms was "coming and going, but always present" (32%).

Conclusion: The first results of the SPARRA questionnaire show multiple symptoms to be present in a high percentage of persons at risk for RA. These are often experienced as severe, with a high impact. References:

Anti-Citrullinated Peptide Antibodies Testing Rate over Time in Newly Diagnosed RA Patients – Data from Three Administrative Claims Databases (2007–2014)

E Alemao, Z Guo and L Burns, Bristol-Myers Squibb, Princeton, NJ

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Current clinical guidelines recommend testing for anti-citrullinated protein antibodies (ACPA) at the time of RA diagnosis.[1] However, there is a lack of information about the frequency of ACPA testing at RA diagnosis or thereafter. The aim of this study was to describe the frequency of ACPA testing over time and to investigate the potential differences in demographics, co-morbidities and hospitalizations between patients (pts) who received ACPA tests versus those who did not.

Methods: Data from the three following US commercial healthcare claims databases (db) were analyzed: IMS PharMetrics Plus (db A), Optum Clinformatics Data Mart (db B) and Optum Clinformatics Data Mart Medicare (db C). Pts with two diagnosis codes for RA from January 1 2007 to December 31 2014, treatment with a DMARD, and continuous enrolment for at least 12 mths before and 6 mths after the index date were included. ACPA and RF testing claims identified by current procedural terminology codes were included in the analysis. ACPA testing rates were evaluated as number of pts with tests divided by total number of pts with and without tests. Multinomial logistic regression

was used to evaluate baseline covariates associated with single ACPA test before the index date, single ACPA test after the index date and multiple ACPA tests.

Results: 67,674 newly diagnosed RA pts in db A (age 18–64 yrs), 14,767 in db B (age 18–64 yrs) and 10,225 in db C (age ≥65 yrs) met the study inclusion criteria. The overall ACPA testing rate (95% CI) was 70.6% (70.3, 70.9) in db A, 72.2% (71.5, 72.9) in db B and 63.5% (62.5, 64.4) in db C. The ACPA testing rates increased from 2007 to 2014 for all three db (Figure). The corresponding RF testing rates were 75.4% (75.1, 75.7), 85.1% (84.5, 85.6) and 77.8% (77.0, 78.6), respectively. Pts tested and not tested had similar characteristics, with a standardized difference of >0.10 in only a few co-morbidities. The odds ratio (OR) for pre-diagnosis testing for each year increase from 2007 to 2014 was 1.26 (95% CI: 1.25, 1.28) in db A, 1.19 (1.17, 1.22) in db B and 1.27 (1.23, 1.31) in db C. Women were more likely to have multiple tests in db A (OR: 1.15; 95% CI: 1.08, 1.21) and in db B (OR: 1.29; 95% CI: 1.14, 1.45), but not in db C (OR: 0.93; 95% CI: 0.80, 1.08). Pts who received ACPA tests, vs those who did not, had a lower rate of 1-yr hospitalization; the hazard ratio (95% CI) after adjustment for covariates was 0.76 (0.71, 0.80) in db A, 0.86 (0.75, 0.98) in db B and 0.76 (0.68, 0.85) in db C.

Conclusion: The ACPA testing rate, especially pre-diagnosis testing, increased significantly from 2007 to 2014. Women aged 18–64 yrs were more likely to have multiple tests. A slightly lower rate was seen in RA pts ≥65 yrs old.[2]

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Calprotectin (MRP8/MRP14, S100A8/A9) is a major leukocyte protein previously shown to be associated with disease activity in patients with established rheumatoid arthritis (RA). Some studies indicate that it may be a more accurate measure of joint inflammation than erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP). Our objective was to compare the associations of calprotectin, ESR and CRP with clinical and ultrasound (US) measures of inflammation in patients with early RA, both before and after 12 months of aggressive disease-modifying antirheumatic drug (DMARD) treatment.

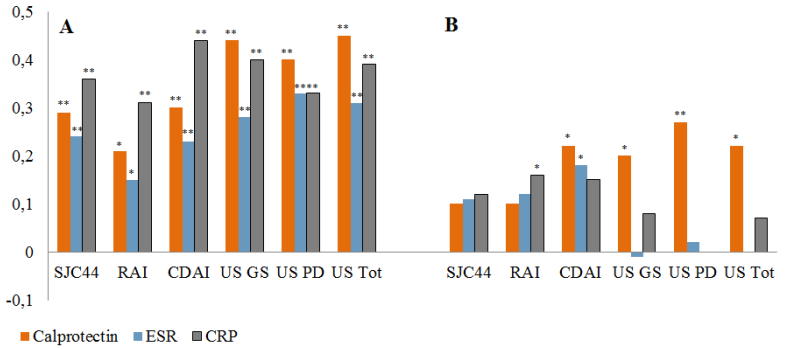
Methods: RA-patients (n=238) who fulfilled the 2010 ACR/EULAR classification criteria were recruited to the ARCTIC trial between 2010 and 2013. All patients had symptom duration from first swollen joint <2 years and were DMARD-naïve with indication for DMARD treatment. Calprotectin in EDTA-plasma was analyzed by ELISA in 212 patients at baseline and 163 patients at 12 months. US inflammation was evaluated using a standardized protocol with semi-quantitative scoring 0-3 for grey-scale (GS) and power Doppler (PD) in 32 joints (1). Clinical inflammation was assessed by 44 swollen joint count (SJC44), Ritchie Articular Index (RAI), ESR and CRP. Disease activity score (DAS) was calculated. Cross-sectional relationships were assessed by Spearman's correlations.

Results: A total of 212 patients were included: 61% female, 71% RF positive, 83% ACPA positive, mean (SD) age 50.8 (13.8) years, mean DAS 3.4 (1.2), median [25, 75 percentile] disease duration 5.9 [2.9, 10.6] months. At 12 months mean DAS was 1.2 (0.7); 75.5% were in remission according to DAS, 15.3% low, 8.7% moderate and 0.5% high DAS. The median baseline/12 month calprotectin was 1020 [562, 2153]/478[293, 794] µg/L, ESR 19 [11, 30]/9[5, 15] mm/h and CRP 7 [3, 17]/3[1, 5] mg/L. Calprotectin was significantly correlated with clinical and US markers of inflammation before treatment onset (table, figure A). After 12 months of treatment, calprotectin had a weaker, but statistically significant correlation with US scores, while no significant associations between ESR/CRP and US scores were found (figure B).

Table: Spearman's correlation coefficients; $^{*}p<0.05$, $^{**}p<0.001$

	Baseline n=212			**12 months n=163**		
	Calprotectin	ESR	CRP	Calprotectin	ESR	CRP
Calprotectin	NA	0.48**	0.64**	NA	0.43**	0.33**
ESR	0.48**	NA	0.62**	0.43**	NA	0.24*
CRP	0.64**	0.62**	NA	0.33**	0.24*	NA

Figure: Correlations between calprotectin/ESR/CRP and markers of inflammation at baseline (A) and after 12 months (B)



Spearman's correlation coefficients; *p<0.05, **p<0.001

Conclusion: Calprotectin was correlated with inflammation assessed by ultrasound before onset of DMARD treatment, and the association was also present after 12 months of DMARD treatment. This association was not found for ESR and CRP. The data support that calprotectin might be of interest when assessing disease activity in different stages of RA.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The 2010-ACR/EULAR criteria were derived to classify RA earlier in time. Previous studies indeed observed that the 2010-criteria were fulfilled earlier than the 1987-criteria. This study determined whether the 2010-criteria perform equally in early detection of autoantibody-positive and autoantibody-negative RA.

Methods: From the total Leiden-EAC (n=3448) and ESPOIR (n=813) RA-patients who fulfilled the 1987-RA criteria at 1-year but not at presentation were selected (n=515 and n=53, respectively). These RA-patients were studied on the presence of ACPA and RF, and on fulfilling the 2010-criteria at baseline, as 2010-positivity indicated that these RA-patients were earlier identified.

Results: In the EAC, 67% of the selected RA-patients did already fulfil the 2010-criteria at baseline. In ESPOIR this was 57%, indeed demonstrating early classification with the 2010-criteria. Among the selected autoantibody-positive RA-patients of the EAC, 85% was identified at baseline already with the 2010-criteria. Within autoantibody-negative RA this was 45% ($p<0.001$). Similarly within autoantibody-positive RA-patients in ESPOIR 92% was 2010-positive at baseline, whereas this was only 25% within autoantibody-negative RA ($p<0.001$).

Conclusion: The 2010-criteria perform well in the early identification of autoantibody-positive RA, but autoantibody-negative RA-patients are still frequently missed with these criteria. This implies that other diagnostics are required for ACPA-negative patients.

Sensitivity and Specificity of 14-3-3η, Anti-CEP-1 and Anti-Sa Antibodies in

a Cohort of Seronegative and Suspected Rheumatoid Arthritis (RA) Patients from a Community Rheumatology Practice

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RA is the most common autoimmune inflammatory joint disease, affecting up to 1% of the world population. Detection of antibodies, specifically against IgM rheumatoid factor (IgM-RF) and anti-cyclic citrullinated peptide (anti-CCP) is widely used for the diagnosis of RA; both of these antibodies are included in the 2010 ACR/EULAR Rheumatoid Arthritis Classification Criteria. However, novel antibodies have been identified that can help further diagnose seronegative (IgM-RF and anti-CCP negative) RA patients. In addition to antibodies targeting cyclic citrullinated peptide (CCP), antibodies to citrullinated alpha-enolase peptide 1 (CEP-1) and citrullinated vimentin (Sa) have been found in RA synovium and serum. 14-3-3η is a protein also found in high levels in synovial fluid and serum of RA patients. The purpose of this study is to examine the sensitivity and specificity of 14-3-3η, anti-CEP-1 and anti-Sa antibodies in a cohort of seronegative RA and suspected RA patients.

Methods: The 3 assays were analyzed by enzyme-linked immunosorbent assay (ELISA) in serum from a community rheumatology practice in Los Angeles, CA (USA) using 176 samples of which, 130 were established RA patients and 46 suspected RA patients. Specificity was tested using 20 SLE, 16 psoriatic arthritis, 12 Sjogren's Syndrome and 20 Non-Rheumatic Disease Patient (NRDP) samples. Levels of 14-3-3η (Augurex Life Sciences Corp.), anti-CEP-1 and anti-Sa antibodies (Euroimmun) where measured using a laboratory developed test (LDT) at Rheumatology Diagnostics Laboratory, Inc. (RDL). Levels of anti-CCP IgG/IgA and IgM-RF were obtained on all serum samples.

Results: Out of 130 established RA patients, 50 (38%) were seronegative for both IgM-RF and anti-CCP antibodies. Of these 50 seronegative patients, 14-3-3η was positive in 5 patients (10%), while anti-CEP-1 and/or anti-Sa antibodies were positive in 5 additional patients (10%). Out of the 46 suspected RA patients, 38 (83%) were seronegative for both IgM-RF and anti-CCP antibodies. Of these 38 seronegative suspected RA patients, 14-3-3η was positive in 4 patients (11%), while no anti-CEP-1 or anti-Sa antibodies were positive.

Specificity of 14-3-3η, anti-CEP-1 and anti-Sa antibodies

		SLE Systemic Lupus Erythematosus	PSA Psoriatic Arthritis	SS Sjogren's Syndrome	NRDP Non-Rheumatic Disease Patient	Total
	n	20	16	12	20	68
14-3-3eta	Positive	0	1	2[b]	1	4
	Negative	20	15	10	19	64
	Specifcity	100%	94%	83%	95%	94%
Anti-CEP-1	Positive	0	0	1	1	2
	Negative	20	16	11	19	66
	Specifcity	100%	100%	92%	95%	97%
Anti-Sa	Positive	4[a]	0	0	0	4
	Negative	16	16	12	20	64
	Specifcity	80%	100%	100%	100%	94%
	Total Specificity	16/20 = 80%	15/16 = 94%	9/12 = 75%	18/20 = 90%	58/68 = 85%

a: ALL 4 SLE patients had predominantly inflammatory arthritis symptoms

b: 1 of 2 SS patients had active synovitis

Conclusion: In an established RA cohort negative for both IgM-RF and anti-CCP antibodies, further testing for 14-3-3η, anti-CEP-1 and anti-Sa antibodies identified an additional 20% of RA patients. In suspected RA patients (seronegative), 14-3-3η was positive in an additional 11%. The overall specificity of the 3 markers was 85%. In the autoimmune disease controls, most of the patients that tested positive for these antibodies had inflammatory arthritis/active synovitis, and therefore may have had an overlap syndrome.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The commonly used version of the 28-joint disease activity score based on C-reactive protein (DAS28-CRP4) includes swollen and tender joint counts (S/TJC), CRP and the patient global assesment of disease activity (PGA), while the 3-component version (DAS28-CRP3) does not include PGA. We examined whether these two instruments can be used interchangeably, and if assessment of disease activity status and treatment response to a tumor necrosis factor inhibitor (TNFi), such as originator adalimumab (ADA) in patients (pts) with rheumatoid arthritis (RA), differs.

Methods: This *post hoc* analysis used data from five randomized controlled trials: PREMIER, OPTIMA and CONCERTO enrolled pts with early RA who were MTX- and TNFi-naïve; DE019 and MUSICA enrolled pts with established RA and an inadequate response to MTX. The correlation between the two versions was calculated by Pearson correlation coefficients. The change from baseline in DAS28-CRP3 and DAS28-CRP4, and the number of patients reaching low disease activity (LDA, DAS28-CRP $\leq$3.2) or DAS28-CRP <2.6, was assessed at Weeks 12 and 24/26. Data from pts with non-missing DAS28-CRP-3 and -4 is included, pooled across trials by randomized treatment into ADA+ MTX, or placebo (PBO)+MTX.

Results: The DAS28-CRP3 and -4 versions showed a strong correlation (0.98, p<0 .001) for pts receiving MTX or ADA+MTX across all 5 trials, at both Week 12 and 24/26. Overall, in both treatment groups, most pts who achieved DAS28-CRP3 <2.6 (or LDA), also achieved DAS28-CRP4 <2.6 (or LDA) at both Week 12 and 24/26 (Table 1). Both versions were comparably responsive, with similar changes from baseline for pts in either treatment group, similar treatment differences, and response rate differences between pts receiving ADA+MTX and pts on PBO+MTX at Weeks 12 (Table 2) and 24 (not shown).

Conclusion: While the patient perspective is important, when PGA is not available, the DAS28-CRP3 score is able to provide an assessment of disease activity which correlates highly with the DAS28-CRP4 version.

Table 1. Patients who achieved DAS28-CRP <2.6 or LDA by the 3-component or 4-component versions at Weeks 12 and 24				
	Week 12		Week 24	
	Patients with DAS3 <2.6	Patients with DAS3<2.6 but not DAS4 <2.6	Patients with DAS3 <2.6	Patients with DAS3<2.6 but not DAS4 <2.6

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RA Patients with anti-citrullinated protein antibody (ACPA) or rheumatoid factor (RF) are known to have worse clinical outcomes compared to seronegative patients. To determine if there were differences in clinical, laboratory features and outcomes of RA patients based on their ACPA and RF status (group I: ACPA+RF+, II: ACPA+RF -, III: ACPA -RF+, IV: ACPA-RF-). All patients fulfilled the 1987 ACR criteria for RA.

Methods: ACPA and RF titres were analysed by ELISA. Statistical analysis was conducted using STATA 13.0 (College Station, TX). We used Chi-square test or Fisher's exact test to compare categorical variables. We used ANOVA or Kruskal Wallis test for continuous variables, followed by posthoc Tukey's HSD test when appropriate. A two tailed significance level of 0.05 was chosen for all tests.

Results: The study population comprises 970 patients (group I 663, II 68, III 106, IV 133) with mean disease duration of 174.4 + 103.4 months. The gender distribution, educational level, smoking status, mean disease duration, age of onset, age at RA diagnosis, duration from onset to 1st DMARD and number of co-morbidities were similar among the 4 groups. At presentation, group I had significantly higher ESR (mean 59.9mm/hr vs 48.5-55.8mm/hr in the other 3 groups, $p = 0.005$). Group I patients were more likely to have deformed joints (65.3 % vs 42.1-65.2 % in other groups, $p<0.001$) despite higher usage of prednisolone (59.3 % vs 39.9-58.8 in other groups, $p <0.001$) and higher number of synthetic DMARDs (2.86 vs 2.31-2.74 in other groups, $p< 0.001$). Fewer patients in groups I & II (66.2% and 62.7% respectively) achieved remission (DAS 28 < 2.6) compared to those in groups III & IV (74.3 % and 78.2 % respectively, $p=0.02$). However, the HAQ and Short form 36 (SF 36) scores did not differ among the 4 groups.

Conclusion: ACPA+RF+ RA patients have higher baseline ESR and fewer achieve remission, despite higher use of synthetic DMARDs compared to ACPA-RF+ and ACPA-RF- patients. However, these differences did not affect their functional status or quality of life.

The Identification of an ACR Score with the Optimal Discriminatory Ability Between Treatments in Patients with Early and Established Rheumatoid Arthritis

Josef Smolen[1], Roy Fleischmann[2], Daniel Aletaha[3], Yihan Li[4], Stefan Florentinus[4] and Ivan Lagunes Galindo[4], [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]Medicine, University of Texas Southwestern Medical Center, Dallas, TX, [3]Medical University Vienna and Hietzing Hospital, Vienna, Austria, [4]AbbVie Inc., North Chicago, IL

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients (pts) with rheumatoid arthritis (RA), the American College of Rheumatology (ACR)20 score was developed to best discriminate effective from placebo (PBO) treatment, minimize PBO response rates, assess the efficacy of a drug vs PBO and clinical outcome over a period. Based on trials of pts with established RA and on use of csDMARDs, ACR20 was determined to be the best discriminator vs ACR 50/70[1]. However, it is unclear if ACR20 is also the best discriminator between treatments in studies conducted in the current era. The aim was to determine the cut-off value of the ACR score which can best discriminate between the efficacies of various treatments in RA pts in a clinical trial (CT). _

Methods: This *post hoc* analysis used data from the PREMIER[2] and OPTIMA[3] CTs in pts with early RA who were methotrexate (MTX) naïve and from the DE019[4] and ARMADA[5] CTs in pts with established RA who had failed prior DMARD(s). To identify the ACR score with best discrimination between treatments, the ACR response rate was calculated for each treatment arm at various time points for each cut-off from 0-100. The p-value was calculated for the difference between treatments at each cut-off to identify the cut-off for which the p-value was the smallest.

Results: In pts from PREMIER (early RA), the maximum difference and best p-value between the PBO+MTX (newly introduced MTX) vs originator adalimumab (ADA)+MTX arms was achieved at ACR60 (fig 1A) at Week (Wk) 26. Similarly, in OPTIMA (early RA), at Wk 26 the maximum difference and best p-value between the PBO+MTX vs ADA+MTX arms was achieved between ACR70-80 (fig 1B). In pts from DE019 (established RA), ACR35 had the best discriminatory ability and p-value, both at Wks 24 and 52, when comparing PBO+MTX [MTX-continued in MTX inadequate responders (MTX-IR)] vs ADA+MTX (fig 1C). Similarly, in established RA pts from ARMADA, for PBO+MTX vs ADA+MTX at Wk 24, smaller ACR cut-offs were more discriminatory and ACR 30 had the best p-value (fig 1D).

Conclusion: The ACR cut-off score with the best discriminatory ability differed in these 2 populations; In early RA higher ACR cutoffs were more discriminatory, while in established RA, lower ACR cutoffs were better. This may be due to the early RA CTs having active comparator arms with newly introduced MTX, while the established RA CTs control arms had PBO on background MTX in MTX-IR pts. Further analysis is needed to determine if an ACR response other than ACR20, should be used in CTs with a newly introduced active comparator. In addition, the optimal ACR cutoff may differ according to the population studied (early vs. established RA). **References**

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The heavy metal Cadmium (Cd) may contribute to the high risk of developing rheumatoid arthritis (RA) through the cigarette smoking and occupational exposure including air pollution. But, there was no definite report about association between heavy metals and RA.

Methods: We analyzed serum heavy metals (Cd, Hg and Pb) [N=53829, RA= 803 vs. control= 5410, from 2008 to 2013], serum Mn, urine As (AAS method), [N=20277, RA=330 vs. control=65, from 2008 to 2009] and serum Zn [N=8958, RA=133 vs. control=27, in 2010] in RA patients from the data of KNHANES. We analyzed the prevalence of RA and performed general linear model and logistic regression with complex sample design method adjusted by age, sex and smoking status to evaluate the association of the serum heavy metals or minerals levels and RA.

Results: The prevalence of RA was 1.59 % [95% CI; 1.33-1.89] from 2008 to 2013. Serum Cd levels were elevated in RA patients (RA vs. control; 1.44 ± 0.06 μg/L vs. 1.02 ± 0.02 μg/L, p=0.02), and serum Pb levels also increased in RA patients (2.33 ± 0.07 μg/dL vs. 2.12 ± 0.03 μg/dL, p=0.01). There were no differences of serum Hg level (4.22 ± 0.24 μg/L vs. 4.00 ± 0.01μg/L, p=0.49), serum Mn level (1.33 ± 0.04 μg/dL vs. 1.33 ± 0.07 μg/dL, p=0.27), serum Zn level (126.51 ± 4.71 μg/dL vs. 119.14 ± 12.65 μg/dL, p=0.48) and urine As level (AAS method; 192.70 ± 15.65 μg/L creat vs. 181.34 ± 42.22 μg/L creat, p=0.79) between RA patients and control.

The odds ratios [OR, 95% CI] of the RA prevalence according to increase 1 μg/L of serum Cd was 1.62 [1.28-2.05, p<0.001]. And the OR of RA prevalence according to increase 1 μg/dL of serum Pb levels is 1.37 [1.18-1.60, p<0.001].

Conclusion:

We showed increased risk of rheumatoid arthritis associated with the serum Cd and Pb levels in the KNHANES data of Korean populations.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Individuals with clinically suspect arthralgia (CSA) with positivity of antibodies to citrullinated protein antigens (ACPA) have articular symptoms without clinical signs of arthritis. CSA patients are considered at high risk for progression to RA. The altered expression of miRNAs contributes to the development and maintenance of autoimmune diseases. Moreover, miRNAs appear promising diagnostic and/or prognostic biomarkers. We aimed to investigate differentially expressed peripheral blood mononuclear cell (PBMC)-contained and cell-free circulating

miRNAs in CSA and healthy controls (HC).

Methods: The study included 19 CSA individuals and 23 HC. Clinical disease activity assessments (DAS28, SDAI) and disease activity assessed by patient on VAS were performed. By definition, all patients had swollen joint count 0. Ultrasound (US) of 28 small joints was performed in CSA to evaluate subclinical synovitis. Total RNA from plasma and PBMC was isolated using phenol-chloroform extraction or miRNeasy Mini Kit. A comprehensive analysis of miRNAs was performed using TaqMan® Low Density Array (TLDA) in 5 samples per group. The expression of miR-451a was further validated by single assays and normalized to RNU44 for PBMC or an average of 3 spike-in C. elegans controls for circulating miRNAs. dCt was used for relative quantification.

Results: All CSA patients were ACPA+ with CRP 9.1±19.6 mg/l. 9 CSA patients had no activity on US (grey scale≤1 and power doppler=0). Out of the 380 miRNAs analysed by TLDA, 194 miRNAs were detected in PBMC of CSA and 198 in HC while 125 circulating miRNAs were detected in plasma of CSA and 124 in HC. TLDA analysis revealed 2.43x higher levels of miR-451a in PBMC and 1.55x lower levels of circulating miR-451a in CSA compared to HC. Further validation confirmed 3.19x higher expression of miR-451a in PBMC in CSA compared to HC (p=0.001). These levels in CSA significantly correlated with DAS28(CRP) (r=0.575; p=0.010), SDAI (r=0.676; p=0.004) and VAS (r=0.484; p=0.036), but not with tender joint count (r=0.401; p=0.089), ESR (r=-0.042; p=0.869) or CRP (r=0.238; p=0.328). No difference in expression of circulating miR-451a or association with disease activity was demonstrated. Subclinical activity as per US findings had no effect on the levels of miR-451 in PBMC or plasma. There was no correlation between circulating and PBMC levels of miR-451a (r=0.265; p=0.124)

Conclusion: Although CSA cannot be considered a disease itself, and is rather a clinical suspicion of a disease, high levels of miR-451 in PBMC distinguish these at high risk individuals from HC. Moreover, miR-451 reflects the activity at this pre-clinical phase. Acknowledgement: MHCR 023728 and SVV 260263 projects.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis is a chronic, systemic, autoimmune disease about 5% -%1 of world population affected. Highly reactive oxygen free radicals are believed to be involved in the pathogenesis of the disease. Our aim was to investigate the thiol/disulphide homeostasis, which has an important role in many cellular activities such as antioxidant protection, detoxification, cell growth and apoptosis in patients with rheumatoid arthritis.

Methods: Twenty female and five male patients diagnosed with RA according to American College of Rheumatology

1987 classification criteria and healthy, age, weight and height-matched 20 women and 5 men were evaluated. Disease activity was assessed using a variety of variables including erythrocyte sedimentation rate and C-reactive protein, tender joint count, swollen joint count, and Disease Activity Score-28.

Results: The mean ages of patients group (32.60±7.18) and control group (31.70±8.23) were similar (p=0.573). When we determine at the thiol/disulphide homeostasis parameters in both groups, we can see the mean native thiol (p=0.004), and native thiol/total thiol (p=0.000) levels is lower in the RA group than the control group. The mean disulphide level (p=0.000) was higher in the RA group than control group. The multiple regression analysis of thiol/disulphide balance and other risk factors was performed. Low thiol levels and high disulphide levels in patients with RA were found to be independent of gender, age and body mass index.

Conclusion: In this study we have shown that thiol/disulphide homeostasis may be used as a novel oxidative stress marker in patients with rheumatoid arthritis. Further studies are needed to confirm the pathophysiologic role of thiol/ disulphide homeostasis in rheumatoid arthritis

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-cyclic citrullinated peptide antibody (Anti-CCP) is a diagnostic tool that predicts the progression of undifferentiated polyarthritis and erosive disease in rheumatoid arthritis (RA). It is more sensitive (60%) and specific (98%) than rheumatoid factor (RF). Despite these advantages, we hypothesize that physicians underutilize anti-CCP and other diagnostic tests for RA, which results in delay of diagnosis of RA and delay of initiation of treatment with disease modifying anti-rheumatic drugs. We aimed to describe the primary care work-up of polyarthritis in patients who eventually received a diagnosis of RA.

Methods: We performed retrospective chart review in patients seen between 1/1/2010 and 6/15/2014 in two rheumatology clinics, one private practice and one in a community health center associated with an academic medical center.

Results: We identified 173 patients seen in one of two rheumatology clinics referred from 141 different primary care providers. The sample was 83% (n=143) female, and the mean±SD age was 55.5±18.6 years. The majority (75.7%) were treated at the private practice. Anti-CCP or RF was ordered by the referring provider (prior to presentation to the rheumatologist) in only 38.7% (95% CI 31.7%, 46.3%) of patients. The presence of anti-CCP or RF did not vary significantly by presenting site: 33.3% at the community health center vs. 40.5% at the private practice, p=0.47. Ordering of anti-CCP varied non-significantly by presenting site: 19.1% of patients at the community health center presented with anti-CCP compared to 32.1% of the patients seen at the private practice (p=0.12). Prior to presentation at the rheumatology clinics, ESR was ordered in 43.9% of patients and CRP was ordered in 33.0% of patients. Ordering of ESR and/or CRP varied by site: 28.6% of patients seen at the community health center presented with ESR or CRP, but 52.7% at the private practice (p=0.008) presented with ESR or CRP. Lyme titre was ordered in 0.0% of community health center patients vs. 9.6% of private practice patients, p=0.04. Radiological imaging performed by PCP was only documented for 38.2% (n=66) of patients, with x-ray being the most frequent (46/66 or 69.7%) and MRI a distant second (6/66 or 9.1%). Functional ability was documented in only 2.3% of referred patients (95% CI 0.9%, 6.1%). About half of all patients (68, 51.1%) had DMARDS initiated immediately on presentation to the rheumatologist. Interval to treatment ranged from 0 weeks to 144, but only 18.1% (n=24) waited longer than one month for treatment. Interval to treatment was not associated with CCP order by referring physician (50% waiting > 1 month if anti-CCP was ordered vs. 30.3% if anti-CCP was not, p=0.13).

Conclusion: Most primary care physicians failed to order diagnostic tests for RA prior to referring a patient with polyarthritis to a rheumatology clinic. In particular, primary care providers failed to order anti-CCP in 61% of referred patients who eventually received a diagnosis of RA. Failure to order anti-CCP did not appear to significantly delay initiation of treatment of RA. These findings suggest educational efforts should focus on emphasizing earlier diagnostic workup, especially anti-CCP, in patients suspected to have RA.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Within the MiDEAR (Mobile medically supervised patient management in rheumatoid arthritis patients using DocuMed.rh and RheumaLive App) project patients (pts) with rheumatoid arthritis (RA) evaluate the usability of a mobile medical Application (mApp) with diary functions over nine months. The mApp includes two computerized patient-reported outcome questionnaires: the Hannover Functional Questionnaire (FFbH) and a modified RA disease activity index questionnaire (RADAI). In addition, it allows pts to document morning stiffness, pain (visual analogue scale), incapacity to work and medication. We studied pts' use of this kind of mApp outside of out-pts clinics, their satisfaction and the reported benefits in real-life settings.

Methods: Inclusion criteria were RA diagnosis, age of consent and German speaking. 268 consecutive RA out-pts (73.5% female) were screened, 157 (58.6%, 77.7% female) owned an App-able device. At baseline 60 out-pts consented to start the project. Pts downloaded the mApp on their own mobile device (either smartphone or TabletPC), documented their data voluntarily on not pre-specified intervals, and were followed on routine out-pts visits. During the out-pts visits pts evaluated the use, usability and feasibility of the mApp on paper-based questionnaires. Ethical approval and signed informed consents were obtained. The study is registered with the identifier NCT02565225 at clinicaltrials.gov.

Results: At baseline pts were predominantly female (78.3%), mean±SD age was 50.1±13.1 years (yrs), mean disease duration 10.5±9.1 yrs. 50% had a high education level. 90.0% already used Apps. 71.7% (n=43) remained in the project until the first follow-up. Reasons for discontinuation were fear of data theft (n=1), incompatible operating system (n=1), and other not App-related reasons (n=15). 97.7% (n=42) of the attending pts evaluated the mApp at first follow-up, n=39 had used the mApp at unspecific dates in between. Due to physical limitations (finger deformations) one patient reported problems to operate the mApp on a smartphone. Most pts (90.7%) rated mApp handling as easy. The average score of satisfaction with the mApp was 2.3±1.0 (Likert scale 1 (very satisfied) - 6 (very unsatisfied)) and the usefulness was 2.1±1.1 (Likert scale 1 (very useful) - 6 (not at all useful). Most pts (51.1%) stated that the mApp assisted them in an optimized self-monitoring of their disease. Better dealing with RA-related physical and medical needs due to App use was answered diversified with positive and negative responses.

Conclusion: At first follow-up the mApp use was feasible in the majority of the pts. mApp users were satisfied with the

mApp and assessed its utility as useful for self-monitoring their disease apart from out-pts visits. mApps - powerful tools at our fingertips - open great options for new management concepts. The ongoing project will deliver further data.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies demonstrated the lower prevalence of anti-CCP antibody and rheumatoid factor (RF) in elderly-onset rheumatoid arthritis (EORA). However, anti-CCP antibody titer in EORA has not been fully elucidated. In the present study, we aim to investigate RF and anti-CCP titers in patients with EORA and young-onset RA (YORA) based on a nationwide RA database, National Database of Rheumatic Diseases by iR-net in Japan (NinJa).

Methods: We analyzed 4,445 RA patients, whose anti-CCP titer data were available in NinJa 2014. The cutoff point used in the present study for defining EORA was 65 years of age. The Student unpaired t-test was used to compare the mean values, with p-values of <0.05 (after Bonferroni correction for multiple comparisons) considered to indicate statistical significance.

Results: Prevalence of RF and anti-CCP antibody in EORA (62.0% and 62.1%) was significantly lower than that in YORA (73.5% and 77.9%, respectively), as was consistent with previous studies. The average RF and anti-CCP titers increased, as the age at RA onset increased. There was thus a significant difference in RF levels between 20-29, 30-39 and 40-49 age groups (111, 118 and 103 IU/mL, respectively) and 70-79 age group (128 IU/mL). Anti-CCP titer was significantly higher in 60-69 age group (284 U/mL) than 20-29 age group (170 U/mL). Anti-CCP antibody levels were subsequently grouped into quartiles (Q1: 4.5-40, Q2: 40-124, Q3: 124-434, Q4: >434 U/mL). As shown in Figure 1, the proportion of anti-CCP negative RA patients was higher in the groups with age at disease onset above 50 years. Furthermore, there was a difference in the pattern of anti-CCP distribution, depending on the ages at RA onset. Thus, the higher titer quartiles (Q3 and Q4) were more frequently observed in RA patients with their age at disease onset above 50 years than in those below 50 years. There was a tendency of higher proportion of Q4 in RA patients with history of former and current smoking. However, since the prevalence of smoking is reported to be lower in the general population above 50 years of age in Japan than younger generations, extrinsic factors other than smoking could be involved in the higher-level production of anti-CCP antibodies in EORA.

Conclusion: We have demonstrated that lower positivity and higher titers of RF and anti-CCP antibodies were associated with increasing age at RA onset. It is suggested that a different pathogenic factors could contribute to anti-CCP production in elderly onset RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-cyclic citrullinated peptide (anti-CCP) auto-antibodies (auto-Abs) represent the current gold standard for the diagnosis of rheumatoid arthritis (RA). However, growing evidence suggests that a variety of other citrullinated or not citrullinated self-proteins may act as autoantigens and lead to the production of auto-Abs. The identification of diagnostic and/or prognostic value of such novel auto-Abs is under intense investigation. We recently demonstrated that RA patients display higher prevalence of auto-Abs against the interferon-inducible protein 16 (anti-IFI16) but these auto-Abs do not have a good diagnostic value (1). Recent data showed that auto-Abs against citrullinated

alpha-enolase (anti-CEP1) are associated with erosive RA (2). The purpose of this study was to investigate the possible prognostic value of anti-CEP-1 and anti-IFI16 as well as the clinical implication of their association with anti-CCP in a cohort or RA patients.

Methods: Two-hundred and fifty-two RA patients were enrolled and serum samples were obtained. Auto-Abs were assessed as follows: anti-CCP EDIA 2nd generation ELISA kit (Eurodiagnostica); anti-CEP-1 IgG ELISA kit (Euroimmun). In a subgroup of 113 patients also anti-IFI16 auto-Abs were assessed with an in-house ELISA kit (1). Clinical and serological records of patients were collected and statistical analysis was performed with SPSS 21.0 software.

Results: One hundred and twenty patients (44%) displayed anti-CEP-1 and, among these, 97 patients (87%) also displayed anti-CCP. Logistic regression analysis revealed an association between both auto-Abs and RA-associated pulmonary disease (odds ratio-OR=2.9; 95%CI= 1.06-7.9; p=0.04). We also confirmed that anti-CEP-1 are associated with erosive RA, but, of interest, to a greater extent compared to anti-CCP (anti-CEP-1: OR=4.12; p=0.04; anti-CCP: OR=2.1; p=0.03). The analysis that included anti-IFI16 revealed that a small proportion of patients display all the three auto-Abs (9%), but the triple positivity was significantly associated with male gender (OR=3.5; p=0.02), the presence of rheumatoid nodules (OR=5,3; p=0.015) and pulmonary involvement (OR=2,6; p=0.007). Anti-IFI16 were associated to male gender independently of the presence of the other two auto-Abs.

Conclusion: Our study suggests that anti-CEP-1 auto-Abs may participate to the development of RA-associated pulmonary manifestation together with anti-CCP and that the assessment of multiple auto-Abs in daily practice may help clinician to stratify RA patients in order to identify those at higher risk to develop extra-articular manifestations. **References** 1-Alunno A et al. The Longitudinal Stability of the RA Biomarkers RF and ACPA in Classifying RA Subtypes over Extended Follow up

Carl Orr, Francis Young and Douglas J. Veale, Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, University College Dublin, Dublin 4, Ireland

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In recent years several studies suggest that first order stratification of RA should be based on the presence or absence of rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) in sera [1,2]. Both RF and ACPA can be detected in the sera of some patients years before the onset of arthritis [3,4]. It has been shown that in patients presenting with undifferentiated arthritis, both RF and ACPA are stable biomarkers, and rarely change over the course of the first year of disease [5]. The longitudinal course of these important and commonly used biomarkers in established RA over a prolonged period of time is less clear. The objective of our study was to determine the rates of seroconversion for RF and ACPA, in patients with RA over an extended period of follow up.

Methods: 155 subjects (111 Female, Age Range 31-90 years) with RA meeting ACR/EULAR classification criteria were included. All subjects had assessments of RF at diagnosis and at their most recent clinical follow up and 58 had assessments of ACPA at diagnosis and most recent follow up.

Results: Subjects were assessed for RF for a median of 4.49 years (IQR 1.92-8.40) following the sample taken at diagnosis. Seroconversion for RF was observed in 15/94 (16.0%) of patients. Where RF was detectable at diagnosis, it became undetectable in the sera of 10/61 (16.4%). Subjects were assessed for ACPA a median of 1.90 years (IQR 0.63-3.54) following the sample taken at diagnosis. Seroconversion was not observed in any of the 25 patients who were negative for ACPA at diagnosis. Where ACPA was detectable at diagnosis, it became undetectable in the sera of 1/35 (2.9%).

Conclusion: In addition to being more specific for RA, ACPA offers the advantage over RF of being more stable over time. Our data suggests little merit in repeat testing of ACPA over time, and suggests the index result can be used to appropriately sub-classify the RA phenotype. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: For patients (pts) with rheumatoid arthritis (RA), quantification of radiographic progression, through measures such as modified total Sharp score (mTSS), is not routinely captured in daily clinical practice. Surrogate markers of radiographic progression may facilitate identification of pts who require closer monitoring. The aim was to assess the relationship between elevations in C-reactive protein (CRP) values, over 10 years (yrs), with physical function

and radiographic progression.

Methods: This post hoc analysis used data from 2 trials: PREMIER,[1]a 2-yr randomized, controlled trial (RCT) in methotrexate (MTX)-naïve, early RA pts, receiving MTX, adalimumab (ADA) or ADA+MTX, and DE019,[2]a 1-yr RCT in RA pts with an inadequate response to MTX, receiving Placebo or ADA on background MTX. In both trials, pts completing the RCT could enter an open label extension (OLE) for a total treatment period of 10 yrs. CRP and the disability index of the health assessment questionnaire (HAQ-DI) were collected at regular visits throughout the RCTs and OLEs. Radiographic data were collected at baseline, 6 months, 1, 2, 3, 5, 6, 8 and 10 yrs. Spearman coefficients assessing correlations between CRP elevations (defined as CRP >upper limit of normal [ULN]) and HAQ-DI were calculated at all visits. The association of radiographic progression (ΔmTSS ≥0.5) with CRP elevations and time-averaged (TA)-CRP was assessed between x-ray reads by logistic regression and descriptive statistics.

Results: In both PREMIER and DE019, a significant, positive correlation was observed between CRP elevations and HAQ-DI at nearly all time points during the RCTs, and approximately half of the time points throughout the OLEs. Further, CRP elevations were associated with radiographic progression during the first half of PREMIER but these associations were not observed at any time point in DE019 **(Table 1)**. For pts who experienced ≥1 CRP elevation >ULN between x-ray reads, TA-CRP was significantly associated with radiographic progression only at yrs 5 and 6 in PREMIER. Radiographic progression was observed frequently among pts with elevations in CRP between x-ray reads; however, radiographic progression was still seen in 20-52% of pts without CRP elevations. Pts receiving MTX monotherapy in both RCTs experienced an increase in CRP elevations compared to those pts receiving ADA+MTX (91% vs 55% for MTX and ADA+MTX, respectively, at 2 yrs in PREMIER; 68% vs 33% for MTX and ADA+MTX, respectively, at 1 yr in DE019). Consistently, treatment was significantly associated with radiographic progression, as assessed by logistic regression.

Conclusion: CRP is an important marker of inflammation that can be used to identify pts at risk of radiographic progression, and this relationship appears dependent on pt disease characteristics. Structural evaluation remains important until further predictors are identified.

Table 1. Relationship between CRP elevations and radiographic progression (ΔmTSS ≥0.5) in patients from PREMIER and DE019 over 10 years

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Association studies in rheumatoid arthritis (RA) have been focused in the pre-clinical phases of the disease in asymptomatic individuals with higher risk to develop RA such as first-degree relatives (FDR). Previous data has shown that obesity, the anti-citrullinated peptides antibodies (ACPA) status and the periodontal condition may modulate the severity and the clinical presentation of RA. The objective of this study were to investigate the body mass index (BMI), ACPA status, the frequency and severity of periodontal disease and the level of antibodies IgG-1, IGG-2 against *P. gingivalis* in healthy FDR individuals of RA-patients and compare these variables with a control group of healthy individuals from general population.

Methods: In total, 100 FDR individuals and 200 healthy controls paired by age and gender were included. Rheumatologic and periodontal assessment was performed as well as anti-*P gingivalis*antibodies and ACPA. The group-comparisons were analyzed using McNemar and Wilcoxon tests. A conditional logistic regression analyses was performed to establish associations between BMI, ACPA status and periodontitis in FDR individuals and control group.

Results: In the FDR-group, seventy percent were female with a mean age of 37.3±13 years. In the FDR-group 17% had obesity (BMI>30), compared to 7.5% in the control group. Additionally, there was association related to the presence of obesity in the FDR group (OR: 2.9, 95% CI 1.03-8.28). ACPA presence was found in 7% in FDR vs 2.5 % in control group (p=0.038), and was associated in the FDR group (OR: 2.4, 95% CI 0.7- 8.32). In the FDR-group 79% had periodontitis in comparison with control group 56% (p=0.001). Fifty percent of severe periodontitis was observed in FDR vs 9% in control group (p=0.009). A significant association was found in FDR individuals regarding the presence of periodontitis (OR: 3.95% CI 1.89–7.29). Results presented in Table 1. Regarding the presence of antibodies anti *P. gingivalis*(IgG1-IgG2) and smoking history, no differences between groups were found.

Conclusion: Obesity, ACPA expression and periodontitis (diagnosis and severity) can be considered as relevant risk factors associated to the development of RA in individuals FDR. The impact of interdisciplinary management, weight-loss interventions, recommendations on physical activity and screening of periodontal status in asymptomatic individuals at high-risk of developing RA such as FDR, should be further investigated. **Table 1.** Conditional logistic regression model for indicators related to the status of first-degree relatives of patients with RA (Obesity, ACPA, Periodontitis Diagnosis and adjusted Age)

	Unadjusted model		Adjusted model	
	OR	CI 95%	OR	CI 95%
Obesity (BMI≥30)	2.93	1.03 – 8.28	2.37	0.28 - 19.84
ACPA IgG-IgA (≥20 U)	2.45	0.72 – 8.32	11.82	0.07 - 1819.30
Periodontitis	3.70	1.88 – 7.29	7.63	1.07 - 54.30
Age	0.53	0.34 – 0.83	0.53	0.34 – 0.84

Periodontitis based on definition of CDC/AAP. Age = continuous Unadjusted model = includes ACPAs IgG/IgA, periodontitis, obesity and age Adjusted Model = includes ACPAs IgG-IgA, periodontitis, obesity, age and interaction of ACPAs IgG-IgA and Periodontitis with age and obesity

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibody (ACPA)-positive and ACPA-negative rheumatoid arthritis (RA) have different genetic risk factors and underlying biological mechanisms. Therefore, we hypothesized that patients' characteristics in the symptomatic phase before clinical arthritis has emerged are also different. We investigated this by studying the arthralgia phase of ACPA-positive and ACPA-negative patients.

Methods: Patients included in a clinically suspect arthralgia (CSA)-cohort were followed for 2 years or until arthritis development. At inclusion, information on initial symptoms and current symptoms was obtained, physical examination and MRI performed and blood samples taken.

Results were compared between ACPA-positive and ACPA-negative CSA-patients that later developed arthritis. Results: 60 patients (25-ACPA-positive, 35 ACPA-negative) included between April 2012 and March 2016 developed arthritis. 80% of ACPA-negative patients experienced morning stiffness as an initial symptom, compared to 52% of ACPA-positive patients (p=0.022). ACPA-positive patients more often had symptoms in both upper and lower extremities than ACPA-negative patients (40% versus 6%, p=0.001). ACPA-positive patients had a longer symptom duration at first presentation (median of 21.3 weeks versus 10.4 weeks, p=0.016) but converted to arthritis quicker (median 5.7 weeks versus 17.9 weeks after inclusion, p=0.015). A combination of variables clustered ACPA-positive and ACPA-negative patients in PLS-analysis.

Conclusion: In the phase preceding clinical arthritis, ACPA-negative and ACPA-positive arthralgia patients have

different characteristics. This contributes to the notion that ACPA-positive and ACPA-negative RA are different disease subsets.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hand bone mineral density (BMD) loss is an independent predictor of radiographic joint progression,[1] and a potential indicator of vertebral and non-vertebral fracture risk.[2] The relationship between hand BMD loss and anti-cyclic citrullinated peptide-2 antibodies (anti-CCP2, a surrogate of anti-citrullinated protein antibodies [ACPA]) in patients (pts) with established RA is unclear. Therefore, we evaluated this association to assess joint progression and fracture risk in pts with established RA.

Methods: Pts enrolled in a single academic center, prospective, observational cohort registry of RA patients, established in 2003, were included. The registry comprises mostly pts with established RA; digitized hand radiographs were collected at baseline and every 2–3 yrs (± 3 mths) over 15 yrs from which hand BMD was measured using digital X-ray radiogrammetry (DXR–BMD; methodology: Sectra [Sweden]). The current cross-sectional analysis is based on available data of DXR-BMD and anti-CCP2 measured within 6 months. Anti-CCP2–IgG-positive (+) pts (≥20 U/mL) were distributed into equal groups (Gp1–3), representing increasing anti-CCP2 concentrations. Associations between DXR–BMD and anti-CCP2 status and titers (Gp1–3; categorical variable) were explored in univariate and multivariate regression analyses controlling for covariates (age, RA duration, BMI, smoking status and use of steroids, biologic DMARD, and osteoporosis medication). The association between DAS28 (CRP) remission (<2.6) and bone loss was analyzed in pts with DXR–BMD ≥0.5 and <0.5.

Results: A total of 149 pts (all women) were included (47 anti-CCP2 negative [–], 102 anti-CCP2+ [34 per group]). Age (mean: 60–63 yrs), BMI (mean: 26–29 kg/m^2), DAS28 (CRP; median 3.7–4.2) and biologic DMARD use (43–56%) did not differ by anti-CCP2 status (+/–) or titer group; mean disease duration was greater in the three anti-CCP2+ titer groups versus the anti-CCP2– group (p=0.0215). DXR–BMD was higher in the anti-CCP2– versus the anti-CCP2+ groups (anti-CCP2– vs Gp1–3: p<0.0001 for left and right hand). DXR–BMD decreased with increasing anti-CCP2 titer increase (Figure 1; linear trend p<0.001 for left and right hand). Patients with low DXR–BMD were less likely to be in DAS28 (CRP) remission (DXR–BMD ≥0.5, 36.5% vs DXR–BMD <0.5, 18.8%; p<0.05). Even after controlling for baseline confounding factors, the odds of being in remission were significantly lower for pts with DXR–BMD <0.5 versus ≥0.5

(odds ratio [95% CI], 0.355 [0.126, 0.998]; p=0.0496).

Conclusion: These data suggest that anti-CCP2+ pts with established RA, particularly those with high anti-CCP2 titers, have lower hand BMD and patients with lower hand BMD are less likely to be in remission. Such patients could be at increased risk of joint progression and fracture. 1. Hoff M, et al. *Ann Rheum Dis* 2009;**68**:324–9. 2. Haugeberg G, et al. *Ann Rheum Dis* 2004;**63**:1331–4.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: C-reactive protein (CRP) is used to assess disease activity in rheumatoid arthritis (RA), and previous work suggests that adiposity also impacts CRP levels. This study assessed associations between BMI and CRP, hypothesizing that increasing levels of obesity are associated with elevations of CRP independent of RA disease activity, paralleling what is seen in the general population.

Methods: Associations between BMI and CRP were assessed in two RA cohorts – 1) a cross-sectional Body Composition (BC) cohort (N = 451) pooled from 3 independent studies from US academic centers that included whole-body DXA measures of fat mass index, and 2) the longitudinal Veterans Affairs Rheumatoid Arthritis (VARA) registry (N = 1652). For comparison, associations were also evaluated in the general population using data from the National Health and Nutrition Examination Survey (NHANES) 2007-2010 (N = 10,813). Linear and logistic regression analyses (defining high CRP as CRP > 1.0 mg/dL and using generalized estimating equations to incorporate repeated measures in VARA) were stratified by sex and adjusted for age, race, and smoking. Sequential models assessed the impact of adjustment for disease activity (swollen/tender joints, patient global score), and fat mass in BC only as this measure was not available for VARA.

Results: In all three cohorts (NHANES, VARA, BC), women in higher BMI categories had significantly higher CRP (all $p < 0.001$; BMI ≥ 35 vs 20-25 kg/m^2) (Figure). This association remained after adjusting for joint counts and patient global scores ($p < 0.001$ in BC; $p < 0.01$ in VARA) but was completely attenuated when adjusted for fat mass in BC. Women with BMI ≥ 35 kg/m^2 were also more likely to have an elevated CRP (Table 1). Again associations remained after adjusting for disease activity (BC: OR 4.05, $p = 0.02$; VARA: OR 2.82, $p = 0.01$), but were attenuated with adjustment for fat mass in the BC cohort (OR 0.99, $p = 1$). Among men, BMI ≥ 35 (vs BMI 20-25 kg/m^2) was not associated with higher CRP in VARA or BC (Figure). In VARA, but not in controls, men with low BMI <20 kg/m^2 had higher CRP and greater odds of an elevated CRP (all $p < 0.01$). In BC, fat mass index was associated with a greater odds of an elevated CRP in women (OR 1.69 per standard deviation, $p < 0.01$) but a lower odds in men (OR 0.60, $p < 0.01$).

Conclusion: Morbid obesity is associated with greater CRP in women with RA, similar to what is seen in the general population. This association is related to fat mass and not RA disease activity, necessitating caution when interpreting CRP among women with a high BMI. Causes of high CRP in low BMI men with RA require further study.

COMPLEMENT C3 AND C4 LEVELS AND ITS CORRELATION WITH DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS

Background/Purpose: Cytokines play a major role in the pathogenesis of Rheumatoid arthritis. However, some studies have also noticed the presence of increased levels of activated products of the complement system, not only in synovial fluid, but also in plasma of these patients, implying that the activation of complement could be another crucial event in the RA inflammatory cascade. Makinde et al. observed that plasma levels of complement C3 and C4 were significantly increased in RA patients when compared to healthy subjects, and they seemed to be correlated with disease activity. The aim of our study was to determine plasma levels of complement C3 and C4 in RA patients and to assess their correlation with disease activity.

Methods: Multicenter, cross-sectional, observational study, that included consecutively RA patients according to 2010 ACR/EULAR criteria. Connective tissue disorders (including secondary Sjögren´s Syndrome) and other conditions that might modify complement levels were excluded. Demographic and RA characteristics, disease activity measures and serological analysis [complement C3 and C4, erythrosedimentation (ESR) and C reactive protein (CRP)] were collected.

Results: Two hundred and eleven patients (98% females) were included. Mean age 50 years (SD 14.7). Fifty-nine percent were under treatment with NSAIDs, 61% with Corticosteroids, 77% with DMARDs (most of them with Methotrexate) and 20.6% patients were on biologic therapy. Mean DAS28 score was 4.29 (SD 1.55). The median ESR and CRP were 46 mm/h (IQR 12-40) and 1.1 mg/dl (IQR 0.3-3.8), respectively. *Complement levels were mostly normal: C3 in 194 patients (92%) and C4 in 180 patients (85%). There was no correlation between DAS28 score and C3 (p*=0.79) or C4 (*p*=0.07) levels. Patients with increased levels of C4 showed a median PCR higher than patients with low C4 levels (1,95 mg/dl versus 0,40 mg/dl, *p*=0,039). This association was not observed with C3 levels. There was no correlation between complement and ESR. DMARs and/or biologic therapy didn´t modify C3 or C4 levels. However, we observed an association between the use of Corticosteroids and C4 levels (*p= 0,003*): patients on Corticosteroid therapy showed a higher proportion of low C4 levels than those without Corticosteroids (13% versus 6%).

Conclusion: Despite the literature findings, most of our RA patients had complement levels within normal ranges. Plasma levels of complement C3 and C4 did not correlate with disease activity. We emphasize the association between RCP and C4 as well as a higher proportion of low C4 levels in patients treated with corticosteroids.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate anti-cyclic citrullinated protein antibody positivity in the general population and to identify its prognosis.

Methods: Anti-cyclic citrullinated protein antibody (ACPA) were measured with immunochromatographic test in 3607 people who visited for routine annual medical check-up from November 2014 to March 2016. Four people with history of rheumatic diseases except for rheumatoid arthritis (RA) were excluded from analysis. For ACPA positive persons, consultation to rheumatology was recommended. They were examined ACPA with CLEIA method, anti-nuclear antibody test, and anti SS-A antibody test. Also rheumatologist performed detail physical examination. The classification criteria of 2010 ACR/EULAR were used for diagnosis of RA. Asymptomatic examinees with ACPA positive were recommended to visit every 6 months. Symptomatic examinees that did not fulfill classification criteria even if they have morning stiffness or joint pain were recommended to visit every 3 months. While follow-up period, an examinee that fulfills classification criteria was prescribed DMARDs in accordance with guidelines.

Results: ACPA positivity with immunochromatographic test was identified in 1.0% (n=37) of examinees. 51.4% were woman. There were no correlations between ACPA positivity and smoking, drinking, BMI, and history of cancer. Among ACPA positive examinees, 64%(n=24) consulted to rheumatology department. They were confirmed ACPA positivity with CLEIA method. 58.3% (n=14) were CLEIA method positive. 57.1% were woman. 4 examinees have already diagnosed as RA and 5 examinees have morning stiffness or joint pain, which did not fulfill classification criteria. Mean follow-up period of ACPA positive examinees with CLEIA and immunochromatographic method was 10.5 month. One of 5

symptomatic patients developed RA and she reached remission after 2 months after starting methotrexate.

Conclusion: Positivity of ACPA in general population was 1%. Regular follow-up of ACPA positive patients could lead prompt diagnosis and treatment.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Vitamin D deficiency in patients with rheumatoid arthritis (RA) is commonly observed. Previous studies have investigated the relationship between vitamin D deficiency and RA and increased risk of cardiovascular events and the role of immunomodulation. While RA is recognized as a risk factor for osteoporosis, there are few reports examining the relationship between vitamin D level and bone mass or metabolism markers in RA patients compared with healthy controls. To examine the relationship between serum 25-hydroxyvitamin D (25(OH)D) level, bone mineral density, and bone metabolic markers of RA patients compared with age-and sex-matched healthy volunteers (Vo group) using a cross-sectional method.

Methods: In 2010, we began a prospective cohort study called the TOMORROW Study (UMIN000003876) which compares data from RA patients with age- and sex-matched controls (Vo) recruited through mass media. Laboratory data were collected for all participants, including 25(OH)D level, insulin resistance, bone metabolic markers (urinary pentosidine, homocysteine, collagen type 1 cross-linked N-telopeptide (NTX), and osteocalcin), and anthropometric parameters. Bone mineral density of the lower extremities and body composition were determined using whole-body dual-energy X-ray absorptiometry (DXA). The parameters were compared with healthy controls, and multiple regression analysis was carried out in the RA population only. In RA patients, disease activity score 28 was measured by clinical assessment.

Results: There were 413 participants (208 RA patients, 205 Vo group; 349 females; mean age of 58 years) enrolled in the study. In RA patients (mean disease duration of 13 years), bone density was significantly lower ($p<0.01$; Student's *t*-test), and urinary NTX ($p<0.01$), pentosidine ($p<0.01$), and homocysteine ($p<0.05$) were higher compared with the Vo group. The serum 25(OH)D level was lower in RA patients compared with the Vo group ($p<0.01$) (Table). Multiple linear regression analysis in the RA population revealed no significant relationship between DXA and vitamin D level ($p=0.18$) or pentosidine ($p=0.61$).

Conclusion: No relationship was found between low vitamin D level and decreased bone mass or bone quality in RA patients.

Table: Differences between RA patients and healthy controls (Vo)

(Student's *t*-test)

variables	Vo (n=205)	RA (n=208)	P -value
HbA1c	5.1	5.2	0.37
HOMA-R	1.06	1.25↑	0.03
Serum 25(OH)D (ng/dL)	21.6	18.5↓	<0.001
DXA (g/cm^2)	1.03	0.97↓	<0.001
Urinary NTX (nM/mM・Cr)	44.3	59.0↑	<0.001
Osteocalcin (ng/mL)	7.3	7.2	0.81
Urinary pentosidine (pmol/mg Cr)	54.1	72.6↑	<0.001
Homocysteine (nmol/mL)	9.1	10.9↑	<0.001

Gender Difference Is Apparent in the Risk of Forefoot Deformity in Patients with Rheumatoid Arthritis

Kentaro Inui[1], Tatsuya Koike[2], Tadashi Okano[1], Kenji Mamoto[3], Kazuki Orita[1], Yuko Sugioka[4], Masahiro Tada[5], Hiroaki Nakamura[3] and Orita incl, [1]Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan, [2]Center for Senile Degenerative Disorders, Osaka City University Medical School, Osaka, Japan, [3]Orthopedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan, [4]Center for Senile Degenerative Disorders (CSDD), Osaka City University Medical School, Osaka, Japan, [5]Orthopedic Surgery, Osaka City General Hospital, Osaka, Japan

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Forefoot involvement in patients with rheumatoid arthritis (RA) is common, and reported to be present in 50–90% of patients without any clear gender predisposition. However, patients with RA that undergo surgical treatment for their forefoot deformities are mostly female, which seems much higher rate than the prevalence of forefoot involvement by arthritis condition. In this study we evaluate the factors that contribute to forefoot deformity in RA, and investigate the significance of gender differences in forefoot deformity.

Methods: In this cross sectional study, 265 patients (530 feet) with RA (165 females) were enrolled. On AP and lateral standing radiographs of the foot, the angle formed by the first and second (M1/M2) and first and fifth metatarsal bones (M1/M5), the angle formed by the first metatarsal bone and the first proximal phalanx (HV), and the calcaneal pitch angle (CPA) were measured. Patient characteristics and laboratory tests were also analyzed for their potential association with forefoot deformity. As the indications for the surgical treatment of rheumatoid forefoot deformities are strongly influenced by the severity of the hallux valgus deformity, we therefore analyzed patient factors in relation to the measured HV angle.

Results: The HV angle was statistically greater in female RA patients than males. Patient age, sex, body mass index, disease duration, Steinbrocker staging, M1/M2 angle, M1/M5 angle, CPA, erythrocyte sedimentation rate, c-reactive protein, matrix metalloproteinase-3, and anti-citrullinated protein antibody measurements were correlated with the HV angle using a single regression analysis. Patient age, BMI, Steinbrocker stage, M1/M2 angle, M1/M5 angle, and the female gender were correlated independently with the HV angle.

Conclusion: The hallux valgus deformity observed in patients with RA was more severe in females, which was independent of other patient factors. This finding emphasizes that the female gender is a risk factor for the progression of the rheumatoid forefoot deformity.

	regression coefficient（β）	Standard Error	P value	Variance Inflation factor

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: An increased body mass index (BMI) has been associated with slightly increased inflammatory

markers in the population. Within rheumatoid arthritis (RA) a high BMI has been associated with less radiographic progression; this phenomenon is unexplained. We explored the hypothesis that the association between BMI and inflammation detected with MRI is different in directionality in RA compared to patients with other arthritides and asymptomatic volunteers.

Methods: We studied 195 RA patients and 159 patients with other inflammatory arthritides at inclusion in the Leiden Early Arthritis Clinic cohort and 193 asymptomatic volunteers from the general population. All participants underwent a unilateral contrast-enhanced 1.5T MRI of MCP, wrist and MTP-joints. Each MRI was scored by two readers on synovitis, BME and tenosynovitis; the sum of these yielded the total MRI-inflammation score. Linear regression models were used.

Results: A higher BMI was associated with higher MRI-inflammation scores in arthritides other than RA (β=1.082, $p<0.001$) and asymptomatic volunteers (β=1.029, p=0.040), whereas it was associated with lower MRI-inflammation scores in RA (β=0.969, p=0.005). Evaluating the different types of inflammation separately showed that a higher BMI was associated with higher synovitis, BME and tenosynovitis-scores in arthritides other than RA (respectively β=1.084, $p<0.001$, β=1.021, p=0.24 and β=1.054, p=0.003), but with lower synovitis and BME scores in RA (respectively β=0.976, p=0.047 and β=0.954, p=0.002).

Conclusion: BMI is correlated with less severe MRI detected inflammation (synovitis and BME) in RA. This might explain the previous finding that BMI is correlated with less severe radiographic progression in RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Many important treatment decisions for patients with RA are conditional on patient preferences and according to the Institute of Medicine mandate a shared decision making approach (SDM). Furthermore, SDM is being increasingly recognized as an important quality measure. One of the most common preference sensitive decisions in RA is how to escalate care when response to methotrexate monotherapy is inadequate. However, because of the number medications currently approved, asking patients to deliberate over the pros and cons related to each of these options in order to develop a preference, is extremely difficult. The objective of this study was to develop representative patient preference phenotypes to enable patient-physician dyads to effectively incorporate patient preferences at the point-of-care.

Methods: Persons with RA were invited to complete a Choice-Based Conjoint analysis survey including seven attributes (route of administration, time to onset of action, bothersome adverse events (AEs), serious AEs, extremely rare AEs, duration of time on the market and affordability) developed iteratively based on patient feedback. Each attribute was

described across three or four levels using plain language. Preference phenotypes were identified by applying latent class analysis to the conjoint data. Class solutions were replicated five times from random starting seeds. A five-group solution was chosen based on Akaike's information criterion. We calculated the percentage of importance assigned to each attribute and performed simulations to estimate preferences for triple therapy, SC and IV biologics, or tofacitinib.

Results: 1100 subjects completed the survey. Of these 49 were eliminated because they completed the survey in less than 10 minutes and an additional 45 people were excluded because they did not respond correctly to a dominant choice task. The mean age was 51.7 (11.2). The majority were female; (92%) and Caucasian (93%). Preferences (assuming low cost across options), and the reasons underlying each respondent's preference, clustered into five groups (Figure 1). There were no differences in the distribution of demographic or clinical characteristics across the five groups. Phenotypes were created based on the stated preference data (Figure 2).

Conclusion: RA patients' preferences vary and can be classified into distinct phenotypes. Ongoing research is evaluating whether enabling patients to identify with a preference phenotype facilitates SDM at the point-of-care.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent clinical data show a clear association between periodontitis (P) and RA. However, there is controversy over whether severity of P is associated with RA activity. Some studies have shown no association or even a negative association and only a study (Mikuls 2014) found a positive association between severity of P and RA activity. 1.To determine whether severity of P affects clinical expression and activity of RA. 2. To define characteristics of P in RA patients with high clinical activity.

Methods: Observational, cross-sectional, case-control study adult RA patients (ACR/EULAR 2010) in a hospital Rheumatology Department,with at least 4 teeth, no dental prophylaxis or antibiotic intake 6 months before. Socio-demographic/ anthropometric variables:smoking status, Graffar scale, annual dental prophylaxis and stress level. RA variables: DAS28 (ESR) DAS28 (CRP),SDAI, RF/ACPA titles, extra-articular manifestations and comorbidities such as osteoporosis (OP), diabetes mellitus (DM), dyslipidemia (DS); glucocorticoids (GC),synthetic and biological therapy (DMARDs/DMARDb). Periodontal variables: plaque index (PI), bleeding on probing (BoP), probing pocket depth (PPD), recession (REC), clinical attachment level (CAL). Dental team: 2 periodontists, 2 general dentists. Full mouth CAL PPD and periapical x-rays were taken. CAL was classified according to the European Workshop 2005 (Tonetti), into level 0 (absence), TL1 (mild), TL2 (severe).Statistical analysis (Stata 13.1) using Student´s t test , Kruskal Wallis and Chi-square test.

Results: We included 187 RA patients, F/M 78.6/21.4%,mean age 54.4 (SD 10.8) y, mean follow-up of 8.8 y, 18.72% had early RA. Positive RF/ACPA:74.9/67.8%. Mean clinical activity: DAS 28 (ESR) 3.81/ DAS 28 (CRP) 3.18/ SDAI 14.49, HAQ 0.76 (0.62). Disease activity: remission 20.86%, low activity 24.06%, moderate activity 45.45%, high activity 9.63%. Treatment: 47.06% received GC (mean daily prednisone 2.85 mg/dl); DMARDs monotherapy/combined 53%/11.76%, DMARDb 30%. Smoking status: current 19,25%/ former 24.6%; low socioeconomic status 36.36% (relative poverty 33.69%); annual dental prophylaxis 43%; dyslipidemia 53.47%, OP 55.86%. Regarding periodontal status,TL2 P in 69. 05% of patients with moderate/high activity vs 30.95% in patients with remission/low activity; 55.34% patients with TL1 P showed RA remission /low activity ($p<0.001$). A strong association was found between severe P and moderate/high RA activity, with an OR 57.65 + 37.40 (CI 95% 16.16- 205.62). Patients with moderate/high RA activity presented increased values of all periodontal parameters compared to low activity ($p<0.005$). We observed association between rheumatoid nodes, pleuritis and OP with severe P ($p =0.028$).

Conclusion: 1.High-activity RA is associated with severe P. 2. Patients with moderate/high activity RA have higher prevalence of both number and percentage of probing pocket depth ≥ 5mm. 3. Presence of rheumatoid nodes and osteoporosis are related to severe P. 4.These results suggest an independent relationship between severe P and RA with high clinical disease activity regardless of classical factors associated with P.

Contribution of Patient Global Assessment on Loss and Gain of Disease Remission in Patients with Established Rheumatoid Arthritis in Clinical Practice

George A. Karpouzas[1], Elizabeth Hernandez[2], Chelsie Cost[2] and Sarah Ormseth[2], [1]Harbor UCLA Medical Center, Torrance, CA, [2]Rheumatology, Harbor-UCLA Medical Center, Torrance, CA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient global assessment (PGA) is part of the remission definitions in Rheumatoid arthritis (RA). We explored the proportion of patients who fail to achieve various remission definitions due to PGA ratings, and further assessed change in remission status attributed to PGA change at follow-up 12 months later.

Methods: We evaluated 271 patients with established RA in a single academic center. Remission definitions included DAS28 (disease activity score-28 joints)<2.6, CDAI (clinical disease activity index)=<2.8, SDAI (simplified disease activity index) =<3.3, and Boolean [tender joints=<1, swollen joints=<1, CRP (c-reactive protein) =<1, and PGA=<1]. Tentative remissions were computed for each scale by omitting the PGA component while retaining the same numeric threshold for definition. Subtracting observed remissions (R) from tentative ones yielded numbers of remissions lost (RL) due to PGA. Non-remissions (NR), observed remissions (R) and lost remissions (RL) at baseline and follow-up were cross-tabulated for each composite index. Differences in proportions of RL among various scales were compared with chi-squared tests, and PGA differences between R and RL for each scale were assessed with Mann-Whitney U tests.

Results: At baseline, tentative remissions were seen in 121 (44.6%), 105 (38.8%), 108 (39.9%), and 90 (33.2%) subjects respectively for DAS28, CDAI, SDAI and Boolean scales. RL comprised 17%, 52%, 57%, and 72% of the tentative ones for the respective scales (figure 1A). PGA was significantly lower for observed R vs. RL for all scales (figure 1B, p<0.0001). Baseline remission was maintained for the majority of patients at follow-up (table 1); of the remainder, roughly half were lost due to PGA change. Of patients with NR at baseline, 5-27% depending on scale remitted at follow-up, while 5-20% failed to do so because of PGA.

Conclusion: A significant proportion of patients with clinical measurements suggesting otherwise good disease control fail to be classified as or retain remission because of PGA ratings. Exploring and therapeutically addressing determinants of PGA will likely improve patient satisfaction and outcomes and lead to a more comprehensive disease remission.

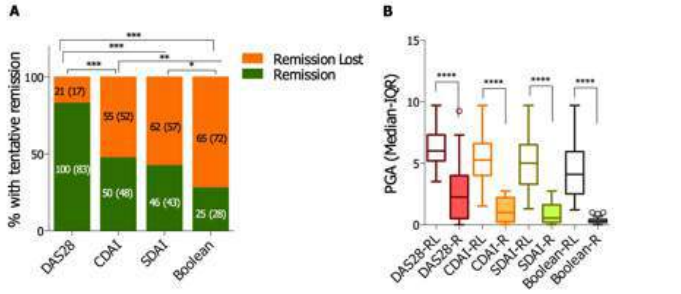

Figure 1: A. Proportion of tentative remissions lost due to PGA at baseline. **B.** PGA magnitude in patients achieving remission vs. those who loose remission due to PGA. *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001

Greater Fatigue at Baseline and Female Gender Predict Worse Disability in Early RA Despite Treatment to Target: A Comparison of Two Observational Cohort Studies from the United Kingdom

Sarah Twigg[1], Elizabeth M.A. Hensor[2], Jane E. Freeston[1], Ai Lyn Tan[1], Alan Tennant[3], Paul Emery[4], Ann Morgan[5] and YEAR consortium, IACON consortium , [1]NIHR Leeds Musculoskeletal Biomedical Research Unit, University of Leeds, Leeds, United Kingdom, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [3]Swiss Paraplegic Research,, Nottwil, Switzerland, [4]NIHR Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, University of Leeds, Leeds, United Kingdom, [5]NIHR-Leeds Musculoskeletal Biomedical Research Unit, University of Leeds, Leeds, United Kingdom

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although disability is part of the ‘core set’ of outcomes for RA research recommended by OMERACT (1), current therapeutic strategies focus on inflammation. The treat to target approach instigated in 2010 (2) saw a step-change in RA management, with frequent clinical review to achieve remission or low disease activity. The aim of this study was to compare disease activity (DAS28) and disability (measured by HAQ) in 2 early RA cohorts, both before and after the implementation of treat to target approaches.

Methods: Cases with recent onset RA recruited to Yorkshire Early Arthritis Register (YEAR) between 2002 and 2009 were treated with a ‘step-up’ approach, using synthetic DMARDs. Of 725 cases included, 585 met 1987 ACR RA classification criteria and a further 115 met 2010 criteria. A second cohort, IACON (INflammatory Arthritis CONtinuum),

recruited patients with early inflammatory arthritis between 2010 and 2014, treated according to 'treat to target' principles including biologic therapies. Data from 384 patients meeting 2010 ACR/EULAR classification were applied to the present study. Latent growth curve models of change in DAS28 and HAQ were compared between YEAR and IACON. Latent class growth analysis identified latent trajectories of change in HAQ-DI and logistic regression tested baseline predictors of HAQ trajectory, including age, gender, BMI, smoking status, CCP (RF considered separately) and fatigue. Presence of one or more common comorbidities was considered for the IACON group.

Results: Mean baseline DAS28 and HAQ were lower in IACON than YEAR (DAS28 4.01 vs. 4.70 and HAQ 1.13 vs. 1.27 in IACON and YEAR, respectively). A greater proportion of overall fall in DAS28 was achieved after 6 months in IACON (84%) than YEAR (68%). There were three latent trajectories of change in HAQ in YEAR and two in IACON (Figure 1). The 'high stable' group was not seen in IACON, possibly reflecting the more favourable change in DAS28 observed in this group. However, 66% of IACON cases followed a 'moderate reducing' HAQ trajectory, similar to the corresponding trajectory in YEAR. In both cohorts, female gender and higher baseline fatigue visual analogue score (VAS) predicted adverse HAQ trajectory. Odds ratios (OR) for moderate reducing compared to low reducing groups for females were 2.58 (95% confidence interval 1.69, 4.49) in YEAR and 5.81 (2.44, 14.29) in IACON. Corresponding OR per cm fatigue were 1.13 (1.07, 1.20) in YEAR and 1.16 (1.12-1.20) in IACON.

Conclusion: More favourable trajectories of change in DAS28 and HAQ were seen in the Treat to Target group, but females and those with greater fatigue were more likely to fit into an adverse HAQ trajectory, suggesting that such patients may benefit from interventions to improve function as well as reduce inflammation. **References**

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) functional impairment is composed of reversible and irreversible components. The aim of this analysis was to assess the reversible and irreversible components of RA physical function as measured by the Health Assessment Questionnaire (HAQ) in Canadian routine clinical practice.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment with IFX or GLM for RA, ankylosing spondylitis, or psoriatic arthritis. Eligible participants for this analysis included RA patients treated with IFX enrolled since 2002 or with GLM enrolled since 2010, who had a HAQ >0 at baseline and at least one follow-up assessment with known HAQ score at remission or achievement of low disease activity (LDA). Remission was defined as SDAI ≤3.3, CDAI≤2.8, DAS28 <2.6, or achievement of the following four criteria: SJC ≤1, TJC ≤3, CRP level ≤0.8 mg/dL and MdGA ≤15mm. Low disease activity was defined as SDAI ≤11.0, CDAI ≤10.0 or DAS28 ≤3.2. HAQ scores at the time of RA remission or achievement of LDA represented the irreversible component of the disease functional limitation, namely the residual HAQ score, while the difference in HAQ scores from baseline to remission or LDA corresponded to the reversible component. In addition, the reversibility of HAQ score was determined as the relative improvement in baseline HAQ score at the time of remission or achievement of LDA and, the fraction of HAQ irreversibility was calculated as the residual HAQ score divided by the maximum possible HAQ score. Descriptive statistics were produced for HAQ reversible and irreversible parameters. The correlation of disease duration with the HAQ irreversible component was described with the Pearson's correlation coefficient. Multivariate linear regressions adjusted for age, gender, anti-TNF, baseline disease duration and HAQ score at baseline were performed to assess the impact of the type of coverage (private and public) on reversible and irreversible components of the disease. Level of statistical significance was set to 0.05.

Results: There were 753 patients included in this analysis (499 patients were on IFX and 254 on GLM) with a mean (SD) age of 56.4 (13.4) years, disease duration since diagnosis of 8.7 (9.3) years and HAQ score of 1.5 (0.7) at treatment initiation. The majority of patients were females (74.8%). At treatment initiation, 356 (47.8%) and 289 (38.8%) patients were on public and private drug coverage, respectively. The HAQ reversible and irreversible components in RA are presented in Table 1. Variation in the reversibility of HAQ score was observed among RA patients depending on the target outcome used for the calculation, with 44.8% reversibility reported based on DAS28 remission to 57.6% with SDAI remission and, from 33.1% based on CDAI-LDA to 36.4% with SDAI-LDA. Weak correlations between disease duration and HAQ irreversible component were observed for all the target outcomes with Pearson's coefficients varying from 0.105 based on derived definition of remission to 0.270 with CDAI remission and, from 0.119 based on SDAI-LDA to 0.202 with DAS28-LDA. Upon adjustment for age, gender, anti-TNF agent, baseline disease duration, and HAQ score at baseline, patients on private insurance were found to have significantly greater HAQ reversibility when assessed with SDAI remission (β= -27.39; P=0.029) and derived definition of remission (β= -17.94; P=0.036) than patients on public coverage. Coverage type was not found to have an impact the fraction of HAQ irreversibility and the irreversible component. **Table 1:**HAQ Reversible and Irreversible Components in Rheumatoid Arthritis.

Target Outcomes	N	Months from BL to Target, Mean (SD)	Change in HAQ score from BL to Target (Reversible component), mean (SD)	% Reversibility of BL HAQ score, mean (SD)	Residual HAQ score (Irreversible component), mean (SD)	Fraction of HAQ Irreversibility, mean (SD)
DAS28 remission	426	13.56 (13.24)	-0.67 (0.68)	-44.78 (45.59)	0.76 (0.67)	0.25 (0.22)
DAS28 low disease activity	573	10.73 (11.22)	-0.58 (0.67)	-34.97 (54.00)	0.86 (0.67)	0.29 (0.22)
CDAI remission	306	17.51 (14.00)	-0.84 (0.69)	-54.69 (53.03)	0.57 (0.56)	0.19 (0.19)
CDAI low disease activity	699	9.65 (9.27)	-0.55 (0.63)	-33.09 (52.32)	0.94 (0.70)	0.31 (0.23)
SDAI remission	266	17.14 (14.25)	-0.89 (0.70)	-57.56 (50.83)	0.57 (0.57)	0.19 (0.19)
SDAI low disease activity	594	10.90 (10.59)	-0.60 (0.65)	-36.39 (54.08)	0.89 (0.69)	0.30 (0.23)
Derived definition of remission	479	13.11 (12.25)	-0.60 (0.67)	-37.72 (53.41)	0.88 (0.71)	0.29 (0.24)

Conclusion: The results of this Canadian longitudinal observational study show variability in the proportions of reversibility and suggest that patients on private insurance at treatment initiation have a greater reversibility of RA functional impairment than patients on provincial coverage. However, the type of coverage did not have an impact on irreversible components of the disease.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adipose tissue macrophages (ATMs) are a potent source of inflammatory cytokines with profound effects on adipose tissue function and systemic inflammation, yet their potential role in rheumatoid arthritis (RA) pathobiology is unstudied.

Methods: Periumbilical subcutaneous adipose tissue was obtained from 36 RA patients and 22 non-RA controls frequency matched on demographics and body mass index (BMI). Individuals with diabetes were excluded. Samples were stained for the macrophage marker CD68 and the average proportion of ATMs relative to total nucleated cells was compared between groups. Using real time polymerase chain reaction (RT-PCR), gene expression profiles for selected inflammatory cytokines, chemokines, and macrophage markers were assessed and their correlations with RA disease characteristics were explored.

Results: The RA and control groups were well matched [mean age=54 years, 75% female, mean BMI=28.1]. Median RA duration was 6.3 years and 77% were seropositive for rheumatoid factor (RF) or anti-CCP antibodies. A total of 78% were treated with non-biologic DMARDs, 44% with biologics, and 25% with prednisone. The proportion of ATMs was 76% higher in RA vs. non-RA samples (37.7 vs. 21.3%, respectively; $p<0.001$). ATMs aggregated into crown-like structures (CLSs) around adipocytes were more than 1.5-fold higher in the RA group compared with controls (0.58 vs. 0.23 CLSs/high-power field, respectively; $p=0.001$). ATMs were significantly more abundant in early RA and in those seropositive for anti-CCP (Fig1A&B). Users of methotrexate, leflunomide, and TNF inhibitors had a significantly lower proportion of ATMs compared with non-users (Fig1C&D). Average CLSs were significantly higher among those with RF (48% higher; $p=0.038$) or a serum CRP$\geq$10 mg/L (112% higher; $p=0.001$). Adipose expression of IL-6, MCP-1, MMP-9, osteopontin, C1q, and the macrophage markers CD64, CD68, and CD163 were all significantly associated with serum CRP, IL-6, DAS28 score, and duration of morning stiffness, all with Spearman correlation coefficients ranging between 0.3 and 0.7 and p-values<0.05. In a multivariable linear regression model predicting serum CRP; gender, biologic use, swollen joints, RF and/or anti-CCP seropositivity, BMI, and adipose MCP-1 expression level accounted for 63% of the explainable variability. Of this variability in CRP, adipose expression of MCP-1 independently accounted for 11% whereas swollen joints only accounted for 5%.

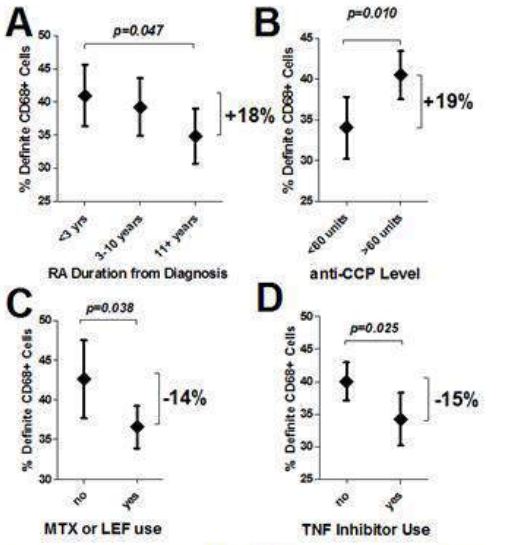

Figure. Associations of Rheumatoid Arthritis Characteristics with the Adjusted Average Proportions of Adipose Tissue Macrophages (i.e. % Definite CD68+ Cells). Adjusted means and 95% confidence intervals are depicted. All four graphs are derived from the same model including the covariates education level, rheumatoid arthritis duration, anti-cyclic citrullinated protein antibody seropositivity, methotrexate or leflunomide use, and TNF inhibitor use. RA=rheumatoid arthritis; CCP=cyclic citrullinated protein; MTX=methotrexate; LEF=leflunomide; TNF=tumor necrosis factor.

Conclusion: ATMs were more abundant in RA and associated with systemic inflammation and autoantibody status, suggesting possible contributions to the RA disease process. Lower levels of ATMs associated with specific RA treatments suggest that adipose tissue inflammation may be ameliorated by immunomodulation.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-provider discordance in global assessment (GA) of disease activity is a potential threat to patient-centered management of individuals with RA. The estimated prevalence of discordance is 33%. A crucial gap remains in the literature regarding the trends and predictors of discordance. Our aim was to determine the persistence over time, predictors and impact of discordance on treatment decisions.

Methods: A retrospective case-control study included 102 patients with discordance (defined as patient GA ≥25 mm higher than provider GA) and 102 patients without discordance matched on age, sex, RA disease duration and Clinical Disease Activity Index (CDAI <10 vs. ≥10). Data were collected for the baseline visit (date of diagnosis or earliest available visit); study visit and 11 additional clinical visits prior to the discordant visit. For the baseline visit, duration of symptoms, date of diagnosis, 1st DMARD/biologic used, and use of MTX in the 1st 6 months of diagnosis were recorded. Data for each clinical visit included the patient and provider GAs (0-100 mm), pain visual analog scales (0-100 mm), tender and swollen joint counts (0-28), HAQ, CDAI, radiographic erosions, ESR, CRP, and DMARD/biologic use or modification. Presence of comorbidities, including depression, anxiety, FM, or OA, and use of glucocorticoids, analgesics, antidepressants or anxiolytics, were also abstracted. Data were analyzed using linear and logistic regression models with smoothing splines for non-linear trends.

Results: The study included 204 patients with mean age of 60 years, mean RA duration of 7 years, mean CDAI score of 15.4. Analysis of the 3-year trends in the patient and provider GA demonstrated persistence and/or progression of discordance over time (see Figure). Cases had a greater percentage (mean 71% vs. 30%; p<0.001) and higher rate of discordant visits (1.6 vs. 0.6 per year; p<0.001) compared to controls. Baseline predictors of future discordance were (odds ratios [OR] are for a 10-unit change for each characteristic) age (OR=0.14, p=0.04), patient GA (OR=1.44, p<0.001), pain score (OR=1.28, p<0.001), and CDAI score (OR=1.70 per 12 unit increase, p=0.047). Depression (OR=2.00, p=0.04), ever use of antidepressants (OR=3.11, p=0.01) or FM pain medications (OR=2.90, p=0.04) also predicted future discordance. No differences were observed in the cumulative numbers of additions or modifications of the DMARD regimen or in treatment with conventional or biologic DMARDs between cases and controls (all p>0.05).

Conclusion: Patient-provider discordance tends to persist and/or progress over time and is associated with consistently higher pain. Early abrogation of inflammatory disease activity through treat-to-target strategies as well as early detection and treatment of comorbid depression and FM could lessen the development of patient-provider discordance.

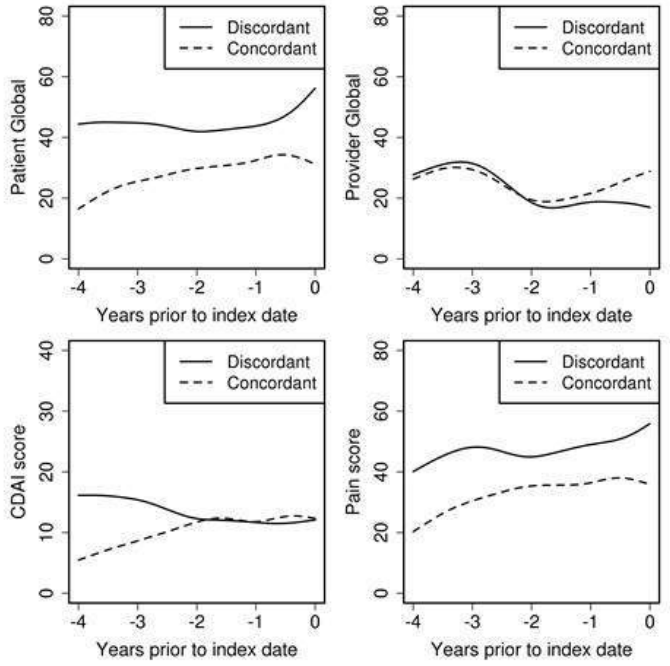

Figure: Comparison of trends in patient and provider global assessments, CDAI, and pain scores in cases with patient-provider discordance and concordant controls, preceding the index visit (time 0).

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an excess of mortality. This risk depends on the disease activity, severity and associated comorbidities. Our objective was to study the mortality profile of RA patients in France using multiple-cause-of-death analysis.

Methods: Data were collected between 2000 and 2011 in the French Epidemiological Center for the Medical Causes of Death database, and death certificates issued upon the death of an adult for whom RA was an underlying cause of death (UCD) or an associated cause of death (ACD) were evaluated using multiple-cause-of-death analysis. Sex, age, sex ratio, standardized mortality rates, as well as frequency of the various causes of death were assessed. For the main causes of death, the observed number of deaths in relation to the expected number of deaths (O/E ratio) was calculated to measure the strength of association between RA listed as an ACD and the corresponding UCD.

Results: During the study period, 13,208 deaths related to RA were identified. RA was identified as the UCD in 4597 (35%) certificates. The number of certificates mentioning RA as the UCD decreased from 41% to 27% between 2000 and 2011. The mean±SD at death was 79 ± 9 years (51% with ≥80 years). The female: male ratio was 3.2 and remained stable during the follow-up period. This ratio was significantly higher in the population where RA was the UCD (4.1 vs. 2.8 p <0.001). The mean standardized mortality rate was 0.25 per 10^5 million people (range 0.21-0.28), and remained stable throughout the period. When RA was the UCD (n=4,597), the main ACDs were cardiovascular diseases (29%), infectious diseases (22%), and respiratory diseases (17%). When RA was an ACD (n=8,611), the most common UCDs were cardiovascular diseases (35% of certificates, including 877/3032 ischemic heart disease), neoplasms (14%), respiratory disease (9%) and infectious diseases (7%). The overall O/E ratio was >1 for infectious (3.58), respiratory (1.38) and cardiovascular diseases (1.25), but was <1 for neoplasms.

Conclusion: This is the first national study using a multiple-cause-of-death analysis to study the mortality profile in RA. Our results show that mortality related to cardiovascular, respiratory and infectious diseases is highly associated with RA. These data support the need to expand new strategies to prevent infectious and cardiovascular diseases in order to improve survival of RA patients.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) may cause joint damage leading to physical dysfunction and associates with increased cardiovascular (CV) risk. Regular physical activity (PA) can attenuate disease-related symptoms and improve function. Self-Determination Theory (SDT), a contemporary theory of motivation, has provided the foundation for PA promotion interventions among different patient groups but has not been applied to facilitating PA engagement in people living with RA. **Objectives:** To examine whether a 3-month SDT-based exercise intervention can lead to improvements in cardiorespiratory fitness (CRF, primary outcome), self-reported moderate PA, self-reported sitting time, functional disability and self-determined motivation towards PA participation in patients with RA.

Methods: Data were collected as part of the Physical Activity in Rheumatoid Arthritis (PARA) randomised controlled trial. The PARA study compared the effectiveness of two 3 month exercise programmes in N = 115 patients with RA (Mage = 54 ± 12.5 yrs). Patients in the experimental (N = 59) and control (N = 56) arm, both received the same gym-based exercise programme which was tailored for people with RA. However, the experimental arm also received one-on-one SDT informed consultations by a trained advisor that aimed to foster more self-determined motivation for PA. Assessments were carried out at baseline, 3, 6 and 12 month follow-up. Data analysed for the present work is from measures taken at baseline and at 3 months (immediately post intervention). CRF was assessed via an exercise tolerance test. Self-reported moderate PA, sitting time, functional disability and self-determined motivation for PA were measured using validated questionnaires. Repeated measures analyses of covariance (ANCOVAs) were conducted to examine main effect and group x time effects on targeted outcomes. Analyses were adjusted for age and exercise programme attendance.

Results: No significant group x time interactions were observed for cardiorespiratory fitness or functional disability. Significant interactions between groups were observed for: self-reported moderate PA (min/week) (F (1) = 4.31, p < .05), daily sitting time (min/day) (F (1) = 4.93, p < .05), and self-determined motivation for PA (F (1) = 5.72, p < .05). Specifically, favourable changes were seen in for these outcomes in the experimental, relative to the control arm (Table 1).

Conclusion: These findings suggest that a SDT-grounded PA intervention promotes adaptive motivational processes that may encourage increased engagement in moderate intensity PA in RA patients involved in a tailored exercise programme. However, more structured exercise interventions with additional support may be required to promote increases in PA engagement towards levels required to improve CRF in people living with RA. Table 1. Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The impact of inadequate therapy behavior in rheumatoid arthritis (RA) patient outcomes may be amplified by the fact that almost all individuals with poor drug compliance, eventually drop out of treatment and out of the health care system completely. In 2004, we established an early arthritis clinic (EAC) in a referral centre for rheumatic diseases. Once enrolled in the inception cohort, recent-onset RA patients underwent regular evaluations that included disease activity and compliance with treatment that was indicated according to a 'treat to target' (T2T) strategy. **Objectives** 1.- To describe the characteristics of patients who dropped out of health care (HDO) in an ongoing cohort of patients with recent onset RA at inclusion. 2.- To explore baseline and cumulative predictors for HDO, with emphasis on disease activity, treatment and persistence with therapy (P) as potential cumulative predictors.

Methods: Charts from patients attending the EAC from 2004 onwards were reviewed. Patients with HDO (*cases*) were defined when they did not return back to the clinic for at least one year. *Control s*were defined if compliant with all their scheduled visits and included patients lost to follow-up but who returned to the EAC within one year since their last visit. Persistence with therapy (P) was defined as length of time patients complied with treatment. A case-control nested within a cohort design was used to compare baseline and cumulative (up to HDO or equivalent follow-up) variables between cases and paired (according to age [±5 years], sex, autoantibodies and follow-up to HDO or equivalent) controls. Cox regression analysis was used to investigate predictors of HDO. Patients provided written informed consent.

Results: Data from 170 patients (89.4% female, [mean±SD] age: 38.2±12.6 years) with ≥1 year of follow-up were analyzed**;** up to December 2015, (median, range) follow-up was 86.6 months (43.2-123) during which 35 (20.6%) patients had HDO after 41.1 months (12.1-58.7) of follow-up. Baseline and cumulative variables related to disease activity, treatment and P entered regression models; cumulative n° of flares (OR: 2.45, 95%CI: 1.35-4.4, p=0.003), n° of DMARD/patient (OR: 2.89, 95%CI: 1.58 -5.27, p=0.001) and P<50% (OR: 3.06, 95%CI: 1.29-7.29, p=0.011) emerged as predictors of HDO. Five cases returned back to the EAC after (median, range) drop out time of 3.8 years (2.3-5.8); they exhibited higher disability and poorer function than 15 paired controls (1:3) and these negative outcomes were sustained up to their last follow-up.

Conclusion: Failure to control disease activity, intensive treatment and poor P predicted HDO in an inception cohort of RA patients. HDO impacted patient´s outcomes.

Changes in the Functional Status of the Rheumatoid Arthritis (RA) Population over the Biologic Era

Brenna Brady[1], Nicole Gerlanc[1], David Collier[2] and Bradley S. Stolshek[3], [1]Health Analytics, LLC, Columbia, MD, [2]Amgen Inc., Thousand Oaks, CA, [3]Amgen, Thousand Oaks, CA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In 1998, the first biologic disease modifying antirheumatic drug was approved in the United States for the treatment of RA. Since that time, biologics have become the standard of care for patients with moderate to severe RA. However, there is limited information on the general impact of biologics on the long term functional status of the RA population. This study examined baseline characteristics from patients enrolling in randomized clinical trials (RCT) from 1987 to 2012 to estimate changes in RA patient functional status following the introduction of biologics.

Methods: A systematic literature review was conducted in the Medline and Embase databases from 1987 to 2012 to identify RCTs enrolling RA patients that reported a baseline Health Assessment Questionnaire (HAQ) score. Weighted means for patient baseline characteristics reported in RCTs were used to construct multivariable linear regression models to examine predictors of change in RA patient functional status over time.

Results: A total of 51 RCTs were identified that met all study requirements; 36 RCTs allowed for weighted mean calculations and were included in the analyses. Correlation analyses and Regression models exploring the association between patient functional status and year of RCT publication were performed for five outcomes: HAQ, disease activity score (DAS-28), tender and swollen joint counts (TJC and SJC), and Sharp scores. Correlational analyses showed an inverse relationship between mean DAS-28 or SJC and year of publication over the study period. Other outcomes (HAQ and TJC) only presented a significant inverse relationship with year of publication for subset of the study period, 2005-2012. Linear regression models for DAS-28 and Sharp scores used all eligible data; models for HAQ, TJC, and SJC were developed using data from 2005-2012 (Table 1). Best fit linear regression models revealed year of publication to be a significant predictor of increased functional status scores over time for all outcomes; increased age was also a predictor of increased functional status in 4 of the 5 models.

Conclusion: Patient baseline characteristics in RCTs from 1987 to 2012 were used as a proxy to assess changes in the functional status of the RA population over time. The increase in the functional status of the RA population observed after the period that biologics became available suggests that biologics have been effective in managing disease and reducing disease severity within the RA population. Disclosure: B.S., and D.C. are employees of Amgen. B.B. and N.G. are employees of Health Analytics, LLC who was contracted by Amgen to conduct this study.

The Summed Bilateral Elbow Extension Angle in Rheumatoid Arthritis Correlates with the DAS28-CRP(4) and May be an Independent Marker of Bad Prognosis

John P. Case[1], Congbin Wang[2] and Heidi Tucker[3], [1]Internal Medicine/Rheumatology, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, [2]Internal medicine, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, [3]Rush Medical College, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

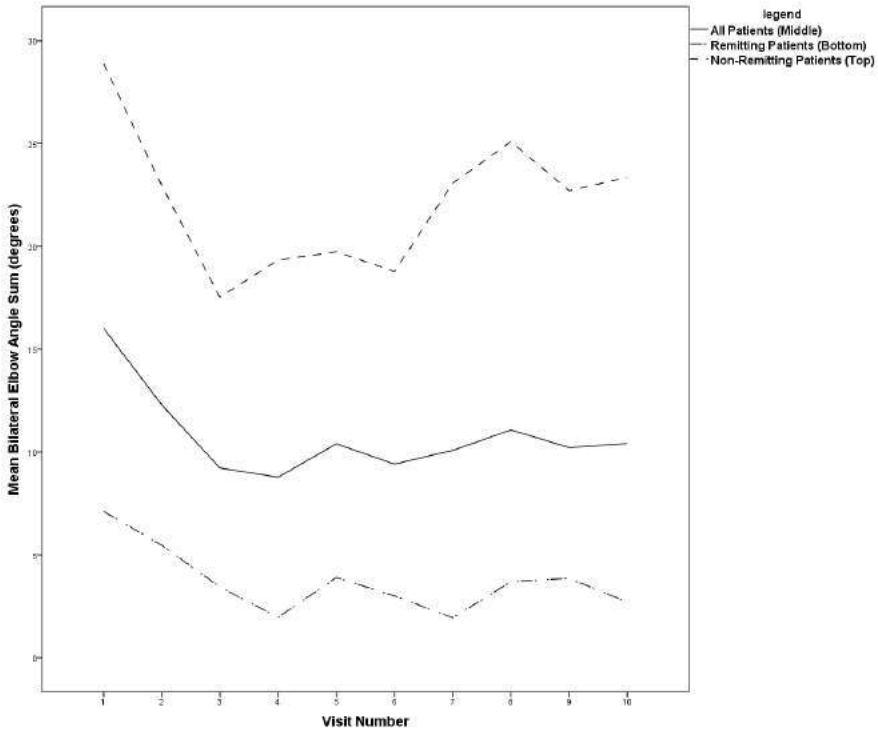
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The elbow is an easily-examined joint and an important determinant of morbidity in rheumatoid arthritis (RA). In active RA the measured elbow extension angle, recorded as degrees of flexion, consists of the sum of a fixed (irreversible destruction) deficit and a functional deficit (potentially reversible by medical or physical therapy). In inactive RA, the angle approaches the fixed, irreversible baseline. One of us (Case) has been measuring the angle and obtaining the DAS28-CRP(4) as part of routine clinical care. We undertook a 3-year retrospective study (5/1/12 – 4/31/15) of RA patients in order to determine a relationship between disease activity and the elbow extension angle.

Methods: All RA patients seen during the first (recruitment) year of study were eligible if they had RA (ACR/EULAR criteria), had at least 4 visits, had at least 3 elbow and DAS determinations and at least one of each during the first and last 3 visits. A Grafco 12-1000 Orthopedic goniometer (GF Health Products, Atlanta GA) was used in all measurements. After determining the high (< 0.0001) correlation between right and left elbow extension angles, the sum (right plus left, in degrees of flexion, "ELB") was used for statistics. A baseline best ELB (i.e., lowest flexion contracture) was determined from the first 3 visits and a final from the last 3 visits up to and including visit 10 (after which patient numbers rapidly dropped off precluding statistics). 166 patients entered into the study. 23 were subsequently excluded. Correlation was assessed by Pearson, and group differences between remitters (defined as DAS < 2.6) and non-remitters (defined as DAS >= 2.6) were assessed by T-test. Statistics were calculated with IBM SPSS 22.

Results: The 143 patients had a mean age of 53.2 (SEM 13.2) years (122 females and 21 males). Patients were followed for a mean of 28.4 (SEM 6.6) months over a mean of 8.68 (SEM 2.41) visits. Because the best (i.e., lowest) mean ELB occurred between the 3rd and 4th visits, we conservatively chose the 4th visit in comparison with the 10th visit for statistical comparison (see Figure). Between visits 4 and 10 ELB increased from 19.3 (SEM 3.91) to 23.3 (SEM 5.91) (4.0 degrees) for non-remitters and from 1.96 (SEM 1.23) to 2.70 (SEM 2.38) (0.74 degrees) for remitters, a greater than 5-fold difference ($p<0.0001$). Correspondingly, the difference between the 4th and 10th visits for non-remitters was significant ($p<0.001$) but for remitters was not ($p=0.264$). The Figure shows all patients (___, middle line) and that remitters (_._., lower line) maintained ELB over the course of the study, while non-remitters (_ _ _, upper line) did not. Non-remitters also had a higher baseline ELB than remitters ($p<0.0001$).



Conclusion: The ELB closely correlates with disease activity. DAS non-remitters had a five-fold poorer ELB outcome than DAS remitters. Measurement of the ELB may be an important supplement to the rheumatologic exam in clinical and research settings.

Assessment of Metacarpal Head Bone Microarchitecture According to Presence or Not of Inflammation in Rheumatoid Arthritis Patients with Low Disease Activity

Shuing Kong[1], Hervé Locrelle[1], Adamah Amouzougan[1], Delphine Denarie[1], Philippe Collet[1], Béatrice Pallot Prades[1], Thierry Thomas[1,2] and Hubert Marotte[1,2], [1]Rheumatology Department, University Hospital of Saint-Etienne, Saint-Etienne, France, [2]INSERM U1059/LBTO, Université de Lyon - Université Jean Monnet, Saint-Etienne, France

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Bone alteration at the metacarpeal head during rheumatoid arthritis (RA) disease remained under investigated. High-resolution peripheral quantitative computed tomography (HRpQCT) allows exploration of microarchitecture of metacarpeal heads during RA. Here, we explored microarchitecture parameters of metacarpeal heads

during in RA patients in low disease activity according to persistence or not of local inflammation assessed by US exam.

Methods: Thirty-three RA patients with erosion on second or third metacarpophalangeal joint were enrolled in this pilot study. All RA patients were treated with bDMARDs for at least 6 months and have low disease activity (DAS28<3.2) since at least 3 months. They were separated in two groups according to local inflammation assessed by US exam on the site of erosion. The group "inactive erosion" was defined by PowerDoppler US (PDUS) ≤ 1 at the metacarpeal joint with erosion, whereas the group "active erosion" was defined by PDUS≥2. Then, HRpQCT of second and third metacarpophalangeal joints was performed. Cortical and trabecular parameters were then assessed and compared in the two groups.

Results: The main characteristics of the RA population was summarized in the Table. Our RA population shared characteristic of RA patients treated with bDMARDs. Among the 33 RA patients, 21 RA patients were enrolled in the "inactive erosion" group, whereas 12 RA patients were enrolled in the "active erosion" group. No clinical or biological were different in the two groups. Bone volume assessed by BV/TV (%), cortical density (Dcort), and cortical thickness (CTh, µm) were similar in both groups. Trabecular parameters were more heterogeneous. Trabecular density (Dtrab) and trabecular number (TbN, mm^{-1}) were decreased in "active erosion" compared to "inactive erosion" (P<0.001 and <0.02, respectively), whereas trabecular separation (TbSp, µm) and distribution of trabecular separation (TbSpSD, µm) were increased in "active erosion" compared to "inactive erosion" (P=0.049 and 0.032, respectively). **Table. RA population characteristics according to local inflammation**

	Active erosion (n=12)	Inactive erosion(n=21)	P values
Female , %	69.2	76.2	NS
Age, years, median [range]	69 [47-78]	62 [42-77]	NS
MCP2/MCP3 assessed	11/1	18/3	NS
Date of diagnosis, years, median [range]	1996 [1976-2010]	2002 [1977-2012]	NS
DAS 28, median [range]	1.87 [0.84-2.85]	2.38 [0.97-3.2]	NS
ESR, mm/h, median [range]	6 [2-21]	8 [2-40]	NS
CRP, mg/L, median [range]	2 [0-6.6]	1.45 [0-12.5]	NS
RF +, %	70	70	NS
ACPA +, %	90	65	NS
Biologics %			
TNF blockers	50	71.4	
Tocilizumab	41.6	9.5	
Abatacept	8.3	19	
Biologics duration, *years* , median [range]	5 [2-11]	6 [2-11]	NS
Methotrexate %	58.3	80	NS

Conclusion: In RA patients in low disease activity treated by bDMARDs, persistence of local joint inflammation is associated with lower bone density at the metacarpal head. Inflammation involved mainly the trabecular compartment. Dtrab parameter was the strongly altered parameter and could be a candidate for prospective study assessing drug effect on periarticular bone damage.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: PROMIS (Patient-Reported Outcomes Measurement Information System) is a self-reported and parent-reported measure of global, physical, mental, and social health for the general population and those living with chronic conditions. Recent studies have demonstrated preliminary evidence of reliability and construct validity of PROMIS to assess Rheumatoid arthritis (RA) symptoms, impact, and feasibility of use in clinical care. The performance of PROMIS domains in subgroups and relationship to other disease activity scores in RA however has not been established. The aim of our study was to compare Clinical Disease Activity Index (CDAI) scores with PROMIS scores overall as well as stratify for disease duration, age and gender in RA patients.

Methods: This was a single center retrospective study. We analyzed the records of all RA patients seen over the last 6 months at the RA clinic in the University of Rochester. We compared the CDAI scores when available to the physical function (PF), pain interference (PI) and depression (Dep) PROMIS scores. We also calculated the effect of disease duration, age and gender on PROMIS PF, PI and Dep domains. Additionally, we compared the PROMIS scores of RA patients to a cohort of orthopedic patients with foot and ankle disease.

Results: We identified a total of 144 patients with RA with a median age of 59 and median disease duration of 10 years. There were 108 females and 36 males. CDAI scores were available for 45 patients. The mean CDAI score was 8.2 (median 2.5). PF decreased while PI and depression worsened with increase in CDAI scores (see Table 1). Scores for Dep (52.1), PF (40.0) and PI (61.6) were also worse for those with disease duration of less than 1 year since diagnosis of RA (median 52.1 and 61.6) compared with those with 1-5 years, 6-10 years and more than 11 years with RA (see Table 2). No significant difference was noted in PROMIS scores based on gender. Similarly, no difference was noted in PROMIS scores for the different age groups: those less 40 years, 40-50, 51-60 and those over 60 years. Surprisingly, no difference was noted in the PROMIS scores between the RA cohort when compared to all rheumatology patients (n=370) and a cohort of patients with foot and ankle disease (n=25,690).

Conclusion: Physical function, Pain Interference and depression PROMIS scores are associated with disease activity in RA patients as measured by CDAI. PROMIS scores are also affected by disease duration but not age or gender among RA patients. PROMIS is a valuable tool in the assessment of RA patients.

	Remission	Low disease Activity	Moderate disease activity	High disease activity
Physical Function	48.92	42.95	37.74	38.16
Pain	46.64	54.92	64.78	65.19
Mood	45.76	49.01	48.39	55.11

Table 1: relationship between CDAI and PROMIS scores

Disease Duration	Physical function	Pain	Mood
Less than 1 year	40.00	61.55	52.12
1-5 years	47.64	52.57	43.01
6-10 years	43.50	57.79	48.18
More than 11 years	41.77	55.98	48.80

Importance of Functional and Utility Evaluation on Disease Activity Level in Rheumatoid Arthritis: Interrelations and Predictive Value

Corina Mogosan[1], Catalin Codreanu[1], Luminita Enache[1], Magda Parvu[2], Simona Rednic[3], Ruxandra Ionescu[4] and On behalf of the Romanian Registry of Rheumatic Diseases, [1]Rheumatology, 'Dr. Ion Stoia' Clinical Center of Rheumatic Diseases, Bucharest, Romania, [2]Rheumatology, Colentina Hospital, Bucharest, Romania, [3]Rheumatology, Emergency County Clinical Hospital Cluj Napoca, Cluj-Napoca, Romania, [4]Rheumatology, Sfanta Maria Clinical Hospital, UMF Carol Davila, Bucharest, Romania

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) treatment targets remission or low disease activity, thus reducing the disease impact in patients' lives. Assessing different tools for effectiveness (disease activity, functional status and utility) could provide a more comprehensive approach in term of "achieve and maintain" the therapeutic goal. The aim of the present study is to evaluate interrelations of disease activity score – functional status – utility in a cohort of RA patients, treated with tumor necrosis factor alpha (TNF) antagonists and anti CD20 molecule.

Methods: Observational study in a cohort of RA patients in Romania, where data was gathered from the Romanian Registry of Rheumatic Diseases, which comprises all RA patients treated with biologics in the country. The three main variables under study were EQ5D (for utility), HAQ score (for functional status) and DAS28 and SDAI (for disease activity). The study cohort included only RA patients for whom were available all these data. The interrelations of the efficacy parameters were analyzed using correlation tests, T test, ANOVA, linear regression.

Results: The cohort included 777 RA patients, mean age 58.72 (±12.37) yrs, 84.4% women, mean RA duration 14.08 (±8.33) yrs, 77.1% retired, treated with etanercept (30.6%), adalimumab (22.7%), infliximab (original 6.3%, biosimilars 0.7%), rituximab (26.3%). 27.3% used steroids (20.2% with <7.5mg prednisone daily); mean current DAS28 score =3.66 (±1.52), mean ΔDAS28= 0.13 (±1.28), mean SDAI =14.27 (±13.79), mean HAQ score =1.14 (±0.64), mean EQ5D= 0.61±0.31. There was a strong negative association between DAS28 (and SDAI) and EQ5D: r = - 0.7 ($p<0.001$). HAQ score positively correlates with DAS28, same as with SDAI: r = 0.5 ($p<0.001$) whereas is a negative association between HAQ and EQ5D: r = - 0.6 ($p<0.001$). Disease activity dynamics (Δ DAS28 for the last 6 months) had a mild association with HAQ: r = 0.1 ($p<0.05$) and a negative one with EQ5D: r = -0.2 ($p<0.01$). Patient global assessment (PGA) on disease activity had a significant association both with HAQ (r=0.6, $p<0.001$) and EQ5D (r = - 0.6, $p<0.01$). Analyzing distribution of EQ5D and HAQ in DAS28 categories, there was a significant difference between categories ($p<0.001$); for EQ5D - DAS28: <2.6= 0.81(±.19), 2.6-3.2= 0.68(±.17), 3.2-5.1= 0.63(±.18), >5.1= 0.16(±.38); for HAQ - DAS28: <2.6= 0.73(±.57), 2.6-3.2= 0.98(±.5), 3.2-5.1= 1.25(±.52), >5.1= 1.76(±.56). There are significant predictive relations between DAS28, HAQ and EQ5D: linear regression model showed that DAS28 is strongly predicted by EQ5D (F = 798.7, t = - 28.2, B = - 3.48, $p<0.0001$), over than 50% of the variability of DAS28 being determined by the variability of EQ5D (adjusted R square = 0.51). HAQ score has a predictive value for DAS28 (F = 341.6, t = 18.4, B = 1.32, $p<0.0001$), roughly 30% of the variability of DAS28 being determined by the variability of HAQ (adjusted R square = 0.30). Disease

duration had not any influence on EQ5D, HAQ or DAS28.

Conclusion: Disease activity influences the patient well-being and functional status. Regression model showed that DAS28 could be predicted by the evaluation of EQ5D and HAQ level, regardless the disease duration.

Disease Activity and Physical Fatigue As Related to Adherence and Health Literacy in Patients with Rheumatoid Arthritis

Jens Gert Kuipers[1], Michael Koller[2], Florian Zeman[2], Karolina Mueller[3] and Ulrich Rueffer[4], [1]Department of Rheumatology, Red Cross Hospital Bremen, Bremen, Germany, [2]Center of Clinical Studies, University Hospital Regensburg, Regensburg, Germany, [3]Center for Clinical Studies, University Hospital Regensburg, Regensburg, Germany, [4]German Fatigue Society, Cologne, Germany

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Disease activity and physical fatigue as related to adherence and health literacy in patients with rheumatoid arthritis J. G. Kuipers[1], M. Koller[2], F. Zeman[2], K. Mueller[2], J. U. Rueffer[3], [1] Department of Rheumatology, Red Cross Hospital Bremen, Bremen, Germany [2] Center for Clinical Studies, University Hospital Regensburg, Regensburg, Germany [3] German Fatigue Society, Cologne, Germany

Background/Purpose:

Disease activity and fatigue are key endpoints to evaluate the outcome of treatment for rheumatoid arthritis (RA). Among factors that may contribute to good outcome are adherence (i.e., the extent to which patients' behaviors corresponds with agreed recommendations from their doctor) and health literacy (patients' understanding and use of health information).

Methods:

The survey included a representative, nationwide sample of German physicians specialized in rheumatology+ and patients with RA. The physician questionnaire included the disease activity score (DAS28) and medical prescriptions. The patient questionnaire included fatigue (EORTC QLQ-FA13) health education literacy (HELP), and patients' listings of their medications.

Adherence was operationalized in various ways: patient-reported (CQR5), behavioral (correspondence between physicians and patients listings of medications), physician-assessed (five-point rating scale ranging from 1=very adherent to 5=not at all adherent) and a combined measure of physician rating (1= very adherent, 0 = less adherent) and the match between physicians' prescriptions and patients' accounts of their medications (1 = perfect match, 0 = no perfect match), leading to three categories of adherence: high, medium and low. Linear regressions were calculated using DAS28 and Physical Fatigue as dependent variables and adherence, health literacy and the set of demographic and clinical variables as

predictor variables.

Results:

A total of 708 pairs of patient and physician questionnaires were analyzed. The mean age of the patients, of whom 73% were women, was 60 years (SD=12). At the time of assessment, 67% of the patients showed low disease activity (DAS28 < 3.2), 26% moderate disease activity (DAS28 3.2 to 5.1), and 4% high disease activity (DAS28 > 5.1).

B, regression coefficient; 95%-CI, 95%- confidence interval, R², coefficient of determination

Multiple regression analyses show, that adherence by doctor (p = .000 and p = .034) as well as the adherence composite score (p = .000 and p = .001) are independent predictors as well as health literacy (p = .000) for DAS and Physical Fatigue when controlling for age, sex, smoking, drinking, sport.

Conclusion:

This study showed that DAS and Physical Fatigue were related to adherence and health literacy. This finding highlights the importance of patient education and counseling in order to increase both, medical understanding and adherence to therapy.

The DAS28 Score May Misread Disease Activity in Rheumatoid Arthritis Patients

Abdul Khan[1] and Apostolos Vrettos[2], [1]Rheumatology, East Kent University Hospital NHS Foundation Trust, Queen Elizabeth Queen Mother Hospital, Margate, United Kingdom, [2]Rheumatology, Queen Elizabeth Queen Mother Hospital, Margate, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The DAS28 is a measure of disease activity in rheumatoid arthritis (RA). DAS28 stands for 'disease activity score' and the number 28 refers to the 28 joints that are examined in this assessment [1, 2]. DAS28 is a composite outcome measure that assesses how many joints in the hands, wrists, elbows, shoulders, and knees are swollen (SJ) and/or tender (TJ), the erythrocyte sedimentation rate (ESR) or C reactive protein (CRP) in the blood to measure the degree of inflammation, the patient's general health (GH) on a Visual Analogue Score (a simple scale) to assess how they are feeling on that day. These results are then fed into a complex mathematical formula to produce the overall disease activity score. A DAS28 of greater than 5.1 implies active disease. In the UK the NICE has approved the use of TNFα<span">inhibitors to treat patients with rheumatoid arthritis in accordance with the British Society for Rheumatology guidelines. Having a DAS28 score equal or greater than 5.1 on two occasions is one of the criteria required. Failure of anti-TNF treatment is defined as having a difference between baseline and 6 months post-treatment DAS28 score of < 0.6. Although DAS28 score is a validated tool for the identification of patients who are likely to benefit form anti-TNF treatment, it takes into account a number of subjective parameters which are likely to influence the overall result and reach the NICE threshold for the initiation of anti-TNF treatment [3]. The purpose of this study is to explore how an increase in the reported number of tender joints and/or GH would affect DAS28 score and to identify patients who although qualify for, might nor benefit from anti-TNF treatment.

Methods: We retrospectively investigated the GH, TJ, SJ, ESR, baseline DAS28 score and the DAS28 score 6 months after treatment of patients who qualified for anti-TNF treatment. The patients were divided in responders and non-responders to treatment. T-test was used to compare continuous variables between groups for parametric data and Mann-Whitney U test for non-parametric data. Pearson's correlation was used to investigate statistical dependence between variables. Multiple regression analysis was performed to assess the ability of a number of factors to predict the degree of reduction in DAS28 score after treatment.

Results: We reviewed the data of patients who received treatment with biologic factors for the last 2 years across East Kent Hospitals. One hundred and ten patients qualifying for and having received anti-TNF treatment for 6 months were included in the study. All baseline parameters where similar between the two groups. Eighty six patients had reduction in the DAS28 by 0.6 or more (responders) and 24 had reduction of less than 0.6 (non-responders). There was a statistically significant difference in the swollen-to-tender joints ratio between the responders and non responders (median difference = -0.55, 99.9%CI 0.46 - 0.64, $p<0.001$). Baseline GH and the number of tender joints were most strongly positively correlated with higher DAS28 score post treatment among all baseline factors (Pearson's $r = 0.87$ and 0.84 respectively, $p<0.001$). Multiple regression analysis revealed that a model containing the GH and the swollen-to-tender joints ratio was able to explain 70% of the variance in post-treatment DAS28 score reduction (F (2, 107)= 129, $p<0.001$). GH and the swollen-to-tender joints ratio each made a strong contribution to explaining the DAS28 score reduction (*beta*= 0.48 and 0.38 respectively, $p<0.001$ and $p<0.05$ respectively). Patients with high swollen-to-tender joints ratio and low GH were

more likely to have a bigger reduction in DAS28 score after treatment.

	Responding to treatment (n = 86)	Non-responding to treatment (n = 24)	p value
age (median)	55	45	p=NS
sex (% of males)	36%	17%	p=NS
number of tender joints (mean)	8.0	15.0	p<0.001
number of swollen joints (mean)	4.0	1.2	p<0.001
Swollen-to-tender joints ratio (mean)	0.7	0.1	p<0.001
GH (mean)	62.0	90.5	p<0.001
ESR (mean)	53.1	23.2	p<0.001
pre-treatment DAS score (mean)	5.7	5.7	p=NS
DAS score reduction post-treatment (mean)	1.9	0.2	p<0.001

Conclusion: We have identified a number of patients who fail anti-TNF treatment and in whom the DAS28 score is mainly the product of an increased score in the subjective components of it (GH and TJ). DAS28 score is the main criterion for the administration of anti-TNF treatment in the UK. We challenge the current practice of using DAS28 score per se for the identification of patients suitable for anti-TNF treatment and we recommend that more focus should be placed upon the individual components of it, especially on those which are objective and reproducible, and finally rely less on subjective criteria such as the GH and the number of tender joints, especially when a discrepancy between the number of swollen and tender joints exists (as in our population). A large study, in the UK population, involving thousands of patients is needed, to adjust the weights of the individual components and increase the reliability of the DAS28 score for the better identification of patients who will really benefit from anti-TNF treatment. This will save the NHS approximately £10,000 per patient and also avoid serious side effects associated with anti-TNF drugs, in this sub-group of patients who, based on our results, is unlikely to benefit from this class of medications. We suggest that the swollen-to-tender joints ratio merits further investigation as a possible predictor of treatment success or failure as other investigators have also suggested.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Physician's Global Assessment of Disease Activity (MDGA) is a measure that is frequently incorporated in disease activity indices which reflects the physician's perception of disease activity in rheumatoid arthritis (RA). **Objectives:**The aim of this analysis was to assess the proportion of patients failing to achieve CDAI and SDAI remission based on MDGA in a real-world, routine clinical care setting in Canada. The aim of this analysis was to assess the proportion of patients failing to achieve CDAI and SDAI remission based on MDGA in a real-world, routine clinical care setting in Canada.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab (IFX) or golimumab (GLM). Eligible patients for this analysis included RA patients treated with IFX or GLM between 2005 and 2015. Modified versions of CDAI (mCDAI) and SDAI (mSDAI) were calculated by omitting MDGA from the formulas. Correlation of the standard and modified versions of each index was assessed with the Pearson's correlation coefficient. ROC curve analysis was used to identify new thresholds for the modified versions of low disease activity (LDA) and remission. Cross-tabulations with the Chi-square test were used to assess the agreement between the standard and modified definitions of remission and LDA.

Results: A total of 1206 patients were included in the analysis with a mean (SD) age of 56.1 (13.4) years and a disease duration of 8.4 (8.9) years. A strong positive correlation was observed between the standard and modified versions of CDAI ($r=0.99$; $P<0.001$) and SDAI ($r=0.99$; $P<0.001$). Based on ROC analysis the new thresholds for remission and LDA were: CDAI (remission=2.65, LDA=10.05) and SDAI (remission=3.31, LDA=10.73). The proportion of patients achieving remission by both indices was 17.8% and 19.5%, patients not achieving remission by both indices was 75.3% and 74.4%, and patients achieving remission by the new thresholds only was 6.9% and 6.1%, for CDAI and SDAI, respectively. Cross-tabulation of the standard and modified thresholds showed that an additional 8.4% and 7.6% of non-remission cases for CDAI and SDAI, respectively, would be classified as remission with the modified definitions. Similarly, an additional 17.6% and 15.1% of non-LDA cases for CDAI and SDAI, respectively, would be classified as LDA.

Conclusion: The results of this analysis showed that MDGA could account for up to 8% of non-remission cases and up to 18% of non-LDA cases as measured by CDAI and SDAI. Omission of MDGA from these disease activity indices could have a significant impact on patient management in preventing overtreatment with DMARDs and biologics and avoiding unnecessary switching of DMARDs and biologics.

Discordance Between Physician-Stated Remission and 28-Joint Disease Activity Score (DAS28)-Defined Remission in Rheumatoid Arthritis Patients

Nan Li[1], Stuart Blackburn[2], Emma Sullivan[2], Danuta Kielar[1] and Steve Peterson[1], [1]Janssen Research & Development, LLC, Spring House, PA, [2]Adelphi Real World, Manchester, United Kingdom

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The goal in treatment of rheumatoid arthritis (RA) is to achieve a state of clinical remission. Updated treatment recommendations by EULAR/ACR task force highlight the importance of using validated composite measures of disease activity in routine clinical practice and emphasize the need for objective and measure-based treatment decision making. The DAS28 (ESR) is a standard tool used to assess RA disease activity endorsed by ACR and EULAR. This study examined the concordance of physician-stated remission and DAS28 remission.

Methods: Data were drawn from the 2014 Adelphi RA Disease Specific Programme in 5 European countries (France, Germany, Italy, Spain, UK). Rheumatologists provided details about the RA patients who visited them, including the use of composite clinical measures. Physician-stated remission was based on the question, "Is this patient currently in remission?" DAS28(3)-ESR remission was defined as a score <2.6. Multivariate logistic regression analyses were performed to investigate factors associated with discrepancies in rheumatologist-reported and DAS28 remission. Variables included in the multivariate model were selected based on clinical relevance and univariate analyses.

Results: This analysis included 307 physicians and 2,536 patients. Overall, 87.6% of rheumatologists practiced in a hospital (vs office only). For the 2,536 patients in this analysis, an objective measure of disease activity was performed for 1,386 (55.0%) of patients at the reference consultation, with notable regional variation. Out of 1,386 patients, 369 (26.6) had rheumatologist-reported remission and DAS28(3)-ESR defined remission; 575 (41.5%) had no remission from neither of the measurement; 41 (3.0%) patients' rheumatologist did not report remission but DAS28(3)-ESR remission was achieved; while 401 (28.9%) had rheumatologist-reported remission but not DAS28(3)-ESR defined remission. Multivariate analyses indicated that physician-reported anxiety and/or depression (odds ratio [OR] = 2.94), medium/high current pain assessment (OR = 3.10), and structural damage (OR = 2.00) were all significantly associated with physician over-reporting of remission compared with both physician and DAS28(3)-ESR agreement of remission (all $P \leq 0.001$). Agreement on a treat-to-target measure was significantly associated with lower likelihood of physician over-reporting of remission (OR = 0.46; $P = 0.001$).

Conclusion: Objective measures of RA disease activity are not universally used in clinical practice when reporting remission; when they are used, discordance exists between physician-reported remission and observed DAS28 remission. Multiple factors including disease severity, joint damage, anxiety/depression and physicians' agreement on treat-to-target were associated with likelihood of over-reporting of remission by physicians. Under-examination of patients and over-reporting of remission may result in sub-optimal treatment of patients with RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The biological variability in MBDA scores over a 24-hour period and day-to-day in patients with rheumatoid arthritis (RA) has not been well characterized. These data were obtained to determine a minimally important difference (MID) and establish a cut point for a meaningful change in MBDA scores over time.

Methods: 28 adults with clinically stable seropositive RA on stable medication (>8 weeks without changes), were recruited to a single US rheumatology research center. Serum samples were obtained 6 times over the first 24-hour period (8 AM, 12 PM, 4 PM, 8 PM, 12 AM and 8 AM) then at 12 PM in the next 24-hour period and at 8 AM the next two consecutive days, for a total of 9 time points. Diurnal variation was calculated using 6 time-points over the first 24 hours. Daily variation was determined using 4 time points taken at 8 AM on successive days. Combined diurnal and daily variation was calculated by using 9 time points over the four days. For each patient (n=28), changes in MBDA scores were calculated for all possible pairs of time points for: (a) Diurnal variation (15 possible pairs/patient, 420 total pairs), (b) Daily variation (6 possible pairs/patient, 168 total pairs) and (c) Diurnal and Daily variation (36 possible pairs/patient, 1008 total pairs). The mean change in MBDA score was determined for all pairs in each of the 3 analyses. The MID was calculated as twice the standard deviation (SD) using all available data.

Results: 28 patients were recruited for the following MBDA disease activity categories: 6 in low, 13 in moderate and 9 in high. Patient baseline characteristics were 64.3% women, mean age 61.9 years, mean MBDA score 39.3, and mean CDAI 19.9. With 96.4% patients on DMARDs, 8 patients were receiving biologics (1 rituximab; 7 anti-TNF, 6 in combination with MTX). No patients were on glucocorticoids. During the first day, the greatest and lowest mean MBDA scores were observed at 12 AM (midnight) and 12 PM (noon), respectively (Figure). The mean absolute change (SD) of MBDA score for diurnal variation was 4.3 (4.2). The largest variability in MBDA scores was observed for patients in the low MBDA category. The mean absolute change was 4.3 (4.4) for daily variation and 4.5 (4.5) in the combined daily and diurnal variation analysis. The MID was calculated as 9. Approximately 91% of the absolute changes determined for all pairs of MBDA score were ≤9.

Conclusion: Based upon short-term variability in the MBDA score among stable RA patients tested serially over time, the minimally important difference in the MBDA score was 9 units. Changes exceeding this threshold are unlikely to be due to diurnal and daily biological variation alone.

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biological markers are objective molecular indicators possessing diagnostic, prognostic and predictive utility. The detection of antibodies to cyclic citrullinated peptides (Anti-CCP) may occur long before the onset of rheumatoid arthritis (RA) symptoms. A positive test is associated with severe erosive disease and can predict disease progression. Diagnostic accuracy is crucial for clinicians to initiate a more aggressive treatment plan early in the course of the disease. Objective of study: to compare diagnostic accuracy of anti-CCP tests from different manufacturers for RA diagnosis.

Methods: A rigorous systematic literature review identified studies from 2004-2015. Pooled estimates for sensitivity, specificity, positive likelihood ratio (LR+), negative LR (LR-) were calculated by random effects meta-regression. Covariates influence was analyzed in sub-analyses (RA-type and control type).

Results: Out of 3100 papers, 88 met the inclusion criteria reporting the diagnostic accuracy of CCP tests from 7 manufacturers, and including 22 studies from early RA patients (< 2 years), 9 studies from established RA patients (> 2 years), while 20 studies used serum samples from a mixed population of RA patients (combination of early and

established). Forty seven studies obtained control serum samples from diseased patients, 12 studies from healthy individuals, 28 studies from a mixed control populations and 5 studied defined the control group as non-RA. The included studies presented data from 34 countries worldwide. The Disease Activity Score in 28 joints (DAS28) was used to assess the severity of disease in rheumatoid arthritis (RA) patients in 17 studies (20.2%). Sensitivity ranged between 65.6-83.1%; specificity between 87.6-96.4%; LR+: 6.5-19; LR-: 0.2-0.4. Overall, the diagnostic performance of EuroImmune/Anti-CCP ELISA, ThermoFisher/EliA and Inova Diagnostics/Quanta Flash distinguished from the others by having high sensitivities, and the highest specificities and positive LRs. This result did not seem to be influenced by the investigated covariates. The single-gate analysis showed that the ThermoFisher/EliA CCP test sensitivity remained stable compared to the overall analysis; in particular, it had significantly better sensitivity than the both the Inova Diagnostics/Quanta Lite 3.0 test and the Euro-diagnostica/Immunoscan test. There was a non-significant trend in favor of the Roche/Elecsys test, however none of the comparator index tests were shown to have significantly better sensitivity than the ThermoFisher/EliA CCP test.

Conclusion: By maximizing LR+ and minimizing false negatives, accurate RA diagnosis is possible, allowing for timely appropriate treatment strategy. Results show: 1) EuroImmune/Anti-CCP ELISA, ThermoFisher/EliA and Inova Diagnostics/Quanta Flash generally have better diagnostic performance; 2) ThermoFisher/EliA and Roche/Elecsys appear as the best tests for diagnosing suspected RA.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are well-known disabling conditions, with high impact on patients functioning and quality of life. However, little is published about the differences in disability between RA and PsA patients. The aim of this study was to evaluate and compare general functional disability and specific hand disability in patients with RA and PsA.

Methods: A cross-sectional study was performed. Consecutive patients with RA and PsA attended in a hospital were selected and their medical records reviewed. Sociodemographic and clinical variables including disease duration and activity (DAS28), physical function (Health Assessment Questionnaire, HAQ), handgrip strength in both hands (using an isometric hand dynamometer), radiographic damage (modified Sharp/van der Heijde score (SHS)), and pharmacological treatments were collected following a standardized protocol. Descriptive and bivariate analyses were performed. Multivariate linear regression models completed were to assess disability associated factors.

Results are expressed as coefficient (coef) and 95% confidence interval (CI). Results: A total of 103 RA patients (82.5% were women, mean disease duration 16 years, mean HAQ 1.29, mean DAS28 3.61, mean SHS 45.81, mean grip strength of the right hand 11.22, mean grip strengh of the left hand 11.02, 60.8% on biologic therapy) and 94 patients with PsA (82.5% were women, mean disease duration 14 years, mean HAQ 0.57, mean DAS28 2.7, mean SHS 7.8, mean grip strength of the right hand 20.79, mean grip strength of the left hand 20.06, 51,1% on biologic therapy) were analyzed. Compared to PsA, RA patients were significantly more active, presented more damage and worse grip strength in both hands. Slightly differences were found between disease in the disease duration (p=0,020). In the multivariate regression analyses, poorer function (HAQ score) was associated with RA (compared with PsA) coef=0.24 (95% CI 0.04-0.45), female sex coef=0.37 (95% CI 0.16-0.57), DAS28 coef=0.23 (95% CI 0.16-0.31), and SHS, but not with disease duration. The same results were obtained when the handgrip strength (in each hand separately) were entered in the regression models.

Conclusion: In our study RA patients presented more general and hand disability compared to PsA patients. Other factors as female sex are also associated with poorer function.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Erosive damage to small joints is a hallmark feature of rheumatoid arthritis (RA). The degree to which early erosive damage contributes to joint pain in well-controlled disease is incompletely understood. The use of magnetic resonance imaging (MRI) combined with erosion segmentation software, such as Early Erosions in Rheumatoid Arthritis (EERA), provides opportunity for the study of small, early erosions. Our objective was to apply multiple linear regression modeling to determine how low levels of erosive damage contribute to joint pain in RA.

Methods: From a single rheumatology clinic, 125 patients satisfying early RA referral criteria were included. Clinical and laboratory disease measures were captured. MRI of both hands were acquired, and a single reader used EERA software to compute total erosive damage in the metacarpophalangeal (MCP) joints, in mm^3. A multiple linear regression model was constructed, with the dependent variable as patient-reported finger joint pain, rated none, mild, moderate, or severe. Predictor variables included age, sex, symptom duration > 1 year, disease-modifying antirheumatic drug (DMARD) or biologic use over preceding 3 months, disease activity score using erythrocyte sedimentation rate (DAS28 ESR), and MCP joint erosion volume. Sensitivity analyses were conducted, using daily or weekly history of illness-associated pain, rated on visual analog scale (VAS, 0 to 100), as alternative dependent variables.

Results: Patients were 76% female, 81% Caucasian, mean (SD) age 56 (13) years, symptom duration 4.3 (5.0) years, DAS28 ESR 4.5 (1.4), pain VAS 45 (31), with 55% using DMARD or biologic over the preceding 3 months. Mean MCP erosive damage was low at 37 (91) mm^3. The regression model ($R^2 = 0.225$, $p < 0.001$) showed no statistically significant relationship between finger pain and erosion volume ($B = 0.00008$, $p = 0.896$). Among other predictor variables, only DAS28 ESR ($B = 0.263$, $p < 0.001$) and 3 month history of DMARD or biologic use ($B = -0.314$, $p = 0.002$) were significantly associated with finger pain. Regression estimates were similar when right and left hands were analyzed independently. Using either of weekly or daily patient-reported illness-associated pain VAS as the dependent variable, again only DAS28 ESR and 3 month history of DMARD or biologic use were significant model predictors.

Conclusion: Low level of MCP joint erosive damage was not associated with increased finger pain or illness-associated pain in well-controlled RA. Lower acute disease activity and concurrent DMARD or biologic therapy were associated with decreased pain. Longitudinal models may help identify the threshold at which MCP joint damage becomes an important contributor to finger pain.

Summary of Parameter Estimates for Regression Models

Outcome Variable:	Finger Pain		Daily RA Pain (VAS)		Weekly RA Pain (VAS)	
Predictor	**Beta**	**Std. Error**	**Beta**	**Std. Error**	**Beta**	**Std. Error**
Constant	1.169	0.298	1.435	15.152	-11.256	14.851
Age (years)	-0.0024	0.0038	0.048	0.196	0.067	0.189
Male Sex	0.187	0.118	7.300	6.191	6.655	6.068
Symptom Duration > 1 year	-0.156	0.108	-5.045	5.483	-8.816	5.374
DMARD or Biologic Use in Previous 3mo.	-0.314*	0.102	-12.811*	5.258	-11.580*	5.154
DAS28	0.263*	0.036	10.804*	1.820	12.054*	1.784
MCP Joint Erosion Volume (mm^3)	-0.00008	0.01	-0.034	0.028	-0.024	0.028

RA, rheumatoid arthritis; VAS, visual analog scale; DMARD, disease-modifying antirheumatic drug; DAS28, disease activity score on 28 joints; MCP, metacarpophalangeal.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: PROMIS® measures were developed to assess physical, mental, and social health across chronic diseases and include brief short forms (SFs; 4-8 items) to assess common symptoms and function. Because people with RA often live with high levels of debilitating symptoms, it is essential that the items query content that is relevant to people living with RA. Here, we report the results of cognitive debriefing of selected PROMIS SFs in people with RA.

Methods: Participants were patients with RA receiving treatment at one of 3 US academic rheumatology centers. One-on-one phone interviews were conducted using a "talk through" format after patients completed the following SFs: Physical Function v1.0 (PF 20a), Pain Interference v1.0 (PI; 8a), Fatigue v1.0 (FAT; 7a, 8a), Participation in Social Activities and Roles v2.0 (PSRA 8a). Perceived relevance of the items and responses were probed by a trained interviewer. Conversations were recorded and transcribed.

Results: The 32 participants were mostly female (72%) with a mean (SD) age of 54 (13) years and well-established disease (13 [10] yrs). Participants were racially (66% white, 19% black, 13% native American, 9% Asian, 13% multi-race) and geographically (34% mid-Atlantic; 41% East; 28% South; 28% rural) diverse. Ninety-seven percent had some college or higher education. On average, compared with the general US population, participants reported higher mean PI (57.9 [10.6]) FAT-7a (53.2 [9.9]), FAT-8a (55.3 [10.3]), and worse PF (42.2 [11.0]) and PSRA (46.7 [10.9]). Across domains, almost all items were rated as somewhat/very relevant (PF 87-100%; PI 87-100%; PSRA 84-100%) and question content and response options as somewhat/very easy to answer (PF 91%, PI 90%, PSRA 91%). Ratings were similar for fatigue except on one item ("How often were you too tired to take a bath or shower") where 25% of respondents rated it "not at all relevant." When asked how they select a response for pain and fatigue items, some (38% and 20%, respectively) thought of the intensity of symptoms, others (28% and 77%, respectively) thought of how the symptom impacted physical and role function, and the rest (34% and 33%, respectively) considered both intensity and function.

Conclusion: Almost all participants rated Physical Function, Pain Interference, Fatigue, and Participation in Social Roles and Activities SFs as relevant to their experience with RA and easy to answer. These results contribute new evidence of construct and content validation and the meaningfulness of scores in people with RA supporting use of these PROMIS SFs in research and clinical applications. The Importance of Outcome Measures in Rheumatoid Arthritis - Validity of the RAPID3 (Routine Assessment of Patient Index Data 3) in a United States "Real World Setting"

Background/Purpose: Over the last five years the concept of "Treat to Target" has been accepted internationally and is gaining momentum in the United States (US). In a real world (RW) setting however, rheumatologists have been slow to consistently obtain and utilize objective outcome measures. It is currently estimated that approximately 50 percent of US rheumatologists are obtaining outcome measures and of those, approximately one third are using the outcome measures in treatment decisions. The RAPID3 is a pooled index of the 3 patient-reported American College of Rheumatology Core Data Set measures. It has been validated against the Disease Activity Score (DAS-28) and Clinical Disease Activity Index (CDAI). The goal, to compare high, moderate, low and remission categories of RAPID3 to DAS28, DAS28-CRP, CDAI and the Simplified Disease Activity Index (SDAI) in RA patients enrolled in the JointMan registry (JM). JM captures RA criteria, disease features, joint counts, outcome measures, serology, medication efficacy and safety.

Methods: Retrospective registry review of data from 22 US rheumatologists. All 5 outcomes were available in 4241 patients over 22876 visits from 2009 to 2016. Standard score ranges for measures were used. All five metrics were compared against each other using the Pearson's and Spearman's correlations.

Results: RAPID3 scores correlated significantly ($p < 0.0001$) with all other scores using both Pearson's and Spearman's correlation coefficients. Overall, 65.5% of patients who met DAS28/CDAI moderate/high activity criteria met similar RAPID3 severity criteria; 47.5% who met RAPID3 remission/low activity criteria met similar DAS28/CDAI criteria.

Category	Value(s)
Average Age, (SD)	64 (14.11)
Female, n (%)	3166 (74.65)
White, n (%)	3266 (77.01)
Fulfilled 1987 or 2010 Criteria for RA, n (%)	3058 (72.11)

General demographics for all patients

Pearson's Correlation Coefficient				
	Rapid3 Raw	CDAI	DAS28	DAS28-CRP
SDAI	0.5994	0.9769	0.8178	0.9091
DAS28-CRP	0.4434	0.9069	0.8907	
DAS28	0.4275	0.8112		
CDAI	0.6046			
Spearman's Correlation Coefficient				
	Rapid3 Raw	CDAI	DAS28	DAS28-CRP
SDAI	0.6979	0.9869	0.7843	0.8694
DAS28-CRP	0.4327	0.76	0.868	
DAS28	0.4043	0.7634		
CDAI	0.7039			

Correlation coefficients for all metrics

Disease Activity State	Rapid3		CDAI		Das28-CRP		DAS28-ESR		SDAI	
	Count	Percentage	Count	Percentage	Count	Percentage	Count	Percentage	Count	Percentage
High	10797	47.23%	3688	16.13%	1191	5.21%	1139	4.98%	2920	12.77%
Moderate	6628	28.99%	7654	33.48%	5082	22.23%	7086	31.00%	7945	34.76%
Low	2940	12.86%	9228	40.37%	2200	9.62%	4061	17.76%	9490	41.51%
Remission	2495	10.91%	2290	10.02%	14387	62.94%	10574	46.26%	2505	10.96%

The distribution of disease activity states for each outcome metric.

Conclusion: In JM, the RAPID3 correlated with the CDAI and the SDAI strongly. RAPID3 correlated with the DAS28 and the DAS28-CRP at a moderate /low level. This data support continued use of the RAPID3 as an outcome measure and is the first publication validating the RAPID3 with the SDAI in a RW setting.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: While clinician goals when treating rheumatoid arthritis (RA) focus on achieving low disease activity or remission, RA patient goals remain largely unexplored. Patient-clinician goal concordance in other chronic diseases such as diabetes is associated with improved self-management. The aim of this literature review is to identify needs, goals, and expectations of RA patients in order to better guide systematic elicitation of patient goals in clinical encounters.

Methods: An academic librarian searched PubMed, Ovid MEDLINE, PsychINFO, and Cochrane database using a specialized algorithm that incorporated the subject terms: rheumatoid arthritis, goals, health priorities, attitude to health, needs, expectations, activities of daily living, quality of life, and treatment outcome. Search was limited to papers in English and adult patient populations. Titles and abstracts were retrieved and manually screened. The inclusion criteria for the papers were empirical investigations, quantitative or qualitative, involving assessments of the needs, goals, and expectations of adult patients with RA. Investigators then reviewed selected papers utilizing an inductive approach.

Results: Thirty-four articles were identified in the search, of which 21 were included in the final review. We identified 453 discrete patient goals (table) which were grouped into four major themes: 1) the bodily experience of RA, 2) achieving normalcy and wellness maintenance, 3) social connectedness and support, and 4) interpersonal and systemic

health care interactions.

***Conclusion*:** RA patients identify many goals not often explicitly considered by clinicians. The four major themes identified in this review will be used to inform a measure designed to capture RA patient goals which reflects that living with RA is a multidimensional experience. RA treatment goals must be collaboratively developed with clinicians and within the context of the patient's life. Future research should include the measurement of patient goals and the development of a tool designed to elicit patient goals for RA treatment and improve patient-clinician goal concordance.

Table - Domain-categorized RA patient goals (*n*=453)

The Bodily Experience of Rheumatoid Arthritis	**Achieving Normalcy and Wellness Maintenance**	**Social Connectedness and Support**	**Interpersonal and Systemic Health Care Interactions**
n=153	***n=127***	***n=30***	***n=143***

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies on association between inflammatory activity and body composition changes in rheumatoid arthritis (RA) are controversial due to some limitations: use of low accuracy methods to evaluate body composition such as body mass index (BMI), or methods with high cost and operational complexity (CT and MRI); analysis not separated by sex; inclusion of women with different menopausal status and inclusion of non validated criteria to assess disease activity. Currently, the best method in clinical practice for body composition analysis is dual energy X-ray absorptiometry (DXA). However, no studies on RA activity and body composition by DXA included evaluation of visceral adipose tissue in patients with long standing RA. Thus, we sought to verify the association between body composition by DXA, including visceral fat, and inflammatory activity in women with long standing established RA.

Methods: 78 postmenopausal women with RA (ACR 2010) were assessed by questionnaire, laboratory tests and body composition by DXA (muscle mass, total body fat and visceral fat). Patients with conditions known to influence body composition were excluded. Disease activity was assessed by composite indices (DAS28, CDAI, SDAI) and C-reactive protein (CRP). The potential association between body composition and disease activity was analyzed by Pearson correlation, Fisher´s test, ANOVA and Tukey´s test ($P < 0.05$).

Results: The mean age and disease duration were 61.1 ± 7.7 and 18.1 ± 10.9 years, respectively. 70.5% of women had BMI ≥ 25kg/m^2. The mean values of DAS28 and CRP were 3.57 ± 1.36 and 9.1 ± 10.9 mg/L, respectively. There was a negative and statistically significant correlation between CRP and appendicular muscle mass index ($r = -0.234$, $P = 0.039$). After adjusting for disease duration, BMI, physical activity, current and cumulative dose of prednisone and comorbidities, we found that women with CRP>10 mg/L had lower appendicular muscle mass index than those with CRP 5-10mg/L and CRP<5mg/L (6.3 ± 0.8 kg/m^2, 7.2 ± 1.2 kg/m^2 and 6.8 ± 1.0 kg/m^2, respectively; $P = 0.013$). Regarding to body fat, women with moderate inflammatory activity (PCR 5-10mg/L) had more total fat than those with CRP>10mg/L and CRP<5mg/L (12.4 ± 3.5 kg/m^2, 9.9 ± 3.6 kg/m^2 and 10.5 ± 2.8 kg/m^2, respectively; $P = 0.014$). Similarly, women with PCR 5-10mg/L had more visceral fat than women with very high and lower PCR (812.5 ± 266.4cm^3, 604.3 ± 236.3cm^3 and 658.9 ± 255.6cm^3; $P = 0.009$).

Conclusion: PCR was the only activity parameter associated with body composition in women with long-standing RA. High inflammatory activity that persists after a long disease duration was associated with lower muscle mass and lower fat mass values (including visceral adipose tissue), suggestive of more exuberant rheumatoid cachexia. Moreover, moderate activity was associated with higher values of visceral fat, which is known to be associated with increased cardiovascular risk. These results point to the existence of different body composition profiles according to RA inflammatory status, suggesting the importance of individualized approaches to sarcopenia and adiposity according to each disease activity level in long-standing established RA.

Synovial Features of Rheumatoid Arthritis and Psoriatic Arthritis Differ in Patients in Clinical and Ultrasound Remission after Anti-TNF Therapy

Stefano Alivernini[1], Luca Petricca[1], Laura Bui[2], Barbara Tolusso[1], Gabriele Di Sante[1], Roberta Benvenuto[2], Anna Laura Fedele[1], Elisa Gremese[1] and Gianfranco Ferraccioli[1], [1]Division of Rheumatology - Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy, [2]Division of Histopathology - Institute of Pathology, Catholic University of the Sacred Heart, Rome, Italy

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Persistent disease remission is the major goal of Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) treatment. The combined use of clinical and ultrasound selection criteria to define remission status reduces the disease flare rate after treatment tapering or discontinuation in RA but not in PsA patients. The aim of the study was to define the synovial features of RA and PsA patients in clinical and ultrasound remission achieved through combination therapy with Methotrexate and TNF-blockers.

Methods: RA patients in stable remission (n=22) (DAS<1.6 for at least 6 months), RA patients in stable low disease activity (LDA) (n=8) (1.6<DAS<2.4 for at least 6 months) and PsA patients in stable remission (n=15) (DAS<1.6 and PASI=0 for at least 6 months) achieved by MTX+anti-TNF agents (Adalimumab 40mg or Etanercept 50mg) with Power Doppler (PDUS) negative Synovial Hypertrophy (SH) (confirmed twice 3 months apart) underwent synovial tissue biopsy. RA patients with high/moderate disease activity naïve to any DMARDs (n=50) were included as comparison group. Immunostaining for CD68, CD21, CD20, CD3, CD31 and Collagen was performed.

Results: PDUS negative RA patients in remission did not differ from PDUS negative RA patients in LDA and PDUS negative PsA patients in remission for age, sex, disease duration, treatment duration and mean dose of MTX or TNF-inhibitor regimen. PDUS negative RA patients in remission showed lower histological scores for synovial $CD68^+$ ($p=0.001$ for lining and sublining), $CD20^+$ ($p=0.01$ for lining and $p=0.03$ per sublining), $CD3^+$ ($p=0.01$ for lining and sublining), $CD31^+$ vessels ($p<0.001$) and collagen deposition ($p=0.03$ for lining and $p=0.01$ for sublining) compared to PDUS positive RA patients naïve to treatment with high/moderate disease activity. However, PDUS negative RA patients in LDA, showed lower histological scores only for sublining $CD68^+$ ($p=0.03$) and $CD20^+$ cells ($p=0.05$), lining $CD3^+$ cells ($p=0.04$), $CD31^+$ vessels ($p<0.001$) and sublining deposition of collagen ($p=0.05$) compared to PDUS positive RA patients naïve to treatment with high/moderate disease activity. In addition, there was no significant difference in terms of lining and sublining $CD68^+$, $CD20^+$, $CD3^+$, $CD31^+$ cells and collagen comparing PDUS negative RA patients in remission and in LDA respectively. On the contrary, PDUS negative PsA patients in remission did show higher histological scores for sublining $CD68^+$ ($p=0.04$) and $CD3^+$ cells ($p=0.04$) as well as $CD31^+$ vessels ($p=0.01$) than PDUS negative RA patients in remission.

Conclusion: PDUS negative RA patients in remission have comparable synovial histological features compared to PDUS negative RA patients in LDA. However, PsA patients in remission are characterized by higher degree of residual synovial inflammation compared to RA patients in remission despite PDUS negativity after TNF-inhibition success.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal ultrasound (MSUS) can detect synovitis by Power doppler (PDUS) and can predict erosive progression on xrays in rheumatoid arthritis (RA) patients. Our previous work has reported an association of active RA with impairment in HDL function and suppression of paraoxonase-1 (PON1) activity, a novel risk factor for cardiovascular disease (CVD), which has been associated with carotid plaque in RA patients. In the current work we evaluated an association of PDUS signal with HDL function and PON1 activity in patients with RA.

Methods: Assessment of PDUS was performed on 24 RA patients naive to biologics in a pilot 12 month open-label study of subcutaneous abatacept. Seven joints were scanned by MSUS of the most affected side (wrist, MCP joint 2/3, PIP joint 2/3 and MTP joint 2/5) according to Backhaus et al. (*A&R* 2009;61:1194-201). PDUS was scored semiquantitatively according to published consensus definitions (*J Rheum.* 2005;32:2485-7). HDL's anti-oxidant function was measured by a cell free assay as described previously (*A&R* 2009; 60(10): 2870-9). PON1 activity was measured by a previously published assay with minor modifications (*A&R* 2012; 64(6):1828-37). Total and HDL cholesterol (HDL-C) levels were determined by standard methods.

Results: Patients with the highest baseline PDUS score (first tertile PDUS) had significantly worse HDL function as measured by a higher HDL inflammatory index (HII) compared to patients with lower baseline PDUS signals in the second and third PDUS tertiles (table). A higher PDUS score was significantly correlated with a higher HII (r= 0.50, p=0.01, n=24). In contrast, HDL-C and PON1 activity levels were lower in patients with high PDUS scores (table) and a significant inverse correlation was noted between PDUS score and PON1 activity (r=- 0.45, p=0.03, n= 24). Associations between other disease assessments (ESR, DAS28, or CDAI) and HDL function and PON1 activity were noted, but were of lesser magnitude than correlations with PDUS score (r values = -0.20- 0.30, all p values >0.15). Following treatment with abatacept for a minimum of 3 months, patients with the greatest decreases in PDUS showed modest associations for greater improvement in HDL function, PON1 activity, and HDL-C levels compared to patients with the lesser change in PDUS (table).

Conclusion: In a pilot study of 24 RA patients naïve to biologics, higher baseline PDUS scores identified patients with worse anti-oxidant function of HDL and lower PON1 activity. Improvement in PDUS score with abatacept treatment showed trends for improvement in HDL function, PON1 activity, and HDL-C levels. This data supports previous work suggesting a direct association of joint inflammation with abnormal HDL function, and suggests that further evaluation of PDUS as a non-invasive CV risk assessment tool in RA may be warranted.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasound has been shown to detect subclinical synovitis in patients who are in clinical remission, in rheumatoid arthritis (RA). The value of power Doppler ultrasound (PDUS) to predict flares in patients with RA in remission has not been fully studied. To determine whether PDUS assessment of synovitis predicts short term flares in patients with RA in clinical remission.

Methods: Consecutive RA patients in clinical remission (DAS28 < 2.6) were included. US examinations were performed at baseline by the same rheumatologist, blinded to clinical data, using an Esaote MyLab 70 machine (6-18 MHz broad band multifrequency linear transducer). A total of 20 joints of both hands were assessed: wrists, first to fifth MCPs and second to fifth PIPs. PDUS signal was evaluated on a semi-quantitative scale from 0 to 3. PD synovitis was defined as the presence of intraarticular USPD signal ≥ 1, and was treated as a dichotomous variable. On the same day a complete clinical assessment was performed by another rheumatologist. Patients were followed-up and regularly assessed every two/three months. Flare was defined as the requirement of a change in disease modifying antirheumatic drugs (DMARDs) (increasing dose, adding or changing DMARDs or biologics therapy) by the treating rheumatologist (blinded to baseline PDUS findings); or an increase in DAS28 >1.2 or a DAS28 >3.2 on follow-up. Baseline variables and the presence of PDUS, were compared among patients with and without flares in univariate analysis. Multivariable analysis using a Cox proportional hazards model, with flare as the outcome variable, and PD signal, demographic characteristics, and baseline disease activity as independent variables were also calculated.

Results: 80 patients fulfilling DAS28 remission criteria were included. Baseline patients' characteristics are shown in the table. Among the 80 patients, 20 (25%) showed at least one joint with positive PDUS signal. Mean number of joints with PD signal was 1.75 (SD: 1.16, range 1-5). In 35 patients a treatment reduction was initiated by the treating rheumatologist, after inclusion in the study (blinded to baseline PDUS findings). Among the 80 patients on remission, 36 (45%) experienced a flare within follow up (median follow up (IQR): 15.4 (9.4-27.3) months). Flare occurred a median of 9.4 (IQR: 4.9-15.7) months after inclusion in the study (US date). In univariate analysis neither a positive PDUS signal, nor the reduction of treatment, nor the use of DMARDs in contrast with biologics, were associated with flares (table). In the multivariate Cox proportional hazards model, none of the variables were associated with an increased risk of flare.

Conclusion: Among RA patients in clinical remission synovial inflammation by PDUS was seen in 25%, but it was not associated with disease flare in the short term. None of the variables studied were associated with increased risk of flare.
Table. Patients' characteristics.

Feature	Patients with flares (n=36)	Patients without flares (n=44)	*p value*

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient global assessment (PtGA), despite not being exclusively related to disease activity, is included in Boolean-based remission (BR) criteria for RA. This study evaluated the US disease activities, sustainabilities, and relapse rates of RA patients in BR by using physician (Ph) GA (BR-PhGA) compared to those in BR by using PtGA (BR-PhGA).

Methods: Established RA patients in clinical remission (DAS28-ESR<2.6) for ≥6 months with a stable treatment regimen were included. Fulfillment of BR-PtGA and BR-PhGA criteria were assessed. A standard gray scale (GS) and power Doppler (PD) US examination of 28 joints (included in DAS28) for the presence of synovitis was performed at baseline

and 6th month (NI). GS and PD synovitis signals were semiquantitatively graded from 0 to 3. US disease activity was also categorized as US remission (PD-/GS-), inactive synovitis (PD-/GS+), and active synovitis (PD+/GS+). Clinical relapse (1. Loss of DAS28 remission; 2. Loss of BR) and US relapse (Loss of US remission due to 1. Any increase in PG/GS scores; 2. Only grade≥2 increase in PD/GS scores) rates (each of 4 definitions) were determined at 6th month.

Results: 96 out of 398 (24.1%) RA patients in DAS28 remission were enrolled (F/M=60/36, age 53±12, disease duration 11±5 yrs, bDMARDs 43%, RF/Anti-CCP positivity 83%). BR-PtGA was fulfilled in 37 (38.5%) and 31 (32.3%) patients and BR-PhGA was fulfilled in 61 (63.5%) and 66 (68.8%) patients at baseline and 6th month, respectively. Baseline US disease activities of patients in BR-PtGA and BR-PhGA were not significantly different (*Table 1*). PD and GS scores of patients in BR-PtGA were similar to those of not fulfilling BR-PtGA. However, patients in BR-PhGA had significantly lower PD and GS scores compared to non-remission counterparts, 0 (1-4) *vs* 4 (2-7), *P*=0.001; 3 (0-7) *vs* 6 (3-10), *P*=0.003, respectively. Loss of DAS28 remission rates were similar in both BR groups (16.2% *vs* 18%, *P*=0.82), whereas loss of corresponding BR was slightly lower in BR-PhGA patients (38% *vs* 21%, *P*=0.08). US relapse rates in BR-PtGA and BR-PhGA patients who were in US remission at baseline (loss of US remission: 3/10 *vs* 7/15, *P*=0.41; loss of US remission due to grade≥2 increase in PD/GS score: 1/16 *vs* 6/20, *P*=0.16), and changes in US disease activities over time were also comparable (*Table 2)*.

Conclusion: US verified disease activity of patients in BR-PhGA is similar to patients in BR-PtGA. BR-PhGA differentiates US inflammation better than the BR-PtGA with higher sustainability and similar US relapse rates. PtGA may be substituted with PhGA in BR, particularly in established RA patients.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasonography (US) has been prevalently used as a valid and objective modality for joint examination in patients with rheumatoid arthritis (RA). This study aimed to examine and compare the concordance between joint symptom, tenderness, or swelling and US synovitis.

Methods: Fifty patients with RA (84% female; median age, 69 years; disease duration, 2.4 years; disease activity score of 28 joints, 3.84) completed the self-evaluation of joint symptoms including pain and considerable stiffness in the (proximal) interphalangeal, metacarpophalangeal, wrist, elbow, shoulder, knee, and ankle joints. These joints were also subjected to physical examination by a physician to evaluate for the presence of tenderness and/or swelling, and to US examination for the presence of synovitis defined as gray-scale score ≥2 or power Doppler signal score ≥1.

Results: In a total of 1492 evaluated joints, symptoms, tenderness, and swelling were observed in 288 (19.3%), 182 (12.2%), and 220 (14.7%) joints, respectively, and US synovitis was observed in 317 (21.2%) joints. The overall concordance rate with US synovitis was the least for joint tenderness ($\kappa = 0.30$) when compared with joint symptoms ($\kappa = 0.39$) or swelling ($\kappa = 0.43$). Furthermore, US synovitis joint count of 28 joints showed a better correlation with swollen joint count ($r^2=0.53$, $p<0.0001$) and with symptomatic joint count ($r^2=0.54$, $p<0.0001$) than with tender joint count ($r^2=0.29$, $p<0.0001$).

Conclusion: Joint swelling and patient-reported joint symptoms showed better concordance with US synovitis than joint tenderness.

Body Mass Index Is Positively Correlated with Diverse Disease Activity Measures in Longstanding Rheumatoid Arthritis

Craig Wiesenhutter, Coeur d'Alene Arthritis Clinic, Coeur D Alene, ID; University of Washington School of Family Medicine, Seattle, ID

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity is a common problem with patients who have rheumatoid arthritis (RA). Adipose tissue has been shown to produce cytokines that are proinflammatory. The measurement of Body Mass Index (BMI) is a proxy for determining the amount of adipose tissue present in an individual. The impact of BMI on disease activity measures in RA have been contradictory, and, in fact, studies have shown that a high BMI is protective, as defined by x-ray changes for patients with early onset RA. The objective of this trial is to determine whether obesity and BMI are positively correlated with diverse disease activity measures (DAMs) in longstanding RA.

Methods: Patients at a community based rheumatology clinic undergo DAM assessments on a routine basis as part of the implementation of a treat to target (T2T) strategy. These assessments include the disease activity score in 28 joints (DAS28CRP), the power Doppler joint count (UPD), and the multibiomarker disease activity test (MBDA), as well as several other commonly assessed DAMs. The UPD includes scoring at six dorsal wrist and six dorsal MCP sites. The average duration of RA in patients at this clinic is > 10 years. Also, as currently mandated by the authorities, BMI and other vital signs are obtained on a regular basis. Correlations were determined by Pearson's coefficients, and categorical data was compared by T tests. Patients were categorized as underweight (BMI < 18), normal weight (BMI > =18 and <25), overweight (BMI >=25 and <30), and obese (BMI >= 30).

Results: Table 1 BMI and Comparisons with Diverse Disease Activity Measures

	N	BMI VS	Prob	Normal Wt Avg +/- SD	Overweight Avg +/- SD	Obese Avg +/- SD	Prob Nl vs Over	Prob Nl vs Obese	Prob Over vs Obese

MBDA	242	r=300	p<0.0001	37.7 +/- 13.6	40.6 +/- 16.2	41.3 +/- 12.7	NS	p=0.05	p<0.0001
HAQ	233	r=289	p<0.0001	1.9 +/- 1.6	1.8 +/- 1.4	2.7 +/- 1.8	NS	p=0.02	p=0.02
Pt Global	229	r=228	p<0.001	3.5 +/- 2.4	3.5 +/- 2.2	5.0 +/- 2.3	NS	NS	p<0.0001
TJC	271	r=222	p<0.001	7.1 +/- 6.8	7.6 +/- 9.7	11.4 +/- 7.5	NS	p=0.003	p<0.0001
CDAI	236	r=206	p<0.001	18.6 +/- 12.2	19.0 +/- 20.4	21.9 +/- 19.4	NS	p<0.001	p=.003
RAPIDIII	244	r=224	p<0.001	8.9 +/- 6.0	8.3+/- 5.1	11.4 +/- 7.5	NS	NS	p=0.02

There were only two patients in the underweight category, and that category was not included in this analysis.

Conclusion: BMI positively correlates with, and shows significant increases in weight categories for several important measures of disease activity in patients with longstanding RA. Though the DAS28CRP, MBDA, and UPD generally correlate significantly in this clinic (r= > 0.500), in this study, UPD was the only one of these measures that did not correlate with BMI (r = 0.090). One possible explanation is that power Doppler signals are very dependent on the distance of the probe from the site of the signal. The UPD method utilized includes assessments of the dorsal wrist at six out of twelve sites. Subcutaneous adipose tissue in overweight patients perhaps blunted the signals. Of interest, Leptin was significantly correlated with BMI and showed significant increases with weight categories. Leptin is produced by adipose tissue and is thought to be proinflammatory. Excess Leptin production might be contributory to the effects of BMI on RA disease activity. BMI is positively correlated with several important DAMs in patients with longstanding RA. Rheumatologists should significantly increase their efforts and resources to address and manage obesity in our RA patients.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: A number of studies have demonstrated the association between disease activity and work productivity in patients (pts) with RA. However, the relationship between work status and poor prognosis is unknown. This analysis characterized the proportion of pts with RA who had poor prognoses in an observational clinical cohort and evaluated poor prognostic factors and pts' work status.

Methods: Using the Corrona RA registry, we identified pts with RA who were biologic naïve at enrollment and had a follow-up visit at 12 months (± 3 months). Pts were characterized by RA prognosis based on factors from the 2008 ACR treatment recommendations,[1] including functional limitation (modified Health Assessment Questionnaire), extra-articular disease (Sjögren's syndrome, RA lung disease and/or nodules), seropositivity (RF and/or anti-cyclic citrullinated peptide antibodies) and erosions. Pts were categorized as having 0–1, 2 or 3+ poor prognostic indicators. Pts with missing information on any factor were excluded. Each of the three prognosis groups was compared at enrollment (including use of prior conventional synthetic DMARDs) according to use of TNF inhibitors vs non-TNF inhibitors. The relationship between poor prognosis category and work status was investigated at baseline and 12 months using a chi-squared test. A dichotomous variable was constructed, with working 'yes' defined as full- or part-time working, and working 'no' including pts who worked from home or were students, disabled or retired. Because a relationship between poor prognosis and work status might be driven by age differences (retirees are generally older), a frequency-matching approach was used

to match people across poor prognosis categories according to age group (18–44, 45–54, 55-64, 65–74, 75+ years).

Results: 3621 pts who enrolled in Corrona on/after January 2005 met the selection criteria: 1554 (42.9%), 1263 (34.9%) and 804 (22.2%) with a prognosis category of 0–1, 2 or 3+, respectively. Pts in the worst prognostic category were older (median age: 62 vs 58 years), had more established disease (median disease duration: 4 vs 1 years) and greater disease activity (median CDAI score: 14 vs 7) compared with those in the best prognosis category. After adjusting for age, there was a significant relationship between work and poor prognosis category; pts in the worst prognosis category were less likely to be in full- or part-time work at enrollment compared with those in the best prognosis category ($p<0.001$; Table). At the 12-month visit, the relationship between poor prognosis category and work status remained statistically significant ($p<0.001$; Table).

Conclusion: These data suggest that the proportion of pts with RA in full- or part-time employment was lower in those with poor prognostic factors. Further studies are needed to investigate whether treatment can prevent or reverse impairment of work status in pts with RA. 1. Saag K, et al. *Arthritis Rheum* 2008;**59**:762–84.

Table. Work status (full time/part time) at enrollment and at the 12-month visit by poor prognosis category after adjusting for age

	Poor prognosis indicators

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In studies of rheumatoid arthritis (RA), disease activity and patient reported outcomes are often used as endpoints. However, these measures may not reflect the full impact of RA on function in all patients. The objective of this study were to: 1) investigate grip strength in early RA; 2) assess grip strength in patients with limited self-reported disability.

Methods: An inception cohort of patients with early RA (symptom duration ≤12 months), recruited in 1995-2005, was investigated. Grip force (Newton, N) was measured using the electronic instrument Grippit (AB Detektor, Gothenburg, Sweden). Average and peak grip force values of the dominant hand were evaluated and compared to the expected, based on age- and sex-specific reference values from the literature (Nilsen T et al. Scand J Occup Ther 2012; 19: 288-96). The paired t-test was used for these comparisons and for analysis of changes in grip force between visits. At each visit, expected values were subtracted from observed grip force values, and delta values were used for age-corrected analysis of changes over time. Limited self-reported disability was defined as a Health Assessment Questionnaire Disability Index (HAQ-DI) score of ≤ 0.5.

Results: A total of 225 patients with early RA (71 % women, mean age 60 years, 61 % RF positive, 57 % anti-CCP2 positive) were investigated. At baseline, the median HAQ-DI score was 0.75 (interquartile range 0.38-1.25). The mean baseline average grip force was 105 N [standard deviation (SD) 78], which was significantly lower than the corresponding expected values [266 N (SD 91) ($p<0.001$)]. Patients were managed according to usual care, with no pre-specified protocol for pharmacotherapy or rehabilitation. At 5 years, 44 % of the patients reported limited disability (HAQ-DI ≤ 0.5). The average grip force improved significantly from inclusion to the 12 month visit [age-corrected mean change: 34 N; 95 % confidence interval (CI) 26-43], and there was also some improvement between the 1-year and 5-year follow-up evaluations (age-corrected mean change 23 N; 95 % CI 14-32). At 5 years, the average grip force was still lower than expected overall (mean 139 N vs 244 N; $p<0.001$), and also among those with HAQ-DI ≤ 0.5 (mean 184 N vs 273 N; $p<0.001$). Similar patterns were observed for all comparisons of peak grip force values.

Conclusion: Grip strength improved in early RA, in particular during the first year, probably due to effects of pharmacologic anti-inflammatory treatment and rehabilitation. A substantial proportion of the patients had limited self-reported disability at 5 years after diagnosis. Among these, there was however still a significant reduction in grip strength. This suggests that further efforts to improve hand function are important in early RA.

Changes in Diverse Disease Activity Measures Are Highly Correlated Following the Initiation of Most Treatment Modalities in the Management of Longstanding Rheumatoid Arthritis

Craig Wiesenhutter, Coeur d'Alene Arthritis Clinic, Coeur D Alene, ID; University of Washington School of Family

Medicine, Seattle, ID

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treating rheumatoid arthritis (RA) patients to target (T2T) has been shown to result in better outcomes in patients with relatively recent onset RA. The implementation of this method requires performing disease activity measures (DAMs) with the disease activity score in 28 joints (DAS28) being the most commonly used. The use of clinically based DAMs in patients with longstanding RA is problematic as structural damage, and other comorbidities can lead to elevated scores because of the impact on composite elements not related to inflammation i.e. patient global and tender joint count. Including additional DAMs, such as a power Doppler joint count (UPD) and multibiomarker disease activity (MBDA) could possibly lead to better assessment of this patient population. The purpose of this abstract is to determine the changes in these three diverse DAMs and the relationships of these changes following the initiation of specific treatment modalities in patient with longstanding RA.

Methods: Patients at a community based rheumatology clinic undergo DAM assessments on a routine basis as part of the implementation of a T2T strategy. These assessments include the DAS28CRP, a UPD, and the MBDA. The UPD includes scoring at six dorsal wrist and six dorsal MCP sites. Patients underwent assessments prior to change in therapy, and then generally about six months later. Patients who were on biologics and found to be under inadequate control, had their biologic discontinued and the new therapy added later, depending on the half-life of the discontinued medication. The average duration of RA in patients at this clinic is > 10 years. The average DAS28CRP 4.18 +/- 1.32, average MBDA 41.4 +/- 14, and the average UPD 7.8 +/- 4.3.

Results:

		Δ DAS28CRP			Δ MBDA			Δ UPD			DAS28CRP Vs MBDA	UPD Vs MBDA	DAS28CRP Vs UPD
	N	AVG	SD	Prob	AVG	SD	Prob	AVG	SD	Prob			
MTX/Leflunomide	10	-1.63	0.83	0.00002	-12.4	8.0	0.00025	-3.2	2.8	0.003	r = 0.510*	r = 0.325	r = 0.425
Anti-TNFs	16	-0.94	1.24	0.0029	-11.5	11.8	0.007	-3.0	3.8	0.003	r = 0.454*	r = 0.488*	r = 0.573*
Tocilizumab	12	-1.44	1.13	0.0004	+6.3	11.4	0.044	-4.5	3.3	0.001	r = -0.252	r =- 0.148	r = 0.277
Abatacept	10	-0.88	2.04	0.08	-2.5	10.8	0.24	-5	6.6	0.02	r =0.341	r =- 0.736*	r = 0.619*
Tofacitinib	11	-1.27	1.03	0.001	-11.3	13	0.035	-2.2	2.6	0.01	r =0.209	r =- 0.707*	r = 0.565*

*P value < 0.05

Conclusion: Changes in diverse DAMs have moderate to high correlations following the initiation of specific therapy with most treatment modalities utilized in the management of longstanding RA. Tocilizumab did not have a positive correlation between DAS and the MBDA, which has been previously reported, and is presumed to be secondary to its mode of action which leads to significant elevation of IL-6 in the serum. Tofacitinib, a Jak-1 inhibitor, did not have a significant correlation between DAS and the MBNA, which has also been reported recently for another Jak-1 inhibitor in development, but had significant correlation with UPD and the MBNA in this study. This data suggest the validity of adding more diverse DAMs, such as UPD, and MBDA to clinical measures, such as the DAS28CRP, as endpoints in the implementation of a T2T strategy in the management of longstanding RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient reported outcome measures (PROMs), including the Health Assessment Questionnaire Disability Index (HAQ-DI), are valuable and reliable instruments for assessment of disease severity and disability in patient with early rheumatoid arthritis (RA), and have also been reported to have prognostic value. The aim of this study was to evaluate how disability varies over time in patients with early RA, and to identify early predictors of future disability in RA.

Methods: An inception cohort of patients with early RA (symptom duration ≤12 months), recruited in Malmö in 1995-2005, was followed in a structured program, including clinical evaluation and PROMs. Changes in HAQ-DI between different time points were assessed using the paired T-test. Potential predictors of moderate/severe disability (HAQ-DI >1.0) at 5 years were examined using logistic regression.

Results: A total of 233 patients (70 % women; mean age at diagnosis 60.5 years; 62 % RF positive; 57 % anti-CCP positive) were included. The median duration of symptoms at onset was 7 months. The median HAQ-DI score decreased from inclusion to 6 months (median 0.88 vs. 0.50; $p<0.001$), remained stable at 12 and 24 months, and then increased significantly again at 5 years (median 0.69; $p=0.002$ vs 24 months) and 10 years (median 0.75; $p=0.004$ vs 5 years). Baseline characteristics that predicted moderate to severe disability included high HAQ-DI scores [age-sex adjusted odds ratio (OR) 3.43 per unit; 95% confidence interval (CI) 1.88-6.27)] and high scores for pain and patient´s global assessment, but not laboratory markers of inflammation (Table). Patients with RF positive RA had a lower probability of a HAQ-DI >1 after five years (Table). Although RF negative patients were slightly older at diagnosis (mean 61.9 vs. 59.5 years) and had higher baseline HAQ scores (median 0.88 vs 0.75; $p=0.09$), there was a trend towards a negative association with 5-year moderate/severe disability also in analysis adjusted for age, sex and baseline HAQ-DI (OR 0.50; 95 % CI 0.23-1.07).

Conclusion: Disability decreased early in the disease course, and thereafter increased consistently from two years after diagnosis and onwards. The latter may be related to chronic joint damage and increasing age. Moderate to severe disability after 5 years was predicted by worse PROMs, but not by standard laboratory measures of disease activity. Patients with RF negative RA had worse disability, likely reflecting distinct factors influencing PROMs in this subgroup.

The relation between baseline characteristics in the early RA cohort and moderate/severe disability (HAQ-DI>1) at 5 years. Logistic regression analyses.

	Crude	Adjusted for age and sex

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Total management including reconstructive joint surgery and rehabilitation should be needed for further improvements of physical function for long-standing RA patients. It is very important to set treatment goal for those management using index of activity speed [Timed Up and Go test (TUG)] and range of motion (ROM). The purpose of this study is to explore the characteristics of functional impairment and relationship TUG and physical function in RA patients who were needed joint surgery using multicenter prospective cohort.

Methods:

We started the prospective study in September, 2012 (Study registration: UMIN000012649). In this study, we used baseline (preoperation) data as follows; age, sex, disease duration, drug therapies, and disease activity, functional evaluations [TUG, HAQ-DI, DASH (upper limb function), joint ROM (hip, knee, ankle, shoulder, elbow, wrist)], and patient-reported outcome [EQ-5D (QOL) and BDI-II (depression)]. Correlation between TUG and other variables were determined. Association between TUG and no disability of daily activity in each 8 HAQ-DI categories and cut-off values for no disability were determined using ROC curve. TUG by disability in 8 HAQ-DI categories was compared by ANOVA with adjustment of age and sex. This study is supported by grant from the Japanese Ministry of Health, Labour and Welfare.

Results:

435 surgical patients were registered. Mean values for age, disease duration, and sex were 64.2 years, 17.1 years, and 89% female, respectively. Actually, even long-standing RA patients who were needed joint surgery had remission or low disease activity in this baseline data (median values for DAS28 (3.0) and CRP (0.2 mg/dl). 23.0% of the patients were treated with biologics. We confirmed the significant correlation ($r>0.3$) between TUG and Age, HAQ-DI, DASH, patient-reported outcome (EQ-5D) and range of motion (hip, knee, shoulder). We also found significant relationship between TUG and 5 of 8 categories in HAQ-DI.

The relevant association between TUG and category Walking, Arising, and Activity (AUC>0.7) was found based on ROC analyses. Cut-off value of TUG for HAQ remission (<0.5) was 8.6 seconds (sensitivity 64%, specificity 65%). Cut-off for no disability in category Arising, Walking, and Activity were 8.6s (sensitivity 74%, specificity 63%), 8.4s (sensitivity 76%, specificity 71%) and 8.2s (sensitivity 69%, specificity 66%), respectively. Age, sex-adjusted TUG for no disability in Arising, 9.2s (95%CI: 8.2-10.1), Waling, 8.6s (95%CI: 7.6-9.6), Activity, 8.6s (95%CI: 7.2-10.0).

Conclusion: TUG was significantly associated with other physical function measurements and patient-reported outcome. The cut-off values of TUG (~9 seconds) should be important for assessment of disability in patients with long-standing RA and could provide target of surgical procedure and rehabilitation program.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Even now, in clinical practice, most of RA patients have long-standing disease and structural damage in their joints. Reconstructive joint surgery should be needed for further improvements of physical function for long-standing RA patients. It is very important to understand how much range of motion (ROM) should be needed to gain better physical function in each case.

The purpose of this study is to explore the characteristics of functional impairment in RA patients who were needed joint surgery based on ROM of joints using multicenter prospective cohort.

Methods:

We conducted this prospective study from 2012 to2015 (Study registration: UMIN000012649) supported by grant from the Japanese Ministry of Health, Labour and Welfare.

We collected data on age, sex, disease duration, drug therapies, disease activity, and physical functional including HAQ-DI. Joint range of motion including shoulder, elbow, wrist, hip knee ankle was also measured. ROM in each joint by disability in HAQ-DI categories was compared by ANOVA with adjustment of age and sex. Association between ROM of each joint and no disability of daily activity in each 8 HAQ-DI categories and cut-off values for no disability were determined using ROC curve. Independent impact of ROM each joint was also determined multivariate analysis.

Results:

460 patients who have data of ROM of any joints in registry were analyzed. Mean values for age, disease duration,

DAS28-CRP and sex were 64.5 years, 16.7 years, 3.14, and 86.8% female, respectively. Median values for CRP was 0.2 mg/dl. We could find significant association between ROM and disability in HAQ-DI category based on area under the ROC curve (AUC>0.7) as follows; shoulder in dressing, wrist in eating, hip, knee ankle in walking, shoulder in hygiene, shoulder in activity. The cut-off values of ROM of each joints for daily activity in each HAQ-DI category was shown in Table 1 using ROC curves (Table 1). Multivariate analysis adjusting disease activity, age, and sex, showed which joint had significant impact on disability of each category (Table 2).

Conclusion: ROMs of the joints were significantly associated with functional impairment. The information should be important for assessment of disability in patients with long-standing RA. The cut-off of ROM as shown in this study could be target of surgical procedure. It will be validated by further analysis of longitudinal data of this study.

Table 1: Cut-off value of ROM of each joint for disability in daily activity based on HAQ-DI category

		HAQ-DI category							
		Dressing	Arising	Eating	Waking	Hygiene	Reach	Grip	Activity
shoulder	abduction	132.8	142.8	131.3	141.0	141.0	133.5	131.3	138.8
elbow	flexion-extension	120.5	125.5	118.8	126.5	126.5	113.8	120.5	113.8
wrist	supination-pronation	150.3		150.8		153.3	156.0		150.3
wrist	flexion-extension	86.3	69.5	76.3		78.8	86.3	89.0	
knee	flexion-extension	133.8	133.8		133.8	131.3	123.8	123.8	133.8
hip	flexion-extension	126.3	131.3	131.3	126.3	126.3	113.8	131.3	126.3
ankle	flexion-extension	53.8	61.3	56.3	58.8	56.3	53.8	53.8	56.3

Cut-off values were determined using ROC curves when a significant association was found between ROM and disability in each category.

Table 2: Association between limited ROM and disability in daily activity based on HAQ-DI category: multivariate logistic regression analysis

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: We compared remission rates, according to different definitions of remission in rheumatoid arthritis (RA) and investigated the potential predictors of sustained remission at the 2-year follow-up.

Methods: We obtained data on 291 RA outpatients, seen from July 2009 to September 2012. Sociodemographic data and answers to questionnaires were collected in face-to-face interviews. Remission was defined according to the Disease Activity Score in 28 joints (DAS28)-ESR, DAS28-CRP, Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), and ACR/EULAR Boolean definition. Sustained remission was defined as when the patient continued in remission at two consecutive annual assessments. Predictors of sustained remission according to the DAS28-CRP were assessed by univariate and multivariate analyses.

Results: For the 291 RA patients, the remission rates of RA were 17.9% (DAS28-ESR), 54.3% (DAS28-CRP), 10.3% (SDAI), 10.0% (CDAI), and 5.8% (Boolean). On follow-up for 2 years, the sustained remission rates of RA were 46.5% (DAS28), 55.0% (DAS28-CRP), 37.5% (SDAI), 32.0% (CDAI), and 30.8% (Boolean). RA patients who achieve sustained remission according to the DAS28-CRP were younger, and had more education, higher monthly income, lower Health Assessment Questionnaire (HAQ) score, lower physician global assessment, lower patient global assessment, lower patient pain assessment, and higher EQ-5D. In multivariate analysis, only the HAQ score predicted sustained remission according to DAS28-CRP (OR=0.257, 95% CI 0.067–0.980, $p = 0.047$).

Conclusion: The remission rates of RA patients differed according to the definition of remission, and the highest sustained remission rate was classified by the DAS28-CRP. A lower HAQ score was an independent predictor of sustained remission over 2 years, according to the DAS28-CRP.

Higher Multi Biomarker Disease Activity Scores Foreshadow Greater Longitudinal Improvement in RA Disease Activity

Jeffrey Curtis[1], Leslie Harrold[2], Joel Kremer[3] and J. Lynn Palmer[4], [1]Division Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [2]U Massachusetts, Worcester, MA, [3]Albany Medical Center, Albany, NY, [4]Corrona Research Foundation, Albany, NY

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biomarkers in patients with rheumatoid arthritis (RA) have the attractive potential to help select patients that have a greater burden of disease activity and might have better treatment response when starting a new RA medication. This feature may be relevant both as inclusion criteria for a clinical trial or for clinical care.

Methods: We used Corrona, a large longitudinal registry of U.S. patients with rheumatoid arthritis that has been collected by more than 625 rheumatologists in 40 states. To be eligible for this analysis, patients had to be initiating one of 8 biologic DMARDs (adalimumab, etanercept, certolizumab pegol, golimumab, infliximab, abatacept, tocilizumab, rituximab) or tofacitinib and have a MBDA score processed no more than 6 months prior or 1 month after their initiation date. We evaluated CDAI at the corresponding 2 CORRONA visits: a baseline visit no more than 6 months prior to the initiation date ('baseline') and a follow-up CORRONA visit within 3-9 months subsequently. Patients also must have had baseline high disease activity as measured clinically using the CDAI (>22). Demographic and clinical variables at baseline were tested to determine their association with the MBDA score. General linear model analysis with change in CDAI between baseline and follow-up as the main outcome were evaluated according to MBDA category [low (<30), medium (30-44), and high (>44)], controlling for age, body mass index, and CDAI at baseline.

Results: There were 74 patients with baseline MBDA scores available that initiated a new medication that also had longitudinal follow-up data. Characteristics of these patients were median (IQR) age 61 (50,71) years, 76% women, 91% white; 14% with diabetes, 11% fibromyalgia, 11% current smokers, and 72% seropositive. Median (IQR) BMI was 30; CDAI 33 (36, 39); CRP 5.2 (2.3,15.2) mg/L; and MBDA score 45 (36-60). Patients with higher MBDA scores (>44) had greater crude mean change in CDAI (-15.5 units) compared to mean change in CDAI (-7.6 units) in those with low or medium MBDA scores. After adjusting for age, BMI, and baseline CDAI, patients in the high MBDA category had a mean 8 unit incrementally greater improvement in the CDAI ($p < 0.01$) compared to patients with baseline MBDA scores in the low to moderate range.

Conclusion: Among RA patients with high disease activity clinically who started a new medication for RA, MBDA scores in the high range (>44) were associated with significantly greater improvement in the CDAI over time compared to those starting with lower MBDA scores. The MBDA test may be useful to select patients who subsequently have a better response to treatment and thus provide utility even beyond clinical assessments of RA disease activity such as the CDAI.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies have reported differences in healthcare utilization and outcome among different socioeconomic and ethnic groups. Complications like atherosclerotic cardiovascular diseases (ASCVD) have been documented to be higher among the African-American population and this disparity is more pronounced in the population with connective tissue disease. Similar disparities based on racial/ethnic background have been reported among treatment options for rheumatoid arthritis (RA). We tried to gain an insight into the differences in hospitalization outcomes among RA patients as per different socioeconomic and demographic variables utilizing a large US inpatient database.

Methods: We selected patients aged ≥18 years with and without RA to compare the differences in mortality, length of stay, cost of hospitalization and ASCVD incidence among different race, gender, type of insurance and income quartile range (Table 1). Patients with RA were selected based on ICD-9 codes (714.0, 714.1 and 714.2). Patients with concomitant diagnoses of SLE, polymyositis, dermatomyositis and systemic sclerosis were excluded. We used Nationwide Inpatient Database from 2009 to 2011. STATA version 13.0 (College Station, TX) for analysis to accommodate for the complex design of survey sample data (NIS). NIS is the largest publicly available all-payer inpatient care database in the United States and is sponsored by the Agency for Healthcare Research and Quality as a part of Healthcare Cost and Utilization Project.

Results: Mortality was most common among Caucasians (RA 2.4%, non-RA 2.37%, p=<0.0001), females (RA 2.67 %, non-RA 2.75%, p=<0.0001) and medicare patients (RA 2.7%, non-RA 3.32%, p=<0.0001). Mortality was lowest in the African American population among RApatients (1.97%, <0.0001) and in hispanics among the non-RA patients (1.58%, <0.0001). Length of stay was highest among the African-American (RA 5.53 days, non-RA 5.27 days, p=<0.0001), females (RA 5.19 days, non-RA 5.22 days, p=<0.0001) and the lowest income quartile (RA 5.27 days, non-RA 4.93 days, p=<0.0001). Patients with the highest income quartile, females and other races incurred the most charges during hospitalization. Incidence of ASCVD was highest among whites (RA 15.08%, non-RA 14.07%, p=<0.0001), females (RA 18.74%, non-RA 17.15%, p=<0.0001) and medicare patients (RA 16.9%, non-RA 19.9%, p=<0.0001).

Conclusion: Our findings indicate differences in clinical outcomes among different socio-economic groups in RA patients. Among patients with RA, we found higher rate of mortality and incidence of ASCVD among Caucasians. Similarly, females were found to have higher incidence of ASCVD, higher length of stay and hospital costs. Socio-economic and racial/ethnic influences may be important in interpreting differences in clinical outcomes relating to patients with RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine clinical, sonographic and immunological biomarkers predicting structural damage progression at 12 months of follow-up as measured by Magnetic Resonance Imaging (MRI) in a population of Rheumatoid Arthritis (RA) patients in clinical remission.

Methods: We included patients with RA in clinical remission defined as disease activity score of 28 joints (DAS28)-erythrocyte sedimentation rate (ESR) <2.6 for > 6 months. Serum cytokines and angiogenic mediators, Ultrasound scans of both hands and knees and MRI of dominant hand were performed at baseline and after 12 months.

Results: Forty-two patients completed the follow-up. 78% female, aged (median) 54 years; disease duration was 93 months; 85% ACPA positive; C-reactive protein (CRP) was 0.10 mg/dl; ESR 9 mm/h and DAS28-ESR: 2.00. Twelve (28%) patients were taking oral prednisone, 34 (81%) conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), and 20 (47%) biological therapies. At baseline, 45% fulfilled criteria for ultrasound defined active synovitis (UdAS) (synovial hyperplasia>2+PD signal). Significant associations between baseline RAMRIS, body mass index (BMI), disease duration, prednisone treatment, lack of csDMARDs and the presence of UdAS (but not PD alone) with RAMRIS progression after 12 months were found. Serum levels of calprotectin were significantly correlated with bone edema progression.

Conclusion: We identified clinical and sonographic biomarkers of RAMRIS progression after 12 months of follow-up in patients with RA in clinical remission. The concept of ultrasound active synovitis, defined as the simultaneous occurrence of relevant synovial hyperplasia and PD is associated with RAMRIS progression after 12 months.

Comparison of Multi-Dimensional Health Assessment Questionnaire (MD-HAQ)-Based and Patient-Reported Outcomes Measurement Information System (PROMIS) 29-Based Routine Assessment of Patient Index 3 (RAPID3) for Assessing Rheumatoid Arthritis Disease Activity

Yong Gil Hwang[1], Juan (June) Feng[2], Heather Eng[2], Jason Lyons[2], Anthony Fabio[2] and Larry W. Moreland[1], [1]Rheumatology & Clinical Immunology, University of Pittsburgh, Pittsburgh, PA, [2]Epidemiology, University of Pittsburgh, School of Public Health, Pittsburgh, PA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-reported outcomes measurement information system (PROMIS) 29 is recommended by the National Institute of Health (NIH) consensus panel as the preferred battery of measures to collect in musculoskeletal pain treatment studies. Physical function domain in the PROMIS29 short form has only 4 questions. We compared Routine Assessment of Patient Index 3 (RAPID3) scores based on multi-dimensional health assessment questionnaire (MD-HAQ)-based and patient-reported outcomes measurement information system (PROMIS) 29 to determine the degree of agreement.

Methods: For rheumatoid arthritis (RA) subjects enrolled in the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER), a cross-sectional analysis was performed for all RACER patients who completed MD-HAQ and PROMIS29 short form. Physical function based on PROMIS29 (PROMIS29-PF) was calculated using raw score of PROMIS29 physical function (PROMIS29-PF = ([20- PROMIS29-PF]/2). Association between physical function based on MD-HAQ and PROMIS29 was evaluated by Pearson¡¯s correlation coefficient. Bland-Altman 95% limits of agreement (LOA), kappa statistics, Lin¡¯s concordance coefficient were used to measure the agreement between RAPID3 score based on MD-HAQ and PROMIS29 (RAPID3-PROMIS).

Results: For the 397 subjects analyzed, age was 64.2 +/- 13.8 (mean +/- SD) years with disease duration of 13.9 +/- 13.1 years. PROMIS-PF was strongly correlated with physical function based on MD-HAQ ($r = 0.83$, $p < 0.0001$). Overall agreement between disease severity categories of RAPID3 and RAPID3-PROMIS were substantial (percent agreement = 87.7, kappa = 0.83) (Table). RAPID3 scores (0-10) were slightly different (RAPID3 = 3.4, RAPID3-PROMIS = 3.6, $p < 0.01$). LOA for RAPID3 score were -0.98 and 0.65, with bias of -0.42 (Figure). Lin¡¯s coefficient of concordance showed substantial agreement (0.976).

Conclusion: There was very good agreement in RAPID3 scores based on MD-HAQ and PROMIS29 short form. Very low bias score and small values for LOA indicate that RAPID3 scores based on MD-HAQ and PROMIS29 are interchangeable.

Table. Disease activity categories by multi-dimensional health assessment questionnaire (MD-HAQ)-based and patient-reported outcomes measurement information system (PROMIS) 29-based Routine Assessment of Patient Index 3 (RAPID3)

There Is No Further Gain from Calculating Disease Activity Score in 28 Joints with High Sensitivity Assays of C-Reactive Protein Because of High Intraindividual Variability of CRP: A Cross Sectional Study and Theoretical Consideration

Inger Marie J. Hansen[1,2,3], Rikke Asmussen[4], Steen Antonsen[5] and Amir Emamifar[6], [1]Department of Reumatology, OUH, Svendborg Hospital, Svendborg, Denmark, [2]University of Southern Denmark, 5000 Odense, Denmark, [3]DANBIO, Glostrup, Denmark, [4]Dep. of Rheumatology, OUH, Svendborg Hospital, Svendborg, Denmark, [5]Biochemestry, OUH, Svendborg Hospital, 5700 Svendborg, Denmark, [6]Rheumatology, OUH, Svendborg Hospital, 5700 Svendborg, Denmark

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The threshold for reporting of C-reactive protein (CRP) differs from laboratory to laboratory. Moreover, CRP values are affected by the intra individual biological variability.[1] With respect to disease activity score in 28 joints (DAS28) and Rheumatoid Arthritis (RA), precise threshold for reporting CRP is important due to the direct effects of CRP on calculating DAS28, patient classification and subsequent treatment decisions[2]

Methods: This study consists of two sections: a theoretical consideration discussing the performance of CRP in calculating DAS28 with regard to the biological variation and reporting limit for CRP and a cross sectional study of all RA patients from our department (n=876) applying our theoretical results. In the second section, we calculate DAS28 twice with actual CRP and CRP=9, the latter to elucidate the positive consequences of changing the lower reporting limit of CRP from <10mg/L to <3mg/L

Results: Theoretical considerations: lower reporting limit of <10mg/L leads to inaccurate patient classification in a great number of patients both because of biological variation, as well as the larger spectrum of numbers (0-9). In addition, reducing lower reporting limit for CRP to minimum<3mg/L results in optimizing patient classification (Figure 1). The logarithmic transformation of CRP in DAS28 formula has an important role Cross sectional study: 769 patients fulfilled the ACR criteria for RA were included, 107 excluded due to missing parameter used for DAS28 calculations. There was a statistically significant difference between patients´ DAS28 and new calculated DAS28 with CRP=9 ($p<0.001$). A total of 109 patients had a disease activity deviation (remission to low: 66, low to moderate: 39, moderate to high: 4)

Conclusion: Respecting DAS28 calculation, lower reporting limit for CRP<3 mg/L is acceptable and should be taken into consideration. A lower reporting limit for CRP<10 mg/l is too high. It is particularly relevant if treatment decisions are solely made on the basis of DAS28. Furthermore, we conclude that DAS28 in studies where the reporting limit of CRP is unknown are incomparable References:1.Macy EM, et al. Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease resulting from an interaction between genetic and environmental factors. Recently, sodium intake was suggested as a risk factor for autoimmune diseases by driving lymphocyte polarization toward a Th17 pathway. Our study aimed to assess sodium intake at RA diagnosis and in established RA and evaluate its impact on disease activity and severity.

Methods: The prospective cross-sectional study included 24 patients with RA at diagnosis (early RA) and 24 controls matched on age, gender and body mass index. Furthermore, 197 patients with established RA were included. Sodium intake was evaluated by 24-hr urinary sodium excretion, and the Food Frequency Questionnaire (FFQ) was used to evaluate potential diet confounding factors.

Results: Sodium intake was greater for patients with early RA (+650 mg/day of sodium, p=0.039) and established RA (p=0.046) than controls (figure 1) and was greater for patients with than without radiographic erosion at the time of diagnosis (p=0.028) (figure 2). It was lower for patients positive for rheumatoid factor and was not correlated with disease activity and severity for patients with established RA.

Conclusion: Patients with early and established RA show increased sodium consumption as compared to matched controls and that sodium consumption was associated with disease severity at diagnosis. Sodium may activate immune cells, which

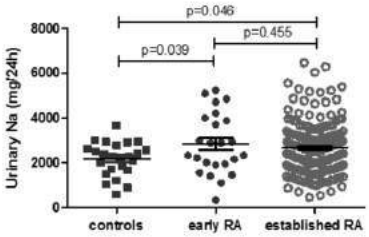

Figure 1. Sodium intake was increased in patients with early RA. Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster I: Clinical Characteristics/Presentation/Prognosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease activity dramatically ameliorated with the use of bDMARD or a recently appeared tsDMARD and more than one-half of the patients with RA were in remission. However, some patients were still difficult to achieve remission due to comorbidities, aging and economic burden of drug cost. Therefore, still some patients needed to undergo surgical reconstruction for the structurally damaged joint due to RA. The purpose of this prospective cohort study was to clarify the effect of surgical intervention to the upper extremity from the aspect of QOL and mental health as well as physical function.

Methods: From December 2012 to September 2014, a primary surgery was scheduled in 150 patients (male:20, female:130) with RA. The mean age was 64 years old, and the mean duration of RA was 16 years. Steinbrocker's stage IV and class 2 were most frequent. The surgical site was 6 shoulders, 26 elbows, 73 wrists and 45 fingers or thumbs. There were 26 synovectomies, 39 arthroplasties without implant, 31 arthrodeses, and 54 joint replacements. EuroQol 5 dimension (EQ-5D), Beck Depression Inventory II (BDI-II), Japanese version of the Stanford Health Assessment Questionnaire (J-HAQ), and Disabilities of the Arm, Shoulder and Hand (DASH) were investigated just before the operation (baseline), and at 6 and 12 months after the operation.

Results: As a whole, EQ-5D improved from 0.708 at baseline to 0.747 ($p<0.001$) and 0.756 ($p<0.001$) at 6 and 12 months after the operation. Significant improvement in EQ-5D was noted in the elbow or the wrist surgeries, and all procedures other than synovectomy. BDI-II decreased from 13.8 at baseline to 12.3 ($p=0.004$) and 12.2 ($p=0.001$) at 6 and 12 months after the operation. At baseline, the patient was on the borderline of mild depression (between 14 and 19) and after the operation the patient was in minimal depression (between 0-13). Significant decrease in BDI-II was noted in the elbow or the wrist surgeries, and joint replacement. J-HAQ improved from 1.11 at baseline to 1.01 ($p=0.008$) and 0.95 ($p<0.001$) at 6 and 12 months after the operation. Significant improvement in J-HAQ was noted in the elbow or the wrist surgeries, and arthroplasty without implant and arthrodesis. DASH score decreased from 43.8 at baseline to 37.4 ($p<0.001$) and 36.3 ($p<0.001$) at 6 and 12 months after the operation. Significant decrease in DASH score was noted in the elbow or the wrist surgeries, and all surgical procedures.

Conclusion: The surgical intervention to the upper extremity in the patient with RA improved QOL and mental health as well as physical function. It made the disabled patient happy.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: For persons with chronic diseases such as rheumatoid arthritis (RA), intact cognitive function is crucial for performing main daily activities and adhering to self-management regimens. Persons with impaired cognitive function have decreased functional independence, reduced quality of life, and increased risk of mortality. Although several mechanisms may influence cognitive function in RA, it has not been well-studied in this population. This study explored the prevalence of cognitive impairment in persons with RA using a set of computerized neurocognitive tests and the factors that were significantly correlated with cognitive impairment.

Methods: Individuals with RA were recruited by their rheumatologists during follow-up visits at one university hospital in Korea. After getting signed consents, a trained research nurse assessed participants with a range of physical, psychosocial, and biological metrics. Cognitive function was assessed using a set of 6 computerized neurocognitive tests yielding 18 indices covering a range of cognitive domains. Subjects were classified as 'impaired' if they performed 1 *SD*below age-based population norms on each test. A total cognitive impairment score was calculated by summing the transformed scores, ranging from 0 (no impairment) to 18 (worst impairment). Pearson correlation coefficient analyses were conducted to identify the variables that might be significantly associated with cognitive impairment.

Results: Thirty three subjects with a mean (±*SD*) age of 64 (±11.8) years were included in the final analyses. 85% were female, 85% were married, and mean educational level was 9.6 (±4.9) years. Mean DAS-28 level was 2.6 (±1.5) and mean disease duration was 114 (±86.8) months. Mean HAQ score was 0.6 (±0.8), mean SPPB score was 7.4 (±2.5), and mean cardiovascular disease (CVD) risk factors were 2.9 (±1.5). 32.4% had depression and 70.6% had sleep problems. The proportion of persons who were classified as cognitively impaired on each test were 29% in Card Sorting Test (executive function), 56% in Trail Making Test (visuo-motor coordination), 74% in Visual Span Test (language memory), 79% in Verbal Learning Test (visuo-spatial memory), 24% in Visual Continuous Performance Test (continuous attention), and 65% in Word-Color Test (selective attention). Mean total cognitive impairment score was 10.7 (±4.1), and ranged from 2-17. 79% were classified as cognitively impaired on five or more test indices. Education (r=-493, $p<.05$), marital status (r=-.424, $p<.05$), income (r=-.661, $p<.05$), and CVD risk factors (r=.447, $p<.05$), SPPB score (r=-.485, $p<.05$) were significantly correlated with total cognitive impairment score.

Conclusion: A significant number of RA patients were cognitively impaired. Low educational levels, non-married status, low income, and increased CVD risk factors, and increased functional limitations may be potential risks of cognitive impairment in this population. These findings suggest that the burden of cognitive impairment in RA is significant, and future studies identifying specific etiological contributors to cognitive impairment are warranted.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) tend to have impaired distribution of adipose tissue and may have the risks of metabolic complications (1,2). The aim of this study was to determine the serum adiponectin levels and body composition in a group of patients with RA.

Methods: Fifty-five RA patients with a mean age of 53.5±9.7 years were recruited to this cross-sectional study. The demographic and clinical variables of the patients (age, sex, BMI, duration of disease) were determined. Disease activity parameters (DAS28-ESR, functional status assessed by HAQ and quality of life (QoL) assessed by RA-QoL questionnaires) were recorded. Serum adiponectin levels and body composition parameters (fat mass (FM) and fat-free mass (FFM)) were determined by ELISA and multi-frequency bioelectrical impedenace analysis respectively. Anthropometric measurements (weight, height, circumferences of waist (WC), mid-upper arm (MUAC), calf (CC) and neck (NC) and muscle strength assessments (hand-grip) were performed by a trained dietitian. The relationship between disease activity parameters, adiponectin levels and body composition variables were analyzed by Pearson and Spearman tests as needed.

Results: Forty-four female, 11 male RA patients with a mean disease duration of 127.0± 120.6 months were included to the study. Based on BMI, 23.6% of patients were overweight and 60% were obese. Obesity prevelance and mean fat mass (%) was significantly higher among female patients (p=0.000, for both). According to DAS28-ESR parameters 38.2% of patients were in remission state, 18.2% had low, 40% had moderate, 3.6% had severe disease activity. Disease activity parameters did not differ among female and male patients, while functional status determined by HAQ and quality of life assessed by RA-QoL scores of female patients were significantly higher than male patients (1.2±1.2 and 0.6±0.6, $p<0.05$; 12.7±8.3 and 6.0±4.5, $p<0.05$, respectively), indicating more disability in women. The mean serum adiponectin value was 16.08±6.95 µg/mL and did not differ significantly between sexes. Adiponectin was positively corelated with body fat (%) (r=0.427 p=0.001) and negatively corelated with fat-free mass (%) (r=-0.316, p;=0.021). Correlation between serum adiponectin and body fat was siginificant among female patients (r=0.409, p=0.006). No statistically significant correlations were found between serum adiponectin levels and anthropometric measurements. Body fat (%) was positively (r=0.609, p=0.047), fat-free mass (%) was negatively (r=-0.609, p=0.047) correlated with disease activity determined by DAS28-ESR.

Conclusion: Our data indicate that body composition is altered in RA patients and related with adinopectin and disease activity, which may increase the risk of cardiovascular disease, and emphasize an unmet need of dietitian consultation in the management of RA. References:

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is the cornerstone of rheumatoid arthritis (RA) treatment. We reported the liver safety with daily dose of MTX[1]. Weekly doses of MTX are frequently associated with gastrointestinal (GI) adverse events (45-60%)[2]. The aim of this study is to determine the frequency of methotrexate GI intolerance and its associated factors in patients with RA that receive daily doses of MTX.

Methods: We applied the Spanish version of methotrexate intolerance severity score questionnaire (MISS) in patients with RA, which consists of four domains: abdominal pain, nausea, vomiting and behavioral symptoms. Each domain was ranked from 0-3 points being no complaint (0 points), mild (1 point), moderate (2 points), and severe (3 points)[3]. The MTX intolerance was determined with a score > 6, and was compared with other variables with Fisher or chi-squared tests; continuous variables were compared with parametric or non-parametric analysis as appropriated. A logistic regression model of MTX intolerance was performed with the relevant variables.

Results: We included 395 unselected patients with RA, 362 (91.6%) were women, mean age was 51.1 ± 12.4 SD years, mean of RA disease evolution 6.4 ± 7.5 SD years and the mean dose of MTX 13.3 ± 4.0 mg/week. The 47.9% (142) of patients had at least one GI adverse event and MTX intolerance was present in 9.4%. Tolerant subjects (52.5%) had at least one gastric symptom: abdominal pain 17.1%, nausea 13.4%, vomiting 1.3%, behavioral symptoms 20.7%. The bivariate analysis for association with MTX intolerance and other drugs showed no statistical significance.

Conclusion: The frequency of GI intolerance using MTX daily doses (9.4%) was similar to MTX weekly as previously reported (11%). Concomitant administration of other drugs was not associated with increasing gastrointestinal intolerance.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - ARHP Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient misunderstandings about DMARDs may contribute to nonadherence. We present longitudinal observational data regarding whether patients can accurately recall medication information about a newly-prescribed DMARD immediately after a rheumatology office visit and whether this is associated with DMARD prescription filling behavior one week after the office visit.

Methods: We recruited a convenience sample of 38 adult English-speaking RA patients who were prescribed a new self-administered DMARD from one rheumatology clinic in a southeastern state. The office visit during which the new DMARD was prescribed was audiotape recorded. Immediately after this visit, patients completed a demographic survey and were asked to recall what their rheumatologist said about how to take the DMARD and its benefits, side effects, and risks. Office visits and patient interviews were transcribed verbatim. Two independent coders who were blinded to study hypotheses compared what the rheumatologist said during the office visit to what the patient recalled for 15 different medication topics (Table 1). Coders recorded whether the rheumatologist discussed this topic during the visit and whether the patient's recall of what the rheumatologist said was accurate (yes/no). Inter-reliability for the 15 topics was 0.89. We calculated descriptive statistics and examined bivariate associations to determine correlates of the patient inaccurately recalling (yes/no) any medication information (α=0.05).

Results: Participants were primarily women (87%) and white (71%). The mean age and disease duration were 49.1 (SD=13.4) and 9.4 years (SD=9.4), respectively. Only 12 (20%) patients were receiving a DMARD prescription for the first time. Nineteen patients (50%) inaccurately recalled information about at least one medication topic immediately after their office visit. Table 1 presents our study results. Patients with inaccurate recall had a longer disease duration ($t_{(36)}$=-3.4, p=0.02), lower health literacy (χ^2=7.1; p<0.01), and a lower household income (<$25,000 annually) ($\chi^2$=4.5; p=0.03). Patients with inaccurate recall were not less likely to get their prescription filled at 1-week follow-up (χ^2=2.6; p=0.11).

Conclusion: Half of patients inaccurately recalled medication information about a newly-prescribed DMARD immediately after their rheumatology office visit. A number of DMARD topics were not explicitly discussed during the office visit, but may have been discussed in previous visits. Patients with low health literacy, lower household income, and longer disease duration were more likely to inaccurately recall DMARD information.

Table 1: Characteristics of rheumatology office visits during which a new DMARD was prescribed

Topic	Rheumatologist **Did Not** Discuss Topic During Office Visit N (%)	Patient **Did Not** Accurately Recall Information About Topic N (%)	Examples of Inaccurate Recall
Long-term effectiveness of DMARD	30(79%)	0	-
How long patient should take DMARD (duration)	19(50%)	0	-
DMARD-other drug interactions	16(42%)	0	-
Contraindications	16(42%)	0	-
Costs of DMARD	12(32%)	0	-
Time until DMARD begins to take effect	11(29%)	2(5%)	Patient said it might take two weeks to see improvement when doctor said three months.
Timing to take DMARD	8(21%)	1(3%)	Patient said medication should be taken in afternoon when doctor said night.
Dosage	8(21%)	1(3%)	Patient says they are supposed to take 1 pill/day and doctor said 4 pills/day.
Severity of side effects	7(18%)	0	-
Mechanism of action	6(16%)	2(5%)	Patient said medication would stop cells from eating the bone in their body when doctor said it would reduce inflammation.
How to take DMARD	3(8%)	2(5%)	Patient said doctor didn't say how medication was supposed to be taken when doctor said it should be taken orally.
How often to take DMARD (frequency)	1(3%)	2(5%)	Patient said they should take pill daily when doctor said it should be taken one day per week.
Benefits of DMARD	1(3%)	10(26%)	Patient lists benefits of medication that were not discussed by doctor.
Side effect risk reduction strategies	1(3%)	5(13%)	Patient mentions having to engage in risk reduction strategies that were not recommended by doctor.
Side effects of DMARD	0	5(13%)	Patient lists kidney damage as side effect of medication when doctor did not mention kidney damage as side effect.

Understanding Contextual Factors That Influence Decisions Related to Health and Work Among People with Recently Diagnosed Rheumatoid Arthritis

Graham Macdonald[1], Catherine Backman[2], Anne F. Townsend[3] and Linda Li[4], [1]Occupational Science and Occupational Therapy, University of British Columbia, Vancouver, BC, Canada, [2]Occup Science & OccupTherapy, University of British Columbia, Vancouver, BC, Canada, [3]Qualitative Research, Arthritis Research Centre of Canada, Richmond, BC, Canada, [4]Department of Physical Therapy, The University of British Columbia, Vancouver, BC, Canada

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - ARHP Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), early diagnosis and treatment are essential to better outcomes. Many people defer seeking help or treatment for reasons that are currently not well accounted for, but often seem to be related to decisions concerning work. This study aims to understand the contextual factors that influence patients' decisions in the early stages of RA when dealing with concerns about their health and employment. Contextual factors are factors that mediate or moderate the effect of an intervention (e.g., a work disability prevention program) on outcomes (e.g., the patient's decision to continue working).

Methods: We conducted a secondary data analysis from 2 qualitative studies[1],[2]Participants were eligible if they were diagnosed with RA within the 12 months prior. The interview questions focused on how RA affected the daily lives of participants. In the first study we conducted 1 in-depth interview per participant, in the second study another set of participants were interviewed 3 times over a 1-year period. In the current analysis, transcripts were examined for participant experiences of the impacts of their health on employment, and the impacts of their employment on health. We used the constant comparison method, a theme-based, iterative, qualitative approach that foregrounds the experience of the participants. The analysis was done by one researcher, in consultation with researchers who previously worked with the dataset.

[1] Townsend A et al. *BMJ Open* 2013; 3(e002164).

[2] Townsend A et al. *Chronic Illness* 2014; 10(4):259-72.

Results: A total of 48 interview transcripts from our two previous studies were examined. Most participants were women (91%) and roughly half (55%) were from rural or remote areas. We found that many participants continued to work despite pain and fatigue, and even if they had alternatives to working for their livelihood. In these instances people seemed to act counter to a "health first" logic. Physical limits and financial concerns were often the catalyst for work-related decisions, however, many participants deferred making a decision until one of these factors became so overwhelming that they were forced to act upon them. In situations where decisions had not been dominated by physical or financial necessity, factors that often influenced decision-making were related to a sense of attachment to work that included: love of occupation, sense of responsibility, the commitment to being a hard worker, and occupation defining identity. We broadly described

these factors as “work ethic.”

Conclusion: Our findings suggested that while physical limits and financial necessity were important contributors to patients’ decisions about work, these decisions might also be influenced by work ethic. Participants revealed the preference to stay at work despite difficulties with their health and challenges related to their work, suggesting that non-medical life-course factors could be as influential as physical or financial factors in one’s decision about employment. Further research is needed to understand the interplay of these contextual factors in the effectiveness of interventions on patient decision-making.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Whilst the exact aetiology of rheumatoid arthritis (RA) remains unclear, current concepts suggest an environmental link with possible microbial triggers. Studying individuals at-risk of RA allows a unique opportunity to explore possible relationships. Furthermore, the identification of predictors of progression from at-risk to RA is of great clinical utility. Triggering receptor expressed on myeloid cells (TREM) modulates the innate immune response by either amplifying or dampening the toll like receptors (TLR) induced signalling[1]. Given the upstream nature of soluble-TREM (sTREM), and its close proximity to TLR in innate immune response to microbial triggers, we hypothesis that sTREM could be one of the first indicators of progression to RA.

Methods: sTREM was measured using Human TREM-1 Quantikine ELISA (R&D Systems, Minneapolis) in 32 at-risk individuals; 16 of whom progressed (ACPA+ Prog) and 16 whom did not (ACPA+ NProg), and 16 early RA (ERA) patients. The ACPA+ cohort had no evidence of ultrasound synovitis at baseline. Binary logistic regression models were conducted on at-risk patients. Model discrimination was assessed using classification plots and the area under the ROC curve. An optimum cut-off for the test variable, plus associated sensitivity and specificity achieved, were also determined. Further analyses were conducted on the same sample augmented with ERA patients, to assess the correlation between TREM, CRP and CCP titre values in this group; and on ERA patients only, to assess the correlation between TREM and DAS28 values in this group.

Results: Duration of follow-up was 0 to 133 months, mean duration of 36 months (SD 31.2). Mean time to RA diagnosis in those that progressed was 11.5 months (SD 14.3).

Variable	Group			
	ERA	ACPA+ Prog	ACPA+ NProg	All
Gender (n (%)) Female	9 (56.2%)	10 (62.5%)	11 (68.7%)	30 (62.5%)
Age (years) (mean (SD))	55.2 (14.8)	53.8 (13.6)	53.9 (10.3)	54.3 (12.7)
TREM IU (mean (SD))	539.3 (207.9)	711.0 (292.0)	405.0 (230.4)*	554.8 (271.9)
CRP ng/l (mean (SD))	40.3 (61.0)	4.77 (5.61)*	4.53 (6.59)**	18.6 (41.6)
CCP IU (mean (SD))	92.4 (127.1)	174.9 (108.8)	132.5 (135.1)	133.3 (126.1)
*n=15; **n=10				

A binary logistic regression model found that TREM was significantly associated with progression (p=0.009). The OR of 1.006 (95% CI 1.002 to 1.011) indicated that at best estimate, the odds of progression increased by 0.6% with each increase of 1 unit of TREM. The model classified 80.6% of cases correctly, with 12 out of 16 (75.0%) of ACPA+ P cases and 13 out of 15 (86.7%) of ACPA+ NP cases correctly classified. The area under the ROC curve was 0.825 (95% CI 0.674 to 0.976). Optimum combinations of sensitivity (81.3%) and specificity (80.0%) were obtained from a cut-off TREM value of 521.3 units. There were no substantive correlations between TREM, CRP values and CCP values.

Conclusion: In this first assessment high level of sTREM is significantly associated with disease progression in at-risk individuals. Furthermore, higher sTREM values are associated with greater odds of progression. It has potential to offer insights regarding disease pathogenesis and warrants further research. References: 1. Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: One unique feature of RA is the presence of ACPA. PTPN22 is a phosphatase that also acts to suppress citrullination independently of its phosphatase activity by inhibiting the function of peptidyl arginine deiminases (PADs). A C-to-T single nucleotide polymorphism, converting an arginine (R620) of PTPN22 to a tryptophan (W620), renders PTPN22 unable to suppress PADs and is associated with higher risk of RA and hypercitrullination in PBMC. Th cells of RA patients are prone to differentiation into Th17 cells and display hypoglycolysis, hyperproliferation, and excessive reductive stress due to abnormal expression of PFKFB3, ATM, and G6PD. We postulate that these abnormal features and hypercitrullination predate the onset of clinical symptoms of RA and can be attributed to attenuated phosphatase and/or non-phosphatase activities of PTPN22.

Methods: PBMC were collected from healthy at-risk individuals (ARIs), including RA first-degree relatives and/or ACPA+ individuals, and healthy ACPA- control individuals. The PBMC were stimulated with anti-CD3. Intracellular staining, western blotting, and real time PCR were used to quantify the level of citrullinated proteins and the expression of various genes. The levels of cytokines and lactate in supernatant were measured with ELISA and a colorimetric assay. PBMC were also transfected with plasmid vectors expressing PTPN22 or PADs to examine the impact of these proteins on the phenotype of PBMC.

Results: Regardless of the ACPA status, a high level of citrullinated histone H3 (cit-H3) was detected in ARIs but not in the control populations. T cells were the major source of cit-H3 in ARI PBMC. Despite a normal level of G6PD, ARI PBMC expressed more IL-2 and IL-17, but less IL-4, ATM and PFKFB3, and were hypoglycolytic. These abnormal features and hypercitrullination correlated with impaired anti-CD3-mediated induction of PTPN22 and were rectified by exogenous PTPN22. A phosphatase-dead PTPN22 was still able to normalize the level of cit-H3, IL-4 and IL-17 but not IL-2, ATM, or PFKFB3. In contrast, W620-PTPN22 normalized the expression of IL-2, ATM, and PFKFB3, but not IL-4 or IL-17. Furthermore, forced expression of PAD2 or PAD4 in control PBMC induced hypercitrullination and reduced the expression of IL-4, whereas only PAD2 was able to enhance the expression of IL-17.

Conclusion: Our data depict a molecular timeline of preclinical RA (Figure 1): impaired induction of PTPN22 leading to attenuated phosphatase activity and PADs-mediated hypercitrullination. The attenuated phosphatase activity results in aberrant expression of IL-2, ATM, and PFKFB3, whereas PAD2- or PAD4-mediated hypercitrullination inhibits the expression of Th2 cytokine. However, only PAD2-mediated hypercitrullination can augment the expression of Th17 cytokines. All of these events take place with or without the development of ACPA and abnormal expression of G6PD.

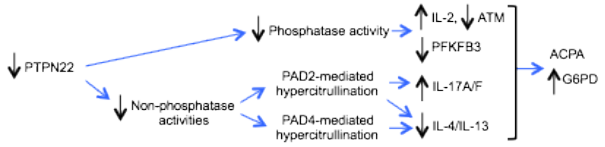

Figure 1: A series of molecular events triggered by impaired induction of PTPN22 in PBMC of ARIs

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Most patients with rheumatoid arthritis (RA) harbor antibodies to citrullinated autoantigens, such as citrullinated fibrinogen. Two isoforms of peptidylarginine deiminase (PAD), PAD2 and PAD4, which catalyze citrullination with different substrate specificities, can be detected in rheumatoid arthritis (RA) synovium. This study was undertaken to determine whether RA patient antibodies preferentially bind PAD2 or PAD4 citrullinated fibrinogen.

Methods: RA patient and normal donor plasma was tested for binding to PAD2 or PAD4 citrullinated fibrinogen, native fibrinogen, or citrullinated fibrinogen peptides in various dilutions by ELISA and Western blot. Bands corresponding to masses demonstrating RA patient reactivity by Western blot were excised and analyzed by mass spectrometry.

Results: As expected, at low titers neither normal donors nor RA patients harbored antibodies to unreactive (native) plasma derived fibrinogen while RA patients harbored significantly elevated antibody to both PAD2 and PAD4 citrullinated fibrinogen. When plasma was further diluted to 1:250 and 1:1000, the OD of RA patient plasma binding of PAD4 citrullinated fibrinogen was significantly greater than PAD2 citrullinated fibrinogen ($p<0.01$). The ratio of ELISA OD of PAD4 citrullinated fibrinogen divided by PAD2 citrullinated fibrinogen was calculated for each patient. The mean ratios of PAD4/PAD2 citrullinated fibrinogen at the 1:250 and 1:1000 dilutions were 1.26 (95% confidence interval 1.18-1.35) and 1.39 (95% confidence interval 1.24-1.53) respectively, indicating preferential binding of PAD4 citrullinated fibrinogen. RA patient plasma also bound PAD4 citrullinated fibrinogen more than PAD2 citrullinated fibrinogen on Western blot at both 56kD and 76kD ($p<0.01$ for both bands). Increasing antibody titer associated with increasing avidity ($p<0.0001$) but there was no difference in avidity for PAD2 or PAD4 citrullinated fibrinogen at low or high titer. Mass spectrometry based analysis of bands corresponding to masses demonstrating RA patient reactivity on western blot identified a hotspot of citrullination of the beta chain of fibrinogen between arginine residues 44 and 74. This hotspot region was modified more heavily than any other site. Both enzymes hypercitrullinated fibrinogen, but PAD4 citrullinates arginines more intermittently, generating peptides with a mix of citrullinated and nonmodifed arginines.

Conclusion: At high titer, RA patient antibodies preferentially bind fibrinogen with a combination of both citrullinated and non-citrullinated arginines.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and periodontal disease (PD) are comorbid conditions that share multiple underlying risk factors and pathophysiological features. A dysbiotic periodontal microbiome might be an environmental trigger for RA, though the underlying mechanisms remain unclear. Several studies have focused on the ability of *Porphyromonas gingivalis* (*Pg*) to citrullinate human α-enolase, suggesting a direct relationship between periodontal bacteria and the development of serological autoimmunity, and possibly eventual autoimmune disease. We investigated the associations between 18 anti-citrullinated peptide antibodies (ACPAs) and antibodies to 18 species of periodontal bacteria in RA-free individuals with and without PD.

Methods: Adults with moderate to severe periodontal disease as defined by the 2000 American Academy of Periodontology definitions and no history of RA or RA symptoms were recruited for the PD group (n = 181). Periodontally healthy controls matched for age and sex were selected from the dental Atherosclerosis Risk in Communities (ARIC) cohort (n = 138). Serum anti-periodontal bacteria antibodies were measured using a rapid checkerboard immunoblotting technique. Analysis of ACPAs was performed using a multiplex assay platform. Linear regression models were used to examine the relationships between PD bacteria antibody titers and ACPA positivity while controlling for age, sex, and smoking status.

Results: Total number of ACPAs was equivalent between the PD and control groups, with 34% having at least one ACPA, and 7% having three or more ACPAs. For all but one PD bacterial species, antibody titers were significantly higher in the PD group compared to controls. Within the PD group, having a total of three or more ACPAs was generally associated with decreased anti-bacteria antibody titers including for *Pg*, *Tannerella forsythia*, and *Treponema denticola* (*Td*), though this reached statistical significance only with *Td* and marginally ($p = 0.09$). These trends were not seen with *Prevotella* species in the PD group, and were generally reduced or absent in the control group. Certain specific ACPAs were more strongly associated with decreased anti-bacterial antibody titers than others. Most notably, significantly decreased *Td* antibodies were associated with clusterin ACPA positivity ($p < 0.05$), and marginally with biglycan, fibrinogenA, and histone 2A ACPA positivity (all p-values < 0.10) in the PD group. Similar trends were seen with *Pg* across multiple ACPAs, and enolase across multiple bacterial species, but were generally weaker. There was no correlation between *Pg* antibody titers and enolase.

Conclusion: Relationships between ACPAs and PD bacteria antibody titers were predominantly inverse though largely not statistically significant in this small sample. The strongest relationships were found between distinct individual ACPAs and *Td* antibodies; results for *Pg* and enolase were relatively weak. Our results suggest an interplay between aberrant immune response to periodontal bacteria and serological autoimmunity, and have implications for future study of *P. gingivalis* and *T. denticola* as possible inciting factors of RA.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by development of humoral and cellular autoimmunity to citrullinated proteins and peptides. Autoimmunity to citrullinated antigens appears years before the onset of clinical symptoms of RA Neutrophil extracellular traps (NETs) are a source of citrullinated autoantigens and activate RA synovial fibroblasts (FLS), cells crucial in joint damage. We investigated the molecular mechanisms by which NETs promote proinflammatory phenotypes in FLS, and whether these interactions generate pathogenic anti-citrulline adaptive immune responses.

Methods: Shared epitope-positive RA FLS and control Osteoarthritis FLS were co-cultured with RA NETs and interactions visualized by confocal microscopy. Induction of inflammatory responses and MHC class II expression were assessed by qPCR. RA-FLS and Ag-specific RA T cells were co-cultured for 5 days and T cell activation was examined. HLADRB1*0401 transgenic mice were immunized with mouse FLS loaded with NETs or FLS alone. Antibodies to citrullinated proteins antigens (ACPAs) were quantified by ELISA, immunoblot and epitope mapping array. Cartilage integrity was assessed by safranin-O staining.

Results: NETs containing citrullinated peptides are internalized by FLS through a RAGE-TLR9 pathway promoting FLS inflammatory phenotype and their upregulation of MHC class II. Once internalized, arthritogenic citrullinated NET-peptides are loaded into FLS MHC class II and presented to Ag-specific T cells. HLADRB1*0401 transgenic mice immunized with mouse FLS loaded with NETs develop cartilage damage as well as ACPAs specific to citrullinated forms of relevant RA autoantigens implicated in disease pathogenesis.

Conclusion: These results suggest that NETs are a source of arthritogenic peptides in the synovium and implicate FLS as mediators in RA pathogenesis, through the internalization and presentation of citrullinated peptides to the adaptive immune system leading to pathogenic autoimmunity and cartilage damage.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Serum anti-CCP antibodies are specific for RA in the setting of inflammatory arthritis (IA) and can be elevated for several years prior to the onset of IA during the preclinical period of autoimmunity in RA. Understanding the origins of anti-CCP is critical to understanding the etiology of RA. Prior studies demonstrate that positivity of autoantibodies (e.g. RF and ANA) increase with increasing age. Similar associations have not been reported for anti-CCP. We sought to further evaluate the association of age and anti-CCP3.1 that detects IgG and IgA reactivity in subjects without RA.

Methods: From the Studies of the Etiology of RA (SERA) cohort, we included 1037 RA-free first-degree relatives (FDRs) of probands with RA, and from the Myogenic and Osteogenic Responses to Exercise and Ibuprofen (MOXI) Study, we included the baseline sample of 187 subjects aged 59-75 years without RA. Serum was tested by ELISA for CCP2 (IgG, Axis-Shield) and CCP3.1 (IgG/IgA, Inova) with positivity based on manufacturerÕs recommendations. A random subset of 279 FDRs also had serum testing by ELISA on a CCP3 substrate using isotype-specific IgA (CCP-IgA) and IgG (CCP-IgG) secondary reagents (Inova, for research only) with positivity based on a cut-off level that was positive in <5% of 154 anonymous blood donors. Analyses included logistic regression and McNemarÕs test.

Results: FDRs were 81% female, 76% white, 40% ever smokers and 53% shared epitope (SE) positive. MOXI Subjects were 66% female, 82% white and 47% ever smokers. Overall in FDRs, anti-CCP3.1 positivity was more prevalent than CCP2 (8.2 v. 2.7%, p<0.01). There was an association between increasing age (per year) and anti-CCP3.1 positivity (OR=1.03 95% CI 1.02-1.05) that remained significant after adjusting for sex, race, smoking and SE. When stratified by age group, the higher prevalence of anti-CCP3.1 was significant after age 50 (Figure). In MOXI Subjects, anti-CCP3.1 positivity was also more prevalent than CCP2 (23.5 v. 1.6%, p<0.01). When considering specific isotypes, in FDRs ³50 years, anti-CCP-IgA positivity was more prevalent than CCP-IgG (17.3 v. 8.3%, p=0.04). Anti-CCP-IgA positivity was also associated with increasing age (per year) (OR=1.04 95% CI 1.02-1.07). There was no association of age and anti-CCP2 (p=0.78) or CCP-IgG (p=0.24).

Conclusion: This is the first study to demonstrate increasing anti-CCP3.1 positivity with increasing age in subjects without RA. This association appears to be driven by IgA reactivity, and may reflect an ongoing mucosal immune process. Additional studies are needed to determine potential pathogenicity or other phenotypic associations of anti-CCP-IgA in older adults, but these findings have important clinical and research implications. Age should be considered in the clinical interpretation of anti-CCP3.1 in subjects without IA, and identifying mechanisms of anti-CCP-IgA generation in older adults could provide insight into the etiology of RA.

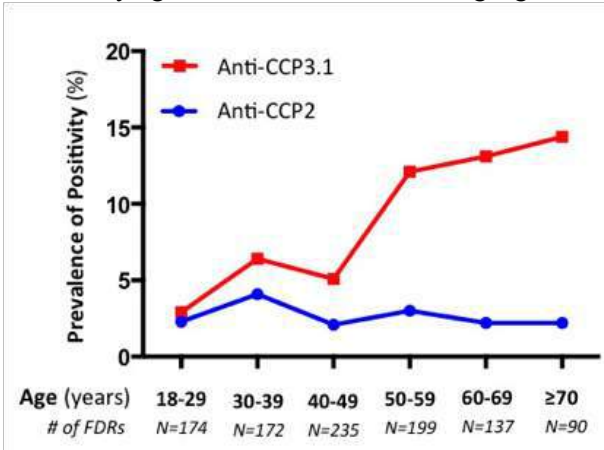

Figure. Anti-CCP2 and anti-CCP3.1 positivity in FDRs by age group. Prevalence of positivity for anti-CCP2 (blue) and anti-CCP3.1 (red) are depicted on the Y-axis by age group (X-axis). The number of FDRs studied per age group are listed under the associated age group. Results of McNemar's test comparing anti-CCP2 and CCP3.1 positivity in each age group are depicted as *<0.01.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Differences in the pathogenesis of ACPA- versus ACPA+ rheumatoid arthritis are still poorly understood. In this study, we compared patterns of synovial changes in both disorders, and how they correlate with clinical parameters of disease activity.

Methods: Semi-quantitative histological scores (0-3) on synovial hyperplasia, diffuse and perivascular lymphocytic infiltrates, vascular hypertrophy and fibrinoid necrosis were obtained retrospectively from 62 ACPA+ and 29 ACPA- synovial biopsies, obtained by needle-arthroscopy from the knee of rheumatoid arthritis patients. Clinical and biological indices of disease activity (DAS28-CRP, SDAI, CDAI and their individual components) were retrieved from the medical records at the time of biopsy (T0), and 6 months later. IL6 and IL6R immunostainings were performed on a subset of the samples. High-throughput transcriptomic data were available for 14 ACPA+ and 6 ACPA- patients.

Results: Synovial hyperplasia, vascular hypertrophy and fibrinoid necrosis scores were significantly higher in ACPA- compared to ACPA+ patients. Diffuse and perivascular lymphocytic infiltrates also scored higher in ACPA- patients, but the difference was not significant. Clinical and biological indices of disease activity were similar in both groups, as were IL6 and IL6R immunostaining quantifications. In ACPA+ patients, all (except vascular hypertrophy) histological scores correlated with clinical and/or biological scores of disease activity at T0. Fibrinoid necrosis in ACPA+ patients also correlated with disease activity 6 months later. By contrast, none of the histological scores displayed any correlation with disease activity measures in ACPA- patients. Transcriptomic analyses demonstrated a significant correlation between synovial hyperplasia and a T cell activation signature (e.g. IL6R, IL23R) in ACPA+ biopsies. This correlation was also present in ACPA- samples, but stronger correlations were found in this group with transcripts pointing at the activation of other T cell related pathways, such as IL10 and TGFβ2.

Conclusion: Synovial biopsies from ACPA- versus ACPA+ rheumatoid arthritis patients display different histological characteristics and histoclinical correlations. In particular, synovial biopsies from ACPA- patients have a higher cellularity, yet are associated with similar clinical disease activity. Preliminary transcriptomic data point at the presence of regulatory cells in ACPA- synovial tissue, as a potential explanation to this discrepancy.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In RA-associated interstitial lung disease (RA-ILD), higher levels of anti-CCP antibodies have been associated with the presence and severity of ILD suggesting a potential role in the pathophysiology. Usual interstitial pneumonia (UIP) is the most common RA-ILD subtype and associated with a poor prognosis. Idiopathic pulmonary fibrosis (IPF) is a distinct form of ILD that is radiographically and pathologically similar to RA-UIP, but the role of anti-CCP in IPF has not been well studied. As such, we sought to compare anti-CCP in subjects with RA-UIP and IPF.

Methods: From the National Jewish Health serum biobank, we identified 36 patients with RA-UIP and 35 patients with IPF without RA (IPF-noRA). Diagnosis was confirmed by chart review. Serum was tested for the commercial assay CCP3.1 (IgG/IgA, Inova) and isotype-specific research assays using the CCP3 substrate for IgG and IgA (Inova). Anti-CCP3.1 positivity was based on manufacturer recommendations, and to evaluate specificity, we also tested 35 healthy Controls who were without RA or ILD based on self-report. For CCP-IgG and IgA assays, cut-off for positivity was set at a level that was positive in <5% in 154 random blood donors. Analyses included comparisons between groups (Chi-square/Fisher's) and within each group (McNemar's). Non-parametric testing compared change in diffusing capacity of the lung for carbon monoxide (DLCO) between anti-CCP(+) and (-) subjects.

Results: Subject characteristics are listed in the Table. Overall, anti-CCP3.1 was more prevalent in RA-UIP. However, anti-CCP3.1 positivity was significantly more prevalent in IPF-noRA than Controls (31 vs. 3%, $p<0.01$). Within IPF-noRA subjects, anti-CCP-IgA was more prevalent than CCP-IgG (31 vs. 6%, $p=0.02$), but within RA-UIP subjects, anti-CCP-IgA and IgG rates were similar (67 vs. 58%, $p=0.45$). In addition, 25/35 IPF-noRA and 20/36 RA-UIP subjects had pulmonary function tests at the time of serum collection and longitudinally within 2 years (median 1.1 years, range 0.3-2 years). In IPF-noRA subjects, anti-CCP3.1 and CCP-IgA positive subjects had a poorer prognosis [median decline in DLCO/year; for anti-CCP3.1 (+) vs. (-), 3.48 vs. 0.80, $p=0.04$; for anti-CCP-IgA (+) vs. (-), 2.78 vs. 0.69, $p=0.05$]. Similar associations were not seen in RA-UIP where the majority of subjects were anti-CCP (+).

Conclusion: We found that almost one third of IPF-noRA subjects are positive for the commercially available anti-CCP3.1, with isotype-specific testing demonstrating predominately anti-CCP-IgA, and positivity being associated with a more rapid progression of lung disease. Further study is needed to determine whether anti-CCP-IgA in these subjects represents a non-specific response to lung injury or a marker of a novel subset of IPF subjects that may be more responsive to immunosuppressive therapy. Longitudinal follow-up is needed to determine the risk of progression to classifiable RA in IPF-noRA subjects.

Table. Clinical Characteristics and Anti-CCP Positivity in RA-UIP and IPF						
	RA-UIP (N=36)	**IPF** (N=35)	**p-value***	**IPF** (N=35)	**Controls** (N=35)	**p-value****

TCZ Modulates the Production of Ccfdna Derived from RA Synovial Cells

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: DNA is fragmented and released into blood circulation as a circulating cell-free DNA (ccfDNA) because of damage or death of cells. Although the lower concentration of ccfDNA is present in peripheral bloods from healthy individuals, significantly higher amount of those are detected in cancer patients or pregnant women (1). Thus, ccfDNA has recently been recognized as biomarkers of several medical conditions. In this study, we measured the amount of ccfDNA in peripheral bloods from RA patients and healthy controls, and in synovial fluid samples of knee joint from RA patients and osteoarthritis (OA) patients. Moreover, we investigated the mechanism of ccfDNA production and found that TCZ inhibited the production of ccfDNA derived from RA synovial cells.

Methods: The amount of ccfDNA was measured by qPCR in peripheral bloods from 29 patients with RA, and 21 healthy controls., and in synovial fluid of knee joint from 13 patients with RA, and 12 patients with OA. By using human synovial cells, culture-supernatants were collected in each steps of cellular-confluency; 40% to 120%. In addition, after stimulated with interleukin(IL)6/soluble IL6 receptor(sIL6R) or TNFα, synovial cells were further treated with and without tocilizumab(TCZ: 100μg/mL) or etanercept(ETN: 10μg/mL) to collect supernatants. When examining ccfDNA in supernatants by qPCR, we amplified both short and long DNA fragments using ALU115-bp primer and ALU247-bp primer to distinguish apoptotic fragments from non-apoptotic fragments, respectively. Viabilities of synovial cells were also examined by WST-8 assay.

Results: The amount of ccfDNA in RA patients was significantly increased as compared to healthy controls, and to OA patients. In supernatants, amounts of ccfDNA (ALU115 and ALU247) increased before 100% confluency cultured-state, and decreased after 100% confluency. Amounts of ccfDNA (ALU115 and ALU247) were significantly suppressed by TCZ treatment, while those with ETN were not changed. Notably, cellular viabilities showed no significant difference between non-treated and biological DMARDs-treated groups, and the ratio of ALU247 to ALU115 was significantly reduced by TCZ.

Conclusion: Results clearly showed that ccfDNA was a diagnostic biomarker for RA in both peripheral blood and joint fluid, and suggesting that ccfDNA in peripheral blood was derived from synovial tissue. Another source of ccfDNA was considered to be physiological cell division because the amount of ccfDNA was increased by cell proliferation and decreased in the growth inhibition by cell-to-cell contact. Thus it appeared that TCZ inhibit the physiological cell division and the ratio of ALU247 to ALU115 could represent the therapeutic response for TCZ, since ALU115 represents the total amount of ccfDNA and ALU247 specifically represents those released by cell division. **References:** (1) T B Hao, et al. 2014 Circulating cell-free DNA in serum as a biomarker for diagnosis and prognostic prediction of colorectal cancer. *British Journal of Cancer* 111(8):1482-9

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibodies against cyclic citrullinated peptides (anti-CCP) have been suggested to identify a more severe phenotype of rheumatoid arthritis. In this study we have analysed a number of antibodies against citrullinated peptides (ACPA) using a multiplex platform in an inception cohort of early RA in relation to disease inflammation and progressive severity.

Methods: Patients with early RA (≤12 months of symptoms) fulfilling the 1987 ARA criteria (n=1012, 681f/331m, mean age56.9±14.0 years) were sampled at the time of diagnosis and evaluated using disease activity score 28 (DAS28) (at baseline, 6, 12, 18 and 24 months) and with radiography using Larsen score (baseline and 24 months). Baseline plasma samples were analysed for presence of 17 different antibodies; ACPA (Fibrinogen α36-50 (Fibα36-50), Fibα573, Fibα591, Fibα621-635, Fibβ36-52, Fibβ60-74, Fibβ62-78 (72), Fibβ62-78 (74), filaggrin (Fil307-324), α-enolase peptide 5-21 (CEP-1), Vimentin (Vim) 2-17, Vim60-75)), or mutated proteins (Bla26, Pept1, Pept5, PeptZ1, PeptZ2) analysed using a custom-made microarray assay based on the ImmunoCAP ISAC system (Phadia AB, Sweden). Cut-off levels set at the 98th percentile of controls. Anti-CCP2 was analysed using ELISA (Euro Diagnostica, Sweden) and rheumatoid factor (RF) according to routine methods with cut-off at 95%.

Results:

The most frequent positive ACPA were; Fibβ60-74 (63%), Vim60-75 (56.6%), Fibβ36-52 (55.1%), Fil307-324 (54.9%), CEP-1 (53.7%) and Pept5 (52.0%) besides CCP2 (67.5%) and RF (74.3%). The median (IQR) number of ACPA positivity was 8 (11). Adding all ACPAs gave additional 13.1% of positivity in the anti-CCP2 negative group, yielding a total positivity of 77.5%. Positivity for CCP-1, Vim60-75, Fibα36-50, Pept5 and Vim2-17 was associated with area under curve (AUC) DAS28 during the 24 months compared with negativity ($p<0.05$). Increased ESR at baseline was associated with positivity vs. negativity for all antibodies except Fibβ62-78(72), Fibβ62-78 (74) and Pept1 ($p<0.05$). Positivity for Fil307-324, CEP-1, Fibα36-50, Fibα621-635, Fibβ36-52, Vim60-75, Vim2-17, PeptZ1 and Pept1 were significantly associated with radiological progression ($p<0.05$). CEP-1, Fibα621-635, Fibα36-50 and PeptZ2 remained significant in a logistic stepwise regression analysis adjusted for sex. Overall 69.1% were good-moderate EULAR responders, no significant relationships between antibodies and response to treatments were found except for positivity for Fibβ36-52 adjusted for all analysed antibodies, sex and being a smoker ($p=0.008$). Of the patients treated with biologics during the first 24 months (11.2%), positivity for antibodies against CCP2, Vim60 75, Fibα36-50, PeptZ1 and PeptZ2 were significantly more frequent vs. negativity.

Conclusion:

Disease activity and radiological progression are associated with different ACPA reactivities at the time of diagnose and during the 24 months follow up.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Within rheumatoid arthritis (RA) bone marrow edema (BME, osteitis) and anti-citrullinated protein antibodies (ACPAs) are associated with radiographic progression. ACPA has been associated with BME, but it is unknown if this association is confined to ACPA and BME. We cross-sectionally studied the association of ACPA, rheumatoid factor (RF) and anti-carbamylated protein (anti-CarP) antibodies with BME and other types of MRI-detected inflammation (synovitis, tenosynovitis).

Methods: 589 DMARD-naïve early arthritis patients, included in the Leiden Early Arthritis Clinic, underwent contrast-enhanced 1.5T MRI of unilateral wrist, metacarpophalangeal and metatarsophalangeal-joints at baseline. BME, synovitis and tenosynovitis were scored by two readers. ACPA, RF and anti-CarP were determined at baseline.

Results: In univariable analyses ACPA-positive patients had higher BME-scores than ACPA-negative patients (median 4.5 vs. 2.0, $p<0.001$), but not more synovitis and tenosynovitis. Also RF (median 3.75 vs. 2.0, $p<0.001$) and anti-CarP antibodies (median 3.5 vs. 2.5, $p=0.012$) were associated with higher BME-scores. Because the autoantibodies were concomitantly present, analyses were stratified for the presence of different autoantibody combinations. ACPA+RF-anti-CarP- patients did not have higher BME-scores than ACPA-RF-anti-CarP- patients. However ACPA+RF+anti-CarP- and ACPA+RF+anti-CarP+ patients had higher BME-scores than ACPA-RF-anti-CarP- patients (median 5.0 and 4.5 vs. 2.0, $p<0.001$ and $p<0.001$). ACPA levels were not associated with BME-scores. Analyses within RA- and UA-patients revealed similar results.

Conclusion: The single presence of ACPA and ACPA-level were not statistically significant associated with BME-scores, but the combined presence of ACPA and RF did associate with more BME. This suggests an additive role of RF to ACPA in mediating osteitis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), bone erosions are caused mainly by osteoclasts. Osteoclasts are derived from monocytes and macrophages (MoMa). MoMa consists of different subtypes such as M1 and M2. Until now, little has been known regarding the relation of characteristic of RA with MoMa subtypes. We attempted to investigate relationship among MoMa subtypes (M1 or M2), ability of osteoclast differentiation, phagocytic ability of osteoclasts, and clinical characteristics in RA patients.

Methods: This study included 40 RA patients and 19 healthy donors. We collected baseline clinical variables including duration of disease, DAS28, positivity of rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (ACPA), and treatments. Peripheral blood mononuclear cells (PBMC) were isolated from RA patients and healthy donors, then we investigated the number of M1/M2 cells by fluorescence-activated cell sorting. We defined M1 as CD14, CD68 and CCR2 positive cells and M2 as CD14, CX3CR1 and CD163 positive cells. We also obtained CD14 positive cells in PBMCs from RA patients and healthy donors using CD14 beads to investigate osteoclast differentiation *in vitro* with stimulation by macrophage colony stimulating factor (MCSF) and receptor activator of NF-*f*ÈB ligand (RANKL). Osteoclast differentiation was evidenced by tartrate-resistant acid phosphatase (TRAP) staining, then we counted number of osteoclasts. We also performed pit formation assay of osteoclasts to assess phagocytic ability of osteoclasts.

Results: Twenty seven patients (68%) had positive RF. Twenty two patients (55%) were ACPA positive. Median M1 rate in CD14 positive cells was 18.5% (6.7%-39.9%, IQR). Median M2 rate in CD14 positive cells was 33.3% (13.2%-65.9%, IQR). Median M1/M2 ratio was 0.59 (0.31-1.11, IQR). There were no differences between RA patients and healthy donors, and between RA patients with high disease activity and low disease activity regarding M1/M2 ratio or number of osteoclasts *in vitro*, respectively. ACPA positive patients had higher M1/M2 ratio *in vivo* (0.87 vs. 0.41, p=0.028) (Figure 1A) and more number of osteoclasts *in vitro* (Figure 1B) than ACPA negative patients (97 per well vs. 37 per well, p=0.003). Furthermore, there was positive correlation between M1/M2 ratio and the number of differentiated osteoclasts *in vitro* in RA patients (*f*Ï=0.81, p<0.01) (Figure 1C). Overall, number of osteoclasts *in vitro* correlated with area of pit formation. There was no relationship among treatments (including methotrexate, prednisolone and biologics), M1/M2 ratio and number of osteoclasts *in vitro*.

Conclusion: The presence of ACPA positively correlated with the circulating osteoclast precursors in RA patients which may attributed to M1 subtypes. Our present data may explain the preferential development of bone destruction in ACPA-positive RA patients.

Cell-Mediated Neutrophil Lysis-a Mechanism Promoting Hypercitrullination in Rheumatoid Arthritis?

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

BACKGROUND/PURPOSE:

Protein citrullination, the post-translational conversion of arginine to citrulline, mediated by peptidylarginine deiminase (PAD) enzymes, is considered a likely mechanism for the stimulation of anti-citrullinated protein antibodies (ACPA) in patients with rheumatoid arthritis (RA). Hypercitrullination, the citrullination of multiple intracellular proteins, was recently demonstrated in synovial fluid (SF) cells from RA patients (Romero *et al.Sci Transl Med, 2013)*. This unique form of citrullination is proposed to occur via immune-mediated, pore-forming membranolytic pathways such as perforin-granzyme activation, but is not found in other physiological processes involving citrullination, such as NETosis. Indeed, recent findings demonstrate perforin and granzyme-producing $CD8^+$T effector cells in the synovium of pre-clinical RA patients as well as in the peripheral blood (PB) and SF of active RA patients, and persisting into disease remission.

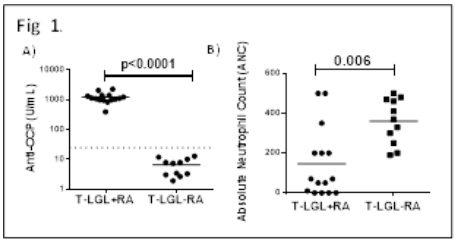
Insight into the existence of potential cytotoxic mechanisms occurring in RA comes from the co-occurrence of RA in up to 36% of cases of T-cell Large Granular Lymphocyte (T-LGL) Leukemia, a clonal condition characterized by severe neutropenia attributed to the killing of neutrophils or their precursors by cytotoxic $CD8^+$ T cells. Interestingly, $CD8^+$T cells with features of LGLs were found in the SF of RA patients without LGL leukemia, but not in the SF of psoriatic arthritis and ankylosing spondylitis patients. We thus decided to test LGL leukemia as a model for neutrophil-directed cytotoxicity contributing to hypercitrullination and disease propagation in inflamed joints of ACPA+ RA patients.

METHODS:

The sera of 11 T-LGL leukemia patients (T-LGL-RA) and 15 T-LGL leukemia patients with co-existing RA (T-LGL+RA) with absolute neutrophil count (ANC) < 500 were analyzed for ACPA positivity by ELISA. ACPA titers and ANC of each group of patients were compared using unpaired two-tailed T tests. Hypercitrullination in PB neutrophils was analyzed by immunoblotting electrophoresed neutrophil cell lysates using a broad-spectrum anti-citrulline antibody. Ionomycin was used as a positive control for hypercitrullination.

RESULTS:

All T-LGL+RA were ACPA positive, in stark contrast to the T-LGL patients without co-existing RA (Fig. 1A). Of interest, T-LGL+RA patients had decreased ANC (Fig. 1B) as compared to T-LGL-RA patients, supporting the hypothesis of neutrophil destruction in development of ACPA positivity. Importantly, hypercitrullination was observed in neutrophils isolated from both RA and T-LGL+RA patients.



CONCLUSION:

These results are consistent with the hypothesis that in T-LGL+RA, ACPA generation may result from neutrophil-directed lysis and hypercitrullination. Elucidating the cause of neutrophil-directed cytotoxicity may help to uncover a mechanism for hypercitrullination, ACPA formation and RA disease propagation.

Background/Purpose : Anti citrullinated protein autoantibodies (ACPA) are the major autoantibodies in rheumatoid arthritis (RA). ACPAs are directed against different citrullinated antigens, including filaggrin, fibrinogen, vimentin and collagen. Presence of ACPA is associated with joint damage and extra-articular manifestations, suggesting that ACPA are most likely arthritogenic autoantibodies in RA.

Methods: To verify the effect of ACPA on RA immune cells, PBMCs from ACPA$^+$-RA patients and healthy controls were co-cultured *in vitro* with ACPA. Binding of the latter to the cells were analyzed by flow cytometry and effect on cytokines mRNA expression by real-time PCR. The stimulating effects induced by ACPA were manipulated by addition of Cit-ME a novel multi-epitope citrullinated peptide.

Results: ACPA bound specifically to PBMCs from ACPA$^+$-RA patients via the Fab portion. ACPA induced an obvious pathogenic cytokine expression (4-13 fold increment) in immune cells derived from ACPA$^+$-RA patients. Moreover, ACPA up-regulated the IL-1b and IL-6 mRNA expression levels by 10 and 6, folds, respectively compared to control IgG.

Cit-ME, a genuine ligand for ACPA, inhibited the ACPA-induced up-regulation of Il-1b and Il-6 by 50% [Fig.].

Conclusion: ACPA binds to immune peripheral cells and enhances the synthesis of pathogenic cytokine expression. Together, these data suggests that ACPA is involved in the pathogenic effects in RA. Targeting ACPA in order to decrease its pathogenic capacity might provide a novel direction in the development of therapeutic strategies for RA.

Figure- ACPA induce IL-1b and IL-6 mRNA up-regulation. The Cit-ME, a multi-epitope citrullinated peptide, inhibited part of the ACPA cytokine up-regulation.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Serum anti-citrullinated proteins (ACPA, including anti-CCP antibodies) and rheumatoid factor (RF) are critical diagnostic markers for RA, and are associated with more severe radiographic damage. The mechanisms of this association are unclear, but might involve serum cytokine levels, given our previous study reporting an association of IFN-γ receptor gene expression in peripheral blood mononuclear cells with radiographic damage in African-Americans with RA.

Methods: ACPA profiles (20 specificities) of 923 and cytokine profiles (17 cytokines) of 825 African-Americans with RA were generated from serum obtained at the time of enrollment into a large observational study. We stratified patents into four subgroups according to autoantibody positivity (CCP+/RF+, CCP+/RF-, CCP-/RF+, and CCP-/RF-). Associations of ACPA specificities and serum cytokine levels with radiographic severity were analyzed using a cross sectional approach, based on disease duration at the time of the enrollment: 0-12 months; 12-24 months; 24-48 months; 48-96 months; 96-120 months; and >120 months. The mean ± SE values of each subgroup of CCP and RF combination were analyzed and compared by student t-test. Correlations were analyzed using a zero-inflated binomial model (ZINB).

Results: After adjustment for disease duration at enrollment in the cohort, strong associations were found between radiographic scores and 11 of 20 ACPA specificities. Among patients with disease duration 0-48 months, radiographic scores were slightly higher for CCP+/RF+ compared to other subgroups. As expected, after 96 months of disease duration, the accrued radiographic damage was much higher in the double positive group compared to others subgroups. Almost all serum ACPA specificities were significantly higher at 0-48 months than at > 48 months disease duration. Among the CCP+/RF+ group, serum IL-1β, IL-6, and MCP-1 levels were higher as disease duration increased. Serum levels of IL-2, IL-5, IL-7, IL-12, IL-13 and IFN-γ were significantly higher in CCP+/RF+ compared to CCP-/RF- (p values <0.05). There was a strong association between total radiographic scores and log transformed serum IFN-γ levels (adjusted for age at disease onset, body mass index, and CCP status) (p = 0.0374, ZINB).

Conclusion: Our findings support the hypothesis that temporal changes in immunologic perturbations play a role in accumulated joint damage in RA. Specifically, the presence of ACPA specificities, the increasing elevation of IL-1β, IL-6, and MCP-1 over time, and elevated serum IL-2, IL-5, IL-7, IL-12, IL-13, and IFN-γ levels may contribute to the accrued joint damage in CCP+/RF+ patients. These findings may have important implications for stratifying African-Americans with RA according to risk of joint damage and may lead to different treatment strategies.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Arterial thrombosis is a major cause of mortality in rheumatoid arthritis (RA),especially in anti-citrullinated protein antibody (ACPA)-positive patients Recent studies suggest that platelet activation is implicated in this pathway[1]. Platelet activation results in proteolytic cleavage and shedding of platelet specific glycoprotein VI (GPVI) detected in the plasma as soluble GPVI (sGPVI). Shedding of GPVI occurs in response to stimuli, including engagement with the low affinity immunoglobulin G (IgG) receptor (FcγRIIa) on platelets[2]. ACPA cause platelet activation *in vitro*, through the FcγRIIa receptor[1]. We hypothesized that ACPA in patients with RA would cause platelet activation via ligand binding with FcγRIIa causing increased shedding of sGPVI.

Methods: Following ethics approval and informed consent, blood samples were taken from patients with RA (n=111) and OA (n=16). Healthy control samples (n=48) were obtained from volunteers. Demographic and clinical data were collected for all participants. Blood samples were processed as double spun platelet poor plasma. sGPVI levels were measured using a standardized ELISA. Mann-Whitney U test and Kruskal – Wallis test was used to compare groups. SpearmanÕs Rank Correlation Coefficient was used to assess for associations between sGPVI levels and demographic and clinical markers. GraphPad Prism Version 6.05 was used for data analysis.

Results: Characteristics of ACPA positive RA vs ACPA negative RA are presented in Table 1. Patients with ACPA positive RA were significantly older, but no signficant correlation was observed between levels of sGPVI and age, CRP, fibrinogen, ESR, platetet count or DAS28 CRP. Patients with ACPA positive RA had significantly higher levels of sGPVI compared to ACPA negative RA and controls (Figure 1). Median (IQR) sGPVI levels were 4.3 ng/ml (3.80, 9.70) in ACPA positive RA , 2.4 ng/ml (31.5,4.3) in ACPA negative RA and 2.1ng/ml (1.6, 3.2) in controls ($p<0.0001$). ACPA titres correlated with sGPVI levels ($r=0.32$, $p=0.0026$).

Conclusion: Our results demonstrate that ACPA are associated with platelet activation as defined by increased levels of plasma sGPVI. These data could explain, in part, the aggravated cardiovascular risk in ACPA-positive patients . A monoclonal antibody targeting GPVI exists and has been shown to reduce myocardial infarct size in mice. The role of sGPVI as a marker of ACPA mediated platelet activation and therapeutic targeting of GPVI warrants further investigation.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: B cells are central drivers of seropositive RA, and B cells that express anti-citrullinated protein antibodies (ACPA) may arise from past and/or ongoing breaches in immune tolerance. While ACPA levels are only modestly affected by commonly prescribed therapeutic agents (e.g, Methotrexate, TNFi), it is unclear whether these treatments significantly affect autoimmune lymphocytes and whether these cells persist after treatment induced clinical remission. We therefore assessed the frequencies and epitope reactivity patterns of ACPA-producing switched-memory B cells, with comparisons to serum ACPA levels and disease activity scores.

Methods: In a cross-sectional study of seropositive RA patients that met 2010 ACR/EULAR criteria, blood samples were biobanked, and later cryopreserved PBMC were cultured +/- sCD40L/CpG2006/IL-21 for 6 days and then ELISpots performed. Synovial fluid mononuclear cells and FACS-sorted switched-memory B cells [CD19+/CD27+/IgD-] were cultured with CpG2006/IL-21 in the presence of a CD40L-expressing feeder cell line for 12 days. Sera, synovial fluid, and culture supernatants were analyzed by multiplex bead-based assay for ACPA-IgG reactivity for 8 citrullinated and native peptide/protein pairs, as well as reactivity with the diagnostic CCP3 peptide (Inova Diagnostics) and glutamine-containing CQP3, plus other control ligands. We then performed Spearman correlations.

Results: In select patients with active disease, we found a high frequency of synovial fluid cells that spontaneously secreted ACPA in culture, suggesting these ACPA producing B cells are especially common at the site of disease, and epitope specificities were similar to those in autologous synovial fluid. For cultures of PBMC from groups of patients receiving different treatment regimens (MTX or TNFi+/-MTX), ACPA-IgG secretion was also detected, although in vitro stimulation was generally required. In the circulation of these RA patients, switched memory B cells were the predominant source of ACPA-IgG. Notably, serum anti-CCP3-IgG levels significantly correlated with frequencies of ACPA-producing switched-memory B cells ($r = 0.57$, $p = 0.003$). For individual donors, the ACPA fine-specificity patterns in serum samples were similar to those in supernatants from cultured B cells. A majority (16/24) of RA patients had wells with detectable in vitro ACPA secretion. Yet frequencies of ACPA memory B-cells did not attain significant correlation with DAS28 scores ($r = 0.35$, $p = 0.09$). In fact, a subset of RA patients, which included patients treated with methotrexate and/or TNFi, had high frequencies of recirculating ACPA memory-B cells despite being in DAS remission.

Conclusion: We have documented that DAS score cannot be used as a predictor of reduced or absent ACPA memory B cell burden, as quiescent disease-associated anti-Cit memory B-cells commonly persist in peripheral circulation despite treatment to clinical remission. Our results help to explain why therapeutic cessation most often results in reactivation or flare. In the future, our platform may be useful for evaluating new agents and for informing treatment decisions in individual RA patients.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Airways abnormalities that are consistent with inflammation are common in anti-CCP2 positive subjects without inflammatory arthritis. Anti-CCP2 antibodies are associated with high-resolution computed tomography (HRCT) parenchymal lung abnormalities in patients with early RA. This study aims to examine the association between ACPA fine specificities and HRCT lung changes in an early RA cohort.

Methods: Patients (n=106) with newly diagnosed RA according to the ACR 1987 criteria and na•ve to treatment with oral glucocorticoids or DMARDs were included. HRCT was performed in order to assess the presence parenchymal (nodules, ground-glass opacities, fibrosis, emphysema) and airway abnormalities (bronchiectasis, air trapping, air wall thickening). Bronchoscopy was performed on 22 patients to retrieve BAL. EliA system (Phadia) was used to detect RF IgA and IgM, anti-CCP2 IgA and IgG, and ISAC peptide microarray (Phadia) was used to detect antibodies against 10 citrullinated (Cit) peptidic antigens: CCP-1 (Filaggrin), CEP-1 (α-enolase), Vim 2-17, Vim 60-75 (Vimentin), Fib α 36-50, Fib α 573, Fib α 591, Fib α 621-635, Fib β 36-52, Fib β 60-74 (Fibrinogen). Logistic regression analysis was performed to examine associations between HRCT lung changes at the time of RA diagnosis and autoantibodies. Due to the potential risk for effect modification of smoking and its strong association with cit-Abs, we stratified the cohort according to current vs non-smokers.

Results: HRCT parenchymal and airway changes was present in 58 (54.7%) and 68 (64.2%) patients, respectively. The forced vital capacity (FVC) was significantly lower in the presence of airway abnormalities, while the ratio FEV_1/FVC was significantly lower in patients with parenchymal lung changes. Higher age, RF IgA, CCP2 IgG, ever smoking and pack-years above 24 were significant predictors of parenchymal lung changes. Some ACPA fine specificities, especially against Cit Fib and Vim peptides, were associated to parenchymal lung changes in ever smokers. The risk of having parenchymal changes increased parallel to the increase in number of ACPA specificities. Having more than 5 ACPA specificities at the time of diagnosis increased the risk of having parenchymal lung abnormalities in current smokers (OR=13.8, 95% CI=1.0-196.2, p=0.05) (Table 1). In the subgroup of patients that underwent bronchoscopy, antibodies against Cit Vim and Fib peptides were detected in the BAL mainly in current smoker (4/9, 45%) and to a lesser extent in non-smokers (3/13, 23%). Patients with Ab positivity in the BAL were also positive for same antibodies in paired serum samples.

Conclusion: The presence of RF IgA, anti-CCP2 IgG and antibodies to Cit Fib and Vim peptides were associated with parenchymal lung changes in early-untreated RA. The more ACPA fine specificities, the higher the risk of having

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Circulating anti-citrullinated peptide antibodies (ACPA) have been proposed as an important clinical test for stratification of patients presenting with rheumatoid arthritis (RA). ACPA may be present in the serum of subjects several years before the onset of symptoms, and studies suggest that the presence of ACPA may predict more severe and erosive disease. However, studies to date investigating whether the two subgroups of RA (defined by the presence and absence of ACPA) have differing pathologies at the level of the synovial tissue, have yielded conflicting results.[1,2] The aims of our study were to examine synovial tissue immunophenotype according to ACPA status in patients with a clinical diagnosis of RA, and to determine the nature of the relationship between synovial infiltrate, response to treatment and erosions on plain film radiographs.

Methods: Consecutive patients with RA were prospectively recruited from rheumatology clinics and underwent clinical, serological and radiological assessment before and after treatment with non-biologic DMARD (nbDMARD) or TNF inhibitors (TNFi). Synovial tissue was obtained by arthroscopy from involved knee joints and immunohistologically stained for cell specific markers of B-cells (CD19), T-cells (CD3, CD4 and CD8), macrophages (CD68) and the blood vessel marker FVIII. Sections were scored using a validated semi-quantitative scoring method and analysis of synovial immuno-phenotype by ACPA status and EULAR response criteria to treatment was performed.

Results: 123 subjects (78 ACPA+) were included in the study. The synovium from ACPA+ RA was characterised by significantly higher CD19+ B-cells ($p<0.05$), CD3+ T cells ($p<0.05$) and CD8+ T cells ($p<0.05$), compared with ACPA- RA. CD19+ B-cells were also significantly higher in the synovium of ACPA+ patients naïve to treatment ($p=0.04$) (fig. 1). In addition, both CD19+ B-cell and CD4+ T-cell infiltrates were higher in patients who had evidence of erosive disease at follow-up ($p=0.0163$; $p=0.0024$, respectively). RA patients achieving a moderate-good EULAR response to nbDMARD or TNFi also had significantly higher infiltrates of CD3+ cells ($P<0.05$). Finally, CD68+ and CD8+ cells were significantly higher in TNFi responders vs non responders ($p<0.05$)

Conclusion: ACPA+ RA patients demonstrate significantly higher synovial B and T cell infiltrates and higher B cells were identified in treatment-naïve patients and associated with the erosions. 1 van Oosterhout M, *et al. Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

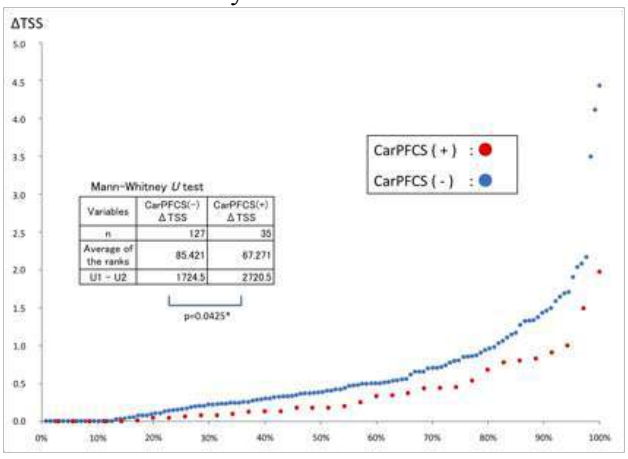
Session Time: 9:00AM-11:00AM

Background/Purpose: A newly discovered anti-carbamylated protein antibody (anti-CarP) is found prior to disease-onset, associates with the conversion towards arthralgia and with a more severe disease course in patients negative for ACPA. We here studied anti-CarP in162 rheumatoid patients who were clinically active and thus under treatment with biological DMARDs, and also in another group of 268 rheumatoid patients whose sera were measured on their first visit to our hospital.

Methods: Anti-CarP-Fetal Calf Serum (aCarPFCS) was measured by using ELISA in sera of 162 Japanese patients with RA who were clinically active (fulfilling either DAS-CRP > 4.0 or DAS-ESR > 4.2 and either CDAI > 22 or SDAI >26) and under treatment with biological DMARDs, and also in 268 patients with RA whose sera were measured for the first time of their visit to the hospital. The change in van der Heijde-modified total Sharp score per year DTSS was assessed using probability plots. Statistical tests were performed using Mann-Whitney U test.

Results: Cumulative probability plot of DTSS for aCarPFCS showed that radiographic progression was less significant in aCarPFCS-positive patients with RA (n=35) as compared with those negative for aCarPFCS (n=127) (Figure). The difference between the groups was p=0.0425 by using Mann-Whitney U test. The cumulative probability plot of DTSS for aCarPFCS in the sera of 268 rheumatoid patients whose sera could be measured on their first visit to the hospital was also similar, where radiographic progression was less significant in aCarPFCS-positive patients with RA (n=80) as compared with those negative for aCarPFCS (n=188). It was noted that radiographic progression seemed particularly less significant in those with relatively larger DTSS, i.e., relatively progressive patients with RA, suggesting that aCarP antibody may be raised in a similar fashion to anti-citrullinated protein antibody (ACPA) possibly cross-reactively but in fact acts rather inhibitory for disease.

Conclusion: Radiographic progression seems to be less significant in anti-carbamylated antibody positive patients with rheumatoid arthritis (RA) especially when they are basically progressive or when they were clinically active and under the treatment with biological DMARDs. The aCarPFCS and aCarPFib are measured by Drs. Verheul MK and Trouw LA,



Department of Rheumatology, Leiden University, Netherlands.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Neutrophil extracellular traps (NETs) have recently been implicated in vascular damage and atherothrombosis. Extruded DNA fibers containing multiple proinflammatory and thrombotic molecules induce the activation and recruitment of monocytes and dendritic cells to the vessel wall. Enhanced NETosis occurs in rheumatoid arthritis (RA), which has been shown related to the pathogenesis of this disorder. However, the relevance of this abnormality in the development of atherosclerosis, and the effects of new therapeutic approaches has not been elucidated yet. The aims of this study were: 1) To evaluate the association of netosis-derived products with the development of atherothrombosis in RA. 2) To study the role of biologic therapies in inhibiting NETosis.

Methods: One hundred RA patients and 30 healthy donors were included. Carotid intima media thickness (CIMT) was used as atherosclerosis marker. Inflammatory and prothrombotic molecules and oxidative stress markers were analyzed in plasma. Neutrophils were isolated and spontaneous and induced NETs formation was assessed through fluorescence microscopy. Oxidative stress status (JC1 and DCFH), myeloperoxidase (MPO), and neutrophil elastase (NE) protein expression were measured in neutrophils by flow cytometry. Cell-free DNA plasma levels were analyzed using specific ELISA-base kits. mRNA expression of peptidyl arginine deiminase 4 (PAD4) and various proatherothrombotic molecules were analyzed by RT-PCR.

Results: NETosis was found increased in RA patients, alongside MPO and NE protein expression in neutrophils. Cell free DNA plasma levels were further elevated, and strongly correlated with clinical parameters such as DAS28, CRP and ESR, and autoimmunity state (RF and anti-CCPs positivity). In addition, high levels of cell-free DNA were associated with elevated levels of IL-6, MCP-1, spSelectin and tPA in plasma, as well as with increased NTyr and decreased TAC and NO. At cellular level, cell free DNA plasma levels correlated with increased oxidative status in RA neutrophils (JC1 and DCFH) and mRNA expression of PADI4. Those patients having pathologic CIMT showed increased cell-free DNA plasma levels. Two new cohorts of 60 RA patients, treated either with Infliximab (n=40) or Tocilizumab (n=20) for six months were further evaluated. Both drugs promoted decreased generation of NETs, along with reduction of MPO, NE, PAD4, and the percentage of low density granulocytes, as well as of the proatherothrombotic profile of RA patients.

Conclusion: 1) Elements associated with the extrusion of NETs are significantly enhanced in RA patients. 2) NETosis-derived products, such as cell-free DNA, strongly correlated with clinical parameters, inflammatory and oxidative markers. Thus, NETosis-derived products demonstrated diagnostic potential for disease activity and atherosclerosis, as well as for analysis of therapeutic effectiveness in RA patients. Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Structural changes, increased tissue citrullination and signs of local inflammation are present in the pulmonary compartment of early seropositive RA and seropositive individuals at risk for developing RA. Cell-derived Microvesicles (MVs) are small particles (0.1-1.0 microns), formed by the outward blebbing of the plasma cell membrane, that can be released during and further contribute to inflammation. The MVs express surface markers similar to the cell of origin and have previously shown to induce tissue injury in the lung. We aimed to study the role of MVs in the lungs of early RA.

Methods: Bronchoalveolar lavage (BAL) fluid was obtained from 20 RA patients (8 females, 12 males, 16 sero-positive and 4 sero-negative, 9 smokers and 11 non-smoker, 59 median age). Additionally BAL samples from disease controls (10 patients with sarcoidosis with active lung inflammation) and healthy volunteers (n=3) were collected. Microvesicles derived from macrophage, endothelial cells, lymphocytes and T-cells were analysed by flow cytometry for phosphatidylserine, CD45, CD63E, CD68, CD154 and CD163 expression. Anti citrullinated protein antibodies (ACPA) were purified from the peripheral blood of RA patients by affinity chromatography, fluorescent labeled and used to identify expression of citrullinated proteins in MVs using flow cytometry.

Results: Elevated numbers of total MVs were observed in the BAL of RA (Mean±SD, 526.2±291.7, events/µL) compared with disease controls (402.3±107.5, $p>0.05$) and healthy volunteers (283.0±52.8, $p<0.05$). MVs derived from macrophage, endothelial cell and lymphocytes were significant increased in the BAL of RA patients (27.2± 13.4, events/ µL for macrophage derived MVs, 20.8±9.0 for endothelial derived MVs and 47.7±24.4 for lymphocytes derived MVs) as compared to both disease controls (16.1±6.0 for macrophage derived MVs, 12.3±3.6 for endothelial derived MVs and 25.1±11.9 for lymphocytes derived MVs) and healthy volunteers (5.9±1.9 for macrophage derived MVs, 10.1±2.9 for endothelial derived MVs and 8.1±5.0 for lymphocytes derived MVs), ($p<0.05$ for all comparisons). Citrulline containing MVs, detected by ACPA were significantly higher in RA compared to disease controls (6.6±2.7 vs 4.3±1.1, $p<0.05$) and healthy BAL (6.6±2.7 vs 3.3±1.4, $p<0.05$) whereas no such difference and significantly lower amount of MVs were detected using RA-derived IgGs others than ACPA as controls.

Conclusion: MVs and citrulline-containing MVs are present in the RA BAL in a higher proportion than in the BAL of either patient with inflammatory lung disease (sarcoidosis) and healthy controls, suggesting a role for MVs in RA-associated lung changes. Confirmation of current findings in larger samples and investigation of potential pathogenic effects of MVs are needed.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: When a tumor necrosis factor inhibitor (TNFi) fails in a patient with moderate to severe rheumatoid arthritis (RA), new American College of Rheumatology (ACR) guidelines recommend a switch to either another TNFi or a non-TNFi biologic. The aim of this study was to evaluate disease activity and patient-reported outcomes (PROs) in RA patients who switched to etanercept after adalimumab failure.

Methods: Adults (age ≥ 18 years) with moderate to severe RA (disease activity score using 28-joint count and C-reactive protein ≥ 3.2) who failed to respond (1º failure) or lost a satisfactory response (2º failure) to adalimumab treatment, based on ACR20% improvement criteria (ACR20) or investigator judgment, were enrolled in an open-label, multicenter, single-arm study. After ≥ 2 weeks of washout for patients on adalimumab, etanercept 50 mg once weekly for 24 weeks was added to ongoing methotrexate treatment. Clinical Disease Activity Index (CDAI), Health Assessment Questionnaire (HAQ) disability index (DI), and pain visual analog scale (VAS) were evaluated at weeks 0, 4, 8, 12, 18, and 24. Other PROs including Medical Outcomes Short Form 36 (SF 36) and Work Productivity and Activity Impairment (WPAI) were assessed at weeks 0, 12, and 24. The primary efficacy endpoint (ACR20 at week 12) and safety data from this study were presented previously; this analysis focused on PROs at each visit.

Results: Of 85 patients studied (80% women; mean age 56.6 years), 84 were evaluable for efficacy. After being switched from adalimumab to etanercept, clinical outcomes and PROs improved from baseline at each study visit (Table). Improvement in mean HAQ DI (–0.31 points from baseline to week 24) exceeded the minimal clinically important difference of 0.22 points. Mean improvement in HAQ DI from baseline to week 24 by adalimumab failure and anti-adalimumab antibodies was –0.05 (1º failure, antibodies; n = 7), –0.65 (2º failure, antibodies; n = 17), –0.15 (1º failure, no antibodies; n = 22), and –0.37 (2º failure, no antibodies; n = 33). Improvements in other PROs (HAQ pain VAS, SF-36

physical function, and WPAI absenteeism/presenteeism) also were greatest for patients with 2º adalimumab failure and anti-adalimumab antibodies. Adverse events were consistent with the known safety profile of etanercept.

Table. Clinical Outcomes and PROs by Study Visit After Switching to Etanercept (N = 84)

Outcome	Baseline	Week 4	Week 8	Week 12	Week 18	Week 24
% with ACR20 response	–	19.0%	29.8%	35.7%	31.0%	34.5%
Mean CDAI	43.7	33.0	30.5	28.7	28.6	26.1
Mean HAQ DI	1.52	1.25	1.24	1.25	1.24	1.21
Mean HAQ pain VAS	63.2	50.3	42.8	44.0	45.8	40.6
Mean SF-36 physical function*	31.4	–	–	35.9	–	36.5
WPAI, % work missed†	15.3%	–	–	9.5%	–	5.5%
WPAI, % impairment working†	41.6%	–	–	29.2%	–	25.8%
WPAI, % activity impairment	57.9%	–	–	43.2%	–	40.0%

* For SF-36 physical function, increased scores indicate improved health; for all other PROs, decreased scores indicate improved health † Among employed patients (n = 41)

Conclusion: Clinical outcomes and PROs improved from baseline at every visit when RA patients switched to etanercept after adalimumab failure, particularly among those with anti-adalimumab antibodies and 2º loss of response to adalimumab. Limitations were small subgroup sample sizes, analysis of secondary endpoints, and lack of long-term outcomes after 24 weeks (6 months).

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) are effective therapy for rheumatoid arthritis (RA) and have been shown to reduce progression of joint structural damage as measured by the modified Sharp Score (mSS). This observational study evaluated the relationship between cumulative adherence to TNFi therapy and progression of structural joint damage during the first year of TNFi therapy in US Veterans.

Methods: US Veterans with RA who were ≥18 years of age and initiated TNFi use after at least six months of enrollment in the Veterans Affairs (VA) health care system were eligible for this study. Subjects were identified through a search of national VA administrative data and copies of digital radiographs retrieved. Subjects were required to have bilateral baseline hand x-rays during the interval of between six months prior and one month after TNFi initiation and a set of follow-up bilateral hand x-rays during the interval between 10 and 18 months after TNFi initiation. Subjects with non-TNFi biologic disease modifying anti-rheumatic drugs (DMARDs) use prior to TNFi initiation or between baseline and follow-up x-rays were excluded. Cumulative TNFi exposure was calculated from VA administrative data and compared to change in mSS interpreted by a single evaluator blinded to sequence of x-rays and drug exposure history. A longitudinal marginal structural model using inverse probability of treatment weights was used to compare the impact of cumulative adherence on mean change in mSS. Baseline disease characteristics (e.g., smoking history, age, seropositive status, co-morbidities, and concurrent medication) and time-varying covariates (erythrocyte sedimentation rate, C-reactive protein, and prednisone) were assessed for clinical and statistical importance and included in the adjusted model in addition to the crude analysis.

Results: There were 114 patients from 36 sites who met enrollment criteria and had baseline and follow-up x-rays acceptable for evaluation. The population's baseline demographic features were: mean±standard deviation age 59±11 years, 84% male, 68% positive for rheumatoid factor, and 58% positive for anti-cyclic citrullinated peptide antibody (aCCP). Baseline mSS was 20.5±14.2 (median 10, range 0-145). We observed decreases in the magnitude of mSS changes with increases in treatment adherence (i.e., cumulative TNFi exposure). In comparison to patients with no TNFi adherence, patients with the highest adherence had 20.2% and 33.3% less radiographic progression for the crude and adjusted model analysis, respectively.

	Mean change in mSS					
Cumulative months of adherence	Crude Model			Adjusted Model		
	Mean change	95% C.I.	Percent Difference*	Mean change	95% C.I.	Percent Difference
<1	0.86	(-0.96, 2.68)		1.11	(-0.70, 2.93)	
3	0.82	(-0.48, 2.11)	5.1%	1.02	(-0.29, 2.33)	8.3%
6	0.77	(-0.11, 1.66)	10.1%	0.93	(0.01, 1.85)	16.6%
9	0.73	(-0.05, 1.51)	15.2%	0.84	(0.00, 1.37)	25.0%
12	0.66	(-0.40, 1.78)	20.2%	0.74	(-0.38, 1.86)	33.3%

* Percent difference is the percent change seen by dividing the difference between the mean change for cumulative months of zero adherence and the mean change for other cumulative months of adherence by the mean change for cumulative months of zero adherences.

Conclusion: The progression of radiographic changes as measured by mSS was very small during the one year of observation. While there was a trend for less progression in patients with increased adherence to TNFi therapy, these differences were not statistically significant.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients (pts) with early rheumatoid arthritis (RA), conventional synthetic DMARDs (csDMARDs), preferably methotrexate (MTX), are recommended as first line therapy.[1,2] For pts who remain in moderate to high disease activity (HDA), despite csDMARDs, TNF inhibitors are a potential treatment option.[1] The purpose of this analysis was to evaluate clinical, functional, and radiographic outcomes following the addition of adalimumab (ADA) to a subgroup of MTX insufficient responders (IR) who experienced rapid radiographic progression (RRP) and/or remained in HDA.

Methods: OPTIMA[3] was a 78-week (wk) randomized, double-blind, double-period trial comparing safety and efficacy of ADA+MTX with placebo (PBO)+MTX in early RA pts. This post hoc analysis included pts who received PBO+MTX for 26 wks (Period 1) and did not achieve stable low disease activity [LDA, DAS28(CRP) <3.2] at wks 22 and 26. These MTX-IR pts received open-label (OL) ADA+MTX for a subsequent 52 wks (Period 2) and were categorized at wk 26 by 1) whether they experienced RRP [change from baseline (BL) in modified total Sharp score (mTSS) >1.5] and 2) disease activity [HDA = DAS28(CRP) ≥5.1 or moderate (MDA) = 3.2≤ DAS28(CRP) <5.1]. For each subgroup, BL values and changes from BL in DAS28(CRP), CDAI, SDAI, HAQ-DI, and mTSS were analyzed.

Results: At wk 26, 348 (75.7%) PBO+MTX pts did not achieve stable LDA and received OL ADA+MTX for up to 52 wks. Among these MTX-IR pts, 64 (18.5%) experienced RRP during Period 1; 111 (31.9%) and 202 (58.0%) were in HDA or MDA, respectively. Pts experiencing RRP had significantly higher mean BL DAS28(CRP), SDAI, and mTSS compared with non-RRP pts (**Table**). Following ADA addition, mean DAS28(CRP) and SDAI decreased in RRP pts to levels that were comparable with those observed in non-RRP pts; while mean mTSS did not progress further in both groups. MTX-IR pts who remained in HDA, versus those in MDA, had significantly higher mean BL disease activity scores and less clinical and functional improvements at wk 26, indicating that high BL activity may be a predictor of poor response to initial MTX therapy (**Table**). Importantly, regardless of wk 26 disease activity status, the addition of ADA resulted in a decrease in mean disease activity and HAQ-DI; among pts starting Period 2 in MDA, but not HDA, mean disease activity scores fell below the LDA threshold after 52 wks of OL ADA+MTX therapy.

Conclusion: The addition of ADA in early RA pts with a poor response to initial MTX therapy led to a reduction in disease activity and prevention of further radiographic progression. Nearly 20% of pts accumulated radiographic damage during the 26 wks of MTX exposure; the identification of unique characteristics within these pts may allow for a differential therapeutic approach to preserve structural integrity. **References:**

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with loss of physical function, work disability, and decreased quality of life. Early treatment with certolizumab pegol (CZP) in combination with optimized MTX improves physical function[1] and workplace and household productivity[2] in DMARD-naïve, early RA patients (pts) after 1 year. Here, we report the impact on physical function, and workplace and household productivity of 2 years of CZP+MTX therapy in early, active RA pts with severe progressive disease.

Methods: Pts treated with CZP (200 mg Q2W+MTX) or placebo (PBO+MTX) from C-EARLY Period 1 (NCT01519791),[1] who achieved sustained low disease activity (sLDA; DAS28[ESR] ≤3.2 at both Weeks [Wks] 40 and 52) entered Period 2 (NCT01521923),[3] a randomized, double-blind dose withdrawal study. At Wk 52, CZP-treated pts in sLDA were randomized 2:3:2 to CZP standard dose (200 mg Q2W+MTX), reduced dose-frequency (200 mg Q4W+MTX), or CZP stopped (PBO+MTX). The percentage of pts achieving normative physical function (HAQ-DI ≤0.5) at Wks 52 and 104; employment status, workplace and household productivity (Work Productivity Survey, WPS),[4] and need for assistance at baseline (BL), Wk 52, and Wk 104 are reported. Missing values were imputed using last observation carried forward (LOCF).

Results: 84, 126, 79 pts in the CZP standard, reduced dose-frequency, and CZP stopped groups, respectively, comprise the full analysis set. Pt characteristics and employment status at BL and Wk 52 were generally similar across all groups. The proportion of pts achieving normative physical function was generally maintained from Wk 52 to Wk 104 in CZP standard and reduced dose-frequency pts. Fewer pts who stopped CZP maintained normative physical function to Wk 104. Employed pts continuing CZP treatment (standard and reduced dose-frequency) maintained improvements achieved at Wk 52 in workplace and household productivity to Wk 104, with some worsening seen in CZP stopped pts. Similar trends were observed in household productivity. At Wk 104, more pts who stopped CZP experienced the need for regular assistance with usual activities than pts continuing CZP treatment (standard and reduced dose-frequency) (Table).

Conclusion: Pts who continued CZP treatment at the standard or reduced dose-frequency maintained the initial improvements over the second year in normative physical function, and workplace and household productivity, and also maintained the reduced need for regular assistance from a relative or friend. A deterioration was seen from Wks 52–104 in pts who stopped CZP after 1 year. **References:** 1. Emery P. Ann Rheum Dis 2016;doi:10.1136/annrheumdis-2015-209057; 2. Emery P. Ann Rheum Dis 2015;74(S2):712; 3. Emery P. Ann Rheum Dis 2016;75(S2):143; 4. Osterhaus J.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with work disability, loss of productivity and reduced quality of life. In established and early RA, compared with MTX alone, certolizumab pegol (CZP)+MTX significantly improves the signs and symptoms of RA,[1] inhibits radiographic progression and improves workplace/household productivity.[2,3] In early RA, the association between reaching clinical targets and patient (pt) treatment targets, in terms of workplace and household productivity, has not been assessed. We evaluated the association between CZP-mediated stringent clinical targets and improvements in workplace/household productivity.

Methods: C-EARLY (NCT01519791) was a double-blind, randomized controlled trial, which enrolled DMARD-naïve pts with active, moderate to severe, progressive, early RA (<1 yr from diagnosis).[2] Pts were randomized 3:1 to CZP+MTX or placebo (PBO)+MTX. MTX was titrated to 15–25 mg/wk by Wk 8; maximum tolerated dose (optimized dose) was maintained to Wk 52. Associations between clinical responses and workplace/household productivity outcomes were evaluated at Wk 52 in CZP pts. Clinical response criteria included sustained remission (sREM: DAS28[ESR] <2.6 at Wks 40 and 52), sustained low disease activity (sLDA: DAS28[ESR] ≤3.2 at Wks 40 and 52), radiographic non-progression (mTSS change ≤0.5), and normative physical function (HAQ-DI ≤0.5). Changes from baseline (BL) at Wk 52 in workplace/household productivity (Work Productivity Survey [WPS][4]) were compared in responders/non-responders, using a non-parametric bootstrap-t method. Missing data were imputed using LOCF for WPS outcomes and NRI for clinical responses.

Results: 879 pts were enrolled; 655 pts in the CZP+MTX group were included in the full analysis set. At BL, 52.3% pts were employed; similar burden at BL was seen between groups, except in absenteeism/presenteeism for pts in sREM/sLDA. Overall, pts achieving sREM/sLDA and normative function reported greater improvements in workplace/household productivity at Wk 52 vs non-responders (Table). An association was not seen between radiographic non-progression and workplace/household productivity (Table). Responders also reported greater improvements in family and social leisure activity participation (data not shown).

Conclusion: Achieving stringent clinical targets, such as sREM/sLDA and normative physical function, were associated with numerically greater improvements in workplace and household productivity after 1 yr in DMARD-naïve pts with early, moderate to severe, progressive RA treated with CZP. The ability to return to maximum levels of participation early in the disease course is an important goal for pts with RA. **References:** 1. Strand V. Arthritis Res Ther 2009;11:R170; 2. Emery P. SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-TNFs neutralize the TNF-mediated component of inflammatory diseases such as rheumatoid arthritis (RA) and Crohn's disease (CD) to reduce disease activity. In this study, we aimed to identify the range of plasma certolizumab pegol (CZP) concentrations ([CZP]) associated with optimal improvement in disease activity for patients (pts) with RA and CD exposed to different dosing regimens.

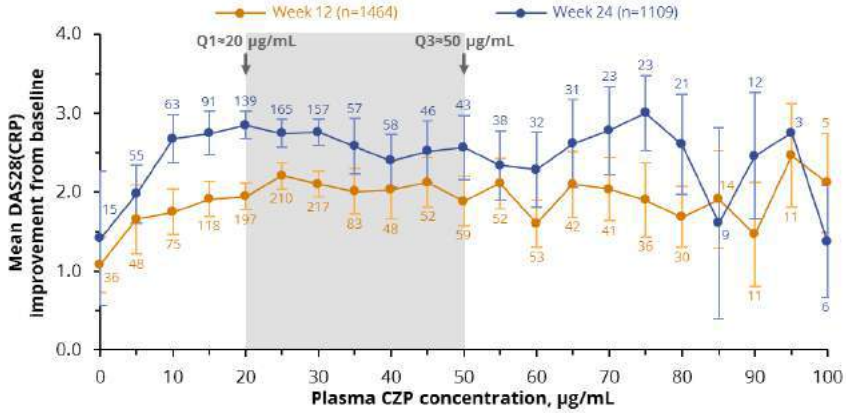
Methods: Efficacy endpoints by [CZP] were assessed using two methods: 1) correlation of measured [CZP] with disease activity (RA); 2) population PK/PD modeling (RA and CD). Observed RA data were from RAPID1 and RAPID2. Data for PK/PD modeling were pooled across multiple placebo-controlled CZP studies in RA and CD. RA pts were treated with a loading dose (CZP 400 mg at Weeks [Wks] 0, 2, 4) followed by a maintenance dose (RA: 200 mg or 400 mg Q2W). CD modeling was performed for the loading dose (CZP 400 mg at Wks 0, 2, 4) during induction phase, and maintenance dose (400 mg Q4W). [CZP] was measured using an ELISA validated in line with FDA/EMA regulatory requirements for bioanalytical methods. In RA, [CZP] was correlated with change from baseline in DAS28(CRP) (ΔDAS) and clinical disease activity index at Wks 12 and 24. In CD, [CZP] was correlated with Crohn's disease activity index (CDAI) remission (≤150 points), CRP response (≤5 mg/L), fecal calprotectin (FC) response (≤250 μg/g) and composite outcome (CDAI ≤150 and FC ≤250 μg/g) at Wks 6 and 26.

Results: In RAPID1/RAPID2 (n=1479 RA pts; data pooled for CZP 200 mg Q2W and 400 mg Q2W), the interquartile range (IQR) of measured [CZP] was 20–50 μg/mL, associated with ΔDAS ≥2.0 at Wk 12, and ΔDAS ≥2.4 at Wk 24 (Figure A). A similar [CZP] range was associated with improvement in clinical disease activity index (not shown). PK/PD modeling in RA (n=2621 pts) confirmed the [CZP] range observed for the CZP 200 mg Q2W and 400 mg Q2W regimens, with [CZP] ≥24 μg/mL associated with ΔDAS ≥2 at Wks 12 and 24. For the 400 mg Q4W regimen, similar ΔDAS improvements were predicted for [CZP] ≥15 μg/mL. In CD (n=2157 pts), receiver operating curve analysis showed a loading dose [CZP] of 36 μg/mL (Wk 6) and a maintenance [CZP] of 15 μg/mL (Wk 12) associated with response for the various outcomes analyzed (Figure B). In both RA and CD, predicted [CZP] thresholds associated with response were consistent with the IQRs of measured [CZP] (Figure C).

Conclusion: Based on these ELISA data, in pts with RA treated with the CZP 200 mg Q2W or 400 mg Q2W regimens, ΔDAS increased with [CZP] up to 20 μg/mL; the majority of pts had [CZP] ≥20 μg/mL, which was associated with a plateau effect in ΔDAS from Wk 12, averaging ~2.0 at Wk 12 and ~3.0 at Wk 24. PK/PD modeling predicted a lower [CZP] range for the 400 mg Q4W regimen, with similar efficacy. In pts with CD, the loading dose [CZP] range and association with efficacy were in line with RA results; maintenance [CZP] ranged 4–28 μg/mL.

Figure: Relationship between CZP concentration and improvement in disease activity in RA and CD patients

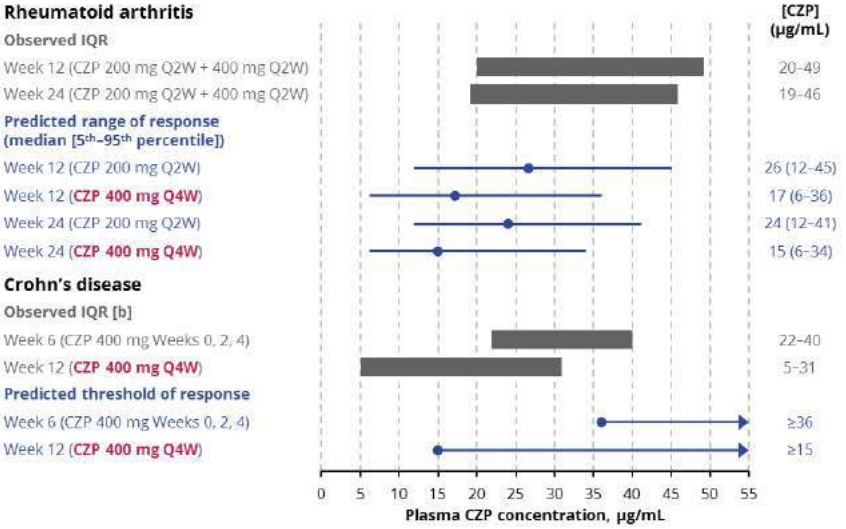
A) Observed concentration-effect curve of CZP in patients with RA (n=1479 patients from RAPID1 and RAPID2) [a]



B) Receiver operating curve analysis in CD of Week 6 and Week 12 plasma CZP concentration, and Week 6 and Week 26 outcomes (n=2157 patients)

Outcome	[CZP] Cut-off Week 6 (µg/mL)	Sensitivity (%)	Specificity (%)	[CZP] Cut-off Week 12 (µg/mL)	Sensitivity (%)	Specificity (%)
CDAI remission						
Week 6	31.8	57.2	55.7	-	-	-
CRP ≤5mg/L						
Week 6	31.9	65.1	69.4	-	-	-
FC ≤250 µg/g						
Week 6	32.7	73.9	60.3	-	-	-
Week 26	-	-	-	13.8	68.1	56.0
CDAI ≤150 and FC ≤250 µg/g						
Week 6	34.5	66.7	59.7	-	-	-
Week 26	36.1	67.1	65.0	14.8	73.2	57.3

C) Observed interquartile ranges of CZP concentration and predicted thresholds of clinical response according to the dosing regimens analyzed



Observed RA data were pooled from RAPID1/RAPID2 (RCTs: NCT00152386, NCT00160602; OLEs: NCT00175877, NCT00160641). Data for PK/PD modeling were pooled across multiple studies in RA (NCT00152386, NCT00160602, NCT00674362, NCT01451203, NCT01255761, NCT00791999, NCT00791921) and CD (C87005, NCT00152490, NCT00152425, NCT00329420, NCT00308581, NCT00552058). [a] Patients were grouped by [CZP] in 5 µg/mL increments (number of patients shown next to each data point); patients with [CZP] >100 µg/ml are not shown (26/1464 at Week 12 and 22/1109 at Week 24); error bars correspond to 95% confidence intervals; [b] Data from Vande Casteele, N. Inflamm Bowel Dis 2016;22:S42(P-103). CDAI: Crohn's disease activity index; FC: fecal calprotectin; IQR: interquartile range.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Although evidence from randomized trials suggest similar efficacy and safety on a group level for the different anti-TNF drugs available for the treatment of RA, and many treatment guidelines rank them as interchangeable in terms of effect, there are few head-to-head comparisons and limited real world data on their comparative effectiveness in clinical practice. Our objective was therefore to perform a head-to-head comparison of the initial effectiveness of different TNF inhibitors among bionaïve patients with RA in a large population-representative sample

Methods: The Swedish Rheumatology Register (SRQ) covers about 95% of all biological treatment of RA, with data on clinical characteristics prospectively recorded at treatment initiation and at subsequent patient visits. We included all patients with RA registered in the SRQ as starting etanercept, infliximab (including originator product and its biosimilar), adalimumab, certolizumab pegol, or golimumab as their first ever biological DMARD (N=6149) between 1st Jan 2010 and 31st July 2015, with follow-up through March 31st2016. Effectiveness was defined as 1) remaining on therapy, 2) being in remission or low disease activity (DAS28<2.6), and 3) having achieved a EULAR response, all at the evaluation visit at 5 (3-8) months after start (defined as the visit closest to 151 days of all visits between 60 and 242 days; this method has previously been shown to capture 95% of patients with follow-up visits within one year of treatment initiation). Differences in crude proportions were tested across drugs using χ^2-tests. To take baseline differences in patient

characteristics into account, relative risks were estimated using generalized log-binomial regression adjusting for sex, age, concomitant use of DMARDs, Rheumatoid Factor, HAQ, and disease duration.

Results: : Across all anti-TNF drugs, about 90% remained on therapy until the evaluation visit, and most patients remaining on drug also had a positive response, with about 40% having DAS28 below 2.6, and almost half reaching a good EULAR response. As shown in the Table, only the crude proportion with DAS28 below 2.6 was statistically significantly different across treatments (p=0.011), but this difference was no longer significant after taking baseline characteristics, and proportions discontinuing drug, into account. Although some one-on-one comparisons approached borderline significance (e.g. lower proportion discontinuing therapy in adalimumab *vs.*etanercept, p=0.06), the number of pairwise tests lead to risk of false positives, and the global test showed no significant inter-drug difference.

Conclusion: These results suggest limited differences in effectiveness among available TNF inhibitors for the treatment of RA in current clinical practice, at least regarding the initial response among previously bionaïve patients

Status at evaluation visit at 5 months among all patients with RA initiating TNFi as first ever biologic DMARD 2010-2015 in Sweden

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is generally believed that a wide variety of patient-specific factors, and in particular gender, are likely to influence the response and tolerability of DMARDs in patients with rheumatoid arthritis (RA).[1] In particular, several prospective studies have suggested that women may have lower remission rates than men as a result of having greater disease burden.[2]Despite this, very little is known about the true extent that many of these risk factors have on RA outcomes. The purpose of this analysis is to elucidate, via a meta-regression, the suspected relationship between female sex, drug retention rates and incidence of adverse events.

Methods: An extensive literature search for all RCT's involving treatment for RA with TNF inhibitors was performed and 18 studies were identified (including 2 studies assessing Certolizumab pegol, 6 that assessed Golimumab, 3 that assessed Infliximab and 7 that assessed Adalimumab). Meta-regression analysis, employing a random-effects model, was performed to evaluate whether gender may have influenced effect size among these four TNF-inhibitors. Outcomes evaluated included drug retention, drug discontinuation, adverse events, serious adverse events, serious infections and infusion reactions.

Results: The proportion of female participants in a given treatment arm was highly statistically significantly correlated with improved drug retention in that, for every 1% improvement in drug retention, a 1.03% increase in female participants (95% CI 0.65-1.41%, p=<0.0001) was observed. Similarly lower rates of drug discontinuation (and in particular - Lack/Loss of efficacy, Adverse events and Other- as a reason for drug discontinuation), serious adverse events, serious infections and infusion reactions were also associated with increasing proportions of female participants in the included studies. These models were adjusted for all relevant covariates of interest including age, study size and disease severity.

Conclusion: Female gender seems to be correlated with increased drug retention and decreased rates of study discontinuation for a variety of causes. This finding belies prior consensus on this topic and warrants further research this potential relationship in larger prospective cohort trials. **References:** 1.- Hider Samantha L, Buckley Caitriona, Silman Alan J, et al. Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis) is a Phase 4 comparator study designed to provide a real-world evidence (RWE) based assessment of intravenous golimumab (G-IV) and infliximab (IFX) in patients (pts) with rheumatoid arthritis (RA). Assessments include medical history, RA disease history, prior biologic RA therapies, clinical outcomes, infusion reactions, cost effectiveness, and safety. Here we report on prior biologic use patterns of an early cohort of AWARE pts.

Methods: This is a prospective, noninterventional, observational multicenter study being conducted in the United States, with 2-year study enrollment period and 3-year study duration. 1,200 adult RA pts will be enrolled to initiate treatment with either G-IV or IFX. All treatment decisions are made at the discretion of the treating rheumatologist; patient (pt) visits occur as per usual clinical practice. The primary objective is to compare the proportion of pts with an infusion reaction in RA pts treated with G-IV vs IFX. Secondary objectives include effectiveness assessments, cost effectiveness and patient reported outcomes (PROMIS-29, Pain Interference SF6b, Fatigue SF7a, SF36) and a novel Treatment Satisfaction Questionnaire for Medication–Intravenous, which assesses patient satisfaction with an infusion therapy.

Results: Mean (±SD) age of pts (n=114) was 59.7 (±12.02) years, with a mean body weight of 85.95 kg, 82.5% of pts were female. A total of 74 pts were administered G-IV and 40 pts were administered IFX. Overall, 69.0% of pts reported to have received at least 1 biologic prior to enrolling. Proportion of bionaive patients among G-IV users and IFX users were 23.3% and 45.0%, respectively. Concomitant methotrexate (MTX) use was reported in 54.1% of G-IV pts and 70.0% of IFX pts. Among all non-bionaïve pts, the most frequently used biologic was adalimumab (31.6%). A similar proportion of G-IV and IFX pts had prior adalimumab (32.4% and 30.0%, respectively), prior etanercept was reported in 29.7% of G-IV pts and 10.0% of IFX pts. Of the G-IV pts, 39.2% had prior exposure to IFX, and 15.0% of IFX pts had prior exposure to G-IV. Subcutaneous golimumab was used in 5.0% of IFX pts, and 2.7% of the G-IV pts. Abatacept was previously used in 18.9% of G-IV pts and 0% of IFX pts. 10.8% of G-IV pts had prior exposure to tocilizumab, 2.5% of IFX pts had prior exposure to that drug. Baseline CDAI scores were 33.67 (±14.8) in G-IV pts and 35.14 (±16.1) in IFX pts.

Conclusion: In this Phase 4 study, early evaluation of patient demographics confirms published data of current patients treated with biologic agents who have RA. Early analysis of previous biologic use in this RWE study exploring potential differences between G-IV and IFX, indicates that there may be differences in the extent of prior biologic experience of pts treated with either one of these drugs. Patients started on G-IV appeared to have had more extensive prior biologic experience and less concomitant MTX use compared to IFX pts. Greater MTX use by IFX pts may be related to the greater proportion of bionaïve pts in the IFX group. Such differences may have relevance in terms of ultimate efficacy, safety, and cost effectiveness in managing RA pts.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Dose escalation is a common strategy for patients (pts) on infliximab (IFX). This study examined the trend in disease activity across dose escalations to determine if dose escalation resulted in progressive lowering of disease activity.

Methods: Rheumatoid arthritis (RA) pts enrolled in the US Corrona registry initiating IFX on or after 1/1/2007 with an initial dose of 3mg/kg/Q8 weeks were identified. Eligible patients had at least 1 dose escalation and at least one follow-up visit after 1st dose escalation. Dose escalation was defined as an increase of >1mg/kg in dose and/or an increase in the frequency of dosing by ≥1 week. Trends in disease activity (CDAI) and functionality (HAQ) were summarized over time and scaled to number of dose escalations (CDAI at visits between escalations scaled to proportion of time between escalations). Locally weighted scatterplot smoothing (Lowess curve) were used to estimate trends over time.

Results: Eligible pts (N=185) had a mean 7.5 years duration of RA and 72.4% were female; mean CDAI (SD) was 19.6 (13.2) at time of initiation and 16.6 (12.0) at 1st dose escalation. Figure 1 shows the estimated mean CDAI over time for pts with 3 dose escalations and Figure 2 shows estimated CDAI for pts with 4 dose escalations. In pts with 3 dose escalations (n=30), there is a progressive decrease in mean CDAI from initiation until the 2nd dose escalation, and then the mean CDAI remains at a plateau. In pts with 4 dose escalations (n=12), the decrease in mean CDAI is less and the overall level of disease is higher; trends in HAQ are flat across 3 dose escalations (Figure 3).

Conclusion: Initial dose escalations (i.e. the first two) provide reduction in mean CDAI, while later dose escalations are related to maintaining disease activity levels. Pts with ≥3 dose escalations had higher levels of initial disease activity, smaller initial response, and little subsequent reduction in disease activity after the first two dose escalations. These results have potentially important clinical implications since these data suggest there may be diminishing clinical benefit in at least a subset of patients beyond the initial 2 dose escalations and that an assessment of the risk-benefit of further dose escalations should be considered.

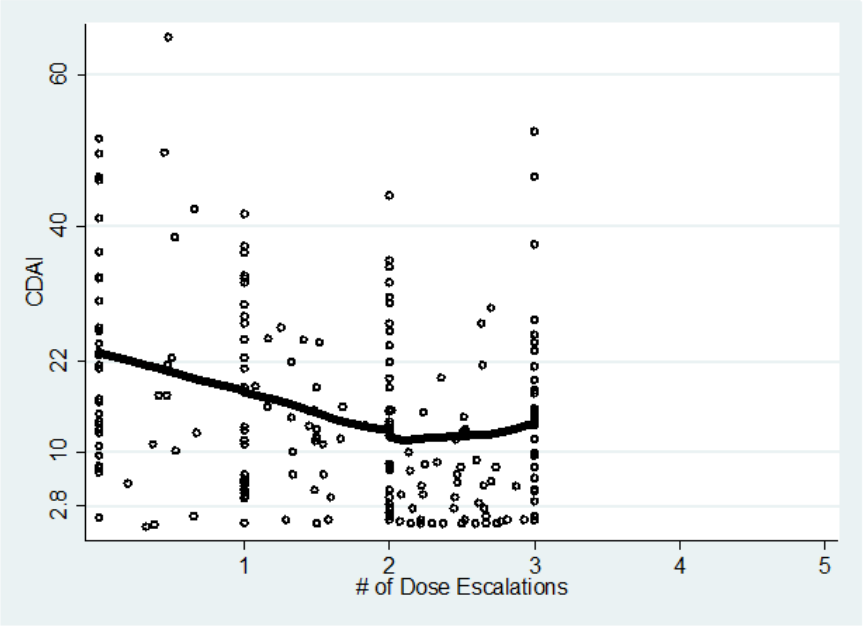

Figure 1. Lowess curve of CDAI in patients with 3 dose escalations

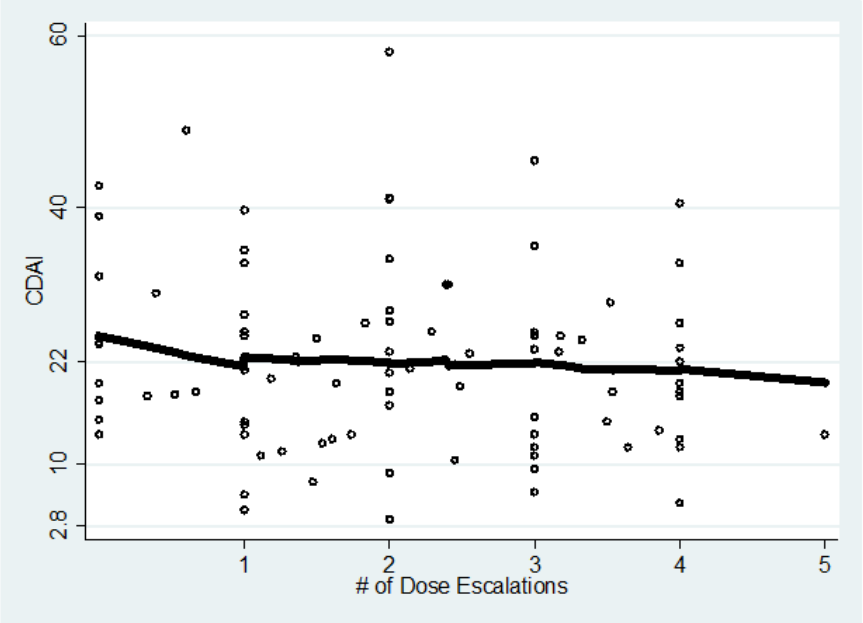

Figure 2. Lowess curve of CDAI in patients with at least 4 dose escalations

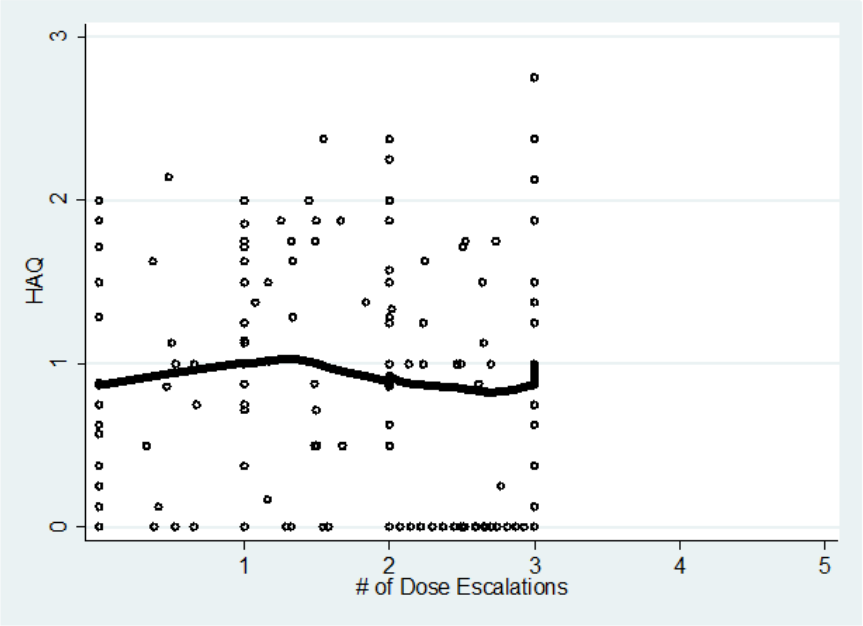

Figure 3. Lowess curve of HAQ in patients with 3 dose escalations

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Methotrexate (MTX) is known to improve exposure and clinical outcome to anti-tumor necrosis factor (TNF) therapy. While the precise mechanism of action for the pharmacokinetic interaction is still elusive, immunosuppression and reduction in the likelihood of antidrug antibodies are likely significant contributors. This pilot study evaluated the impact

of MTX polyglutamation on anti-TNF exposure.

Methods:

The study was cross sectional by design, multicentered (three sites), and enrolled 230 consecutive adult rheumatoid arthritis subjects under MTX in combination with infliximab (61 subjects), adalimumab (83 subjects) or etanercept (86 subjects) for at least 12 weeks. At the time of a single visit, anti-coagulated blood was collected immediately before the infliximab infusion (trough) or randomly in relation to the last subcutaneous injection of adalimumab or etanercept. Steady state trough infliximabemia, random adalimumabemia or etanerceptemia were determined using a TNF reporter gene assay with chemiluminescent detection (expressed as µg/ml plasma). Red blood cells (RBC) MTX polyglutamates ($MTXPG_3$) were determined using liquid chromatography (expressed as nmol/L RBC). C-reactive protein (CRP) levels were determined using standard chemistry techniques (expressed as mg/L). Statistical analysis consisted of multivariate linear regression with anti-TNF exposure as dependent variable and RBC $MTXPG_3$ as independent predictor, adjusting estimates for TNF dosage, obesity status (BMI>30 Kg/m^2) and CRP levels. Estimates are reported as average±SEM.

Results:

All subjects enrolled in this study (59±1 years; 82% females) were under MTX therapy 8.8±0.4 years and prescribed anti-TNF therapy for 5.2±0.2 years. MTX dosage was 16±0.4 mg/week and RBC $MTXPG_3$ levels were 36±1 nmol/L. CRP levels were 8.7±0.6 mg/L with 35% obese subjects. Exposure to Infliximab (7.4±0.6 mg/Kg every 8 weeks), adalimumab (42±1 mg every other week) and etanercept (49±0.7 mg weekly) was 11.8±0.8 µg/ml, 6.2±0.9 µg/ml, and 3.2±0.2 µg/ml respectively. Higher anti-TNF dosage resulted in higher exposure to all biologics, while obesity status had a negative impact on infliximab and adalimumab exposure. Elevated CRP levels tended to be associated with lower exposure to all monoclonal antibodies. Heightened $MTXPG_3$ levels resulted in increased infliximabemia (partial R^2=0.09; p<0.01) and adalimumabemia (partial R^2=0.06; p=0.02) while polyglutamation had no impact on etanercept exposure.

Conclusion:

These data are consistent with the notion that MTX polyglutamation may impact exposure to infliximab and adalimumab that are immunogenic and prone to anti-idiotype antibody formation. Because etanercept is a fusion TNF receptor construct with little incidence of antidrug antibodies, the impact of MTX metabolism on its exposure is negligible.

Table: Multivariate analysis of anti-TNF exposure in relation to MTX polyglutamation after adjusting for dosage, obesity status, and CRP levels.

	Trough Infliximabemia µg/ml [n=61]	Random Adalimumabemia µg/ml [n=83]	Random Etanerceptemia µg/ml [n=86]

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: EULAR, ACR and treat-to-target guidelines recommend switching treatment in inadequate responders (IRs) to alternative therapy by Week (Wk) 12.[1-3] Although any biological (b)DMARD can be initiated in conventional synthetic (cs)DMARD IRs, many practitioners use a TNF inhibitor (TNFi) for primary biologic treatment. For TNFi IRs, an immediate switch to a second TNFi may be proposed despite there being no blinded, prospective clinical trials demonstrating the efficacy and safety of the immediate use of a second TNFi. EXXELERATE is the first randomized controlled trial (RCT) to address immediate switching to another TNFi, in a TNFi IR patient (pt) population.

Methods: EXXELERATE (NCT01500278) was a 104-wk randomized, investigator-blind, parallel-group, head-to-head superiority study comparing the early (Wk 12)- and later (Wk 104)-term efficacy and safety of certolizumab pegol (CZP)+MTX vs adalimumab (ADA)+MTX (Figure). Pts were randomized 1:1 to CZP+MTX or ADA+MTX. At Wk 12, pts were classified as responders (achieving either DAS28[ESR] ≤3.2 or a DAS28[ESR] reduction from baseline [BL] of ≥1.2), or non-responders (NRs). NRs originally randomized to CZP were switched to ADA, while NRs to ADA were switched to CZP (Figure). A pre-defined exploratory objective assessed early- and later-term efficacy of switching to a second TNFi using ACR20/50/70, low disease activity (LDA) and remission (REM). The safety of switching TNFi without a washout period was assessed by monitoring all TEAEs occurring after treatment switch and within 70 days of the final dose of initial study drug.

Results: At BL, 457 pts were randomized to CZP and 458 to ADA. Of the 122 pts who switched and continued after Wk 12, 65 CZP NRs were switched to ADA and 57 ADA NRs switched to CZP. Clinical improvement was observed in a considerable proportion of pts (Table); 33 pts (55.9%) switching to CZP and 40 pts (60.6%) switching to ADA responded 12 wks later (Wk 24) by achieving DAS28(ESR) ≤3.2 or a DAS28(ESR) reduction from Wk 12 of ≥1.2 and were classed as secondary responders. Further improvements in various measures of clinical efficacy were observed, though less so than the level achieved by primary responders (Table). A similar proportion of ADA to CZP and CZP to ADA pts reported TEAEs occurring after treatment switch and within 70 days of the final dose of initial study drug (n=24, 40.7%; n=30, 45.5%). There were no reported serious infectious events (SIEs).

Conclusion: EXXELERATE demonstrated that efficacy can be achieved using a second TNFi in a proven primary TNFi failure pt population. Furthermore, these results expand current RCT data by providing, in a controlled setting, clinical evidence for the safety of an immediate switch from one TNFi to another without a washout period, and demonstrating no increase in SIEs. **References:** 1. SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: SB4 is approved by the European Medicines Agency as a biosimilar of the reference etanercept (ETN). Long term safety and efficacy of SB4 up to Week 100 have been reported previously.[1] Additional long term efficacy results will be reported.

Methods: In the phase III 52-week randomized, double-blind period of the study, patients with moderate to severe rheumatoid arthritis (RA) were treated with either 50 mg/week SB4 or ETN with background methotrexate (MTX). Patients in Czech Republic and Poland were enrolled into the following 48-week open-label, extension period of the study and received SB4. Efficacy in terms of ACR responses, disease activity score based on 28 joints (DAS28), simplified disease activity index (SDAI), clinical disease activity index (CDAI), and health assessment questionnaire-disability index (HAQ-DI) up to week 100 were compared. Radiographic progression was measured through modified Total Share Score.

Results: 245 patients from the randomized, double-blind study period enrolled into the extension study: 126 patients continued to receive SB4 (SB4/SB4) and 119 patients switched from ETN to SB4 (ETN/SB4). The ACR responses were comparable between SB4/SB4 and ETN/SB4 and they were also sustained in the extension period. The mean DAS28, SDAI, and CDAI were comparable between SB4/SB4 and ETN/SB4 during the extension period (Figure). At Week 100, similar proportion of patients achieved low disease activity based on DAS28, SDAI, or CDAI (49.2% vs. 54.8%; 33.3% vs. 38.3%; 30.9% vs. 40.0% in SB4/SB4 and ETN/SB4, respectively) and remission based on DAS28, SDAI, or CDAI (30.3% vs. 34.8%; 30.9% vs. 33.9%; 32.5% vs. 28.7% in SB4/SB4 and ETN/SB4, respectively). Patient-reported outcome measured by HAQ-DI was also comparable between SB4/SB4 and ETN/SB4 up to week 100. Radiographic progression was comparable and negligible between SB4/SB4 and ETN/SB4.

Conclusion: Long-term efficacy including DAS28, SDAI, CDAI, and HAQ-DI was comparable between SB4/SB4 and ETN/SB4 during the extension period. Efficacy was sustained after switching from ETN to SB4.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: SB5 has been developed as a biosimilar of the reference adalimumab (ADL). The 24-week results of the phase III study have been reported.[1] Efficacy, safety, and immunogenicity results in the transition period (Week 24 to Week 52) will be presented.

Methods: Patients with RA were randomized in a 1:1 ratio to receive either 40 mg of SB5 or ADL every other week with background methotrexate. After 24 weeks of treatment, patients in the ADL group were re-randomized (1:1) to either be transitioned to SB5 (ADL/SB5) or continue on ADL (ADL/ADL) up to Week 50. Patients receiving SB5 continued to receive SB5 (SB5/SB5) but they followed the randomization procedure for blinding purposes. Efficacy, safety, and immunogenicity were assessed up to Week 52.

Results: After 24-weeks of treatment, 254 patients from SB5 continued to receive SB5 (SB5/SB5), 125 patients from ADL were transitioned to SB5 (ADL/SB5), and 129 patients from ADL continued to receive ADL (ADL/ADL). Baseline characteristics at baseline and disease activities at re-randomization were comparable across treatment groups. The ACR responses were sustained and comparable across treatment groups during the transition period in the full analysis set (Figure). At Week 52 the ACR20 response rates were 76.9% vs. 81.1% vs. 71.2% in SB5/SB5, ADL/SB5, and ADL/ADL in the per-protocol set. Other efficacy endpoints including radiographic change were also comparable across the treatment groups. The mean change from baseline in modified Total Sharp Score was 0.17 in SB5/SB5 vs. 0.25 in ADL/SB5 vs. 0.50 in ADL/ADL. The safety profile during the transition period was comparable across treatment groups. The proportion of patients with any treatment-emergent adverse events after transition was 32.3% in SB5/SB5, 37.6% in ADL/SB5, and 33.1% in ADL/ADL and two patients in ADL/ADL group only newly reported injection site reactions. The incidence of anti-drug antibody after transition was 15.7% vs. 16.8% vs. 18.3% in SB5/SB5, ADL/SB5, and ADL/ADL, respectively.

Conclusion: Efficacy, safety, and immunogenicity profiles were comparable between SB5/SB5, ADL/SB5, and ADL/ADL during the transition period (Week 24 to Week 52). There were no treatment emergent issues or clinically relevant

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: M923 (BAX923), which is jointly being developed by Momenta and Baxalta, is a proposed biosimilar of reference adalimumab. Reference adalimumab is recognized to elicit antidrug antibodies (ADAs; seroconversion) in a significant proportion of patients, with a potential negative impact on efficacy. Host factors, including nature of the disease and background immunosuppressive therapy, are associated with the frequency of seroconversion. Normal healthy volunteers provide a relatively homogeneous and sensitive population in which to assess the relative immunogenicity of M923 and reference adalimumab with a focus on factors that are inherent to the products.

Methods: 324 healthy volunteers were randomized 1:1:1 to receive a single 40 mg dose of M923, US-sourced reference adalimumab, or EU-sourced reference adalimumab by subcutaneous injection then followed for 10 weeks, during which serum concentration of adalimumab and ADAs were recorded. Samples were screened for antibodies to M923, then confirmed for binding, sequentially, to EU reference adalimumab, US reference adalimumab, and M923. Samples positive on any confirmation assay were assessed for titer, neutralizing capacity (nADAs), and the presence of ADAs of IgE isotype. Bioequivalence of primary PK endpoints (C_{max}, AUC_{0-inf}, and AUC_{0-336}) was assessed in the primary analysis set (all evaluable subjects), and explored in subsets characterized by ADA and nADA status.

Results: The incidence, titer, time to emergence of ADAs, and proportion with nADAs were similar across groups (proportion of subjects with confirmed ADAs/nADAs positive titers: M923 = 78.0%/16.5%; US reference adalimumab = 80.6%/27.8%; EU reference adalimumab = 78.5%/20.6%). Presence of high titer nADAs was also associated with presence of IgE ADAs and with a reduction in exposure. PK bioequivalence, defined as 90% confidence intervals (CIs) for the geometric least squares mean ratios for all comparisons were within the confidence bounds of 80.00 to 125.00%, was achieved for all primary PK endpoints. Specifically, for the comparison of M923 with US reference adalimumab, the geometric LS mean ratios (90% CI) were C_{max} = 102.58 (97.31-108.14); AUC_{0-inf} = 104.20 (96.47-112.54); and AUC_{0-336} = 102.94 (97.88-108.27); similar results were observed for comparisons of M923 with EU reference adalimumab, and between US and EU reference adalimumab.

Conclusion: M923, demonstrated equivalent PK and comparable immunogenicity relative to both US- and EU-sourced reference adalimumab following administration of a single dose in normal healthy volunteers. Seroconversion and nADA formation were sufficiently frequent to support a robust comparison of immunogenicity and assessment of impact of ADA formation on PK.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ONS-3010 is being developed as a biosimilar candidate of Humira® (Adalimumab), a full-length recombinant human IgG1 monoclonal antibody specific for TNFα. This study evaluated the bioequivalence (BE) of single-dose pharmacokinetics (PK), safety and tolerability of ONS-3010 with specific assessment of immunogenicity compared to EU Humira® and US Humira®.

Methods: One hundred and ninety-eight (198) healthy male/female subjects (66 subjects per treatment group, gender balanced), were randomized to this double blind, single-dose study. The study duration was 14 weeks (screening: 4 weeks; PK/safety: 10 weeks). The subjects received a subcutaneous dose of 40 mg with either ONS 3010 or Humira® (EU or US product). PK and immunogenicity blood samples were collected at regular intervals. BE was assessed using general linear model procedures in SAS®, ANOVA on ln-transformed $AUC_{0-\infty}$, C_{max} (primary endpoints) and $AUC_{0\text{-last}}$. The ratio of geometric means with its 90% confidence intervals (CI), were calculated for $AUC_{0\text{-last}}$, $AUC_{0-\infty}$, and C_{max}. Equivalence bounds of 80.00-125.00% were used (ratio of geometric means [ONS-3010/Humira]: $AUC_{0-\infty}$, $AUC_{0\text{-last}}$, C_{max},). Adverse events (AEs) and serious AEs (SAEs) were monitored and recorded. Positive immunogenicity samples were investigated for specificity of binding.

Results: The PK profiles for EU Humira®, US Humira® and ONS-3010 were similar in shape (Figure 1). On the primary endpoints, $AUC_{0-\infty}$ and C_{max}, equivalence was demonstrated (i.e., ratio of geometric means ONS-3010/EU Humira® 1.03 [CI: 0.94 – 1.20] and 1.00 [0.92 – 1.08], ONS-3010/US Humira® 1.06 [0.94 – 1.20] and 1.06 [0.98 – 1.15], EU Humira®/US Humira® 1.04 [0.92 – 1.17] and 1.07 [0.99 – 1.15], for $AUC_{0-\infty}$ and C_{max} respectively). Equivalence was also demonstrated for the secondary PK endpoint, $AUC_{0\text{-last}}$. One SAE reported in the ONS-3010 treatment group led to hospitalization (bacterial abscess [Lymphadenitis colli]). AEs were evenly divided over treatments, usually mild in severity, and self-limiting (Table 1). Immunogenicity results showed similar profiles in the 3 treatment groups for anti-drug and neutralizing antibodies.

Figure 1 Concentration-Time Profiles

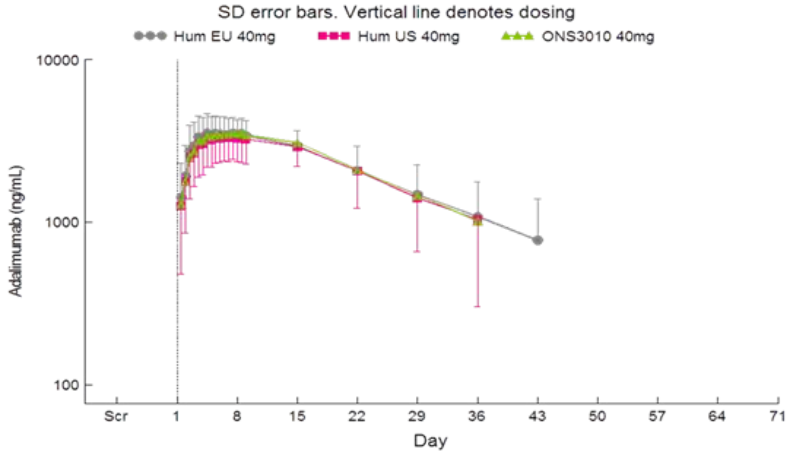

Table 1 Most Frequently Reported* Adverse Events

Preferred Term	ONS-3010 N (%)	Humira® EU N (%)	Humira® US N (%)
Burning sensation	12 (18.2)	29 (43.9)	31 (47.0)
Headache	29 (43.9)	20 (30.3)	27 (39.4)
Nasopharyngitis	12 (18.2)	19 (28.8)	12 (18.2)

*Regardless of relationship

Conclusion: The PK data for Humira® and ONS-3010 showed similar profiles over time. Equivalence was demonstrated on the primary ($AUC_{0-\infty}$ and C_{max}) and secondary (AUC_{0-last}) endpoints. There was no significant difference in immunogenicity or overall safety, except for a reduction in the burning sensation at the ONS-3010 injection site.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have reported that women with RA had higher level of pain, disease activity and functional impairment compared to men. In addition, women also seem to response less than men to biologic DMARDs (bDMARDs) and non-biologic DMARDs (nbDMARDs). Outcomes: Describe the disease activity and the clinical response to methotrexate (MTX) and bDMARDs in men and women with RA and evaluate the factors that could influence difference observed between genders.

Methods: Data on RA patients starting a treatment with MTX or a first bDMARD were extracted for the Rhumadata clinical database used in two rheumatologic centers. The baseline characteristics, the duration of the disease before the initiation of treatment, the concomitant treatments, the inflammatory markers (sedimentation rate, C-reactive protein) and the immunologic factor (rheumatoid factor, Anti-CCP) were extracted according to gender. A univariate analysis comparing the mean change between the men and women in the methotrexate and in the biologic groups was conducted for the « Health Assessment Questionnaire (HAQ)» and the « Clinical Disease Activity Index (CDAI) » at 6 and 12 months. A mutivariate analysis comparing those same parameters to adjust for the different baseline's characteristics is being conducted.

Results: 922 women (mean age: 53 (± 13); mean disease duration: 1.3 years (± 5.3)) and 316 men (mean age: 57 (± 12); mean disease duration: 1.5 years (± 5.4)) started MTX. 548 women (mean age: 54 (± 13); mean disease duration: 7.6 years (± 7.7)) and 159 men (mean age: 56 (± 12); mean disease duration: 6.6 years (± 7.4)) started a first bDMARD (TNFi: 84%). In the univariate analysis, the mean HAQ score at baseline, 6 and 12 months were higher in women than in men in the MTX group. However, both groups had a similar means change in HAQ score at 6 and 12 months. For the CDAI score, women and men in both groups had similar score at baseline, 6 and 12 months. Mean change in the CDAI score at 6 and 12 months was a slightly higher in men than women in both treatment groups, but the change was not statistically significant.

Conclusion: In this cohort of RA patients, women seem to have a more severe functional impairment throughout their illness, but do not seem to have a poorer response to nbDMARDs and bDMARDs compared to men. The analysis evaluating factors influencing disease activity changes over time in men and women is ongoing. Table

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although available data have suggested successful withdrawal of anti-TNF monoclonal antibodies after achieving low disease activity (LDA) or remission in patients with rheumatoid arthritis (RA), longer term follow-up data are needed to confirm these findings. The purpose of this study was to evaluate the feasibility of long-term adalimumab (ADA) discontinuation after achievement of LDA in Japanese patients with early RA.

Methods: In HOPEFUL-1, patients received initial therapy with either ADA 40 mg eow plus methotrexate (MTX weekly 6-8 mg) (intensive therapy) or MTX alone (MTX 6-8mg weekly, standard therapy) for 26 weeks, together followed by OL ADA+MTX for 26 weeks. In HOPEFUL-2, patients, who have continued ADA at the end of HOPEFUL-1, received OL ADA+MTX (ADA continuation) or OL MTX alone (ADA discontinuation) based on patient and physician decision for 52 weeks. HOPEFUL-3 was an observational study which included patients who had completed HOPEFUL-2 and continued for up to an additional 104 weeks. To assess efficacy, the primary endpoints were changes in 28-joint disease activity scores using C-reactive protein (DAS28-CRP) and the proportion of patients who achieved sustained LDA (DAS28–CRP <3.2) at week 208. Other endpoints, including modified total Sharp score (mTSS), were also evaluated. We compared the efficacy results between patients who received initial intensive therapy and standard therapy in HOPEFUL-1, and between patients who continued and discontinued ADA in HOPEFUL-2, using Fisher's exact test or the chi-square test for categorical variables, and the Wilcoxon rank sum test for continuous variables. To assess safety, all adverse events during HOPEFUL-3 were recorded. Fisher's exact test was used to compare the total number of adverse events between the ADA continuation and discontinuation groups.

Results:

Of 172 patients enrolled, 135 (ADA continuation, n=61; ADA discontinuation, n=74) with DAS28–CRP at both week 52 (start of HOPEFUL-2) and week 208 (end of HOPEFUL-3) were included in the effectiveness analysis. . Initial intensive therapy was associated with better outcome in terms of structural remission at week 208 compared with standard therapy (64% vs. 30%). At week 208, 59/74 (79.7%) and 58/61(95.1%) patients who discontinued and continued ADA, respectively, were in sustained LDA (p=0.01). The incidence of adverse events was significantly lower in the ADA discontinuation group than in the ADA continuation group (9.7% vs. 34.2%, p<0.001).

Conclusion: Approximately eighty percent of patients who discontinued ADA for 3 years after achieving LDA with ADA+MTX had sustained LDA with a lower incidence of adverse events than patients who continued ADA. Initial intensive therapy with ADA+ MTX demonstrated greater structural remission at 4 years compared to initial standard therapy with MTX alone despite 3 years of ADA discontinuation.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Rheumatoid Arthritis (RA) experience loss of productivity such as missing their work and lowering their performance incurred by impaired physical functioning. Treatment with ADA resulted in significant sustained improvements in RA-related work productivity and activity impairment (AI) in Japanese patients with RA (DOI: 10.1136/annrheumdis-2016-eular.3068). The objective of this study is to assess economic impact of ADA on Japanese RA patients in the real-world setting.

Methods: In this 48-week, multicenter, prospective single-cohort study (ANOUVEAU study), 1,973 RA patients treated with ADA were asked to complete self-reported questionnaire on their work every 12 weeks. Of those, the data of 1,196 patients were available and were included in this analysis. The cohort was stratified into the following baseline employment status: Paid Worker (PW), employed for ≥ 35 hours/week n=649, Part Time Worker (PTW), employed for < 35 hours/week n=172 and Home maker (HM), non-employed n=375. Work-related outcomes including absenteeism (work time missed), presenteeism (impairment while working) and Overall Work Impairment (OWI) as well as AI were evaluated using the Work Productivity and Activity Impairment questionnaire for Rheumatoid Arthritis (WPAI-RA). The amount of productivity loss was estimated by multiplying absenteeism, presenteeism and OWI by the national average occupational wage rates for PW and PTW, and by multiplying AI by the estimated wage rate for domestic work for HM. Primary outcomes were 12-week change in productivity loss and cumulative reductions achieved with ADA treatment

during the study period.

Results: The amounts of productivity loss estimated from OWI at baseline and 12-week productivity loss at week 12, week 24, week 36, and week 48 were 5,106 USD, 3,322 USD ($p< 0.01$), 2,978 USD ($p< 0.01$), 2,901 USD ($p< 0.01$), and 2,828 USD ($p< 0.01$) for PW, and 3,791 USD, 2,899 USD ($p= 0.11$), 2,618 USD ($p= 0.02$), 2,424 USD ($p< 0.01$), and 2,278 USD ($p< 0.01$) for PTW, respectively (1 USD= 110 JPY, p-value for change from baseline, t-test). Moreover, the productivity loss estimated from AI at week 12, 24, 36 and 48 were 4,261 USD, 2,954 USD ($p< 0.01$), 2,618 USD ($p< 0.01$), 2,623 USD ($p< 0.01$) and 2,558 USD for HM, respectively ($p< 0.01$). The cumulative reductions in productivity loss for OWI, obtained from ADA treatment, at week 48 were 6,740 USD for PW and 3,148 USD for PTW. The reduction for AI at week 48 was 6,239 USD for HM.

Conclusion: In this study, the annual amounts of reduction in productivity loss of RA patients achieved from ADA treatment were estimated 6,740 USD for PW, 3,148 USD for PTW and 6,239 USD for HW. Given that the average annual income in Japan in 2014 was 37,727 USD, the results show that ADA has considerable economic impact on RA patients.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previously, several studies have meta-analyzed clinical, functional or structural efficacy of biologics in treating rheumatoid arthritis (RA) patients. However, the comparative efficacy of biologics in inhibiting radiographic progression from a long-term perspective is still not fully understood. We compared 1-year radiographic efficacy of biologics using a Bayesian network meta-analysis (NMA), and reviewed radiographic data for up to 10 years

follow-up.

Methods: A systematic literature search of published peer-reviewed articles and scientific meeting abstracts identified randomized controlled trials investigating approved biologic therapies in combination with methotrexate (MTX) or tocilizumab alone in predominantly biologic-na•ve (< 20% biologic experienced) RA patients. Structural damage was analyzed as change from baseline using the modified van der Heijde Total Sharp Score (vdHS). One-year data were included in the NMA. Model parameters were estimated in a Bayesian framework using noninformative prior distributions. Longer term data (>1 year) was reviewed qualitatively in absence of sufficient data points for analysis. To assess the effect of biologic therapies in specific subpopulations, subgroup analyses were performed on: DMARD na•ve, DMARD inadequate responders, early RA, and established RA.

Results: Eleven clinical trials were identified and included in the NMA model. All biologics in combination with MTX showed decreased radiographic progression at 1 year compared to MTX alone, as defined by negative mean difference in vdHS change (Figure). Most interventions showed statistically significant effect, except for golimumab 50 mg every 4 weeks and tocilizumab 8mg/kg every 4 weeks.The largest statistically significant mean difference at 1 year was in adalimumab, where the increase in vdHS was 3.8 fewer units in patients administered adalimumab 40 mg every 2 weeks + MTX compared with those receiving MTX alone. Patients treated with infliximab 3 mg/kg every 8 weeks had the next highest relative effect at -3.7 versus MTX alone. Longer term radiographic data were found in 8 unique trials spanning 2 to 10 years of follow-up that demonstrate sustained slowing of radiographic progression for the following biologics (abatacept, certolizumab, etanercept, golimumab, infliximab and tocilizumab) in combination with MTX and adalimumab (+/-MTX). While the long term data did not contradict the efficacy of the 1-year outcomes, only 3 biologics (adalimumab, golimumab, tocilizumab) had 5 years of follow-up and only adalimumab had 10 years of follow-up. Subgroup results yielded consistent findings.

Conclusion: Biologics generally inhibit the progression of structural damage from a long-term perspective. Although some biologics like adalimumab have demonstrated radiographic benefits for up to 10 years, more research is needed to replicate this finding.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

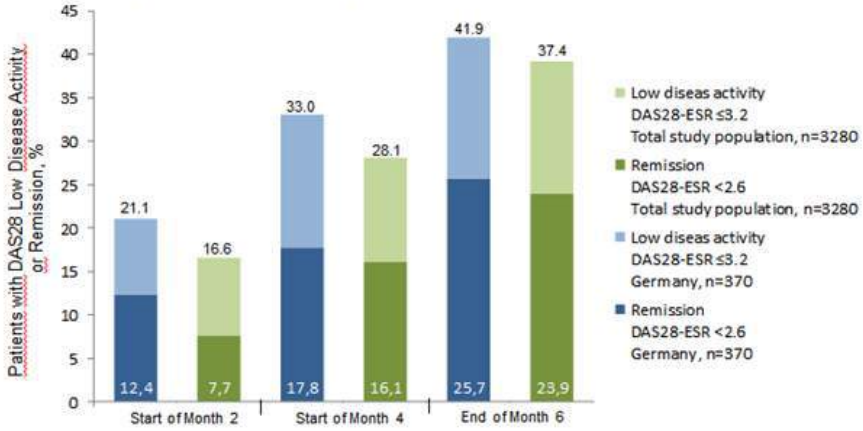
Session Time: 9:00AM-11:00AM

Background/Purpose: In previous clinical studies the human monoclonal TNFα-antibody golimumab (GLM) showed a good clinical response and a favorable benefit:risk profile in the treatment of moderate to severe active rheumatoid arthritis (RA). This was also shown in the clinical practice of the GO-MORE-study*. Until today it has not been examined whether the gathered GO-MORE study results can be referred to the clinical practice in Germany. The scope of the German subpopulation (GER) analysis was to investigate which are the treatment modalities of GLM in combination with predominately used methotrexate (MTX) and the different doses as well as other DMARD-combinations (e.g. leflunomide, LEF).

Methods: GO-MORE was a large open-label, multinational, prospective study in biologic-naïve patients (pts) with active RA*. The GER (n=370) was analysed in the context of the total study population (TSP, n=3.280; including GER) – purely descriptively as no formal comparison was performed. Good/moderate EULAR-(DAS28-ESR)-response depending on different DMARD-combinations and quality of life were evaluated. Enrolled pts (DAS28-ESR ≥3.2 despite DMARD-therapy) received 50mg GLM SC once monthly for 6 months.

Results: Within both groups females were more often affected than males (82.8% in TSP; 74.1% in GER). After 6 months of treatment 80.3% (297/370) of the pts of the GER achieved good/moderate EULAR-(DAS28-ESR)-response (TSP 82.1% (2.692/3.280)). 70.5% received GLM as add-on-therapy to MTX-treatment (81.2% TSP). The pts were preferably treated with GLM in combination with only MTX (207/368, 56.3%). At 6 months good/moderate EULAR-(DAS28-ESR)-response was achieved by 81.2% of the GLM+MTX treated pts (GLM+LEF (66/368, 17.9%): 81.8%; GLM+MTX+LEF (34/368, 9.2%): 73.5%) and furthermore 25.7% of the GER pts got into remission. GLM was well tolerated.

Figure: Percentage of patients achieving DAS28 remission/low disease activity (GER and TSP)



MTX 15mg/week was most frequently used (29.7% compared to >15mg MTX/week: 22.2% and <15mg MTX/week: 18.7%). The respective EULAR-good/moderate-response rates at 6 months were: 82.7% (110/368), 78% (82/368) and 78.3 % (69/368). Moreover the good clinical response rates were concordant with the improvement of functionality and the quality of life. At 6 months 31.1% of the pts showed no/minimal functional impairment (HAQ-DI≤0.5) and the EQ-5D increased from 0.49 to 0.67 (37%).

Conclusion: German pts showed continuous clinical improvement rates over 6 months when treated with GLM, regardless to the chosen concomitant LEF/MTX-therapy. The collected data concerning EULAR-(DAS28-ESR)-response, quality of life and safety profile were comparable to those of the multinational GO-MORE-study. This validates the applicability of

the data from the multinational GO-MORE-study to German clinical practice. **Reference:** * Combe B, et al. Ann Rheum Dis 73:1477–1486

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tapering of TNF blockers (TNFb) in rheumatoid arthritis (RA) patients in sustained remission is feasible in short-term randomized controlled trials (RCT). Less data are available on the sustainability of such a strategy over a longer term in real life settings. The main objective was to assess the probability of sustained dose reduction or discontinuation of TNFb in a 3-year long-term observational follow-up of the *Spacing of TNFb injections in Rheumatoid ArthritiS Study (STRASS)*. This trial compared the effect of progressive spacing of TNF-blocker injections (S arm) to their maintenance (M arm) for patients with established RA in remission for at least 6 months.

Methods: The STRASS investigators of the STRASS trial were contacted between April and October 2015, i.e., 3 years after the end of the trial, to collect evolution data at 1, 2 and 3 years after trial completion of patients having completed the RCT. During this long-term follow-up period, physicians were free to either keep the same regimen as in the arm patients were initially randomized or change injections frequency or drugs. The main endpoints were the rate of patients with spaced TNFb injections, the rate of TNFb-free patients and the mean TNFb dose compared to full dose or dose quotient (as a % of full dose).

Results: Ninety-six patients (76.2% of the completer population) had data available up to 3 years. At this term, mean DAS28 was 2.6±1.3 (respectively 2.7±1.4 in the initial Maintenance-arm, 2.6±1.2 in the initial Spacing-arm, p=0.89) and 72.9% were in low disease activity or remission (respectively 72.1% and 73.0%, p=0.93) (Table 1). Thirty patients (31.2%) had a tapered regimen (respectively 30.8% and 31.8%, p=0.96) and 11.5% (respectively 5.8% and 18.2%, p=0.07) discontinued TNFb (Figure 1). The mean TNFb dose quotient among the 96 patients was 72% of full dose (respectively, 77 and 66%, p=0.16). Eighteen (30.2%) had structural damage progression during the follow-up (respectively 25.0% and 36.8%).

Conclusion : Sustained TNFb de-escalation (injection tapering or discontinuation) is achievable in only 43% of patients over 3 years with limited dose reduction (28% on average). More optimal strategies remain needed to durably maintain remission in patients for whom bDMARD have been tapered or discontinued. Table 1 Patient outcome over 3 years of follow up

Session Time: 9:00AM-11:00AM

Abstract

Immunogenicity of anti-TNF therapies in Patients with inflammatory rheumatic Diseases and secondary failure: a multicentre study of 570 patients.

Background/Purpose: The treatment of rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) has been greatly improved by the introduction of TNF inhibitors (TNFi). However, a proportion of patients receiving these biologic therapies still persist with active disease, either because the treatment fails to initiate a response (primary failure), or initial responsiveness gives rise to non-response (secondary failure). One of the potential reasons for secondary failure is the development of anti-drug antibodies. The **primary objective** of the study was to evaluate the prevalence of anti-drug antibodies in patients with RA or SpA who had a secondary failure to anti-TNF therapy. **Secondary** objectives included the evaluation of the relationship between anti-TNF concentration, presence of antibodies against anti-TNF, and clinical response. The study **also aimed** to evaluate the relationship between presence of antibodies against anti-TNF and concomitant use of DMARDs, **and** the correlation of antidrug antibody positivity and RF and anti-CCP status in patients with RA.

Methods: Cross-sectional, observational study in 45 rheumatology centers across Spain between November 2012 and July 2014. Patients were eligible for inclusion if they were aged ≥18 years, had active RA or SpA (including PsA), and had received and complied with anti-TNF [etanercept (ETN), infliximab (INF) or adalimumab (ADA))] treatment. Patients with secondary failure to anti-TNF at the time of the study visit were consecutively included. Secondary failure was defined as: good response during at least three months (Disease Activity Score (DAS28) ≤3.2, Ankylosing Spondylitis Disease Activity Score [ASDAS] ≤ 2.1 or Bath Ankylosing Spondylitis-Disease Activity Index [BASDAI] < 4) to the current anti-TNF and current moderate-to-high disease activity (DAS28 >3.2 or ASDAS >2.1 or BASDAI ≥ 4). Concomitant non-biologic DMARDs during the observation period was permitted. Trough serum anti-TNF concentration and serum anti-drug antibody concentration were measured with two-site enzyme-linked immunosorbent assay (ELISA) using the Promonitor® (Proteomika) kits. All assays were performed in a central reference laboratory. Tests were considered positive when serum drug levels and anti-drug antibody concentrations exceeded stated limits (INF: 50µg/ml and 37 AU/ml; ADA 4 µg/ml and 35 AU/ml; ETN: 52 µg/ml and 138 AU/ml, respectively). Demographic and clinical characteristics were summarised using descriptive statistics. Quantitative variables were analysed using measurements of central tendency and of dispersion. Qualitative variables were defined according to their absolute and relative frequencies. Student's t-test, Mann-Whitney-U test or Kruskall Wallis H test were used to compare quantitative variables and Pearson's chi-square or Fisher exact tests for qualitative variables.

Results: A total of 583 patients with secondary failure were recruited into the study and 570 were considered evaluable (RA, n=276; SpA, n=294). Patient demographics and patient characteristics were significantly different between patients with RA and SpA at baseline. Patients with RA were majority female (80%), older and took longer to obtain good clinical disease control; more patients with RA than SpA were taking concomitant DMARDs (83 vs 47%), but approximately 75% of patients in both groups took concomitant methotrexate. 114/570 (20.0%) patients with secondary treatment failure developed anti-drug antibodies (Table 1). 51/188 (27.1%) patients were found to be positive for anti-INF antibodies and 63/217 (29.0%) patients for anti- ADA antibodies. Significantly more patients with SpA had anti-INF antibodies than those with RA (23% vs 15.9%; P=0.015). Antibodies were not detected in patients treated with ETN. In patients treated

with ADA and INF, the majority of patients with no detectable drug levels also had anti-drug antibodies (Table 2). Low serum drug levels were detected mainly in patients with no anti-drug antibodies, though some patients with antibodies still had low but measurable levels of drug. Of the 114 patients who developed anti-drug antibodies, 81% of them had no detectable drug levels in their serum. The proportion of patients with anti- ADA and anti-INF antibodies was statistically lower in patients receiving concomitant DMARDs versus those on monotherapy ($p<0.05$). No statistically significant differences were observed between groups of patients with or without anti-drug antibodies, and positive levels of RF or anti-CCP antibodies for any biologic treatment for RA

Conclusion: In this observational study of patients diagnosed with RA or SpA, we found that antibodies against TNFi were present in 20% of patients (28% of those treated with monoclonal antibodies [63/217 (29%) treated with ADA; 51/188 (27%) treated with INF and in any patient treated with ETN] who developed secondary failure to TNFi. Most patients with antidrug antibodies had no detectable trough drug serum levels. The development of anti-drug antibodies is a a major contributor to secondary treatment failure in patients treated with monoclonal antibodies, immunogenicity could not explain a significant proportion of secondary failures in this population. Further investigations are needed to determine all possible causes of failure to anti-TNF therapy

Table 1. Prevalence of anti-drug antibodies (whole cohort; n=570)

	SpA	RA	P-value	Total
N Anti-drug antibodies, n (%)	294 70 (23.8)	276 44 (15.9)	0.015	570 114 (20.0)

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adalimumab (ADA) is a TNF-alpha inhibitor indicated for use in various inflammatory autoimmune diseases including rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA). Patients receiving ADA in Canada are eligible to enroll in a patient support program (PSP) providing personalized services including tailored interventions. This retrospective cohort study assessed the impact of specific factors, including PSP services and patient characteristics, on persistence and adherence to ADA.

Methods: An algorithm based on probabilistic matching was developed to link patients in the ADA PSP database to the IMS Health longitudinal pharmacy transaction database. Patients that started ADA therapy between July 2010 and August 2014 were selected and their prescriptions were evaluated for a period of 12 months after the index date to calculate days until end of persistence (defined by a gap in therapy of ≥90 days), censored for patients who remained on therapy through month 12. Cox proportional hazards modelling provided hazard ratios (HR) for the association between persistence and patient characteristics and PSP services. Adherence, measured by medication possession ratio (MPR), was calculated and multivariable logistic regression provided adjusted odds ratios (OR) for the relationship between high adherence (MPR >= 80%) and patient characteristics and PSP services.

Results: The linkage algorithm yielded a final sample of 10,857 patients (2,067 RA; 2,499 AS or PsA). Statistically significant differences in the hazard rate of discontinuation and the odds of high adherence were identified across multiple variables. Male patients demonstrated 20% less likelihood of discontinuation (HR = 0.801, $p<0.0001$) and had a significantly greater odds of adherence (OR = 1.118, $p<0.015$). Relative to the 30-39 year category, older age groups had significantly greater odds of adherence (40-49, 50-59, 60-69, 70+; OR = 1.247, 1.234, 1.323, 1.411, $p<0.01$). Patients receiving ongoing motivational interventions, in the form of nurse-provided phone calls, were 72% less likely to cease therapy when compared to those that did not receive the interventions (HR = 0.282, $p<0.0001$) and were also more adherent (OR = 1.483, $p<0.0001$). Treatment abandonment (failure to initiate therapy after enrolment in the PSP) was >80% more frequent in patients that did not receive a pre-ADA intervention ($p<0.0001$).

Conclusion: Ongoing motivational interventions, as provided by the ADA PSP, were found to have a large and statistically significant association to greater patient persistence and adherence over the first 12 months of treatment. These results may help refine interventions aiming at improving treatment adherence.

Pharmacokinetic Similarity of ABP 710 Relative to Infliximab: Results from a Randomized, Single-Blind, Single-Dose, Parallel Group Study in Healthy Subjects

Primal Kaur[1], Vincent Chow[2], Nan Zhang[3] and Eswar Krishnan[4], [1]Amgen, Thousand Oaks, CA, [2]Clinical Pharmacology, Amgen, Inc., Thousand Oaks, CA, [3]Biosimilars, Amgen, Inc., Thousand Oaks, CA, [4]Biosimilars, Amgen, Inc, Thousand Oaks, CA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: ABP 710, a biosimilar candidate to infliximab, has the same amino acid sequence as infliximab, an anti-TNF therapy. Analytical and biofunctional comparisons between ABP 710 and infliximab have been conducted and completed. This report describes the results of a study comparing pharmacokinetics (PK) of ABP 710 and infliximab sourced from the United States.

Methods: This was a single-blind, single-dose, parallel-group study among healthy adults, 18 to 45 years of age and with a body mass index of 18 to 30 kg/m^2. Subjects were randomized to receive a 5 mg/kg intravenous (IV) infusion of either ABP 710 or infliximab after pretreatment with an antihistamine and acetaminophen 30 minutes prior to the start of the infusion. The primary objective was demonstration of PK similarity of ABP 710 to infliximab based on area under the serum concentration-time curve from time 0 extrapolated to infinity (AUC_{inf}; primary endpoint). PK equivalence was deemed achieved if the geometric mean (GM) ratio and its 90% confidence interval (CI) fell within the range of 0.80 and 1.25. Secondary endpoints included maximum observed serum concentration (C_{max}), safety, and immunogenicity.

Results: Pharmacokinetics: A total of 49 subjects received ABP 710 and 50 subjects received infliximab. Following a single dose, the adjusted least square (LS) GM of AUC_{inf} and C_{max} for ABP 710 were 33559 µg·h/mL and 123 µg/mL. The adjusted LS GM of AUC_{inf} and C_{max} for infliximab were 37523 µg·h/mL and127 µg/mL. Ratios of adjusted LS GM (90% CIs) between ABP 710 and infliximab for AUC_{inf} and C_{max} were 0.894 (0.812–0.985) and 0.972 (0.917–1.030). The 90% CIs of these ratios were fully contained within the 0.80 to 1.25 interval, confirming PK similarity between ABP 710 and infliximab. Safety: There were no deaths, serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study. The incidence of TEAEs was similar in the two treatment groups (ABP 710: 83.7%; infliximab: 86.0%). The majority of TEAEs were mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy. Immunogenicity: All subjects tested negative for antidrug antibody (ADA) prior to dosing. At the end of study (Day 57), 40% subjects in the ABP 710 group and 32% in the infliximab group were positive for binding ADAs, and 13% subjects in the ABP 710 group and 10% in the infliximab group were positive for neutralizing ADAs.

Conclusion: Results of this phase 1 study demonstrate PK similarity between ABP 710 and infliximab following a single 5 mg/kg IV infusion in healthy subjects. The safety and immunogenicity profile were similar among the treatment groups.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ABP 501 is a biosimilar candidate to adalimumab, a fully human recombinant monoclonal antibody. Totality of evidence to date suggests that ABP 501 is similar to adalimumab. Subjects receiving either ABP 501 or adalimumab in the active-controlled comparative pivotal phase 3 study in rheumatoid arthritis continued on to this ongoing open-label extension (OLE) study if they had completed the week 26 visit of the active-controlled pivotal phase 3 study (parent study) and met study entry criteria. Objective: To report results from the interim analysis of this OLE study.

Methods: This was a single-arm OLE of the parent study; the objective was to assess long-term safety and efficacy of ABP 501. The study design included 68 weeks of treatment followed by an assessment at week 70 and an end of study visit at week 72. All subjects received 40 mg ABP 501 every other week; starting earliest at the week 26 visit of the parent study.

Results: Of the 466/467 treated subjects, 237 transitioned from adalimumab to ABP 501. At the time of this interim analysis one (0.2%) subject had completed the OLE study and 37 (7.9%) had terminated early, mostly due to consent withdrawal. Demographics and disease characteristics were balanced between subjects who transitioned from adalimumab and those who continued on ABP 501. The incidence of treatment-emergent adverse events (TEAEs) was 57.1% (266/466) and that of grade ≥3 TEAEs was 6.2% (29/466); incidence of TEAEs leading to discontinuation of investigational product was 1.7% (8/466). The most frequently reported TEAEs included nasopharyngitis (8.2%), upper respiratory tract infection (7.3%), and bronchitis (4.3%). No fatal adverse events were reported; 6.9% (32/466) subjects experienced serious adverse events (SAEs), of which 1.9% (9/466) experienced musculoskeletal and connective tissue disorders. There were 2 SAEs of interest (infections: n=1; malignancies: n=1). The overall exposure-adjusted incidence rate for SAEs occurring in the OLE study was 8.4 per 100 patient-years (32 subjects/382.4 total subject exposure-time [patient-year]). At the time of this interim analysis, 45.9% (214/466) subjects had developed binding antidrug antibodies (ADAs), 11.6% (54/466) had developed neutralizing ADAs in the OLE study. The rates of TEAEs and ADAs were similar between subjects with single transition from adalimumab and those who continued on ABP 501. The ACR20 response rate (using the parent study baseline) was 73.3% (340/464) at the OLE study baseline, 77.6% (361/465) at week 4, 74.2% (336/453) at week 24, 76.5% (224/293) at week 48. The overall mean DAS28-CRP change from parent study baseline was −2.25 (n=440) at the OLE study baseline, −2.36 (n=463) at week 4, −2.41 (n=450) at week 24 and −2.52 (n=292) at week 48. Efficacy was similar in subjects who transitioned from adalimumab as compared with the subjects who continued on ABP 501.

Conclusion: In this ongoing OLE study of ABP 501, efficacy was maintained with no new safety findings. Long term safety and efficacy results were similar between subjects who transitioned from adalimumab and those who continued on ABP 501.

Abstract Number: 617

Therapy in Patients with Rheumatoid Arthritis (RA) with Inadequate

Response to Tumor Necrosis Factor Alpha Inhibitors (TNFi): A Systematic Review and Meta-Analysis of Randomized Controlled Trials (RCTs

Maria A. Lopez-Olivo[1], Aliza Matusevich[2,3] and Maria Suarez-Almazor[4], [1]Section of Rheumatology and Clinical Immunology, Department of General Internal Medicine,The University of Texas MD Anderson Cancer Center, Houston, Texas, USA,, Houston, TX, [2]General Internal Medicine, The University of Texas, MD Anderson Cancer Center, Houston, TX, [3]The University of Texas, School of Public Health, Houston, TX, [4]Section of Rheumatology and Clinical Immunology, Department of General Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, Texas, USA., Houston, TX

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Up to one-third of the patients who receive TNFi lose responsiveness over time. Options available to these patients include treatment with an alternative TNFi (cycling strategy) or switching to another therapy with a different mode of action (swapping strategy). We conducted a systematic review and meta-analysis of RCTs to compare the efficacy of various approaches.

Methods: Five electronic databases were searched (MEDLINE, EMBASE, Cochrane Library, and Web of Sciences). Sources of gray literature (unpublished records) were searched through clinicaltrials.gov and other websites. The search was broad in scope to capture all available evidence. The selection process was performed by two independent reviewers. We included studies evaluating the efficacy and safety of targeted therapies in RA that included only adult patients with failure to respond to at least one TNFi. We excluded non randomized studies, RCTs with no separate data for TNFi failures, evaluating retreatments (e.g. rituximab or tocilizumab vs. placebo after one or two cycles of rituximab or tocilizumab), with insufficient data to evaluate the outcomes of interest, or comparing a brand-name product with a biosimilar (with no control group). Outcomes included: 50% improvement according to the American College of Rheumatology criteria (ACR50), serious adverse events, and withdrawals.

Results: Out of 44,651 citations we found 13 studies (with multiple publications n=68). The mean age of patients ranged between 45.1 and 58.2 years. The majority of the patients were females (82%) with a disease duration ranging between 8.6 and 13.2 years and a baseline disability score ranging from 1.1 to 1.9. Cycling strategies included: golimumab, certolizumab, adalimumab, etanercept or infliximab in patients failing any other TNFi. Swapping strategies included rituximab, tocilizumab, abatacept, or tofacitinib. Four studies were head-to-head comparisons, one compared two different doses of tocilizumab combined with methotrexate with tocilizumab monotherapy, one compared nonTNFi plus TNFi versus TNFi only and the remaining studies compared a targeted agent combined with a disease modifying anti-rheumatic drug (DMARD) versus DMARD monotherapy (with or without placebo). Three studies (n=898) for the cycling strategy and four studies (n=1,774) for the swapping strategy were suitable for direct meta-analysis. When an alternative TNFi was used in combination with DMARD, ACR50 response rates were statistically significantly improved at 12 to 24 weeks compared to the DMARD alone group (pooled for all TNFi = RR 2.6 (95% CI 1.6 to 4.3). Improvements were also observed with each swapping strategy (pooled RR including rituximab, abatacept, tocilizumab, or tofacitinib was 6.1 (95% CI 4.1 to 8.9)). No differences were observed in the rates of withdrawals due to adverse events or serious adverse events between groups for any of the strategies.

Conclusion: Current evidence from RCTs shows that cycling to a different TNFi after failure can be effective, and can be considered before switching to a different targeted therapy, suggesting that many patients fail a specific agent and not TNFi as a class.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this analysis was to assess the frequency of treatment optimization in cases where treatment target was not achieved, and to describe the type of changes made in RA patients initiating treatment with infliximab or golimumab in Canadian routine clinical care.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis, or psoriatic arthritis with infliximab, golimumab or ustekinumab. RA patients enrolled during 2002-2014 and with available CDAI information at both months 6 and 12 were included. DA was defined according to the CDAI criteria (remission: ≤2.8; low: >2.8 to ≤10; moderate: >10 to ≤22; high: >22). The association between treatment changes and target achievement was assessed with the Chi-square test.

Results: A total of 498 patients were included, with a mean (SD) age and disease duration of 56.4 (13.2) and 8.6 (8.6) years, respectively. The majority of patients were female (74.1%) and treated with infliximab (74.5%). After 6 months of treatment, 46% of patients had achieved treatment target of remission or low DA, and 54% were still at moderate/high DA. Among the latter, treatment was adjusted in 36.4% (34.7% when looking only at patients enrolled since 2011) and was significantly associated with target achievement at month 12 (46.9% vs. 31%; P=0.009). The frequency of treatment changes by type were: DMARD switch/add-on (11.9% of patients), biologic up-titration (10%), DMARD up-titration (8.2%), steroid initiation (7.8%), NSAID initiation (5.6%), and DMARD initiation (3%). Among patients at moderate/high DA at both visits for whom no treatment adjustment was made, mean (SD) disease parameters at 6 months were: SJC28 = 5.7 (5.0); TJC28 = 8.6 (6.5); MDGA = 3.8 (2.0); PtGA = 4.5 (2.4). In comparison, among patients with treatment adjustment, disease parameters were: SJC28 = 5.8 (4.2); TJC28 = 9.4 (7.0); MDGA = 4.7 (2.3); PtGA = 5.8 (2.1). Among patients at moderate/high DA at 6 months who achieved target at month 12 without treatment adjustment, disease parameters at month 6 were: SJC28 = 4.7 (4.5); TJC28 = 5.5 (5.1); MDGA = 3.2 (1.7); PtGA = 4.3 (2.5). Among those with a treatment adjustment, disease parameters at month 6 were: SJC28 = 3.5 (3.0); TJC28 = 5.1 (3.3); MDGA = 4.2 (2.2); PtGA = 4.7 (2.8).

Conclusion: These results suggest that a considerable portion of patients on biologics are not treated to a CRA recommended target in Canada. Treatment adjustment was found to be mainly associated with the physician's global

assessment of disease activity and resulted in better outcomes. PtGA and TJC28 were also significantly higher in those receiving treatment adjustments, while SJC did not correlate with treatment adjustments. The reasons for lack of treatment adjustment in patients not at DA target levels should be further explored.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown that, when sustained good clinical response has been achieved with a biologic therapy, traditional disease-modifying anti-rheumatic drugs (DMARDs) and other treatments can be reduced or discontinued. The aim of this analysis was to assess the discontinuation of concomitant treatment and DMARD tapering in rheumatoid arthritis (RA) patients treated with golimumab (GLM) in Canadian routine clinical practice.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis, psoriatic arthritis with infliximab or GLM as first biologics or after having been treated with a biologic for <6 months. Patients with RA treated with GLM who were enrolled between 2010 and 2014 were included in this analysis. DMARD, steroid and NSAID discontinuation were defined as no use of any drugs in these categories. Time to treatment discontinuation or tapering was assessed both with descriptive statistics and the Kaplan Meier estimator of the survival function.

Results: 273 RA patients treated with GLM (mean dose = 50 mg s.c. monthly) were included in the analysis; 72.2% were female, mean (SD) age was 57.4 (13.5) years and disease duration was 8.1 (8.6) years. Mean (SD) disease parameters at baseline were: DAS28 = 5.1 (1.7), CDAI = 27.8 (15.9), SJC28 = 7.9 (5.9), TJC28 = 8.9 (7.0), HAQ-DI = 1.3 (0.7), MDGA (0-10 NRS) = 5.5 (2.2), PtGA (mm VAS) = 54.6 (27.9). At baseline, 74.7% were taking concomitant DMARDs, 30.8% were on NSAIDS, and 21.2% on corticosteroid. Mean (SD) available follow-up was 13.8 (9.4) months. Upon

treatment with GLM, 11.8% of the patients on a DMARD at baseline discontinued DMARD treatment after a mean (SD) of 15.3 (10.0) months. Furthermore, 56.9% and 86.7% of patients completely discontinued steroid and NSAID treatment after a mean (SD) follow-up of 8.9 (5.4) months and 6.2 (1.3) months, respectively. DMARD dose tapering was documented for 32.4% of patients on DMARDs after a mean (SD) follow-up of 11.2 (8.9) months.

Conclusion: The results of this Canadian longitudinal observational study have shown that treatment with GLM was associated with discontinuation of concomitant DMARD, steroid, and NSAID treatment as well as DMARD tapering in RA patients. The long-term benefits of this practice for patients have to be determined.

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess clinical activity, ultrasound synovitis and drug levels in rheumatoid arthritis (RA) patients receiving anti-TNFα therapy with extended interval of administration (EIA).

Methods: Prospective observational study. Population: Patients diagnosed with RA, in clinical remission, receiving adalimumab (ADL) or etanercept (ETN) with EIA. Clinical activity was assessed by DAS28-ESR, DAS28-CRP, CDAI (Clinical Disease Activity Index) and SDAI (Simple Disease Activity Index) scores at each visit. Twelve-joint ultrasound assessment (elbows, wrists, 2nd and 3rd metacarpo-phalangeal, knees and ankles) was performed evaluating synovitis through B-mode (BM) and Color Doppler signal (CD). A BM and CD score was calculated summing the highest score from each joint to a maximum of 36 points. The sonographer was blinded to the clinical and laboratory data. Serum drug levels were measured using Promonitor® ELISA kits (Progenika Biopharma - Grifols, Spain).

Results: A total of 34 patients were included since February 2011 to January 2016. One patient was excluded due to blindness violation and 2 patients never reduced anti-TNFα due to low drug levels. 27 patients were women (79,4%)

and the mean age was 61 years. Most patients were RF positive (85,3%) and ACPA positive (74,2%). 18 patients were with ADL treatment and 16 with ETN. 28 patients (82,35%) were with DMARD concomitant treatment (14 MTX, 11 LEF, 2 HCQ, 1 SSZ) and 7 patients were with low-dose CS. Mean time from diagnosis was 15,19 years (range 2,15 – 52,31) and Mean time with current biologic drug was 4,11 years (range 1,39 – 11,07). Nine patients (26,5%) returned to standard interval due to worsening of clinical activity and one discontinued treatment due to septic arthritis.

Clinical activity scores, ultrasound scores and drug levels are summarized in table 1.

Table 1. Clinical activity scores, ultrasound scores and drug levels.

	Basal visit	6 months	12 months
n	30	26	17
DAS28-ESR	2,0 (0,94)	1,77 (0,81)	1,49 (0,58)*
DAS28-CRP	1,17 (0,53)	1,76 (0,47)**	1,57 (0,34)**
SDAI	4,23 (2,63)	4,11 (2,81)	2,99 (1,27)*
CDAI	3,82 (2,48)	3,61 (2,33)	2,76 (1,3)
BM score	3,9 (4,65)	3,96 (3,93)	5,41 (4,29)
CD score	0,86 (0,79)	1,44 (1,8)	1,35 (1,46)
BM score (%)	80,95%	92,00%	100,00%
CD score (%)	61,90%	52,00%	58,82%
ADL	12,38 (7,37)	9,17 (5,51)	6,96 (2,84)*
ETN	4,16 (2,74)	3,59 (2,9)	3,03 (0,84)

BM: B-mode; CD: Color Doppler; ADL: adalimumab; ETN: etanercept; *p<0,05; **p<0,005. All results mean (SD) otherwise specified.

Conclusion : 1. Clinical remission was sustained in most patients receiving ADL or ETN in extended interval of administration. 2. Some patients (26,5%) returned to standard interval of administration due to clinical worsening. 3. Some patients show subclinical ultrasound synovitis in B-mode or Color Doppler from baseline, although we found no significant worsening over time. 4. Drug levels decrease over time as we extend interval of administration. 5. It would be advisable to perform periodic ultrasound and monitoring of anti-TNFα levels to maintain clinical remission in patient with extended interval of administration.

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Over the past decade, the use of biologics has significantly changed the management of rheumatoid arthritis (RA) and ankylosing spondylitis (AS). However, the high cost of biologics imposes limits on their use, particularly in developing countries. The development and commercialization of biosimilars can help address unmet medical needs by improving access to well-established therapeutic interventions while improving healthcare affordability. CT- P13 was the first monoclonal antibody biosimilar approved in the EU, as well as recently by the FDA. The study objective was to demonstrate the safety and effectiveness of CT- P13 when administered in a real-life setting in adults with active RA or AS.

Methods: This multicenter, non-interventional, observational study was conducted in Romania, Czech Republic and Bulgaria in patients with severe, progressive RA (with inadequate response to methotrexate /other DMARDs) or severe AS (with inadequate response to conventional therapy). Study investigators determined specific doses/timing of infusions based on the CT- P13 SPC. Patients received CT- P13 at baseline (visit 1), week 2 (visit 2), week 6 (visit 3), between weeks 12 and 14 (visit 4: month 3). Safety was assessed by early dropouts and adverse events (AEs). Effectiveness was assessed at baseline and visit 4 (month 3) using the Disease Activity Score (DAS28) for RA patients and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for AS patients.

Results: At 14 June 2016, 151 subjects (47% male, mean [SD] age 48.9 [14.1] years) have been enrolled (median follow-up 159 days). At visit 4 (month 3), mean (SD) CT- P13 doses were 240 (61) mg/3.3 (0.6) mg/kg for RA, and 384 (87) mg/5.0 (0.5) mg/kg for AS. There were 31 AEs: 5 definitely related, 0 probable related, 5 possibly related, and 21 unrelated to CT- P13. Among the AEs related to CT- P13 treatment 5 were mild, 3 moderate and 2 severe. Altogether 16 patients have been withdrawn prematurely from the study so far, and in 6 cases AE was listed as reason for dropout. Last available observation were carried forward (LOCF) for patients who did not have effectiveness measurement at visit 4 due to early termination. Thus, 111 patients (RA: 61; AS: 50) have baseline and follow-up primary effectiveness measurements at month 3 so far. After 3 months of CT- P13 treatment, patients showed significant improvements in disease activity relative to baseline in terms of DAS28 (baseline: mean [SD]=5.8 [1.0], month 3: mean [SD]=3.6 [1.6]; t=10.5, df=60, $p<0.0001$, Cohen's d=1.7) and BASDAI (baseline: mean [SD]=6.8 [1.7], month 3: mean [SD]=3.4 [2.3]; t=11.6, df=49, $p<0.0001$, Cohen's d=1.7). Patients with RA and AS analyzed together showed a significant decrease in C-reactive protein (CRP) levels after 3 months. (baseline: mean [SD]=26.3 [23.6], month 3: mean [SD]=10.2 [17.6]; t=6.0, df=105, $p<0.0001$, Cohen's d=0.8).

Conclusion: CT- P13 (biosimilar reference infliximab) is safe and effective in a real-life setting in patients with RA or AS.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : SB5 has been developed as a biosimilar of the reference adalimumab (ADL). The 52-week efficacy and safety results were reported previously. [1] Here we report the efficacy results by anti-drug antibody (ADA) during the transition period.

Methods : Patients with moderate to severe rheumatoid arthritis (RA) despite methotrexate treatment were randomly assigned to receive 40 mg of either SB5 or ADL administered subcutaneously every other week. After 24 weeks of treatment, patients in the ADL group were re-randomized (1:1) to either be transitioned to SB5 (ADL/SB5) or continue on ADL (ADL/ADL) up to Week 50. Patients receiving SB5 continued to receive SB5 (SB5/SB5) but they followed the randomization procedure for blinding purposes. Efficacy, safety, and immunogenicity were assessed up to Week 52. Patients with detectable ADA were those who newly developed ADA or developed ADA with increased titer after transition.

Results : The proportion of patients with detectable ADA after transition was 15.7% vs. 16.8% vs. 18.3% for SB5/SB5, ADL/SB5, and ADL/ADL, respectively. In all treatment groups, the mean DAS28 tended to improve in patients without ADA while it tended to worsen in patients with detectable ADA between Week 24 and Week 52 (Figure). The mean change in DAS28 from Week 24 was comparable across treatment groups within each ADA subgroup. In other efficacy parameters such as EULAR response rates, proportion of patients with low disease activity and remission based on DAS28, there was a trend towards decreased efficacy in patients with detectable ADA compared to those without ADA (Table).

Conclusion : Patients with detectable ADA after transition were more likely to have reduced efficacy compared to those without ADA. Efficacy was comparable across treatment groups within patients with detectable ADA and within patients without ADA.

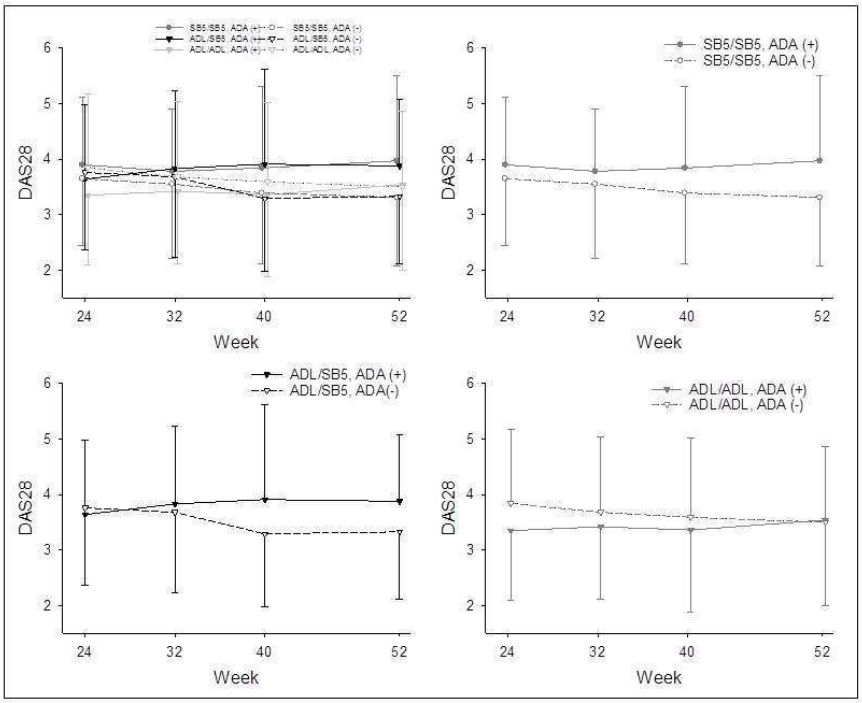

Figure. Mean and Standard Deviation of DAS28 by ADA Status after Transition

Table. Efficacy Results at Week 52 by ADA Status

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In general, the concomitant use of methotrexate (MTX) and biologic disease-modifying antirheumatic drugs (bDMARDS) plays an important role in treating bio-naïve patients with rheumatoid arthritis (RA); however, whether concomitant use of MTX is associated with the effects of second bDMARDS treatment in RA patients for whom first bDMARDS treatment has failed remains unclear.

Methods: We used demographic and clinical data obtained from the Tsurumai Biologics Communication Registry, which comprises the Nagoya University and 20 affiliated hospitals in Japan. Patients aged 20–80 years who fulfilled the ACR 1987 revised or the 2010 ACR/EULAR classification criteria for RA were selected, and only those switching to second bDMARDS treatment were included. Linear multiple regression analysis was used to assess the association between MTX use and effects of second bDMARDS treatment, as defined by DAS28-ESR improvement at week 24. Unstandardized coefficients were calculated. Adjustment variables included sex, age, DAS28 at pre-treatment with second bDMARDS, tumor necrosis factor inhibitor (TNFi) or non-TNFi in RA treatments with first and second bDMARDS, MTX use with first bDMARDS, and glucocorticoid use with second bDMARDS.

Results: Table 1 summarizes the baseline demographic and disease characteristics of the patients. Some characteristics differed between patients with MTX use and non-use; however, they were adjusted using linear multiple regression analysis. Table 2 presents the unstandardized coefficients. The value of interest was 0.67 ($P < 0.05$), suggesting that DAS28 improvement in second bDMARDS treatment with MTX is superior to that without MTX. Other variables affecting the treatment effects were sex and TNFi or non-TNFi with second bDMARDS, which are well-known influential factors for biologic therapy.

Conclusion: This study demonstrated that the concomitant use of MTX was independently associated with increased effects of second bDMARDS treatment.

Table 1. Baseline characteristics of patients with MTX use and non-use

	MTX non-use (n = 49)	MTX use (n = 136)	P value
Age, Mean ± SD years	62.9 ± 15.1	57.5 ±12.7	<0.05
DAS28ESR at pre-treatment	5.24 ± 1.33	5.02 ± 1.42	0.33
Sex, % female	83.7	86.0	0.65
MTX use with first bDMARDS, %	49.0	95.6	<0.05
TNFi as first bDMARDS, %	77.6	97.1	<0.05
TNFi as second bDMARDS, %	26.5	61.0	<0.05
Oral steroid use with second bDMARDS, %	65.3	66.9	0.86

MTX: methotrexate, bDMARDS: biologic disease-modifying antirheumatic drugs, TNFi: tumor necrosis factor inhibitor

Table 2. Coefficients of variables in relation to effects of second bDMARDS treatment

	Estimate	Standard error	P value
(Intercept)	−0.20	0.87	0.82
MTX use with second bDMARDS	0.67	0.28	<0.05
MTX use with first bDMARDS	−0.21	0.31	0.50
DAS28ESR at pre-treatment with second bDMARDS	0.66	0.072	<0.01
Sex (male as reference)	−0.61	0.28	<0.05
Age	−0.013	0.0075	0.08
TNFi or non-TNFi as first bDMARDS (TNFi as reference)	0.058	0.38	0.88
TNFi or non-TNFi as second bDMARDS (TNFi as reference)	0.43	0.21	<0.05
Oral steroid use with second bDMARDS	0.023	0.21	0.91

MTX: methotrexate, bDMARDS: biologic disease-modifying antirheumatic drugs, TNFi: tumor necrosis factor inhibitor

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a paucity of data on the use of anti-TNF therapy in patients >65 years. In this sub-analysis of GO-FURTHER, we compare the safety, efficacy, prednisone use, and discontinuation rates in patients age ≤65 years vs those >65 years through 2 years of treatment with intravenous (IV) golimumab (GLM) plus methotrexate (MTX) in an open-label extension of a Phase III trial of pts with active rheumatoid arthritis (RA) despite MTX therapy.

Methods: In this Phase III, double-blind, randomized, placebo-controlled GO-FURTHER trial, 592 patients with active RA were randomized (2:1) to IV GLM 2 mg/kg plus MTX (Group 1) or placebo (PBO) plus MTX (Group 2) at weeks 0 and 4, then every 8 weeks thereafter. PBO patients crossed over to GLM at week 16 (early escape) or week 24 (crossover by design). The final GLM infusion was at week 100. Assessments included ACR 20/50/70 response criteria. Safety was monitored through week 112.

Results: In total randomized patients, 523 patients aged ≤65 years and 69 patients >65 years were analyzed in the intention-to-treat population with last observation carried forward through week 100. Clinical response by ACR 20/50/70, respectively, was observed in 62%, 34.2%, and 17.5% of those ≤65 years at week 24 (primary endpoint) and was similar

(67.9%, 39.6%, and 17%) in those >65 years of age. The ACR response rates were significantly higher ($p<0.001$) in GLM+MTX group compared with the PBO + MTX group in both age groups. At week 52 and week 100, ACR 20/50/70 values for patients ≤65 years and patients >65 years remained similar to those at week 24 (Table). Mean baseline prednisone dose (mg) was higher in the ≤65 (7.04±2.47) vs the >65 years age group (6.76±2.69). Discontinuation rates were similar among patients aged ≤65 years who received PBO + MTX and GLM + MTX, respectively, at week 24 (2.8% vs 2.9%). Among patients >65 years, discontinuation rates were higher in the GLM + MTX group vs PBO + MTX, respectively, at week 24 (11.3% vs 6.3%). The 2 most common reasons for discontinuation in both age groups for PBO + MTX and GLM + MTX were adverse events and withdrawal of consent. Serious adverse events (SAEs) were numerically higher in patients aged >65 years (26.4%) vs those ≤65 years (18.7%) with infections, gastrointestinal disorders, and fractures being the most commonly reported events in the >65 years age group.

Conclusion: Clinical response to IV GLM + MTX were significantly higher than PBO + MTX in both age groups and the response was maintained through week 100 in those patients who were ≤65 years and those >65 years. Mean prednisone dose was slightly higher in patients ≤65 years, but prednisone use based on percentage was similar in both groups. SAEs were higher in patients >65 years vs ≤65 years, but no increase in unexpected events was observed in those >65 years. These data suggest IV GLM + MTX treatment in patients >65 years is not associated with loss of clinical response or an increase in unexpected adverse events vs patients ≤65 years.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Evaluate the reason of exchange of biologic therapy in patients with rheumatoid arthritis and describe the frequency of remission or low activity, according to the disease activity score (DAS28).

Methods: A retrospective study including patients with rheumatoid arthritis, according to the ACR/EULAR 2010 criteria, age over 18 years, who were using any biologic therapy. We collected demographic and therapy data, disease duration, presence of rheumatoid factor and bone erosion on X-rays, reasons for exchange of biologic therapy: primary failure, secondary failure or adverse events and assessment of disease activity, according DAS28.

Results: 94 patients were included, 40% had moderate activity disease and 60% had high activity disease at the beginning of biologic therapy. Anti-TNF was the first choice therapy in 85 patients: 37% were using adalimumab, 36% etanercept, 13% infliximab, and 4% golimumab. Abatacept was the first choice therapy in 5% of the patients and tocilizumab in 4% of the patients. The mean follow-up was 8 years. In this period, we found 103 exchanges of biologic therapy. The reason for switching was primary failure in 26% of the patients, secondary failure in 43% and occurrence of adverse events in 31%. There was no need of switching in all 5 patients who started abatacept as first choice therapy. At the end of follow-up 28% achieved remission of disease ($p < 0.05$) and 18% achieved low activity disease ($p < 0.05$). 54% remained in moderate or high activity ($p < 0.05$). At this time, 59% were using anti-TNF (27% Adalimumab, 19% Etanercept, 3% Infliximab, 7% certolizumab and 2% golimumab), 19% abatacept, 9% Tocilizumab and 14% Rituximab. Table – Reasons for switching biologic agent in 94 RA patients in a mean follow-up of 8 years.

Conclusion: In this population there were 103 exchanges of biologic agents. The average of follow-up was 8 years. At the end of follow-up, we found 28% remission and 18% of low disease activity, but 54% of patients remained in high or moderate activity.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilar infliximab is registered in Europe for the same therapeutic indications as innovator infliximab. In 2015, four rheumatology departments in the Netherlands decided to switch from innovator infliximab to biosimilar infliximab based on comparable results in randomized controlled trials and favourable costs. Since data on switching to biosimilar infliximab in daily clinical practice were still scarce, we decided to collect clinical outcomes in a large observational multicentre prospective cohort study. The objective of our study was to investigate the effects of switching treatment from innovator infliximab to biosimilar infliximab on efficacy, safety and immunogenicity in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondylarthritis (SpA).

Methods: Of all innovator infliximab-treated patients, 192/211 (91%) agreed to switch to biosimilar infliximab and were eligible for inclusion in this study. Primary outcome was change in DAS28-CRP (for RA and PsA) and BASDAI (for SpA) after 6 months of treatment. Secondary outcomes included C-reactive protein (CRP), adverse events and infliximab trough levels. Antidrug antibodies against infliximab were measured if the trough level was below 1 µg/ml.

Results: In total, 75 patients with RA, 50 with PsA and 67 with SpA who switched treatment to biosimilar infliximab were included. 44/192 (23%) patients discontinued biosimilar infliximab during 6 months follow-up, respectively due to experienced inefficacy (n=35), adverse events (n=23) or an infusion reaction (n=2). Most frequently reported adverse events resulting in biosimilar discontinuation were fatigue (n=10), malaise (n=5) and headache (n=3). No serious adverse events occurred. 34 patients restarted innovator infliximab, 7 patients switched to another biological (2 adalimumab, 3 etanercept, 1 golimumab, 1 rituximab) and 3 patients maintained biological-free. In RA and PsA patients, mean DAS28-CRP remained stable from month 0 to 6: 2.19 [SD 0.89] to 2.22 [SD 0.84] (p=0.51). In SpA patients, mean BASDAI increased from 3.8 to 4.3 (change +0.5, 95% CI 0.12-0.89, p=0.01). CRP levels at baseline (median 1.5 mg/l [p25-p75:0-5]) and 6 months (median 1.0 mg/l [p25-p75: 0-5]) were not statistically different (p=0.60). To date, 138 baseline samples and 129 follow-up samples have been analyzed. Median infliximab trough levels were similar: 2.05 µg/ml versus 2.00 µg/ml (p=0.18). Antidrug antibodies were detected in 15/32 (47%) patients at baseline and in 10/26 (38%) patients after 6 months.

Conclusion: In the majority of RA, PsA and SpA patients innovator infliximab can be switched to biosimilar infliximab without changes in efficacy, safety and immunogenicity during 6 months follow-up. However, 23% of the patients discontinued biosimilar infliximab, mainly due to a subjective increase in BASDAI score and/or adverse events, possibly explained by nocebo and/or attribution effects rather than pharmacological differences.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Currently, the most widely used biological agents for rheumatoid arthritis (RA) patients are the inhibitors of the tumor necrosis factor (TNFi), although other biological agents with different mechanisms of actions, such abatacept, have been approved in the recent years. Although all these drugs are indicated in RA, there is limited data on their use in clinical practice. Our objective is to analyze if there are differences in baseline characteristics of RA patients treated with abatacept, a T-cell costimulation inhibitor, compared with those treated with a TNFi

Methods: All BIOBADASER 2.0 register patients diagnosed with RA and treated with abatacept from January 2008 to December 2014 were selected. Baseline sociodemographic and clinical characteristics were analyzed compared them with RA patients treated with TNFi during the same period. Variables analyzed: age; gender; disease duration; positivity of rheumatoid factor (RF); disease activity at index time (time when the biological drug was initiated) measured by the DAS28-ESR score; number of previous biological agents (0, 1, ≥ 2); and concomitant glucocorticoid treatment. Differences between groups (abatacept vs TNFi) in the baseline DAS28-ESR were analized according to the number of previous biological drugs received

Results: From January 2008 to December 2014, 252 RA patients treated with abatacept and 640 with TNFi were included in the BIOBADASER 2.0 register. Baseline characteristics are shown in Table 1. At baseline, patients treated with abatacept were significantly younger [52.2 (± 13.1) vs 54.6 (± 13.7) years, p=0.018]; had a longer disease duration [12.1 (± 8.1) vs 7.3 (± 8.0) years; p<0.001] and had received a higher number of previous biologics (28.2% vs 7.8% had received one previous biologic; p<0.001; 61.1% vs 1.88% had received ≥ 2 previous biologics; p<0.001). When baseline DAS28-ESR was analyzed, both clustered and stratified according to the number of previous biologics, higher DAS28-ESR was found in RA patients treated with abatacept compared with those treated with anti-TNF, that was statistically significant in patients who had received one previous biologic [DAS28-ESR: 5.20 (± 1.53) vs 4.09 (± 1.95); p<0.001]. No differences were found in gender, positivity of RF and concomitant treatment with glucocorticoids between groups.
Table 1. Baseline Characteristics of Abatacept and TNF inhibitors patients in BIOBADASER 2.0 Registry

Variable Number of patients		Total	Abatacept group	TNF inhibitor group	p-value*

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Golimumab (GLM) has shown its efficacy and safety in various randomized clinical trials with patients eligible for clinical studies. Data from patient-reported outcomes (PROs) and socio- and health-economic parameters in daily clinical practice in Germany are still lacking.

Methods: Patients were enrolled in the non-interventional prospective study GO-NICE at 158 German sites to explore the disease activity by DAS28, PsARC and BASDAI, the quality of life, fatigue, days of sick leave, quality of work, as well as safety.

Results: 1,613 patients were enrolled. A total of 1,458 (90.4%) patients had a baseline assessment and at least one additional visit and were thus eligible for final analysis. Proportions of patients who completed the study and were still on treatment with GLM at the end of month 24 were as follows: RA (44.9%), PsA (54.6%), and AS (59.2%). At baseline (BL): RA: n=474, mean age 54.9 yrs, 72.8% female, 64.7% biologic-naïve, PsA: n=501, mean age 50.5 yrs, 54.1% female, 56.5% biologic-naïve AS: n=483, mean age 43.6 yrs, 66.5% male, 61.0% biologic-naïve. An improvement of quality of life (EQ-5D-3L) was seen after 6 months and was maintained over 24 months. The patients' health state today (EQ VAS) improved from 51.0 (BL) to 63.4 (RA-), from 48.4 to 64.3 (PsA-) and from 46.8 to 66.5 (AS-patients), the functional ability (FFbH) improved significantly ($p<0.0001$ vs. BL) from baseline 68.2 to 76.1 points (RA-), from 69.0 to 76.8 (PsA-) and from 69.0 to 78.5 (AS-patients), and the mean FACIT-Fatigue score increased significantly ($p<0.0001$ vs. BL) from baseline 32.4 to 38.3 points (RA), from 30.0 to 35.9 points (PsA), and from 29.9 to 37.9 points (AS) over the time until month 24. Days of absenteeism from work due to the underlying disease in the last 6 months were evaluated at BL and after 2 years of treatment. These dropped from 16.2 to 4.1 (RA), from 10.6 to 2.0 (PsA) and from 14.7 to 3.9 days (AS). Days with reduced productivity dropped in patients with RA from 64.5 days (BL) to 29.9 days (month 12) to 23.1 days (month 24), in patients with PsA from 66.6 to 26.6 to 19.8 days, and in patients with AS from 66.3 to 26.1 to 17.3 days within the past six months. The disease impact on quality of work, determined by 0 (no impact) to 10 (very severe impact) decreased within 24 months of treatment from 4.8 to 2.4 (RA-), from 4.8 to 2.2 (PsA-) and from 4.8 to 2.0 (AS-patients) referred to the past 6 months. The proportion of patients who required hospitalization decreased from 10.6% to 1.6%, physiotherapy from 28.8% to 16.6%, and massage treatment from 10.9% to 6.4% within the two years of treatment. The safety profile of GLM was consistent with that observed in other studies of GLM. 4 deaths occurred: 1 patient unlikely related and 3 patients not drug-related to the treatment of GLM

Conclusion: GLM SC once monthly was an effective treatment in patients with RA, PsA and AS in a real-life setting in Germany. Treatment with GLM showed remarkable improvements in clinical effectiveness, patient-reported quality of life parameters and socio- and health economic and. No new safety signals were detected.

Strategies for Biological Drug Quantification in Biological Drug Immune Responses

Michael Kruse Meyer[1,2], Marlene Andersen[1,3], Troels Vindbæk Stausbo[4], Tue Bjerg Bennike[4,5], Grethe Neumann Andersen[1,6] and Allan Stensballe[3,4], [1]Department of Rheumatology, North Denmark Regional Hospital, Hjørring, Denmark, [2]Laboratory for Medical Mass Spectrometry, Aalborg University, Aalborg, Denmark, [3]Department of Health Science and Technology, Aalborg University, Aalborg, Denmark, [4]Laboratory of Medical Mass Spectrometry, Aalborg University, Aalborg, Denmark, [5]Research Unit for Molecular Diagnostic and Clinical Research, Harvard Medical School, Boston, MA, [6]Center for Clinical Science, Aalborg University, Hjørring, Denmark

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The development of the biological DMARDs has benefitted patients, who previously had no treatment options. Currently no method for stratifying patients to these drugs exist. The biochemistry profile of the patients varies (Meyer et. al. 2016), suggesting that patients need an individualized biochemistry evaluation to improve the stratification process. This is, however, a long term and challenging goal, that will possibly reduce the overall cost of treatment and reduce side effects. Meanwhile, patients in current treatment could benefit today by optimizing their current treatment, through drug concentrations measurements in addition to immune response evaluation. This can be done my immunoassays, but these are not readily scalable, thus we apply targeted proteomics. This requires sequence information of the biological drug, which might not be available. Thus, we present strategies for de-novo sequencing prior to analysis, and show that this proteomics approach readily transfers between biosimilar drugs. The aim of this study was to develop generic scalable and multiplexed targeted mass spectrometry assays to measure four selected biological drugs abatacept, tocilizumab, infiliximab, and biosimilar infliximab in patient sera for therapeutic drug monitoring in RA patients.

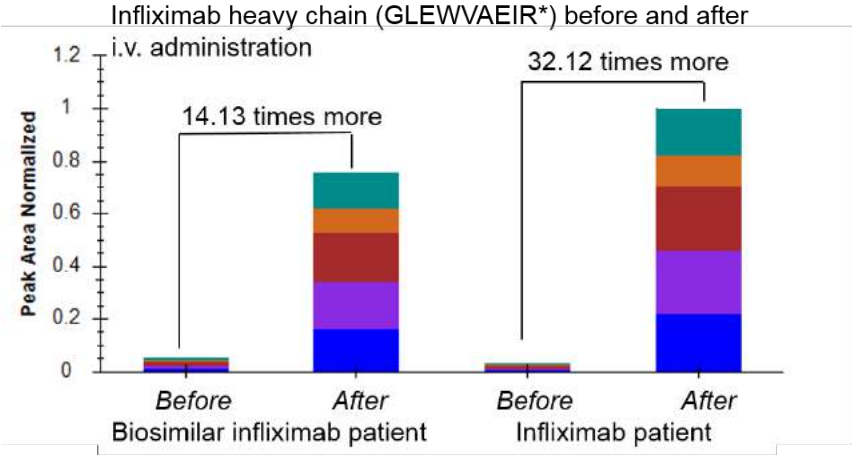
Methods:

30 patients with rheumatoid arthritis in stable i.v. treatment with the four selected biological drugs, are being enrolled in this study and sampled before and after administration of drug. Tandem mass spectrometry, i.e. MALDI-TOF lift-mode, and LC-MS/MS on pure biological drug samples were used to de-novo sequence peptides, build spectral libraries, and subsequently utilized for patient analysis. A parallel-reaction monitoring (PRM) LC-MS/MS assay was developed and applied to targeted peptides unique to the biological drugs.

Results:

Peptides were readily sequenced using MALDI-TOF, and the resulting data, i.e. unique peptide sequences of the four biologics, molecular mass, charge, and chromatographic retention time were used for quantitative targeted PRM on patient samples.

Using the exact preparation and analysis method on infliximab, and biosimilar infliximab provides the same result, due to the shared peptide sequence (Figure 1). This indicates that future biosimilar drugs can be readily quantified with targeted proteomics with no method modifications.



*Peptide target was originally published by Willrich et. al. 2015 (doi:10.1016/j.intimp.2015.07.007)

Conclusion:

Our targeted strategy highlights the strength of proteomics, and targeted proteomics for therapeutic drug monitoring in RA patients. This data-driven strategy will be important in personalized rheumatic medicine by enabling treat-to-concentration therapy.

Biologic free remission rate with etanercept in rheumatoid arthritis: a potential role of gender A.M. Lurati and A. Laria, D. Mazzocchi, K.A. Re, M. Marrazza, M. Scarpellini Rheumatology Unit, Fornaroli Magenta Hospital, Milan, Italy

Abstract

Background/Purpose: Etanercept is a subcutaneous antiTNF inhibitor approved to treatment of Rheumatoid Arthritis (RA). In literature there are few data about the achievement of a biological free remission in patients treated initially with a combined therapy (i.e. MTX plus antiTNF agent) and there are no data about influence of gender on clinical response to biological or DMARD therapy. Aims of our study were to evaluate the Òbiologic-freeÓ sustained remission rate in patient with RA that achieved a persistent DAS28< 2.6 with a combined therapy MTX plus etanercept and to evaluate the possible influence of gender or menopausal status on clinical response to etanercept.

Methods: A cohort of 169 Italian patients with active (DAS28 >5.1) rheumatoid arthritis (RA) attending the outpatient clinics of the Division of Rheumatology of Fornaroli Magenta Hospital (Milan, Italy) from January 2000 to January 2005 were enrolled in this study and treated with Etanercept as first line biological therapy (50mg/weekly) combines with methotrexate (MTX) (7.5-15 mg/weekly). All patients were prospectively followed every 3 months until now. When a clinical remission (DAS28-ESR <2.6) was obtained and sustained for at least 12 months, the patient interrupted biological treatment. Clinical, laboratory and disease activity measures were obtained at 3, 6 and 12 months after biological discontinuation. If after 12 months a DAS28-ESR worsening > 1.2 was observed, then etanercept was reintroduced and the patient was categorized as relapsed, otherwise the patient was considered as in persistent remission. Statistical Analysis was performed with a Cox regression model based on clinical variables collected was used to predict the odds of develop a biologic free remission status and the cumulative probability of persistent remission

Results: 169 patients were enrolled (37 males, 132 females). Mean etanercept treatment duration was 3.01± 2,7 (0,08-11,35) years. Mean disease duration from diagnosis to last follow up was 15 years ± 8.4. Mean disease duration from diagnosis to enrolment was 8±7.7 years. During the study 34 patients (20.12%) obtained a biologic free persistent remission (25% observed in 3.9 years of treatment, 50% observed in 6.59 years of treatment, 75% observed in 7.8 years of treatment) (Figure 1). Our model showed a increased risk of disease relapsing in women (odd ratio of 1.306, p=0.01) and in long standing disease (odd ratio of 1.11, p=0.03) (Figure 2) (Figure 3). The 50% of remission in males were observed in 2.8 years of treatment with etanercept, in females in 4.1 years.

Conclusion: In our study we observed a significant rate of biologic free persistent remission with etanercept. Gender seems to influence the clinical response with a lower probability of persistent remission in females. Others study are necessary to confirm these data in the future.

Comparative Improvement in Health-Related Quality of Life for RA Patients Between TNF-α Inhibitors, Other Biologics, and Tofacitinib: Results from a US-Wide Observational Study

Miriam G. Cisternas[1] and **Kaleb Michaud**[2,3], [1]MGC Data Services, Carlsbad, CA, [2]University of Nebraska Medical Center, Omaha, NE, [3]National Data Bank for Rheumatic Diseases, Wichita, KS

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: We compared changes from baseline for 8 health-related quality of life (HR-QOL) outcomes over two years for patients with rheumatoid arthritis (RA) treated with TNF-α inhibitors (TNFi), non-TNFi biologics (Abatacept (ABA), Rituximab (RIT), and Tocilizumab (TOC)), and Tofacitinib (TOF).

Methods: Participants were patients with RA initiating 1st- and 2nd-line biologic treatment from 2004 to 2015 in the National Data Bank for Rheumatic Diseases, a US-wide observational study that assesses outcomes and medications semi-annually. Over a 2-year period, we evaluated changes in 8 HR-QOL measures (Global assessment [Global], Health Assessment Questionnaire-II [HAQ2], Pain VAS [Pain], Patient Activity Scale-II [PAS2], Short Form 36 Physical [PCS] and Mental [MCS] Component Summary, EuroQOL US [EuroQOL], and Fatigue VAS [Fatigue]). 1st-line therapy was defined as initiation of a TNFi for which the patient was na•ve to any biologic or TOF; 2nd-line therapy was the initiation of the next biologic or TOF after first-line therapy. We calculated change scores for assessments completed after drug initiation by subtracting the baseline (observation before drug initiation) score. Our predictors of change in outcomes were study drug and time since drug initiation. We used mixed models to include fixed effects for drug and random effects for the intercept and slope of time for each individual. The interaction between drug and time was also included. To account for the non-randomization of drug groups, several covariables were added including: baseline age, sex, race, marital status, body mass index (BMI), Rheumatic Disease Comorbidity Index (RDCI), RA duration, and concomitant use of methotrexate and/or prednisone.

Results: The 913 patients analyzed for 1st-line therapy were 79% female with a baseline mean±SD age of 59 ±12 years, RA duration of 16±13 years, and RDCI of 1.7±1.5. There were no statistically significant differences in HR-QOL change scores among TNFis for 1st-line therapy. The 2nd-line cohort (N=2612) was 84% female with mean±SD age and RA duration of 60±12 and 18±12 years, and RDCI of 1.9±1.6. Analyses showed statistically significant superior improvement of Pain (0 – 10) for RIT vs. TNFi (differences of 1.0 at month 1 and ending at 0.6 at month 8) and vs. TOC (differences of 1.6 at month 1 and ending at 1.2 at month 5). RIT also showed significant improvement vs. TNFi at months 1 – 7 for PAS2 (0 – 10), with differences starting at 0.6 at month 1 and ending at 0.4 at month 7 (See Figure).

Conclusion: Results suggest that for 2nd-line therapy, RIT may be superior to TNFi and TOC during the first 5 to 8 months for pain, and during the first ~7 months when compared to TNFi for improving patient activity. For both lines of treatment, most medications were associated with modest improvement for the majority of outcomes in at least part of the study period.

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Better prediction of treatment response to biologics in rheumatoid arthritis (RA) would contribute to optimal individualized treatment. Clinical data suggest that the response of RA patients to treatment with golimumab is much lower among those who switched from adalimumab than among those who switched from etanercept.[1] To elucidate the mechanism behind this difference in response to sequential biologic treatment, we examined the effect of TNF inhibitors on ex-vivo cytokine production.

Methods: In a prospective longitudinal cohort study, blood samples were obtained from patients at baseline (before start biologic). Peripheral blood mononuclear cells (PBMCs) were isolated, washed and pre-incubated for 1 hour with the therapeutic in-vivo concentration of adalimumab, etanercept or golimumab and stimulated for 24 hours with heat killed *Candida albicans* or Pam3Cys. Cytokine concentrations of IL-1β, IL-6 and TNFα were determined by ELISA. Absolute changes in cytokine levels after inhibition by each TNF inhibitor were calculated and analyzed by means of Spearman rank correlations (r_s).

Results: Ex-vivo cytokine profiling was performed in 71 patients: 66% female, age (mean ± SD): 58 ± 11 years, disease duration (mean ± SD): 10 ± 8 years. Golimumab, adalimumab and etanercept significantly ($p<0.01$) decreased *Candida albicans*-induced cytokine production of IL-1β and IL-6 and Pam3Cys-induced cytokine production of IL-6. In contrast to etanercept, golimumab and adalimumab decreased the concentration of TNFα below the detection limit (Figure 1). Absolute changes in cytokine levels after inhibition by golimumab or adalimumab were all strongly correlated (r_s 0.52 – 0.99, $p<0.001$). These correlations were much lower or non-significant between etanercept and either golimumab or adalimumab (Figure 2).

Conclusion: High similarity between ex-vivo inhibited cytokine profiling by golimumab and adalimumab provides a putative explanation for the previously found inferior treatment response to golimumab after adalimumab failure in RA. This suggests that RA patients who are non-responsive to adalimumab should preferably not switch to golimumab and vice versa. **References:** 1. Smolen JS, Kay J, Matteson EL, et al. SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In March 2015 the first infliximab biosimilars CT-P13 (Remsima™; Inflectra™), entered the Swedish market. The aim of this study was to evaluate the uptake and factors associated with use of the originator product (Remicade®) and its biosimilars.

Methods: Data from the Swedish Rheumatology Quality register (SRQ) was used to identify all patients with a rheumatic disease who started a treatment with the originator product or with its biosimilars between 1st March 2015 and 29th February 2016. Demographic and disease characteristics were collected and tabulated; and differences were assessed using linear and logistic regression models adjusted for age, gender and residential region. Kaplan-Meier curves were used to visualize survival on drug.

Results: During the study period, 1044 patients started treatment with infliximab; 318 started Remicade, 118 started Inflectra and 608 started Remsima (Table 1). Most patients (68%) who started a biosimilar did so following a switch from the originator product. There were large geographical variations in the relative use of originator vs. the biosimilars. Comparing the relative use across indications, the odds of being treated with a biosimilar was higher among patients with RA (OR: 1.54 (1.09-2.17)) as compared to all the other rheumatic diagnosis. There was no statistically significant difference between patients treated with originator vs. biosimilar regarding age, gender, DAS28 at start of treatment, and duration between start of symptoms and disease diagnosis. By contrast, there was a 35% decreased odds of receiving biosimilar for each unit increase in HAQ (OR: 0.64 (0.44-0.94)), that was not statistically significant after stratification by line of treatment. Biosimilars were preferred over the originator product as second or third line of treatment (OR: 1.69 (1.18-2.41)) compared to other lines of treatment and they were more likely to be prescribed among patients whose most recent biologic was Remicade as compared to other biologic drugs (OR: 4.96 (2.98-8.39)). The Kaplan-Meier curve did not show any difference in survival on drug between the originator product and the biosimilars.

Conclusion: In Sweden, during the 1st year of marketing, most prescriptions of infliximab were made up by the biosimilars products than by the originator product. The choice to prescribe a biosimilar instead of the originator product varied more with contextual factors than with the disease.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

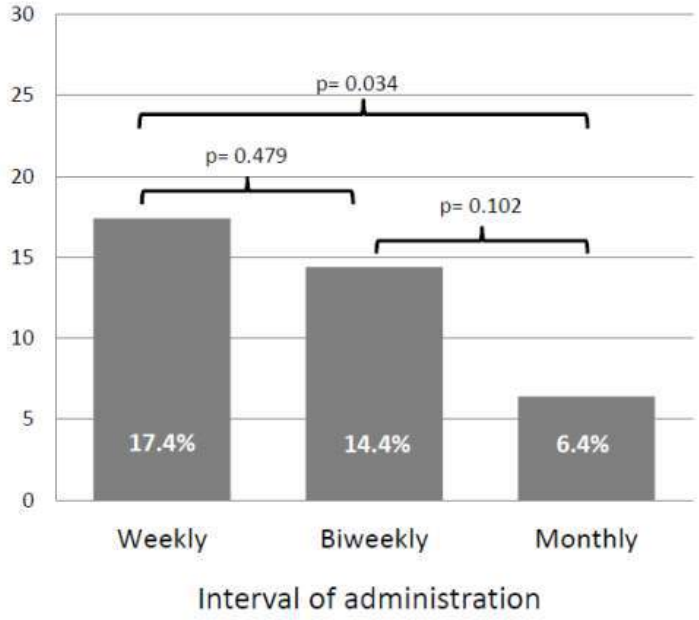
Background/Purpose: To investigate the variables associated to lack of adherence to subcutaneous (SC) biological drug in patients with rheumatoid arthritis (RA) after 1 year of starting therapy.

Methods: ARCO was a retrospective study in RA patients ≥18 years-old from 42 Spanish hospitals, who started a new SC biological drug 12 to 18 months prior to the study visit. Adherence was evaluated through the Medication Possession Ratio (MPR) (number of days covered by the taken medication / days of study period). The number of days covered was calculated with the vials taken by the patient from the hospital pharmacy, taken into account the prescribed interval of administration, changes in this interval and if induction was prescribed. The number of days was the study period, subtracting drug suspension periods. Patients with MPR ≤ 80% were considered non-adherent. Variables associated with non-adherence were studied in a multivariable model that included age, gender, RA duration, interval of administration, induction, order of administration, and changes in the interval of administration.

Results: 364 patients were included (age 54.9 years [12.5]; 77.5% women, median RA duration 7.8 years). The initial interval of administration was weekly (44.2%), biweekly (39.1%) and monthly (17.3%); the median duration of the period studied 14.8 months. A total of 52 patients were non adherent (MPR ≤ 80%) to the prescribed schedule (14.3%; 95% CI: 11.1 – 18.3). Non adherence was more frequent in patients with weekly administration (17.4%) and in those receiving induction (21.6% vs 12.5% without induction, p= 0.068) and less frequent in those with monthly administration (6.4%, figure). The multivariable analysis identified RA duration, induction and interval of administration as independently associated to lack of adherence (table).

Conclusion: Non-adherence to SC biological drugs occurred in 14.3% of patients with RA and was associated to RA duration above the median, weekly interval of administration and prescription of induction.

Figure. Percentage of non-adherent patients (MPR ≤80%) and administration intervals.



Multivariable analysis. Variables associated with non-adherence.			
	Odds ratio	**95% CI**	**p-value**
RA duration above median (>7.8 years)	1.63	0.89–3.05	0.117
No induction (vs. induction)	0.41	0.18–0.93	0.033
Biweekly administration (vs. weekly)	0.54	0.24–1.16	0.125
Monthly administration (vs. weekly)	0.32	0.09–0.87	0.042

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Adalimumab (ADL) dose tapering based on clinical assessment is a usual practice especially in patients who have achieved clinical remission. The primary aim of this study is to analyze how personalized management guided by biological drug monitoring (BDM) in moderate to severe rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) patients impacts the annual direct costs of these patients to the Health System and the quality-adjusted life year with respect to conventional practice in Spain. Secondly, to evaluate the effectiveness of BDM in the reduction of the number of days with high disease activity compared with conventional practice. Follow up will be completed in December 2016; here we present partial descriptive data at 34 weeks.

Methods: Adult patients with RA, PsA or AS treated with ADL who have remained clinically stable for at least 6 months were recruited in three sites. Patients were grouped in Control and Intervention groups according to the recruiting site. All patients were treated with 40 mg of subcutaneous ADL and treatment frequency was adjusted based on physician criteria. All patients are assessed at 8 timepoints (8 visits) for up to 18 months. Trough ADL and anti-drug antibodies levels are measured with Promonitor-ADL and Promonitor-ANTI-ADL (Progenika, Spain). BDM data are released only to the Intervention group, and blinded to the Control group (managed according to clinical assessment only). Physicians in the Intervention group are not obliged to follow any therapeutic algorithm based on BDM results but can use tests to alter doses based on their judgement. Endpoints include DAS28, BASDAI, BASFI and HAQ-DI scores at every timepoint. Criteria for assessing disease scores are identical in the three sites. Cost-effectiveness will be evaluated according to associated costs and QALY.

Results: A total of 169 patients have been recruited (Disease, N Intervention, N Control groups, %) (RA, 30, 33, 37.3%; PsA, 33, 21, 32%; and AS, 46, 6, 30.8%). Median disease duration was 117, 98.5 and 101.5 months for RA, PsA and AS, respectively. At baseline, 10 (16.7%) and 29 (26.6%) patients had low disease activity and 50 (83.3%) and 80 (73.4%) patients were in remission in the Control and Intervention groups respectively, with median trough ADL levels 5.5 and 5.3 mg/L in the Control and Intervention groups respectively. At week 34 median trough ADL levels were 5.2 and 5.5 mg/L in the Control and Intervention groups respectively. Out of the total number of patients who were in remission at baseline (n=117), 69.6% (32/46) and 76.1% (54/71) remained in remission at week 34 in the Control and Intervention groups, respectively. Out of the patients who had low disease activity at baseline (n=35), 28.6% (2/7) and 35.7% (10/28) were in remission at week 34 in the Control and Intervention groups, respectively.

Conclusion: Partial descriptive data point towards a positive effect of BDM-complemented management compared to conventional practice only. This study will provide evidence on the clinical utility of personalized management of patients based on clinical assessment and biological drug monitoring (drug and anti-drug antibody levels) for adalimumab in rheumatoid arthritis, psoriatic arthritis and ankylosing spondylitis compared to management based on clinical assessments alone.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of this study was to describe biologic initiation patterns over a 1-year follow-up period in rheumatoid arthritis (RA) patients with moderate or high disease activity (M/HDA) while on conventional disease modifying anti-rheumatic drugs (cDMARDs).

Methods: Biologic-naïve RA patients on cDMARD were selected in a US national observational cohort (Corrona RA registry) between 1/1/2006 and 1/31/2016. All patients selected were in M/HDA based on the Clinical Disease Activity index (CDAI >10) and had ≥ 1 year of follow-up and no change in the treatment during 3 months prior to the index date. Index date was the earliest visit the patient met the inclusion criteria. Patients were excluded if their age of RA onset was <18y, or they were exposed to biologics prior to the index date. Patients' demographics, RA disease characteristics, and biologic initiation patterns were described. Baseline demographic and clinical characteristics were compared, using descriptive statistics, between patients who initiated a biologic during the follow-up vs. those who did not.

Results: Out of 11874 cDMARD users in Corrona, 3345 (28%) were in M/HDA and 2217 (19%) met the study inclusion/exclusion criteria. Most patients were female (78%), white (88%) and 64 years of age on average [SD=12]. The mean duration of RA was about 11 years [SD=10] with mean CDAI score of 20 [SD=10] at the index date. About a quarter (n=537) of the patients initiated a biologic, on average, 4 months [SD=3] after the index date. Of biologic initiators, most (85%) received a TNF-inhibitor as their first biologic. There were significant differences between the biologic initiators and non-initiators in baseline demographic and clinical characteristics (Table 1). The initiators were younger, had shorter duration of RA, had fewer comorbidities, but had higher CDAI scores and a higher proportion reported morning joint stiffness. Other RA disease baseline characteristics indicated more severe RA for the initiator group (Table 1). Most (92%) of these patients had M/HDA at the time of the biologic initiation. Among those who did not initiate a biologic, two-thirds remained on their index cDMARD therapy. Of the non-initiators, 11% had unknown disease activity status during the follow-up; among those who had disease activity reported, 53% had achieved LDA and 16% had achieved remission on at least 1 visit during the follow-up; 32% remained in M/HDA.

Conclusion: A minority (24%) of cDMARD users in M/HDA initiated a biologic therapy during the 1 year follow-up. Factors associated with biologic initiation were younger age, shorter duration of RA, less cancer and cardiovascular disease, more severe RA at baseline and higher disease activity during the follow-up.

Table 1. Demographic & clinical characteristics of M/HDA RA patients at the index date

	Treatment status during 1-year follow-up

Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of this study was to describe the pharmacokinetics (PK), safety and immunogenicity of GP2017, a proposed adalimumab biosimilar, administered as a single subcutaneous injection by autoinjector (AI) or prefilled syringe (PFS).

Methods: This was a single-center, open-label study in healthy male subjects with body weights (BW) ranging from 50 to 140 kg. Subjects were stratified by BW category and randomized 1:1 to treatment with GP2017 40 mg administered by AI or PFS, with follow-up until Day 72. The primary objective was to describe area under the curve (AUC_{0-360h}) and maximum drug concentration (C_{max}) of GP2017 after administration by AI or PFS in subjects with BW between 50.0 and 94.9 kg. Secondary objectives included characterisation of AUC up to the last measurable concentration (AUC_{0-last}) and total AUC (AUC_{0-inf}) for the 50.0–94.9 kg BW category. PK parameters were also characterized in the 50–64.9, 65.0–79.9, 80–94.9 and 95–140 kg BW categories. Safety, immunogenicity and local tolerance were assessed in all treated subjects.

Results: A total of 108 subjects (aged 18 to 55 years) received GP2017 administered by AI (n=54) or PFS (n=54). Of these, 45 and 44, respectively, were in the 50.0–94.9 kg BW category. Demographics and baseline characteristics were well balanced across the treatment groups. For subjects in the 50.0–94.9 kg BW category, 90% confidence intervals (CI) for the ratio of geometric means between treatment groups were contained within standard bioequivalence limits (0.8 to 1.25) for primary and secondary PK parameters (Table). For subjects in the 50.0–140.0 kg BW category, 90% CI were contained within bioequivalence limits for C_{max}, AUC_{0-360h}, AUC_{0-last} and AUC_{0-inf}. The incidence of antidrug antibody (ADA) development was similar for the AI and PFS treatment groups: 69% and 72% of subjects, respectively. The proportion of subjects with neutralizing antibodies was also similar; 57% in the AI group and 59% in the PFS group. As expected, mean serum concentrations of GP2017 decreased at a faster rate in ADA-positive subjects than in ADA-negative subjects, irrespective of whether treatment was administered by AI or PFS. Overall, the incidence of treatment-emergent adverse events (AE) was similar in the AI and PFS treatment groups (reported by 74% and 76% subjects, respectively). Only one serious AE (appendicitis) was reported following administration by PFS, which was considered unrelated to treatment. Five subjects had a mild-to-moderate injection site reaction (n=3 in the AI group and n=2 in the PFS group). Most subjects had no pain, as assessed by the visual analogue scale.

Table. PK comparisons of AI and PFS for subjects with body weights between 50.0 and 94.9 kg.

			Ratio AI/PFS; 90% CI		
PK parameter	AI (n=45)	PFS (n=44)	Estimate	Lower	Upper
C_{max}, µg/mL	4.23	4.46	0.9501	0.8785	1.0275
AUC_{0-360h}, h×µg/mL	1219	1328	0.9176	0.8501	0.9905
AUC_{0-last}, h×µg/mL	2799	2755	1.0159	0.8839	1.1677
AUC_{0-inf}, h×µg/mL	3101	3002	1.0329	0.8946	1.1925

Conclusion: The primary objective of the study was met. Primary and secondary AUC parameters were similar for GP2017 40 mg administered by AI or PFS across a wide range of body weights. GP2017 was well tolerated by healthy male subjects, with no clinically relevant differences between the two treatment groups.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilars of originator biologic therapeutics are entering the market, and health care professionals and patients need a clear understanding of these new treatments. The advantage of biosimilars is the greater patient access which will follow the probable lower costs, although financial savings will vary between regions. With lower costs, switching from originators to biosimilars will probably be considered. However, clinical and real-word data on the effects of switching are currently limited to transition studies of approved biosimilars. This constitutes a gap in our understanding of the switching process (both originator→biosimilar and between different biosimilars). This study was carried out to summarize the current literature on switching.

Methods: A MEDLINE/Web of Science search identified studies where healthy volunteers or patients receiving infliximab (INF), etanercept (ETN), adalimumab (ADA), or rituximab (RTX) switched between originator biologics and biosimilars.

Results: Switching data was available for 12 studies in rheumatic diseases (Table): INF/CT-P13 (4^{1-4}), INF/SB2 (1^{5}), INF/unidentified biosimilar ($2^{6,7}$), ETN/SB4 ($2^{8,9}$), ETN/GP2015 (1^{10}), ADA/SB5 (1^{11}), and RTX/CT-P10 (1^{12}). The INF/CT-P13 studies showed efficacy and safety of INF and CT-P13 to be similar in switch and maintenance groups, and similar pre- and post-switch. Immunogenicity was assessed in 3 studies and did not change post-switch. In the INF/SB2 study, switch and maintenance groups had similar safety, efficacy, and immunogenicity profiles; comparisons pre- and post-switch were not made. The other 2 INF/biosimilar switch studies showed no difference in efficacy or safety 6 months post-switch. The ETN/SB4 and ETN/GP2015 Phase 1 studies showed similar PK parameters for ETN and the 2 biosimilars. In patients with RA, similar safety, efficacy, and immunogenicity profiles were seen between ETN/SB4 (switch) and SB4/SB4 (maintenance) groups. The ADA/SB5 study showed clinical measures of efficacy, safety, and immunogenicity to be similar in the switch and maintenance groups; comparisons pre- and post-switch were not made. The RTX/CT-P10 study showed clinical measures of efficacy and safety to be similar in the switch and maintenance groups. Efficacy pre- and post-switch could not be compared.

Conclusion: Switching data is starting to become available; mostly with INF but also emerging for other drugs. The one-way switch (originator→biosimilar) with observations ranging from 24 to 56 weeks seems to be the typical design. While initial transition data confirm maintenance of efficacy and safety, additional data from clinical and real-world switching studies, especially of switching between biosimilars, are required, as is continuing pharmacovigilance. Any switching should remain a clinical decision made jointly by the treating physician and patient on an individual patient basis supported by scientific evidence.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Obese rheumatoid arthritis (RA) patients (pts) may have higher levels of inflammatory mediators, greater joint swelling and tenderness, and suboptimal response to therapy. We assessed disease activity and treatment response in obese RA pts, using ultrasonography (US) and clinical measures.

Methods: This *post hoc* analysis used observed data from the MUSICA trial which evaluated the efficacy of high [20 mg/week (wk)] or low (7.5 mg/wk) doses of methotrexate (MTX) in combination with adalimumab (ADA) for 24 weeks (wks) in RA pts with previous inadequate response to MTX who initiated ADA. Pts were grouped according to body mass index (BMI) at baseline (BL): normal BMI<25; overweight BMI ≥25-<30; obese BMI ≥30. Synovial vascularity and hypertrophy were measured by Power Doppler US and Greyscale respectively, bilaterally, at metacarpophalangeal (MCP) joints 2, 3, 5, metatarsophalangeal joint 5 (MTP5) and wrists. Swollen joint count (SJC) of 66 joints, tender joint count (TJC) of 68 joints, 28-joint count Disease Activity Score using C-reactive protein (DAS28-CRP), and numbers of pts reaching American College of Rheumatology (ACR) criteria, Clinical Disease Activity Index [CDAI] low disease activity (LDA,<10), DAS28-CRP low disease activity (LDA; DAS<3.2), were assessed at wks 12 and 24.

Results: Out of 308 pts at BL, 69 pts (22.4%) had BMI <25,102 pts (33.1%) had BMI ≥25-<30 and 137 pts (44.5%) had BMI ≥30. Disease characteristics and ultrasound disease assessments were similar for the 3 BMI subgroups at BL**.** At wks 12 and 24, compared with pts in the normal and overweight categories, obese pts tended to have numerically smaller mean changes from BL in SJC66, TJC68, DAS28-CRP, synovial hypertrophy and synovial vascularity **(table)**. Compared to pts in the normal and overweight categories, significantly fewer obese pts reached ACR20/50 at wks 12 and 24. Significantly fewer obese pts reached CDAI LDA and DAS28-CRP LDA at wk 12; this difference was driven by those obese pts receiving low dosage of concomitant MTX (7.5 mg/wk), although by wk 24, the differences were no longer significant. There was low to no correlation between synovial vascularity/hypertrophy and clinical findings of swelling and tenderness. The proportion of pts with synovial vascularity=0 in the 3 BMI subgroups at wks 12 and 24 was not statistically different.

Conclusion: Among obese RA pts initiating ADA, those on low dosage of concomitant MTX had poorer responses than pts in the normal and overweight categories, as measured clinically and by ultrasound imaging, although this effect was partly overcome by wk 24. Obese RA pts may have an improved clinical benefit if ADA is initiated with high (20 mg/week), rather than low dosage of concomitant MTX.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA) patients (pts) receiving corticosteroids (CS) or methotrexate (MTX) with an anti-TNF, such as adalimumab (ADA), the concomitant CS or MTX dose may be reduced if pts respond well or have side-effects. The objective of the study was to assess treatment effectiveness in pts whose MTX or CS oral dose was reduced over 10 years (y) of open label (OL) ADA treatment.

Methods: This was observed data from OL extensions (OLE) of the PREMIER and DE019 trials.[1,2] In PREMIER, MTX-naïve, early RA pts received ADA/MTX/ADA+MTX for 2y, and optional OL ADA for upto 8y. In DE019, biologic-naïve, established RA pts received 20 mg ADA+MTX/ 40mg ADA+MTX/PBO+MTX for 1y and optional OL ADA+MTX for upto 9y. In both OLEs, MTX could be added/adjusted at the investigator's discretion, and oral CS dose could be tapered in pts who responded. Effectiveness at final visit (FV) was assessed by the numbers of pts achieving TJC68 = 0, SJC66 = 0, improvement from baseline in HAQ-DI ≥0.5 (HAQ-DI 0.5), ACR20/50/70 criteria and 28-joint disease activity score based on C-reactive protein (DAS28-CRP)<2.6. Additionally, in PREMIER, modified EULAR remission (REM) criteria [DAS28-CRP<2.6, TJC68 ≤1, SJC66 ≤1], "Good EULAR response" [DAS28-CRP<3.2 with a change from baseline ≤-1.2] were used.

Results: In **PREMIER,** by the pt's FV, out of 375 pts who had any oral CS, 220 (58.7%) were on ongoing CS; 155 (41.3%) had stopped. Among the 375 pts, 32% had a stable CS dose and 26.1% had a CS dose reduction. Dose reduction did not affect the proportion of pts reaching ACR criteria, HAQ=0.5 and DAS28-CRP<2.6 by FV **(table)**. Out of 497 pts in the OLE, 261 (52.5%) used concomitant MTX in the OLE, 236 pts did not. With/without MTX, the number of pts with DAS28-CRP<2.6 increased from 2- 10y, and the proportion of pts with SJC or TJC=0, good EULAR response, or modified EULAR REM criteria and the HAQ-DI scores were comparable in the +/- MTX groups. In **DE019,** by the pt's FV, out of 352 pts who received any oral CS, 207 (58.8%) were on ongoing CS and 145 (41.2%) had stopped CS. Among the 352 pts, 141 (40%) had a stable CS dose and 82 pts (23.3%) had a dose reduction. Out of 550 pts on MTX during the study, 497 (90.4%) were receiving MTX, and 53 (9.6%) had stopped by FV; 345/550 pts (62.7%) had stable MTX and 158 (28.7%) had a reduction. Reduction of CS or MTX did not affect the proportion of pts who reached the ACR criteria, HAQ DI 0.5 and DAS28-CRP<2.6 by FV.

Conclusion: Overall, effectiveness associated with continuous ADA treatment was not sacrificed in pts in whom concomitant oral CS or/and MTX doses were reduced or discontinued, although many of these pts were likely responding well at the time of taper. **References:** 1. SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: CHS-0214 is in development as a proposed biosimilar of etanercept. This Phase III confirmatory, safety and efficacy study randomized and dosed 644 subjects with rheumatoid arthritis (RA) in 13 countries. Health-related quality of life (QOL) outcomes were based on the Health Assessment Questionnaire – Disability Index (HAQ-DI), Subject Pain Assessment (SPA), Subject Global Assessment (SGA), and Physician Global Assessment (PGA).

Methods: Subjects had moderate/severe RA and an inadequate response to methotrexate (MTX). Subjects were randomized 1:1 to CHS-0214 or etanercept (commercial European-sourced) at 50 mg SC QW for 24 weeks (Part 1) and then received CHS-0214 50 mg SC QW open-label for 24 weeks (Part 2). Subjects continued on their stable dose of MTX throughout the study.

Results: The evaluable population for efficacy analysis in Part 1 included 512 subjects of mean age (50.6 vs 51.4 years), most of whom were female (81% vs 81%) and white (73% vs 71%) or Asian (25% vs 26%) for CHS-0214 vs etanercept, respectively. At baseline, subjects had a mean duration of RA of 6.9 vs 6.8 years and a mean DAS28-CRP(4) of 5.4 vs 5.4 for CHS-0214 vs etanercept, respectively. The primary endpoint of the study, ACR20 response at 24 weeks, was met in 91.0% vs 90.6% of subjects for CHS-0214 vs etanercept, respectively. The 95% CI of the treatment difference (0.41%) was [-4.55%, 5.37%], which fell within the predefined margin for equivalence of [-15%, 15%]. Mean scores on the HAQ-DI were 1.2 vs. 1.2 at Baseline with CHS-0214 and etanercept, respectively, and decreased 53% vs. 51% to 0.6 vs. 0.6 at Week 24. Mean scores on the SPA were 58.5 vs. 57.4 at Baseline with CHS-0214 and etanercept, respectively, and decreased 64% vs. 64% to 20.2 vs. 19.9 at Week 24. Mean scores on the SGA were 59.8 vs. 58.8 at Baseline with CHS-0214 and etanercept, respectively, and decreased 66% vs. 64% to 19.9 vs. 20.6 at Week 24. Mean scores on the PGA were 60.2 vs. 58.1 at Baseline with CHS-0214 and etanercept, respectively, and decreased 72% vs. 69% to 17.1 vs. 17.7 at Week 24. Overall, treatment emergent adverse events in Part 1 were reported in 60.8% of 324 subjects in the CHS-0214 treatment arm and 65.0% of 320 subjects in the etanercept treatment arm. The majority of adverse event were mild or moderate in severity. No deaths were reported.

Conclusion: This randomized, double-blind, active-control, global study demonstrated equivalence of CHS-0214 to etanercept based on the primary endpoint. The levels of improvement in health-related QOL measures were similar in both treatment groups.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ABT-122 is a novel dual-variable domain immunoglobulin (DVD-IgTM), which specifically neutralizes both TNF alpha (TNFα) and interleukin-17A (IL-17). Both cytokines are expressed at increased levels in rheumatoid synovial tissue and are believed to contribute to joint inflammation and structural damage to bone and cartilage that are hallmarks of rheumatoid arthritis (RA). Drugs individually neutralizing TNFα and IL-17 have demonstrated efficacy in patients with RA. The objective of this work was to quantitatively characterize the relationship between ABT-122 serum concentrations and time course of ACR20/50/70 and DAS28 (CRP) response following treatment with ABT-122 in subjects with RA who had an inadequate response to methotrexate in a Phase 2 study.

Methods: ABT-122 doses of 60 mg every other week (EOW; N=55), 120 mg EOW (N=56) and 120 mg every week (EW; N=55) were evaluated in this 12-week Phase 2, randomized, double blind, active comparator [adalimumab, 40 mg EOW (N=56)] study. Serial ABT-122 and adalimumab serum concentrations, collected every week and time course of efficacy data collected at baseline and weeks 2, 4, 6, 8, and 12, were analyzed using non-linear mixed-effects modeling. The relationships of ABT-122 and adalimumab average serum concentrations (C_{avg}) during the dosing interval and ACR20/50/70 responses were characterized using a Markov model, where active therapies enhanced transition of the status of patients to higher levels of response (e.g. no response to ACR20, ACR20 to ACR50, ACR50 to ACR70). For DAS28 (CRP), indirect response models with ABT-122 and adalimumab suppressing the DAS28 (CRP) scores were utilized.

Results: ABT-122 dose of 120 mg EOW provided comparable molar serum exposures to adalimumab 40 mg EOW, whereas the 60 mg EOW dose and the 120 mg EW doses provided exposures lower and higher than adalimumab, respectively. The EC_{50} (the concentration associated with 50% of maximal effect) on the transition rates to higher ACR response for ABT-122 and adalimumab were estimated to be 2.6 nM and 7.2 nM, respectively, with largely overlapping confidence intervals. The IC_{50} values, the concentrations associated with 50% of maximal reduction of DAS28 (CRP) scores for ABT-122 and adalimumab were both estimated to be 8 nM, with maximum inhibition of the baseline DAS28(CRP) level fixed to 60% based on observed data. These analyses indicate that the ACR20/50/70 and DAS28 (CRP) responses of ABT-122 plateau at exposures associated with 120 mg EOW dose in RA patients.

Conclusion: ABT-122 dose range evaluated in this Phase 2 study was adequate to describe the exposure-response relationships for ACR and DAS28 (CRP). ABT-122 and adalimumab potency values were not distinguishably different and Week 12 efficacy was comparable for the two agents at similar molar exposures (i.e. after pharmacokinetic differences are accounted for, both agents appear to provide similar efficacy). No significant increment in ABT-122 efficacy is estimated at doses higher than 120 mg EOW in patients with RA.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: High titers of rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (ACCP) are poor prognostic factors for rheumatoid arthritis (RA) patients. Only few studies have investigated the detailed clinical subtypes or radiographic changes based on serologic status; double (RF/ACCP) positive (+ve), RF or ACCP +ve, double negative (-ve) (seronegative, SN). We aimed to analyze the clinical and radiographic features of RA patients with robust disease activity, based on their serologic status.

Methods: RA patients registered in the Korean College of Rheumatology Biologics Registry (KOBIO), a nationwide inception cohort, were analyzed. Data regarding patient demographics, comorbidity, disease activity, medication, imaging and laboratory exams were utilized. After adjusting for gender, age, disease duration, and smoking history, we analyzed the association of seropositivity and bony erosion (hands and feet X-ray), and the association of the ACCP titer and joint damage, both at baseline (initiation of biologics) presented as odd ratio (OR) and its 95% confidence interval [95% CI].

Results: Data of 1198 RA patients were investigated. Mean age was 57.2 years, and disease duration was 8.3 +/- 7.6 years. Mean DAS28-ESR was 5.71, and erosion were found in 40.1% of patients. Being ACCP+ve was significantly associated with bony erosions (OR 1.69 [95% CI 1.13-2.52], p= 0.0096), compared with RF+ve (OR 1.03 p= 0.83), or RF+ve/ACCP+ve (OR 2.19 [95% CI 1.19-4.01], p= 0.012). Of note, being ACCP+ve/RF-ve was strongly associated with radiographic damage (OR 4.93 [95% CI 2.29-10.61], p< 0.0001) in our analysis (figure). In contrast, a multivariate logistic regression analysis showed that baseline ACCP titers were not positively associated with joint damage; a multivariate linear regression model revealed disease duration (estimate -3.95, p< 0.0001) and RF titer (estimate +0.0665, p= 0.0157) were associated with ACCP titers.

Conclusion: Our data demonstrate the significance of ACCP in predicting radiographic damage in established Korean RA patients with persistently high disease activity. Longitudinal studies would be needed to clarify the impact of ACCP titers on radiographic progression.

Session Date: Sunday, November 13, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Current guidelines consider MTX as initial gold standard treatment for patients (pts) with RA. They also propose various strategies for MTX inadequate responders, among which the most frequent are optimization of MTX therapy (alone or in combination with other csDMARDs or biological treatment). The objective of the trial was to explore the strategies applied in daily practice in RA pts with inadequate response to MTX.

Methods: STRATEGE is a prospective, observational, multicenter study. Main inclusion criteria were: confirmed RA diagnosis (ACR 1987 or ACR/EULAR 2010 criteria) and treatment by MTX monotherapy with clinical, structural, functional and/or therapeutic evolution leading to therapeutic management modification. Data were obtained at 2 time-points: baseline and 6-month follow-up.

Results: Between Sept 2014 and July 2015, 176 rheumatologists, at 90% with private practice, included 854 pts, 801 of

which composed the analyzable baseline set. Pts baseline characteristics were [mean (SD)]: age: 57.4 (13.7) yrs; RA duration: 5.3 (6.7) yrs; DAS28: 4.0 (1.1), with the following distribution: <2.6 for 10%, >3.2 for 74% and >5.1 for 16%; HAQ: 1.1 (0.84); and extra-articular features and erosive disease for respectively 10.5% and 39.9% of pts. All pts were receiving MTX monotherapy, orally for 67.6% and at mean (SD) dose of 14.2 (4.1) mg/wk for oral and 16.6 (3.8) mg/wk for parenteral administration. Auto-injections were performed by 50.7% of pts treated parenterally. Concomitant treatment included corticosteroids for 45.8% of pts, at a mean (SD) dose of 8.2 (6.3) mg/d, and folic acid for 90.0%. After the inclusion visit, MTX prescription has been identically maintained (dose and route) for 28.1% of pts, interrupted for 1.9% and modified for 70.0%. Changes included dose increasing for 50.2%, dose tapering for 1.8% and a route modification for 21.4% (88.2% oral -> parenteral). After inclusion visit, MTX oral versus (vs) parenteral balance was respectively 49.8% at mean (SD) dose 16.2 (4.0) mg/wk vs 45.8%, 18.0 (3.9) mg/wk. Biologic treatment was initiated for 14.6%, in association with MTX for 95.7%. Other csDMARD treatment was initiated for 1.2% in monotherapy and for 3.6% in association with MTX. The reasons for treatment modification were mainly active RA (72.0%), worsening of clinical and biologic parameters (31.4%), radiographic progression (14.5%), remission not achieved (12.4%), steroid dependence (11.3%), and MTX intolerance 5.0%. Six-month follow-up results show that all the active treatment strategies were significantly and equally successful in improving disease activity (Table).

	N	DAS28 Baseline	DAS28 M6	D DAS28	*p*
MTX unchanged (Ref.)	126	3.4 (1.3)	2.5 (1.0)*	- 0.8 (1.2)	-
MTX optimization	519	4.0 (1.0)	2.9 (1.2)*	- 1.1 (1.3)	0.10
bDMARDs	117	4.6 (1.1)	3.2 (1.1)*	- 1.4 (1.3)	0.22
csDMARDs	39	4.3 (1.2)	3.1 (1.3)*	- 1.3 (1.4)	0.37

Data presented: mean (SD) * $p < 0.0001$ (M6 *vs* baseline), ANCOVA, adjusted for DAS28 at baseline

Conclusion: Consistently with all current guidelines, results of the large prospective observational French study STRATEGE reveal an important place held by initial MTX treatment optimization before initiation of a biotherapy and emphasize the importance of treat-to-target strategy.

Population Pharmacokinetics of ABT-122, an Immunoglobulin Targeting Both TNF-α and IL-17A: Analyses Across Phase 1 Studies in Healthy Volunteers and Phase 2 Studies in Subjects with Rheumatoid or Psoriatic Arthritis

Amit Khatri and Ahmed A. Othman, AbbVie Inc., North Chicago, IL

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ABT-122 is a novel dual-variable domain immunoglobulin (DVD-Ig™), which specifically neutralizes both TNF alpha (TNFα) and interleukin-17A (IL-17). Drugs individually neutralizing TNFα or IL-17 have demonstrated efficacy in patients with RA and PsA. The objective of this work was to characterize the pharmacokinetics of ABT-122 and the effect of patient-specific covariates on ABT-122 exposures using available Phase 1 and 2 data in healthy volunteers (HV) and subjects with RA and PsA.

Methods: ABT-122 serum concentrations (approximately 4400 samples) from two Phase 1 single-dose studies in HV (N=72 subjects; ABT-122 doses: 0.1 to 10 mg/kg administered intravenously [IV] and 0.3 to 3 mg/kg administered subcutaneously [SC]), two Phase 1 multiple-dose studies in subjects with RA (N=31 subjects; ABT-122 doses: 1 mg/kg SC every other week [EOW] and 0.5 to 3 mg/kg SC every week [EW] for 8 weeks) and two Phase 2 studies, one each in subjects with RA (N=165 subjects; ABT-122 doses: 60 mg SC EOW to 120 mg SC EW for 12 weeks) and PsA (N=144 subjects; ABT-122 doses: 120 mg SC EW to 240 mg SC EW for 12 weeks) were included in this analysis. The effect of clinically relevant covariates on ABT-122 exposures were evaluated. Data were analyzed using non-linear mixed-effects modeling.

Results: ABT-122 serum concentrations were characterized using a two-compartment pharmacokinetic model with a combination of first-order (linear) and saturable (non-linear) eliminations. For reference intravenous administration, ABT-122 linear clearance and steady-state volume of distribution were 0.419 L/day and 6.0 L, respectively. The contribution of saturable elimination was negligible in the dose range evaluated in Phase 2 studies (range of 60 mg EOW to 240 mg EW SC). ABT-122 absolute SC bioavailability ranged from about 35% to 55% for different formulations and studies. ABT-122 terminal elimination half-life was approximately 9 days. Subjects with bodyweights of 42 and 137 Kg (lowest and highest in the dataset) were estimated to have about 30% lower and 60% higher ABT-122 clearance, respectively, relative to a 70 kg individual. ABT-122 clearance increased with the increase in ABT-122 anti-drug antibody titers, with an anti-drug antibody titer of 100 units estimated to result in 5-fold increase in ABT-122 clearance. In Phase 2 studies, incidence and titers of ABT-122 anti-drug antibodies decreased as the dose increased.

Conclusion: ABT-122 clearance is estimated to be approximately 3-fold faster than the well characterized values for adalimumab, leading to 3-fold higher ABT-122 dose needed to provide equivalent serum exposures to adalimumab. The developed pharmacokinetic and covariate models for ABT-122 enabled integrated exposure-response analyses across ABT-122 development program, allowing better understanding of the responses to dual TNF and IL-17 inhibition with this novel DVD.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: ABT-122 is a dual variable domain (DVD-Ig) biologic which inhibits TNF-α and IL17A. In a 12-wk phase 2 study (NCT02141997) in MTX-IR patients (pts) with RA, ABT-122 120 mg administered either every other week (eow) or every week (ew) (but not 60 mg eow) had efficacy at least comparable to adalimumab (ADA) 40 mg eow. However, dual inhibition was not significantly differentiated from TNF-α inhibition alone. Biomarker investigations were designed to assess the on-target effects of ABT-122 and the contribution of the anti-TNF-α and anti-IL17A components to pts ACR20 response at wk-12 in this trial.

Methods: Consenting pts provided whole blood and Paxgene blood tube samples (baseline [BL], wk-4) and serum samples (BL, wk-4, wk-12). Gene expression (Affymetrix GeneChip Human Gene 2.0 ST arrays), DNA methylation (Illumina Infinium Human Methylation 450K BeadChips), and multiplex serum protein (Milliplex or Myriad-RBM) analyses were conducted in 132 ACR20, 96 ACR20, and 30 ACR20 responders, respectively. Cell populations were estimated from DNA methylation profiles in whole blood (*Genome Biol.* 15:R31). Wk-4 changes in gene expression and DNA methylation were correlated with wk-12 continuous DAS28 change. Ingenuity Pathway Analysis software was used for pathway analysis. Repeated measures analysis of log-transformed serum protein changes used linear mixed models.

Results: Wk-4 changes in expression of genes associated with IL17A signaling (eg, IL23, MMP9, S100A8, S100A9, LCN2) indicated inhibition of IL17A by ABT-122. Serum protein changes (S100A8/A9, LCN2) were seen at wk-4 and wk-12 of ABT-122 treatment. Expression of 3756 genes was changed significantly at wk-4 in responders. Few genes (eg, MMP9, NAMPT; associated mostly with IL17A signaling) showed statistically significant differences in the ABT-122 arms vs the ADA arm. Differentially expressed genes plotted for ABT-122 responders were highly concordant with those from ADA responders. Pathway analysis of the nearest neighbor genes to these CpG sites indicated that ABT-122 inhibited IL17A pathways. Upstream driver pathway analysis of nearest neighbor genes and DAS28 found strong correlation with TNF-α responsive pathways (second highest rank) and weak correlations with IL17A- and IL17 receptor-responsive pathways (223rd and 1691st ranks, respectively). ABT-122 and ADA drove similarly robust changes in several protein biomarkers (eg, MMP3, CXCL13, CXCL9, IL6, S100A8/A9), suggesting TNF-α–driven effects. Methylation signatures in whole blood indicated significant changes in CD4 T-cell and granulocyte populations in ABT-122 vs ADA responders, indicating ABT-122–mediated inhibition of IL17A. Methylation of 6190 CpG sites was significantly correlated with DAS28 in responders at wk-4 (false detection rate <5%).

Conclusion: ABT-122 successfully engaged TNF-α and IL17A qualitatively, compared with adalimumab. However, correlation of wk-4 changes in gene expression and DNA methylation with wk-12 DAS28 response indicated that response to ABT-122 in pts with MTX-IR RA was primarily driven by TNF-α inhibition, with little added contribution from IL17A inhibition.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ABT-122 is a dual variable domain antibody which neutralizes both TNF and IL-17 and is in Phase II trials for rheumatoid arthritis (RA) and psoriatic arthritis. Because anti-TNF treatment in RA patients has been reported to increase IL-10^{+}CD4 T helper cells and Th17 cells, we evaluated whether the dual neutralization of TNF and IL-17 by ABT-122 would have additional effects on T cell cytokine production and T helper phenotypes in subjects receiving ABT-122.

Methods: In a Phase 1 study peripheral blood mononuclear cells (PBMCs) were taken from healthy volunteers at baseline, day 15, day 36 and day 57 following a single 1.5mg/kg dose of ABT-122 and cryopreserved. The PBMCs were thawed and either stimulated with anti-CD3/CD28 for 48hrs and supernatants evaluated for cytokine levels (Milliplex MAP technology) or stimulated with PMA/ionomycin for 4hrs and performed cytometric time of flight (CyTOF) analysis for T helper cell populations, including cytokine and transcription factor expression. Serum from 80 MTX-IR RA patients in a Phase II clinical trial with ABT-122 (60mg/EOW, 120mg/EOW, 120mg/EW) or anti-TNF (adalimumab, 40mg/EOW) was also evaluated for several cytokines that drive or are produced by T helper populations, including IL-23, IL-13, IFNγ, IL-22, IL-12, IL-10 and TGF-β (Myriad-RBM, Singulex, MSD or Milliplex).

Results: The PBMC of healthy volunteers produced significantly lower levels of the cytokines IFNγ, IL-4, IL-2, GM-CSF, and IL-22 following ex vivo stimulation withanti-CD3/CD28 after a single dose of ABT-122 compared to pre-dose levels. In contrast, IL-1RA and IL-21 were significantly elevated in stimulated PBMC cultures, whereas IL-17A, IL-17F, IL-6, IL-1β and IL-10 levels were unchanged. To explore whether these alterations in cytokines reflect a shift in T helper cell populations, PBMCs from these Phase 1 studies were further evaluated with CyTOF. Decreases in IL-22+ T helper cells and increases in IL-21+ T helper cells were confirmed by the CyTOF analysis, but other ex vivo cytokine changes, including decreased IFNγ, IL4 and GM-CSF were not reflected in either proportion of cells or magnitude of expression. Similar to reports with anti-TNF in RA patients, there were increased percentages of Th17 cells following ABT-122 administration, but minimal changes in percentages of Th1, Th2 and Treg cells. From Phase 2 RA subjects, the levels of serum IL-23, a cytokine that promotes Th17 development, trended higher with ABT-122 compared to adalimumab treatment. Conversely, there was a significant increase in serum IL-10 levels, an immunoregulatory cytokine, with ABT-122 compared to adalimumab treatment, suggesting promotion of both Th17 and regulatory pathways with the dual neutralization.

Conclusion: While circulating Th17 cells increase following administration of ABT-122, there appears to be a compensatory regulatory mechanism that restrains proinflammatory cytokine production following T cell receptor stimulation that may contribute to the dual mechanisms of action of ABT-122 in modulating pathogenic inflammation.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The OPTIBIO study is a clinical trial whose primary endpoint is to evaluate the proportion of patients that after one year are maintained in clinical remission with a dose reduction treatment regimen of biological therapy in patients with Rheumatoid Arthritis (RA), and to evaluate if the proportion of patients in remission with new regimen dose of treatment is not inferior to patients in remission with standard dose regimen. In our present work, we describe the preliminary results obtained so far.

Methods:

Open, randomized and controlled study of patients in clinical remission (DAS 28 <2.6 or SDAI <5 or ACR/EULAR 2011 criteria) at least 6 months followed in Third level Hospital Rheumatology Department. Patients treated with TNF inhibitors therapies (Etanercept, Infliximab, Adalimumab, Certolizumab, Golimumab), Tocilizumab and Abatacept. Patients are assigned to two groups randomly. Intervention group: according to a standardized protocol of dose reduction of biological therapies, Control group: according to standard dose regimen. Flare is considered when DAS28>2.6 or SDAI>5 or ACR/EULAR criteria are not fulfilled. Patients are following during after a minimum period of one year and maximum period of 3 years. The frequency of visits is every 12 weeks.

Results:

66 patients have been included from 14 April 2014 to 28 April 2016. Fifty-five women (83.33%) and 11 men (16.66%) with a mean age of 59.68 ± 11.72 years. Thirty-four patients in standard regimen dose and 32 patients in dose reduction regimen with comparable baseline characteristics for both groups. Positive Rheumatoid Factor (RF) in 80.30%. Forty-seven patients have erosive disease. None of the patients had tender or swollen joints at the beginning. At baseline, ESR and CRP values were 16.65 ±10.48 mm/1hour y 0.22 ± 0.23 mg/dl respectively, DAS 28-ESR value was 1.83 ±0.72 and DAS28-CRP was 1.35 ± 0.26. SDAI baseline value was 1.36 ± 1.00. Eighteen patients have presented a flare: 20.58 % in control group and 34.37 % in intervention group without statistical signification (p=0.209) with a Relative Risk (RR) 1.66 [0.73 - 3.77]. Baseline characteristics of the patients are described in tables 1 and 2

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor (TNF) and interleukin 17 (IL-17) appear to independently contribute to the pathophysiology of rheumatoid arthritis (RA), synergistically inducing inflammatory mediators leading to joint destruction. Selective dual neutralization of TNF and IL-17 confers superior protection compared with inhibition of either target in a mouse collagen-induced arthritis model. ABT-122 is a novel dual variable domain immunoglobulin (DVD-Ig™) targeting both human TNF and IL-17A, hypothesized to provide greater clinical responses in RA patients (pts). The objective of this study was to investigate the safety and efficacy of ABT-122 in RA pts with inadequate response to methotrexate (MTX).

Methods: Two hundred twenty-two pts were enrolled in this 12-week (wk) phase 2, randomized, double-blind, active-controlled, parallel group, study in active RA pts receiving concomitant MTX. Pts were randomized in a 1:1:1:1 ratio to receive ABT-122 (60 mg every other wk [eow], 120 mg eow, 120 mg every wk [ew]) or adalimumab (ADA, 40 mg eow) subcutaneously. The primary efficacy endpoint was the American College of Rheumatology (ACR) 20 response at wk 12. Additional secondary efficacy endpoints included responses of ACR50/70, low disease activity (LDA) and clinical remission (CR) based on DAS28 (hsCRP) or CDAI. The analysis presented here used non-responder imputation for missing data.

Results: ACR20 responses for ABT-122 demonstrated dose-dependence, with numerically higher responses for the 120 mg ew dose compared with 40 mg eow ADA. These ACR20 responses were consistent with the secondary efficacy endpoints suggesting that ABT-122 at doses ≥120 mg eow has efficacy at least comparable to ADA 40 mg eow **(Table 1)**. Treatment-emergent adverse events (AEs) were similar across all treatment groups with the majority being of mild or moderate severity. Across all treatment groups, there were no discernable differences in serious AEs or discontinuations; infection rates were similar for all treatment groups with no serious infections reported. There were no systemic hypersensitivity reactions reported with ABT-122. There were no dose-limiting or clinically-concerning laboratory abnormalities.

Conclusion: Efficacy data showed at least comparable efficacy of ABT-122 at doses ≥120 mg eow to 40 mg eow ADA in RA pts on concomitant MTX over 12 wks. With dual inhibition of TNF- and IL-17, there were no observed increases in safety findings. These results demonstrate that dual inhibition of TNF and IL-17 with a DVD-Ig provides an acceptable safety profile at the doses tested. Dual inhibition cannot be differentiated from TNF inhibition alone based on this dataset.

Table 1. Results From ABT-122 Phase 2 Study M12-963

	ADA 40 mg eow (n = 56)	ABT-122 60 mg eow (n = 55)	ABT-122 120 mg eow (n = 56)	ABT-122 120 mg ew (n = 55)

Calprotectin Serum Levels Strongly Predict Disease Flare in RA and Psa

Patients with Low Disease Activity Treated with TNF Inhibitors. a One-Year Prospective Cohort Study

Jose Inciarte-Mundo[1], M. Victoria Hernández[1], Virginia Ruiz-Esquide[1], Sonia Cabrera-Villalba[1], Julio Ramirez[1], Andrea Cuervo[1], Mariona Pascal[2], Jordi Yagüe[2], Juan D. Cañete[1] and Raimon Sanmarti[1], [1]Rheumatology Department, Hospital Clínic de Barcelona, Barcelona, Spain, [2]Immunology Department, Hospital Clinic de Barcelona, Barcelona, Spain

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: An increasing number of RA and PsA patients achieve low levels of disease activity under biological therapy. Thus, new biomarkers are needed to stratify disease activity, guiding therapeutic decisions. Calprotectin is a major S100 leucocyte protein, is associated with disease activity in this group of patients. Calprotectin is a potentially biomarker more sensitive of disease activity than conventional acute-phase proteins

Methods: Prospective 1-year follow-up, single center study (INMUNOREMAR cohort). RA (ACR 1987) and PsA (CASPAR) patients in clinical remission (**CR**) (DAS28-ESR <2.6) or low disease activity (**LDA**) (DAS28-ESR <3.2) in ≥2 consecutive visits treated with adalimumab (**ADA**), etanercept (**ETN**) or infliximab (**IFX**) for ≥3 months were included. Demographic data, disease duration, time to initiate csDMARD and bDMARD, time to achieve remission, remission duration, autoantibody status, radiological data, concomitant csDMARD therapy, dose and duration of biological therapy were collected. Clinical and laboratory assessment was made every 4 months and at the time of flare. Calprotectin serum levels (ELISA Kit Calpro AS®) and TNFa trough serum levels (ELISA Kit Promonitor®, Progenika) were determined. Disease flare was defined as DAS28-ESR>3.2 and increase in ΔDAS28-ESR >0.6. Univariate and multivariate regression models were used to identify predictors of disease flare.

Results: 103 patients (47RA, 56PsA) were included. Mean Age 57 (30–81) years. 78 (75.8%) had CR and 25 (24.2%) LDA. Mean CR/LDA duration was 58 (4–163) months. 36 patients had received treatment with ADA, 50ETN, and 17IFX. Mean biologic treatment duration 61 (7–166) months. 47.4% patients were on monotherapy, 47% on reduced dose, and 17.9% received steroids. 84 patients (91%) remained in CR/LDA for 12 months, and 12 patients (13%; 8 RA, 4 PsA) experienced flares. Patients with flares had a longer time to achieve CR/LDA [CR/LDA (n=81) 3.1 (1–6) months vs. Flare (n=12) 20 (5–31) months, p<0.001], a shorter CR/LDA duration [CR/LDA (n=81) 59 (5–163) months vs. Flare (n=12) 25 (3–134) months, p=0.031], higher calprotectin levels [CR/LDA (n=81) 1.4 (0.6–3.7) µg/mL vs. Flare (n=12) 6 (4.5–7.9) µg/mL, p<0.001], and lower drug trough serum levels at baseline [CR/LDA (n=83) 2.6 (0.6–12) µg/mL vs. Flare (n=12) 0.6 (1–1.2) µg/mL; p<0.001], even when analyzed by biologic [ADA CR/LDA (n=30) 7 (0.2–12) µg/mL vs. Flare (n=4) 0.5 (0.4–1) µg/mL; p=0.003; ETN CR/LDA (n=44) 1.5 (0.7–4.7) µg/mL vs. Flare (n=5) 0.8 (0.9–1.2)µg/mL; p=0.039; IFX CR/LDA (n=14) 3.1 (0.5–7.7) µg/mL vs. Flare (n=3) 0.1 (0–1) µg/mL; p=0.021]. Baseline TNFi trough serum levels [hazard ratio (**HR**) = 0.47], steroid treatment (HR=3.21), time to CR/LDA (HR=1.17), and baseline calprotectin levels (HR=2.38) significantly predicted flare in the univariate analysis. However, only baseline calprotectin levels significantly predicted flare in the multivariate analysis [HR=2.74 (1.74–4.31); p<0.0001].

Conclusion: Calprotectin was a strong independent predictor of flare in RA and PsA patients treated with TNF inhibitors with low levels of disease activity.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We recently reported that real-world persistence in Veteran's Affairs (VA) patients was lower in Rheumatoid arthritis (RA) patients receiving triple therapy [methotrexate (MTX), sulfasalazine (SUL) and hydroxychloroquine (HCQ)] at 17.5% in comparison to patients receiving MTX-Tumor necrosis factor inhibitor (TNFi) combination therapy at 45.2%. ($p<0.001$). This study reports and compares the specific reasons for discontinuation of these two combination regimens.

Methods: In this historical cohort study, US Veterans with RA enrolled in VA between January 1, 2006 to December 31, 2012 were identified using clinical and administrative data. Patients receiving MTX monotherapy to which either a TNFi (MTX-TNFi) or the simultaneous addition of HCQ/SUL (triple Rx) were followed over 12 months after initiating the combination. Discontinuation of combination therapy was defined as discontinuing any of the combination medications with a >90day gap and/or starting new drug treatments for RA. Patients discontinuing triple Rx or MTX-TNFi were matched to each other on age (±5 years), sex and site of care. The specific drugs discontinued and the reasons for discontinuing the combination therapy were determined by medical record review with the reason for cessation classified as one of the following: lack of efficacy, adverse drug event, or other (step-down therapy, preoperative discontinuation, noncompliance, lost to follow-up).

Results: There were 50 matched pairs between the two combination therapy groups evaluated. The drugs discontinued (table 1) and reasons for discontinuation (table 2) are shown below. The absolute rates for discontinuation by cause were estimated by extrapolating data over the entire cohort for the two combination treatment groups. Comparing discontinuation of triple therapy discontinuation of MTX-TNFi, the triple Rx group was associated with more discontinuations due to adverse drug events by both absolute and relative comparisons. Discontinuation due to lack of efficacy and other reasons for discontinuation were similar for the two groups. Methotrexate had the lowest discontinuation frequency in either group, with sulfasalazine being the most common drug discontinued in the triple Rx group.

Conclusion: The differences in persistence between the MTX-TNFi and Triple Rx groups in this real world observation cohort study appear to be primarily related to adverse drug events. The most common drug associated with adverse drug events was sulfasalazine, which was also the drug most frequently discontinued.

Table 1 Number of patients discontinuing specific drugs alone or in combination at termination of combination therapy (n=50 matched pairs)

	Triple Rx	MTX+ TNFi
Single drug Discontinued (n= 60)		
TNFi	N/A	34
MTX	2	10
SUL	13	N/A
HCQ	1	N/A
One or more drugs discontinued simultaneously (n = 40)		
SUL +HCQ	19	N/A
MTX+HCQ	2	N/A
All drugs of the combination	13	6
Total discontinuations (n=100)	50	50

Table 2 - Reasons for termination of combination therapy (n=50 matched pairs)

	Triple Rx		MTX+ TNFi	
Lack of Efficacy	6 (12%)		13 (26%)	
Adverse Drug Event	25 (50%)		17 (34%)	
GI toxicity		9		0
Rash		4		2
Infection		3		3
Other adverse drug event		9		12
Other	19 (38%)		20 (40%)	
Step down of therapy following clinical improvement		6		2
Discontinued prior to surgery		0		5
Lost to follow-up/unknown		13		13
Total discontinuations	50		50	
Estimated absolute percentages for discontinuation of combination therapy for entire cohort during 12 months of observation.				
	Triple Rx		MTX+ TNFi	
Overall combination termination rate in initial study	82.5%		54.8%	
Lack of Efficacy	10.8%		15.4 %	
Adverse Drug Event	39.4%		19.1 %	
Other	32.3%		20.2 %

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Sjögren's Syndrome - Poster I: Translational Science
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS) patients manifest inflammation in salivary glands (SG) (lymphocytic infiltration of salivary and lachrymal glands) and evidence of intrinsic activation in the salivary epithelial cells (SGEC). Recent evidence from this laboratory has indicated that the aberrant exposure of SGEC of SS patients to necrotic debris may be a major cause of inflammatory reactions via the activation of inflammasome and may hold a key role in the pathogenesis of the disorder. Thrombospondin (TSP-1) is a matricellular glycoprotein with proinflammatory, antiangiogenic and proapoptotic properties. TSP-1 also activates TGF-β1 and has been shown to be involved in TH-17 response. It was originally characterized as an α-granule glycoprotein in platelets, although can be synthesized and released by a variety of cell types, including epithelial cells. Herein, we assessed the expression of TSP-1 in cultured ductal SGEC lines obtained from SS patients and controls. We also sought to investigate the effect of necrotic cell debris (NEC) on mRNA synthesis and release of TSP-1, in healthy epithelium.

Methods: non neoplastic SGEC lines from SS patients and non-SS controls (healthy) were comparatively evaluated for the constitutive expression of TSP-1 and IL-1β (both at mRNA and protein level in culture supernatants). In addition, SGEC lines treated with NEC were evaluated for the mRNA and protein expression of TSP-1 and IL-1β, by RT-PCT and ELISA, respectively.

Results: SS patients (n=14) displayed significant upregulation of TSP-1 mRNA levels in cultured epithelial cells, compared to controls (n= 10, p=0.0005), that correlated with the severity of histopathologic lesions (tarpley score of the respective Salivary Gland tissue biopsy) (Kruskal-Wallis test, p=0.001). SS-SGEC (n=16) were also found to secrete constitutively more TSP-1 and IL-1β in their culture supernatants, compared to non-SS SGEC (n=15) (p=0.0001 and p=0.06, respectively). There was a positive correlation among the constitutively expressed levels of TSP-1 and IL-1β (Spearman's r= 0.66 for mRNA and r=0.41 for protein). Treatment of healthy SGEC lines (n=4) with NEC led to the induction of TSP-1 and IL-1β mRNA (2.1-fold and 2-fold increase, respectively), as well as protein in culture supernatants (3.0-fold and 2.5-fold increase, respectively) (for all comparisons, $p<0.05$), that were abrogated upon pre-treatment of NEC with DNase1.

Conclusion: Preliminary results suggest for the first time that salivary gland epithelial cells from SS patients manifest increased TSP-1 and IL-1β levels that correlate with severe lymphocytic infiltrates in salivary glands. Chronic exposure to necrotic cells debris may hold a key pathogenetic role in the tissue inflammatory reactions of SS patients and may also explain the "intrinsic activation status" that characterizes the epithelia of these patients.

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

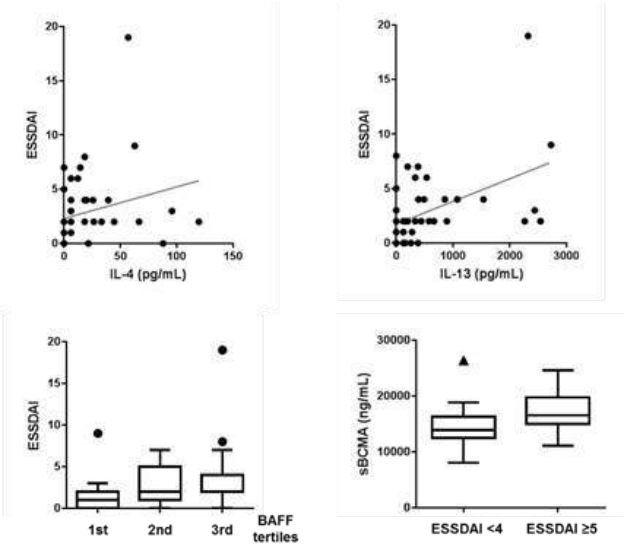
Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren`s syndrome (pSS) is an autoimmune diseases characterized by lymphocytic infiltration of exocrine glands and dysregulated proliferation and differentiation of B cells. Two TNF ligand superfamily members (B cell activating factor [BAFF] and a proliferation inducing ligand [APRIL]) and their receptors (BAFF-receptor, B-cell maturation antigen [BCMA], and transmembrane activator and cyclophilin ligand interactor [TACI]) are involved in the regulation of B-cell activation. Soluble BCMA (sBCMA) or TACI (sTACI) was recently reported to be increased in body fluids of several lymphoproliferative or chronic inflammatory diseases. We measured plasma levels of B cell-targeted cytokines, sBCMA and sTACI and investigated their correlations with clinical parameters of pSS patients.

Methods: Blood samples were collected from 45 pSS patients who satisfied the American-European Consensus Group (AECG) criteria and 16 age- and gender-matched healthy controls. The plasma concentrations of IL-4, IL-13, BAFF, APRIL, sBCMA, and sTACI, were measured by using magnetic bead-based multiples assays. Disease activity was assessed by the European-SS disease activity index (ESSDAI).

Results: Plasma levels of IL-4, IL-13, and BAFF were significantly increased in patients with SS, compared with healthy controls (p=0.037, p=0.010, and p=0.004 respectively). There were no differences in the levels of APRIL, sBCMA, and sTACI between two groups. pSS patients with extraglandular manifestations had higher levels of higher levels of BAFF than those without (6.46 [4.79~ 7.65] vs. 5.03 [4.02~6.15], p= 0.042). Total IgG and beta2-microglobulin levels were found to be correlated with the levels of IL-4, IL-13, and sBCMA, while BAFF was correlated with only beta2-microglobulin. IL-4 and IL-13 levels showed significant correlations with ESSDAI (r=0.432, p=0.003, and r=0.446, p=0.002, respectively). ESSDAI scores tended to increase across BAFF tertiles (p=0.031 by by Jonckheere-Terpstra test). pSS patients with ESSDAI score >= 5 showed higher levels of sBCMA than those without (16.56 [14.99~19.76] versus 13.92 [12.48~16.29], p=0.029).

Conclusion: Circulating levels of IL-4, IL-13, and BAFF was elevated in pSS patients but sBCMA and sTACI levels were not. These findings suggest that pSS may have a less efficient negative feedback exerted by soluble BAFF/APRIL



receptors.

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by immune cell infiltration in the salivary glands resulting in ocular and oral dryness. Abnormalities in B cell activation and skewing of T cell polarization toward Th2 and T follicular helper (TFH) associated with ectopic germinal center formation in the salivary gland are observed in pSS. However, the interplay between B cell subsets, T cells, and other immune abnormalities, as well as relationship to disease status, has yet to be fully elucidated. In this study, we evaluated changes in peripheral blood B and T cell populations in pSS patients compared to disease and healthy controls.

Methods: Two cohorts of patients with pSS according to European-American Consensus and ACR criteria and age-

matched healthy controls (HC) were recruited (Rochester, USA and Strasbourg, France). The Rochester cohort also included rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) (n=9 and 10 respectively) classified based on ACR criteria. PBMCs were isolated by Ficoll-Hypaque and the frequencies of B and T subpopulations measured by multi-parameter flow cytometry as further defined in the results. Data are reported as median [25^{th}-75^{th} quartile].

Results: pSS patients from the Rochester cohort had a higher frequency of circulating TFH (CXCR5+ICOS+PD1+) than HC (pSS (n=15): 5.83 [4.38-8.13]%; HC (n=27): 4.18 [2.95-4.58]%, p=0.002). Although there was no significant difference in the relative frequency of TFH subpopulations (TFH1, TFH2, TFH17 and TFH1-17) between pSS, HC, RA, and SLE, the frequency of TFH1 ICOS+ PD1+ cells was significantly higher in pSS than HC (pSS (n=15): 7.29 [5.51-10.8]%; HC (n=27): 4.44 [3.2-5.86]%, p=0.001). pSS patients from the Strasbourg cohort had an increase in the frequency of circulating TFH (CD4+CD45RA- CXCR5+) in comparison to HC (pSS (n=48): 27.65 [20.45-34.1]%; HC (n=217): 21.70[18.02-26.11]%, p=0.02). The frequency of TFH1 cells was significantly higher in pSS than HC (pSS (n=48) 29.1 [25.5-33.9]; HC (n= 24): 24.01 |19.7; 31.5]%, p= 0.04). In the Rochester cohort, we characterized B cell populations. pSS patients had a significant reduction in switched memory (SM) B cells (CD27+IgD-) compared to HC (pSS (n=16): 3.94 [2.68-7.18]; HC (n=28): 8.95 [6.2-14.22]% of B cell, p=0.001). In similar fashion, the frequency of unswitched memory B cell (CD27+IgD+) in pSS was significantly lower than HC (pSS (n=16): 8.69 [4.71-13.99]; HC (n=28): 16.91 [12.98-21.36]% of B cell, p=0.003). We also observed significant reductions in frequencies of CD95+ SM B cells (pSS (n=16): 1.87 [0.93-2.88]; HC (n=28): 3.29[2.13-5.11]% of B cell, p=0.0037) and ICOSL+ SM B cells (pSS (n=16): 0.075 [0.05-0.28]; HC (n=28): 0.28 [0.17-0.84]% of B cell, p=0.01).

Conclusion: Our data highlight the significant abnormalities in the peripheral TFH and B cell compartment in pSS and further suggest the critical role of TFH- B cell interactions. The decrease in ICOSL+ SM B cells suggests their interaction with ICOS+ T cells in germinal center-like structures in salivary glands. Relationship to clinical parameters and pathologic and ultrasound abnormalities in salivary glands are currently under investigation.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Sjögren's Syndrome - Poster I: Translational Science
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome is a chronic autoimmune disorder that affects mainly the exocrine glands. The

initiation and causative agents are still unknown. Endoplasmic Reticulum (ER) stress proteins have been suggested to participate in autoimmune and inflammatory responses, either by acting as autoantigens themselves, or by modulating factors in inflammatory responses.ERdj5 is anER-resident chaperone proteinwith a disulfide reductase activityand is required for the translocationof misfolded proteins across the ERfor proteasomaldegradation. In this study we sought to investigate the role of ERdj5 in the salivary glands, in associationwith inflammation and autoimmunity.

Methods: *In situ*expression of ERdj5 was studied immunohistochemically in minor salivary gland tissues (MSG) from primarySjögren's Syndrome (SS)-patients and non-SS sicca-complaining controls. Submaxillary glands and sera from both male and female ERdj5-knockoutmice andage-matched wild types were collected at 6,34 and 52 weeks of age. Tissue samples were analyzed microscopically, while sera were screened for anti-nuclear antibodies(ANAs).

Results: Human MSGs expressed ERdj5,with higher stain intensity in MSGs of SS patients with severe inflammatory lesions.Mice deficient in ERdj5 spontaneously developed SS-like inflammation in submaxillary glands and ANAssystemically. Inflammation was characterized by T and B infiltrating lymphocytes. Notably, female ERdj5-knockout mice developed severe chronic periductal inflammation in contrast to the much milder phenotype found in male littermates.

Conclusion: Salivary glands of ERdj5-knockout mice resemble the pathologic lesions of human Sjögren's syndrome whereasERdj5 wasinduced in MSGs of SS patients. Our findings suggest a critical connection betweenthe function of the ER stress chaperone protein ERdj5 andautoimmune inflammatory responses in the salivary glands.

Session Date: Sunday, November 13, 2016

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Type-III IFNs or IFNλs(IFNλ1/IL29, IFNλ2/IL28A and IFNλ3/IL28B) consist a recently identified group of IFNs,initiallyimplicated inseveral human diseases, including cancer and autoimmunity. In this study, we sought to investigatethe expression of type-III IFNs (IFNλ1/IL29, IFNλ2/IL28A and IFNλ3/IL28B) and their common receptor IFNλR1/IL28Ra in Sjögren's Syndrome (SS).

Methods: The *in situ* expression of all molecules was studied immunohistochemically in minor salivary gland tissues (MSG) from primary SS-patients (n=46) and sicca-complaining controls (n=17). Expression in peripheral blood

mononuclear cells (PBMCs) and sera was investigated by ELISA and real-time PCR, respectively. Expression in resting or TLR-stimulated salivary gland epithelial cells (SGEC) was assessed by both qPCR and ELISA.

Results: All type-III IFN family members were detected in ductal and acinar epithelia of MSGs from both SS-patients and sicca-controls.IFNλ2/IL28A and IFNλ3/IL28B were also expressed in infiltrating mononuclear cells (MNCs). In SS-patients with intermediate MSG lesions, the epithelial expression of IFNλ2/IL28A was more intense ($p<0.05$) compared to sicca-controls. The receptor IFNλR1/IL28Ra was detected in all types of cells except fibroblasts and was exceptionally strong in plasmatocytoid dendritic-cells, indicating that they are susceptible to type-III IFN-mediated regulation.Although none of the type-III IFNs was constitutively expressed in SGECs, they were all readily induced by TLR3 stimulation, suggesting that the *in situ*epithelial expression can be attributed to local microenvironment. Type-III IFN-mRNAs were not expressed in PBMCs, whereas only IFNλ1/IL29 was detected in the sera and was significantly elevated in SS patients with intermediate MSG inflammatory lesions compared to sicca-controls ($p<0.0053$).

Conclusion: Type-III IFNs are expressed in the MSGs and their expression is likely subjected to micro-environmental regulation. Our findings suggest that they may be implicated in SS pathogenesis.

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Plasmacytoid dendritic cells (pDCs) are indicated to be key players in the pathogenesis of primary Sjögren's syndrome (pSS) and important producers of type-1 interferon (IFN). This is based on their increased presence in pSS salivary glands, potential role in experimental animal models and the presence of an IFN signature in pSS patients, which is associated with disease activity measures. MicroRNAs are key regulators of cellular function and play a pivotal role in cellular function. To study potential dysregulation of pDCs of pSS patients, we investigated the expression of micro-RNAs (miRNA) in these cells in patients with pSS.

Methods: Two independent cohorts (discovery and validation) were established including a total of 30 pSS patients who were classified according to the 2002 criteria. 15 healthy controls (HC) were included as control group and divided over the two cohorts. CD304-expressing cells were isolated from peripheral blood using MACS and profiling of 758 miRNA was performed using the OpenArray platform. miRNAs found to be differentially expressed in the discovery cohort ($p<0.05$, with at least a difference between the groups of log2) were subsequently measured in an independent validation cohort using a custom made array. Experimentally supported targets of validated miRNAs were used to perform pathway enrichment in order to assess the functional role of the dysregulated miRNAs.

Results: Twenty-four miRNAs were significantly downregulated in pSS patients versus HC in the discovery cohort. 15 of these miRNAs were selected to be measured in the validation cohort, of which ten miRNAs were subsequently validated ($p<0.05$). Pathway enrichment indicated that these miRNAs are mainly involved in regulation of growth factor signalling and cell cycle (FDR corrected, $p<0.05$). We are currently studying the involvement of these miRNAs in pDC function and their correlation with their experimentally supported targets.

Conclusion: Ten miRNAs are expressed at lower levels in pDCs of patients with pSS as compared to healthy controls. Considering the potential of miRNAs in regulation of cell function, these data suggest a significant contribution to pDC function of miRNA dysregulation. Further analysis of the pathways in which these miRNAs are involved will expand our understanding on the role of pDCs in pSS.

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The therapy for sjogren's syndrome (SS) focuses on biological agents, immune inhibitors and glucocorticoid which can't correct the problem of unbalance of Th17 and Regulatory T (Treg) cells in refractory patients. It was reported that IL-2 had a critical effect on homeostatic maintenance of the Th17 and Treg cells and the ratio of them. The study is to explore the effect of low dose IL-2 therapy on the balance of Treg and Th17 cells in refractory patients with SS and observe the efficiency and side effects of the therapy.

Methods: SS patients (n=18) (from march 1st to may 30thin 2016, both outpatients and inpatients in our department, according to American-European Consensus Group criteria for SS) with decreased Treg cells (18/18) and increased ratio of Th17/Treg (16/18), who were refractory to standard therapy including glucocorticoid, immune-suppressants, biological agents or combination of them, were given low-dose IL-2 (50 WIU/day for 5 days) by hypodermic injection. Laboratory indicators were compared before and after IL-2 treatment. The side effects were observed in the course of therapy.

Results: The number of Treg cells significantly increased after the treatment and returned to normal range in 89% (16/18) of patients by 1 week (12.24±3.95 vs. 48.10±33.21, $p<0.01$). At the same time, there was a significantly decrease in the ratio of Th17/Treg cells (0.66±0.52 vs. 0.36±0.41, $p<0.1$), which returned to normal range in 7 patients and was lower in 14 patients. Besides, Th17 cells were also increased (8.11±6.72 vs. 12.91±10.04, $p<0.1$). Clinical manifestations were improved after the combitional treatment of IL-2 and traditional drugs. No obvious adverse reactions were observed.

Conclusion: Low dose IL-2 therapy can restore and maintain the balance of Th17 and Treg cells in the refractory patients with SS. Manifestation improved after the combitional therapy. The therapy is safe. More research is needed to investigate long term efficiency of the therapy and the prognosis of the patients.

Expression of the Chemokine Receptor CXCR5 Is Decreased in the Periphery of Patients with Primary Sjogren's Syndrome

Marie Wahren-Herlenius[1], Lara Adnan Aqrawi[1], Margarita Ivanchenko[1], Albin Björk[1], Jorge Ramírez[1], Marika Kvarnström[1], Janicke Cecilie Liaaen Jensen[2] and Kathrine Skarstein[3], [1]Karolinska Institutet, Stockholm, Sweden, [2]University of Oslo, Oslo, Norway, [3]University of Bergen, Bergen, Norway

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Sjögren's Syndrome - Poster I: Translational Science
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: CXCR5 is a chemokine receptor expressed on B and T cell subsets, which binds the CXCL13 ligand produced by follicular dendritic cells. It is involved in cell migration and germinal centre reactions. The latter is observed ectopically in the salivary gland (SG) target organ of the rheumatic autoimmune disease primary Sjögren's syndrome (pSS). Further, genome-wide association studies have linked polymorphisms of CXCR5 to pSS, making the pathway important to explore for identification of novel treatment targets and for understanding disease pathogenesis. In this study we aimed to investigate the expression of CXCR5 in the peripheral blood and minor SG biopsies of pSS patients.

Methods: Flow cytometry was performed for cell populations and activation markers on PBMCs acquired from 14 untreated pSS patients, 10 pSS patients treated with the antimalarial drug hydroxychloroquine, and 15 sex and age matched healthy controls. Moreover, minor paraffin-embedded SG biopsies from the same pSS patients were stained for the detection of CXCR5+ cells using immunohistochemistry.

Results: HLA-DR expression was significantly increased in the untreated pSS patients compared to controls, on both CD19+ B cells ($P < 0.04$) and CD14+ monocytes ($P < 0.001$), with a significant decrease in expression following treatment on both CD19+ B cells and monocytes ($P < 0.009$). A trend towards a decreased percentage of CXCR5+ cells as well as CXCR5 cell surface expression was observed for most B and T cell subsets in untreated patients with pSS, reaching statistical significance in CD19+CD27+IgD+ marginal zone ($P < 0.001$) and CD19+CD27+IgD- memory ($P < 0.006$) B cells as well as in CD3+CD4+CCR6+ Th17 cells ($P < 0.03$). These observations were not reversed, but rather aggravated by hydroxychloroquine treatment. Meanwhile, immunohistochemical staining of SG biopsies revealed high numbers of CXCR5+ cells both within the focal infiltrates and interstitially in the target organ of these patients.

Conclusion: We conclude that the decrease of CXCR5 levels in the periphery of patients with Sjögren's syndrome result from homing of B and T cells to the autoimmune target organs. Hydroxychloroquine treatment appears not to be efficient in inhibiting the factors driving the trafficking, although it decreases the MHC class II expression. Therapeutic drugs targeting the CXCR5/CXCL13 axis may be useful in pSS.

Epitope Specificity and End-Organ Susceptibility Dictates Anti-Ro52 Mediated Salivary Gland Dysfunction

Magdalena Sroka[1], Indranil Biswas[1], Brian Shepherd[1], Dat C Truong[2], Harini Bagavant[1] and **Umesh S Deshmukh**[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Oklahoma, Norman, OK

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Circulating autoantibodies reactive against Ro52 are detected in the sera of 70% of patients with Sjögren's syndrome (SS), and their presence has been associated with higher severity of the disease. Previous work from our laboratory has demonstrated that interaction between anti-Ro52 and activated innate immunity induces salivary gland (SG) dysfunction in the New Zealand Mixed (NZM) 2758 strain of mice. This study was undertaken to investigate the mechanisms involved in anti-Ro52 mediated salivary gland dysfunction.

Methods: To determine the role of B cell epitope specificity in glandular dysfunction, NZM 2758 mice (5-10 per group) were immunized with recombinant fusion proteins representing the 3 structural domains of Ro52: Ring-B-Box (amino acids 16-123), Coiled-coil (amino acids 128-238) and SPRY (amino acids 268-465). Control mice were immunized with Maltose-binding protein (MBP). All immunization used Alum as the adjuvant. Antibody reactivity was analyzed by immunoprecipitation assay employing 35S-Met labeled Ro52, and by flow cytometry, using mouse ductal cell line SCA9-15. The ability of antibodies to penetrate live SCA9-15 cells was investigated by immunofluorescence. To determine end-organ susceptibility, anti-Ro52 serum generated in rabbits was passively transferred into either untreated or alum treated NZM2758 and lupus-prone NZM2328 mouse strains. SG function was assessed by measuring pilocarpine stimulated saliva.

Results: All groups of NZM2758 mice, except the MBP immunized control mice, generated IgG antibodies capable of immunoprecipitating whole Ro52. While antibodies in the sera from most of the coiled-coil immunized mice (7/8) penetrated live SCA9-15 cells, only 1/5 SPRY and 0/10 Ring-B-box immunized mice had cell penetrating antibodies. This antibody uptake was not dependent on the Fc gamma receptor expression. Only mice immunized with the coiled-coil domain showed a significant drop ($p=0.0027$) in saliva production. Passive transfer of rabbit anti-Ro52 readily induced SG dysfunction in NZM2758 mice, which was further amplified, if the mice were pretreated with alum. No such functional loss was observed in the lupus-prone NZM2328 mice.

Conclusion: Our study demonstrates that anti-Ro52 mediated salivary gland dysfunction is regulated by antibody epitope specificity and the genetic susceptibility of the end-organ. Our data provides an explanation for the lack of concordance between the presence of anti-Ro52 and the extent of dry mouth observed in some patients. Thus, in SS patients, measuring the relative levels of anti-Ro52 domain reactive antibodies might be more informative than just determining the presence or absence of anti-Ro52.

Session Date: Sunday, November 13, 2016

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjogrens syndrome (SS) is a chronic autoimmune inflammatory disease the characterisitic features of which includes hypofunction of exocrine glands leading to decrease in salivation (dry mouth) and lacrimation (dry eyes). The presence of antibodies against Ro and La autoantigens serves as one of the hallmarks in the diagnosis of SS. Anti-muscarinic receptor 3 antibodies are another set of antibodies also found in SS patients. Muscarinic receptor 3(M3R) is a parasympathetic end organ seven transmembrane GPCR present on salivary and lacrimal glands, the stimulation of which is known to produce salivation and lacrimation. M3R has three extracellular domains (ECD) that plays an essential role in ligand binding and stimulation of the receptor. We found that monoclonal antibodies derived from salivary glands of SS patients that are positive for 2^{nd} and 3^{rd} ECDs of M3R are highly reactive to Ro peptides.

Methods: Monoclonal antibodies (MAbs) from salivary glands: Patients having dry eyes and dry mouth were classified according to AECG criteria into SS group and Do not meet criteria group (DNMC-Control). Plasmablasts (antibody secreting cells) with CD3- CD4- CD8- CD19+ CD27high CD38high IgG+ surface markers were sorted out using FACS from the salivary glands obtained following biopsy. The variable(V),diversity(D),joining(J), complementarity determining region(CDR) portions of heavy and light chain from each individual plasmablast were sequenced, amplified by PCR, cloned into a vector, transfected and expressed in HEK293A cell line. Ro and M3R Experiments: Reactivity of each Mab towards Ro were tested either by Bioplex 2200 or invitro transcription/translation system employing Ro52 and Ro60 labeled with ^{35}S-methionine and biotinylated-Lys or both methods. Reactivity to M3R peptides were determined by ELISA employing peptides encoding either 2nd (A.A. 213-218) or 3rd ECD (A.A.514-527) respectively.

Results: In the SS group, 23 Mabs were positive for Ro. 9 mabs were postive for 2nd ECD and 5 were positive for 3rd ECD of M3R. 4 Mabs were positive for both the M3R domains. (Cutt off 2 S.D. above DNMCs average O.D.). We found that 7/9 (77%) of ECL2 +ve MAbs were positive for Ro whereas 4/5 (80%) of ECD3 +ve MAbs were positive for Ro. Four Mabs that were positive for both 2nd and 3rd ECD, all (100%) were positive for Ro. None of the Mabs in the DNMC group were positive for 2nd ECD.

Conclusion: We have found a sequence similarity between Ro and M3R ECDs. This high cross reactivity of anti-M3R antibodies with Ro possibly suggests a mechanism where antibodies formed against these shared portion of Ro with M3R could cross react with M3R and may cause inhibition of the receptor leading to major symptoms observed in SS. We are further studying functional aspects of anti-M3R antibodies on the receptor function and getting a significant higher

inhibition from Mabs from SS when compared to DNMCs. Our future studies are also aimed at discovering the functional aspects of anti-M3R monoclonal antibodies on lacrimation and salivation when passively transferred to mice.

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Evidence suggests that levels of different cytokines in primary Sjögren´s syndrome (pSS) are associated with cell infiltration degree within lacrimal and salivary glands and severity of the disease. Chemokines appear to contribute to the pathogenesis of pSS. Purpose: To evaluate the association between serum and tear Th1/Th2/Th17 cytokine and chemokine levels and disease activity in patients with pSS.

Methods: Case-control study including 19 patients with pSS and 13 healthy controls. Disease activity was assessed by EULAR Sjögrens´s Syndrome Disease Activity Index (ESSDAI); serum and tear IFN-γ, TNF. IL-2, IL-4, IL-6, IL-10, IL-17, IP10, MCP-1, MIG, RANTES and IL-8 levels were measured by bead-based assays following the sandwich immunoassay principle (BD Cytometric Bead Array; BD Biosciences). Differences between groups were analyzed using the Mann-Whitney U test. Correlation was estimated by Spearman´s correlation coefficient.

Results: TNF, IL-2, IL-4, IL-6, IL-10, IP-10, MCP-1, RANTES and IL-8 tear levels were statistically different between controls and patients with pSS ($p<0.005$). A significant correlation ($p>0.005$) was shown in patients between serum IL-6 and serum IL-2 (r=0.652), IL-4 (r=0.731; serum IL-2 and serum IP-10 (r=0.640); serum IL-2 and tear IL-2 (r=0.614, IL-8 (r=0.723), IP-10 (r=0.795), MIG (r=0.755); serum IL-4 and tear IL-8 (r=0.696), MIG (r=0.707); serum IP-10 and serum MIG (r=0.847), RANTES (r=0.626); serum IP-10 and tear IP-10 (r=0.619); serum MIG and serum RANTES (r=0.719); serum MIG and tear IL-17 (r=0.619); serum RANTES and tear IL-2 (r=0.628), IL-4 (r=0.619), IL-6 (r=0.736), IL-8 (r=0.770), IP-10 (r=0.687), MCP-1 (r=0.566), MIG (r=0.740).

Conclusion: Increased tear Th1/th2 cytokine levels were found in pSS. No correlation was found between serum or tear cytokine and chemokine levels and pSS disease activity.

Abstract Number: 664

Regulation of Interferon Signaling By a Calcium-Induced miRNA in Primary Human Salivary Gland Epithelial Cells

Shyh-Ing Jang, NIDCR, NIH, Bethesda, MD
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Sjögren's Syndrome - Poster I: Translational Science
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS), an autoimmune disease that targets the salivary and lacrimal glands which causes dry eyes (xerophthalmia) and dry mouth (xerostomia) phenotypes. In the salivary gland, the reduction or complete loss of saliva secretion has been attributed to acinar cell dysfunction. Although the underlying mechanisms are unclear, more than 50% of SS patients display high activity of type I and II interferon (IFN) responses.

Methods: We established primary human salivary gland epithelial cell culture (phSG) conditions that either retains highly proliferative growth or display differentiated acinar-like phenotype. Whole Transcriptome profiling (RNA-Seq) revealed calcium-regulated and differentially expressed miRNAs.

Results: One of these differentially expressed miRNAs, miR-1248, increases more than 8-fold in phSG cells after calcium switch. Transfection of miR-1248 mimics into phSG cells results in up-regulation of Stat1 (6-fold), Stat2 (3-fold), JAK1 (2.5-fold) and JAK2 (4-fold). Also interferon-stimulated genes (ISG) of MX1, OAS1 and ISG15 were markedly elevated indicating the involvement of miR-1248 in regulation of IFN signaling pathway. Knockdown of IFNAR1/IFNAR2 in miR-1284 mimic-transfected phSG cells showed greatly reduced MX1 induction. IFN-b and -g were detected in culture media in miR-1248 mimic-transfected phSG and primary T cells, respectively, confirmed the production and secretion of these cytokines. Digital PCR assays revealed that the level of endogenous miR-1248 in human salivary glands biopsy from SS patients was higher than that in healthy control.

Conclusion: our data provide a potential underlying mechanism for the elevation of IFN responses regulated by differentially expressed miRNA in Sjögren's syndrome patients.

Session Date: Sunday, November 13, 2016

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Salivary gland biopsy is essential in primary Sjögren's syndrome (pSS) diagnostics. However, tissue analysis using the traditional method has several limitations including inaccuracy of quantification of lymphocytic infiltration and poor correlation with dryness. To perform biomarker identification in the target organ, tissue would have to be sacrificed. By performing saliva proteomics the biopsy tissue can be saved, but this technique has not yielded consistent biomarkers and is limited by the absence of saliva production in many sicca patients. We explored whether Luminex analysis of a multitude of cytokines in salivary gland secretomes could provide biomarkers to stratify sicca patients and insights in pathogenesis.

Methods: Labial salivary gland (LSG) tissues were rinsed after biopsy and incubated in 200µL of saline for 1h at room temperature. Tissue supernatants were rendered cell-free, frozen in liquid nitrogen and stored at -80°C. Hundred and four soluble mediators were measured in supernatants from pSS and non-Sjögren's sicca (nSS) patients by Luminex. Tissue supernatants from 8 pSS and 8 nSS patients were selected for analysis based on matched biopsy weights. Findings from this discovery cohort were validated in an additional cohort (n=34 nSS, 26 pSS) and correlations with clinical parameters were assessed.

Results: Levels of 20 cytokines were significantly different between the nSS and pSS patients in the discovery cohort (all at least $p<0.05$). These 20 and 13 additional cytokines based on a trend towards statistical significance ($p<0.10$) were measured in an additional cohort. Weights of the biopsies did not significantly differ between the groups (65.9±8.0mg versus 66.5±5.5mg). Fifteen out of the 20 significantly different cytokines were validated and an additional 7 cytokines were significantly elevated in pSS as compared to nSS patients without autoimmune features (including IL-21, IFN-γ, CXCL10, CXCL13 and sIL-7R, all $p<0.05$). Interestingly, CXCL10 and MIP-3β were also significantly elevated in nSS patients with signs of autoimmunity (eg. CXCL10 nSS: 0.9±0.5pg/mL, nSS with LFS>0 and/or anti-SSA: 7.8±4.4pg/mL, pSS 41.0±21.0pg/mL). In pSS patients numerous cytokines strongly correlated with each other and significantly correlated with lymphocytic focus scores, serum IgG levels and interestingly Schirmer's tests (n=11, 23 and 3, respectively). Additionally, various cytokines were associated with autoimmunity including elevation in anti-SSA+ versus anti-SSA- patients (n=11, all at least $p<0.05$).

Conclusion: Reproducible detection of aberrant cytokine expression in LSG secretomes seems a valuable novel tool to unravel cytokine networks correlating with clinical parameters in sicca patients. This new method represents a helpful aid to provide insights in pSS immunopathology and to identify therapeutic targets and biomarkers for diagnosis, prognosis and treatment response.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Sjögren's Syndrome - Poster I: Translational Science
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS) is a systemic autoimmune disease characterized by lymphocytic infiltration of the salivary and lacrimal glands resulting in tissue destruction, pathological dry mouth and dry eyes and in increased risk for lymphoma. The presence of ectopic germinal centers, clonally related B cells and autoantibody production from antibody-secreting cells (ASCs) isolated from the salivary glands indicate that at least some of the ASCs arise from an antigen-driven immune response. Analyses of immunoglobulin sequences can be instrumental for determining somatic mutational patterns shaped by selective pressures, where positive selection in the Complementary Determining Regions (CDRs) and negative selection in the framework regions (FWRs) would indicate antigen-driven antibody production. An alternative would be a non-specific mode of B cell activation. Immunoglobulin variable region N-linked glycosylation acquired by somatic hypermutation (AcN-glycs) has been strongly correlated to follicular lymphoma. Bacterial lectins can bind and activate B cells via AcN-glycs - a possible non-specific mechanism for antibody production and proliferation of B cells.

Methods: To explore immunoglobulin selective pressures in our cohort, we single cell-sorted IgG+ ASCs isolated from the minor salivary glands of 4 SS patients meeting the American-European combined and ACR criteria, and 5 sicca controls. The immunoglobulin variable regions were sequenced by RT-PCR. AcN-glyc motiffs were identified using the online NetNGlyc tool. An IMGT/V-QUEST sequence analysis was performed to confirm that all identified AcN-glyc motifs were introduced by somatic mutation and not germline-encoded. To analyze for antigen-driven selection we utilized BASELINe Version 1.3, an online tool for predicting positive or negative selective pressures.

Results: We sequenced 56 variable regions from 3 SS and 21 sicca control immunoglobulins. Analysis of heavy and light chain sequences revealed SS patients had an increased frequency of AcN-glycs motifs in the FWRs and a decreased frequency in the CDRs as compared to controls (20% vs 5%; 4% vs 10%). The BASELINe analysis showed positive selection in the CDRs and negative selection in the FWRs of sequences from both SS patients and controls. When the selection strengths for immunoglobulins based on glycosylation status were compared (regardless of classification), we found that heavy chains with CDR AcN-glycs and light chains with FWR AcN-glycs had significantly less positive selection than those without AcN-glycs ($p=0.05$ and $p=0.04$, respectively).

Conclusion: Overall, immunoglobulins from ASCs infiltrating the minor salivary glands of SS patients and sicca controls in our cohort undergo positive selection in the CDRs and negative selection in the FWRs, indicating antigen-driven immune

responses. Immunoglobulins with AcN-glycs have lower positive and negative selection pressures in the heavy chain CDRs and FWRs as compared to those that are non-glycosylated, indicating a potential non-specific mechanism for activation in these ASCs that could potentially give rise to autoreactive proliferations or lymphoproliferative neoplasms.

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Background Evidence suggests that levels of different cytokines in primary Sjögren's syndrome (pSS) are associated with cell infiltration degree within salivary and lacrimal glands and severity of the disease. Chemokines appear to contribute to the pathogenesis of pSS. **Objectives** To evaluate the association between serum and salivary Th1/Th2/Th17 cytokine and chemokine leves and disease activity in patients with pSS.

Methods: Case-control study including 18 patients with pSS and 13 healthy controls. Disease activity was assessed by EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI); serum and salivary IFN-γ, TNF, IL-2, IL-4, IL- 6, IL-10, IL-17, IP10, MCP-1, MIG, RANTES and IL-8 levels were measured by bead-based assays following the sandwich immunoassay principle (BD Cytometric Bead Array; BD Biosciences). Differences between groups were analyzed using the Mann-Whitney U test. Correlation was estimated by Spearman´s correlation coefficient.

Results: IL-17, IL-2, IL-4, IFNγ, MIG and RANTES salivary levels were statistically different between controls and patients with pSS ($p < 0.005$). A significant correlation ($p < 0.005$) was shown in patients between serum IL-6 and serum IL- 12 (r=0.004), IL-10 (r=0.006); serum IL-12 and serum RANTES (r=0.008); serum IP-10 and serum MIG (r=0.000), RANTES (r=0.003); serum MIG and serum RANTES (r=0.014); salivary IL-17 and salivary IL-2 (r=0.004), IL-4 (r=0.001), INFγ (r=0.000), TNF (r=0.002), IL-10 (r=0.000); salivary IL-6 and salivary IL-2 (r=0.000), IL-4 (r=0.000), TNF (r=0.000), IL- 10 (r=0.000), IL-8 (r=0.0003), MCP-1 (r=0.007); salivary IL2 and salivary IL4 (r=0.000), INFγ (r=0.006), TNF (r=0.001), IL10 (r=0.000); salivary IL4 and sallivary TNF (r=0.001), IL10 (r=0.000), MCP-1 (r=0.009); salivary TNF and salivary INFγ (r=0.002), IL-10 (r=0.000), IP-10 (r=0.006); salivary MCP-1 and salivary TNF (r=0.000), IL-10 (r=0.001), IL-8 (r=0.003).

Conclusion: Increased salivary Th1/Th2/Th17 cytokine and chemokine levels were found in pSS. No correlation was found between serum or salivary cytokine and chemokine levels and pSS disease activity.

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: TNFAIP3 gene encodes the A20 protein which is an important negative feedback regulator of the NF-κB pathway. A coding TNFAIP3 polymorphism, namely rs2230926, has been previously found to be associated with primary Sjogren's syndrome (SS) related lymphoma in French and UK populations. In this study we aimed to determine the prevalence of rs2230926 in a Greek primary SS cohort and to investigate possible associations with clinical and laboratory disease characteristics.

Methods: The rs2230926 polymorphism was genotyped in 327 primary Greek SS patients, according to European American classification criteria and 448 Greek healthy controls (HC) of similar age and sex distribution. Ninety-one patients were complicated by lymphoma development. Clinical and laboratory characteristics were also recorded and gene expression of relevant genes of the NF-κB pathway was quantitated by real-time PCR in whole peripheral blood of 165 primary SS patients. Statistical analysis was performed by SPSSv.22.

Results: The prevalence of rs2230926 mutant variant was higher in both SS-lymphoma and SS-non lymphoma subgroups compared to HC [8/91 (8.8%) and 18/236 (7.6%) versus 16/448 (3.6%), p= 0.04 and p=0.03, respectively] and found to be associated with earlier age of SS diagnosis, elevated LDH levels and lower white blood cell and neutrophil number at baseline. Of interest, when patients were divided according to age of SS diagnosis, only primary SS with age at SS onset ≤ 40 years complicated by lymphoma had increased frequency of the rs2230926 compared to HC [4/22 vs 16/448, 18.2% vs 3.6%, OR 95%(CI): 6.0 (1.8-19.8, p=0.01 by Fisher's exact test]. Whole peripheral blood transcript levels of the anti-apoptotic gene BCL2L1 were significantly higher in SS patients carrying the variant compared to non-carriers (p=0.02).

Conclusion: The TNFAIP3 rs2230926 polymorphism increases lymphoma risk among primary Greek SS patients with early disease onset possibly through deregulation of the NF-κB pathway.

Session Date: Sunday, November 13, 2016

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS) is an autoimmune disease characterized by autoantibodies to Ro and/or La proteins and lymphocytic infiltration into exocrine glands. Multiple sclerosis (MS) is an inflammatory and degenerative disorder of the central nervous system characterized by damage to the myelin sheath. Even though SS and MS have different clinical manifestations, genetic studies have suggested that the underlying etiology is common in both diseases. We used RNA-seq to compare the expression of (DE) protein-coding and non-coding transcripts in 15 MS patients to SS anti-Ro positive (n=27) and SS anti-Ro negative (n=30) patients as well as 27 healthy controls.

Methods: Whole blood RNA samples were isolated using the NuGEN Encore kit. Sequencing was performed using the Illumina HiSeq 2000. Raw FASTQ files were aligned to the human genome using Tophat. The read counts per transcript were generated using easyRNASeq in R. DE transcripts were determined using DESeq with a false discovery rate q-value of 0.05 and a fold change (FC) of >2 or <0.5.

Results: We observed 1638, 3324, and 4052 DE transcripts when comparing each group of SS anti-Ro positive, SS anti-Ro negative, and MS patients versus healthy controls, respectively. Relevant pathways from MS DE transcripts included synaptic transmission, nervous system development, and cell differentiation among others (P<0.0001) similar to those of SS anti-Ro negative patients. Using DE transcripts relevant to distinguish two groups of SS patients, we also found MS patients clustered together with SS anti-Ro negative patients in the principal components analysis plot. In addition, we observed the expression of interferon-inducible genes and the B-cell cytokine, APRIL, were significantly higher in SS anti-Ro positive patients compared to MS patients and to healthy controls (P<0.01).

Conclusion: Our analysis shows that RNA profiles of MS patients are more similar to SS anti-Ro negative patients than the SS anti-Ro positive patients. This suggests that MS treatments may be beneficial for SS anti-Ro negative patients. Furthermore, these data have identified several putative DE in both coding and lncRNA regions in SS and MS. Further comparisons of different SS and MS subtypes are needed to confirm and expand these findings.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Sjögren's Syndrome - Poster I: Translational Science
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS) is an autoimmune-mediated disease with hallmark features of dry eyes/mouth and autoantibodies. Genetic susceptibility to SS involves many loci, including the previously identified association of variants at the *IL12A* and *DDX6-CXCR5*loci.

Methods: Fine mapping and imputation were used to enrich existing datasets. To improve resolution, additional data was added to total 1916 SS cases and 3684 controls. Improved imputation reference panels increased the number of variants 10-fold in the *IL12A* region and nearly 2-fold in the *DDX6-CXCR5*interval. Functional significance was studied using electrophoretic mobility shift assays (EMSA) with DNA probes encompassing the variant regions and nuclear extracts from cell lines. Bands were quantified and paired t-tests performed with replicates across multiple cell lines comprising T and B lymphocyte and monocyte lineages, as well as a non-lymphoid cell control.

Results: In the region of *IL12A*, rs485497 remained the most statistically significant variant. This variant links two haplotypes upstream and downstream of this polymorphism. The downstream haplotype was an eQTL for the *IL12A* locus, peaking at rs4680536. Variant rs4680536 and SNP rs485789 were shown to be in high linkage disequilibrium (r^2=0.88). Database prediction of rs485789 revealed interaction of this variant with multiple immune-relevant transcription factors, changes in consensus transcription factor binding, and altered expression of *IL12A*. In the *DDX6-CXCR5* region, imputation showed a pattern of association spanning beyond the length of the *DDX6* coding sequence to the proximal promoter of *CXCR5*. The top associated variants (rs7125066 and rs7119038) did not yield evidence of regional functionality. However, 46 other variants that span the region of association were identified, and four variants predicted to affect gene binding or expression were selected for further study. DNA probes for variants rs4938572, rs12365699, rs57494551, and rs10892294 were used to test for altered protein binding in EMSA assays. Across all probe sets, three distinct nuclear protein complexes were observed in both the reference and alternate alleles, with the majority of signal in the two lower sized bands. Of the 4 probe sets, the rs4938572 variant was the only one to show a significant difference in binding between the reference and alternate alleles, with increased binding by the alternate allele. The major complexes showed significantly increased binding ($p<0.05$) of the alternate relative to the reference allele in 5/6 lymphocytic cell lines, but no difference in non-lymphoid cells. The most prominent differences were observed in assays using cell extracts from less differentiated cell lines.

Conclusion: Genetic variants in the *IL12A* and *DDX6-CXCR5* loci associated with SS are likely functionally impacting genes in these loci. This study adds further evidence that genetic variants in the *IL12A* and *DDX6-CXCR5* loci are functionally involved in the etiology of SS.

Session Date: Sunday, November 13, 2016

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Sicca Syndrome patients represent a diagnostic challenge for the wide variety of etiologies that can afford it. Beta-2 Microglogulin (B2MG) is a non-glycosylated protein, found in all nuclear cells and it is release from an inflammatory stimuli [1]. The use of B2MG to differentiate between subjects with presence of autoimmunity, of those who do not, is under study. Objective: Evaluate the performance of the B2MG in distinguishing Sicca Syndrome of Sjšgren's from those with non- Sjšgren«s syndrome origin.

Methods:

This is a comparative, cross-sectional study, of diagnostic test type, registered by the local IRB (Registry number RE14-009). We included made four groups of patients: Group 1: Primary Sjšgren Syndrome (pSS), according to the 2002/2012 AECG/ACR classification criteria, Group 2: Secondary Sjšgren Syndrome to Rheumatoid Arthritis or Systemic Lupus Erythematosus, Group 3: Sicca of non-Sjšgren«s syndrome origin, Group 4: Healthy controls. Clinical test included determination of Rheumatoid factor (IgA, IgG and IgM), Anti- Ro/SSA and Anti- La/SSB levels. We record the results of patients who had biopsy of minor salivary gland. We obtained saliva according to Fleissig et al [2]. Salival B2MG was measured using a Human ELISA kit abcam¨. Medians and interquartile ranges were assessed to describe the characteristics of the groups. Finally, we categorize patients into 2 groups: SS (group 1 and 2) and No-SS (groups 3 and 4) for ROC curves.

Results:

Demographic and serological variables from the 256 subjects included in this study are shown in Table 1. In Figure 1 we showed a graphic that compares the performance of different auxiliary diagnostic methods for the SS. A value of B2MG of 0.28 µg/mL (95% CI 0.64 to 0.76), with a sensitivity of 88% and a specificity of 31% can distinguish between SS and non-SS.

Conclusion:

We propose that salival B2MG is an easy, non-invasive tool, as a first-step on a steered screening to differentiate patients with Sjšgren Syndrome of Sicca Syndrome from others etiologies.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Sjögren's Syndrome - Poster I: Translational Science
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To analyse the influence of geolocation (North-to-South gradient) on the clinical presentation of primary Sjögren syndrome (SjS) at diagnosis.

Methods: The Big Data Sjögren Project Consortium is an international, multicentre registry designed in 2014. By January 2016, 20 centres from five continents were participating. Patients were classified according to the geolocation of the country of the diagnosing hospital. Patients were first classified by continent, with an additional north-south sub-classification according to latitude in continents including patients from > 1 country (latitude > or < 50'N in Europe, equator > or < in America and latitude > or < 30'N in Asia).

Results: We included 7748 (93%) women and 562 (7%) men, with a mean age at diagnosis of primary SjS of 53 years. Multivariate analysis adjusted by age and gender showed that northern European patients (latitude > 50´N) had a lower frequency of ocular dryness (OR=0.39, 95%CI 0.29-0.53), abnormal ocular tests (OR=0.51, 95%CI 0.40-0.65), ANA (OR=0.59, 95%CI 0.47-0.73) and Ro/La autoantibodies (OR=0.71, 95%CI 0.58-0.88) and a higher frequency of abnormal oral tests (OR=1.62, 95%CI 1.26-2.11) and RF (OR=1.86, 95%CI 1.55-2.23) compared with southern European patients. North American patients had a lower frequency of abnormal oral tests (OR=0.55, 95%CI 0.35-0.84) and positive salivary biopsy (OR=0.43, 95%CI 0.18-0.91), and a higher frequency of ANA (OR=1.56, 95%CI 1.03-2.35), Ro/La autoantibodies (OR=2.92, 95%CI 1.95-4.41) and low C4 levels (OR=6.02, 95%CI 1.78-37.63) compared with South American patients. Northern Asian patients had a lower frequency of dry mouth (OR=0.47, 95%CI 0.26-0.83), dry eyes (OR=0.35, 95%CI 0.20-0.59), abnormal ocular tests (OR=0.34, 95%CI 0.19-0.60) and positive salivary biopsy (OR=0.43, 95%CI 0.25-0.74), and a higher frequency of ANA (OR=2.95, 95%CI 1.78-4.97) compared with southern Asian patients.

Conclusion: These results suggest, for the first time, that geolocation may influence the phenotypic expression of primary SjS at diagnosis, including significant geoepidemiological variations in the prevalence of dryness, the frequency of

abnormal diagnostic tests and the positivity of the main immunological markers. Geoepidemiology and ethnicity should be considered as key variables that should be analysed in multi-ethnic studies of patients with primary SjS.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Diagnosing SS is often challenging, particularly distinguishing patients with primary SS from xerostomia and xerophthalmia (sicca). Recently, an IL-14 transgenic murine model led to the discovery of autoantibodies directed against exocrine gland antigens. These antibodies termed salivary protein-1 (SP-1), carbonic anhydrase VI (CA-6), and parotid secretory protein (PSP) were found to precede traditional antibodies and normalize once the diagnosis is established. Our goal is to explore the initial diagnostic role of these antibodies in patients suspected of having SS.

Methods:

Serum concentrations of SS-A, SS-B, and SP-1, CA-6, PSP isotypes (IgG/A/M) were examined in 94 patients being evaluated for SS. The results were recorded and analyzed. Charts were reviewed. Patients were divided among four antibody patterns: I) novel and traditional Ab +, II) novel Ab - traditional Ab +, III) novel Ab + traditional Ab -, and IV) novel and traditional Ab -. The relationship of these antibody patterns was examined in relation to diagnosis. Patients with primary SS met American-European Consensus criteria, whereas patients labeled "sicca" had nonspecific ocular and oral symptoms.

Results:

Among 94 patients, 43 (45.74%) had abnormal novel antibodies of any isotype. 27 (28.7%) were CA6+, 18 (19.10%) were SP-1+, and 15 (16.0%) were PSP+ , The IgG isotype response was the strongest: Anti CA-6 IgG was 10.4 (+/- 0.9) EU/ml, whereas SP-1 and PSP IgG were 5.1 (+/- 0.8) and 4.8 (+/- 0.6) EU/ml, respectively (P<0.0001; K-W test). The antibody patterns differed significantly between the diagnostic groups (P <0.0001,- Fisher's exact test). The traditional antibodies showed a sensitivity, specificity, PPV, and NPV of 86.53%, 92.85%, 93.75%, 84.78% compared to 32.69%, 35.71%, 38.63%, 42.85%, for the novel antibodies. Patients with abnormal novel antibodies had significantly (P<0.05; K-W test) shorter duration of symptoms in years (6.1 +/- 1.4) compared with abnormal traditional antibodies (12.8 +/-1.5).

Conclusion:

The pattern of Sjögren's associated antibodies differs between primary SS and xeropthalmia/xerostomia. Traditional antibodies have excellent sensitivity and specificity for patients clinically diagnosed with primary SS, however, novel antibodies are more prevalent in the xerophthalmia/xerostomia group and may identify a subset with early SS.

Session Title: Sjögren's Syndrome - Poster I: Translational Science

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-21 plays a central role in plasma cell differentiation and germinal center (GC) formation and is likely involved in the pathogenesis of primary Sjögren's syndrome (pSS). T follicular helper (Tfh)-cells are the main producers of this cytokine. Interleukin-21 protein and mRNA are present in minor salivary glands of pSS patients. Also serum levels of IL-21 are increased, compared with healthy controls. However, effects of immunomodulatory treatment on local IL-21 levels in pSS patients remain unknown. Treatment of pSS with rituximab or abatacept modulates B-T cell interaction and reduces numbers of circulating Tfh-cells. The objective of this study is to investigate if IL-21-producing cells in parotid gland tissue of pSS patients are also targeted by immunomodulatory treatment with rituximab or abatacept.

Methods: Ten pSS patients treated with rituximab (n=5) or abatacept (n=5) were included. Paraffin-embedded parotid gland tissue sections were available before and after treatment (16 weeks after the first dose of rituximab, 25 weeks after the first dose of abatacept). Sections were deparaffinized, heat-induced antigen retrieval was performed and slides were

incubated with rabbit anti-human IL-21 and goat anti-rabbit IgG-AF594. Slides were analyzed by immunofluorescence. Serum levels of rheumatoid factor (RF), anti-SSA, anti-SSB, IL-21 and numbers of circulating Tfh (cTfh)-cells were available before and after treatment.

Results: Interleukin-21-positive cells were found in parotid glands of nine out of ten patients at baseline. Baseline numbers of glandular IL-21-positive cells/mm^2 correlated strongly with serum IL-21 levels (ρ=0.83, P=0.008) and moderately with RF levels (ρ=0.60, P=0.073). Numbers of IL-21-positive cells/mm^2 were significantly higher (P=0.032) in patients with GC(s) in their biopsies (n=5), compared with GC-negative patients (n=5). No difference in age, disease duration or ESSDAI score was observed between GC-positive and GC-negative patients. After treatment with rituximab or abatacept, a decrease in IL-21-positive cells/$mm^2$was observed in all GC-positive patients, but this was not evident for GC-negative patients, possibly due to low numbers of IL-21-positive cells in GC-negative biopsies at baseline. In the whole study population a trend towards lower serum levels of IL-21 and a significant decrease in cTfh-cell numbers (P=0.023) was observed after treatment. Furthermore, treatment resulted in reduced titers of RF, anti-SSA and –SSB in all patients.

Conclusion: This pilot study shows that pSS patients with GC-positive biopsies have high numbers IL-21-positive cells in their glands. Numbers of IL-21-positive cells/mm^2 correlate strongly with serum levels of IL-21 in all patients. This study further indicates that interference with T-B-cell interaction, either by B-cell depletion or inhibition of T cell co-stimulation in pSS can abrogate the pathogenic IL-21-pathway, with a concomitant decrease in systemic autoantibody levels.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The relevance of structural lesions in non-radiographic axial SpA (nr-axSpA) is unclear, particularly without signs of MRI inflammation. In a post hoc analysis we evaluated the association between structural lesions in the sacroiliac joints (SIJ) and spinal inflammatory lesions on MRI in early nr-axSpA. We hypothesized that structural lesions indicate a more extensive disease phenotype that includes early spinal involvement visible on MRI.

Methods: The EMBARK study (ClinicalTrials.gov: NCT01258738) enrolled patients 18-49 yrs old with axial SpA per ASAS imaging or clinical criteria without meeting modified New York radiographic criteria. Patients had symptoms for >3 months and <5 yrs, BASDAI score ≥4, and had failed ≥2 NSAIDs. Bone marrow edema (BME) in the SIJ and spine at baseline (BL) was assessed on short tau inversion recovery (STIR) scans by 2 independent readers using Spondyloarthritis Research Consortium of Canada (SPARCC) SIJ and 23-DVU scores, respectively. BL structural lesions were evaluated on T1 weighted spin echo scans blinded to STIR scans, using the SPARCC MRI SIJ structural score (SSS). Univariate analysis evaluated the relationship between BL spinal inflammation and these BL characteristics: gender, presence/absence of any structural MRI lesions in the SIJ (SSS>0 or =0), presence/absence of specific MRI SIJ structural lesions, and SPARCC SIJ ≥2 or <2. Multivariate stepwise regression analysis evaluated the relationship between spinal inflammation and MRI SIJ lesions after including age, gender, and symptom duration.

Results: BL MRI scans were available for 185 patients. Mean (standard deviation [SD]) age was 32.0 (7.8) yrs, 60.5% were male, mean (SD) symptom duration was 2.4 (1.8) yrs, 133/182 (71.9%) patients were human leukocyte antigen B27+ and 152 (82.2%) met ASAS MRI imaging criteria. At BL, mean (SD) SPARCC MRI 23-DVU spinal score was 4.0 (8.0); 128/183 (69.9%) patients had SPARCC SIJ BME scores ≥2 and 55/183 (30.1%) had scores <2. A total of 77/185 (41.6%) patients had ≥1 structural lesion on MRI comprised of erosion (65/185, 35.1%), backfill (26/185, 14.1%), fat metaplasia (15/185, 8.1%) and ankylosis (4/185, 2.2%). Higher spine 23-DVU scores were observed in males, in the presence of definite SIJ inflammation (SPARCC SIJ ≥2, p=0.01), and in the presence of any one of the SIJ structural lesions, Table. Multivariate analysis indicated that erosion and backfill are independent factors associated with spinal inflammation; parameter estimates (SE): erosion: 2.9 (1.3), p=0.03; backfill: 3.9 (1.8), p=0.03.

Conclusion: MRI structural lesions in the SIJ occur in a substantial proportion of patients with nr-axSpA and their presence suggests a more extensive phenotype of disease associated with early spinal involvement.

Table. Univariate analysis of the relationship between spinal inflammation and select baseline characteristics, including MRI SIJ structural lesions, in patients with nr-axSpA

Abstract Number: 676

Syndesmophytes in the Thoracic Spine in Ankylosing Spondylitis As Detected By Computed Tomography and Association with Lumbar Radiographic Involvement

Sovira Tan and Michael Ward, NIAMS/NIH, Bethesda, MD

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Because the thoracic spine has traditionally been excluded from radiographic examinations of spinal damage in ankylosing spondylitis (AS) due to poor visualization, little is known about the extent and degree of involvement of the thoracic spine with syndesmophytes. In particular it is not known if thoracic syndesmophytes are often present in the absence of lumbar syndesmophytes. We used computed tomography (CT) to investigate the presence of syndesmophytes in the thoracic spine, and examined the concordance between thoracic syndesmophytes in CT scans and syndesmophytes on lumbar radiographs.

Methods: Sixteen patients with modified Stoke AS Spine Score (mSASSS) in the lumbar spine ranging from 0 to 12 underwent thoracic and lumbar spine CT scans and lumbar radiography. Using a validated semi-automated computer algorithm, we quantitated syndesmophytes in 11 intervertebral disk spaces (IDS) from T5-T6 to L3-L4 on CT scans. We measured syndesmophyte height in 72 angular sectors of 5 degrees around the vertebral rim. In each angular sector, we recorded the height of the tallest syndesmophyte and normalized it to the IDS height (a score of 0 indicating no syndesmophyte and a score of 1 indicating bridging). The 72 angular sectors were summed to form the circumferential height for each IDS (a score of 72 indicating complete fusion). Anterior-posterior and lateral radiographs of the lumbar spine were read for the presence or absence of syndesmophytes and bridging in lumbar IDSs.

Results: 94% of all patients had syndesmophytes at the thoracolumbar junction (Table). Syndesmophytes were slightly more frequent in the thoracic than lumbar spine. In the thoracic spine the average frequency of IDSs with syndesmophytes was 73%, compared to 69% in the lumbar spine. Bridging was more frequent and extensive in the more superior vertebral levels ($p<0.005$). There was low concordance between thoracic syndesmophytes on CT scans and lumbar syndesmophytes seen on radiographs (Figure). All 16 patients had thoracic syndesmophytes on CT but only 12 had visible lumbar syndesmophytes on radiographs. All 6 patients with lumbar mSASSS of 0 had thoracic syndesmophytes.

Conclusion: Syndesmophytes are common in the thoracic spine in AS, and are often present among patients without lumbar syndesmophytes on radiographs. The low concordance between thoracic syndesmophytes detected on CT and lumbar syndesmophytes seen on radiographs suggests that studies that rely on radiographic measures such as the mSASSS may underestimate the extent of bone proliferation, which may confound biomarker discovery.

	Proportion of patients with any syndesmophyte	Mean (std) circumferential height (0-72)	Proportion of patients with any bridging	Mean (std) extent of bridging (0-360)
T5/T6	73%	23.4 (25.9)	60%	137 (130)
T6/T7	71%	13.5 (15.6)	50%	83 (86)
T7/T8	79%	16.9 (20.5)	50%	117 (115)
T8/T9	64%	16.4 (17.4)	50%	92 (89)

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been shown in the past that radiographic spinal progression is an important determinant of the functional outcome in patients with advanced axial spondyloarthritis (SpA). The objective of the current study was to investigate functional relevance of structural damage development in the spine in patients with early (up to 10 years symptom duration) axial SpA.

Methods: Altogether 210 patients with early axial SpA from the German Spondyloarthritis Inception Cohort (GESPIC) were included. Clinical data reflecting disease activity (BASDAI), functional status (BASFI), and spinal mobility (BASMI) were collected at baseline and every 6 months thereafter. Structural damage in the spine was assessed on spinal radiographs at baseline and after two years according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS).

Results: The association between the mSASSS and BASFI status scores at baseline was rather weak: the BASDAI-adjusted parameter estimate (b) in the linear regression analysis was 0.04 (95%CI 0.02-0.07). At the same time, BASDAI itself was strongly associated with BASFI at baseline: b=0.87 (95%CI 0.78-0.96). For the mSASSS change score after 2 years, the parameter estimate b was 0.04 (95%CI -0.05-0.21), meaning that radiographic progression in 25 mSASSS points over 2 years would be responsible for a 1-point difference in BASFI (adjusted for the BASDAI change and mSASSS at baseline). The cumulative probability plot (figure) also shows a week association between mSASSS change and BASFI change values. Similar results were obtained for the association between mSASSS and BASMI: b=0.09 (95%CI 0.07-0.12) for the status scores and b=0.01 (95%CI -0.08-0.09) for the change scores. Results of the linear regression analysis were confirmed in the mixed model analysis: the BASDAI-adjusted parameter estimates for the association between mSASSS and BASFI / BASMI were 0.06 (95%CI 0.04-0.08) and 0.08 (95%CI 0.05-0.11), respectively. In contrast, BASDAI change score demonstrated a strong association with the BASFI change score: b=0.61 (95%CI 0.50-0.71); association with the BASMI change score was weaker: b=0.16 (95%CI 0.05-0.26).

Conclusion: The functional relevance of the structural damage development in the spine in the majority of patients with early axial SpA seems to be low, while disease activity has a major impact on the function of the spine and should be, therefore, considered as the primary treatment target in these patients.

Figure. Association between progression of structural damage in the spine (mSASSS change) and change in the functional status (BASFI) – **A** – or spinal mobility (BASMI) – **B** – over 2 years in patients with early axial spondyloarthritis.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis of ankylosing spondylitis (AS) is anchored on definitive changes of sacroiliits by radiography. This is relevant not only to clinical diagnosis, but also for reimbursement and access to treatment modalities such as TNF inhibitors. However, radiographic grading of sacroiliitis is plagued by lack of interrater reliability. This study evaluated the impact of additional information from sacroiliac MRI or CT images on rheumatologists correctly identifying definite sacroiliitis by radiography.

Methods: Pelvis images from all three modalities (X-ray, CT and MRI) performed within a period of 1 year were available , from 50 patients with chronic back pain. Consensus reads for radiographic sacroiliitis, based on the interpretation of all three imaging modalities by four spondyloarthritis experts (one radiologist and 3 rheumatologists) was the gold standard grading. In the TRIMAGE project 6 rheumatologists and 2 rheumatology fellows scored radiographs online in a random order for the presence of radiographic sacroiliitis, in the first round before and after viewing the MRI images and in the second round before and after viewing the CT images. The same set of images were scored again one month later, following a two day training meeting, which included lectures for each imaging modality and supervised scoring exercises on a training set of 15 patients. Intrarater agreement, was computed for each rheumatologist before and after training. Kappa statistic and percent agreement were used to compare agreement between the expert consensus scoring and those of the rheumatologists/fellows. Sensitivity and specificity of the radiographic ratings by the rheumatologists/fellows were calculated using the final expert consensus classification as the gold standard.

Results: Based on expert consensus grading, 32 of the 50 patients (64%) had radiographic sacroiliitis. The results are summarized in Table 1 and Table 2.

Table 1. Performance of rheumatologists/fellows before and after training for diagnosing radiographic sacroiliitis when the expert consensus scoring is taken as the gold standard

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic intermittent diarrhea (CID) is a common clinical problem in axial spondylarthritis (axSpA) patients and eventually up to 13% of these are diagnosed with inflammatory bowel disease (IBD). Magnetic resonance (MR) enterography, i.e., MRE with the highest accuracy for Crohn's disease (CD) lesions is becoming the recommended complimentary intervention to ileocolonoscopy in patients with suspected CD. We aimed to determine if a complimentary MRE (a) may change the rate of CD diagnosis in axSpA and (b) may be used as a non-invasive screening test for CID.

Methods: A total of 820 consecutive axSpA patients meeting the ASAS classification criteria (Mean disease duration of 4.3 years (6 months - 25 years) were screened for the presence of CID. Patients with a prior diagnosis of IBD, Celiac disease, inflammatory bowel syndrome (IBS) and amyloidosis were excluded. The cause of CID was investigated in 44 patients (mean age 39.5 years, 25 female) by: MRE (mural disease, bowel wall thickening and extra-luminal complications of Crohn's disease) gastro-duodenoscopy, ileocolonoscopy with histopathologic assessment, testing for Celiac disease, bacterial and parasitic agents. MRE findings assessed were Four patients refused MRE and in additional three patients had contrast medium intolerance. And seven patients refused endoscopy. Patients with either intervention missing at the time of statistical analysis were excluded from the study.

Results: Thirty-seven patients with a non-bloody, mucous diarrhea (200-400 ml / per defecation, with a monthly duration of ≥ 2 - 3 days, four times a day accompanied by stomachache) were analyzed. Mean duration of diarrhea was 21 months (3 – 120 months) Thirty-six percent were smokers, 55% were NSAID users, and 20% were under anti-TNF treatment. Nine teen percent (n=6/32) were HLA-B27 positive, only. Family history of IBD was present in one patient.IBD was

diagnosed in 12 patients; Ten with CD and two with Ulcerative colitis (UC). Four patients had normal histopathology, MRE and endoscopic findings. Remaining 21 had no conclusive diagnosis as no parasitic infections were detected by direct microscopy and stool cultures, as well as Entamoeba, clostridium difficile-, giardia antigens and celiac antibodies were negative in all patients. MRE was positive in all CD patients but abnormal endoscopic findings were detected in six CD patients, only. Both UC patients were diagnosed by ileocolonoscopy, i.e. MRE were negative. In the remaining patient group with non-specific chronic histopathologic changes and normal ileocolonoscopy only one had non-specific MRE findings.

Conclusion: Complimentary MRE increased the number of CD diagnosis in axSpA patients with CID. Evaluation of mural and extramural findings of the small intestine adds valuable information for diagnosis. Biopsy proven CD cases being all MRE positive may suggest a value of MRE as a non-invasive screening tool and larger clinical trials may be necessary.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Computed tomography (CT) is considered the imaging benchmark for the assessment of certain structural lesions in the sacroiliac joints (SIJ) of patients with axial spondyloarthritis (axSpA). Availability of low dose radiation techniques may lead to more widespread use, potentially as a structural endpoint in clinical trials research. We aimed to validate a new CT-based scoring method, the CT Sacroiliac Structural Score (CT-SSS), for assessing structural lesions in the SIJ.

Methods: CT scans of the SIJ from 44 patients (26 females, mean age 49.4 years, mean symptom duration 9.1 years) were reconstructed in the semicoronal plane parallel to the superior border of the sacrum and scoring of lesions was confined to this plane. Structural lesions were scored in consecutive slices in SIJ quadrants (erosion, sclerosis) or SIJ halves (ankylosis) on a dichotomous basis (present/absent) using the same anatomical principles as developed for the SPARCC MRI SIJ inflammation and structural scores. The most anterior slice is defined as visible joint >1cm vertical height and when <3 cm is defined as having only upper iliac and sacral quadrants. A visible joint >3cm vertical height is defined as

having 4 quadrants. At the posterior aspect of the SIJ, there is a natural separation of iliac and sacral cortical bone by structures in the ligamentary portion. Scoring is terminated when <1cm of iliac and sacral bone is appositional. Two readers independently scored CT scans without a prior calibration exercise and using direct online data entry onto a schematic of the SIJ. Reliability was assessed by kappa statistics, intra-class correlation coefficient (ICC), and Bland-Altman limits of agreement.

Results: Scoring was feasible (5-10 minutes per scan) and both ankylosis (ICC=0.95) and erosion (ICC=0.81) were scored to a high degree of reliability (Table). Sclerosis was less reliably scored (ICC=0.39). Presence/absence of ankylosis was reliably detected irrespective of whether this was based on a single slice (κ=0.77) or 3 consecutive slices (κ=0.81). Reliable detection (presence/absence) was lower for erosion (κ=0.50 for 1 or 3 slices) and sclerosis (κ=0.44 and 0.48 for 1 and 3 slices, respectively). Bland-Altman graphs illustrate reliability across the range of scores for ankylosis and erosion (Figure).

Conclusion: The CT-SSS method is feasible and reliable for scoring ankylosis and erosion with minimal calibration. Sclerosis requires further standardization and calibration.

	Mean (SD) score		**Median (IQR) score**

Can Bridging Syndesmophytes Independantly Affect Spinal Mobility?

Ismail Sari[1], Ahmed Omar[1], Mansour Alazmi[1], Renise Ayearst[2], Robert D Inman[1] and Nigil Haroon[1], [1]Rheumatology, Toronto Western Hospital, University of Toronto, Spondylitis Clinic, Toronto, ON, Canada, [2]Medicine, University Health Network, Toronto, ON, Canada

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: One of the hallmark characteristics of the disease is new bone formation that manifests as syndesmophytes and spinal fusion. Spinal fusion results from bridging syndesmophytes extending across a discovertebral unit. The true impact of radiographic spinal fusion on function and spinal mobility is still debated. We studied the location and number of bridging syndesmophytes and their relation to spinal mobility measures.

Methods: The following patients were included from a longitudinal observational AS cohort: (i) patients who met the NY criteria for AS, (ii) who had complete sets of X-rays, and (iii) who had available spinal mobility measures including cervical rotation, lateral lumbar flexion and Schober's test. Schober's test and lateral lumbar flexion reflects thoracolumbar spine mobility. Cervical rotation reflects cervical spine mobility. Trained rheumatologists did all spinal measurements. Bridging syndesmophytes were scored in the anterior corners of cervical and lumbar vertebrae. Two expert rheumatologists scored X-rays. A third expert reader settled discordant results. Demographics, clinical data and BASDAI were recorded. The independent effects of bridging syndesmophytes on mobility were assessed by multivariable regression after controlling for other clinical variables.

Results: From the cohort of 800 AS patients, 113 had bridging syndesmophytes in the cervical or lumbar or both vertebrae. Ninety-two patients had cervical and 47 had lumbar bridging syndesmophytes. The mean age and disease duration of the patients was 47±11.3 and 21.6±11.4 years respectively. 86.7% of the patients were male and B27 was present in 75%. The number of cervical bridging syndesmophytes showed moderate negative correlations with cervical rotation in patients with both active and inactive disease states (r=-0.56 and -0.59 respectively). Similarly lumbar bridging syndesmophytes had moderate inverse correlations with lateral flexion and Schober's measurements (r=-0.41 and -0.38 respectively). The total number of syndesmophytes and the degree of limitation of the spine both cervical and lumbar movements showed restrictions as the number increased (Table 1). In regression models where age, sex, disease duration, increased acute phase response and B27 was included the strongest predictor for the cervical rotation, lumbar lateral mobility and Schober's was the number of cervical (β=-0.59) or lumbar bridging syndesmophytes (β=-0.42 for lumbar side flexion and -0.37 for Schober's).

Conclusion: Bridging syndesmophytes independently influenced spinal mobility. The study also provides reference values regarding the location and number of syndesmophytes and their respective impact on spinal mobility. **Table 1:**Association between localization, number of bridging syndesmophytes and degree of limitation

Which Is the Most Reliable Imaging Method for Detection of Structural Changes in the Sacroiliac Joints of Patients with Ankylosing Spondylitis? a Cross-Sectional Study Comparing MRI, CT and Conventional Radiographs

Xenofon Baraliakos[1], Florian Hoffmann[2], Xiaohu Deng[3], Yanyan Wang[4], Feng Huang[5] and Jürgen Braun[2], [1]Rheumatology, Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Chinese PLA General Hospital, Chinese PLA General Hospital, Beijing, China, [4]Rheumatology, Chinese PLA General Hospital, Beijing, China, [5]Chinese PLA General Hospital, Beijing, China

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) is the gold standard for detection of inflammation and fat metaplasia in the sacroiliac joints (SIJ) and the spine of patients with axial spondyloarthritis (axSpA). Structural changes (erosions, sclerosis and ankylosis) assessed by conventional radiographs (CR) or computed tomography (CT) are characteristic for ankylosing spondylitis (AS). Direct comparisons of these imaging techniques have not been performed to date. In this study we compare the reliability of CR and MRI as compared to CT for detection of structural changes in SIJs of AS patients.

Methods: Complete sets of MRI, CT and CR of SIJs of 69 AS patients and 49 age- and gender-matched controls in whom CTs had been performed for other reasons than back pain were analyzed. Two readers evaluated the images independently and blinded to diagnosis and clinical characteristics in random order. Assessment of lesions was performed based on SIJ-quadrants (SQ). Only definite erosions, sclerosis and ankylosis were recorded, and only SQ changes for which readers agreed on were used for analysis.

Results: The mean age of AS patients was 44.6 years, 72.5% were male, 85.5% were HLA-B27 positive, the mean time since diagnosis was 4.8±5.8 years (range 1 14 years), the mean BASDAI was 4.9±1.8 and the mean CRP was 1.9±2.3mg/dl. In total, 552 SQ (276 pairs) were analyzed. *Erosions* were found in 131 (23.7%) SQ by CR, 141 (25.5%) by CT and in 167 (30.3%) SQ on T1-MRI. Agreement for erosions was seen for 64 SQ assessed by CR/CT, 100 SQ by CT/MRI and 70 SQ by CR/MRI, with 48.9% of SQ detected by CR also seen on CT and 45.4% detected on CT also seen by CR. The corresponding numbers for CT/MRI were 70.9% and 59.9% and for CR/MRI 53.5% and 41.9%, respectively. Disagreement for erosions was found in 144 (26.1%), 108 (19.6%) and 158 (28.6%) SQ, respectively. *Sclerosis* was seen in 86 SQ on CR (15.6%), 91 SQ on CT (16.5%) and 63 on T1-MRI (11.4%). Agreement was found in 31 SQ on CR/CT, 22 SQ on CT/MRI and 45 SQ on CR/MRI, with 36.0% SQ detected on CR also seen on CT and 34.1% detected on CT also seen by CR. The corresponding numbers for CT/MRI were 24.2% and 34.9% and for CR/MRI 52.3% and 71.4%. Disagreement for sclerosis was found in 95 (17.2%), 72 (13.0%) and 66 (12.0%) SQ, respectively. *Ankylosis* was seen in 91 SQ pairs on CR (33,3%), 130 SQ pairs on CT (47,1%) and 106 SQ pairs on MRI (38,4%). Agreement was found in 87 SQ pairs on CR/CT, 94 SQ pairs on CR/MRI and 72 SQ pairs on CT/MRI, with 95.6% SQ detected on CR also seen on CT and 66.9% detected on CT also seen by CR. The corresponding numbers for CT/MRI were 72.3% and 88.7% and for CR/MRI 79.1% and 67.9%. Disagreement for ankylosis was seen in 47 (17.0%), 48 (17.4%) and 53 (19.2%) SQ pairs, respectively. In controls, 392 SQ were analyzed. Erosions were found in only 19 (4.8%) SQ and sclerosis in 23 (5.9%) SQ, while no patient showed ankylosis.

Conclusion: Erosions and ankylosis are more common than sclerosis in SIJs of AS patients and rarely seen in controls. The agreement between methods was rather limited. Compared to CT, less erosions were detected by MRI and CR when only erosions agreed on were counted. CT and MRI were more reliable than CR for the detection of ankylosis. The superiority of MRI to detect erosions may be related to early disease stages, while erosions seen on CT seem to be due to detection in later stages of AS.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Uveitis is the most common extra-articular manifestation in patients with ankylosing spondylitis (AS).The prevalence and characteristics of uveitis in AS have been studied in previous literatures while its associated risk factors have not been clarified. Therefore,this study analysed the risk factors of uveitis in patients with AS.

Methods:

A total of 390 patients with AS who fulfilled the modified New York criteria were enrolled from January to December in 2015.The history of uveitis was accepted only if diagnosed by ophthalmologists.The medical records of the patients were retrospectively reviewed and associated information was collected,such as disease duration,HLA-B27 and the number of peripheral arthritis.Hip-joint lesion was identified by imaging examination.Meanwhile, biochemical examinations were performed to determine the patient's physical function.

Results: Of 390 patients with AS (80.5% male, mean age 33.3 years), 38 (9.7%) had experienced one or more episodes of uveitis. The incidence rate for hip-joint lesion was obviously higher for patients with uveitis than the non-uveitis group (44.7% vs 22.2%; $P<0.01$). The number of peripheral arthritis was also larger for the uveitis group than non-uveitis group (2.18±0.23 vs 0.55±0.04; $P<0.001$). Meanwhile, patients with uveitis had a significantly higher level of antistreptolysin O (ASO) and circulating immune complex (CIC) than those without ($P<0.05$ and $P<0.0001$, respectively). However, there were no significant differences in disease duration, HLA-B27, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) between the two groups. Binary logistic regression results showed that ASO (OR=12.2, 95% CI:3.6-41.3, $P<0.01$) and the number of peripheral arthritis (OR=4.1, 95%CI:2.6-6.3, $P<0.01$) are significantly associated with uveitis in AS.

Conclusion: This study provides some evidence that hip-joint lesion, the number of peripheral arthritis, ASO and CIC may be associated with higher rates of uveitis in AS. The results of this comprehensive analysis suggest that the possible occurrence of uveitis in AS should not be neglected if the patients have those concomitant risk factors.

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Sclerosis in the sacroiliac joints (SIJ) on radiography and computed tomography (CT) is common but widely considered a non-specific finding of sacroiliitis due to an association with degeneration and osteitis condensans ilii, despite little formal study. Availability of low dose radiation (CT) may lead to more widespread use for diagnostic evaluation. We standardized the definition of sclerosis on CT and then aimed to determine whether this lesion could be reliably detected and its diagnostic utility.

Methods:

215 CT scans were obtained from patients with a history of low back pain. 107 patients had a clinical diagnosis of spondyloarthritis (SpA) and 108 patients were clinically proven not to have SpA. Both groups were age and gender matched (140 males, 75 females). The mean age was 45 years. Three musculoskeletal radiologists, blinded to patient demographics and diagnosis, scored the CTs after standardization of lesion definitions and calibration. Erosions, sclerosis, and ankylosis were graded by size and number of articular surfaces/ joints involved. Sclerosis was considered definite if located along the cartilaginous compartment, measured >5mm in all 3 planes, and present >5mm from the joint surface. Discrepant scores were arbitrated and inter-reader reliability calculated by intra-class correlation coefficient (ICC). Diagnostic utility of CT lesions was determined by calculating sensitivity and specificity for the clinical diagnosis and by logistic regression.

Results:

Inter-observer reliability for scoring sclerosis for each articular surface ranged from 0.65-0.76, 0.71-0.78 for erosion, and 0.87-0.95_ for ankylosis. Sclerosis occurred in 87(81%) cases with SpA and 25 (23%) controls. For a single articular surface the specificity for sacroiliitis ranged between 88-94%, and for any two articular surfaces 95-100%. If all 4 articular surfaces were affected, specificity was 100%. Sensitivity ranged from 14% (4 articular surfaces) to 55% (either ilium). Erosion and ankylosis had a similar specificity range of 91-100% and 92–93%, respectively depending on number of joint surfaces involved. The odds ratio was 4.9 for absence/presence of sclerosis, increasing to 12.55 where there was bilateral joint involvement. For erosion the odds ratio increased to 84.2 for bilateral disease and 22.79 for bilateral ankylosis.

Sclerosis of articular surface(s) involved	**Specificity, with 95% confidence intervals**	**Sensitivity, with 95% confidence intervals**
Single articular surface	Single ilium: 88% (85-93%) - 93% (89-96%)	Single ilium: 46% (39 - 52%) - 51% (44 - 58%)
	Single sacrum: 94% (91-98%) – 94% (91-98%)	Single sacrum: 20% (14 – 25%) - 21% (15 – 26%)
Any two articular surfaces	95% (93-98%) – 100% (100-100%)	14% (9-19%) – 41%(35-48%)
All four articular surfaces	100% (100-100%)	14% (9% - 19%)
Subchondral erosion of articular surface(s) involved	**Specificity, with 95% confidence intervals**	**Sensitivity, with 95% confidence intervals**
Single articular surface	Either ilium: 91% (87-96%)	Either ilium: 74%(67 – 80%)
	Either sacrum: 94% (91-98%)	Either sacrum: 58% (51 – 66%)
Any two articular surfaces	93% (90-97%) – 100% (100-100%)	34% (27-41%) - 60% (53 – 67%)
All four articular surfaces	100% (100-100%)	34% (37-41%)
Ankylosis of articular surface(s) involved	**Specificity, with 95% confidence intervals**	**Sensitivity, with 95% confidence intervals**
Single joint involved	92% (88 – 95%)	56% (49-62%)
Both joints involved	93% (89 – 96%)	54% (47-60%)

Table demonstrating the specificities and sensitivities with 95%CI of subchondral sclerosis, erosion, and ankylosis.

Conclusion:

When sclerosis measures > 5mm in three planes and is located > 5mm from a joint perimeter, it has high specificity for sacroiliitis, regardless of how many articular surfaces are involved, with similar specificity to erosion.

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-tumor necrosis factor-alpha (anti-TNFa) agents are established as the mainstay of treatment for ankylosing spondylitis (AS). Recently, paradoxical induction or exacerbation of psoriatic skin reaction during anti-TNFα therapy has been reported. The aim of this study is to investigate the incidence of psoriatic skin reaction in AS patients following anti-TNFa therapy and to compare the risk across anti-TNFα agents.

Methods: A nationwide population-based cohort study was performed using the Korean National Health Insurance Claims database. All patients with AS were collected between 2009 and 2013. The case group (anti-TNFα therapy group) included all AS patients who had been treated with anti-TNFα agents for over 6 months, and an age- and sex-matched control group (conventional therapy group) was selected randomly, with two controls per case, from AS patients who had not been administered an anti-TNFα agent. Newly-developed psoriasis and palmoplantar pustulosis after 1-year washout period of 2009 were assessed and compared between the two groups using multivariable logistic regression models.

Results: Among a total of 36,311 AS patients, 5,838 and 11,676 patients were enrolled in the anti-TNFα and conventional therapy groups, respectively. The incidence rates of psoriasis and palmoplantar pustulosis in the anti-TNFα therapy group were significantly higher than those of conventional therapy group (1.66% vs. 0.80% for psoriasis and 0.48% vs. 0.13% for palmoplantar pustulosis, all P <0.0001). After adjusting for age and sex, the anti-TNFα therapy group had increased risks of psoriasis (odds ratio [OR] 2.112, 95% confidence interval [95% CI] 1.586–2.812) and palmoplantar pustulosis (OR 4.343, 95% CI 2.248–8.392). Infliximab (OR 2.801, 95% CI 1.793–4.375) had the highest association with incident psoriasis, followed by adalimumab (OR 1.980, 95% CI 1.359–2.886) and etanercept (OR 1.906, 95% CI 1.278–2.843).

Conclusion: The use of anti-TNFα agents was significantly associated with the development of paradoxical psoriasis and palmoplantar pustulosis in patients with AS.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Spinal radiographic progression is a highly variable process in ankylosing spondylitis (AS). Our aim was to develop a combined AS spine score (CASSS) in which the cervical facet joint score is combined with the mSASSS, and to investigate the additional value of the CASSS in the evaluation of spinal radiographic progression in AS patients.

Methods: Baseline and 4-year radiographs from 98 consecutive AS patients treated with TNF-α inhibitors in the GLAS cohort were scored by two readers; vertebral bodies according to mSASSS (0-72) and cervical facet joints (C2-C7) according to the method of de Vlam (0-15). The CASSS was calculated by summing up the total scores of both methods (range 0-87) and was compared to mSASSS (gold standard) using three aspects of the OMERACT filter: feasibility, discrimination, and truth.

Results: *Feasibility:* Scoring cervical facet joints took a few minutes, no additional radiographs were necessary. The CASSS could be calculated in 91 (93%) and mSASSS in 94 (96%) patients. *Discrimination:* Both scoring methods had very good inter-observer reliability (ICC's status scores >0.99, progression scores 0.92). Measurement error was similar for CASSS and mSASSS, smallest detectable change was 1.9 and 1.8, resp. Sensitivity to change was moderate for both methods with a standardized response mean of 0.63 for CASSS and 0.59 for mSASSS. *Truth:* The use of CASSS resulted in 41 (46%) patients with higher baseline scores and 22 (25%) with higher progression scores compared to mSASSS. Baseline damage of facet joints was moderately correlated with damage of vertebral bodies (rho=0.49). Radiographic progression of facet joints was not correlated with progression of vertebral bodies (rho=0.16).

Conclusion: According to the OMERACT filter, the new CASSS performed similar to mSASSS in respect to feasibility and discrimination. The CASSS showed better truth value since it provides a broader range of structural changes and captures more AS patients with progression which is very important in the evaluation of radiographic outcome in this heterogeneous and slowly progressing disease.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RAPID-axSpA (NCT01087762) investigated the efficacy and safety of certolizumab pegol (CZP) in patients (pts) with axial spondyloarthritis (axSpA), including ankylosing spondylitis (AS) and non-radiographic (nr)-axSpA. Previously, CZP treatment has been shown to improve the signs and symptoms of axSpA over 96 weeks (wks).[1]

Methods: RAPID-axSpA was double-blind and placebo-controlled to Wk 24, dose-blind to Wk 48 and open-label (OL) to Wk 204. Pts fulfilled ASAS criteria and had active axSpA with positive sacroiliac joint MRI and/or raised CRP (>7.9 mg/L). Pts randomized to CZP (200 mg Q2W or 400 mg Q4W) continued their assigned dose in the OL period. Efficacy data are presented for pts originally randomized to CZP (combined doses) as observed case (OC) and with imputation: NRI for categorical measures; LOCF for continuous measures. The safety set included all pts treated with ≥1 dose of CZP.

Results: 218/325 pts were randomized to CZP from Wk 0, of whom 65% (n=142) completed to Wk 204 (AS: 67% [n=81]; nr-axSpA: 63% [n=61]). In the OL period, 9.2% of pts withdrew due to an adverse event and 1.4% due to lack of efficacy. The proportion of pts achieving ASAS20/40 and partial remission (PR) responses at Wk 24 was maintained to Wk 204 in pts remaining in the study (Figure/Table). All other clinical and patient-reported outcomes also showed maintenance of efficacy to Wk 204, with similar improvements in AS and nr-axSpA pts (Table) and in both CZP dose regimens (data not shown). Spinal mobility (BASMI-linear) and function (BASFI) also improved in both subpopulations, improvements that were maintained until Wk 204. Nr-axSpA pts had lower scores at Wk 204, but also lower levels of impairment at baseline (BL). 148 pts had BL enthesitis (MASES >0). Increasing proportions of this group who completed to Wk 204 achieved complete enthesitis clearance (MASES=0; OC): 39.6% at Wk 12, 52.5% at Wk 24, and 63.5% at Wk 204. Similarly, of 52 pts with BL heel enthesitis (tenderness at proximal insertion of ≥1 Achilles tendon; OC), 48.0%

achieved clearance at Wk 12, 65.3% at Wk 24, and 74.3% at Wk 204. Pts in the safety set (N=315) had a total CZP exposure of 981 patient-years (PY), with a serious adverse event rate per 100 PY of 10.4. Event rate for serious infections was 2.3/100 PY, for malignancies 0.5/100 PY and for serious cardiovascular events 0.4/100 PY. No new safety signals were identified from Wk 96 to Wk 204, and no deaths were reported over 4 years.

Conclusion: The RAPID-axSpA trial is the first study to report on the efficacy of an anti-TNF across the broad axSpA population, including both AS and nr-axSpA pts. Long-term data from this study show that pts from both subgroups treated with CZP were able to maintain improvements in disease activity, measured both clinically and by patient-reported outcomes, with no new safety signals, over 4 years of treatment. **References:** 1. Spondyloarthritis Research Consortium of Canada (SPARCC) Baseline MRI SI Joint Score ≥2 Better Predicts Response to Golimumab Than Does Assessment of Spondyloarthritis International Society (ASAS) MRI Positivity in Nonradiographic Axial Spondyloarthritis

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Golimumab (GLM) was shown to be effective for nonradiographic axial spondyloarthritis (nr-axSpA) in a randomized, double-blind, placebo-controlled, phase 3 study (GO-AHEAD; NCT01453725).[1] The SPondyloArthritis Research Consortium of Canada (SPARCC MRI index for SI joint (SIJ) inflammation score assesses inflammation in a dichotomous manner in SIJ quadrants. Both Assessment of SpondyloArthritis international Society (ASAS) MRI SIJ positivity and the SPARCC SIJ score cut-off of ≥2 reflect positivity for MRI in nr-axSpA, yet each relies on different methodologies with different levels of scientific precision. We analyzed whether the SPARCC SIJ score cut-off of ≥2 is a better predictor of treatment responsiveness to GLM in the GO-AHEAD trial than is ASAS MRI SIJ positivity.

Methods: Patients with nr-axSpA (ASAS criteria, centrally read SIJ X-rays, disease duration ≤5 years, chronic back pain ≥3 months, high disease activity, and inadequate response or intolerance to NSAIDs) were randomized (with ASAS-defined MRI sacroiliitis by a single central reader [yes, SIJ+; no, SIJ–] and CRP level [≤ULN or >ULN] as stratification factors) to GLM 50 mg SC or placebo Q4W for 16 weeks. Baseline ASAS MRI SIJ positivity was assessed by one blinded reader. The SPARCC SIJ score was scored by two independent blinded readers. SPARCC SIJ adjudicated score

(if it existed) was used. If no adjudication was required, the mean of the two independent readers' score assessments was used.

Results: In total, 197 patients were treated (GLM=97; placebo=100). Treatment-group differences in ASAS 20, ASAS 40, ASAS PR, BASDAI 50, and SPARCC SIJ score responses were greater in patients with baseline SPARCC SIJ score ≥2 than in those with ASAS-defined MRI SIJ positivity (Tables). By contrast with the ASAS MRI–negative group, no GLM treatment benefit was observed in patients with baseline SPARCC SIJ score <2. Results should be interpreted with caution given the small subgroups, absence of multiplicity control, and post-hoc nature of the analysis.

Conclusion: Compared with ASAS MRI SIJ positivity, the categorization of patients according to a more standardized definition of MRI positivity, as defined by the SPARCC ≥2 cut-off, may provide a more accurate reflection of responsiveness to GLM in patients with nr-axSpA. **Reference**

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Tumour necrosis factor alpha inhibitors are effective in reducing inflammation in rheumatic diseases while increasing the risk of infections. We aimed to study the relationship between trough serum concentrations of infliximab (CIFX) and the risk of a first infectious episode (IE) in treated patients.

Methods: We retrospectively included all patients who started infliximab treatment in our department. Patients were followed-up based on recommended infliximab infusions schedule. We studied the relationship between the occurrence of a first IE requiring hospitalization, anti-infectious treatment or infliximab infusion deferral, and the last CIFX and mean of 3 last CIFX (mean-CIFX) measured before the IE.

Results: From 201 patients retrieved, 173 spondyloarthritis patients with a mean age of 46 (±12) years and disease duration of 6.2 (±6.1) years were included in the analysis. During a median follow-up of 1.1 year, 87 patients had at least one IE. Using Cox models we found that the probability of survival without IE was significantly higher in patients with a mean-CIFX under the median (<11.3 mg/L) than in patients above the median (log-rang p=0.048). Glucocorticoid use and CIFX were significantly associated with the risk of a first IE in the multivariable analysis (p=0.004 for both). The risk of IE was significantly increased in the highest quartile of mean- CIFX (>20.3 mg/L, HR=2.65, 95%CI [1.14, 6.14], p=0.023; see figure 1)

Conclusion: We showed that a high infliximab concentration was correlated with a higher risk of a first infectious episode in spondyloarthritis. This finding needs to be replicated in further prospective studies.

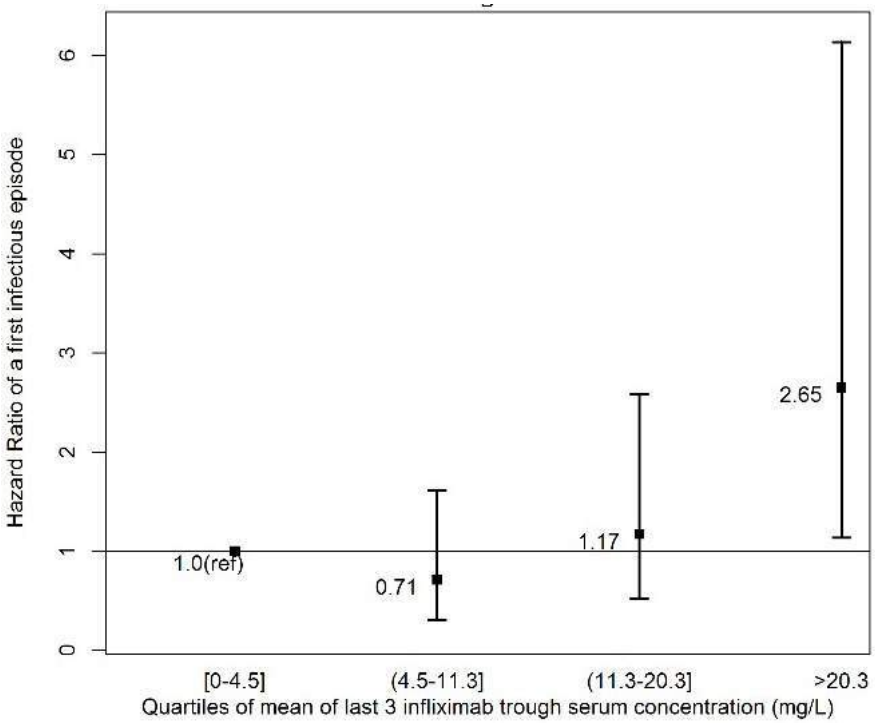

Figure 1: Estimated Hazard Ratios (points) and 95% CI (vertical segments) for a first infectious episode in quartiles of the last 3 infliximab trough serum concentrations, adjusted for weight, CRP, ESR, disease activity, presence of ATI, methotrexate and glucocorticoid use.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The immunomodulatory effects of adipokines have been extensively studied in rheumatic diseases, there is a paucity of information regarding their effects on bone metabolism. Our study aimed to investigate the relationship between changes in serum adipokines levels and radiographic progression in patients with ankylosing spondylitis (AS).

Methods: Twenty male patients with AS naïve to biologics and 11 age- and gender-matched male healthy subjects were consecutively recruited at a university-affiliated rheumatology center. Serum levels of leptin, adiponectin, resistin, TNF- α, IL-6, and DKK-1 were assessed by enzyme-linked immunosorbent assay at baseline and 2 years later. AS patients underwent lateral cervical and lumbar spine radiography baseline and 2 years later. Radiographic progression was defined as worsening of modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) by ≥ 2 units over the 2 years from baseline.

Results: Baseline serum leptin and adiponectin levels in AS patients did not differ significantly from those in the controls; however, AS patients had a significantly higher resistin levels (5.5 [3.8-7.7] ng/ml) compared to controls (3.8 [1.9-5.1] ng/ml) at baseline (p=0.049). Baseline serum leptin, adiponectin and resistin levels were not correlated with disease activity, functional, metrological indices or mSASSS. Two years later, a significant increase in serum leptin and resistin levels and mSASSS was observed in AS patients, whereas serum DKK-1 levels significantly decreased. Seven (35%) of the 20 AS patients showed radiographic progression after 2 years. Median changes of serum leptin levels during the 2-year follow-up in AS patients with radiographic progression was significantly higher than in those without this feature (1.6 [0.7-7.1] ng/ml vs -0.2 [-0.6-0.5] ng/ml, p=0.002). In multivariable logistic regression models, the magnitude of changes in serum leptin levels over the 2-year period was significantly associated with radiographic progression in AS patients (OR=8.24, 95% CI=1.1-61.6, p=0.04). Additionally, changes in serum adiponectin, resistin, TNF- α, IL-6 and DKK-1 levels were not related to radiographic progression.

Conclusion: Increase in serum leptin levels over a 2-year period significantly correlated with radiographic progression in AS patients. Our findings suggest that leptin may be involved in the pathogenesis of new bone formation in AS. Table 1. Logistic regression models for the radiographic progression in patients with ankylosing spondylitis

Variables	Crude OR (95% CI)	p	Adjusted OR [a] (95% CI)	p

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of the study was to develop and validate a Spanish-language translation of the ASAS Heath Index (ASAS-HI) testing its reliability, construct validity and responsiveness in Colombian patients with SpA

Methods: Translation was done using a standardized operating procedure (forward-backward procedure). Patients fulfilling ASAS classification criteria for either axial (axSpA) or peripheral SpA (pSpA) participated. Test-retest reliability was assessed by intraclass correlation coefficient (ICC) in patients without treatment changes (stable disease state). In patients who required a therapeutic change because of high disease activity, responsiveness was assessed using a standardized response mean (SRM). Construct validity against other health outcomes was evaluated by Spearman

correlation. Internal consistency (Cronbachs-α) and discriminative ability between ASAS-HI and ASDAS were assessed

Results: In total 50 patients were included: 54% male, mean (SD) age 44.8 (13.1) years, symptom duration 15.8 (9.7) years, BASDAI 4.6 (2.2), BASFI 4.7 (2.5), ASDAS-CRP 2.2 (1.0). The diagnosis of axSpA was established in 44 patients (AS =30, nr-axSpA =14) and pSpA in 6 patients. The total score of the ASAS-HI was 8.2 (5.1). The test-retest reliability (n=18) was good ICC: 0.84 (95%CI 0.71 to 0.93, p<0.001). Sensitivity to change was tested in 10 patients and SMR was 2.58 (1.75 to 3.37), and 2.94 (2.13 to 4.24) for those patients receiving TNFi (n=7). Construct validity showed a good correlation with clinical parameters (r≥0.60) for pain, BASDAI, BASFI, and ASDAS (Table 1). A high internal consistency was found with a Cronbachs-α of 0.91. The ASAS-HI discriminated well between patients with different stages of disease activity and function irrespective of the tool applied (BASDAI, BASFI and ASDAS) Table 2

Conclusion: The Spanish-language translation of the ASAS Health index was found relevant and comprehensive by patients with SpA. This version is available to evaluate the state of health and functioning in these patients and can be used in clinical practice **Table 1** Correlation coefficient (95%IC) between ASAS-HI and clinical characteristics

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: As part of the update of the ASAS/EULAR recommendations for the management of axSpA, we performed a systematic literature review to assess the efficacy and safety of biological (b) and targeted synthetic (ts) DMARDs in patients with axSpA published since the last SLR in 2009.

Methods: We searched in Medline, EMBASE, and Cochrane Central databases (2009-2016), supplemented by searches in 2014-2015 EULAR and ACR abstracts, for randomized clinical trials (RCT) and controlled CTs, including long-term extensions, strategy trials, and observational studies (only for safety assessment and as long as a comparator group was included). Interventions were any bDMARD, tsDMARD and biosimilar. All relevant efficacy and safety outcomes were included and meta-analyses performed whenever appropriate.

Results: Of 10,244 articles and 428 conference abstracts screened, 76 papers and 26 abstracts fulfilled the inclusion criteria. A Cochrane review confirmed the efficacy and safety of etanercept, infliximab, adalimumab and golimumab in patients with r-axSpA. In addition, we found large treatment-effects both in r-axSpA and nr-axSpA for these drugs and also for certolizumab pegol (table 1). For nr-axSpA, results were better among those with objective signs of inflammation (either sacroiliitis on MRI or CRP) before treatment start (table 2). Secukinumab has shown good efficacy results in two large phase 3 RCTs [ASAS 20 pooled RR (95% CI) at week 16: 2.1 (1.7; 2.7) for 150 mg; NNT: 3.1] and overall good safety data. Ustekinumab, apremilast and tofacitinib have shown good (preliminary) results in phase 2/proof of concept trials; Rituximab, IL-6 antagonists (tocilizumab and sarilumab) and abatacept failed to do so. Infliximab biosimilar (CT-P13) proved to be as effective and safe as the infliximab originator. Although long-term observational safety data are still scarce, no new safety signals were identified.

Conclusion: New evidence strengthens the efficacy and safety of TNFi both in patients with r-axSpA and nr-axSpA. Secukinumab is the first drug targeting a new pathway showing efficacy and safety in axSpA.

Table 1. Effect of TNFi on ASAS 20 and ASAS 40 responses in patients with r-axSpA and nr-axSpA

The Prevalence of Axial and Peripheral Spondyloarthritis in Inflammatory Bowel Disease: A Systematic Review & Meta-Analysis

Maren C. Karreman[1,2], Jolanda J. Luime[3], Johanna M.W. Hazes[2] and Angelique E.A.M. Weel[1], [1]Rheumatology, Maasstad Hospital, Rotterdam, Netherlands, [2]Rheumatology, Erasmus University Medical Center, Rotterdam, Netherlands, [3]Rheumatology, Erasmus Medical Centre, Rotterdam, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory Bowel Disease (IBD) is a chronic disease that affects up to 0.5% of the population, comprising both Crohn's Disease (CD) and ulcerative colitis (UC). Various extra-intestinal manifestations can occur, among which spondyloarthritis (SpA). SpA can manifest with both axial and peripheral manifestations, but prevalence estimates of these manifestations differ widely. The objective of this study therefore was to provide a pooled estimate of the prevalence of axial and peripheral manifestations of SpA in patients with IBD and to identify factors that might influence the prevalence estimates.

Methods: We systematically searched Embase, Pubmed, OvidSP, Scopus and Web-of-science databases from inception to May 2014. All articles addressing the prevalence of axial and/or peripheral manifestations of spondyloarthritis in adult IBD patients were included. Risk of bias was assessed using a quality assessment tool including items on selection bias, non-response bias, sample size and misclassification of SpA diagnosis.

Results: Out of 4846 studies, 60 studies were included. Sample size varied from 9 to 4454. Methodological quality of the included studies was moderate, with only a slight majority scoring positively on the individual items of the quality assessment tool. With regard to axial manifestations, the pooled prevalence of sacroiliitis was 0.11 (95% CI 0.08-0.014), whereas the pooled prevalence for ankylosing spondylitis was 0.03 (95% CI 0.03-0.04). For peripheral arthritis the pooled prevalence was 0.14 (95% CI 0.12-0.16). Few estimates were available for the prevalence of enthesitis (range from 0.01 to 0.54) and dactylitis (range from 0 to 0.04). For both axial and peripheral manifestations, the prevalence was higher in patients with CD than in patients with UC. Heterogeneity between studies was large, which might be explained by methodological quality as well as difference in geographic area, clinical setting and the use of criteria for case ascertainment as shown for the prevalence of SI and AS.

Conclusion: Spondyloarthritis is a common extraintestinal manifestation in IBD. Peripheral arthritis is slightly more common with a pooled prevalence of 0.14 than axial manifestations as sacroiliitis (pooled prevalence 0.11) and ankylosing spondylitis (pooled prevalence 0.03). For both axial and peripheral manifesations, the prevalence is higher in patients with CD than in patients with UC.

Session Time: 9:00AM-11:00AM

Is there a clinical patient profile for PsA Patients with a diagnostic delay?

Background/Purpose: Psoriatic arthritis (PsA) is a progressive inflammatory musculoskeletal disease. Several recent studies have shown that a delay in diagnosis leads to a worse outcome. Haroon et al showed that a delay of more than 6 months from symptom onset contributes to the development of erosions and worse long-term physical function. [1] In this study we will investigate the patient profile of PsA patients with a diagnostic delay.

Methods: Data of incident PsA patients was used from the Dutch South-West Psoriatic Arthritis Registry (DEPAR) study between August 2013 and March 2016. The DEPAR includes newly diagnosed PsA patients from 8 hospitals in the South-West of the Netherlands. Patients are followed every 3 months during the first year. PsA core measurements were collected: Swollen and Tender join count (66/68), enthesitis (LEI and MASES), dactylitis (LDI) and psoriasis (PASI). In addition measures of quality of life (SF-36) and health (HAQ) are collected The groups with symptom duration longer than 6 months and shorter than 6 months were compared using parametric and non-parametric tests where appropriate.

Results: In total, 316 patients had a baseline assessment. Average age was 50.4 years (SD 13.7) and 50% were male. The median duration of complaints to diagnosis was 11.6 months (range 0-586). The median time from first visit to the general practitioner to diagnosis was 4.4 months (range 0-374). Patients with symptom duration shorter than 6 months were slightly older (52.7 (SD 14.6) vs. 49.1 (SD13.3) $p<0.05$) were more frequently male (60% vs 40%, $p<0.05$) and had less enthesitis (39% vs 52%, $p<0.05$). There was no difference in the other disease features nor quality of life or health. (table 1) Patient with a shorter symptom duration than 6 months seemed to have a better response to treatment as shown by the lower PASDAS and CPDAI scores at 3 and 6 months.

Conclusion: PsA patients with diagnostic delay for more than 6 months were more likely to be female and enthesitis more frequently and seemed to have a higher disease during follow-up as measured by CPDAI and PASDAS at 3 and 6 months.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The assessment of achieving, maintaining, and improving clinical response to biologics in Ankylosing Spondylitis (AS) is part of treat-to-target recommendations aimed at optimizing treatment goals. Here we present patient-level secukinumab data to assess the likelihood of achieving an Assessment of Spondyloarthritis international Society (ASAS) response and maintaining or improving that response from Week (Wk) 2 (early response) to Wk 16 (primary endpoint) and from Wk 16 to Wks 52 and 104 (sustained effect) in patients with active AS from the MEASURE 2 trial.[1]

Methods: This was a *post-hoc* analysis of AS patients originally randomized to secukinumab 150 mg (currently approved dose) who completed the 16-wk double-blind treatment period, followed by long-term uncontrolled treatment. Shift analyses on ASAS responses between Wks 2 and 16 and Wks 16 and 52/104 were performed for subgroups of secukinumab-treated patients, based on response at the earlier time point (non-responders for ASAS 20 or ASAS 40 [ASAS NR], ASAS 20 only, or ASAS 40 only) by evaluating whether these responses were decreased, maintained, or improved at the later time point using observed data.

Results: Overall, 65, 61, and 59 AS patients treated with secukinumab 150 mg had available data to determine ASAS responses for shift analyses from Wks 2 to 16, Wks 16 to 52, and Wks 16 to 104, respectively. At baseline, mean age was 41.9 ± 12.5 years, mean time since diagnosis was 7.0 ± 8.2 years, and mean Bath Ankylosing Spondylitis Disease Activity Index score was 6.6 ± 1.5. Approximately half of the ASAS NR patients at Wk 2 or 16 subsequently developed an ASAS response at the later time point of Wk 16 or 52, respectively. A majority (71% and 67%) of ASAS 20 responders at Wk 2 or 16 showed improved responses to ASAS 40 by Wk 16 or 52, respectively, whereas 21% and 16% of ASAS 20 responders maintained their response by Wk 16 or 52, respectively. A majority (64% and 84%) of ASAS 40 responders at Wk 2 or 16 maintained this response by Wk 16 or 52, respectively. Similar trends were observed in shift analyses of ASAS responses from Wks 16 to 104 (Table).

Conclusion: In this *post-hoc* analysis of patients with active AS, the majority of patients on secukinumab treatment maintained or improved their ASAS responses over time, consistent with the sustainability of group-level ASAS responses

reported previously.[1] In particular, the vast majority of patients who achieved either an ASAS 20 or ASAS 40 response at Wk 2 or 16 maintained or improved their response by Wks 16, 52, or 104, respectively. Reference: 1. Baeten D et al. *N Engl J Med.* 2015;373:2534–48.

Table: ASAS Shift Analyses for AS Patients on Secukinumab 150 mg from Wk 2 to Wk 16 and from Wk 16 to Wk 104 in MEASURE 2

Wk 2 (N = 65)	Wk 16# (N = 65)			Wk 16 (N = 59)	Wk 104# (N = 59)		
	ASAS NR n (%)	ASAS 20 n (%)	ASAS 40 n (%)		ASAS NR n (%)	ASAS 20 n (%)	ASAS 40 n (%)
ASAS NR (N1 = 37)	19 (51.4)	12 (32.4)	6 (16.2)	**ASAS NR (N1 = 17)**	7 (41.2)	3 (17.6)	7 (41.2)
ASAS 20 (N2 = 28)	2 (7.1)	6 (21.4)	20 (71.4)	**ASAS 20 (N2 = 42)**	5 (11.9)	12 (28.6)	25 (59.5)
ASAS 40 (N3 = 14)	0 (0.0)	5 (35.7)	9 (64.3)	**ASAS 40 (N3 = 25)**	2 (8.0)	4 (16.0)	19 (76.0)

ASAS NR = patients who are NR for ASAS 20/40 endpoints; N = number of patients at Wks 2 and 16 and Wks 16 and 104 with ASAS 20/40 endpoints; N1 = number of patients who were non-responders at Wk 2 or 16; N2 = number of patients who achieved ASAS 20 at Wk 2 or 16; N3 = number of patients who achieved ASAS 40 at Wk 2 or 16; N1 to N3 is the denominator for ASAS 20/40 endpoints at Wks 16 and 104. #At Wks 16 and 104, patients were counted only once between ASAS 20/40 to the maximum response achieved. NR, non-responder to ASAS 20 and 40

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and

Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Acute anterior uveitis (AAU) is common in ankylosing spondylitis (AS) (1). Golimumab, a tumor necrosis factor alpha (TNF-α) blocker, has proven to be effective in the treatment of AS (2). We have shown earlier that treatment with adalimumab, another TNF-α blocker, leads to a significant decrease in the recurrence rate of AAU (3) in AS. At present, the effect of golimumab on the recurrence rate of AAU in AS is unknown. The objective was to investigate the effect of golimumab treatment on the recurrence rate of AAU attacks in AS patients.

Methods: Consecutive AS patients were enrolled who all fulfilled the 1984 Modified New York criteria, and fulfilled the criteria for initiating treatment with a TNF-α blocker in the Netherlands. All patients were treated with golimumab 50mg once a month for 12 months. During treatment, all occurring AAU attacks were assessed. The historic presence of AAU attacks was assessed from the year before baseline for non-biological treated patients, or the year before the first treatment with a TNF-α blocker in case of a switch from another TNF-α blocker to golimumab. Disease activity was measured with the Ankylosing Spondylitis Disease Activity Score – C-reactive protein (ASDAS). Response to treatment was assessed with the ASAS-20.

Results: In total, 93 patients (65% male) were evaluable as per protocol, with a mean age of 44±13 years and a median disease duration of 7 (0-53) years. Fifty-one patients (55%) were TNF-α blocker naive. Median ASDAS score at baseline was 3.1 (0.7-5.5), which decreased to 1.9 (0.1-5.1) at 12 months. ASAS-20 response was achieved by 36% of patients at month three ($p<0.001$), and by 49% of patients at month twelve ($p<0.001$). Six patients (7%) had a prior history of AAU with a total of nine attacks in the year prior to the first TNF-α blocker use (9.8/100 patient years). During golimumab treatment, the rate of recurring AAU attacks was reduced to two new attacks (2.2/100 patient years), a significant reduction of 78% ($p<0.001$). These two AAU attacks occurred in two separate patients, of whom one had no history of AAU.

Conclusion: Treatment of AS patients with golimumab leads to a significant decrease in disease activity. Simultaneously, the rate of recurring AAU attacks decreased significantly during golimumab treatment. (1) Stolwijk C, van TA, Castillo-Ortiz JD, Boonen A. Does Axial Spondyloarthritis Phenotype Correlate with Imaging Morphotype?

Xenofon Baraliakos[1], Annette Szumski[2], Heather Jones[3] and Lianne S. Gensler[4], [1]Rheumazentrum, Ruhr University, Bochum, Germany, [2]inVentiv Health, Princeton, NJ, [3]Inflammation & Immunology, Pfizer, Collegeville, PA, [4]Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Traditionally, radiographic imaging was used to describe morphological differences between various types of axial SpA (axSpA). MRI has advanced understanding of disease, enabled earlier diagnosis and visualization of structural changes, and facilitated the identification of non-radiographic axial SpA (nr-axSpA). The magnitude of the pathologic changes in the axial skeleton is used to quantify inflammatory and structural outcomes in clinical trials and treatment of patients with axSpA. **Objectives:** To examine the MRI morphology of sacroiliitis (SI) and vertebral corner lesions in primary axSpA (1º) patients vs. secondary axSpA (2º) patients with concomitant psoriasis.

Methods: This posthoc analysis was performed on data from patients with axSpA enrolled in the EMBARK trial (NCT01258738). Patients with no baseline MRI lesions were excluded. Symmetric and asymmetric SI, structural lesions, and corner inflammatory lesions were analyzed in 1º axSpA vs. 2º axSpA patients with psoriasis. Data were analyzed using one-way analysis of variance for continuous parameters, Fisher's exact tests for categorical parameters, Fisher's exact chi-square for small sample sizes, and parametric and non-parametric approaches for structural lesions.

Results: The baseline demographics and disease characteristics between the 122 patients with 1º axSpA and 19 with 2º axSpA were similar. Asymmetric sacroiliitis was seen in significantly fewer 1° (43%) vs. 2° (68%) axSpA patients. There were no differences in mean SpondyloArthritis Research Consortium of Canada (SPARCC) scores between 1° and 2° axSpA for any of the 4 SI joint (SIJ) quadrants. However, the lower iliac quadrants had the highest SPARCC SIJ score and the upper iliac quadrants had the lowest SPARCC SIJ scores. When analyzing the 4 spine quadrants (lower/upper anterior and lower/upper posterior), 1° patients had higher total SPARCC spine scores than 2° patients for all 4 quadrants at baseline (Table). Collapsing the 4 quadrants shows that 1° axSpA patients had higher SPARCC MRI of the entire spine (23 discovertebral units (DVU); mean=5.6) compared with 2° axSpA patients (mean=2.2).

Conclusion: We found 1° axSpA patients had more symmetric sacroiliitis and extensive spinal bone marrow edema compared with 2° axSpA patients. In addition, women appeared to have more asymmetric sacroiliitis. These data may help physicians accurately diagnose patients and decide best treatment options.

Table:

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Due to lack of validated outcome measures in non-psoriatic peripheral spondyloarthritis (pSpA), recent studies in this patient (pt) population have used varying endpoints [1]. Thus, developing new pSpA-specific indices may be worthwhile. Minimal Disease Activity (MDA) has been validated in psoriatic arthritis but not in pSpA. The objective of this study is to evaluate the performance of a modification of the MDA criteria (excluding psoriasis) in pSpA patients (pts) from the ABILITY-2 study [2].

Methods: This post-hoc analysis evaluated the validity of a modified MDA (mMDA) in pSpA. ABILITY-2 was a 12-week trial comparing adalimumab (ADA) with placebo (PBO) in pSpA followed by a 144 week extension. The mMDA for pSpA was defined as achieving at least 4 or 5 out of the following 6 criteria: (1) tender joint count (TJC, 78 joints) ≤ 1; (2) swollen joint count (SJC, 76 joints) ≤ 1; (3) pt pain visual analog scale (VAS) ≤ 15 of 100 mm; (4) pt global activity (PtGA) VAS ≤ 20 of 100 mm; (5) health assessment questionnaire–disability index (HAQ-DI)≤ 0.5; and (6) tender entheseal points ≤ 1. Enthesitis was assessed by the Leeds Enthesitis Index (LEI) or the Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index for this analysis. The proportion of pts achieving the 4 different versions of mMDA were evaluated (either 4 or 5 of 6 using LEI and either 4 or 5 of 6 using SPARCC). The correlations between mMDA and the novel pSpA response criteria [PSpARC] remission from ABILITY-2 and Ankylosing Spondylitis Disease Activity Score Inactive Disease [ASDAS ID] were evaluated by tetrachoric correlation (r_{tet}).

Results: Of the 163 pts (82 ADA, 81 PBO) who completed wk 12, significantly greater proportion of pts receiving ADA achieved mMDA (regardless of the definition) compared with PBO (P<0.001 for all comparisons, **Table 1a**). The proportion of mMDA responders at yrs 1, 2, and 3 was numerically higher in pts initially randomized to ADA. The mMDA response showed a stronger positive correlation with PSpARC remission (r_{tet} > 0.9) than ASDAS ID (r_{tet} > 0.75) at wk 12, and yrs 1-3. Among pts who fulfilled the 4/6 criteria (LEI or SPARCC), approximately 20-30% of pts did not meet TJC and SJC criterion (**Table 1b)**. However, the 5/6 criteria (LEI or SPARCC) were more stringent with approximately 5% and 13% not meeting the TJC and SJC criterion, respectively.

Conclusion: All 4 versions of mMDA discriminated between ADA and PBO treatment groups; both entheseal indices performed similarly. The mMDA (particularly the 5/6 versions which closely represents the concept of MDA) could be an appropriate treatment target in pSpA pts. **References:**

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Response to tumor necrosis factor inhibition (TNFi) has been shown to be similar in nonradiographic axial spondyloarthritis (nr-axSpA) and ankylosing spondylitis (AS) in patients with objective signs of inflammation, such as an elevated C-reactive protein (CRP) and/or sacroiliitis on MRI. As men and women with axSpA differ with regard to the proportion of patients with elevated CRP and acute inflammation observed on MRI, we aimed at comparing response to TNFi in nr-axSpA versus AS after stratification by sex.

Methods: Patients within the Swiss Clinical Quality Management cohort fulfilling the Assessment of Spondyloarthritis international Society (ASAS) classification for axSpA were included in the current study if they a) had a baseline pelvic X-ray, b) started a first TNFi after inclusion in the cohort and c) had a follow-up visit at 1 year (± 6 months). We excluded patients with known fibromyalgia as a co-morbidity. The proportion of patients achieving the ASAS criteria for 40% improvement (ASAS40) as well as Ankylosing Spondylitis Disease Activity Score (ASDAS) improvement criteria and status scores were evaluated at 1 year. Patients having discontinued the TNFi were considered non-responders.

Results: Baseline characteristics of 152 women and 267 men included in the analyses are shown in Table 1, stratified by classification status. In contrast to men, the proportions of patients with elevated CRP levels, peripheral arthritis and enthesitis were similarly distributed in nr-axSpA versus AS in women starting a first TNFi. The proportion of patients with different numbers of classifying axSpA features was comparable in AS versus nr-axSpA in both genders. With regard to response to TNFi, similar proportions of men with nr-axSpA and AS achieved an ASAS40 response (38% versus 45%; odds ratio (OR) 0.75, 95% confidence interval (CI) 0.35-1.56, p=0.49), as well as all ASDAS response criteria (Table 2). By contrast, a significantly lower proportion of women with nr-axSpA compared to women with AS achieved a clinical response according to the different criteria assessed (ASAS40 response of 17% versus 42%, OR 0.28, 95% CI 0.10-0.70, p=0.004 in women with nr-axSpA versus AS, respectively).

Conclusion: While men with nr-axSpA have similar response rates as men with AS, significantly lower response rates are found in women with nr-axSpA in comparison to women with AS. The results are in line with randomized controlled trials of adalimumab and golimumab in nr-axSpA, showing lower response rates in women compared to men. **Table 1. Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adalimumab (ADA) is approved for treatment of Crohn's disease (CD) and ulcerative colitis (UC); therefore, it is postulated that new onset or flare of inflammatory bowel disease (IBD) is a rare occurrence in ADA clinical trials for non-IBD indications. The purpose of this analysis was to determine the rates of IBD adverse events (AEs) in ADA clinical trials, particularly in spondyloarthritis (SpA) patients (pts) who are at higher risk of IBD as a feature of SpA.

Methods: The rates of IBD AEs in 73 phase 2–4 interventional ADA clinical trials in rheumatoid arthritis (RA), polyarticular juvenile idiopathic arthritis (pJIA), pediatric enthesitis-related arthritis, uveitis (non-infectious intermediate, posterior, or pan-uveitis), hidradenitis suppurativa (HS), adult and pediatric psoriasis (Ps), psoriatic arthritis (PsA), non-PsA peripheral SpA (pSpA), non-radiographic axial spondyloarthritis (nr-axSpA), and ankylosing spondylitis (AS) were analyzed (trials in UC, CD, and intestinal Behcet's disease [BD] were excluded). The search criteria for IBD events included the following standardized MedDRA queries preferred terms: inflammatory bowel disease (IBD), ulcerative colitis (UC), Crohn's disease (CD), IBD-not otherwise specified (NOS), and ulcerative proctitis. The incidence rates (IR) for events of IBD (combined new onset and flare) in interventional clinical trials of ADA are reported as events per 100 pt-years (PY). 95% confidence intervals (CI) were based on exact Poisson confidence limits.

Results: ADA was administered to 23735 pts, representing 36404.6 PY of exposure. Overall, the IR for IBD events in all interventional ADA trials included in this analysis was 0.1/100PY (**Table**). The rates of IBD events varied across therapeutic indications from <0.1 to 0.8/100PY. There were no reports of IBD events in pediatric pts. The IR for IBD events in RA, uveitis, HS, and Ps trials were <0.1, 0.2, 0.4, and <0.1/100 PY. In SpA, the overall rates of IBD were 0.5/100 PY, while the rates were 0, 0.8, 0.5, and 0.7/100 PY in PsA, non-PsA pSpA, nr-axSpA, and AS, respectively. 2216 pts with axSpA (AS: 2026, nr-axSpA: 190) were exposed to ADA; in AS, 14 IBD events (7 new onset and 7 flares) were reported in 12 pts (7 new onset and 5 flares), while in nr-axSpA, 2 IBD events were reported in 1 pt (2 flares).

Conclusion: The rates of IBD AEs in ADA clinical trials were generally low across all indications, with all events occurring in adult pts. In AS pts, who are at increased risk of manifesting IBD, the rates of IBD for pts treated with ADA (0.7/100 PY [95% CI, 0.4–1.1]) were similar to published placebo rates pooled across multiple clinical trials (1.3/100 PY [95% CI, 0.2–4.8]).[1] In pts at risk for IBD requiring biologic therapy, ADA is a reasonable therapeutic option based on the observed low IBD event rates in ADA clinical trials and its demonstrated efficacy in treating UC and CD pts.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with rheumatoid arthritis, methotrexate (MTX), improves the clinical efficacy of anti-TNF (TNFi), among other reasons, for reducing the immunogenicity. However, there are doubts of their benefit in patients with ankylosing spondylitis (AS) The purpuse of this study is to evaluate the influence of combined treatment with DMARD in clinical efficacy in patients with AS treated with adalimumab (ADL).

Methods: Prospective, observational study was done in 62 consecutive patients diagnosed with axial AS, treated with ADL, receiving DMARD, according to clinical practice, at the discretion of the rheumatologist. Epidemiological patient data (age, gender, body mass index), type of concomitant DMARD, EA characteristics (time of evolution of disease, presence of psoriasis or inflammatory bowel disease, HLA-B27), were collected, and information of ADL, too (order of introduction of TNFi treatment and time, and presence of serum anti-ADL antibodies). Clinical response was assessed using the Spanish version of BASDAI and ASDAS-ESR index. Serum concentrations of free ADL (trough level) and anti-ADL antibodies (Ab), were measured using Promonitor-ADL and Promonitor Anti-ADL Ab ELISA kits (Progenika Grifols SA, Spain), as standardised conditions, specified by the manufacturer, cut-off value were >0.024 mg/L for the serum levels of ADL and >3.5 AU/mL for positive anti-ADL Ab. The anti-ADL Ab and ADL serum level were determined by ELISA (Progenika, Grifols SA, Spain). Cut-off level for ADL were <0.004 mg/L and anti-ADL Ab >3.5 AU/mL. Samples was obtained just before subcutaneous (s.c.) injection of ADL (trough level) and was stored at -80 °C until analysis.

Results: Of the 62 patients with axial involvement included, 31 (50%) were women, with a mean age of 46±10.years and a mean BMI of 27.47±4.49. The average time of evolution of the AS was 9.5±9.25 years. HLA-B27 was positive in 74%. DMARD was combined to ADL in 14 (23%) patients (methotrexate: 10, sulfasalazine: 3 and azathioprine 1 patient). In 47 (76%) patients, they were not associated with another extraskeletal manifestation of AS, but 12 (19%) patients had AS associated with inflammatory bowel disease and 3 (5%) patients, with psoriasis. ADL was the first TNFi in 66% of patients. The average duration of treatment with ADL was 1.33±1.44 years (median: 1 year). The average serum level of ADL was 8.62±8.59. In 19 (31%) patients were detected anti-ADL Ab, all of them (100%), in the group of patients not receiving DMARD. When comparing the group of patients treated with ADL combined with DMARD and those without (Table 1), the group treated without DMARD only presented significantly the presence of anti-ADL Ab (40% vs 0%; p <0.0001) and trend to lower serum level ADL (10.82±02.05 mg/L vs 7.59±5.5 mg/L; p=0.064). The group with anti-ADL Ab versus those without anti-ADL Ab, showed levels of ADL almost undetectable (mean: 0.082±0.16 vs 10.32±4.49; p <0.0001) and significant loss of clinical efficacy by BASDAI and ASDAS: mean: 5.53±2.0 vs 3.59±2.0 (p <0.0001) and 3.2±2.1 vs 1.92±0.74 (p = 0.038), respectively.

	DMARD Yes (n: 14/23%)	DMARD No (n: 48/77%)	p
ADL monitoring, n (%)	34 (31)	79 (69)	
Age (years): mean (SD) Median	48,07 (10.80) 48.5	46.13 (10.75) 45.0	0.56
Male, n (%)	8 (57)	23 (49%)	0.69
BMI (kg/m^2): mean (SD) Median	28.12 (3.89) 28.16	27.18 (4.73) 27.51	0.46
Time of disease evolution (years): mean (SD) Median	7.45 (7.09) 6,25	10.46 (9.87) 5.33	0.22
HLA B27 positive, n (%)	10 (71)	36 (77)	0.69
ADL order of treatment, n (%): First TNFi Second TNFi Third TNFi	8 (57) 4 (29) 2 (14)	33 (70) 14 (26) 3 (4)	0.48 0.90 0.68
Time (years) on ADL: mean (SD) Median	1.67 (1.57) 1.0	1.36 (1.27) 0.91	0.51
ADL serum level, mg/L: mean (SD) mediana	10.82 (5.16) 11.25	7.59 (5.5) 8.34	**0.064**
anti-ADL Ab, AU/L, n (%):	0 (0)	19 (40)	**0.0001**
BASDAI: mean (SD) Median	4.09 (2.14) 4.1	3.98 (2.20) 4.05	0.86
BASFI: mean (SD) Median	3.67 (2.0) 4.05	3.87 (2.40) 3.90	0.75
ASDAS: mean (SD) Median	2.09 (0.62) 2	2.23 (1.40) 2.1	0.60

Conclusion: 1) The prevalence of anti-ADL Ab in AS is 31%. 2) In our cohort, 100% of patients with AS who have immunogenicity, were been treated with ADL in monotherapy. 3) Patients with anti-ADL Ab has ADL levels almost undetectable and loss of efficacy. **Funding**: The study was supported by a research grant from the Spanish Foundation of Rheumatology (2012) and the Association for Research in Rheumatology of Marina Baixa (AIR-MB). Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We evaluated the effect of the anti-tumor necrosis factor (TNF) agents, golimumab (GLM) and infliximab (IFX), on healthcare resource utilization (HCRU) and work productivity in patients with ankylosing spondylitis (AS) in the QUality of Life as Outcomes and its VAriation with DIsease States (QUO-VADIS) study.

Methods: This was a prospective observational study in bionaïve AS patients (modified New York criteria) newly treated with GLM or IFX (originator) in a clinical practice setting. Patients were followed-up for ~6 months of treatment with GLM or IFX and data was collected at baseline (BL), and at 3 and 6 months. The assessment of HCRU was done by evaluating data on the use of concomitant medications, hospitalizations (inpatient care or acute care) and visits in day care and outpatient settings; HCRU data reflected the prior 3 months for each timepoint. Work productivity and activity impairment (WPAI) was assessed by the number of work days missed as well as quantifying absenteeism, presenteeism, work impairment, and activity using the WPAI instrument adapted to Spondylarthritis (WPAI-SpA)(1); WPAI was based on the 7 days prior to the administration of the questionnaire.

Results: 963 patients received ≥ 1 dose of medication. The vast majority (78%, n=751) was treated with GLM, while the rest (22%, n=212) received IFX. Mean age of the patients was 42.7 years, 61.4% were male. Concomitant medication usage for AS treatment was reported by 84.3% of patients, the vast majority of whom received NSAIDs, followed by analgesics, DMARDs and corticosteroids. At BL, the percent of patients who reported hospitalizations (inpatient care) in the prior 3 months was 13.6%, which decreased to 3.1% at 6 months, while outpatient care in the 3 months prior to BL was reported by 39.4% of patients, which decreased to 19.0% at 6 months. The percent of patients receiving acute emergency care in the 3 months prior to BL reduced from 1.6%0.3% at 6 months. Further details on HCRU at BL and at 6 months are shown in the Table. The mean (SD) number of days at work, missed due to AS, was reduced from 6.3 (31.1) days at BL to 2.7 (12.3) days at 6 months. Results for WPAI-SpA assessment are presented in the Table.

Conclusion: In patients with AS newly treated with GLM (almost 80% of the study population) or IFX for 6 months, HCRU was reduced, as shown by the shorter mean duration of hospitalizations and the proportion of patients receiving acute, inpatient or outpatient care. Additionally, work productivity and activity increased, and patients reported fewer days of work missed due to AS after 6 months of treatment. **References:** Tang et al. *Arthritis Care Res* 2011; 63: S337-349 **Table: Health Care Resources Utilization and WPAI-SpA Scores**

Mean (SD) Health Care Resource Utilization Among All Patients		
	Baseline	**6 months**
Acute Care (duration of stay, hours)	13.7 (32.5)	3.3 (2.08)
Acute Care (number of admissions)	1.1 (0.3)	1.3 (0.6)
Hospitalization (duration of stay, days)	7.3 (6.1)	4.1 (4.5)
Outpatient/Day Care (number of visits)	2.4 (1.8)	2.1 (2.7)
Mean (SD) Work Productivity and Impairment Among All Patients[(1)]		
Absenteeism	16.4 (32.3)	6.3 (19.8)
Presenteeism	51.9 (30.6)	28.0 (26.0)
Work Impairment	48.3 (34.0)	25.1 (26.4)
Activity	62.5 (24.7)	36.1 (26.9)

Score interpretation: For all 4 WPAI outcomes, greater scores (range 0–100%) indicate greater impact of health [(1)]

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ASAS recommends using BASMI for evaluation of axial mobility in patients with Axial Spondyloarthritis (axSpA). The EDASMI (Edmonton Ankylosing Spondylitis Metrology Index) is another index of spinal mobility which includes cervical rotation (CR), chest expansion (CE), lumbar flexion (LF) and internal rotation of the hips (IRH). This method does not require the use of goniometer, it would be less influenced by the position of the cervical spine and includes the measurement of chest expansion, which is not consider by BASMI. Our objective was to evaluate the performance of EDASMI in patients with axSpA.

Methods: Patients with axSpA ≥18 years old according mNY 1984 AS and/or ASAS 2009 axSpA criteria belonging to ESPAXIA (Estudio de Espondiloartritis Axial, IREP Argentina) cohort were studied. Data regarding sociodemographic characteristics (age, sex), disease duration, treatment, disease activity (BASDI, ASDAS-ESR, SASDAS, global patient VAS), functional capacity (BASFI), quality of life (ASQoL), enthesitis (MASES), tender and swollen 44/46 joint count, CRP and ESR were assessed. Axial mobility using a measuring tape and goniometer whenever appropriate was performed by a single trained physician and included all measures for calculating BASMI-2, BASMI-10 and EDASMI. The time to perform and calculate both indexes was evaluated. X-rays from cervical and lumbar spine, pelvis and sacroiliac joints were taken and scored by mSASSS and BASRI, by a blinded reader.

Results: 30 patients were included, 86.7% male, with a median age of 48 years (IQR 34.7-56.2) and a median disease duration of 24.5 (IQR 16.7-32.5). 90.9% were *HLA-B27* positive. Measurements of axial mobility: median BASMI-2 was 5 (IQR 3-7), median BASMI-10 4.8 (IQR 3.7-6.5) and median EDASMI 12 (IQR 8.7-13.2). EDASMI had very good correlation with BASMI-2 and BASMI-10 (Rho= 0.80 and Rho= 0.84, respectively p= 0.0001) and good correlation with mSASSS (Rho= 0.5, p= 0.006) and BASRI (Rho= 0.5, p= 0.004) and did not correlate with BASDAI, SASDAS-ESR, SASDAS-CRP, BASFI, ASQoL and morning stiffness. BASMI-2 and BASMI-10 had similar performance to that observed with the EDASMI. The mean time for measurement was significantly lower with EDASMI, compared with BASMI-2 and BASMI-10 (1.8 ±0.23 minutes vs 2.64 ±0.23 and 2.67 ±0.34 minutes, p= 0.02 and 0.01, respectively).

Conclusion: EDASMI is a valid alternative index to measure the axial mobility in patients with axSpA. It incorporates the measurement of chest expansion. It is easy to perform and calculate and does not require the use of a goniometer.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In axial Spondyloarthritis (axSpA), treatment is targeted at reducing disease activity with the aim of improving the health-related quality of life (HRQoL). Therefore, it is very important to know if a change in disease activity is indeed related to a change in HRQoL. The aim is to assess the association between the change in disease activity and change in HRQoL between baseline and one year in patients with early axSpA.

Methods: The Spondyloarthritis Caught Early (SPACE) study is a prospective cohort study in patients with chronic back pain (≥3 months, ≤2 years, onset <45 years) recruited from various rheumatology centers across Europe. The 36-item Short-Form (SF-36) was completed by patients to assess HRQoL at baseline and one year. Physical (PCS) and Mental Component Summary (MCS) scores were calculated (adjusting converted scale scores for country, gender, and age) and were compared to the general population mean of 50 with a standard deviation (SD) of 10. The Ankylosing Spondylitis Disease Activity Score (CRP based; ASDAS) was calculated to assess disease activity. Linear regression models were made with change of ASDAS between baseline and one year (DASDAS) as a determinant and the change of PCS (DPCS) or MCS (DMCS) as an outcome. The models were adjusted for age. Fulfilment of the imaging or clinical arm and gender were tested for interaction.

Results: A total of 94 patients fulfilled the ASAS axSpA criteria; 51 patients fulfilled the clinical arm and 43 patients the imaging arm. Mean age was 29.4 years (SD 7.2), 50.0% was male, and mean duration of back complaints was 14.8 months (SD 8.9). As the MCS was not different from the general population (baseline: 50.1 (SD 13.0); one year: 50.3 (SD 11.7), only the effect of ASDAS on PCS was determined. Patients had a mean PCS of 26.4 (SD 17.1) and mean ASDAS of 2.5 (SD 1.0) at baseline (Table 1). Differences in ASDAS between men (2.2) and women (2.8) and in PCS between clinical arm (28.3) and imaging arm (24.0) were found. DPCS was different between men and women, clinical and imaging arm. In the univariable model, a decrease of one unit of ASDAS between baseline and one year resulted in an improvement in PCS of 9.2 (SE 1.6) over one year. Fulfilment of the clinical or imaging arm (p=0.036) and gender (p=0.082) were effect modifiers in the model for PCS. Results were stratified for these variables. The effect of DASDAS on DPCS was most pronounced in men (β=-13.0; SE 2.7) and patients fulfilling the imaging arm (β-12.3.8; SE 2.7). It was also significant in women (β= -6.5; SE 1.6) and patients fulfilling the clinical arm (β=-6.6; SE 1.8) but the effect sizes were smaller.

Conclusion: In axSpA, a decrease in disease activity is associated with a clear improvement in health-related quality of life, but the effect is the highest in men and patients with imaging abnormalities.

Table 1: Association between the change in ASDAS and the change in Physical Component Summary (PCS) at baseline and one year among axial Spondyloarthritis patients in the SPACE-cohort (n=94)

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess whether presence of spondyloarthritis (SpA) manifestations in first- and second-degree relatives of patients with chronic back pain (CBP) is associated with higher risk for axial spondyloarthritis (axSpA).

Methods: The SPACE cohort includes patients with CBP (≥ 3 months, ≤ 2 years, onset <45 years) from various European rheumatology centers. DESIR is a French prospective multi-center cohort of patients with inflammatory back pain (IBP; ≥ 3 months, < 3 years, onset < 50 years), suggestive of axSpA. Patients underwent a full diagnostic work-up at baseline including MRI and radiographs of sacroiliac joints (local reading), laboratory assessments (e.g. HLA-B27), and assessment of all other SpA-features. Patients were asked about the presence of SpA manifestations in first- and second-degree relatives. A positive family history (PFH) was defined as having a positive family history in first- and second-degree relatives for at least one of the following SpA manifestations: ankylosing spondylitis (AS), psoriasis, uveitis, inflammatory bowel disease (IBD), and reactive arthritis. First, we assessed the association between PFH manifestations and HLA-B27 positivity in patients. Secondly, we assessed the association between PFH manifestations and axSpA using fulfilment of the ASAS axSpA classification criteria as a proxy for diagnosis. This approach circumvents circular reasoning in diagnosis but allows only assessment of the relative contribution of the various manifestations.

Results: In total, 438 patients from the SPACE cohort and 647 patients from the DESIR cohort with complete information on SpA manifestations in relatives were analysed. In the SPACE and DESIR cohort mean age (SD) was 31.3 (8.3) years and 33.6 (8.6) years, 38% and 47% of patients were male, and mean symptom duration was 13.4 (7.4) and 18.1 (10.5) months, respectively. In 20.6% and 19.6% of patients AS was reported in first- and second-degree relatives, psoriasis in 19.0% and 19.9%, uveitis in 6.2% and 4.5%, IBD in 7.5% and 5.0%, and reactive arthritis in 3.2% and 0.9%. Any PFH was reported in 42.2% and 38.5% of SPACE and DESIR patients, respectively. In both the SPACE and DESIR cohort AS (OR 5.9 [3.5-9.9] and OR 3.3 [2.1-5.2]), uveitis (OR 9.8 [3.3-28.9] and OR 21.6 [2.9-160.1]), and any PFH (OR 2.5 [1.7-3.8] and OR 1.4 [1.0-2.0]) were significantly associated with presence of HLA-B27 in CBP and IBP patients, respectively (Table 1). Fulfilment of the ASAS-criteria showed similar results: AS (OR 3.3 [2.0-5.3] and OR 2.1 [1.3-3.3]), uveitis (OR 7.4 [2.5-21.7] and OR 5.0 [1.5-16.7]). No association was found for psoriasis, IBD, or reactive arthritis in both cohorts. Multivariate regression analysis showed the same trends for both cohorts (not shown).

Conclusion: These data suggest that in the diagnostic work-up of patients with chronic back pain suspected of axSpA only a positive family history for AS or uveitis is of value.

Table 1 Univariate regression analysis of the presence of family history manifestations for both HLA-B27 status and the fulfilment of ASAS axSpA criteria in patients with chronic back pain in the SPACE cohort (n=438) and in patients with recent inflammatory back pain in the DESIR cohort (n=647).

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Assessment of SpondyloArthritis international Society (ASAS) has developed and validated classification criteria for axial spondyloarthritis (axSpA) and peripheral SpA (pSpA). Following their release, the ASAS criteria have been 'challenged' in different cohorts, thus warranting a review of the so-far accumulated evidence on the criteria validity and applicability. Our aim was to summarize the evidence on the performance of the ASAS classification criteria for axSpA (also imaging and clinical arm separately), pSpA and the entire set of SpA, when tested against the Rheumatologist's diagnosis ('reference standard').

Methods: A systematic literature review was performed to identify eligible studies. Only studies with full-text available

were included and, thereafter, raw data was obtained from the authors of the selected publications. A meta-analysis was performed to obtain pooled estimates for sensitivity, specificity, positive (LR+) and negative (LR-) likelihood ratios, by fitting random effects models. With a series of sensitivity analyses we assessed the possible effects of: i) target population (original validation study inclusion criteria *vs* different inclusion criteria); iii) setting (hospital *vs* community); and iii) disease duration (< 2 years *vs* ≥ 2 years).

Results: Of the 1,647 retrieved articles, 8 fulfilled the inclusion criteria (N=5,042 patients). The entire set of the ASAS SpA criteria yielded a high pooled sensitivity (73%) and specificity (88%), but with limited available data (Table). Similarly good results were found for the axSpA criteria (sensitivity: 82%; specificity: 88%) in a larger number of studies. Splitting the axSpA criteria in 'imaging arm only' and 'clinical arm only' resulted in much lower sensitivity (30% and 23% respectively) but retaining very high specificity (97% and 94% respectively). The 'imaging arm only' compared to the 'clinical arm only' had a much higher LR+ (9.6 *vs* 4.5, respectively). The pSpA criteria were less tested than the axSpA and have shown a similarly high pooled specificity (87%) but lower sensitivity (63%). Sensitivity analyses yielded consistently good results for the axSpA criteria (sensitivity (range): 78%-86%; specificity (range): 86%-93%). For pSpA there were few studies therefore hampering sensitivity analyses.

Conclusion: Accumulated evidence from more than 5,000 patients confirms the good performance of the various ASAS SpA criteria as tested against the Rheumatologist's diagnosis. The clinical and imaging arm have high specificity but lack sensitivity if applied separately, indicating that the full set of axSpA criteria is the preferred set.

Table. Results of the meta-analysis

	Number of studies	Number of patients	LR + (95% CI)	LR – (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)
ASAS SpA criteria	2	1,750	6.3 (3.2; 12.4)	0.31 (0.13; 0.70)	0.73 (0.47; 0.89)	0.88 (0.81; 0.93)
ASAS pSpA criteria	3	749	4.7 (3.5; 6.3)	0.43 (0.30; 0.62)	0.62 (0.47; 0.76)	0.87 (0.81; 0.91)
ASAS axSpA criteria	6	4,293	6.9 (3.8; 12.4)	0.19 (0.15; 0.27)	0.82 (0.76; 0.87)	0.88 (0.79; 0.94)
axSpA criteria (imaging arm +/-clinical arm)	5	3,426	13.6 (4.8; 38.7)	0.45 (0.37; 0.56)	0.57 (0.47; 0.66)	0.96 (0.88; 0.99)
axSpA criteria (clinical arm +/- imaging arm)	5	3,426	6.0 (2.9; 12.4)	0.56 (0.43; 0.72)	0.49 (0.34; 0.64)	0.92 (0.82; 0.96)
axSpA criteria (imaging arm only)	5	3,426	9.6 (4.4; 20.7)	0.72 (0.59; 0.88)	0.26 (0.16; 0.40)	0.97 (0.94; 0.99)
axSpA criteria (clinical arm only)	5	3,426	4.5 (2.3; 8.8)	0.81 (0.72; 0.91)	0.23 (0.17; 0.29)	0.94 (0.89; 0.96)

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Herpes zoster virus (HZV) reactivation disproportionately affects patients with systemic rheumatic diseases and it is commonly described in short- and long-term use of anti-Tumor Necrosis Factor (TNF) drugs. However, it is unclear whether anti-TNF therapy elevates herpes zoster risk in patients with spondyloarthritis (SpA). The aim of this study was to evaluate the incidence of HZV infections in the TNF-inhibitors-treated SpA patients in the Gruppo Italiano Studio Early Arthritis (GISEA) Registry, and assess the predictors of their occurrence.

Methods: The Registry, which is designed to collect real-world clinical data concerning RA and SpA patients receiving biological drugs as part of routine care, was approved by local Ethics Committees, and enrols patients aged ≥18 years who have given their written informed consent. The baseline information includes demographics, disease duration, HAQ, DAS28, BASDAI, BASFI and BASMI scores, steroid use (defined as actively receiving oral steroids at the time of recruitment), smoking history and comorbidities.

Results: The analysis involved 3321 SpA patients (1731 males, 52.2%; mean age 47±13 years; median disease duration three years, interquartile range [IQR] 0, 8 years): 1065 (32%) treated with infliximab (IFN), 1052 (32%) with adalimumab (ADA), and 1204 (36%) with etanercept (ETN). Two thousand, one hundred and five (63.4%) had a median of one comorbity (IQR 0, 2], the most frequent being hypertension (701), thyroid diseases (281), diabetes mellitus (207), cardiopathy (189), and osteoporosis (145). In combination with the biological drug, 919 patients (27.7%) received steroids and 2451 (79.9%) at least one DMARD. The median follow-up was three months (IQR 1, 2 years) 12 years. Herpes zoster involed 21 patients (0.6%). Crude incidence rates among anti-TNF users were 2.4 per 1000 patient years (95% CI, 1.5-3.6). Univariate analysis showed that female gender (p=0.512) and comorbidities (p=0.861) were not associated with a high risk of HVZ reactivation, and that the use of IFN rather than the use of ETN and ADA (p=.133 and p=00.129) was not associated with a higher risk of HVZ reactivaction. Furthermore, univariate models showed that the HAQ (HR 3.71 p=0.012) and BASFI (HR=1.39 p=0.004) were statistically significant predictors of HVZ infections.

Conclusion: These data add to currently available evidence suggesting that anti-TNF therapy is not associated with a increased risk of HZV infections in SpA patients.

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Little is known on the development of spondyloarthritis (SpA)-features over time in patients with recent onset chronic back pain (CBP). The aim was to explore whether patients with suspicion of axial spondyloarthritis (axSpA) develop SpA-features over time in the SPACE-cohort, and to study the effect of gaining features on the clinical diagnosis and classification according to the Assessment of SpondyloArthritis international Society (ASAS)-criteria for axSpA.

Methods: SPACE is an inception cohort study in which CBP patients (≥ 3 months, ≤ 2 years, onset < 45 years) from various rheumatology centres across Europe are included. Baseline (BL) and one-year (FU) data were used for this study. Patients underwent a full diagnostic work-up consisting of MRI and radiographs of the sacroiliac joints (MRI-SI and X-SI), acute phase reactants, HLA-B27, and assessment of all other SpA-features. For the purpose of this study positive SpA-features were accumulated according to the principle of "once a feature always a feature" meaning patients were not able to 'lose' features over time. Total number of SpA-features was calculated excluding sacroiliac imaging and HLA-B27 status. Clinical diagnosis (axSpA yes/no) of patients was provided by the treating rheumatologist with use of local reading and the ASAS-criteria for axSpA (based on central scoring and agreement of 2/3 readers) were used for classification.

Results: A total of 270 patients with CBP with both baseline and one-year follow-up visits were included: 36.7% were male, mean age (SD) at inclusion was 31.2 (8.0) years, mean number of SpA-features (SD) at BL and one-year FU were 2.8 (1.5) and 3.5 (1.6), respectively. After one year 49.3% of patients had gained one or more features. Most common features were IBP (BL: 77.0%, FU: 88.2%), good response to NSAIDs (BL: 48.5%, FU: 70.6%), elevated CRP/ESR (BL: 29.5%, FU: 43.3%), and positive family history for SpA (BL: 48.9%, FU: 52.6%). For 16 out of the 270 patients information on diagnosis at either BL or FU was missing. In the remaining 254 patients, rheumatologists diagnosed 150 (59.1%) and 66 (26.0%) patients with axSpA and no axSpA at both time points, respectively (Figure 1). In 15.0% (38/254) of patients the diagnosis changed; 16 patients with no axSpA diagnosis at BL were diagnosed with axSpA at FU of which 11/16 (68.8%) had acquired one or more features. In 22 patients with axSpA at BL rheumatologists reconsidered their diagnosis at FU. In the 150 patients diagnosed with axSpA, 108/150 (72%) of patients already fulfilled the ASAS-criteria at BL and 79/150 (52.7%) patients gained a minimum of one feature, which led to a new axSpA classification for 9 patients at FU.

Conclusion: In patients with CBP of short duration almost half developed at least one new SpA-feature within one year, however the impact on diagnosis and classification was limited.

Figure 1. Number of acquired SpA-features (after medical history taking, physical examination and measurement of acute phase reactants; excluding sacroiliac imaging and HLA-B27 status) at one-year follow-up (FU) in patients with and without axSpA diagnosis.

	Number of features gained after one year					
Diagnosis	0	1	2	3	>3	**Total**
AxSpA baseline and FU	71	50	18	9	2	150
AxSpA only at FU	5	9	2	-	-	16
AxSpA only at baseline	11	8	2	1	-	22
No AxSpA baseline and FU	40	23	2	1	-	66
Total	127	90	24	11	2	254

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adherence to systemic therapies, such as tumor necrosis factor inhibitors (TNFi's), is affected by various factors and may be critical for optimal disease outcomes in patients (pts) with inflammatory diseases such as ankylosing spondylitis (AS). An adherence prediction model may help rheumatologists identify pts with AS at high risk of non-adherence to systemic therapies.

Methods: The global cross-sectional non-interventional ALIGN study enrolled >7000 adult pts with 6 immune-mediated inflammatory diseases, including AS as diagnosed by treating physician, currently being treated with conventional systemic therapies and/or TNFi's. Validated questionnaires, including the 4-item Morisky Medication Adherence Scale (MMAS-4©) and the Beliefs about Medicines Questionnaire (BMQ), were administered to pts at a routine visit. The objective of this analysis was to identify an accurate adherence prediction model by 1) identification of factors significantly associated with high medication adherence (MMAS-4 = 4) in multiple regression analysis based on backward selection and dichotomization of quantitative variables for simplicity reasons, 2) selection of the model, consisting of up to 10 variables, with the highest cross-validated area under the receiver operating characteristic curve (AUROC), and 3) visual

representation of certain pt profiles in the adherence probability matrix based on the best model.

Results: A total of 812 pts with AS were analyzed (mean age, 42.5 y; disease duration, 9.3 y; prior TNFi therapy, 51%; male, 71%). Based on MMAS-4 items, more pts with csDMARD or NSAID vs TNFi monotherapy admitted forgetting to take their medication (32 49% vs 18%) or stopping medication when feeling better (20 48% vs 17%). The best model had an AUROC of 0.7492 and included the following variables: age, ethnicity, sex, type of treatment, medication necessity beliefs (BMQ-Specific *Necessity* score), illness perception (Brief Illness Perception Questionnaire scores), and number of prior treatments. According to the model, the highest predicted probability of full adherence was seen in pts with AS ≥44 years of age, with high treatment necessity beliefs and TNFi treatment (especially in combination; **Table)**. The predicted probability of full adherence was higher in Caucasian pts compared with non-Caucasian pts with the same characteristics.

Conclusion: Results from the first medication adherence prediction model for pts with AS suggest that the majority of pts with NSAID or csDMARD treatment are not completely adherent to their therapy. The developed prediction model visualizes the impact of factors on medication adherence in pts with AS, which could help clinicians identify pts at high risk of non-adherence to systemic treatment. Further studies need to confirm the developed model.

Table. Predicted Probability of High Adherence* to Maintenance Treatments According to the Final Model for Average† Caucasian vs Non-Caucasian Patients With Ankylosing Spondylitis

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In an open-label extension (OLE) of a 16-week, randomized, double blind (DB), placebo (PBO)-controlled, phase 3 study (GO-AHEAD; NCT1453725) in patients with nonradiographic axial spondyloarthritis (nr-axSpA)[1], we assessed quality of life (QoL) in patients with objective signs of inflammation at baseline.

Methods: Patients received GLM 50mg Q4W during the 44-week OLE (36-week efficacy period; 8-week safety follow-up). QoL evaluations were specified in patients with objective inflammation (MRI sacroiliitis+ and/or C-reactive protein >upper limit of normal) and included Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL), 36-item Short Form Health Survey (SF 36), and EuroQol Group 5 Dimensions Health Questionnaire (EQ-5D) Index and Health State (0–10cm VAS), and Work Productivity and Activity Impairment (WPAI) at weeks 16 and 52 and the Patient's Global Disease Assessment (PGDA; 0–10cm VAS) at weeks 16, 20, 24, 32, 40, and 52.

Results: There were 153 patients with objective inflammation at baseline (of the DB period: GLM=76; PBO=77) who were then treated in the OLE. At week 52, patients continuing GLM and those switched from PBO to GLM in the OLE demonstrated improvement in QoL parameters (Figure) Mean (SD) change from baseline in Overall Work Impairment scores were -21.2 (24.7) (GLM) and -8.4 (28.5) (PBO) at week 16; at week 52, mean (SD) changes were -31.1 (GLM/GLM) and -26.5 (27.2) (PBO/GLM).

Conclusion: Among patients with objective inflammation before treatment in the DB phase, those who continued GLM in the OLE had continued benefits in QoL and work productivity, and those who switched to GLM in the OLE from PBO in the DB phase had notable improvement in QoL and work productivity. **Reference:** 1. The Diagnostic Value of the Symptom of Inflammatory Back Pain in the Rheumatology Setting

Denis Poddubnyy[1], Inge Spiller[1], Joachim Listing[2], Jürgen Braun[3], Joachim Sieper[1] and Martin Rudwaleit[4], [1]Charité Medical University, Berlin, Germany, [2]German Rheumatism Research Center, Berlin, Germany, [3]Rheumazentrum Ruhrgebiet, Herne, Germany, [4]Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory back pain (IBP) as a symptom has been shown to perform effectively for selecting patients in primary care / orthopaedic settings for referral of chronic back pain patients to the rheumatologist for further diagnostic work-up. IBP is also being used as a diagnostic test of axial spondyloarthritis (axSpA) by rheumatologists, but

no validations studies have been performed so far with IBP as a diagnostic tool. The aim of the DIVERS study was to evaluate the diagnostic value of the IBP symptom in axSpA in the rheumatology setting.

Methods: A total of 405 consecutive patients referred to a rheumatologist because of chronic back pain starting at an age <45 years and suspicion of axSpA were included in this multicentre study. A questionnaire containing all relevant IBP parameters was first answered by the patient, followed by a rheumatologist blinded for presence or absence of other SpA features and for the diagnosis, and finally by the rheumatologist responsible for the diagnosis. A global evaluation of IBP by rheumatologists, and IBP according to the previously published Calin's, Berlin and ASAS criteria as well as single items of IBP were compared regarding their diagnostic performance.

Results: The diagnosis of definite axSpA was made in 180 (44.4%) patients (88 with ankylosing spondylitis and 92 with non-radiographic axSpA). The sensitivity, specificity and the positive likelihood ratio of IPB for the axSpA diagnosis was 81%, 44%, and 1.5, respectively, if globally assessed by the blinded rheumatologist, and 90%, 58% and 2.2, respectively, if globally assessed by the diagnosing rheumatologist - table. There was no clear superiority of any of the three criteria sets regarding sensitivity for the axSpA diagnosis with an overall sensitivity of about 80% and specificity between 25% and 45% if symptoms were assessed by a rheumatologist - table. The performance of the criteria sets based on patient's own evaluation of IBP symptoms was generally lower. No single IBP parameter showed superiority regarding sensitivity or specificity in comparison to the criteria sets.

Conclusion: IBP demonstrated high sensitivity but rather modest specificity for the diagnosis of axSpA among patients with chronic back pain referred to a rheumatologist. A resulting moderate diagnostic value of IBP in the rheumatology setting is likely to be counterbalanced by increase in the pre-test probability of axSpA in this patients population.

Table. Sensitivity, specificity, a positive and a negative predictive value (PPV and NPV) of inflammatory back pain (IBP) for the diagnosis of axSpA.

Assessor	IBP according to...	Sensitivity, % (95% CI)	Specificity, % (95% CI)	PPV (95% CI)	NPV (95% CI)	LR+	LR-

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Efficacy of golimumab (GLM) for nr-axSpA was demonstrated in a randomized, double-blind (DB), placebo (PBO)-controlled, phase 3 study (GO-AHEAD; NCT01453725).[1] In a subgroup analysis, we now investigate the effects of GLM based on presence or absence of objective inflammation (sacroiliitis on MRI and/or C-reactive protein [CRP] > upper limit of normal [ULN]) at baseline.

Methods: Patients with nr-axSpA (ASAS criteria, centrally read SI joint X-rays/MRIs, disease duration ≤5 years, chronic back pain ≥3 years, high disease activity, and inadequate response or intolerance to NSAIDs) were randomized (with ASAS-defined MRI sacroiliitis by single central reader [yes, SI+; no, SI–] and CRP level [≤ULN or >ULN] as stratification factors) to GLM 50 mg SC or PBO Q4W for 16 weeks. The primary endpoint was ASAS20 response at week 16. Estimated between-group differences in response at week 16 on ASAS20, ASAS40, BASDAI50, and ASAS partial remission (PR) were compared for four patient subgroups (MRI SI+ & CRP >ULN; MRI SI– & CRP >ULN; MRI SI+ & CRP ≤ULN; MRI SI– & CRP ≤ULN) by Miettinen-Nurminen methods; no multiplicity control was used.

Results: In total, 197 patients were treated (GLM=97; PBO=100). Treatment-group differences in ASAS20, ASAS40, BASDAI50, and ASAS PR response were greater in patients with baseline objective inflammation (Figure). Results should be interpreted with caution, given the small subgroups and absence of multiplicity control.

Conclusion: In the GO-AHEAD trial, responses to GLM (vs PBO) were greater in patients with objective inflammation (particularly with CRP >ULN) at baseline.

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Remission has become a target to achieve in rheumatic diseases and it also could be linked to treatment retention. The aim of this analysis was to identify independent predictors of retention in patients with RA or AS treated with infliximab (IFX).

Methods: BioTRAC is an ongoing, prospective registry of patients (pts) treated with IFX or golimumab. This analysis included RA and AS pts treated with IFX, and that had at least 2 years of follow-up. Independent predictors of retention were assessed with multivariate cox regression. Receiver operator curve (ROC) analysis was used to determine the optimal cut-off points of CDAI and ASDAS for long-term retention.

Results: A total of 490 RA and 201 AS pts were included in the analysis. Table 1 summarizes the disease parameters and characteristics at IFX initiation. With respect to disease activity, mean CDAI score was 35.9 in RA pts and ASDAS was 3.8 in the AS group. Table 2 presents the probability of retention over time by indication. In univariate analysis, among RA pts at baseline (BL): CDAI [HR (95% CI): 0.99 (0.99-1.00)], DMARD use [HR (95% CI): 0.70 (0.51-0.97)], steroid use [HR (95% CI): 1.23 (0.99-1.52)], at 24 months: CDAI [HR (95% CI): 1.02 (1.00-1.03)], and DMARD use [HR (95% CI): 0.82 (0.66-1.01)] were identified as potential predictors (P<0.150) of retention. No significant impact was observed for age, gender, disease duration, prior biologic experience, enrolment period, and steroid use at 24 months. In multivariate analysis, CDAI score at 24 months was the only significant (P=0.013) independent predictor of treatment retention [HR (95% CI): 1.02 (1.00-1.03)]. ROC analysis showed that the optimal 24-month CDAI cut-off score for downstream (non-)discontinuation was 11.7. In AS pts, ASDAS levels at 24 months were the only significant predictor of subsequent treatment discontinuation, with higher ASDAS score being associated with an increased hazard for discontinuation [HR (95% CI): 1.63 (1.12-2.38)]. Maintaining an ASDAS score of 2.7 or less at 24 months was associated with optimal retention on treatment long-term. **Table 1. Baseline Disease Parameters and Patient Characteristics**

	RA (N=490)	**AS (N=201)**
Age, years, mean (SD)	56.4 (13.0)	46.8 (11.8)
Disease duration, years, mean (sd)	9.4 (9.5)	9.8 (10.0)
Female gender, %	73.9%	35.1%
Enrolment period, n (%)		
2002-2004	43.1%	0.0%
2005-2007	25.5%	40.8%
2008-2014	31.4%	59.2%
Biologic naïve, n (%)	90.0%	91.5%
DAS28	5.8 (1.5)	
CDAI	35.9 (16.8)	
28-SJC	12.5 (8.1)	
28-TJC	10.8 (7.3)	
HAQ-DI	1.63 (0.72)	1.22 (0.64)
ASDAS		3.8 (1.0)
BASDAI		6.4 (2.1)

Table 2. Kaplan-Meier Survival Point Estimates* of Retention

	Retention Probability (%)	
Time point (months) post 2 years of stable treatment	**RA (N=490)**	**AS (N=201)**
6	92%	94%
12	85%	89%
18	76%	85%
24	71%	79%
30	66%	73%
36	62%	70%
42	59%	65%

** Values represent n at risk, retention probability (standard error)*

Conclusion: Results have shown that, among pts remaining on IFX after 2 years, disease activity at 2 years is the single determinant of subsequent long-term retention on IFX treatment both in RA and AS pts, highlighting the importance of the

treat-to-target strategy to achieve remission but also maintaining it over time in order to ensure optimal treatment benefits.

Functional Relevance of Structural Damage in the Sacroiliac Joints in Patients with Axial Spondyloarthritis – Results from the German Spondyloarthritis Inception Cohort

Mikhail Protopopov[1], Hildrun Haibel[1], Jürgen Braun[2], Martin Rudwaleit[3], Joachim Sieper[1] and **Denis Poddubnyy**[1], [1]Charité Medical University, Berlin, Germany, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze the association between the presence of structural damage in the sacroiliac joints and physical function / spinal mobility in patients with axial spondyloarthritis (SpA), which has not been investigated so far.

Methods: A total of 210 patients with early axial SpA (105 patients with radiographic axial SpA and symptom duration up to 10 years and 95 patients with non-radiographic axial SpA and symptom duration up to 5 years) from the German Spondyloarthritis Inception Cohort (GESPIC) were included in this cross-sectional analysis. Pelvic radiographs were scored by two trained readers (DP, HH) in a concealed and randomly selected order according to the grading system of the modified New York criteria (grade 0 to 4). For the current analysis, a mean of two readers score was calculated for each sacroiliac joint. A sum of two sacroiliitis grades (left and right sacroiliac joints) was calculated for each patient giving a total sacroiliitis score between 0 and 8. Structural damage in the spine was assessed by the same readers according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Disease activity was assessed by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and C-reactive protein (CRP), functional status by the Bath Ankylosing Spondylitis Functional Index (BASFI), and spinal mobility - by the Bath Ankylosing Spondylitis Metrology Index (BASMI).

Results: In the univariable linear regression models, the crude parameter estimates for the association between sacroiliitis score and BASFI / BASMI were 0.09 (95%CI -0.07 to 0.25) and 0.23 (95%CI 0.11 to 0.33), respectively. After adjustment for parameters, which could be associated with radiographic sacroiliitis and might have an impact on the outcome (function / spinal mobility) – structural damage in the spine (mSASSS), disease activity (BASDAI and CRP), and gender – the parameter estimates indicating an association between sacroiliitis score and BASFI / BASMI changed to 0.10

(95%CI -0.01 to 0.21) and 0.12 (95%CI 0.01 to 0.23), respectively. These data indicates that change by one radiographic sacroiliitis grade in one joint is associated with a BASFI / BASMI worsening by 0.10 / 0.12 points irrespectively of structural damage in the spine and disease activity.

Conclusion: Presence of structural damage in the sacroiliac joints has an impact on functional status spinal mobility independently of structural damage in the spine and disease activity in patients with axial SpA, an association which had been mostly neglected previously.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In view of the continuous pressure of biologicals on healthcare budgets, it is essential to assess the value of biologicals for patients from different perspectives. A Willingness To Pay (WTP) represents the patients' preference for health as a consequence of treatment in monetary terms. The aim of this study was to investigate WTP for treatment with infliximab by patients with ankylosing spondylitis (AS) and explore factors associated with WTP.

Methods: Data were used from patients participating in the European AS Infliximab Cohort (EASIC) open-label extension of the AS Study for the Evaluation of Recombinant Infliximab Therapy (ASSERT). Demographics, clinical data (including BASDAI, BASFI, BASMI, BAS-G and Assessment of SpondyloArthritis International Society 20 (ASAS20) response) and data on WTP were collected at baseline of EASIC. WTP comprised a hypothetical scenario exploring whether the patient would be willing to pay for beneficial effects of infliximab and, if so, what amount they would be willing to pay per administration. To investigate factors associated with WTP, a series of models were explored using a zero inflated negative binomial regression (ZINB) technique.

Results: Eighty-five patients completed the WTP. Average age was 43.4 years, 67 patients (78.8%) were male and 62 patients (72.9%) had achieved an ASAS20 response. Sixty-three patients (74.1%) were willing to pay, and among these patients the mean (median) [Interquartile Range] amount willing to pay was €275 (100) [50-200] per administration. Multivariable ZINB analysis showed that ASAS20 response was associated with a 7-fold increase in the likelihood to be

willing to pay (OR=6.91, 95%-confidence interval [95%CI] 1.40-34.07) and a 3-fold increase in the amount willing to pay (exp(B)=3.32, 95%CI 1.44-7.69). In addition, country of residence was associated with willingness to pay (residence in the Netherlands vs. other participating countries: OR=0.07, 95% CI 0.02-0.36), while increased age was associated with the amount willing to pay (exp(B)=1.05, 95%CI 1.01-1.09).

Conclusion: In a hypothetical scenario, three quarter of patients with AS stated to be willing to pay an out-of-pocket contribution for treatment with infliximab. Treatment response contributed to the willingness as well as to the amount patients were willing to pay. Despite its limitations, the WTP method seems a valuable addition to the common approaches used for investigating treatment benefits in AS.

Table 1. Final multivariable ZINB regression model exploring determinants of willingness to pay for infliximab treatment in AS

Possibly willing to pay[§]	OR[‡]	95% CI OR	p
Gender (male)	0.41	0.06-2.68	0.35
Age	0.94	0.86-1.03	0.17
ASAS20 response	6.91	1.40-34.07	0.02
Country of residence (Netherlands)[¥]	0.07	0.02-0.36	<0.01
Amount willing to pay*	**Exp(B)[†]**	**95% CI Exp(B)**	**p**

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Only few studies have investigated long-term radiographic progression in the spine of patients with ankylosing spondylitis (AS). Moreover, no studies have reported changes in MRI lesions of inflammation and structural damage in the sacroiliac joints (SIJs) and spine assessed with annually repeated scans over 5 years. The aim was to investigate radiographic progression and evolution of MRI inflammation and structural lesions during treatment with TNFα inhibitors over 5 years assessed with serial examinations.

Methods: The study included 33 patients with AS followed for 5 years. All patients had participated in the BIOSPA study(1), which included 60 patients initiating treatment with TNFα inhibitor (infliximab, etanercept or adalimumab). Spinal radiographs were obtained 4 times (at week 0, 46, year 3 and 5) and MRIs of the SIJs and the lower spine (Th9-S1) were acquired 7 times (at week 0, 22 and 46 and annually to year 5), respectively. The images were evaluated in known time order without other information available. The SPARCC Sacroiliac and Spine Inflammation Index and Structural Scores (SSS) (2) and the Canada-Denmark (CanDen) scores of inflammation, fat(3), erosions and new bone formation (4,5) were used for the MRI evaluations. The modified Stoke AS Spine Score (mSASSS)(6) were used for the evaluation of the radiographs.

Results: During 5 years of TNFα inhibitor treatment, mSASSS increased significantly at all study visits ($p<0.01$) (Figure 1), and the structural MRI spine score SASSS increased significantly from year 2 ($p<0.05$). The mSASSS progression rate was significantly lower from week 46 to year 3 (0.45 units/year) than from week 0 to 46 (1.71 unit/year), whereas there was no difference in the progression rate from week 0 to 46 versus year 3 to 5 (0.66 units/year, $p=0.055$). MRI inflammation decreased significantly in SIJ ($p<0.05$) and spine from week 22 ($p<0.01$, except for year 5), together with a significant decrease of SIJ erosion from week 46 ($p<0.05$) and throughout the study. Conversely, the SIJ and spinal MRI fat ($p<0.05$) and SIJ ankylosis scores increased significantly from week 22 ($p<0.05$). Only minor changes were observed for SIJ backfill and spine erosion score.

Conclusion: Radiographic progression decreased significantly after the first year of treatment with TNFα inhibitor. Spine and SIJ MRI inflammation and structural scores changed significantly short after initiation of treatment, and thereafter the scores remained statistically unchanged except. References: 1. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease with significant burden to patients and society. NSAIDs are the first line pharmacologic therapy in AS with proven efficacy. This efficacy is class-wide and we hypothesize a higher effect with more use of medication. An important aspect of treatment efficacy is its effect on functionality. -This study aims to identify the effect of NSAID use in AS as defined by the percent of the full inflammatory dose taken over time (the NSAID Index) on functional impairment

Methods: A prospective cohort of 823 AS patients who met the modified New York criteria were followed for at least 2 outpatient visits from multiple sites. Patients underwent a comprehensive clinical evaluation including assessment of functional impairment by the Bath AS Functional Index (BASFI) in addition to demographic, social, and psychological variables collected. Medications taken concurrently, inflammatory markers and radiographs were taken at each visit. NSAID use was captured by self-report of numbers of pills taken in the last week, month, and 6 month interval. Longitudinal multivariable analyses using mixed effect negative binomial regression models that account for the correlation of repeated measures over time were conducted to assess associations between NSAID use (NSAID index of 0%, >0 & ≤50%, and >50%) and BASFI while controlling for other variables.

Results: . Of the 5456 visits included in this analysis, 40%, 28% and 25% had an NSAID index of 0%, >0 & ≤50%, and >50% respectively. No significant differences were found analyzing the data over a one month and six month interval. Table 1 shows the longitudinal associations between NSAID use and other covariables over a 6 month period on BASFI scores. We found that NSAID use was significantly associated with higher BASFI (overall p=0.002); patients who had high NSAID index (>50%) and low NSAID index (>0 and ≤50%) were more likely to have higher BASFI compared to patients with no NSAID use (ARR=1.13; p=0.0019 and ARR=1.08; p=0.0172, respectively). There was no association of NSAID use with BASFI when we compared patients with high NSAID index to those with low NSAID index (ARR= 1.05;

p=0.1948).. C-reactive protein (CRP), Disease duration, baseline radiographic disease, depression (defined by Center for Epidemiologic Studies Depression Scale (CESD) score>16), comorbidty and opioid use were positively associated with BASFI.

Conclusion: We found an association between any NSAID use and higher functional impairment, while high vs. low NSAID use was not associated. This may be due to AS patients with higher functional impairment taking more NSAIDs. Our findings also hint at a modest treatment effect of NSAIDs in AS as high vs. low use was not associated with change in functional impairment. Table 1. NSAID Use and Covariables Associated with Longitudinal Functional Impairment in Multivariable Regression Modeling

Variable	Adjusted Rate Ratio (95% CI)	p-value

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although current evidence suggests that anti-TNF treatment may not inhibit spinal radiographic progression, its effect on hip involvement in AS is not known. The aim of this study is to assess the impact of long-term anti-TNF treatment on radiographic progression of hip arthritis in AS, by adding a quantitative scoring method, previously applied in hip osteoarthritis, to BASRI-hip score.

Methods: 205 consecutive AS patients (136 men, age: 49±11years, disease duration: 23±11 years) under anti-TNF treatment were included in this retrospective study. Anteroposterior X-rays of pelvis and lateral spine X-rays were scored blindly, by 2 independent readers at 3 time points: at baseline (i.e. prior anti-TNF treatment initiation), 2.6±0.7 and 7.2±2.4 years after anti-TNF initiation. Both hips were scored using: a) BASRI-hip score, b) mean joint space width (MJSW), estimated by measurement of 3 distinct points of interbone distance: 2 mm inner of the external end of the acetabulum, vertical line through femoral head center, head-neck center line(Figure). Spinal X-rays were scored by the mSASSS. Hip involvement was assessed clinically (pain, reduced range of motion and intermalleolar distance) and radiographically, as BASRI-h score ³ 2 at baseline anteroposterior pelvis X-rays. The significance of changes was tested by mixed models for longitudinal data.

Results: Definite hip involvement at baseline, was detected in 67/205(33%) patients, who had significantly higher BASRI-hip score[2(2-2.5)median(IQR) vs. 0.5(0-1) p<0.0001] and lower MJSW (3.6±0.7 vs. 4.5±0.7, p<0.0001), compared to those without. In AS patients with hip arthritis at baseline, both BASRI-h score and MJSW remained unchanged during follow up, regardless of gender. In patients without hip arthritis, the BASRI-hip score remained unchanged after 2.6±0.7 years, but increased significantly after 7.2±2.4 years compared to baseline. In particular, the BASRI-hip score showed significant increase in AS males without hip arthritis at the two intervals, compared to correspondence females, who had significant increase only at follow-up end. In contrast, the MJSW in patients without hip arthritis remained unchanged at the three time points, both in males and females. The mSASSS raised significantly during the follow-up period, regardless of gender and hip involvement (table).

Conclusion: One third of the AS patients suffer from radiographic hip involvement, that appears to stabilize during long-term anti-TNF treatment. The new scoring system may contribute to detect minor changes in contrast to BASRI-hip scoreÕ rough estimation.

Variables		Baseline	After 2.6±0.7 years	After 7.2±2.4 years	P

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

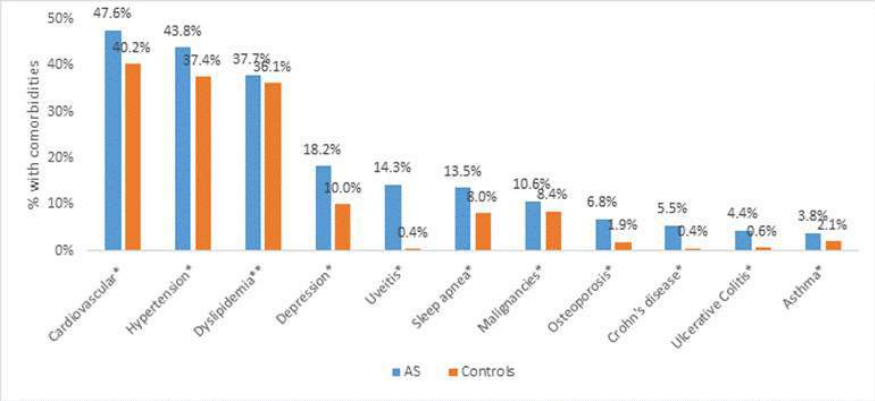
-

Background/Purpose: Comorbidities associated with ankylosing spondylitis (AS) have been inadequately studied in American populations. This study used a large US national claims database to compare prevalence and incidence of comorbidities of AS patients and general population.

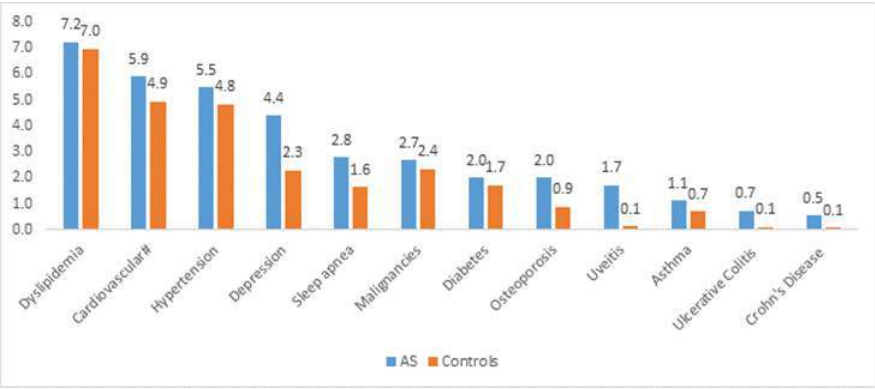
Methods: Adults with ≥1 inpatient or 2 outpatient diagnoses of AS (ICD-9-CM 720.0) in 1/1/2008 - 6/30/2014 were extracted from MarketScan Commercial and Medicare Databases. Of those identified, patients with ≥1 AS diagnosis in 2013 were included in the study, with the first AS diagnosis in 2013 set as the index date. Patients had ≥12 months pre-period and were followed for ≥12 months until patient death or the end of the study (6/30/2015). The prevalence of comorbidities was evaluated in a prevalent AS cohort. The incidence of new comorbidities (not present in a 24-month pre-

period) was evaluated in an incident AS cohort with newly diagnosed AS (no AS in the 12-month pre-period). General population included patients with no AS diagnosis in 2007-2015 and were matched to the AS patients on calendar year, age, gender, and geographic region.

Results: The prevalent AS cohort had 6,679 AS patients and 19,951 matched general population (mean age: 50.8 years for AS vs. 51.7 for general population; male: 60.5% vs. 60.8%; mean length of follow up period: 2.0 vs. 2.0 years). Compared with general population, a significantly higher proportion of AS patients had cardiovascular disease, hypertension, dyslipidemia, depression, sleep apnea, uveitis, malignancies, Crohn's disease, ulcerative colitis, osteoporosis, and asthma (Figure 1). The proportion of patients with diabetes was similar between AS patients and general population (11.8% vs. 13.6%, p=0.343). The incident AS cohort included 6,370 newly diagnosed AS patients and 14,998 matched general population. Incidence rates of newly diagnosed comorbidities were higher in incident AS patients than in general population (Figure 2). Figure 1. Proportion of Patients with Comorbidities: Prevalent AS vs. General Population



*p<0.001; ** p=0.017. Figure 2. Incidence Rates per 100 Person-Years of Top New Comorbidities for Incident AS vs. General Population



Conclusion: AS patients had significantly more comorbidity burden than general population in the US. Understanding these comorbidity profiles will help evaluate the impact of comorbid conditions on patients' health outcomes and healthcare utilizations. Future research is needed to determine optimal screening and management strategies for comorbidities in AS patients.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The human leukocyte antigen (HLA)-B27 allele is one of the strongest known genetic factors associated with the development of ankylosing spondylitis, however, previous studies have shown that approximately 10-25% of AS patients are HLA-B27 negative (HLA-). The aim of this analysis was to compare the profile of HLA - and HLA+ AS patients initiating anti-TNF treatment in Canadian routine clinical care.

Methods:

BioTRAC is an ongoing, prospective registry of patients initiating treatment with infliximab (IFX) or golimumab (GLM) for RA, AS, or PsA, or with ustekinumab for psoriasis. Patients eligible for this analysis included AS patients treated with IFX or GLM, enrolled since 2005 and 2010, respectively with available information on HLA B27 status. Descriptive statistics were used to assess patient and disease characteristics at Baseline and Month 12. Multivariate general linear models were used to assess the impact of HLA status on BASFI, BASDAI and ASDAS at Month 12 while adjusting for age, gender, disease duration, anti-TNF type, and baseline scores.

Results:

A total of 147 HLA+ and 78 HLA- AS patients were included, of which 93 had available data at Month 12 (62 HLA+, 31 HLA-). Table 1 summarizes the baseline patient characteristics and disease parameters by HLA status. HLA+ patients were significantly younger compared to HLA- patients both at diagnosis (32.2 vs. 46.8 years; P=0.001) and at anti-TNF initiation (42.1 vs. 48.2 years; P=0.002). Furthermore, HLA+ patients had significantly higher disease duration (7.7 vs. 3.9 years; P=0.002) and were more likely to be male (69.0% vs. 42.1%; P<0.001). Geographic distribution was comparable between HLA+ and HLA- groups (P=0.886). With respect to disease parameters, baseline BASDAI, BASFI and ASDAS were significantly higher in the HLA- group ($P < 0.05$), as was the proportion of HLA- patients reporting very high ASDAS disease activity (62.5% vs. 38.2%). Mean baseline CRP levels, although higher in HLA- patients compared to HLA+ patients (16.7 vs. 10.5 mg/L), were not found to be significantly different between groups (P=0.085).

Upon adjusting for potential confounders, HLA+ patients experienced greater improvements from baseline to Month 12 in BASDAI (-2.13 vs. -0.24; P=0.008), BASFI (-1.64 vs. 0.11; P=0.030), and ASDAS (-0.95 vs. -0.26; P=0.067). At Month 12, ASDAS DA categories were found to be statistically comparable across both groups (P=0.396), although a lower proportion of HLA - patients reported inactive-moderate disease (30.0% vs. 51.2%).

Table 1. Patient and Disease Characteristics at anti-TNF Initiation by HLA Status

Parameter	HLA+ (N=147)	HLA- (N=78)	P-value
Age, years, mean (SD)	42.1 (13.2)	48.2 (13.4)	0.002
Age at diagnosis, mean (SD)	32.2 (9.0)	46.8 (14.0)	0.001
Disease duration, years, mean (SD)	7.7 (10.3)	3.9 (4.4)	0.002
Gender, male, n (%)	98 (69.0)	44 (31.0)	< 0.001
Anti-TNF at baseline			
Infliximab, n (%)	27 (18.4)	15 (19.2)	0.504
Golimumab, n (%)	120 (81.6)	63 (80.2)	
CRP levels, mg/L, mean (SD)	10.5 (20.2)	16.7 (29.2)	0.084
BASDAI, mean (SD)	5.9 (2.2)	6.6 (1.7)	0.022
BASFI, mean (SD)	5.0 (2.6)	5.9 (2.2)	0.026
ASDAS, mean (SD)	3.2 (0.96)	3.7 (0.90)	0.002
ASDAS Disease Activity (DA), %			
Inactive DA	2.7	0.0	
Moderate DA	5.5	3.6	0.022
High DA	53.6	33.9	
Very high DA	38.2	62.5	

Conclusion: In this Canadian real-world cohort, HLA- AS patients were found to be demographically distinct from HLA+ patients and present with more advanced disease at baseline. Furthermore, HLA- was identified as an independent predictor of worse treatment outcomes, highlighting the importance of early diagnosis and management of HLA- AS patients.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilar infliximab (INX) was recently approved by the European Medicine Agency based on comparable pharmacokinetics, safety and efficacy profile to innovator INX for the treatment of Rheumatoid Arthritis, Ankylosing Spondylitis (AS), Crohn's disease, Ulcerative Colitis, Psoriatic Arthritis (PsA), and psoriasis. (1,2) Switching from originator to biosimilar INX offers cost savings but, up to now, limited evidence (from conference abstracts of open-label extension studies suggesting similar clinical efficacy) and no guidelines are available.(3) Aim of the study was to investigate efficacy and safety of switching from originator to biosimilar INX in patients affected by spondyloarthritis (SpA) in real life clinical practice.

Methods: Thirty-six patients (18 with diagnosis of AS, 7 with enteropathic arthritis, 8 with PsA and 3 with undifferentiated SpA), from three Italian Rheumatologic centers with a previous diagnosis of SpA, treated for more than 6 months with originator infliximab (in according with the ASAS/EULAR guidelines) and clinically with an inactive or moderate disease activity (ASDAS-CRP < 2.1), were switched to biosimilar infliximab for pharmacoeconomic reasons. A six months evaluation of BASDAI, BASFI, ASDAS-CRP, DAS28-CRP (if peripheral disease), MASES, VAS pain and collection of adverse events (AE) were performed.

Results: At switch, patients had a median age of 51.8 years (range 23-80 yrs), with a median disease duration of 137,1 months (range 14-372) and median ongoing treatment with originator INX of 76.4 months (range 14-372). After 6 months of biosimilar INX therapy we cannot find any statistical difference in terms of median values of BASDAI (2.66 ± 1.6 Vs 2.5 ± 1.4 p= 0.31), BASFI (2.3 ± 1.3 Vs 2.2 ± 1.2 p= 0.051), ASDAS-CRP (1.39 ± 0.4 Vs 1.38 ± 0.4 p= 0.8), DAS28-CRP (2.66 ± 0.69 Vs 2.67 ± 0.34 p= 0.93), MASES (0.33 ± 0.66 Vs 0.2 ± 0.4 p= 0.08), VAS pain (18.1 ± 14.7 Vs 16.7 ± 11.3 p= 0.55). During the first six months of biosimilar INX a very low number of patients experienced an AE without a significance difference with the AE collected the six months before the switch (Fisher Test p=0.13). Two patients (5.5%) stopped biosimilar INX therapy, after the first two administrations, for the appearance of de novo psoriasis.

Conclusion: No statistically significant differences in terms of BASDAI, BASFI, ASDAS-CRP, DAS28-CRP, MASES, VAS pain values and number of adverse events were found six months after the switch from originator to biosimilar INX in an SpA multicentre Italian cohort. **References.**

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The current ASAS recommendations for the management of the ankylosing spondylitis suggest, beside pharmacological therapy, a significant part of physical therapy with supervised exercises. The importance and the beneficial impact of the physiotherapy and spa-therapy is known for a long time and numerous studies confirmed this. The impact of the aerobic fitness on the disease is not clear. The objective of this work is, after a systematic review of the literature and meta-analysis, to evaluate the impact of an aerobic fitness program on disease activity, defined by the BASDAI, and the function, defined by the BASFI, in case of axial spondyloarthritis.

Methods: A systematic review of the literature, following the prisma recommandations, was performed by two reviewers on the PubMed and Embase databases with the following keywords: ("Ankylosing spondylitis"OR "Spondyloarthritis") AND ("Physical activity" OR "Aerobic fitness"). The diagnosis axial spondyloarthritis was meeting the New York criteria and/or the ASAS criteria. Aerobic fitness was defined as an exercise performed at 50–90% of the maximal heart rate or between 50% and 80% VO2 pick.

Results: 520 abstracts were identified and, 93 abstracts were analysed. 8 studies were meeting the selection criteria and 6 were finally included in this work because of the presence of a control group. Both groups were similar in terms of age, sex ratio, disease duration. Aerobic fitness provides in the intervention group (148 patients) a positive impact on the BASDAI (weighted mean difference (WMD): - 0.52 [95% CI -0.9; -0.13]) (I^2: 10.3%, P=0.35). When compared to a control group (152 Patients) aerobic exercise does not provide a more positive impact on the BASDAI (WMD : - 0.25 [95% CI -0.83; 0.32]) (I^2: 0%, P=0.41). Aerobic exercise does not provide in the intervention group a positive impact on the BASFI (WMD: - 0.31 [95% CI -0.73; 0.1]) (I^2: 0 %, P=0.79). When compared to a control group, aerobic fitness does not provide a more positive impact on the BASFI (WMD -0.41 [95% CI -1.09; 0.27]) (I^2: 0 %, P= 0.62)

Conclusion: Aerobic exercise did not provide beneficial effects neither on disease activity nor on physical function when compared to a control group.

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease that affects the spine, sacroiliac joints, hips and peripheral joints. Clinical hip involvement is a common manifestation seen in many AS patients. 5% of AS patients have severe hip disease requiring total hip arthroplasty (THA). NSAIDs and TNFi are the pharmacologic standard of care in AS. Little is known about the impact of any treatment on hip disease while some studies have shown TNFi to be associated with less spinal radiographic progression. It is not clear whether TNF inhibitors (TNFi) prevent radiographic hip progression. Our hypothesis to be tested is that TNFi delays radiographic hip progression in AS patients.

Methods: We included 613 AS patients meeting the modified New York criteria and had at least 2 sets of hip radiographs. Using the Bath Ankylosing Spondylitis Radiologic Index (BASRI) for the hips, a progressor was defined as having hip scores change by at least two units between the first and last visits. We included patients with BASRI hip scores below 4 (n=579) for the progression analysis and selected a grade-2 BASRI score change to eliminate concerns associated with reliability for reading grade-1 scores. We performed a logistic regression analysis evaluating multivariable associations between TNFi use (defined as those who used TNFi for more than 50% of their follow-up period) and hip progressors after controlling for other factors such as follow-up period, baseline hip scores, baseline TNFi use, NSAID index over follow-up period, study sites and clinical/demographic variables (disease duration, sex, education level, race, current smoking status, BASDAI, CRP and comorbidities).

Results: Of the 576 patients analyzed, 551 were deemed to be non-progressors and 25 were progressors (median follow-up years=3). TNFi use was related to a lower probability of being a hip disease progressor (adjusted OR=0.02; p=0.003 – Table 1). There was not a significant interaction between NSAID and TNFi use.

Conclusion: TNFi use was associated with less radiographic hip progression in our cohort of patients with AS. There was no significant interaction effect found between NSAID and TNFi use.

Variable	Adjusted Odds Ratio (95% CI)	P
TNFi use (Yes vs. No)	**0.02 (0.001, 0.24)**	**0.0027**
NSAID index (%) ≤50 & >0 vs. 0 (low vs. no)	0.76 (0.10, 5.63)	0.7853
>50 vs. 0 (high vs. no)	1.54 (0.23, 10.31)	0.6570
>50 vs. ≤50 & >0 (high vs. low)	2.03 (0.40, 10.30)	0.3910
Baseline Hip score (Continuous)	1.61 (1.07, 2.43)	0.0225

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In AS, spinal radiographic progression shows a very heterogeneous course. Our aim was to

investigate which patient characteristics are of influence on the course of spinal radiographic progression in AS patients treated long-term with TNF-α inhibitors.

Methods: Consecutive patients from the Groningen Leeuwarden AS (GLAS) cohort who started TNF-α inhibitors, with baseline and biannual spinal radiographs until 6 years of follow-up were included. Radiographs were scored using mSASSS by two independent readers. Generalized estimating equations (GEE) were used to explore the associations between baseline characteristics and radiographic damage over time. The course of radiographic progression was investigated with different time functions (linear and non-linear), stratified for significantly associated patient characteristics. In case of missing radiographic data at one or more intermediate follow-up visits, single linear imputation was used.

Results: 80 AS patients reached 6 years of follow-up (mean mSASSS 8.2±12.9) of which 53 patients had complete radiographic data at all 2-year time points. Baseline syndesmophytes, male gender, older age, longer disease duration, and higher BMI were significantly associated with more radiographic damage over time. Baseline syndesmophytes was the only independent risk factor. GEE analysis in patients with these characteristics revealed that mSASSS progression followed a non-linear course; mean mSASSS progression rate reduced from maximal 2.8 units over 0-2 years to minimal 0.9 units over 4-6 years (Table 1). A linear course with overall lower progression scores over the 2-year intervals (≤1 mSASSS units/2yrs) was found in patients without risk factors (Table 1). Complete case analysis in 53 patients revealed similar results.

Conclusion: AS patients who are at risk of poor radiographic outcome showed the largest but diminishing spinal radiographic progression over time during long-term treatment with TNF-α inhibitors. Only little and linear progression was observed in patients without risk factors such as no syndesmophytes, shorter symptom duration, and normal BMI.

Table 1. Radiographic damage at baseline and estimated mean spinal radiographic progression scores over time of AS patients stratified for baseline risk factors.

		n	Baseline mSASSS	Best time model	mSASSS progression scores

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

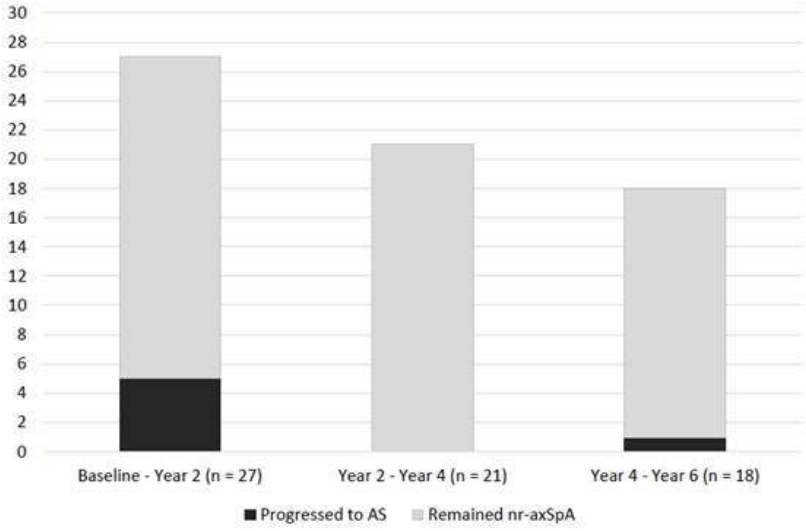
Session Time: 9:00AM-11:00AM

Background/Purpose: Data from observational studies suggests a 10-12% biannual rate of progression from non-radiographic axial SpA (nr-axSpA) to ankylosing spondylitis (AS)[1] in patients not treated with tumor necrosis factor α (TNF) blockers. It is not known, whether anti-TNF treatment might be able to prevent such a progression in patients with nr-axSpA. To assess the radiographic progression in the sacroiliac joints (SIJ) during long-term (up to 6 years) treatment with the TNF-blocker etanercept in patients with early axSpA.

Methods: In the ESTHER trial[2] a total of 76 patients with early (=<5 years symptom duration) and active axSpA were randomized to be treated with either etanercept or sulfasalazine for one year. At year 1, all patients who were not in remission continued with etanercept directly; patients in remission discontinued their therapy and were followed-up until year 2, in case of disease flare the etanercept therapy was (re)-introduced and continued until the end of year 6. X-rays of SIJ were collected at baseline and every 2 years thereafter. Two trained readers (VRR and DP), who were blinded for all clinical data, scored independently the SIJ y-rays in a concealed and randomly selected order, according to the grading system of the modified New York (mNY) criteria for AS. Patients were classified as having AS if both readers recorded the presence of definite radiographic sacroiliitis according to the mNY criteria. Active inflammatory and fatty lesions on magnetic resonance imaging (MRI) of SIJ were assessed according to the Berlin MRI scoring system (KGH and CA).

Results: A total of 55 patients from the 76 patients of ESTHER trial were included in the current analysis due to the availability of x-rays of SIJ. 19 patients (34.5%) were classified at baseline as AS and 36 (65.5%) as nr-axSpA based on the independent reading results with a fair agreement between both readers (k=0.33, p=0.01). Radiographic progression from nr-axSpA to AS was observed mainly between baseline and year 2 – in 18.5% (5/27) of the patients classified as nr-axSpA at baseline with available SIJ x-rays at year 2. There were no patients who progressed to AS between year 2 and year 4 and only one patient (5.6%, 1/18) progressed to AS between year 4 and year 6 – Figure. Treatment arm in the first year (etanercept or sulfasalazine) had no significant impact on progression from nr-axSpA to AS. Elevated C-reactive protein – CRP (>=5mg/l) at baseline was associated with a higher odds for progression: odds ratio = 7.0 (95%CI 0.7-73.9). There was no difference in the baseline osteitis score on MRI of SIJ between progressors and non-progressors (since MRI inflammation was an entry criterion), however, progressors had higher fatty lesions score at baseline as compared to non-progressors: 10.3±7.1 vs. 4.9±5.8, respectively, p=0.064.

Figure. Progression from nr-axSpA to AS in patients treated with etanercept for up to 6 years in the ESTHER trial.



Conclusion: In the ESTHER trial, there was a substantial reduction of radiographic sacroiliitis progression between year 2 and year 6 of anti-TNF treatment. Higher baseline CRP and higher MRI fatty lesions score demonstrated a positive association with progression from nr-axSpA to AS. **References**

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Infliximab is a biological agent frequently used for inflammatory arthritis (IA) such as spondyloarthritis, rheumatoid arthritis, psoriatic arthritis as well as for the inflammatory bowel diseases (IBD) such as Crohn's disease or ulcerative colitis. A major limitation to infliximab is loss of response due to the development of anti-drug antibodies (ADABs).However, It is unclear if the underlying medical condition influences antibody development. The first aim was to compare the prevalence of ADABs IA patients to IBD patients receiving treatment with infliximab. The second aim was to evaluate the correlation between ADABs and trough levels. The final objective was to determine if there were any clinical predictors of the development of ADABs.

Methods: A retrospective study was performed of all patients with IA and IBD treated with maintenance infliximab. A trough level and ADABs were obtained prior to the next infusion and drug monitoring was performed in a pro-active manner at certain. Reproducibility was confirmed in exposed and unexposed patients. Clinical data was extracted from a central database and patient medical records. Clinical predictors of ADABs development were analyzed using regression analysis. They comprised: gender, age, duration of the disease, duration of the treatment, co-medication, doses of infliximab and schedule, previous biologic exposure.

Results: A total of 166 evaluated of whom 76 were treated for IA and 90 for IBD. IBD patients were significantly younger than IA patients (mean: 37 versus 51 years) with shorter disease duration (mean: 6.9 versus 9.4 years) and a shorter duration of treatment (median: 18 versus 44 months). Overall, ADABs were detected in 35 patients (21 %) and markedly elevated (defined as >200 ug/ml) in 21 patients (12 %). There was a trend to higher prevalence of ADABs in IA patients (26%) compared to IBD patients (26% vs 15%; p= 0.08). A markedly elevated ADAB level was significantly more prevalent in IA compared to IBD (17% versus 6%; p=0.035). In both groups ADAB were highly correlated with undetectable through level.

*:ADABs+ versus ADABs- / ADAB>200 versus ADABs - In the overall cohort, no predictive factors for the development of ADABs were found (table). This was also the case when analyzing IBD or IA patients separately (table).

Conclusion: In this cohort of IA and IBD patients treated with maintenance infliximab, who received pro-active, trough level and ADABs monitoring, the prevalence of ADAB was higher in IA patients than in IBD patients. This may be explained by differences in baseline clinical characteristics. No clear predictive factors could be identified in either group.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: NSAIDs are the first line pharmacologic therapy in ankylosing spondylitis (AS). Several NSAIDs are efficacious in AS without superiority demonstrated by any particular drug. The literature frames NSAID use in terms of type, dose and duration through the NSAID index. This study aims to identify the effect of NSAID use in AS as defined by the percent of the full inflammatory dose taken over time (the NSAID Index) on disease activity over time.

Methods: A prospective cohort study of 755 AS patients who met the modified New York criteria were followed for at least 2 visits from multiple sites. Patients underwent a comprehensive clinical evaluation including assessing their disease activity by the Bath AS Disease Activity Index (BASDAI) in addition other demographic, social, and psychological variables collected. . Medications taken concurrently, inflammatory markers and radiographs were taken at each visit. NSAID use was captured by self-report of numbers of pills taken in the last week, month, and 6 month interval. Longitudinal multivariable analyses using mixed effect Poisson regression models that account for the correlation of repeated measures over time were conducted to assess associations between NSAID use (NSAID index of 0%, >0 & ≤50%, and >50%) and BASDAI in tandem with other covariables..

Results: Of the 5101 visits included in this analysis, 41%, 29% and 26% had an NSAID index of 0, >0 & ≤50, and >50 respectively. Table 1. show the longitudinal associations between NSAID use and other covariables over a 6 months period on BASDAI scores. We found that NSAID use was significantly related to higher BASDAI (overall $p<0.0001$); the patients who had high NSAID index (>50%) and low NSAID index (>0 and ≤50%) were more likely to have high BASDAI compared to the ones with no NSAID use (ARR=1.21; $p<0.0001$ and ARR=1.15; $p<0.0001$, respectively). This effect was attenuated when we compare patients with high versus low NSAID index (>50% vs. >0 and ≤50%) (ARR= 1.05; $p=0.0809$). Smoking, C-reactive protein (CRP), baseline radiographic disease, depression (defined by Center for Epidemiologic Studies Depression Scale (CESD) score>16) and opioid use were positively associated with disease activity. Negative associations were seen with TNF inhibitors (TNFi), male gender, higher education. associated with disease activity (ARR=0.9; $p=0.007$). Nearly identical results were found if only the NSAID index of the previous month was considered.

Conclusion: We found a positive association between any NSAID use and higher disease activity, while high vs. low NSAID use was not associated. This may be due to AS patients with higher disease activity taking more NSAIDs. Our findings also hint at a modest treatment effect of NSAIDs in AS as high vs. low use was not associated with change in disease activity. Table 1. NSAID Use and Covariables Associated with Longitudinal Disease Activity in Multivariable Regression Modeling

Variable	Adjusted Rate Ratio (ARR) (95% CI)	p

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : Recent prospective data suggest that spinal inflammatory damage in patients with ankylosing spondylitis will eventually convert into fat. In these complex inflammatory lesions, bone formation and inflammation are not synchronized. The molecular basis responsible for new bone formation in SpA patients is still unclear. Serum level of

dickkopf-1 (Dkk-1), the natural inhibitor of WNT protein, is a main factor in limiting new bone formation. In this study, we aimed to assess the correlation between the secreted protein Dkk-1 and abnormal findings on spinal MRI through a prospective study of SpA.

Methods: Thirty patients with active axial SpA (axSpA) who fulfilled the ASAS axSpA criteria were enrolled. All patients received an injection of recombinant human TNF receptor-antibody fusion protein (YISAIPU) at a dosage of 50 mg/week for 6 months. Patient report outcome measure questionnaires and physical examination, blood tests were completed according to the study protocol. All patients were scored for bone marrow edema and fat infiltration on spinal MRI imaging. The spinal MRI imaging of the patients before and after the treatment were blindly reviewed and scored using the SPARCC scoring system by two individuals who were familiar with the system.

Results: There are 28 male and two female patients (mean age: 31 +/- 5.5 yrs, range: 22-41; mean duration: 93.5 +/- 75.8; HLA-B27(+): 96.7% (29/30)). In patients who finished the 6 month anti-TNF treatment, the ESR, CRP, BASDAI, BASFI, BASMI and ASDAS-CRP were significantly decreased ($P < 0.01$). Serum Dkk-1 concentration was also significantly decreased ($P < 0.05$), as were the edema measurements of spinal bone marrow ($P < 0.05$). (Table1). Correlation analysis found that serum Dkk-1 concentration before treatment was significantly correlated with spinal bone marrow edema scores ($P < 0.01$). The differences in serum Dkk-1 levels significantly correlate with differences in spinal MRI bone marrow edema scores after treatment ($P < 0.05$).(Figure 1 and 2).

Table 1 Clinical indexes, serum Dkk-1 and spinal imaging scores before and after treatment

	Before treatment	After treatment
ESR (mm/h)	23.78 ± 22.27	5.03 ± 4.63**
CRP (mg/dl)	2.59 ± 2.90	0.40 ± 0.52**
BASDIA	6.23 ± 1.29	2.52 ± 1.84**
BASFI	5.78 ± 1.44	2.69 ± 1.72**
BASMI	2.46 ± 1.91	0.69 ± 1.21**
ASDAS-CRP	3.77 ± 0.83	1.58 ± 0.74**
DKK-1 (ng/ml)	98.23 ± 113.41	51.88 ± 41.90*
Spinal-BME	20.27 ± 23.53	6.08 ± 8.09**
Spinal-FAT	10.08 ± 10.38	13.81 ± 15.34

* $P < 0.05$; ** $P < 0.01$

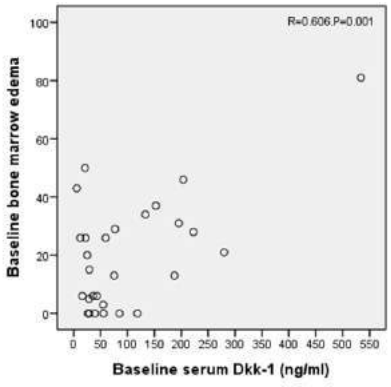

Figure 1. Serum Dkk-1 level is correlated with bone marrow edema at baseline

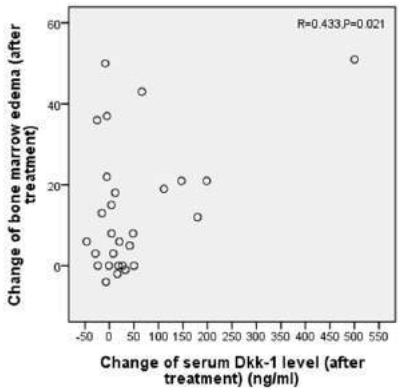

Figure 2. After treatment，the change of serum Dkk-1 level is correlated with change of bone marrow edema

Conclusion: Spinal marrow edema may have a role in predicting new bone formation in the spine, since the change of serum Dkk-1 level is correlated with change of spinal marrow edema. And Dkk-1 may participate in the molecular basis of the TNF inhibitor¡¯s blockade of new bone formation. Further research is needed on patients who have received long-term TNF antagonist treatment to find the time points when serum Dkk-1 level reaches a stabilized plateau. Increased knowledge in this area will be helpful when assessing a predictive marker for the timing of treatment withdrawal.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The number of clinical spondyloarthritis (SpA)-features plays an important role in the Assessment of SpondyloArthritis international Society (ASAS) modified Berlin algorithm for the diagnostic work-up of patients with a suspicion of axial SpA (axSpA). Therefore, we investigated whether all patients with short duration chronic back pain (CBP) and multiple SpA-features are always diagnosed as axSpA by rheumatologists and to describe the features of these patients.

Methods: The SPondyloArthritis Caught Early (SPACE)-cohort includes CBP patients (≥ 3 months, ≤ 2 years, onset < 45 years) from various rheumatology centers. Following a fixed protocol all patients underwent a full diagnostic work-up consisting of performance of MRI and radiographs of sacroiliac joints, acute phase reactants, HLA-B27, and assessment of other SpA-features (inflammatory back pain (IBP), good response to NSAIDs, family history for SpA, peripheral arthritis, dactylitis, enthesitis, uveitis, inflammatory bowel disease (IBD), and psoriasis). Each center interpreted the MRI-SI and X-SI on presence of sacroiliitis (yes/no) using global assessment as part of routine clinical practice. Total number of SpA-features was calculated after medical history taking, physical examination and measurement of acute phase reactants, excluding sacroiliac imaging and HLA-B27 status. The treating rheumatologist provided clinical diagnosis of patients and the ASAS-criteria for axSpA were used for classification.

Results: A total of 500 baseline patients were analysed in this study: 159 (31.8%) patients had ≤1 SpA-feature, 143 (28.6%) patients had 2 SpA-features, 79 (15.8%) patients had 3 SpA-features, and 119/500 (23.8%) patients had ≥4 SpA-features (Table 1). IBP, good response to NSAIDs, and positive family history for SpA were most common in all subgroups (≤1 feature: 27.0%, 8.2%, and 16.4%; 2 features: 72.0%, 35.0%, 39.9%; 3 features: 89.9%, 59.5%, 54.4%; ≥4 features: 94.1%, 82.4%, 67.2%). Of the patients with 2 and 3 SpA-features without radiographic sacroiliitis 20/127 (15.7%) and 9/74 (12.2%) did not have axSpA diagnosis despite being HLA-B27+. All patients with ≥4 SpA-features and radiographic sacroiliitis (n=28) were diagnosed with axSpA. In contrast to what would be expected by following the modified Berlin algorithm for patients with ≥4 SpA-features 18/91 patients (19.8%) with negative imaging, 4 of whom were HLA-B27+, were not diagnosed with axSpA. In the majority of patients there was concordance between fulfilment of the ASAS classification criteria and axSpA diagnosis, however 40 patients who met the criteria were not diagnosed with axSpA.

Conclusion: In this cohort of CBP patients neither the mere presence of numerous SpA-features nor fulfilment of the ASAS classification criteria did automatically lead to axSpA diagnosis. Positive imaging was the main driving factor to diagnosis

Table 1 Diagnosis and classification of patients (n=500) with ≤1, 2, 3 and ≥4 spondyloarthritis (SpA)-features after medical history taking, physical examination and measurement of acute phase reactants, followed by sacroiliac imaging and HLA-B27 testing.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : We assessed baseline parameters associated with health-related quality-of-life (HRQoL) improvement in AS patients with anti-TNF treatment (golimumab [GLM]; infliximab [IFX; originator]) in the QUality of Life as Outcomes and its VAriation with DIsease States (QUO-VADIS) study

Methods: This prospective observational study included bio-naïve AS patients (modified New York criteria) newly treated with GLM or IFX (originator). Patients were followed-up for ~6 months (data collected at BL, 3, and 6 months). Demographic and clinical characteristics, disease activity and HRQoL were summarized accordingly. The Classification and Regression Trees (CART) analysis evaluated the association of BL parameters (demographic, clinical, disease severity) with change in HRQoL at 6 months, measured by an improvement of ≥ 5 points of the Short-Form 36 (SF-36) Physical Component Summary (PCS) score. Clinical parameters included Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI), and AS Disease Activity Scores (ASDAS).

Results: 963 patients received ≥ 1 dose of medication; 78% received GLM and 22% received IFX. Mean age was 42.7 years, 61.4% were male, and 65.3% had ≥ 1 comorbidity. Mean symptom and diagnosis duration were 11.6 and 5.3 years, respectively, and 63.8%of patients were Human Leukocyte Antigen (HLA)-B27 positive. At BL, mean BASDAI, ASDAS-CRP and BASFI scores were 6.21, 3.59 and 5.34, respectively. High and very high ASDAS disease activity was observed in 41.4% and 49.3% of patients, respectively. Clinical and HRQoL improvements were shown in all collected measures following 6 months of treatment with GLM or IFX, as documented in the Table. PCS response at 6 months (improvement of ≥ 5 points from BL) was achieved in 52.3% (n=504) of patients. Using CART analysis, the baseline parameters, and their cutoff values, associated with HRQoL improvement as measured by SF-36 PCS response at 6 months were ASDAS (≥ 3.48), C-Reactive Protein (CRP) (≥ 8.55 mg/L), age (≤ 35.5 years), and BASFI (≥ 1.15). This algorithm correctly identified 57.5% (sensitivity) of the patients who had improvement on PCS >=5 points and 61.0% (specificity) of the patients who had improvement on PCS <5 points with ROC-AUC=0.61.

Conclusion: The QUO-VADIS study demonstrated clinical and HRQoL improvements over 6 months in a large, real-world population of AS patients newly treated with GLM or IFX, with results similar to clinical studies [(1)]. The study also demonstrates, for the first time, the association of parameters such as higher ASDAS, elevated CRP and younger age with improvements in HRQoL and with a more robust response. The use of these predicting factors may aid clinicians in better evaluating which patients to start on antiTNF therapy with GLM or IFX. **References:** Inman et al. *Arthritis Rheum.* 2008 Nov; 58(11): 3402-12.

Table: Improvement in Clinical and QoL Parameters Following 6 months of Treatment

	Overall population N=963	Golimumab-only cohort N=751
Mean (SD) BASDAI change from BL	-2.7 (2.3)	-2.6 (2.3)
Mean (SD) BASFI change from BL	-2.1 (2.3)	-2.2 (2.2)
BASDAI50 Response	39.5%	39.9%
ASAS20 Response	50.6%	52.6%
ASDAS Major Improvement	26.6%	26.0%
ASDAS Disease Activity Category Inactive (<1.3) Moderate (≥1.3 to ≤2.1) High (>2.1 to ≤3.5) Very High (>3.5) Missing	19.9% 21.2% 29.4% 7.0% 22.5%	20.4% 22.2% 29.6% 5.1% 22.8%
SF36 PCS responders (improvement of ≥ 5 points from BL)	52.3%	53.3%

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hip involvement is the most frequent extraspinal arthritic manifestation of Ankylosing Spondylitis (AS) and a common cause of disability. It is present in 24% to 36% of AS patients, leading to total hip replacement (THR) in 5%. The purpose of this study was to examine the prevalence of hip arthritis in AS, to identify predictors of its development and possible gender differences.

Methods: 241 consecutive AS patients (162 men, age: 48.6±11years (mean±SD), disease duration: 23.6 ±11.2 years) were included in this cross-sectional study. The patients received initially: etanercept (n=117), adalimumab (n=89) infliximab (n=25), or golimumab (n=10). Anteroposterior X-rays of the pelvis, obtained before anti-TNF treatment initiation (i.e. baseline), were scored according to BASRI-hip scoring system. In parallel, the lateral x-rays of cervical and lumbar spine were scored using the mSASSS. The patients' disease activity and functional limitation, prior entering anti-TNF treatment, were recorded by BASDAI, ASDAS-CRP/ESR, BASFI and BASMI. Mann-Whitney, two-sample t-test and logistic regression analysis were applied. The groups averages are expressed as mean±SD, or median(IQR) according to the normality of data.

Results: Hip involvement was assessed both clinically (as pain, reduced range of motion and intermalleolar distance) and radiographically, as BASRI-h score ≥ 2 at baseline anteroposterior pelvis X-rays. Definite hip involvement was detected in 85/241(35%) patients. Bilateral THR and unilateral THR underwent 10/241(4%) and 6/241(2.5%) patients respectively. No gender difference was observed (females: 25/85(30%) vs. males 54/156(35%). The patients with hip arthritis had significantly higher BASDAI-scores (6.1± 1.7 vs. 5.4± 1.9, p=0.03), ASDAS-CRP (3.9± 0.8 vs. 3.4± 0.9, p<0.0001), CRP [12.4(4.2-32) median(IQR) vs. 7(2.5-21), p=0.001], ESR [26(8-39) vs. 14(7-30), p=0.006], compared to those without. Additionally, the aforementioned patients had higher BASFI-score (6.2±1.9vs. 4.8± 2.3, p<0.0001), BASMI-score (5±2.3vs. 3.3± 1.9, p<0.0001) and reduced intermalleolar distance (88±23 vs. 104±19 cm, p<0.0001). AS patients with hip arthritis had also higher mSASSS-scores [13.5 (2- 38.5) vs. 3(0-14), p<0.0001] and increased percentage of presence of syndesmophytes [52/84 (62%) vs.58/153 (38%), p=0.001] and peripheral arthritis [48/83 (58%) vs. 66/155 (42%), p=0.001). According to multivariate logistic regression analysis, independent risk factors for hip arthritis in AS are: ASDAS-CRP (OR:1.8, CI: 1.2-2.8), presence of syndesmophytes (OR: 2.4, CI: 1.2-5) and intermalleolar distance(OR: 0.97, CI: 0.95-0.9).

Conclusion: The prevalence of hip arthritis in AS is very high (1/3) and related to high disease activity and a high mSASSscore. No gender difference in prevalence of hip arthritis was found. Considering the large impact on function, this manifestation might need more attention.

Long-Term Effect of TNF Inhibitors on Radiographic Progression in Ankylosing Spondylitis Is Associated with Syndesmophytes at Baseline and Time-Averaged CRP Levels

Maria Konsta[1,2], Grigorios Sakellariou[3], Alexios Iliopoulos[4], PETROS P SFIKAKIS[5] and I.E. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although the radiographic progression in AS is associated with both baseline and time-averaged level of CRP in TNF naïve patients, the effect of level of acute phase reactants on radiographic progression in anti-TNF treated patients has not yet been investigated. The purpose of this study is to investigate whether the impact of long-term treatment with TNF inhibitors on radiographic progression in AS is associated with the level of acute phase reactants.

Methods: Seventy consecutive AS patients with long-standing anti-TNF treatment [47 men; age: 49 ± 11years (mean±SD); disease duration: 25 ± 12 years] were included in this retrospective study. Lateral X-rays of cervical and lumbar spine obtained before anti-TNF initiation were compared to those obtained after a period of 7±2.3 (range: 3-12) years. The levels of CRP and ESR were evaluated at least every 6 months. The radiographic damage was assessed by the mSASSS. New syndesmophyte formation or ΔmSASSS-score/year ≥1 unit/year was defined as radiographic progression. As ΔmSASSS-score/year was defined the difference between mSASSS at last visit and mSASSS at baseline, accounting for the time gap between radiographs. Mann-Whitney test was used to test for the differences in continuous variables between two groups, and Spearman's coefficient was used for correlations between continuous variables. Additionally, logistic regression analysis was applied.

Results: Thirty-eight AS patients (54%) showed radiographic progression. ΔmSASSS score/year was positively correlated with baseline CRP (r=0.44, p=0.0001) and baseline ESR (r=0.35, p=0.004), as well as with time-averaged CRP (r=0.3, p=0.004). Furthermore, ΔmSASSS score/year was significantly greater (p<0.0001) in patients with syndesmophytes at baseline [1 (0.6-1.8), median (IQR)] compared to those without [0 (0-0.4)]. In multivariate logistic regression analysis, independent risk factors for spinal radiographic progression during anti-TNF treatment were the presence of syndesmophytes at baseline (OR: 9.8, CI: 3-33) and the time-averaged CRP >5mg/L (OR: 6.4, CI: 1.9-21).

Conclusion: In AS patients with long-term anti-TNF treatment, radiographic progression is associated with elevated levels of time-averaged CRP. Furthermore, patients with syndesmophytes at baseline have greater radiographic progression.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: As part of the 2016 update of the ASAS/EULAR recommendations for the management of axSpA, we performed a systematic literature review (SLR) to assess the efficacy and safety of non-biological therapy in patients with axSpA published since the last SLR in 2009.

Methods: This SLR was performed in Medline, Embase and Cochrane databases (2009-2016) and also in 2014-2015 EULAR and ACR abstracts and included randomized controlled trials (RCT), clinical controlled trials (for efficacy and safety) and observational studies with a comparator (for safety). Any non-biological drugs or non-pharmacological therapies were eligible. All important efficacy and safety outcomes were analysed. Risk of bias was assessed according to the Cochrane and Hayden tools. Due to heterogeneity no meta-analyses were performed. When possible the Cohen´s Effect size was calculated for non-pharmacological treatments.

Results: Of 10,244 articles and 428 conference abstracts, we included 42 papers and 3 abstracts [non-biological drugs (table 1): 15 trials, 1 Cochrane review; non-pharmacological therapies: 29 trials]. A Cochrane review strengthened the efficacy and safety of NSAIDs for the treatment of axSpA. This was confirmed by two additional studies (table 1). NSAIDs used continuously compared with on-demand did not reduce the mSASSS mean change over 2 years in AS-patients with normal CRP (≤5mg/l) [1 negative RCT (0.9 vs. 0.8; p=0.62)]; while for patients with high CRP an unclear effect was found [1 positive RCT (0.2 vs. 1.7; p=0.003), 1 negative RCT (1.68 vs. 0.96; p=0.28)]. Based on 4 observational studies, there were no new findings on safety of NSAIDs. No efficacy was shown for two different doses of systemic glucocorticoids in short-term treatment (BASDAI50 week 2: 8% PBO; 27% prednisolone (PDN) 20mg; 33% PDN 50mg). No new trials on conventional synthetic (cs) DMARDs were found. Studies on non-pharmacological therapies were very heterogenous regarding type of therapy, study duration, group size and outcome parameters. All studies included patients fulfilling the mNY-criteria, only one followed the ASAS criteria. Overall they show that regular exercises can improve disease activity, function and spinal mobility in axSpA, but mostly with small improvements (table 2).

Conclusion: Efficacy and safety of NSAIDs in axSpA is confirmed. No data is found on csDMARDs. Glucocorticoids did not demonstrate efficacy in axSpA. Regular exercises can improve outcomes, but with modest effects.

Table 1 Characteristics of pharmacological non-biological studies assessing efficacy

Study	Intervention	n	Primary endpoint	Primary endpoint in each group	Time point of primary endpoint	Trial	Risk of bias

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is well known that osteoporosis is paradoxically common in patients with ankylosing spondylitis (AS) in spite of their new bone formation and extraosseous calcification. However, some features of advanced disease such as syndesmophyte can cause overestimation of bone marrow density (BMD) resulting normal or high BMD values even when osteoporosis is present. The aim of this study was to evaluate lateral spine BMD and trabecular bone score (TBS) as the methods to measure actual bone loss and thus redeem the obstacles of conventional BMD in patients with advanced AS.

Methods: Fifty-four patients with AS (38 males, 16 females) who assessed BMD using dual-energy X-ray absorptiometry (DXA) were retrospectively reviewed. BMD was measured by anterior-posterior (AP) lumbar (L)1-L4, lateral (Lat) L2, L3, and proximal femur projection. Trabecular bone score (TBS) L2-L4 which provides an indirect index of trabecular microarchitecture was calculated by reanalyzing AP lumbar spine image. Radiologic variables including Bath Ankylosing Spondylitis Radiology Index for the spine (BASRI-s) score, modified Stroke Ankylosing Spondylitis Spine Score (mSASSS), and the presence of syndesmophyte were determined. AS patients were divided into mild, moderate, and advanced stages according to each radiologic variables, and the BMD measured by different methods were compared among those 3 groups using ANOVA.

Results: Radiologic progression of AS patients represented by BASRI-s, mSASSS, and the number of syndesmophyte was negatively correlated with Lat-L3 BMD (r=-0.431, r= -0.364, r=-0.464) and with TBS (r=-0.352, r=-0.355, r=-0.382). Moreover, patients in advanced stage (BASRI-s¡Ã3, mSASSS¡Ã10, syndesmophyte¡Ã1, respectively) showed significantly lower Lat-L3 BMD (*P*=0.047, *P*=0.012, *P*=0.006) and TBS (*P*=0.050, *P*=0.014, *P*=0.090) compared with those in mild stage, while they displayed no difference in conventional BMD from AP and femur DXA.

Conclusion: The Lat-L3 BMD and TBS have higher potency to mirror a bone loss in AS patients independent of their radiologic changes. Further studies evaluating TBS cutoff value for expecting vertebral fracture are needed.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) patients (pts) were found to respond better to TNF inhibitors (TNFi) if treated early in the disease course. The objective of this analysis was to examine the impact of time since diagnosis, age, and number of prior NSAIDs as surrogates for disease duration on clinical outcomes in AS pts treated with adalimumab (ADA) in ATLAS trial.

Methods: ATLAS[1,2] was a phase III randomized double-blind trial comparing safety and efficacy of ADA with placebo (PBO) in pts with active AS who failed NSAID therapy. In this post hoc analysis, pts were categorized by baseline (BL) (1) time since diagnosis (<2 vs ≥2, <5 vs ≥5, and <10 vs ≥10 years [yrs]), (2) age (<35, 35 – 45, and >45 yrs), and (3) number of prior NSAIDs (≤ 2 vs >2). The effect of time since diagnosis, age and number of prior NSAIDs on AS outcome measures at week (wk) 12 was determined in pts who received at least one dose of ADA during the PBO-controlled period or open label extension and received prior NSAID(s) at BL.

Results: Of the 301 pts included in this analysis, a majority of them had ≥5 yrs since AS diagnosis (205 [68.1%]), were <45 yrs of age (182 [60.5%]), and had ≤2 prior NSAIDs (170 [56.5%]). Pts with shorter time since diagnosis were generally younger, while those with longer time since diagnosis were more frequently HLA-B27+. There were more men than women across all subcategories. CRP was numerically higher in patients with ≤2 prior NSAIDs. The BL disease activity measures were however numerically similar across most categories (**Table 1**). At wk 12, the proportions of pts achieving ASAS20 and ASAS40 responses were numerically higher and mean decreases in BASDAI and BASFI scores from baseline larger in subcategories with shorter time since diagnosis, lower age, and fewer prior NSAIDs (**Table 2**). The differences in the clinical outcomes were significant between <35 and >45 yrs age categories (ASAS20: P<0.001; ASAS40: P=0.003; BASDAI: P=0.002; BASFI: P=0.012).

Conclusion: Shorter time since diagnosis, younger age, and lower number of prior NSAIDs resulted in numerically greater clinical responses and improvements in disease activity and functionality following ADA treatment in pts with AS. The younger age (<35 yrs) had the largest positive impact on the clinical outcomes as compared with higher age (>45 yrs), suggesting its closest association with the actual disease duration. Overall, the results support the need for early effective treatment intervention in AS pts to improve clinical outcomes. **References:**

Session Date: Sunday, November 13, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster I: Axial and Peripheral Spondyloarthritis – Clinical Aspects, Imaging and Treatment

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare the clinical、radiographic and magnatic resonance imaging change in active

ankylosing spondylitis patients with etanercept and celecoxib alone/combined treatment，and to evaluate the effectiveness and safety on clinical and structural change of AS patients with different treatments after 24 weeks.

Methods:

A total of 92 active ankylosing spondylitis patients were included, disease activity was defined as the following three aspects: BASDAI ≥ 4 or ASDAS≥ 2.1；CRP＞6 mg/L or ESR 28 mm/1st hour；more than 2 and less than 16 syndesmophyts between cervical spine and lumber spine detected by X-ray. All patients were randomly assigned （1：1：1）to one of the three treatment groups：celecoxib 200mg bid，etanercept 50mg qw and combined therapy for 24 weeks. Disease activity was assessed with BASDAI and ASDAS, ASAS response rate was used for the evaluation of clinical efficacy. Structural change was detected using the mSASSS and SIJ SSS, and inflammation was assessed by SIJ SPARCC.

Results: A total of 92 active AS patients were included, the average age was 32.02 with mean disease duration of 9 years, the positive rate of HLA-B27 was 94.8%. The average syndesmophyts was 5.61 per patient, mSASSS and SIJ SPARCC score was 8.76 and 15.13 respectively in baseline. Erosion, fat metaplasia, backfill and ankylosis score of SSS was 3.26, 5.26, 1.09 and 3.26. After completing 24 weeks' treatment, the ASAS20 response in celecoxib, etanercept and combined group are 69.2%, 71.8% and 88.2% respectively. Of the three groups, 46.1%, 65.6% and 70.6% of patients fulfilled ASAS40 response, and almost half of patients acquired ASDAS major change. The back pain score, BASDAI, BASFI and ASDAS of three different treatment groups decreased as time extend, the combined therapy group obtained most significant change. After 24 weeks, SIJ and spine SPARCC inflammation score decreased sharply, and no statistical difference was found between three groups in four indexes of SSS. Adverse events such as upper respiration infection and slightly elevated ALT were more seen in the combined group and no SAE occurred during the research.

Conclusion: Etanercept and celecoxib alone/combined treatment were efficacious and safe in improving the symptom and sign of active AS patients, combined therapy group had the best result. The use of etanercept can alleviate inflammation detected by MRI, there were no difference of structural change between the three groups.

Hydroxychloroquine Whole Blood Levels Do Not Associate with Hydroxychloroquine Retinopathy

Michelle Petri[1], Wei Fu[2] and Syed Mahmood Shah[3], [1]Rheumatology Division, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The American Academy of Ophthalmology guidelines on hydroxychloroquine retinopathy were

recently revised (Ophthalmology 2016;1-9). These guidelines recommend optical coherence tomography (OCT) with multifocal electroretinogram (mfERG) and fundus autoflorescence (FAF) as corroboratory tests. These tests can be subject to interpretation differences and require validation and repeat testing. Whether hydroxychloroquine blood levels predict retinopathy is currently unknown.

Methods: SLE patients on hydroxychloroquine underwent screening with OCT, mfERG and FAF. Hydroxychloroquine retinopathy, possible or definite, was determined by retina specialists. Patients had hydroxychloroquine blood levels (Clarke et al) determined at every clinic visit.

Results: Among the 117 patients, 95.7% were female; 50% Caucasian and 44% African-American. 12 had definite and 7 possible hydroxychloroquine retinopathy. 83.8% had no hydroxychloroquine retinopathy. Table 1: HCQ Retinopathy by HCQ Blood Level

Highest HCQ level (ng/mL)	No toxicity N (%)	Possible Toxicity N (%)	confirmed toxicity N (%)	Total
Greater than 2,000	25 (83.3)	2 (6.7)	3 (10.0)	30
1,500 to 1,999	23 (79.3)	4 (13.8)	2 (6.9)	29
1,000 to 1,499	30 (85.7)	1 (2.9)	4 (11.4)	35
500 to 999	13 (100)	0 (0)	0 (0)	13
Less than 499	7 (70.0)	0 (0)	3 (30.0)	10

Pair-wise comparison using t test with pooled Standard deviation showed that the average highest HCQ levels were not significantly different among the three groups (No vs. Possible vs. Yes) After grouping those with “confirmed” and “possible” toxicity, the average highest HCQ level was 1511.6 ng/mL vs 1591.1 ng/mL in those with vs. without retinopathy. The difference between these two groups is not significant (P = 0.7094) using t test.

Conclusion: We confirm a much higher frequency of hydroxychloroquine retinopathy (when defined by preclinical testing) than expected based on previous reports. Some SLE patients have high hydroxychloroquine levels, while on appropriate dosing by real weight. This does not correlate with current hydroxychloroquine retinopathy. Further followup will be able to prove if hydroxychloroquine blood levels predict future retinopathy.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Premature atherosclerosis is one of the major complications of systemic lupus erythematosus (SLE). Preventing atherosclerosis is a key objective while monitoring patients with SLE. Recently, the biological linkage between atherosclerosis and osteoporosis has garnered much attention. The aim of this study was to explore and evaluate associations between development of atherosclerosis and anti-osteoporotic treatment. We focused on the combined treatment with bisphosphonate and vitamin D (BP+VD) on atherosclerosis and performed an unbiased cross-sectional and longitudinal study using inverse probability of treatment weighting (IPTW) based on propensity score.

Methods: Two hundred and twenty one SLE patients who received glucocorticoids (GC) at Hokkaido University Hospital between January 2012 and August 2014 were examined. Of these patients, patients who underwent carotid ultrasonography to assess subclinical atherosclerosis in clinical practice were enrolled in this study. Carotid ultrasonography was performed at baseline and during the follow-up period. Carotid plaque and plaque scores were defined as surrogate markers of subclinical atherosclerosis. Propensity score was calculated for each patients as the probability of receiving BP+VD treatment, using 8 baseline covariates including age, postmenopausal state, duration of disease, duration of GC use, current dose of GC, statin use, bone mineral status and SLEDAI-2K.

Results: A total of 108 consecutive patients with SLE were included in this study. Thirty-seven (34%) were receiving BP+VD, 26 (24%) BP alone, 29 (27%) VD alone, and 16 (%) other agents to treat or prevent osteoporosis. In 12 out of 108 patients, the propensity score could not be estimated due to unavailability of the baseline covariates. Eighty-three out of 108 patients underwent a re-evaluation of carotid ultrasonography after 104±21 months (mean ± SD). After adjustment with IPTW, the prevalence of carotid plaque at baseline was significantly less frequent in BP+VD than other treatment groups (p=0.03, McNemar test). The progression of plaque scores between baseline and follow-up was also significantly less frequent in BP+VD group (p=0.006).

Conclusion: Combined treatment with BP+VD may prevent atherosclerosis in patients with SLE. This study suggested that the new strategy in terms of preventing atherosclerosis and reducing morbidity and mortality in SLE patients might include those anti-osteoporotic medications.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Response to the anti-CD20 agent rituximab (RTX) in SLE is variable but it is still widely used for refractory SLE. Our aim was to describe the rate of response and adverse events to RTX in a large multicentre cohort.

Methods: We established a national multicentre prospective registry of patients with SLE. Patients are recruited who receive either standard therapy or a biologic, including RTX. BILAG 2004 and SLEDAI-2K are collected at baseline, 3, 6 and 12 months, then annually. We included patients who received RTX before November 2015. For efficacy analysis, we analysed those who had active SLE at baseline according to the national RTX prescribing guidelines (≥1 BILAG A or ≥2 BILAG B scores or a SLEDAI-2K ≥6 or oral steroids ≥20mg daily) and who had BILAG 2004 and SLEDAI-2K at baseline and 6 months. The primary endpoint was a modified BILAG-Based Composite Lupus Assessment (BICLA) endpoint defined as: improvement of active systems on BILAG 2004 with no worsening in other systems (all BILAG As at entry to B/C/D, all Bs to C/D, no new As, <2 new Bs); no worsening of SLEDAI-2K; no increase in oral steroid dose at 6 months. Secondary endpoints included change in global BILAG 2004 score; change in SLEDAI-2K score; change in steroid dose from baseline. We also explored a Major Clinical Response (MCR) defined as BILAG 2004 C/D/E only; SLEDAI-2K ≤4; daily oral steroid dose ≤7.5mg.

Results: 167 prospective patients commenced RTX before November 2015. 158 fulfilled ≥4 of 11 ACR criteria for classification of SLE, 3 of the remaining 9 had lupus nephritis. Baseline demographics and disease activity are shown in Table 1. The commonest RTX regime was 2x1000mg dose 14 days apart, given to 134/136 patients (98.5%) for whom dosing schedules were available. 118 patients have complete baseline and 6 month disease activity data. A BICLA response at 6 months was achieved in 57(48.3%). Over 6 months, mean global BILAG 2004 fell from 20.4 to 9.6 (mean difference 10.8, 95%CI 9.0 – 12.6, p <0.01). Mean SLEDAI-2K fell from 9.6 to 4.5 (mean difference 5.1, 95%CI 4.2 – 6.1 p<0.01) and mean daily oral steroid dose reduced from 17.0 to 11.6mg (mean difference 5.4 95%CI 3.2-7.6 p<0.01). Twelve (10.2%) patients discontinued oral steroids by 6 months and 2 commenced oral steroids. MCR was achieved in 18(15.2%) patients. In the first 6 months, 189 adverse events were reported in 90/167(54%) patients. There were 10 infusion reactions and 90 infections in 53(32%) patients including 14 serious infections. Four deaths occurred: one due to infection, two of organ failure, one of cause unknown.

Conclusion: In a large national cohort of SLE patients receiving RTX, disease activity and steroid use reduced significantly by 6 months and 48.3% achieved a BICLA response. Steroid withdrawal and MCR was evident by 6 months in some, suggesting excellent early responses in a subset warranting further characterisation.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lack of adherence to treatment recommendations is a serious confounder to assessment of treatment efficacy for systemic lupus erythematosus (SLE). Estimates of nonadherence with medications for SLE patients range from 10%-60%.

Methods employed to assess medication adherence in the SLE population include patient self-report questionnaires, pharmacy refill record review, physician impressions of patient adherence, and therapeutic drug monitoring; however, few studies undertake a multifactorial methodology. Mycophenolate mofetil is a viable option for induction and maintenance of lupus nephritis which lacks the gonadotoxic side effects of cyclophosphamide. However, treatment adherence is a concern. This study utilized all four methods of adherence assessment to determine the most reliable predictor of adherence for SLE patients on MMF. Methods: Adult SLE patients enrolled under the Pathogenesis and Natural History of SLE protocol receiving mycophenolate mofetil at a stable dose ranging from 0.5 grams to 1.5 grams twice daily for at least six weeks from the NIH Clinical Center Pharmacy were included in this study. Patient self-assessment of adherence was quantified using a modified Medication Adherence Self-Report Inventory (MASRI); a study tool that has been validated in SLE patients. Physicians (blinded to the patient's MASRI scores) scored patient adherence using a Likert scale with 0 being completely noncompliant and 10 being 100 % compliant. Pharmacy refill percentage for one year or from the initial date of prescription of MMF was calculated; a refill percentage greater than 80% was considered "adherent." As an objective measure of adherence, serum trough mycophenolic acid (MPA) levels were drawn with undetectable levels considered nonadherent. Patients were surveyed for demographic information and other mediators possibly related to low adherence.

Results: Adherence was assessed on 30 patients; 20 patients were considered adherent by resultant detectable MPA levels. In a univariate regression model, pharmacy refill percentage had the strongest correlation with detectable MPA levels (Pearson's Correlation r value=0.464, p-value=0.0128), while both the MASRI and the physician rating showed only modest correlations with MPA level (Pearson's Correlation r values of 0.227 and 0.202, respectively). There was a statistically significant (p=0.0041) difference in the refill percentages, with majority of the adherent cohort (80%) having refill percentages of 80% or greater. Patients in the adherent group were slightly older, with a mean age of 40.8 (p=0.0473) and were more likely to be married (p=0.0187).

Conclusion: Refill percentage was the best predictor of a detectable serum MPA level and patient adherence. Older age and being married also influenced adherence to the treatment regimen. Factors such as medication side effects, total number of medications prescribed, physician's assessment of patient adherence and educational status were not found to be significant predictors of patient adherence. Future studies are needed to more completely define specific contributors to patient nonadherence to MMF in the SLE population.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is frequently used to treat autoimmune diseases. The HCQ package insert and online drug information resources report an increased risk of hemolytic anemia in patients with G6PD deficiency. However, no published studies quantify this potential risk, and the genetic forms of severe G6PD enzyme deficiency are very rare in the United States. A single abstract reported a 170 chart review, finding one G6PD deficient patient on HCQ with no adverse event. Through a retrospective chart review, we aimed to quantify the percentage of G6PD deficient patients with clinically significant hemolysis attributed to HCQ.

Methods: The Duke Medicine IRB granted approval for this study. We used a clinical search engine (Duke Enterprise Data Unified Content Explorer [DEDUCE]) to identify all patients who had a clinical visit with Duke Rheumatology, HCQ usage, and a G6PD level checked at Duke Health since 1996. A retrospective chart review was performed on all identified patients, recording demographics, G6PD levels, laboratory values consistent with hemolysis, etiology of hemolysis, and outcome of HCQ use. Data were analyzed using simple statistics.

Results: Two hundred seventy five patients met inclusion criteria by having a prior G6PD level and a prescription for HCQ. Our study population included 232 (84%) females and 43 (16%) males; 126 (46%) African Americans, 131 (48%) Caucasians, and 18 (6%) others. The leading diagnoses included 88 (32%) patients with lupus, 80 (29%) patients with rheumatoid arthritis, and 37 (14%) patients with other forms of inflammatory arthritis. Of the 275 charts reviewed, 11 (4%) of patients were G6PD deficient. The G6PD deficient patients had a total of 711 months of exposure to HCQ. One of the 11 G6PD deficient patients (9%) was found to have sulfamethoxazole/trimethoprim (TMP/SMX) induced hemolysis prior to the initiation of HCQ. This patient was later started on HCQ with no clinical adverse events noted. In 3 of 11 G6PD deficient patients, HCQ was discontinued: one after discovering G6PD deficiency (< 3 months HCQ exposure), one self-discontinued (24 months HCQ exposure), and one discontinued by hematology due to neutropenia (108 months exposure). Of the 264 patients with normal G6PD levels, 14 (5%) had hemolytic anemia at some point, caused by TTP (n=4), autoimmune hemolytic anemia (n=9), and pure red cell aplasia (n=1).

Conclusion: This is the largest study to date evaluating G6PD deficiency with concurrent use of HCQ. Among 11 patients with G6PD deficiency, only 1 had evidence of hemolytic anemia, induced by TMP/SMX prior to successfully tolerating HCQ for SLE without further hemolysis episodes. In this cohort, no G6PD deficient patients developed hemolytic anemia attributable to HCQ during 711 months exposure to the drug. These data do not support routine G6PD level measurement prior to initiating HCQ therapy.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is an autoimmune disease associated with elevated levels of B Lymphocyte Stimulator (BLyS). This study assessed the efficacy and safety of belimumab (BLyS-specific inhibitor) 10mg/kg when added to standard of care therapy compared with placebo over 52 weeks (wks) in patients with SLE located in NE Asia (China, Japan, and S. Korea).

Methods: 707 patients with SLE age ≥18 yrs with a Safety of Estrogen in Lupus National Assessment (SELENA) SLE Disease Activity Index (SLEDAI; SS) disease activity score of ≥8 at screening were randomized (2:1) 10mg/kg belimumab or placebo (NCT01345253, study BEL113750). Patients were dosed on Days 0, 14, 28 and then every 28 days through Wk 48, with a final evaluation at Wk 52. The primary endpoint was the SLE responder index (SRI) response rate at Wk 52 (reduction ≥4 points in SS score; no worsening (<0.3 increase) in Physician's Global Assessment (PGA); no new British Isles Lupus Assessment Group (BILAG). A domain score or 2 new BILAG B domain scores vs baseline. Secondary endpoints included percent of patients with ≥4 point reduction in SS score over baseline at Wk 52, SRI7 responders (SRI and ≥7 points reduction in SS) at Wk 52, number of days of daily prednisone dose ≤7.5mg and/or reduced by 50% over 52 wks, and time to first severe modified SLE Flare Index (SFI) flare.

Results: The primary endpoint was reached as an SRI response at Wk 52 was achieved in 242/446 (54.3%) evaluable patients receiving belimumab vs 87/217 (40.1%) of placebo patients [odds ratio 2.03 (95% CI 1.43, 2.88), p<0.0001]. Benefits of belimumab therapy were also observed for all 4 secondary endpoints. 55.7% of patients receiving belimumab achieved a ≥4 point reduction in SS at Wk 52 vs 42.2% on placebo (odds ratio 2.00 (95% CI: 1.41, 2.83), [p=0.0001]). An SRI7 response rate of 32.7% was achieved on belimumab vs 23.5% for placebo (odds ratio 1.78 (95% CI: 1.15, 2.77) [p=0.0099]). Among 536 patients receiving >7.5 mg/day prednisone at baseline, the median number of days prednisone was reduced to ≤7.5 mg/day and/or by 50% from baseline over 52 wks was zero for both treatments, and the 75% percentile was larger for belimumab; 213.5 days vs 172 days, rank ANCOVA p=0.0288. Belimumab patients had a 50% lower risk of experiencing a severe SFI flare relative to placebo patients (hazard ratio=0.50, 95% CI: 0.34, 0.73), p=0.0004. The overall incidence of AEs was similar between placebo (75.7%) and belimumab (74.9%). The incidence of SAEs was higher for placebo (18.3%) vs belimumab (12.3%). There were similar rates of infectious SAEs in placebo patients (5.5%) and in belimumab patients (5.3%). There was one fatality reported in the placebo group and none in the belimumab group.

Conclusion: This is the fourth pivotal belimumab trial in SLE which has achieved statistical significance for the primary endpoint. All 4 pre-specified secondary endpoints also reached statistical significance. The safety profile of IV belimumab in this NE Asia population is consistent with belimumab IV and subcutaneous data to date; no new safety issues are identified. **Disclosures:** Study funded by GSK. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a mainstay of treatment in patients with SLE. It has been demonstrated to reduce disease activity and prevent damage accrual and suggested to give benefits on thrombosis prevention [1-2]. We have recently pointed out a role of low dose aspirin (ASA) in the primary prophylaxis of cardiovascular disease (CVD) in SLE [3]. In that study, we did not detect any time and dose-independent protective effect of antimalarials. The present analysis was performed to investigate the role of distinct HCQ cumulative dosages and treatment durations.

Methods: patients consecutively admitted to a tertiary center, who, at baseline, satisfied 1992 ACR and/or 2012 SLICC classification criteria for SLE and had not experienced any CV event, were enrolled. ASA treatment, daily and cumulative dosages of HCQ and treatment duration were noticed. A number of attempts were performed to identify the dosage of HCQ and its treatment duration associated with a lower incidence of CV events as assessed by evaluating CV events free survival by Kaplan-Meier curves.

Results: 189 consecutive SLE patients were enrolled and followed up for a median of 13 years (range 1-15 years). Out of them, 80.9% (153/189) had ever used HCQ, with a median treatment duration of 4 years (range 1-15). 80/153 (52.2%) had a treatment duration >5 years and 83/153 (54.2%) patients had cumulative HCQ dosages>600g. Out of the 189 patients, 31(16.4%) were treated with ASA alone and 134 (70.8%) were treated with both ASA and HCQ. During follow-up, there were 10 CV events (1 stroke, 5 TIA, and 4 MI). CV event-free rate was higher in patients treated with HCQ for more than 5 years (log-rank test $\chi 2 = 6.10$; $p= 0.01$) and in patients with a cumulative HCQ dosage >600g (log-rank test $\chi 2 = 6.45$; $p= 0.01$) [figure1-2]. Comparing the 76 patients treated by ASA and HCQ with a cumulative dosage>600g and a treatment duration >5 years with 87 the patients treated by ASA and either no HCQ or HCQ of a dosage<600g and a treatment

duration <5 years, a nearly significant difference was detected in CV events free rates (p=0.069) [figure 3].

Conclusion: Antimalarials, when administered for more than 5 years at a cumulative dosage>600g, may furtherly reduce the CV risk in SLE patients. Larger, prospective studies are needed to fully address this topic.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To identify factors associated with blood concentrations of hydroxychloroquine (HCQ) and its major metabolite, N-desethylhydroxychloroquine (DHCQ), in patients with systemic lupus erythematosus (SLE) receiving long-term oral HCQ treatment.

Methods: SLE patients who had been taking HCQ for more than 3 months were recruited. Various clinical characteristics, laboratory values, and SLE disease activity index (SLEDAI) scores were examined. The concentration of HCQ and DHCQ ([HCQ] and [DHCQ]) was measured by liquid chromatography-mass spectrometry, and the relationship between [HCQ], [DHCQ], and [HCQ]/[DHCQ] ratio to various factors was investigated.

Results: In total, 189 SLE patients on long-term HCQ treatment were included in the analysis. The median [HCQ] was 515 (353~720) ng/ml, the median [DHCQ] was 417 (266~591) ng/ml, and the median [HCQ]/[DHCQ] ratio was 1.3 (1.0~1.7). [HCQ] was closely associated with [DHCQ] (r=0.81, p<0.0001). The weight-adjusted oral HCQ dose was strongly associated with both [HCQ] (p<0.001) and [DHCQ] (p<0.001). Time from last dose was associated with [HCQ] (p<0.001). No statistically significant association was found between renal function or smoking and [HCQ] or [DHCQ]. Additional use of immunosuppressants increased both [HCQ] and [DHCQ] after adjusting for possible confounders (p=0.04, 0.03). The lower SLEDAI score was significantly related to higher [HCQ] after adjusting for age, gender, weight adjusted HCQ dose, time from last dose, number of other immunosuppressants, and smoking status (p=0.007) (see table).

Conclusion: Various factors affected [HCQ], [DHCQ], or the [HCQ]/[DHCQ] ratio in the blood of SLE patients on long-term oral HCQ treatment. Notably, a higher [HCQ] was associated with a lower SLEDAI score, in our typical outpatient clinic population with lupus.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The SRI (SLE responder index) is a composite measure established as a primary endpoint in SLE clinical trials. However, it has been questioned whether the SRI response represents a clinically meaningful change in disease state. Therefore, in order to clarify the clinical relevance of achieving the SRI, we studied clinical and laboratory correlates of the response.

Methods: Patients with SELENA-SLEDAI (SS) score ≥8, receiving stable standard of SLE care (SoC) for ≥30 days were randomized (2:1) to weekly belimumab (BEL) 200 mg or placebo (PBO), subcutaneously (prefilled syringe), plus SoC in the BLISS-SC clinical trial (BEL112341; NCT01484496). The primary endpoint of the trial was the SRI response at week 52 (≥4-point SS reduction, no worsening [<0.3 increase] in Physician's Global Assessment, and 0 new BILAG A or ≤1 new BILAG B organ domain scores, all vs baseline). Regardless of treatment received, SRI responders were compared with SRI non-responders based upon changes in clinical and laboratory parameters assessed at week 52 using the Fisher's exact test, logistic regression, analysis of covariance, and Cox regression, as appropriate.

Results: Of the 833 patients who reached week 52, 475 were SRI responders and 358 were SRI non-responders (observed population). SRI responders had statistically significantly better outcomes in multiple domains: improvements in the individual SRI components, number of improved SS and BILAG organ domain systems, reduction in prednisone use, less SFI flares (overall and severe), improvement in the FACIT-Fatigue score, and improvements in complement and anti-dsDNA antibody levels. CD20+ B cells were similar between the two groups. These results are summarized in **Table 1**. Similar observations have been seen in the Phase 3 BLISS trials following intravenous administration of belimumab or

Table 1. A comparison of changes from baseline to week 52 in clinical and laboratory parameters between SRI responders and non-responders (based upon observed population unless indicated otherwise).

	SRI responders	SRI non-responders	p-value
Patients, n	475	358	
≥4-point SELENA-SLEDAI reduction, n (%)	475 (100%)	7 (2%)	<0.0001
≥7-point SELENA-SLEDAI reduction, n (%)	231 (48.6%)	3 (0.8%)	<0.0001
BILAG improvement (no new As; ≤1B), n (%)	475 (100%)	180 (50.3%)	<0.0001
Number of organ domains improved per patient among those with organ involvement at baseline			
SELENA-SLEDAI, mean ± SE	2.08 ± 0.03	0.42 ± 0.03	<0.0001
BILAG (improvement from A or B score), mean ± SE	1.61 ± 0.03	0.45 ± 0.04	<0.0001
No worsening in PGA, n (%)	475 (100%)	178 (49.7%)	<0.0001
% change in PGA from baseline in patients, mean ± SE[a]	-64.4 ± 1.4	-23.2 ± 2.1	<0.0001
Prednisone >7.5 mg/day at week 52 in patients with baseline prednisone ≤7.5 mg/day, n/N (%)[a]	6/187 (3.2%)	20/144 (13.9%)	0.0009
Prednisone reduction by ≥25% from baseline to ≤7.5 mg/d during weeks 40–52 in patients with baseline prednisone >7.5 mg/d, n/N (%)	61/288 (21.2%)	20/214 (9.3%)	0.0002
Patients with SFI flares (all), n (%)	272 (57.3%)	256 (71.5%)	
Time to first SFI flare, median days (Q1, Q3)	223 (85, -)	113 (57, 330)	<0.0001
Patients with no SFI severe flares, n (%)	459 (96.6%)	260 (73.7%)	<0.0001
% change in FACIT-Fatigue score from baseline, mean ± SE	35.4 ± 4.0	24.7 ± 5.7	0.0102
Anti-dsDNA shifts from baseline to week 52			
Positive to Negative, n/N (%)	71/336 (21.1%)	9/140 (6.4%)	<0.0001
Negative to Positive, n/N (%)	4/127 (3.1%)	8/67 (11.9%)	0.0251
% change in anti-dsDNA from baseline, median (Q1, Q3)	-46.7 (-68.3, -10.7)	-16.7 (-49.5, 5.5)	0.0171
C3 complement shifts from baseline to week 52 Low to Normal/High, n/N (%)	87/205 (42.4%)	14/78 (17.9%)	<0.0001
% change in C3 complement from baseline, median (Q1, Q3)	6.3 (-6.8, 21.8)	-2.1 (-10.9, 12.2)	0.0024
C4 complement shifts from baseline to week 52 Low to Normal/High, n/N (%)	59/120 (49.2%)	14/45 (31.1%)	0.0523
% change in C4 complement from baseline, median (Q1, Q3)	16.7 (0, 44.4)	5.9 (-14.3, 24.1)	0.0540
% change in CD20+ B cells, median (Q1, Q3)	-44.8 (-69.5, -5.5)	-40.6 (-68.0, 3.4)	0.849

Anti-dsDNA=anti-double stranded DNA; BILAG=British Isles Lupus Assessment Group; PGA=Physician's Global Assessment; SFI=SLE Flare Index; SLEDAI=Systemic Lupus Erythematosus Disease Activity Index; FACIT=Functional Assessment of Chronic Illness Therapy; SE=standard error.

[a]Based on last observation carried forward.

placebo plus SoC (1).

Conclusion: Patients who were SRI responders in this trial, regardless of treatment, had numerous clinical and serological

benefits versus non-responders, providing strong support that the SRI response represents a clinically meaningful outcome for patients with SLE.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with lupus nephritis (LN) achieve variable clinical response following Rituximab (RTX) based B-cell depletion therapy, with rituximab treatment aiming to decrease the use of cyclophosphamide rescue therapy. In LN, the presence of interstitial B cells is known to be associated with renal dysfunction and active lesions. However, data on renal B-cell depletion and the clinical response to RTX in LN is limited. Therefore, we investigated the relationship between B-cell depletion in peripheral blood and the kidney, and clinical response to RTX in LN.

Methods: Six patients with LN (2 male, 4 female) had a renal biopsy performed following treatment with RTX (2 x 1g, a week apart) for on-going disease activity. Patients underwent a renal biopsy for the following reasons: decline in renal function (n=4) and nephrotic syndrome (n=2). 5 of the 6 patients had a previous renal biopsy, with 3/5 of the patients having a preceding renal biopsy in the year (between 5-8 months) prior to rituximab therapy. B-cell depletion in peripheral blood was assessed by measurement of CD19+ cells by flow cytometry. Renal B-cells were investigated using immunohistochemistry (IHC) on formalin-fixed paraffin-embedded sections using 2 different monoclonal antibodies against 2 different B-cell markers: anti-PAX-5 and anti-CD79.

Results: Patient characteristics including treatment prior to renal biopsy, serum creatinine, urine protein-creatinine ratio (PCR) and the histological type of LN are shown in Table 1. The patients had renal biopsies a median of 3 months (range 0.5 to 5 months) following rituximab. *Anti-CD79 immunohistochemistry* Five of six patients had detectable interstitial B cells with anti-CD79 staining. These patients had: (i) progressive chronic kidney disease, (ii) required 3 months of dialysis and subsequently recovered renal function but had progressive CKD and 6 years post-biopsy is approaching end-stage renal disease (ESRD) (iii) commenced peritoneal dialysis within 6 months of the renal biopsy. (iv) stable chronic kidney disease (CKD) (v) had predominantly sclerosed glomeruli with little B-cell staining and subsequently did not recover renal function and remained dialysis dependent. The 6th patient without detectable staining had a Class V LN with normal renal function at follow-up in complete disease remission. *Anti Pax-5 immunohistochemistry* Immunohistochemistry with anti-Pax-5 showed similar staining patterns to that with anti-CD79 in 4 patients. The 2 patients without detectable staining with anti-Pax-5 had Class V (patient 2) and Class VI (patient 4), Therefore staining was only present in proliferative glomerular lesions. *Peripheral B-cells* Four patients had less than 0.002 x 10^9 CD19+ cells/L; 1 patient CD19 0.042 x 10^9 cells/L and 1 patient with a Class V and with no detectable B cell infiltration, had a CD19 count of 0.03 x 10^9 cells/L at the time of renal biopsy.

Conclusion: This retrospective study demonstrates clinically relevant discrepancy in B-cell depletion between peripheral blood and the kidney in patients with LN with the persistence of interstitial B-cells suggesting resistance to rituximab-induced B-cell depletion and on-going renal inflammation. This, was associated with progressive CKD and end-stage renal failure in four patients whereas the patient with preserved renal function had no detectable B cells in the kidney. Therefore, we consider that improving B-cell depletion in the kidney may enhance clinical response to B-cell depletion therapy in lupus nephritis. Table 1. Renal biopsy data and parameters before and after rituximab.

The Long-Term Outcomes on Leflunomide Treatment in Patients with Lupus Nephritis: A Twelve-Year Follow-up Study

Minjun Wang[1], Gong Yinhua[2] and Fei Xiao[3], [1]Gothic Internet Technology Corporation, Shanghai, China, [2]Cinkate Pharmaceutical Corporation, Shanghai, China, [3]Cinkate Corporation, Shanghai, China

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Leflunomide(LEF) is an effective immunosuppressant. In China, one phase III study has reported that compared with cyclophosphamide, LEF in combination with prednisone was effective in the induction therapy of proliferative lupus nephritis (LN). In 2009, The China Food and Drug Administration(CFDA) has approved LEF(leflunomide tablets, Cinkate) in the treatment of LN. However, long-term data of LEF in the maintenance treatment of LN are lacking.

To investigate the long-term outcomes of LEF in the maintenance treatment of LN in an open-label extension of a prospective multi-centre observational study.

Methods:

As the registration study, 70 patients were enrolled into LEF induction group with a loading dose of 50mg/day for 3 days, followed by 30mg/day for six months. The partial and complete remission rate was 52% and 21%. Among them, 15 patients voluntarily entered an open labeled extension study.

Results:

A total of 15 patients (mean age 39.9±7.7years) were treated with LEF for >12 months,the mean duration of LEF treatment was 11.5 years (range 8.0–13.6 years); 86.6% (13/15) of the patients were female. The mean disease duration was 14.2±3.5 years (range 8.5–23.4 years). During a median follow-up period of 11.9 years, 1 patient died from sepsis, 4 patients developed renal flare, none of patients developed in sustained doubling of serum creatinine or end-stage renal failure. The 12-year cumulative survival rates for the composite end point of death and chronic renal failure were 93.3% and 100%, respectively. At the final follow-up, the complete remission rate in the remaining patients was 64.28%(9/14), the partial remission rate was 35.72%(5/14),the mean proteinuria leval was 0.47g/day(range 0.09–1.62g/day), and the mean serum creatinine leval was 66.1umol/L(range 46-90umol/L).

Conclusion:

Our data suggest that a remission-inducing regimen of LEF followed by maintenance therapy with LEF resulted in good long-term patient survival and renal preservation. LEF can be considered as a option as maintenance therapy for patients with lupus nephritis, but its role as a long-term maintenance agent warrants further investigation.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Intravenous (IV) belimumab 10 mg/kg is approved in patients with active, autoantibody-positive systemic lupus erythematosus (SLE) as add-on to standard SLE therapy (SoC). This study aimed to assess the impact of belimumab on immune response to pneumococcal vaccination in patients with SLE.

Methods: This Phase 4, randomized, open-label study (GSK Study 115470; NCT01597492) was conducted at 13 centers in the United States. Patients were randomized (7:9) to receive a 23-valent pneumococcal vaccination 4 weeks prior to (pre-belimumab cohort) or 24 weeks after (concurrent belimumab cohort) commencing 4-weekly belimumab 10 mg/kg IV treatment. All patients received SoC. All analyses of vaccine titer were performed on the as-treated population, defined as all patients who received ≥1 dose of belimumab. The primary endpoint was the proportion of patients with positive antibody responses (≥2-fold increase from pre-vaccination levels or post-vaccination level ≥0.6 µg/mL if pre-vaccination levels were unquantifiable) to ≥1 of the 23 pneumococcal vaccine serotypes 4 weeks post-vaccination. Other endpoints included the proportion of patients with positive antibody responses to ≥2 to ≥10 of the serotypes. Safety was assessed by monitoring adverse events (AEs).

Results: A total of 79 patients were enrolled and randomized to receive the pneumococcal vaccine (pre-belimumab cohort, n=34, concurrent belimumab cohort, n=45). The majority (87.3% [69/79]) completed the study; 10 patients (12.7%) withdrew (patient request, n=3; AEs, n=3; lost to follow-up, n=2; other, n=2). At Week 4 post-vaccination, 97.0% (32/33) of patients in the pre-belimumab cohort and 97.6% (40/41) in the concurrent belimumab cohort had a positive response to ≥1 of the 23 pneumococcal serotypes (as-treated population). Similarly, little difference was observed across a broader response, with 87.9% (29/33) of patients in the pre-belimumab cohort and 85.4% (35/41) in the concurrent belimumab cohort responding to ≥10 of the serotypes. The proportion of patients with an AE considered by the investigator to be treatment-related was 23.5% (8/34) in the pre-belimumab cohort and 8.9% (4/45) in the concurrent belimumab cohort. There were seven patients with non-fatal serious AEs (pre-belimumab cohort, 11.8% [n=4], concurrent belimumab cohort; 6.7% [n=3]), and no deaths were reported.

Conclusion: The proportion of patients generating a response to ≥1 pneumococcal serotype did not differ between those who were vaccinated prior to commencing belimumab and those who were vaccinated after treatment with belimumab for 24 weeks. No significant difference was also observed across a broader response (from ≥2 serotypes to ≥10 serotypes). Study funded by GSK and Human Genome Sciences, Inc. Nicole Cash, MRes, PhD, Fishawack Indicia Ltd, UK, provided submission and editorial assistance, funded by GSK.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF-related weak inducer of apoptosis (TWEAK) promotes renal inflammation, mesangial proliferation, tubular cell death and fibrosis in lupus nephritis (LN). TWEAK acts through its receptor, Fn14, which is upregulated in inflamed tissue but not expressed on T or B cells. We postulated that blocking the TWEAK/FN14 pathway in lupus nephritis with BIIB023, a humanized monoclonal antibody against TWEAK, would attenuate inflammation and enhance the renal response to standard-of-care (SOC) therapy without compromising safety.

Methods: ATLAS is a phase II, placebo controlled, double blind, RCT to determine whether the addition of BIIB023 (3 mg/kg or 20 mg/kg q4wk) to MMF and steroids could increase the 52-week complete or partial renal response (RR) rates in patients with proliferative lupus nephritis. Patients had centrally verified biopsies demonstrating ISN/RPS class III or IV LN and urine protein creatinine ratio (UPCR) >1 mg/mg. All patients were induced with MMF and steroids during the run-in period, but only patients with persistent UPCR >0.5 mg/mg at week 12 were eligible for the addition of BIIB023 or placebo to SOC.

Results: The study enrolled 276 subjects and randomized 188 subjects. 38 (14%) subjects completed run-in but did not qualify for randomization. The trial was prematurely terminated with 145 completing BIIB023/placebo infusions through wk 44. This group was designated the modified-ITT group, with 48 patients on placebo, 49 patients on 3 mg/kg and 48 patients on 20 mg/kg. At wk 52, complete and partial RR were: placebo: 25% (95% CI 15-35); BIIB023 3 mg/kg: 16% (8-25), and BIIB023 20 mg/kg: 31% (20-42). There were no differences between placebo and BIIB023 in time to RR or duration of RR. Dose-dependent reductions of serum and urinary TWEAK were observed. Treatment emergent adverse events were reported in 76% and 85% of placebo and BIIB023-treated subjects respectively. Serious adverse events were reported in 11% and 17% of placebo and BIIB023-treated patients, respectively.

Conclusion: The addition of an anti-TWEAK monoclonal antibody to SOC LN therapy did not improve 52-week RR rates in proliferative LN despite observed pharmacodynamic effects. This unique LN trial design, which excluded subjects who responded rapidly to SOC, requires additional assessment in order to determine the merits of studying a cohort enriched in potentially less responsive patients.

Factors Associated With Oral Glucocorticoid Use in Systemic Lupus Erythematosus :

Results From a Large International Inception Cohort. Jayne Little[1], Mark Lunt[1], Ben Parker[1], Ian N. Bruce[1] and The Systemic Lupus International Collaborating Clinics (SLICC) Group, [1]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Institute of Inflammation and Repair, MAHSC, The University of Manchester, Manchester, United Kingdom

Background/Purpose: Glucocorticoids (GCs) are widely used in systemic lupus erythematosus (SLE). Whilst there is significant variability in how they are used, little is known about factors that explain this variability. We aimed to examine factors associated with oral GC use in a large international inception cohort.

Methods: From 2000-11, we recruited patients within 15 months of developing four or more 1997 American College of Rheumatology (ACR) criteria for SLE. Data including disease characteristics and treatment were collected at enrolment and annually thereafter. Univariate analyses were performed to explore the cross-sectional relationship between predefined demographic and clinical (independent) variables and two measures of GC use at enrolment: 1) Taking oral GCs (yes/no) and 2) Current average daily dose of oral GCs (prednisolone equivalent). For each GC outcome, independent variables significant in univariate analysis ($p<0.20$) were entered into multivariate models using backwards selection to create the final models. **Results:** We studied 1700 patients at enrolment including 1506 (88.6%) women of whom 1189 (70.0%) were taking oral GCs at a median (IQR) dose of 20 (10-30) mg daily. Over the period of study recruitment (2000-11, there was no significant temporal trend in the proportion of patients taking GC at enrolment nor in the doses used. As can be seen in Tables 1 and 2, a number of factors were independently associated with GC use including male sex, younger age, the use of immunosupressants, renal disease and higher SLEDAI2K. In addition, race/ethnicity was independently associated with higher GC use. Compared to Caucasians, the OR (95%CI) for being on GCs were 3.32 (CI: 2.14-5.15), 6.56 (CI: 4.02-10.71) & 2.80 (CI: 1.96-4.01) for patients of Hispanic, Asian and African descent respectively (table 1). Hispanics and patients of African ancestry were taking an average (CI) 3.57 (1.19-5.96)mg and 2.49 (0.16-4.82)mg more GC per day than Caucasians respectively (table 2).

On antimalarials (yes/no)		-5.154	-6.971, -3.337	0.000
On immunosupressants (yes/no)		5.585	3.847, 7.324	0.000
Systolic BP (mmHg)		0.0864	0.034, 0.139	0.001

Table 2: Multivariate linear analysis of factors associated with outcome 2 (average daily dose of oral GC at enrolment). Date of diagnosis was non-significant at univariate analysis (p=0.196). BMI, sex & diastolic BP were removed from the multivariate model through backwards elimination (p=0.879, 0.257 & 0.189 respectively).

Conclusion: Standard of care therapy for SLE remains inadequate and over the period of study recruitment there was no significant change in how GCs were used in this cohort. A number of factors independent of disease activity and phenotype correlate with GC use and GC dose taken including race / ethnicity. A better understanding of the sources of this variation (including disease factors, socioeconomic factors, access to healthcare and physician and patient choice) may help to reduce GC use in SLE.

Complement C4d Split Products on Erythrocytes Are Associated with Composite Measure of Disease Activity in Systemic Lupus Erythematosus Subjects Receiving Methotrexate and Hydroxychloroquine

Michelle Petri[1], Ying Qu[2], John Conklin[3], Kelley Brady[4], Robert Apilado[5] and Thierry Dervieux[6], [1]Rheumatology Division, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Exagen Diagnostics, Vista, CA, [3]1261 Liberty Way Suite C, Exagen Diagnostics, Vista, CA, [4]R&D, Exagen Diagnostics, Vista, CA, United Kingdom, [5]Exagen Diagnostics, vista, CA, United Kingdom, [6]Research and Development, Exagen Diagnostics, Vista, CA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

We evaluated the relationships between disease activity measures and C4d split products on erythrocytes (EC4d) in SLE subjects from a subset of the Hopkins Lupus cohort treated with methotrexate (MTX) and hydroxychloroquine (HCQ). We also determined compliance by determining blood levels of these medications.

Methods:

All subjects enrolled in this longitudinal study received MTX and HCQ for at least 6 months. Disease activity was assessed at each visit using the Physician Global Assessment (PGA) and the non-serological SELENA-SLEDAI (without low complement and anti-dsDNA components). Whole blood HCQ levels and red blood cells (RBC) methotrexate polyglutamate ($MTXPG_3$) levels were determined using liquid chromatography and communicated to the clinicians within 4 days of blood collection. Serum C3 and C4 levels were determined using standard immunochemistry techniques while EC4d was measured by quantitative flow cytometry (expressed as net mean fluorescence intensity [MFI] and log normalized for the analysis). Clinicians were blinded to EC4d levels throughout the study. Statistical analysis consisted of a linear mixed effects model with random intercept and fixed slope. Kruskall Wallis ANOVA was used as appropriate. Estimates are shown as average ± SEM.

Results:

Twenty-three subjects (all females, 56±3 years, average [SEM]) were enrolled and followed prospectively for at least two consecutive visits (average 4.5 visits per subject, total of 107 study visits). At baseline, whole blood HCQ levels were 1245±115 ng/ml (average dose 379±10 mg/day) and average RBC $MTXPG_3$ levels were 35±5 nmol/L (average dose 13.5±1.1 mg/week). Serum complement C3 was 105±6 mg/dl, C4 was 22±2 mg/dl, and EC4d density was 14±6 net MFI. Average ns-SELENA-SLEDAI and PGA were low in this population of SLE (1.3±0.3 and 0.6±0.1 points, respectively). Complete non-compliance to HCQ treatment (HCQ<50 ng/ml) was detected in one subject who was also not compliant to MTX therapy (RBC MTXPG<5 nmol/L). Following consultation, compliance to treatment improved as demonstrated by HCQ and $MTXPG_3$ levels rising to 539 ng/mL and 22 nmol/L at subsequent visits, respectively. Changes in C3, C4, EC4d were not associated with the change in PGA ($p>0.15$). In contrast, the change in EC4d was associated with the change in ns-SELENA-SLEDAI (intercept: 0.2±0.6, slope estimate [Log net MFI]: 0.7±0.2, $p=0.007$). Of the 107 study visits, 23 presented with active disease (ns-SELENA-SLEDAI score of 4 points or above), and 47 presented with inactive disease (ns-SELENA-SLEDAI score of 0 point). As presented in the Figure, heightened EC4d expression was associated with higher disease activity ($p<0.01$).

Conclusion:

This pilot study indicates that complement C4d split products deposited on erythrocytes are associated with the ns-SELENA-SLEDAI. Further investigations are required to establish the utility of this marker in the management of SLE.

Anti-Ro Positivity Is a Predictor of Responsiveness to Topical Steroids or Hydroxychloroquine in Patients with Discoid but Not Subacute Cutaneous Lupus

Rajaie Namas[1], Corey Powell[2] and J. Michelle Kahlenberg[3], [1]Department of Medicine [Division of Rheumatology], University of Michigan, Ann Arbor, MI, [2]Consulting for Statistics, Computing and Analytics Research, University of Michigan, Ann Arbor, MI, [3]Internal Medicine, Division of Rheumatology, Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) lesions are difficult to treat and medications are often chosen based only on provider experience. Thus, we chose to assess the role of autoantibodies in predicting the response to disease modifying medication in subjects with subacute (sCLE) and discoid (DLE) lupus.

Methods: 306 subjects with a biopsy proven CLE diagnosis at the University of Michigan (168 sCLE; 138 DLE) between 2000-2015 were studied. Subjects with more than 2 visits with either Rheumatology or Dermatology were included in this study to assess treatment response. Demographics, clinical, immunological and SLE-related medications, including topical corticosteroids and hydroxychloroquine (HCQ) were collected. The 1997 ACR SLE criteria were used to determine the presence or absence of systemic disease at the time of CLE diagnosis. Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) for either activity or damage were assessed at the time of diagnosis and on the subsequent follow-up visit to assess response. Univariate and multivariate logistic regression analysis was used to evaluate the role of anti-Ro positivity in CLASI activity, response to HCQ and topical steroids in DLE and sCLE patients.

Results: A female predominance was observed in both groups (sCLE: 84% and DLE: 79%) with a higher percentage of

whites in the sCLE (85%) and more African Americans in the DLE (38%) subset. Age at the time of skin biopsy was (mean ± SEM) 50±17 for sCLE and 46±12 for DLE; p=0.01. ACR criterion for SLE was met in 59% of subjects with sCLE and in 28% in DLE (P<0.01). In DLE, but not sCLE, patients,simple linear regression and multivariate linear regression adjusting for age, gender, race, SLE diagnosis, lupus nephritis, the ACR criterion, marriage status, thyroid cancer status, malignancy, ANA status, Anti-sm status, APS status, and dsDNA revealed that the presence of Anti-Ro Ab is associated with higher levels of CLASI activity at the time of biopsy (simple linear regression estimate for difference between Anti-Ro positive and Anti-Ro negative: 1.83, 95% CI for difference: 0.51-3.16; P=0.007 and multivariate estimate for difference 2.27, 95% CI 0.55-4; P=0.01). Univariate logistic regression revealed that the presence of Anti-Ro in DLE is associated with decreased response to HCQ (OR: 0.34, CI: 0.14-0.83; P= 0.02) and topical steroids (OR: 0.12, CI: 0.02-0.61; P= 0.01) but is associated with increased treatment response in sCLE patients for HCQ (OR: 2.28, CI: 1.20-4.39; P=0.01). Multivariate logistic regression adjusting for age, gender, SLE diagnosis, smoking, ANA status, and Anti-sm status suggested a trend toward increased response to topical steroids in the sCLE group (OR: 3, CI: 0.81-12.94,; p=0.11). No significant predictive value for anti-Ro was noted when patients were categorized as CLE-only vs. systemic lupus.

Conclusion: Sub-classification of CLE patients by cutaneous lesion subtype and anti-Ro antibody status may help to predict which patients will respond to first line treatments such as topical steroids or hydroxychloroquine. This knowledge may help to lower the threshold for changing or modifying treatment in patients with a higher risk of non-response.

Vitamin D Improves Systolic Blood Pressure in SLE

Michelle Petri[1], Erik Barr[2] and Laurence S Magder[3], [1]Rheumatology Division, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Epidemiology, University of Maryland, Baltimore, MD, [3]Epidemiology and Public Health, Division of Rheumatology, School of Medicine, Johns Hopkins University, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Vitamin D insufficiency/deficiency is common in SLE. Both a cohort study and a randomized clinical trial have proven that Vitamin D supplementation improves SLE global activity and the urine protein/cr ratio. We assessed whether there was an association between serum Vitamin D and blood pressure.

Methods: This analysis is based on clinic visits of a large SLE cohort after May 2009 when serum 25-hydroxyvitamin D was measured regularly. 1305 different patients were observed from 1 to 32 visits (the median was 10). The patients were 92% female, 50% Caucasian, 41% African American. Age ranged from 17 to 89. When the 25-OH Vitamin D level was below 40 mg/ml, the patient was prescribed supplemental vitamin D, usually 50,000 IU weekly.

Results: The “between-person” analysis addressed the question of whether those who tend to have low vitamin D also tend to have high systolic blood pressure. Among patients whose mean vitamin D was under 40, those whose mean vitamin D was 10 points higher had a mean SBP that was 3.8 mmHG lower (p<0.0001). For example, comparing those with a mean of vitamin D of 25 to those with a mean vitamin D of 35, we found a 3.8 mmHG lower mean SBP in the latter group

(Table 1). There was no evidence of an association between vitamin D levels and SBP among those with mean vitamin D greater than 40 (p=0.27 or p=0.31 for unadjusted or adjusted analysis respectively). Table 1: Difference in person-specific mean SBP per 10 ng/ml difference in person-specific mean vitamin D

Range of mean Vitamin D	Unadjusted		Adjusted[1]	
	Estimated difference in mean SBP per 10 ng/ml difference in mean Vitamin D (95% CI)	P-value	Estimated difference in mean SBP per 10 ng/ml difference in mean Vitamin D (95% CI)	P-value
0-40 ng/ml	-3.8 (-4.9, -2.8)	<0.0001	-3.5 (-4.5, -2.4)	<0.0001
40+ ng/ml	-0.7 (-2.0, 0.5)	0.27	-0.6 (-1.8, 0.6)	0.31

[1] Adjusted for age, age-squared, sex, race, proportion of time on Plaquenil, mean prednisone dose, mean BMI. The "within-person" analysis addressed the question of whether a person tends to have higher SBP when his/her vitamin D is lower than his average vitamin D (Table 2). Table 2: Difference in SBP at each visit per 10 ng/ml difference in the person's vitamin D at that visit and the person's average vitamin D.

Range of Vitamin D	Unadjusted		Adjusted[1]	
	Estimated difference in SBP (relative to a person's average SBP) as a function of differences in a person's Vitamin D levels (relative to that person's average Vitamin D levels)	P-value	Estimated difference in SBP (relative to a person's average SBP) as a function of differences in a person's Vitamin D levels (relative to that person's average Vitamin D levels)	P-value
0-40 ng/ml	-1.3 (-1.7, -1.0)	<0.0001	-1.3 (-1.7, -0.9)	<0.0001
40+ ng/ml	-0.1 (-0.3, 0.1)	0.48	0.1 (-0.4, 0.1)	0.30

[1] Adjusted for age, age-squared, sex, race, proportion of time on Plaquenil, mean prednisone dose, mean BMI. If a person's vitamin D was higher than her mean vitamin D by 10 ng/ml and she had vitamin D below 40 ng/ml, then the expected blood pressure will decrease by 1.3 mmHG (p<0.0001).

Conclusion: Both the "between person" and "within person" analyses provide evidence that among those with vitamin D below 40 ng/ml, a higher vitamin D level was associated with lower systolic BP. As with disease activity, achieving a level above 40 ng/ml did not lead to further improvement. Vitamin D supplementation has now been seen to help not just disease activity but also the most important traditional cardiovascular risk factor, hypertension.

The Duration of Anti-Malarial Agent Intake in the First 5 Years of the Disease and Prognosis in Patients with Systemic Lupus Erythematosus

Rattapol Pakchotanon[1], Dafna D. Gladman[2], Jiandong Su[2] and Murray Urowitz[3], [1]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, Centre for Prognosis Studies in the Rheumatic Diseases, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada, [3]Medicine, Centre for Prognosis Studies in the Rheumatic Diseases, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-malarial agents (AM) prevent damage in patients with systemic lupus erythematosus (SLE). We aimed to examine whether the duration of AM therapy early in the disease was associated with a reduced disease activity and the development of early damage in SLE.

Methods: An inception cohort was identified from among SLE patients, followed prospectively in a single Clinic between 1970 and December 2015. We identified the patients who had a minimum of 5 years of follow-up after the diagnosis of SLE. Duration of AM therapy was based on the percentage of the time that the patients took the medication. They were divided into three groups: patients who took AM more than 60% of the time (group A), those who took AM for less than 60% of the time (group B), and those who did not receive AM (group C) during the 5 years of follow-up. We compared the demographic, disease activity, and treatment variables among the three groups. The outcomes were measured between the baseline and the 5-year follow-up. These outcomes included the change of SLICC/ACR damage index (SDI), flare event (defined by any increase of SLE disease activity index-2K (SLEDAI-2K) between 2 consecutive visits), low disease activity at year 5 (defined by a clinical SLEDAI-2K score of 1-2 regardless of serology), adjusted mean SLEDAI-2K over 5 years of follow-up, and AM related retinal toxicity. Regression analysis models were constructed to identify the predictors of the outcomes in multivariate models controlling for gender, age, disease duration, ethnicity, disease activity, and treatment.

Results: A total of 459 patients were identified, 236 (51.4%) in group A, 88 (19.2%) in group B, and 135 (29.4%) in group C. At enrollment, gender, ethnicity, age, SLE duration, SLEDAI-2K and SDI were comparable in the three groups. The patients in group A had significantly lower cumulative dose of glucocorticoids (GC) compared to the patients in the other groups ($P<0.001$). Multivariate analysis revealed that the patients in group A had a lower risk of increasing SDI (relative risk = 0.71; 95% confidence interval (CI): 0.52, 0.95; $P = 0.02$) and were more likely to achieve low disease activity at year 5 (odd ratio = 1.96; 95% CI: 1.18, 3.26; $P = 0.01$) compared to the patients in group C. The patients taking AM more consistently had a lower cumulative dose of GC over the 5 years of follow-up ($P<0.0001$). There was only one patient with AM related retinal toxicity in each group.

Conclusion: Longer duration of anti-malarial therapy within the first 5 years of disease is associated with less disease activity and reduced risk of early progressive damage in patients with SLE.

Hydroxychloroquine Blood Level Monitoring in a Predominantly Hispanic Systemic Lupus Erythematosus Cohort

James Miceli[1], Kayla Neville[1], Laura Geraldino-Pardilla[2] and Anca D. Askanase[3], [1]Rheumatology, Columbia University Medical Center, New York, NY, [2]Division of Rheumatology, Columbia University College of Physicians & Surgeons, New York, NY, [3]Department of Medicine, Rheumatology, Columbia University College of Physicians & Surgeons, New York, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose**:** Hydroxychloroquine (HCQ) is recommended for all patients with SLE. While patient reported adherence rates are between 51-64%, blood HCQ level testing may be a more accurate measure of compliance. This study aimed to evaluate the role and feasibility of blood HCQ level monitoring in a predominantly Hispanic, socioeconomically disadvantaged SLE cohort.

Methods : This is a cross-sectional study of SLE patients treated with HCQ 200–400 mg/day at the Columbia University Lupus Center. HCQ levels were measured from samples obtained during routine blood draws by high performance liquid chromatography (Avise HCQ, Exagen Diagnostics ©). Patients on HCQ for ≥ 6 months were included; patients who admitted to non-adherence before testing were excluded. Differences in demographic and clinical features between patients with therapeutic and sub-therapeutic levels were evaluated.

Results : 55 patients had blood HCQ levels tested. 50 (90.9%) were women, 41 (74.5%) Hispanic, and 8 (14.5%) Black. 46 (83.6%) resided in the Bronx or Washington Heights; 41 (74.5%) were insured by public assistance programs. 28 (50.9%) were on additional immunosuppressants; 8 (14.6%) had abnormal renal function. The mean SLEDAI was 4.7 (range 0-20). Therapeutic blood HCQ is considered to be ≥ 1000 ng/mL based on prior data; in this cohort, median HCQ level was 722 (range 0-2466 ng/mL); 34 (61.8%) patients had sub-therapeutic levels (mean 346.6 ng/mL), and 10 (18.2%) had undetectable levels. Hispanic ethnicity and normal renal function were associated with sub-therapeutic HCQ. Patients on mycophenolate mofetil (MMF) for any indication were more likely to have therapeutic HCQ (Table). In a subset of patients on MMF with concurrent mycophenolate levels (n=7), the two drug levels correlated (r=0.544). Median SLEDAI scores were 2 in patients with therapeutic HCQ vs. 5 in sub-therapeutic patients (p=0.066). SLEDAI scores inversely correlated with HCQ levels (r= -0.326).

Conclusion : 62% of SLE patients in this cohort had sub-therapeutic HCQ levels despite self-reported adherence, suggesting that blood HCQ testing may be more accurate at assessing compliance. Low HCQ levels were associated with increased SLE activity; routine testing of HCQ levels and compliance counseling—especially when immunosuppression is withdrawn—is likely to improve outcomes. Future studies are needed to identify how genetics, renal clearance, and MMF might affect HCQ's pharmacokinetics.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

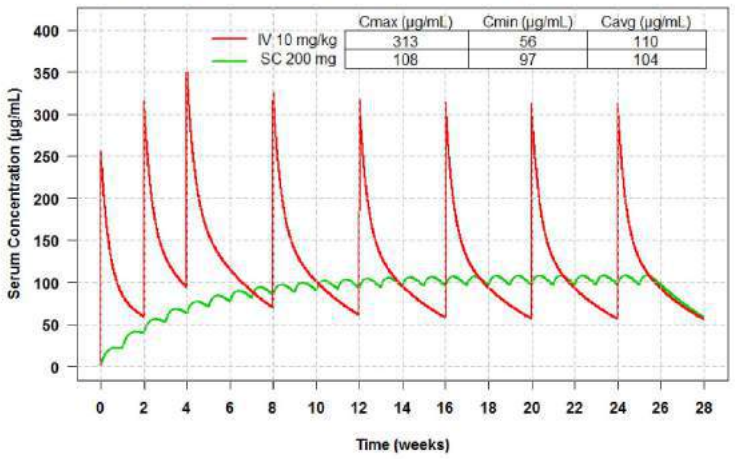
Session Time: 9:00AM-11:00AM

Background/Purpose: Monthly (q4w) intravenously (IV) administered belimumab 10 mg/kg is approved for the treatment of adults with active, autoantibody-positive SLE receiving standard therapy. The present analysis was conducted to characterize the exposure and exposure-response of belimumab administered subcutaneously (SC) in adult SLE patients.

Methods: Belimumab PK (n=554) and clinical response data from the SC SLE Phase 3 trial (BEL112341/NCT01484496) combined with serially sampled PK data in healthy volunteers from two Phase 1 trials (n=134; BEL114448/NCT01583530, BEL116119/NCT01516450) were analyzed with a population PK/PD (popPK/PD) approach. Following popPK model development, typical PK profiles were simulated using population parameters from this analysis and the IV popPK. A logistic regression model for efficacy response (SRI; SLE Responder Index) was developed to characterize dependencies of SRI response to individual exposures and other patient characteristics.

Results: The PK of belimumab administered SC was best described by a linear 2-compartment model with first order absorption and absorption lag time with a terminal half-life of 18.3 days. Body weight, BMI, albumin and IgG had statistically significant effects on the PK parameters, albeit with a minor effect size compared to random exposure variability. Simulations with PK parameters from this and the IV popPK analysis, demonstrated that the weekly 200 mg SC regimen results in steady-state Cavg equivalent to the 10 mg/kg IV every 4 weeks regimen (Fig.1). In the final SRI logistic regression model exposure (Cavg) was not statistically significant (α=0.05); only baseline disease activity (SELENA-SLEDAI), proteinuria (>0.5 g/day), African-American and American-Indian/Alaskan-Native race categories were identified as significant predictors of responder status.

Fig. 1: Comparison of simulated PK profiles and steady-state PK parameters for proto-typical subject receiving belimumab IV 10 mg/kg 3xq2w then q4w vs. SC 200 mg qw



Conclusion: 200 mg SC qw dosing in SLE patients resulted in steady-state belimumab Cavg comparable to the Cavg for 10 mg/kg IV q4w dosing, the approved belimumab IV dosing regimen. The popPK/PD analysis showed that exposure did not have a statistically significant impact on the SRI response. These results confirm that 200 mg qw belimumab is appropriate for subcutaneous administration to SLE patients and that no dose adjustment is required for adult patients to maintain efficacy and safety demonstrated in BLISS-SC. **Disclosure:** GSK funded this study.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Multiple outcome measures have been utilized in SLE clinical trials. Consistency of response assessed by different instruments enhances confidence in the efficacy of pharmacologic interventions. We recently reported results from both phases of a two-part pilot study [8 week double-blind (DB) placebo (PBO)-controlled phase followed by a 44 week open-label extension (OLE)] of repository corticotropin injection (RCI) in subjects with persistent SLE disease activity requiring corticosteroids. Although the primary endpoint of the DB phase (a novel responder index described below, assessed at Week 4) was not met, RCI therapy led to improvement in several measures of disease activity by week 8. This post hoc analysis evaluated the efficacy of RCI over the entire 52 week study, as assessed by multiple standard disease activity indices (DAIs) and by a novel composite measure of organ-specific disease activity.

Methods: Thirty eight subjects with active SLE including rash and/or arthritis despite moderate dose corticosteroids were randomized to RCI (n=26) or PBO (n=12) for the DB period; 33 completed through Wk 8 and entered the OLE (RCI/RCI n=22, PBO/RCI n=11), and 20 completed through Week 52 (RCI/RCI, n=13; PBO/RCI, n=7). There were 36 subjects in the mITT population (RCI/RCI, n=25; PBO/RCI, n=11). Efficacy of RCI was assessed every 4 weeks by total BILAG, SLE responder index (SRI), Cutaneous Lupus Disease Area & Severity Index (CLASI) Activity, Tender & Swollen Joint Count, Physicians Global Assessment (PGA), severe flare by SFI, and by hybrid SLEDAI (hSLEDAI) score every 2 weeks for the first 8 weeks, then every 4 weeks for the remainder of the combined 52 week study. A novel organ-specific composite responder index, defined as decrease in hSLEDAI score from 4 to 0 for arthritis OR decrease in hSLEDAI score from 2 to 0 for rash AND no BILAG worsening in any other organ systems as compared to study baseline, was also evaluated at 4 week intervals. RCI dose was defined by the protocol during the DB phase (Weeks 1-8), but could be adjusted within specified parameters by the investigator to achieve stable improvement in disease activity during the OLE (Weeks 9-28). Corticosteroid dose was required to remain stable through Week 20, after which taper was encouraged.

Results: See Table

Conclusion: Disease activity, reflected by several standard outcome measures, was generally concordant at both Weeks 8 and 52, with improvement in most DAIs seen at Week 8 for subjects randomized to RCI, but not PBO, during the DB phase, and for all subjects in the OLE at Week 52. Directional trends in the novel organ-specific responder index employed were similar to those for standard DAIs at week 8 but did not seem to mirror other DAIs at Week 52. Inconsistency between the novel organ-specific responder index and standard DAIs at Week 52 likely relate to a higher BILAG threshold to be considered a responder for the novel index.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Corticosteroids (CSs) are widely used in Systemic Lupus Erythematosus (SLE) patients, but have side-effects when used for prolonged periods of time. Our aim was to obtain a better understanding of the relationship between exposures to CSs and adverse events (AEs) in a large trial.

Methods: We used data from the BLISS-76 trial, phase 3 randomized, placebo-controlled study of belimumab[1]. Reported AEs were grouped according to medical relevance. The frequencies of these groups were compared between the lowest versus the highest tertile of cumulative CS doses. Additionally, we studied the relationship between AEs and patients with and without CSs at baseline.

Results: 991 AEs were reported in 819 patients of the trial. Of 714 patients (86%) treated at least once with CSs prior/during the trial, 235 were in the lowest tertile of cumulative CS dose(<5.3g) and 236 in the highest (≥10.5g) tertile. The following AEs: viral upper respiratory tract infection, viral gastroenteritis, allergic rhinitis, sinusitis, arthralgia, dental caries and bronchitis were more frequent in the lowest as compared to the highest tertile of CS doses. Only tachycardia and proteinuria were significantly more frequent in the highest tertile (Table1). Eight groups of AEs were more frequent in the lowest tertile as compared to the highest (Table2). At baseline, 76% of patients were treated with CSs. The frequencies of 4 AEs (anaemia, pyrexia, oral herpes and malaise) were significantly higher compared to those not treated with CSs. Conversely, the frequencies of several AEs was higher in patients without CSs at baseline (Table 3), most notably; asthma, infusion related reaction, nausea, seasonal allergy, sinusitis and viral upper respiratory tract infection.

Conclusion: Our study demonstrates the association of CSs with CS-specific AEs in a large RCT and highlights the feasibility of post-hoc analysis of data from RCT to extract valuable safety signals. Contrary to expectations, there were also associations between lower cumulative CS dosage and a range of AEs.

AEs	AEs with Cumulative CS Dose (%)		P value

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Steroids are widely used in clinical practice for treating systemic lupus erythematosus (SLE), and can have a strong effect on immune cells in Whole Blood (WB), especially B cells and T-cells. Steroids are often used as background medication during clinical trials of SLE drugs and therefore can easily confound efficacy end points associated with therapies targeting B cells and T cells in the trials. Moreover, response to steroids might vary from individual to individual and might not completely agree with protocol steroid usage. Our goal is to create a gene signature as an objective measure of steroid response that can be used in SLE trials to aid in the interpretation of potential confounding steroid effects.

Methods: We conducted 5 in vitro experiments where PBMCs from normal healthy volunteers were treated with prednisolone. Differential gene expression analysis identified genes that were up regulated by prednisolone treatment, and 64 common genes were identified as a potential prednisolone gene signature. Composite scores of the prednisolone signature were calculated using the Single-sample Gene Set Enrichment Analysis (ssGSEA) algorithm (Barbie et al., 2009) for WB samples treated in vitro with prednisolone. The same was done for whole blood samples from normal healthy subjects who had in vivo administration of either a selective glucocorticoid receptor agonist (SEGRA) or prednisolone in a phase I study. The prednisolone signature was further investigated in baseline WB samples of SLE patients from a multicenter, exploratory, phase IIb randomized, double-blind, placebo controlled trial, and signature scores were compared to neutrophil counts and protocol steroid usage.

Results: Both the in vitro and in vivo studies showed the high specificity of the prednisolone signature. When applied to WB gene expression data from SLE patients, the prednisolone signature scores were positively correlated with neutrophil counts (CBC) in WB, and negatively correlated with in vitro derived T cell and B cell signature scores. Both of these observations can be explained by the steroid mechanism of action. Steroid signature scores did not completely correlate with protocol steroid usage.

Conclusion: We identified a highly specific steroid gene signature that can be used to account for effects of steroids in global clinical trials where PAX gene tubes are routinely collected.

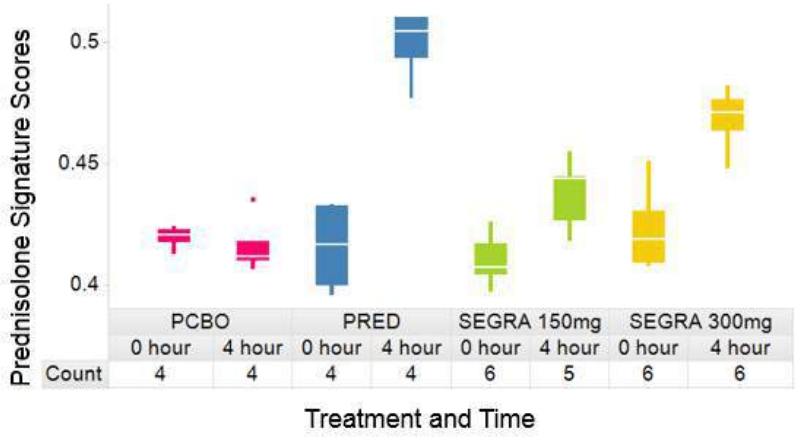

Figure 1: Prednisolone signature scores increased in a dose responsive manner in GR compound trial.

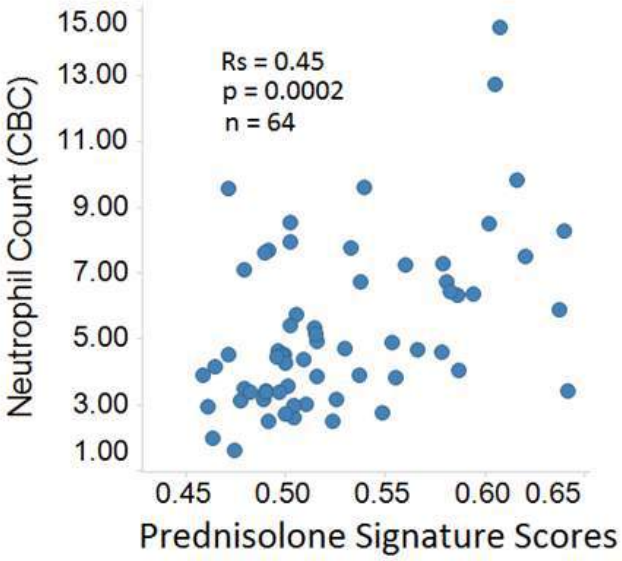

Figure 2: Prednisolone signature scores significantly correlate with netrophil counts in WB from baseline SLE patients

Effects of Type I Interferon Inhibition on Blood Leukocyte Subsets in Patients Treated in a Phase IIb Clinical Study of Anifrolumab in SLE

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A Phase IIb randomized controlled study (NCT01753193) was conducted with anifrolumab, a fully human, anti-interferon (IFN)–α receptor (IFNAR1) specific antibody in adults with moderate to severe systemic lupus erythematosus (SLE). Anifrolumab binds to subunit 1 of the IFNAR and inhibits the activity of all type I IFN. A complete blood count (CBC) analysis demonstrated that anifrolumab reversed leukopenia. However, the types of peripheral immune cells affected following treatment have not been reported. To better understand how changes in the immune cell repertoire may be associated with SLE severity, the type I IFN test status (IFN high vs. IFN low), and treatment with anifrolumab, we performed flow cytometry to assess several peripheral blood cell types: dendritic cells (myeloid and plasmacytoid), B cells (naïve, memory, and plasma cells), neutrophils, and T cells (CD4, CD8, naïve, memory, central memory, and effector).

Methods: Patients were randomized to anifrolumab at 300, 1,000 mg, or placebo (PBO) every 4 weeks for 48 weeks. Peripheral blood was collected from a subset of patients (91 total) on days 1 (prior to first dose), 85, 141, 169, 253, 337, and 365. Patients were approximately evenly distributed between the treatment and PBO groups. Baseline absolute immune cell numbers were compared over treatment course in the context of SLEDAI scores, the type I IFN test, and response to therapy. Statistics were calculated using the Student's t-test, and p-values ≤ 0.05 were considered significant.

Results: At baseline, several blood cell types were lower for patients with SLEDAI $\geq$10 including naïve B cells, and memory T and B cells. In IFN-high patients, neutrophils, memory T cells, and plasmacytoid dendritic cells (pDCs) were significantly decreased. Anifrolumab led to significant increases in absolute numbers of T-cell subsets in the blood of IFN-high patients. In contrast, no significant changes were observed for IFN-low patients. Observed increases were within normal reference ranges. The alterations did not appear to be secondary to tapering of oral corticosteroids, as these cell types were not significantly different in PBO groups, regardless of tapering. Patients with $\geq$6-point SLEDAI reductions following anifrolumab demonstrated significant increases in total CD4 and CD8 T cells, and decreases in memory B cells Significant increases in pDCs were also evident. Anifrolumab did not cause significant differences in the other cell types measured.

Conclusion: Memory T cells numbers, among other cell types, were significantly reduced in patients with SLEDAI $\geq$10 and those classified as IFN-high at baseline suggesting that, for patients with more severe disease, type I IFN may be involved in cell migration into the peripheral tissues from the blood. Consistent with this, we found that neutralization of type I IFN with anifrolumab promoted immigration and/or prevented emigration of potentially pathologic immune cells between the tissues and the blood. These data suggest that some of the effects observed following anifrolumab treatment might be a result of altering the migration patterns of T and other immune cells, which may partially explain its biological activity.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anifrolumab is a fully human IgG_1 monoclonal antibody directed against subunit 1 of the type I interferon–α receptor (IFNAR1) currently in development for the treatment of systemic lupus erythematosus (SLE). An exposure-response (E-R) model was developed to support the rational dosage selection for the pivotal anifrolumab studies.

Methods: In the Phase IIb MUSE study (NCT01438489),[1] adult patients with seropositive moderate to severe SLE, who had inadequate responses to standard-of-care (SOC) medications, were randomized 1:1:1 to receive anifrolumab 300 or 1,000 mg or placebo intravenously every 4 weeks, in addition to SOC medications, for 48 weeks. Patients were stratified by interferon (IFN) test status as IFN high or IFN low based on a validated 4-gene expression assay, dosage of oral corticosteroid (<10 or ≥10 mg/day of prednisone or equivalent), and SLEDAI–2K score (<10 or ≥10) at screening. A mechanistic target-mediated drug disposition model, previously developed for a first-in-human study in scleroderma patients,[2] was used to describe the pharmacokinetics (PK) of anifrolumab. The dichotomous efficacy endpoint, SLE responder index [SRI(4)], was modeled using logistic regression. A dropout hazard function was introduced to describe the voluntary patient withdrawals during the treatment period. Clinical simulations were conducted to evaluate different dosing scenarios in patients with SLE.

Results: There was no PK difference between patients classified as IFN high or IFN low. SRI(4) modeling suggested there was no treatment effect of anifrolumab in IFN-low patients, although the interpretation of this result could be limited by the small sample size. In IFN-high patients, a log-linear logistic model was selected to describe the treatment effect of anifrolumab. Patient dropouts were more likely in nonresponders. Clinical simulations demonstrated dosages less than 300 mg would result in inadequate PK exposure and suboptimal efficacy in some patients with SLE. In contrast, simulations indicated minimal improvement in efficacy for dosages higher than 300 mg, consistent with the outcome observed in the Phase IIb MUSE study.

Conclusion: Based on E-R analyses and overall risk assessment, an every-4-week 300-mg intravenous dosage regimen is recommended for pivotal anifrolumab trials in patients with SLE. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: B cell depletion therapy based on rituximab is a therapeutic option for refractory disease in patients with Systemic Lupus Erythematosus (SLE). Hypogammaglobulinemia can be an important adverse outcome of B-cell depletion therapy with rituximab (a chimeric anti-CD20 monoclonal antibody). However, the probability of, and factors associated with, the incidence of persistent hypogammaglobulinemia after rituximab in the routine clinical setting, has not been explored. The aim of this observational study was to explore long-term effects on B cell function by following serum immunoglobulin levels in patients with SLE treated with rituximab in routine clinical practice.

Methods: In this cross-sectional observational study, we included 57 consecutive patients with SLE treated with rituximab and concomitant/sequential immunosuppressants and measured serum total IgG, IgM, and IgA and IgG anti-dsDNA antibodies over a median of 48 months most recent follow-up. Flow cytometry was used prospectively to assess B-cell phenotypes in 17/57 patients.

Results: Lupus Nephritis was diagnosed in 29/57 (51%) patients with similar percentages in each group (7/12 (58%) in the low IgM group and 22/45 (49%) in the normal IgM group). All patients had received previous treatment with at least 2 different immunosuppressants not including corticosteroids, which were continued at a low dose (<10mg/day prednisolone). We noted a hierarchy in percentage reduction, IgM > IgG > IgA (-18.4%; -2.8% ; 10.3%). Twelve patients (22%) had persistent IgM hypogammaglobulinemia (<0.4 g/L) and 3/55 (5%) had low IgG (<7g/L) at most recent follow-up (range 12-144 months). This was not associated with serious adverse events or high anti-dsDNA antibodies (≥1000IU/ml; normal<50IU/ml). Factors predictive of low serum IgM included: baseline serum IgM ≤0.8g/L (receiver-operated-curve analysis) and subsequent therapy with mycophenolate mofetil (MMF) (odds ratio=6.8 compared with other immunosuppressants). In patients maintaining normal IgM levels (9/17 included), the frequency of circulating IgD+CD27+ B cells was significantly higher (*p=0.05*). 7/30 SLE patients with baseline anti-dsDNA≤1000 IU/ml lost seropositivity 12 months after rituximab.

Conclusion:

- In SLE patients at long-term follow-up after multiple cycles of rituximab IgG hypogammaglobulinaemia was rare
- Rituximab normalized raised IgG in the majority of patients
- Low levels of serum total IgM presented in a quarter of SLE patients and were associated with low baseline levels, older age and sequential therapy with mycophenolate mofetil
- Low IgM was not associated with persistently high levels of antibodies to dsDNA

Therefore, lower baseline serum IgM levels and sequential therapy with MMF are predictive of IgM hypogammaglobulinemia after rituximab in SLE, but this was not associated with higher levels of anti-ds DNA antibodies or an increased risk of infections. This provides useful directions for clinicians regarding rituximab and sequential immunosuppressive treatment for patients with SLE.

Rituximab As a Corticosteroid-Sparing Agent in Patients with Systemic Lupus Erythematosus

Na Ri Kim[1], Jung Su Eun[1], Jong Wan Kang[1], Eon Jeong Nam[1] and Young Mo Kang[2], [1]Division of Rheumatology, Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, Korea, Republic of

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

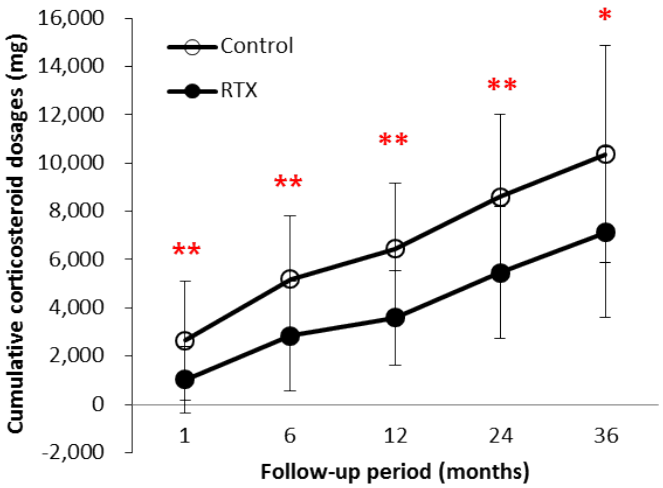
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : The treatment of active systemic lupus erythematosus (SLE) remains problematic because the current treatment regimen based on corticosteroids and immunosuppressive agents have significant side effects. Rituximab (RTX), a chimeric monoclonal antibody that selectively targets CD20-positive B cells, has proven optimistic results in a number of open-label trials, despite the fact that two randomized controlled trials in SLE did not meet the primary end points. In this study, we evaluated the efficacy of RTX as a steroid sparing drug in patients with moderate to severe SLE.

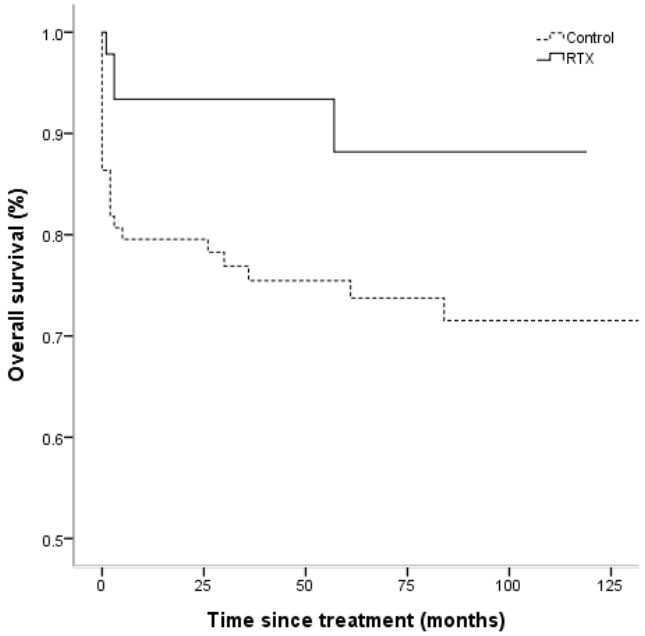
Methods : All patients satisfied the American College of Rheumatology 1997 revised criteria for SLE. Forty-six patients who were treated with immunosuppressive regimen including RTX (RTX group) were enrolled in this retrospective study. To compare the outcomes, SLE patients who were treated with immunosuppressive regimen that did not include RTX were matched for SLE Disease Activity Index (SLEDAI) score in 2:1 ratio compared to RTX group. Data of the disease activity, infection rate and mortality, treatment modalities, and cumulative dosages of corticosteroid and cyclophosphamide were collected at baseline and at 1-, 6-, and 12-month, then every 12 months up to 36 months of follow-up.

Results : Disease activity was similar in the RTX and control groups with mean SLEDAI scores of 22.3 ¡¾ 12.0 and 22.2 ¡¾ 12.0, respectively at baseline and 4.5 ¡¾ 6.2 and 3.5 ¡¾ 3.1, respectively at 36 months of follow-up. The cumulative corticosteroid doses at month 1 and 36 in the RTX group (1020.5 ¡¾ 1379.2 and 7130.1 ¡¾ 3548.7 mg, respectively) were significantly lower that those of the control group (2640.9 ¡¾ 2450.8 and 10371.7 ¡¾ 4489.7 mg, respectively). The difference in cumulative corticosteroid dosages at each visit, remained significant at all follow-up time points.



$^{**}p < 0.001$, $^{*}p = 0.002$

The mean cumulative dose of cyclophosphamide was lower in the RTX group compared with that in control group (2639.2 ¡¾ 3085.5 mg vs. 4169.5 ¡¾ 2464.0 mg, $p = 0.028$). Frequency of infection was significantly lower in RTX group (1.3 ¡¾ 1.5 vs. 1.9 ¡¾ 1.7 in control group, $p = 0.040$). The survival rate was significantly higher in RTX group compared with that in control group (91.3% vs. 73.9%, $p = 0.022$).



Conclusion : These data indicate that addition of RTX in standard immunosuppressive regimen revealed steroid-sparing effects for the treatment of moderate to severe SLE while it significantly improved the mortality and morbidity. Further studies with larger number of patients are needed to confirm the value of RTX.

Atacicept: Integrated Safety Profile from Phase II Randomized Placebo-Controlled Studies in Autoimmune Diseases

Patricia Fraser, Wai Chin and Amy Kao, EMD Serono, Billerica, MA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Atacicept, a recombinant fusion protein, targets both BLyS (B lymphocyte stimulator) and APRIL (a proliferation-inducing ligand), B cell activating factors involved in the pathogenesis of B cell-driven autoimmunity. This study aims to summarize safety data from double-blind, placebo-controlled, phase II studies of atacicept in autoimmune diseases.

Methods: Safety data were pooled from 7 studies of atacicept 25, 75 or 150 mg in rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), multiple sclerosis (MS), optic neuritis (ON), and lupus nephritis (LN).

Results: A total of 1262 subjects were included (RA, n=513 [41%]; SLE, n=455 [36%]; MS, n=254 (20%); ON, n=34 (3%); LN, n=6 [1%]); 30% received placebo (PBO), and 10.2%, 22%, and 37.1% received atacicept 25, 75, or 150 mg, respectively. Treatment-emergent adverse events (TEAEs) were similar across groups (atacicept: 75.2%, 77.7% and 75.6% with 25 mg, 75 mg and 150 mg; PBO: 72.3%) (Table 1). Infections/infestations were the most frequent TEAE (atacicept: 33.3%, 47.9% and 49.1% with 25 mg, 75 mg and 150 mg; PBO: 43.1%) and were reported in subjects with SLE (62.4%, 60.4% with 75 mg and 150 mg; PBO: 55.2%), RA (34.8%, 19.4%, 37.4% with 25 mg, 75 mg and 150 mg; PBO: 32.7%), MS/ON (31.7%, 39.7%, 62.2% with 25 mg, 75 mg and 150 mg; PBO: 40.0%), and LN (75% with 150 mg; PBO: 0%). Pneumonia was the most common serious TEAE (atacicept: 0%, 2.1% and 1.1% with 25 mg, 75 mg and 150 mg; PBO: 1.0%) and the most common severe TEAE (atacicept: 0%, 1.1%, 0.9% with 25 mg, 75 mg and 150 mg; PBO: 0.5%). SLE subjects accounted for the majority of serious and severe pneumonia cases (80% and 67%, respectively). Six treatment-emergent deaths were reported (n=3, 2, 1 in RA, SLE, MS), atacicept n = 1, 1, and 3 with 25 mg, 75 mg and 150 mg, PBO n=1; mortality rate/100 subject-years was atacicept 1.05 vs. PBO 0.43. Herpes zoster (HZ) infections were mild/moderate and infrequent (1.3%) but occurred more commonly with atacicept (1.6% vs 0.8%, with atacicept [n=14] vs PBO [n=3]). All 3 PBO-treated subjects and 57% atacicept-treated subjects with HZ had SLE. The proportion of subjects experiencing HZ by dose was: 25 mg (0.8% overall); 75 mg (1.8% overall; 2.5% SLE); and 150 mg (1.7% overall; 2.8% SLE). No serious HZ infections were reported with atacicept.

Conclusion: TEAE rates were similar between atacicept and PBO groups, with infections the most commonly reported. Subjects with SLE appeared more likely to develop infection-related TEAE (ie, HZ) and serious/severe TEAE (ie, pneumonia). Numbers of deaths were low and were observed across the diseases. The safety profile of atacicept appears to be similar to other B cell-targeted therapies, and is being further evaluated in clinical studies of SLE patients. **Table 1. Overall analysis set**

High Baseline B Lymphocyte Stimulator (BLyS) Levels Predict Response While Smoking and Organ Damage at Baseline Predict Failure to Belimumab in Three Swedish Clinical Practice Settings

Ioannis Parodis[1], Christopher Sjöwall[2], Andreas Jönsen[3], Agneta Zickert[1], Daniel Ramsköld[1], Martina Frodlund[2], Laurent Arnaud[1], Vivianne Malmström[1], Anders A. Bengtsson[3] and Iva Gunnarsson[1], [1]Department of Medicine, Rheumatology Unit, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [2]Rheumatology/AIR, Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden, [3]Lund University, Department of Clinical Sciences, Rheumatology, Lund, Sweden

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Belimumab is a biologic drug approved to treat Systemic Lupus Erythematosus (SLE). The efficacy of belimumab has been demonstrated in phase III clinical trials. Here, we provide results from real-life

experiences in three Swedish clinical practice settings, with focus on predictors of treatment response. As smoking is coupled with unfavourable prognosis and treatment outcomes, we particularly looked at the effects of smoking on treatment response to belimumab.

Methods: Fifty-eight patients from Karolinska (n=30), Skåne (n=19), and Linköping (n=9) University Hospitals treated with belimumab were enrolled and followed longitudinally. Global disease activity was assessed using the SLE Disease Activity Index 2000 (SLEDAI-2K), British Isles Lupus Assessment Group (BILAG) index, and a 100 mm Visual Analogue Scale (VAS) for Physician's Global Assessment (PGA). Organ damage was evaluated using the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI). Response to treatment was defined in line with the SLE responder index (SRI) as a reduction of ≥4 points in SLEDAI-2K, no new BILAG A or ≤1 new BILAG B, and no deterioration in PGA by ≥30 mm. B lymphocyte stimulator (BLyS) levels were determined by ELISA (R&D Systems).

Results: SLEDAI-2K decreased over time (median baseline score: 8.0; IQR: 4.0–13.8; p<0.0001), corresponding to a decrease of 3.9 over one year and 5.5 over three years. PGA decreased also (p<0.0001), corresponding to a decrease of 28.2 over one year and 39.7 over three years. We also observed decreasing prednisone equivalent dosages (p<0.0001), corresponding to a decrease of 6.3 mg/day over one year and 8.9 mg/day over three years (median baseline dose: 10.0 mg/day; IQR: 7.5–15.0). SDI scores remained stable (p=0.16). We found that a baseline SLEDAI-2K score ≥10 yielded a 2.5-fold increase in the probability of SRI response (HR: 2.553; 95% CI 1.339–4.896; B: 0.937; p=0.004). Baseline prednisone equivalent dosages also predicted SRI response (HR: 1.029; 95% CI 1.003–1.056; B: 0.029; p=0.029). An SDI score >1 at baseline yielded a >2-fold decrease of the probability to attain SRI response (HR: 0.449; 95% CI: 0.208–0.967; B: -0.801; p=0.041). After adjustment for baseline SLEDAI-2K scores and prednisone equivalent dosages, ever smokers had a decreased probability to attain SRI response compared with never smokers (HR: 0.460; 95% CI: 0.223–0.951; B: -0.776; p=0.036), and current smokers showed also a lower probability to attain SRI response compared with non-current smokers (HR: 0.103; 95% CI: 0.025–0.427; B: -2.276; p=0.002). Moreover, higher baseline BLyS levels predicted SRI response after adjustment for the same items (HR: 1.609; 95% CI: 1.149–2.252; B: 0.475; p=0.006).

Conclusion: In this real-life observational study, disease activity and corticosteroid usage decreased while damage remained stable during treatment with belimumab. Higher baseline SLEDAI-2K scores, corticosteroid dosages and BLyS levels predicted treatment response, whereas smoking and established damage at baseline predicted failure to belimumab treatment. Our results might contribute to a better selection of patients who are likely to respond to belimumab treatment.

Withdrawal of Mycophenolate Mofetil after Maintenance Treatment of SLE Nephritis Associated with Renal Relapse

H. Michael Belmont[1] and **Adey Berhanu**[2], [1]New York University School of Medicine, New York, NY, [2]Rheumatology Fellowship Program, NYU Langone Medical Center/NYU School of Medicine, New York, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Current ACR and EULAR evidence based guidelines provide recommendations for therapeutic choices to induce and maintain remission of lupus nephritis, however, the appropriate duration of maintenance treatment remains unclear. Data from the ALMS, MAINTAIN, and NIH-funded clinical trials in support of duration greater than three years is absent. In an effort to balance drug toxicities with the desire to prevent late disease recurrence some authors recommend maintenance therapy for as long as five years. There is an active NIH sponsored clinical trial for randomization of MMF maintenance withdrawal in SLE patients in remission, however, these results are not yet available. We analyzed the prevalence of renal flare after MMF maintenance therapy withdrawal in NYUÕs large, multi-ethnic cohort of SLE patients.

Methods: We queried the NYU SAMPLE Lupus Registry and biorepository to identify SLE nephritis patients with complete response who experienced renal flare within 12 months of discontinuing maintenance MMF therapy. The NYU SLE SAMPLE registry was initiated in September 2013 and includes 612 patients fulfilling ACR and/or SLICC criteria for SLE of which 42% have clinical nephritis.

Results: The NYU SAMPLE registry has 612 SLE patients (90% female; mean age 43.0±0.9 years), 54% Caucasian, 31% African American, 15% Asian; 30% Hispanic white, 5% Hispanic Black and 256 patients (42%) have nephritis. Of the 256 SLE nephritis we identified four patients with renal relapse within 12 months of MMF withdrawal summarized in Table 1. Table 1. Characteristics of patients with renal flare after MMF maintenance treatment withdrawal

	Case 1	Case 2	Case 3	Case 4
Age (years)	38	35	64	48

Urine Protein:Creatinine (g)	3.9	3.6	7.5	2.2
Albumin (g/dL)	3.4	2.8	3.0	4.1
Medications continued after MMF withdrawal	HCQ	HCQ, ARB	ARB	HCQ, ACE

*Patient with renal flare within 2 months upon the initiation of MMF tapering from 2g to 0.5mg daily.

Conclusion: In the two year period between 3/2014 and 3/2016 we identified 4 patients with a renal relapse within 12 months of maintenance therapy withdrawal. All of the patients were on MMF for maintenance and for a duration >4 years of treatment. Based on this experience we recommend that maintenance of SLE GN with MMF absent contraindication should be at least 5 years and in the interval after withdrawal at any juncture careful monitoring and laboratory studies should be performed no less often than every 3 months for at least 2 years from time of maintenance therapy withdrawal. The occurrence of a renal flare during tapering, also highlights the need for guidelines regarding the rate of withdrawal. Determining risk factors for renal flare after maintenance withdrawal is necessary to facilitate clinicians identifying

candidates for discontinuations or instances when to exercise caution.

Hydroxychloroquine Induced Retinopathy in SLE

Michelle Petri[1] and Wei Fu[2], [1]Rheumatology Division, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Retinal toxicity from hydroxychloroquine (HCQ), has been recognized for many years. But poor compliance of HCQ might confound results of previous studies. Therefore, we tried to understand HCQ induced retinopathy by investigating association between retinopathy and HCQ serum level.

Methods: 117 patients with HCQ toxicity report and HCQ level measured were included in the analysis. Patients were then followed quarterly since cohort entry. HCQ level were measured at each visit and patients taking HCQ were referred to Ophthalmologists for eye exams.

Results: Among 117 patients, 112 (95.7%) were female. Majority (49.6%) were Caucasian, 44.4% African American. 12 of them have HCQ toxicity confirmed while 7 were possible and majority (83.8%) don't have HCQ toxicity. Table 1 showed HCQ toxicity in each HCQ group. Table 1: HCQ toxicity in each HCQ group

Highest HCQ level (ng/mL)	No toxicity N (%)	Possible Toxicity N (%)	confirmed toxicity N (%)	Total
Greater than 2,000	25 (83.3)	2 (6.7)	3 (10.0)	30
1,500 to 1,999	23 (79.3)	4 (13.8)	2 (6.9)	29
1,000 to 1,499	30 (85.7)	1 (2.9)	4 (11.4)	35
500 to 999	13 (100)	0 (0)	0 (0)	13
Less than 499	7 (70.0)	0 (0)	3 (30.0)	10

Pair-wise comparison using t test with pooled Standard deviation showed that average highest HCQ levels are not significantly different among three groups (No vs. possible vs. Yes) After grouping people with "confirmed" toxicity and "possible" toxicity together, average highest HCQ level is 1511.632 ng/mL. While highest HCQ level is 1591.051 ng/mL on average among those who didn't show HCQ toxicity. The difference between these two groups is not significant (P = 0.7094) using t test.

Conclusion: Retinopathy is not associated with highest HCQ level.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The availability of published long-term data from systemic lupus erythematosus (SLE) clinical trials is limited [1]. To complement existing belimumab data, we examined the long-term safety and efficacy of belimumab plus standard SLE therapy (SoC) in patients who participated in the open-label extension that followed BLISS-76.

Methods: This was a multicenter, continuation study (GSK study 112233; NCT00724867) of patients who completed BLISS-76 in the US. In this study patients received the same dose of belimumab as in BLISS-76 (1 or 10 mg/kg IV, every 28 days) plus SoC; patients who had previously received placebo received belimumab 10 mg/kg IV. Following licensing of belimumab, the dose for patients who received 1 mg/kg was increased to 10 mg/kg. Primary outcome measures included long-term safety, assessed by adverse event (AE) frequency and Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) evaluated every 48 weeks (Study Year). Other assessments included SLE Responder Index (SRI), prednisone use, B cell levels, and flare rates (modified SLE Flare Index [SFI]).

Results: 268 patients comprised the modified intent-to-treat (MITT) population; 140 patients completed the continuation study (52.2%), and 128 (47.8%) withdrew (patient request, 24.2%; AE, 19.5%). At baseline, the mean (SD) Safety of Estrogens in Lupus Erythematosus National Assessment SLE Disease Activity Index (SELENA-SLEDAI) score was 7.8 (3.86), and the mean (SD) SDI score was 1.2 (1.51). The incidence of overall AEs, treatment-related AEs, and serious AEs remained stable or declined through Study Year 7 (**Table**). The mean (SD) SDI score increased by 0.4 (0.68) from

Table: Incidence of treatment-emergent AEs by Study Year

Number (%) of patients[a]	Any time post-baseline (N=268)	Year 1 (N=268)	Year 2 (N=259)	Year 3 (N=244)	Year 4 (N=219)	Year 5 (N=202)	Year 6 (N=192)	Year 7 (N=130)	Year 8+ (N=65)
At least 1 AE	267 (99.6)	260 (97.0)	235 (90.7)	206 (84.4)	184 (84.0)	167 (82.7)	145 (75.5)	87 (66.9)	31 (47.7)

Deaths	2 (0.7)	0	1 (0.4)	0	1 (0.5)	0	0	0	0

[a]Patients reporting multiple AEs within a Study Year are only counted once in each of the appropriate categories; [b]Possibly, probably, or definitely related; [c]Per GSK adjudication; [d]Recurrent, or disseminated (more than three adjacent dermatomes affected or crossing the midline). AEs, adverse events; NMSC, non-melanoma skin cancer;

baseline to Study Year 7 (MITT population).

An SRI response was achieved by 41.9% (96/229) of patients overall at Study Year 1 Midpoint (Week 24), increasing to 75.6% (90/119) at Study Year 7 Midpoint. At Study Year 7 Midpoint, relative to baseline, 78.2% (93/119) of patients overall achieved a ≥4-point SELENA-SLEDAI score reduction, 98.4% (125/127) had no new British Isles Lupus Assessment Group (BILAG) 1A/2B organ domain scores, and 93.7% (119/127) of patients had no worsening in Physician's Global Assessment (PGA). The median decrease in prednisone dose from baseline was 47.1% (n=77, those receiving prednisone), and the median change in CD20+ B cells was -83.2%, at Study Year 7 Midpoint. Severe SFI flare was experienced by 20.6% (55/267) of patients through Study Year 7 Midpoint.

Conclusion: Long-term exposure to belimumab was generally safe and well tolerated. The incidence of AEs remained stable or declined throughout the study. These results are consistent with data from the Phase 2 extension study and the known profile of belimumab in patients with SLE. Study funded by GSK/Human Genome Sciences, Inc. Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate effectiveness and identify predictors of response to belimumab in patients with active SLE in clinical practice setting.

Methods: One hundred eighty eight active SLE (ACR criteria) patients with positive anti-dsDNA antibody and low C3 and/or C4, from 11 Italian prospective lupus cohorts, were treated with belimumab (10 mg/kg day 0, 14, 28 and then every 28 days), as add-on therapy. They were 174 (92.6%) females, mean age 40.7+-10.1 years, mean disease duration 12.7±8.5 years. SLEDAI-2K, anti-dsDNA, C3, C4, prednisone daily dose, DAS-28, 24-hours proteinuria, CLASIa (Cutaneous LE Disease Area and Severity Index Activity) were recorded at baseline, at month 12 and 24. Anti-dsDNA levels were measured by ELISA in 98 patients, IIF in 62 patients, Farr assay in 28 patients. The following variables were included in the univariate and multivariate analysis to determine baseline predictors of response (according to SLE Responder Index-4, SRI-4) at 12 and 24 months: gender, age, disease duration, disease activity pattern (relapsing remitting or chronic active), SLEDAI-2K ≥10, prednisone dose >7,5 mg/day, concomitant immunosuppressants (yes/no), polyarthritis, skin rash, glomerulonephritis (GN), hematologic involvement. Pattern of disease activity was identify as chronic active disease in patients with a SLEDAI-2K ≥2 excluding serology in at least two out of the three annual visits and relapsing-remitting disease in patients with a SLEDAI-2K ≥2 excluding serology in one out of three annual visits. Statistics were performed by pairs T-test, chi-square test and multiple logistic regression analysis using SPSS package (version 22.0).

Results: Mean follow-up period was 17.5+-10.6 months (range 3-36). Active manifestations which required the use of belimumab were polyarthritis in 45.7%, skin rash in 26.1%, GN in 13.8%, and hematologic involvement in 14.4% of cases. Clinical and serological variables at baseline and after 12 and 24 months of follow-up are reported in Table. SRI-4 was achieved by 71.3% and 68.7% of patients at 12 and 24 months, respectively. Baseline independent predictors of response by logistic regression at month 12 were: SLEDAI-2K ≥10 (OR 25.8, 4.19-159.2) and polyarthritis (OR 8.33, 1.88-36.78). Predictors at month 24 were: SLEDAI-2K ≥10 (OR 12.11, 1.63-89.80), polyarthritis (OR 32.56, 2.94-360.56), and prednisone dose >7.5 mg/day (OR 7.88, 1.02-61.48). Discontinuation was observed in 49 patients (26.1%) after 9±7 months of follow-up. Twenty seven patients (55.1%) discontinued for disease activity, 13 (26.5%) for adverse events, 5 (10.2%) for pregnancy. Retention rate was 89.4% at 6 months, 81.4% at 12 months, 76.1% at 18 months, 75.0% at 24 months.

Conclusion: SLEDAI ≥10, polyarthritis and prednisone dose >7,5 mg/day at baseline were the best predictors of response

in our cohort of patient with active SLE.

Table. Variation of clinical and serologic disease activity variables at 12 and 24 months of follow-up in 188 patients with active SLE and high disease activity treated with belimuma

	Baseline	12 months		24 months

Introducing a Novel SLE-Specific IFN-I Inhibitor CNTO 6358: Laying the Groundwork for Precision Medicine in Lupus

Jarrat Jordan[1], Matteo Cesaroni[1], Jessica Schreiter[1], Chichi Huang[2], Tanesha Cash-Mason[3], Marc Chevrier[1] and Jacqueline Benson[1], [1]Estrela Lupus Venture, Janssen Research and Development, LLC., Spring House, PA, [2]Biologics Research, Janssen Research and Development, LLC., Spring House, PA, [3]Cardiovascular and Metabolism Research, Janssen Research and Development, LLC., Spring House, PA

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The type I interferon (IFN-I) family of cytokines signal through a ubiquitously expressed heterodimeric receptor (IFNAR) composed of IFNAR1 and the high-affinity binding chain IFNAR2 eliciting antiviral, antiproliferative, and immunomodulatory effects. IFN-I is thought to play a central role in the pathogenesis of systemic lupus erythematosus (SLE) and therapeutic approaches to down-modulate this pathway have demonstrated efficacy in SLE clinical trials. The IFN-I pathway is composed of multiple closely related IFN-α subtypes and single functional molecules for IFN-β, IFN-ε, IFN-κ and IFN-ω. Some members of the IFN-I family are thought to contribute to SLE pathogenesis,

while others may be more relevant for host defense. We developed a fully-human monoclonal antibody (CNTO 6358) to selectively neutralize the most prevalent soluble IFN-Is expressed in SLE, while retaining the functions of IFN-β, including critical antiviral contributions to host defense. Here we illustrate *in vitro* bioactivity using endogenous SLE patient-derived IFN-I preparations, including immune complexes and serum/plasma from racially diverse SLE populations, providing evidence that the neutralization and potency profile of CNTO 6358 may enable potent suppression of IFN-Is prevalent in SLE without suppression of other IFN-Is more essential for other host defense processes. We further describe an *in vitro* assay that may enable the prediction of responders and non-responders with CNTO 6358, providing a transformational framework for SLE precision medicine.

Methods: Pooled SLE serum and plasma or conditioned media from cells exposed to pooled SLE patient immune complexes or recombinant human IFN-Is were utilized as stimuli in an ISRE reporter gene assay (RGA) in the presence of CNTO 6358 or control. SLE patient whole blood was incubated *in vitro* for 24 hours in the presence or absence of CNTO 6358 and the impact of inhibitor treatment on gene expression was determined by RNA-Seq relative to untreated healthy donor samples. All patient samples were collected under informed consent.

Results: IFN-I activity present in plasma and serum preparations from multiple SLE cohorts and activity present in conditioned media from PBMCs exposed to SLE patient immune complexes was neutralized to levels seen in healthy control samples. The *in vitro* addition of CNTO 6358 to blood from individual SLE patients enabled the identification of donors having robust normalization of baseline elevated IFN-I signature gene expression and those having moderate to minimal transcriptional changes.

Conclusion: Our SLE IFN-I inhibitor CNTO 6358 exhibited potent neutralization of multiple SLE patient-derived IFN-I preparations, demonstrating a bioactivity profile targeting the most prevalent IFN-I subtypes elevated in SLE patients, while preserving the functionality of other IFN-Is which may be more important for host defense. Furthermore, our *in vitro* assay and *in silico* methodologies may enable prediction of responders to our treatment, providing a transformational framework for SLE precision medicine.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several cross-sectional studies have shown a progression of atherosclerosis in SLE was associated with activities of SLE but not with glucocorticoid therapy. However, a few evidence showed correlations between the progression of atherosclerosis in SLE and glucocorticoid therapy in longitudinal studies. Moreover, races and regions are known to be important in atherosclerosis. We conducted a longitudinal cohort study to clarify relevant clinical factors to influence the progression of atherosclerosis in Japanese patients with SLE.

Methods: In our cohort of the patients with SLE who regularly visit our department, the patients who underwent echography of the carotid arteries twice or more, with an interval of two years or more, were enrolled into the present study. Atherosclerosis was evaluated with echography of the carotid arteries. A mean of the bilateral intimal carotid artery media thickness (mIMT) was measured with the three-point method (TOSHIBA Xario200, Aplio400). The annual progression rate of mIMT (mIMT/y) was calculated from the difference between the baseline and the subsequent echo studies. We analyzed clinical factors associated with mIMT and mIMT/y using multiple regression analysis. For mIMT, clinical factors assessed in the analysis were as follows: age, disease duration, smoking habits, comorbid conditions, total cumulative prednisolone dosage (tPSL), history of other medications including HMG-CoA inhibitors, SLICC/ACR damage index (SDI), Ankle-Brachial Index, Cardio-Ankle Vascular Index, HbA1c, C-reactive protein, serum creatinine, high density lipoprotein cholesterol, and low density lipoprotein cholesterol at baseline. For mIMT/y, in addition to the factors above, we assessed mean daily prednisolone dosage during the follow-up period (mPSL) and other medications during the follow-up period. The analysis was performed by SPSS version 22. Data were represented as median (25-75 percentile).

Results: Thirty-nine Japanese patients with SLE were recruited in our study. Of these, 35 were women; age, disease duration, tPSL at baseline, and daily prednisolone dosage during the follow-up period (mPSL) were 60 (48-65) years, 25 (12-32) years, 58 (36-82) g and 5.0 (4.0-7.5) mg/day, respectively. The intervals of echo studies were 4.0 (2.7-6.1) years. At baseline, the mIMT was 0.60 (0.50-0.75) mm. Age (B=0.005, SE=0.002, p=0.011) and SDI (B=0.05, SE=0.02, p=0.019) were selected as positive contributory factors for mIMT, while tPSL was selected as a negative factor (B=-0.002, SE=0.001, p=0.007). For mIMT/y, mPSL (B=-0.005, SE=0.002, p=0.004) was a negative contributory factor, and diabetes mellitus requiring medical therapy was a positive factor (B=0.032, SE=0.014, p=0.035).

Conclusion: These results suggested that glucocorticoid therapy might be protective against the progression of atherosclerosis in Japanese patients with SLE.

Effect of HMG-CoA Reductase Inhibitor Drugs (Statins) on Systemic Lupus Erythematosus Disease Activity: A Systematic Review and Meta-Analysis

Givenchy Maree Garcia, Annalyn Urbano and Evelyn Salido, Section of Rheumatology, University of the Philippines - Philippine General Hospital, Manila, Philippines

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and

Current Therapies

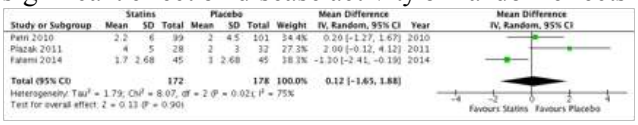
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Statins have been shown to have anti-inflammatory and immunomodulatory effects. In vitro studies show that these drugs inhibit inflammatory cells, decrease the expression of major histocompatibility complex (MHC), decrease adhesion molecules and inflammatory cytokines (IL6 and IL10), that are also implicated in SLE pathogenesis. In terms of immunomodulary effects, animal studies demonstrate that statins exacerbate/trigger cellular apoptosis and induce a shift in the Th1/Th2 balance leading to B-cell reactivity and production of pathogenic autoantibodies. Whether statins have clinical effects in SLE have not been widely studied. In terms of disease activity, these studies show contradicting results. **Objective:** To determine the effect of statins on the disease activity of SLE based on the best available evidence.

Methods: A systematic literature search of PubMed, Scopus, and Cochrane databases was done with no date and language restrictions. Included studies were on adult SLE patients and randomized controlled trials that used statins as intervention and reported SLE disease activity as an outcome measure. Two reviewers did quality appraisal, risk bias assessment, and data extraction.

Results: Three studies met the eligibility criteria and were included in this review. Quantitative synthesis was done. The pooled analysis of these studies suggests that statins have no significant effect on disease activity on random effects model with an overall effect of 0.13 (P=0.90, 95% CI -1.65, 1.88).



Conclusion: Statins neither increased nor decreased SLE disease activity; therefore possibly it can be safely given to SLE patients without the risk of triggering or exacerbating a flare.

Session Time: 9:00AM-11:00AM

Background/Purpose: The use of Rituximab (RTX) in patients with autoimmune diseases has been associated with an increased incidence of infection and risk factors for this complication are not well established. The aim of our study was to compare the incidence of infections and its related factors in the first six months after RTX infusion in two rheumatic diseases: systemic lupus erythematosus (SLE) and inflammatory myopathies (IM).

Methods: From August 2009 to March 2015, a total of 48 SLE and 39 IM consecutive patients were longitudinally followed in the biologic therapy center of Rheumatology Division of a tertiary university hospital using a standardized electronic database protocol including demographic data, clinical and laboratorial findings and treatment. RTX is regularly administered in our center with infectious screening and the protocol consisted of either 4 weekly doses of 375mg/m^2 or two doses of 1g (day 0 and 14). IM standard treatment also included the recommendation of IVIG 2-4 weeks pre RTX infusion, whereas IVIG was only indicated for lupus for severe refractory activity. Severe infection was defined as episode that required the use of intravenous antibiotics or hospitalization.

Results: SLE patients presented a significant higher incidence of overall (50.0 vs. 7.7%, p<0.001) and severe (22.9 vs. 0%, p<0.001) infections than IM patients in the first 6 months after RTX infusion. SLE and IM patients had similar age (38.0±13.3 vs. 41.5±13.2, p=0.230) and frequency of female gender (93.8 vs. 82.1%, p=0.105). At baseline, both groups had similar mean IgG level (1168.8±527.0 vs. 1346.3±397.0 mg/dL, p=0.087). With regard to treatment, mean prednisone dose (32.0±21.1 vs. 22.3±15.4mg/day, p= 0.018) was higher in SLE but the frequency of patients with associated immunosuppressants was lower in SLE (79.2 vs. 97.4%, p=0.020). IVIG infusion (2g/Kg) before RTX infusion was less often used in SLE than in IM patients (14.6 vs.69.2%, P<0.001). Previous history of severe infection 6 months before RTX was alike in SLE and IM (10.4 vs. 2.6%, p=0.218). Further analysis of 11 severe infection episodes revealed that they only occurred in SLE, more than half (64%) were sepsis and they were observed at a mean of 3.6 months (range 1 – 5 months) post infusion. At baseline, these patients were under a mean prednisone dose of 41.4±30.2mg/day and their mean IgG level was 1361.5±753.1 mg/dL.

Conclusion: We observed that SLE was associated with an unexpected higher incidence of overall and severe infections than IM patients in spite of adequate and comparable baseline IgG levels. Risk factors identified were high glucocorticoid dose and less use of pre-RTX IVIG infusion. Further studies are necessary to determine if the recommendation of IVIG pre-RTX treatment will reduce severe early infection in SLE.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Type I interferons (IFN-I) are implicated in the pathogenesis of systemic lupus erythematosus (SLE). In SLE, immune complexes stimulate plasmacytoid dendritic cells (pDCs) to secrete large amounts of IFN-I. BDCA2 is a pDC-specific surface receptor that has been demonstrated to inhibit the production of IFN-I when engaged. Targeting BDCA2 therefore represents an attractive therapeutic strategy for inhibiting pDC-derived IFN-I and may be an effective therapy for the treatment of SLE. BIIB059, an investigational anti-BDCA2 monoclonal antibody, has been shown to engage BDCA2, and this interaction leads to BDCA2 internalization and the consequent in vitro inhibition of TLR-induced IFN-I by pDCs *(Pellerin et. al 2015)*. This first-in-human study aimed to assess the safety, tolerability, PK and PD profiles of single ascending doses of BIIB059 in healthy volunteers (HV).

Methods: A randomized, double-blinded, placebo-controlled, single ascending dose-escalation study was conducted in adult HV. In cohorts 1-7 HV were randomized to receive single IV doses of 0.05, 0.3, 1, 3, 10, or 20 mg/kg or one 50 mg SC dose of BIIB059. Each cohort had an active:placebo ratio of 2:1 or 3:1. Blood samples were obtained before and after dose administration up to week 16. Target modulation of BDCA2 and serum BIIB059 concentrations were measured using flow cytometry, and an enzyme-linked immunosorbent assay (ELISA), respectively, and anti-drug antibodies (ADA) were measured using a bridging ELISA.

Results: 54 HV were assigned to cohorts 1-7 (38 BIIB059: 16 placebo). BIIB059 demonstrated non-linear PK consistent with target mediated drug disposition. Bioavailability of SC administration was ~50%. Treatment with BIIB059 led to rapid and complete down-modulation of BDCA2 on the surface of pDCs at all dose levels. Time to reappearance of BDCA2 on pDC cell surface correlated with circulating levels of BIIB059, establishing an in vivo pharmacokinetic/pharmacodynamic (PK/PD) relationship. Single dose administration of BIIB059 was well tolerated across all dose levels. All AEs were mild to moderate in severity with no serious AEs. There were no clinically significant changes in laboratory assessments, physical examinations, or electrocardiogram (ECG) values. Anti-drug antibodies were detected at low levels in a small number of BIIB059-treated subjects. Responses were largely transient and demonstrated no impact on BIIB059 exposure or association with any safety event.

Conclusion: This first-in-human study demonstrated acceptable safety/tolerability and PK profile in healthy subjects and supports further multiple-dose studies with BIIB059. BIIB059 treatment showed dose-dependent target engagement and internalization of BDCA2 establishing a PK/PD correlation *in vivo* on circulating pDC. These data support further evaluation of clinical efficacy and safety of BIIB059 as a potential novel therapy in SLE patients.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studying clinical effectiveness of belimumab treatment in real world clinical practice of Systemic Lupus Erythematosus (SLE) is relevant in assessing external validity of randomized controlled trials.

Methods: Retrospective chart review in 14 sites, including 58 patients. Primary objective: change in overall clinical manifestations assessed by a 6-point scale similar to PGA. Secondary objectives: change in SELENA SLEDAI; number of flares by mSS Flare index; steroid dose; other drugs and evaluation of health economic parameters, all assessed 6 months before and 6 (n: 58), 12 (n: 52) & & 18 (n: 25) months after treatment with 10±1 mg/Kg of belimumab. GSK sponsored this study #201282 (OBSErve).

Results: These results evaluate the use of Belimumab in the clinical practice setting in Argentina for up to 18 months. Baseline parameters: Age 41±13 yrs; female 91%; SLE duration ≥ 5 yrs 59%; hypocomplementemia 72%; high anti-dsDNA 64%; steroid dose ≥ 7.5 mg/day 77% and SELENA SLEDAI >10, 53%. Change in overall manifestations and secondary objectives are shown below:

Overall change in PGA	Worsened	No change	Improved			
			<20%	20-49%	≥ 50-79%	≥ 80%
6 months	0%	5%	10%	16%	48%	21%
12 months	2%	6%	8%	8%	25%	52%
18 months	0%	0%	0%	4%	36%	60%

	SELENA SLEDAI score (SD)	Number of Flares mean/6months (SD)	Steroid dose mg/day (SD)	Steroid Sparing Effect mg/day (SD)
Baseline	11,6 ±6,3	1,1 ±0,7	16,3 ±13,5	Not applicable
6 months	5,1 ±4,5*	0,2 ±0,4*	6,6 ±4,5*	-10 ±11,3*
12 months	4,1 ±5,0*	0,1 ±0,4*	5,3 ±6,6*	-11,5 ±13,8*
18 months	4,1 ±5,0*	0,3 ±0,6°	4,4 ±3,0°	-10,9 ±10,7°

**p<0.001 ° 0,001 vs baseline (Wilcoxon)*

The overall rate of suspension of steroids, azathioprine and belimumab after 18 months was 31%; 42% & 24% respectively. Key health economic parameters assessed did not vary after treatment although a tendency to reduced hospital admissions was observed (15,5% 6 months before treatment vs 6,7% pooled q6month after treatment, p: 0.09).

Conclusion: More than two thirds of patients obtained ≥ 50% overall response with relevant reductions in SELENA SLEDAI, number of flares, steroid and azathioprine treatment with sustained effects through 18 months follow up. Results are consistent with randomized controlled trials and similar observational real word studies performed in US and Europe therefore supporting the use of belimumab in our clinical practice.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is no data on the efficacy of the EUROLUPUS regimen associated with initial low steroids daily dose in African descent patients with proliferative lupus nephritis (LN). Here we report the 3 years prognosis of LN in black Martinican patients treated with low dose of cyclophosphamide and low dose steroids.

Methods: All patients suffering from LN in our unit have the choice after information to receive mycophénolate or IV cyclophosphamide (CY) as attack treatment. In the absence of rapidly progressive glomerulonephritis and severe extra-renal manifestations (mainly CNS involvement, auto-immune anemia or thrombocytopenia), the patients received no prednisolone assault, 6 IV 500mg fortnightly CY pulses and an initial 0.5 mg/kg/d daily dose of prednisone. On 117 consecutive SLE Afro-Caribbean patients biopsied with LN (ISN-RPS class III, IV) from 11/2008 until 9/2015, 38 living in Martinique were treated in our unit and retrospectively evaluated for complete remission (CR, daily proteinuria < 0.5 g, no urine sediment, no > 10% increasing creatininemia), partial remission (PR, same criteria than CR except for daily proteinuria < 1g), treatment failure (persistance of nephrotic proteinuria or creatininemia < 114 microM if initially < 228 microM or no decrease under half the initial creatininemia level if > 228 microM), dialysis, All patients were followed the same way. Maintenance treatment was azathioprine (n=8), mycophenolate (n=30). No patient was excluded on a creatininemia level or incompliance basis (based on self declaration).

Results: Mean (+/-SD) age at LN diagnosis was 30 (+/-9.5) years. 44.7% of patients had LN recurrence. The renal biopsy classes were: III+/-V (39.5%), IV+/-V (60.5%). Mean (+/-SD) follow up time was 49.8 (+/-27.3) months. Mean (+/-SD) baseline parameters were: glomerular filtration rate 74.75 (+/-44.17) ml/min/1.73 m^2, proteinuria 2.92 (+/-2.17) g/d, high blood pressure (57.9%), mean initial prednisone daily dose 32.2 (+/-13.2) mg/d. Five patients (13.1%) received initially at least one 1g prednisolone assault. Total remission (CR+PR) rates were 21.1% at 3 months (CR15.8%, PR 5.2%), 52.6% at 6 months (CR 34.2%, PR 18.4%), 68.4% at 1 year (CR 50%, PR 18.4%), 78.9% at 2 year (CR 65.8%, PR 13.2%), 81.6% at 3 year (CR 71.1%, PR 10.5%). No patient died and none were lost to follow up. Treatment failure was 15.8% at 3 years, 5/6 (83.3%) being non compliant. At 3 years, 5 patients were on dialysis.

Conclusion: Despite inclusion of non compliant patients, our results suggests that EUROLUPUS with low steroid use can be an effective regimen in African descent patients with proliferative LN.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with diverse clinical and serological manifestations. B-cell-targeted therapies have been promising new treatments for SLE. Despite the failure of randomized controlled trials, a considerable number of studies report good clinical efficacy of Rituximab, an anti-CD20 monoclonal antibody, in patients with SLE. Herein, we aimed to analyse the effects of Rituximab in lupus patients with involvement of different domains.

Methods: This a retrospective analysis of 79 lupus patients treated with rituximab at the rheumatology outpatient clinic. Disease activity was assessed using SLE disease activity index (SLEDAI) and treatment response was defined according to the system involved: A partial response was defined as ≥ 50% improvement in renal parameters, in cutaneous lesions or vasculitis, in the number of painful and/or swollen joints, increase in hemoglobin by at least 2 g/dl, doubling of basal platelet levels or platelet count between 50-100x10^9/mm^3. A complete response was defined as proteinuria<0.5/day, normal urinary sediment, normal hemoglobin levels, >100x10^9/mm^3 platelets, disappearance of cutaneous manifestations or arthritis. For patients with general disease activity a reduction of SLEDAI score at least by half was defined as partial and a score ≤2 as complete response.

Results: Cyclophosphamide(Cy) was used in 64% of the patients as previous treatment, mycophenolate mofetil(MMF) in 62%, azathioprine(AZA) in 63%, methotrexate(MTX) in 23%, calcineurin inhibitors(CNI) in 5%, leflunomide in 4% and intravenous immunoglobulin in 5% of the patients. Treatment response at 6 months revealed a complete response in 27%, 60%, 67%, 43% and 88% in patients with lupus nephritis (LN), thrombocytopenia/AIHA, arthritis, vasculitis and general disease activity respectively. In the LN group there were more partial and non responders compared to other domains. 50% of those patients went into remission and mean time to remission was 10+/-1.7 months. Concomitant treatment with Rituximab included MMF in 46, %, AZA in 13%, CNI in 5% and MTX in 10 % of patients. Comparison of treatment response between proliferative and membranous subtypes of LN revealed a a significantly higher number of complete responders (CR) in class IV whilst there were no CR among patients with membranous nephritis at the 6^{th}month of treatment. Comparison of baseline mean SLEDAI scores, antidsDNA positivity rate, C3 levels and mean daily steroid dose to 6th month of treatment favored rituximab use. Overall there were 9 infusion reactions: angioneurotic edema in 4, serum sickness in 2, rhabdomyolysis and fever in 1, urticarial rash and fever in 1 and thrombocytopenia in 1. 4 patients had zona zoster, 3 pneumonia, 3 urinary tract infections, 1 infective endocarditis and 1 tooth abscess. 3 needed to be hospitalized and 2 received intravenous immunoglobulin.

Conclusion: Regardless of the discouraging results of randomized controlled trials with Rituximab in lupus patients, our

clinical experience also shows that it still remains as a therapeutic option, especially in severe and refractory cases.

Factors Determining Hydroxychloroquine Serum Levels in a Cohort of Chinese Patients with Systemic Lupus Erythematosus

Chi Chiu Mok[1], Ling Yin Ho[2] and Paul Jannetto[3], [1]Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Dept of Medicine, Tuen Mun Hospital, Hong Kong SAR, Hong Kong, [3]Director, Toxicology and Drug Monitoring Laboratory, Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To study the factors determining the hydroxychloroquine (HCQ) serum concentration in a cohort of Chinese patients with systemic lupus erythematosus (SLE).

Methods: Consecutive patients who fulfilled ≥4 of the 1997 ACR criteria for SLE and had received HCQ for 6 months or more were recruited from our lupus clinic and hospital admissions in a 9-month period starting from November 2011. Patients were prescribed HCQ at fixed daily dosages of 400 mg, 300 mg, 200mg or less than 200mg (eg. 200mg 3 or 5 times per week) at the discretion of their attending doctors according to disease activity, organ manifestations and risk factors for HCQ toxicities. Blood was assayed for the serum levels of HCQ by an in-house technique using the tandem mass spectrometry (SPE-MS/MS). Factors affecting HCQ serum concentrations were studied by univariate and multivariate linear regression analyses. Covariates being tested in the regression models included age, sex, body mass index (BMI), prescribed dosage of HCQ, SLE disease activity score (SLEDAI), ever smoking, estimated glomerular filtration rate (eGFR) and concomitant prednisolone.

Results: 276 SLE patients were studied (94% women; mean age 41.0±13.8 years; SLE duration 8.7±6.6 years). HCQ was primarily used for the treatment of mucocutaneous or musculoskeletal manifestations, or both, in 73%, 78% and 93% of the patients, respectively. Patients were stratified into 3 groups according to the HCQ levels: (1) Total non-compliance (<10 ng/ml); (2) Sub-therapeutic (10-500 ng/ml); and (3) Therapeutic (≥500 ng/ml). The proportion of patients with HCQ levels

of <10, 10-500, ≥500 ng/ml was 11%, 77% and 12%, respectively. Patients with total non-compliance to HCQ were more likely to be in clinical and serological remission when compared to the remaining patients (42% vs 24%; p=0.04). However, no difference in the clinical manifestations could be observed between patients with total non-compliance and other patients. After excluding patients with total non-compliance to HCQ therapy, the mean and median HCQ serum concentration of the remaining 245 patients was 300±87ng/ml and 276ng/ml (interquartile range 167-401), respectively. Univariate linear regression revealed that the prescribed HCQ dosage (beta 0.47; p<0.001) and the SLEDAI score at the time of recruitment (beta 0.16; p=0.02) were the significant factors associated with the HCQ serum concentrations. Multivariate linear regression with all the factors being considered in the model showed that the prescribed HCQ dosage (beta 0.50; p<0.001) and eGFR (beta -0.14; p=0.02) were independent factors associated with HCQ serum levels. Age, sex, BMI, smoking, SLEDAI score and concomitant prednisolone were not significantly associated with the HCQ serum concentrations.

Conclusion: Non-compliance and sub-therapeutic HCQ serum levels were frequent in our cohort of SLE patients, which was related to the low prescribed dosage for maintenance treatment in those with clinical and serological remission. Patients with lower eGFR or receiving higher doses of HCQ were more likely to achieve higher HCQ serum concentrations. Thus, HCQ level monitoring and dosage adjustment may be helpful in SLE patients with impaired renal function to reduce the risk of toxicities.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Belimumab is an anti-BAFF monoclonal antibody approved for the treatment of auto-antibody positive patients with SLE. In two large phase 3 clinical trials, belimumab plus standard of care reduced SLE disease activity compared with standard of care alone. However, African-American SLE patients in these studies had no such improvements resulting in clinicians unsure of the efficacy of belimumab in this group. This study examines the effect of belimumab on clinical outcomes and disease activity in a cohort of African- American patients with SLE being treated at an academic medical center.

Methods: All SLE patients who were African-American and who had been prescribed belimumab as part of their medical care at our center were identified in a retrospective chart review. Data was analyzed for up to 24 months of therapy. Patient demographics, disease manifestations, medication usage, and labs were recorded for visits at Day 0 (day of initial belimumab infusion), and at months 3, 6, 12, 18, and 24. Whenever all appropriate labs, clinical exam and history were

available, a SLEDAI was calculated. For any patient who discontinued belimumab therapy at any time point prior to 24 months, additional information as to reason was recorded.

Results: 23 African-American SLE patients were identified; mean age 38.9 years (22-58), 87% female, with a mean duration of disease of 12.7 years (4-31). At the time of their initial belimumab infusion, 91.3% of the patients were on prednisone at an average dose of 20 mg /day (5-60), 78.3% of patients were taking lupus DMARDs, and 91.3% were on HCQ. The mean SLEDAI score was 8.5 (2-20) with 39% of patients having a score ≥10. 65% of patients were hypocomplementemic (low C3/C4) at baseline, 60% had elevated anti-dsDNA titers, and 47% had both. The most common clinical disease manifestation at belimumab initiation was arthritis (56.5%) followed by cutaneous (47.8%). Over the subsequent observation period, 5 patients (22%) discontinued belimumab therapy at a mean duration of 8.4 months, 2 due to inefficacy, 1 secondary to abnormal LFTs, one patient moved away, and 1 patient self-discontinued secondary to feeling well. For the remainder of the patients, by month 3 the mean SLEDAI had decreased 3.6 points (8.5 to 4.9) and by month 24 the mean SLEDAI was 3.5 ($p < 0.001$). Prednisone dose among those still taking the medication also decreased, going from a mean of 20 mg/day to 8.06 mg/day by month 24 ($p < 0.001$). Four patients came off of prednisone completely. 53.8% of those patients with low C3/C4 normalized their levels and 25% of those with elevated anti-dsDNA titers became undetectable. One patient was hospitalized for community acquired pneumonia during the observation period but no other major infections were noted.

Conclusion: Belimumab is well tolerated and may be effective in African-American patients with SLE. Prednisone doses as well as SLEDAI scores decreased significantly and were maintained through 2 years of treatment in most patients. Ongoing prospective placebo controlled studies with belimumab in African-American SLE patients will hopefully provide more definitive answers.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the long term steroid saving capacity and clinical effectiveness of B-cell depletion therapy (BCDT) in newly diagnosed SLE patients.

Methods: Sixteen female SLE patients were treated at, or shortly after diagnosis, with BCDT aiming to minimize the routine use of oral steroids. Post-treatment, most patients were given hydroxychloroquine (n=14) and azathioprine (n=10). The BILAG disease activity index was used for clinical assessment. Serum anti-dsDNA antibodies, complement (C3),

ESR, circulating B lymphocytes (CD19+) and total inmmunoglobulins were tested every 2-6 months for an average of 4.5 years (SD 2) post-treatment. Disease activity and steroid requirement over the follow-up period (ranging from 1 to 7 years) were compared with three SLE patients treated conventionally, each carefully matched for ethnicity, sex, age, clinical features, disease duration at diagnosis and length of follow up.

Results: All patients given rituximab achieved B-cell depletion. The mean number of flares during the follow-up period (defined as a new BILAG A or B) was 2.63 (SD 3) in the BCDT group and 4 (SD 3.6) in the control group (NS, p=0.14). Post-BCDT, mean anti- dsDNA antibody level fell from 1,114 U/ml (SD 1,699.3) to 194 (SD 346.7) for 18 months (p= 0.043), mean serum ESR fell by >70% at 6 months maintained during the follow-up and serum C3 level normalized during the follow-up in 8 patients. The mean time to complement normalization was 12.75 months after treatment. At diagnosis, the mean of the Inmunogloblulin G levels in the BCDT group was 17.8 +/- 6.09 g/L and 17.8 +/- 4.3 g/L in the HC (p = 0.98). These values were decreasing progressively to a final average of 10.34 +/- 5.4 g/L in the BCDT group and 12.14 +/- 3 g/L in the HC at 2 years of follow-up and 5.2 +/- 9.35 g/L and 10.2 +/- 2.2 g/L respectively on the fifth year. The mean cumulative prednisolone dose at 60 months for the BCDT patients (n=11) was 4,745.67 mg (SD 6,090 mg) vs 12,553.92 mg (SD 12,672 mg) for the controls (p=0.01). At the end of the follow-up, the SLICC/ACR Damage Index scale showed that the BCDT group had a mean of 1.06 (SD 1.4) and HC a mean of 1.35 (SD 1.5) (p = 0.9).

Conclusion: Early treatment of SLE patients with BCDT is safe, effective and enables a reduction in the overall steroid burden. The accumulated damage in both groups measured by SLICC/ACR Damage Index showed a trend to a lower score in the BCDT group although this did not reach statistical significance. These results support the idea that the use of rituximab as a first-line treatment has similar efficacy to long term conventional treatment but with significantly lower prednisolone dose requirement.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Mycophenolate mofetil (MMF) is widely used in the treatment of SLE however little is known about factors that may predict response or other outcomes following MMF therapy. We aimed to undertake a systematic review to (1) identify predictors of outcomes to MMF in SLE (in randomized clinical trials (RCTs); and (2) to identify

'risk factors' for clinical outcomes following MMF treatment for SLE in observational cohorts.

Methods: We searched Medline, Embase, Web of Science and Cochrane Central Registers for Controlled Trials up to November 2015 for relevant studies. Two reviewers independently assessed the methodological quality of the RCTs using the Cochrane Collaboration risk of bias tool and cohort studies using the Quality In Prognosis Studies tool. The quality of subgroup analysis was also evaluated. The Grading of Recommendations Assessment, Development, and Evaluation working group approach summarized the quality of evidence (QoE), considering the risk of bias, imprecision, inconsistency, indirectness, and publication bias.

Results: The QoE for the prognostic value of age at study entry, gender and race was low, mainly due to exploratory or insufficient subgroup analysis, risk of bias and imprecision. The prognostic value of baseline laboratory parameters (glomerular filtration rate, proteinuria, serum creatinine) and changes during treatment (complement, proteinuria, anti-dsDNA) is very low due to post hoc subgroup analyses, risk of bias, indirectness and imprecision. One low QoE observational study showed that concomitant membranous lupus nephritis (LN) on biopsy may be an independent factor for no remission. This was not confirmed by subgroup analysis of RCT or other observational cohorts. Concomitant HCQ therapy and MMF treatment for less than 18 months were associated with response and relapse, respectively; MMF dose was not associated with adverse events (reduced IgG levels) in very-low to low QoE studies. One small cohort study found that a mycophenolic acid area under the curve ≥30 mg·h·L-1 was associated with renal response but not with side effects (infections).

Conclusion: In SLE, evidence for predictors of outcomes with MMF is limited and is mainly from secondary and post-hoc analyses. We identified between-study heterogeneity and a high risk of bias across studies. Well-designed studies are required to confirm whether demographic factors, LN biopsy class, concomitant therapy or pharmacokinetic markers truly predict MMF responses and adverse events in SLE. **Study supported by CONACYT Table 1** Characteristics of studies on prognostic factors

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The use of Rituximab (RTX) has been documented via published cohort data from over 20 sites worldwide (1,2) demonstrating its useful role in the treatment of Systemic Lupus Erythematous (SLE). UCLH have been using RTX for SLE since 2000 and have records from the 139 patients treated to date. The aim of this retrospective review of this cohort data to was determine if there are any relatively simple clinical aspects or bio markers that can help the clinician anticipate the likely response to B Cell depletion with Rituximab.

Methods:

Patients in the UCLH cohort are included once they meet ACR criteria for a diagnosis of SLE. During their routine clinic visits they have prospective data collected which was utilised in this review. Patient files were then reviewed to collect the available laboratory results. From this retrospective analysis 139 patients were identified as having received Rituximab, 121 patients were used in the analysis. We excluded 3 patients due to follow up time <6months and 15 due to missing BILAG scores for the times of interest. We compared the responders (defined using BILAG scores - Complete Response (CR) loss of all A's or Bs; Partial Response (PR) loss of some A's and B's but not all, at 6 month follow up) versus Non-Responders (NR) these do not meet criteria for CR/PR, developed a new A or B during 6months follow up or had died. We only analysed the first dose of RTX with response for each patient.

The cohort is described in table 1.

	Responders		**Non-Responders**
	Complete Responder **(n = 52)**	***Partial Responder*** **(n=32)**	**(n=37)**
Female	50 (96%)	28 (87.5%)	37 (100%)
Age at diagnosis	26.3 (8-69)	25.2 (10-59)	26.9 (8-51)
Age at RTX	34.4 (16-69)	33.2 (15-73)	34.9 (19-57)
Caucasian	29 (56%)	11 (34%)	13 (35%)
Ro	24 (47%)	17 (53%)	24 (64%)
La	11 (21%)	5 (16%)	10 (27%)
Sm	13 (25%)	11 (34%)	11 (30%)
RNP	23 (45%)	17 (53%)	16 (43%)
Fatigue	15 (29%)	8 (25%)	18 (49%)
Raynauds	9 (17%)	6 (19%)	8 (22%)
Photosensitivity	2 (4%)	1 (3%)	1 (3%)
Rash	31 (60%)	12 (38%)	25 (62%)
Alopecia	10 (19%)	8 (25%)	16 (43%)
Oral ulcers	10 (19%)	8 (25%)	10 (27%)
Arthritis	33 (63%)	25 (78%)	31 (84%)
Serositis	13 (25%)	9 (28%)	7 (19%)
Renal	18 (35%)	17 (53%)	15 (41%)
Neurological	4 (8%)	3 (9%)	6 (16%)
Haematological	12 (23%)	9 (28%)	11 (34%)
B Symptoms	8 (15%)	6 (19%)	8 (22%)
Lymphadenopathy	2 (4%)	5 (16%)	2 (6%)
Vasculitis	9 (17%)	6 (19%)	5 (14%)
Sicca Syndrome	3 (6%)	1 (3%)	2 (6%)
Myositis	1 (2%)	2 (6%)	0
No Steroids and ≥ 1 immunossupressor	5 (10%)	0	3 (8%)
Steroids	2 (4%)	2 (6%)	2 (6%)
Steroids and 1 immunosuppression	7 (13%)	4 (12%)	6 (16%)
Steroids and >1 immunosuppression	38 (25%)	26 (81%)	26 (70%)
dsDNA pre-treatment			
mild elevation <5xULN,	17 (33%)	6 (19%)	7 (19%)
moderate elevation >5xULN	14 (27%)	17 (53%)	13 (35%)
CD19 depletion at 3 months	38 (73%)	27 (84%)	26 (70%)

Variables including age, sex, ethnicity, age at diagnosis, age at first dose of rituximab, clinical phenotype, ENA, previous medications, C3 levels pre and at 6months, dsDNA levels pre and 6months, CD19 count pre and at 3 months were examined via univariable analysis to determine if there was a statistically significant correlation.

Results:

Alopecia and fatigue presence were inversely correlated with response to treatment (p value 0.014 and 0.023, respectively) however for fatigue this was not maintained in the sub group analysis (comparison between complete responders and non- responders only). In this cohort there were no statistically significant association between response and CD19 depletion, dsDNA or C3 levels pre and post-Rituximab.

Conclusion:

During this retrospective review of the SLE cohort from UCLH we were unable to identify any routine laboratory

biomarkers to predict response. In this cohort the only clinical feature was alopecia which was inversely correlated with response.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SRI is a composite endpoint designed to ensure that clinical improvement (measured by SLEDAI) is not accompanied by deterioration in other organ systems (measured by BILAG and PGA). This novel endpoint, coupled with trial completion and adherence to treatment rules, has defined response in many SLE trials. The current investigation sought to identify those components of the SRI that were critical to defining response. Additionally, individual organ systems were examined to determine those which impacted SLEDAI improvement.

Methods: Data were analyzed from two large phase 3 multinational trials that evaluated the impact of an anti-BAFF antibody or placebo, when added to *s*tandard of *c*are (SOC) on SLE disease activity using the SRI-5 endpoint (combined n=2262 SLE patients) (1,2).

Results: The overall SRI-5 response rate was 32.8% (743/2262). Non-response due to lack of a 5-point SLEDAI improvement, conmed violation or dropout were observed in 31% (702/2262), 16.5% (373/2262) and 19.1% (433/2262), respectively. In contrast, only 0.5% (7/2262) failed to meet responder criteria due to deterioration by BILAG or PGA after achieving ≥ 5 point reduction in SLEDAI, trial completion and adherence to concomitant medication rules. As expected,the predominant individual SLEDAI organ systems involved at baseline were mucocutaneous (90.6%), musculoskeletal (82.9%) and immunologic (71.6%) In the mucocutaneous organ system, the baseline prevalence of rash was 69.2%;

alopecia 58.2%; mucosal ulcer 32.5%. In the musculoskeletal system, the baseline prevalence of arthritis was 82.6%; myositis 1.1% SLEDAI organ systems with low prevalence and high point value (≥ 4 pts/feature) were also examined. At baseline, 18.1% of patients in Trial 1 and 17.2% in Trial 2 had renal, vascular or CNS organ involvement. SRI-5 response rates for placebo + SOC were CNS: 66.7%, 57.1%; renal: 45.2%, 53.3%; and vascular: 56.7%, 48%, in Trials 1 and 2, respectively. SLEDAI improvement for the 4 most common individual features was examined in the placebo plus SOC population (analysis based on observed data). Response rate for arthritis: 58.4%, 66.5%; rash: 47.8%, 54.3%; alopecia: 43.1%, 48.4%; and mucosal ulcer 85.4%, 74.7% in Trials 1 and 2, respectively.

Conclusion: The primary drivers of SRI-5 response in these trials were SLEDAI improvement, concomitant medication adherence and trial completion, which have intrinsic clinical meaningfulness. When SLEDAI scores improved by ≥ 5 points at wk 52 in pts with stable SOC, worsening in other disease activity instruments was rare, making their contribution less relevant to the outcome of a trial. Patients with infrequent yet severe manifestations had high placebo group response rates. Thus, for clinical trials that are intended to study new therapeutics in SLE patients with non- major organ threatening disease manifestations, a simple, dichotomous improvement in SLEDAI score, coupled with successful trial completion and medication stability, may provide a simple and potentially more clinically relevant approach to assess outcome.

What Is the Prevalence of Cognitive Impairment in Lupus and Which Instruments Are Used to Measure It? a Systematic Review and Meta-Analysis

Hanan Al Rayes[1], Chiara Tani[2], Marta Mosca[2], Jorge Medina-Rosas[3], Ahmed Moustafa[4], Panayiotis Lambiris[5] and Zahi Touma[1], [1]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Clinical and Experimental Medicine, University of Pisa, Rheumatology Unit, Pisa, Italy, [3]Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [4]Medicine, Western University, London, ON, Canada, [5]University Health Network, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To systematically review literature on: 1) the prevalence of Cognitive Impairment (CI) in SLE patients in the presence or absence of neuropsychiatric involvement (NPSLE), 2) the metrics of CI and 3) the relative risk (RR) for CI in SLE compared to Rheumatoid Arthritis (RA) and healthy individuals.

Methods: This review was prepared with a protocol following the Preferred Reporting Items for Systematic Reviews and

Meta-Analysis-Protocols statement. Literature search (1900-2016) in Ovid Medline, Embase and Psyc INFO for articles on the prevalence of CI in adult SLE patients using a specified neuropsychological instrument of cognitive function (CF) was conducted. Included studies were critically appraised and analyzed. The prevalence of CI was studied for all instruments and whenever possible Pooled Prevalence (PP) was determined in the commonly used instruments [standardized batteries, Modified Mini–Mental State Exam (MMSE), Automated Neuropsychological Assessment Metric (ANAM) and Montreal Cognitive Assessment (MoCA)].

Results: Of 3422 references, 670 were selected for detailed review and 84 were included in the final analysis. Standardized batteries (including ACR battery) were utilized in 41 studies in 3338 patients and found a PP of CI of 34% (95% CI: 28-40%) (Figure 1). CI was higher in NPSLE with PP of 41 (95% CI: 26-57%) (Pooled from 13 studies in 647 NPSLE patients). ANAM was utilized in 9 studies in 773 patients and yielded a PP of CI of 37% (95% CI: 20-55%). MMSE was utilized in 9 studies in 766 patients and yielded a PP of CI of 19% (95% CI: 10-30%). MoCA was utilized in 2 studies in 100 patients and yielded a PP of CI of 45% (95% CI: 14-77%). A large variability in the prevalence of CI and a high statistical heterogeneity (I^2> 75%) among studies was identified. This could have resulted because of: 1-the lack of standardization in the metrics and definitions of CI in SLE, 2) heterogeneity in the studied sample size (which involved patients with and without NPSLE) and 3) variability in other demographics such as patients age, education levels and others factors. _ The RR for CI in SLE was 1.77 (95% CI: 1.19-2.64) compared to RA (data from 6 studies of 343 lupus and 193 RA patients. The RR for CI in SLE compared to healthy individuals was 2.57 (95% CI: 1.62-4.08) (data from 10 studies of 529 SLE patients and 328 healthy individuals).

Conclusion: Patients with lupus have a high prevalence of CI ranging from 2.7–80% and largely depending on the metrics and the presence or absence of NPSLE. There is a lack of a standardized approach on how to measure and define CI in SLE. ANAM and standardized batteries (including ACR) yielded similar CI prevalence, while MMSE carried the lowest prevalence. NPSLE patients are as well at a higher risk for CI compared to non-NPSE. Lupus patients are at a higher risk to develop CI compared to RA and healthy individuals. **Figure 1. Forest Plot of CI in SLE patients using standardized batteries including ACR**

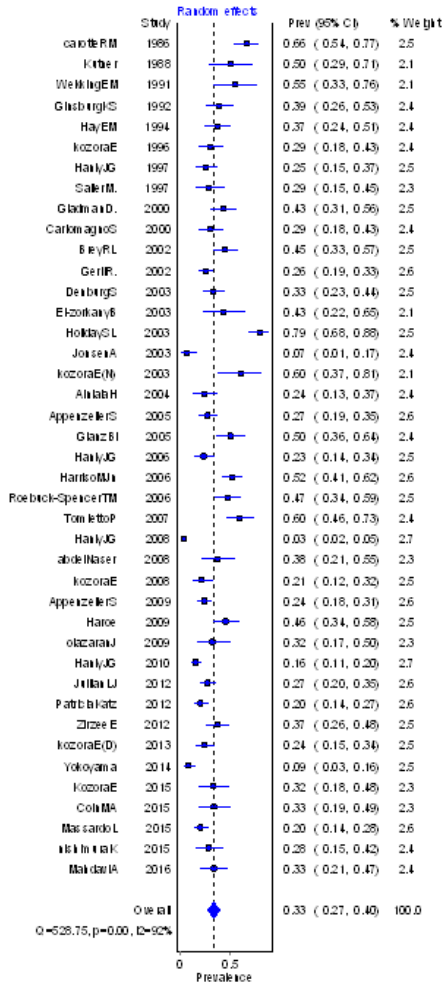

Figure 2. Forest Plot of CI in SLE patients using ANAM test:

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A major unmet need in SLE is the identification of a biomarker that consistently tracks with disease activity. One current approach is measuring complement activation by evaluating consumption of serum C3 and C4. However, since they are acute phase reactants, interpretation of these levels is challenging as serum levels may not decrease until late in a disease flare. iC3b is a proteolytically derived molecule of C3b, and increases with complement activation. iC3b/C3 ratio measures complement consumption relative to production, which may provide for a more accurate assessment of complement activation. We hypothesize that blood iC3b and iC3b/C3 levels will provide a more specific and reliable marker of complement activation and disease activity in SLE.

Methods: 137 adult SLE patients were enrolled in this prospective, longitudinal, observational study. 79 patients with 3-7 study visits were used for this longitudinal analysis. C3 and C4 were measured by nephelometry; iC3b by a lateral flow assay using an investigational medical device. SLE disease activity was measured using the SLEDAI 2K Responder Index-50 instrument. Multilevel regression models were performed to examine associations for SLE disease activity. Ordinal logistic regression models with generalized estimating equation modeling (GEE) were used to examine associations for clinically meaningful changes since the outcome variable is ordinal (i.e. clinical deterioration, stability, and improvement). Odds ratios and 95% confidence intervals for iC3b, C3, iC3b/C3 ratios, C4, ESR, CRP, dsDNA values, prednisone usage, and race were estimated using Proc GLIMMIX and Proc GENMOD (SAS v9.4).

Results: Blood levels of iC3b, C3, iC3b/C3 ratio, C4, dsDNA, and prednisone use each correlated with SLE disease activity. Multilevel multiple logistic regression analysis revealed only iC3b/C3 ratio, dsDNA levels, and prednisone use were significant predictors of disease activity (Table 1A). To determine whether iC3b/C3 ratio can predict clinically meaningful changes in SLE disease activity, we evaluated the interpatient longitudinal associations between clinical deterioration, stability, and improvement and iC3b/C3 ratios. Only iC3b/C3 ratio and prednisone use significantly predicted clinically meaningful changes in disease activity (Table 1B).

Conclusion: In this prospective, longitudinal study, blood iC3b/C3 ratios are predictive of active SLE disease. Furthermore, iC3b/C3 ratio is predictive of clinical meaningful changes in SLE disease activity. These data warrant further investigation of iC3b/C3 ratio as a potential biomarker for SLE disease activity.

Using the American College of Rheumatology and Systemic Lupus International Collaborating Clinics Criteria to Measure Disease Severity in Discoid Lupus Erythematosus

Jenna K. Presto[1,2], Jessica S. Haber[1,2] and Victoria P. Werth[1,2], [1]Department of Dermatology, University of Pennsylvania, Philadelphia, PA, [2]Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Discoid lupus erythematosus (DLE) progresses to systemic lupus erythematosus (SLE) in up to 28% of cases. The Systemic Lupus International Collaborating Clinics (SLICC) SLE criteria were developed to improve the American College of Rheumatology (ACR) criteria, but have not been assessed in DLE patients.

Methods: This was a retrospective study of 172 DLE patients enrolled in a cutaneous lupus database at the University of

Pennsylvania. Patients were assessed for the presence of ACR and SLICC criteria using the database and respective electronic medical records. The Fischer's exact test was used for each criterion in the ACR and SLICC to determine a difference between patients with DLE/SLE and DLE-only disease.

Results: Using the ACR criteria, 74 patients (52%) were classified as DLE/SLE and 68 (48%) as DLE-only, compared with 66 (46%) DLE/SLE and 76 (54%) DLE-only patients using the SLICC criteria (p=0.08). This net increase of 8 patients meeting ACR criteria was due to the presence of the photosensitivity criterion and fewer immunologic criteria under ACR. Due to the immunologic criteria requirement under SLICC, it can be challenging to determine an SLE diagnosis retrospectively. Overall, DLE/SLE patients were more likely than DLE-only patients to exhibit significant systemic symptoms with regard to arthritis (ACR 73% *vs.* 9%, p<0.0001; SLICC 70% *vs.* 18%, p<0.0001), serositis (ACR 22% *vs.* 0%, p<0.0001; SLICC 22% *vs.* 3%, p<0.0001), and renal disorder (ACR 27 % *vs.* 2%, p<0.0001; SLICC 33% *vs.* 0%, p<0.0001). SLE was more common in generalized DLE than in localized DLE using ACR (p=0.0001) and SLICC (p=0.0068) criteria. DLE/SLE patients were more likely to have worse skin disease compared to DLE-only patients when classified according to ACR criteria, with 40.5% of DLE/SLE patients having CLASI^{TM} activity ≥ 10 and 25.0% of DLE-only patients having CLASI^{TM} ≥ 10 (Table 1).

Conclusion: DLE/SLE patients have more significant internal disease than DLE patients who do not meet SLE criteria. Our findings trended toward the ACR criteria classifying more DLE patients with SLE than the SLICC criteria, particularly in patients without extensive laboratory testing. DLE-only patients may have significant skin disease with approximately 25% of DLE-only patients having moderate to severe skin disease.

	DLE with SLE n (%)	DLE without SLE n (%)	P-value
CLASI^{TM} ≥ 10	30 (40.5)	17 (25.0)	0.0493*
CLASI^{TM} < 10	44 (59.5)	51 (75.0)	

Table 1A. Skin activity in DLE/SLE vs DLE-only patients using ACR criteria. DLE/SLE patients are more likely to have worse skin disease compared to DLE-only patients when classified according to the ACR criteria.

	DLE with SLE n (%)	DLE without SLE n (%)	P-value
CLASI^{TM} ≥ 10	27 (40.9)	20 (26.3)	0.0653
CLASI^{TM} < 10	39 (59.1)	56 (73.7)	

Table 1B. Skin activity in DLE/SLE vs DLE-only patients using SLICC criteria. There is a trend of DLE/SLE patients having worse skin disease compared to DLE-only patients when classified according to the SLICC criteria.

Unresolving C4 Hypocomplementemia Associates with a Different Spectrum of Disease in SLE and Is More Important Than Transiently Low Levels

Laura Durcan[1], Wei Fu[2] and Michelle Petri[3], [1]University of Washington, Seattle, WA, [2]Division of Rheumatology, School of Medicine, Johns Hopkins University, Baltimore, MD, [3]Rheumatology Division, Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hypocomplementemia is common in systemic lupus erythematosus (SLE) and is included in classification criteria and disease activity indices. Whether persistently low complement levels (C3, C4 and both) are more important as serological markers, than levels which transiently drop in SLE is unknown. This work was undertaken to characterize SLE patients with persistent hypocomplementemia and to compare them to those with intermittently low levels.

Methods: Patients were identified as part of a longitudinal lupus cohort. Levels of C3 and C4 were measured quarterly, by nephelometry. Patients were considered with complement levels (either C3, C4 or both), which never returned to the normal range on longitudinal follow-up. Further analysis included those with intermittently low levels. To assess associated clinical manifestations, univariate and multivariate logistic regression were used. The multivariate analysis controlled for ethnicity, and gender.

Results: 2399 SLE patients, 53% Caucasian and 38% African-American, were evaluated. A history of ever having had low C3 was present in 55% and low C4 in 47%. There were 83 (4.0%) patients with persistently low C3, which never normalized and 65 (3.2%) individuals with persistently low C4. The clinical manifestations associated with persistent hypocomplementemia are outlined in Table 1 whilst those associated with transiently low levels are in Table 2. Persistently low C3 associates with renal, hematologic and serologic abnormalities with similar manifestations in those with intermittently low C3. Contrarily, chronically low C4 associates with a myriad of abnormalities, serologic and hematologic whilst intermittently low levels associate only with a positive anti-double stranded DNA, anticardiolipin and a false positive rapid plasma reagin. Persistently low C3 and C4 in combination associated with serologic abnormalities and the presence of antiphospholipid antibodies, whilst in those with transiently low levels there was cutaneous, neurologic, hematologic and immunologic dysfunction demonstrated.

Conclusion: Low complement is an important finding in SLE. Transiently low C4 is a weak marker which associates with few clinical manifestations. However, chronically low C4, which may represent a subset of patients with genetic deficiency, associates with a different spectrum of disease and has different, more severe, clinical implications.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Criteria for the classification of SLE are being developed with the support of EULAR and ACR. Two independent exercises (expert-based Delphi exercise and data-driven cohort evaluation of early SLE and controls) were undertaken to generate candidate criteria, and then reduce them to a smaller set. The objective of this study was to select a set of items that maximizes the likelihood of accurate classification of SLE, particularly early disease.

Methods: In the Delphi exercise, 120 international SLE experts proposed 196 items useful for the classification of a broad spectrum of SLE, including early and late stage disease.[1] Features distinguishing early SLE (<3 years) and controls were also evaluated in a cohort from 2 European and 2 North American centers.[2] The candidate criteria were rated, and low ranking and redundant criteria were removed, leaving 41 criteria.[1] An independent panel of seven international SLE experts (reflecting practice in Spain, France, Germany, United States, Canada and Mexico) was asked to rank the 41 candidate criteria. The ranking was presented at a face-to-face meeting of the expert panel and steering committee. A consensus meeting using nominal group technique (NGT) was conducted to reduce the list of criteria for consideration.

Results: The expert panel NGT exercise reduced the candidate criteria for SLE classification from 41 to 21. The panel distinguished potential “entry criteria”, which would be required for classification, from other potential “additive criteria”, summarized in Table 1. Potential entry criteria were ‘ANA ≥1:80 (by HEp 2 immunofluorescence)’ and ‘low C3 and/or low C4.’ The use of low complement as an entry criterion was considered potentially useful in cases with negative ANA. **Table 1.** Additive Criteria

Lupus nephritis by renal biopsy with immune deposits
Rash with dermoepidermal interface changes and/or immunoglobulin and/or complement deposition on immunofluorescence
Anti-dsDNA antibody
Anti-Smith antibody
Presence of multiple autoantibodies*
Anti-phospholipid antibodies (*lupus anti-coagulant, anti-cardiolipin, anti-beta2GPI, or prolonged RVVT*)
Leukopenia (<4000/mm^3 on 2 or more occasions)
Thrombocytopenia <100,000 on 2 or more occasions
Autoimmune hemolytic anemia
Active urine sediment (without UTI)
Persistent proteinuria (≥0.5g/day)
Acute cutaneous lupus: SLICC definition (includes subacute cutaneous lupus)
Chronic cutaneous lupus: SLICC definition
Alopecia with associated scalp inflammation
Arthritis*
Serositis *(pleural, pericardial effusion, pleurisy, pericarditis, peritonitis)*
Oral mucosal lesions on the hard palate
CNS manifestations *(seizures, psychosis, chorea, myelitis, optic neuritis, stroke or acute confusional state*)
Fever*

* to be defined. Additional work is needed to refine definitions, to evaluate their independence and relationships within domains, and to ascertain item weights.

Conclusion: The expert panel's NGT exercise resulted in 21 candidate SLE classification criteria. Refinement of definitions, ability to cluster criteria into domains and weighting of criteria will be ascertained in the next phase.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) has historically lacked clear treat-to-target definitions. The recently reported Lupus Low Disease Activity State (LLDAS) definition, combining disease activity and treatment domains, was shown to be associated with protection from damage accrual in a longitudinal cohort study. Before acceptance in clinical practice and research, any new measure should undergo rigorous validation including face, content, construct and criterion validity. The objective of this study was to assess the construct validity of LLDAS by testing the operational definition against SLE expert opinion.

Methods: Fifty SLE case summaries based on real patients and without manipulation were prepared by experts in 4 countries in the Asia Pacific. Each case detailed past history, current disease features, current treatment and investigation results. Fifty rheumatologists with expertise in SLE, from multiple centres and countries, but with no prior involvement in the LLDAS project, responded to a survey in which they were asked to categorise the current disease activity state of each case as either remission, low, moderate or high, without reference to the operational definition. Two investigators independently assessed whether each case met the operational definition of LLDAS. Agreement between expert opinion and the operational definition of LLDAS was assessed using Cohen's Kappa.

Results: In total, 2500 unique responses were collected. Overall agreement between expert opinion and the operational definition of LLDAS was 77.96% (95% CI 76.34 – 79.58%), with a Cohen's Kappa of 0.57 (95% CI 0.55 – 0.61). Of the cases (22 of 50) that fulfilled the operational definition of LLDAS, only 5.34% of responders classified the cases as moderate/high activity. In contrast, of the cases that did not fulfill the operational definition of LLDAS (28 of 50), 35.14% of responders classified the cases as remission/low activity. Common reasons for this discordance were assignment to remission/low activity of cases with higher corticosteroid doses than defined in LLDAS (prednisolone ≤ 7.5mg) or serological activity (high anti-dsDNA antibody and /or low complement).

Conclusion: LLDAS has good construct validity with high overall agreement between the operational definition of LLDAS and expert opinion. Discordance of results suggests that the operational definition of LLDAS is more stringent than expert opinion at defining a low disease activity state, and that expert definition of acceptable corticosteroid dose in SLE varies.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The indirect immunofluorescence (IIF) pattern observed in the antinuclear antibody (ANA) test provides an initial assessment of autoantibody responses in candidate patients who have or may be at risk of developing systemic autoimmune rheumatic diseases (SARD). Despite its wide clinical use, a universal nomenclature to describe ANA IIF patterns has not been adopted. The International Consensus on ANA Patterns (ICAP) Initiative originated workshops that began in Sao Paulo (2014), followed by the 2nd workshop in Dresden (2015). The goal of ICAP is to promote harmonization of ANA pattern nomenclature and provide guidelines for ANA interpretation, thereby optimizing adoption in diagnostic laboratories and extended to patient care.

Methods: A working committee addressed collective issues on ANA nomenclature that were raised by participants representing research, clinical, and diagnostic laboratories. Post-workshop exchanges were held with the goal of reaching consensus on key issues.

Results: ANA IIF patterns were separated into three major categories (nuclear, cytoplasmic, and mitotic patterns) and each pattern was defined and described in detail. Consensus was achieved for 28 IIF patterns that were designated with an alpha-numeric code (AC-1 to AC-28) and summarized under a nomenclature and classification tree (ANApatterns.org). Important findings include, e.g., the Homogeneous and Coarse Speckled nuclear patterns are linked to autoantibodies strongly associated with SARD whereas the Dense Fine Speckled (DFS) nuclear pattern in isolation virtually rules out a SARD diagnosis. ICAP initiatives include translation of the website into other languages, establishing guidelines in ANA reporting, and programs for continuing education. The translation initiative promotes the establishment and dynamic engagement of a worldwide network. To date, the website displays its content in English, Spanish, Portuguese, Italian and German while, Chinese, Japanese and French translations are ongoing. Continuous education courses aim to spread and update the ICAP nomenclature/conceptual framework and to promote competency in ANA interpretation.

Conclusion: ICAP has provided a common platform to address issues that are of great interest to the community. The establishment of a consensus on ANA reporting will require interaction with committees in charge of establishing disease classification and diagnostic criteria. Future goals include building collaborative data on ANA IIF patterns, selection of new consensus patterns, and establishment of an interpretative clinical description for each AC pattern for clinical use. The 3rd and 4th ICAP workshops are planned for Kyoto (October 2016) and Dresden (September 2017).

Systemic Lupus Erythematosus (SLE) Responder Index [SRI(4)] Response Is Associated with Global Benefit in Patients with Moderate to Severe SLE

R Furie[1], L Wang[2], J Drappa[2] and G Illei[2], [1]Northwell Health, Great Neck, NY, [2]MedImmune, Gaithersburg, MD

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: *Post-hoc* analysis of two Phase III studies of belimumab[1] showed that an SRI(4) response is associated with clinically meaningful benefits, irrespective of treatment assignment. Confirmation of these findings in independent cohorts will enhance the acceptance of SRI(4) as a measure of clinically meaningful improvement. This analysis assessed global clinical benefit represented by an SRI(4) response.

Methods: Changes from baseline in clinical, laboratory, and patient-reported outcome measures at Day 365 were compared between SRI(4) responders (n=396) and non-responders (n=340) in the combined dataset of two Phase IIb studies evaluating sifalimumab and anifrolumab (MUSE) in moderate to severe SLE.

Results: Baseline demographics were similar between the studies. At Day 365, a greater percentage of responders than non-responders had ≥7-point reduction in SLE Disease Activity Index 2000 (SLEDAI-2K) and had their oral corticosteroid dose reduced to ≤7.5 mg/day (Table). Responders also had greater percentage changes from baseline in clinical SLEDAI scores, and greater improvements in Physician's Global Assessment (PGA) score and number of SLEDAI-2K organ domains with improvement. British Isles Lupus Assessment Group (BILAG) "A" or "2B" flare rates were lower in SRI(4) responders. A larger percentage of responders with ≥8 swollen and ≥8 tender joints at baseline had ≥50% improvement in swollen and tender joint counts. In patients with moderate to severe skin disease at baseline, defined as Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) activity score ≥10, more responders had ≥50% improvement in CLASI. In patients with detectable anti–double-stranded DNA (anti-dsDNA) antibodies at baseline, responders had greater improvements in anti-dsDNA concentrations; however, in patients with low complement concentrations at baseline, the improvements in complement C3 and C4 concentrations were similar between responders and non-responders. Responders also had greater improvements in patient-reported outcomes: percentage change from baseline in Patient Global Assessment, and absolute change in Short Form 36 Health Survey (SF-36; Physical Component Summary, Mental Component Summary, Vitality) and Functional Assessment of Chronic Illness Therapy (FACIT)–Fatigue scores.

Conclusion: SRI(4) response in patients with moderate to severe SLE was associated with broad improvements in clinical and patient-reported outcomes. SRI(4) response in this analysis was driven by clinical components and confirm previous findings suggesting SRI(4) response is associated with global clinically important benefits. Session Time: 9:00AM-11:00AM

Multi-parametric model development for assessing lupus nephritis and disease activity Christopher Sjöwall[1], Chelsea Bentow[2], Mary Ann Aure[2], Gabriella Lakos[2], Peter Martis[2], Michael Mahler[2] [1]AIR/Rheumatology, Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden [2]Research and Development, Inova Diagnostics, San Diego, CA, USA

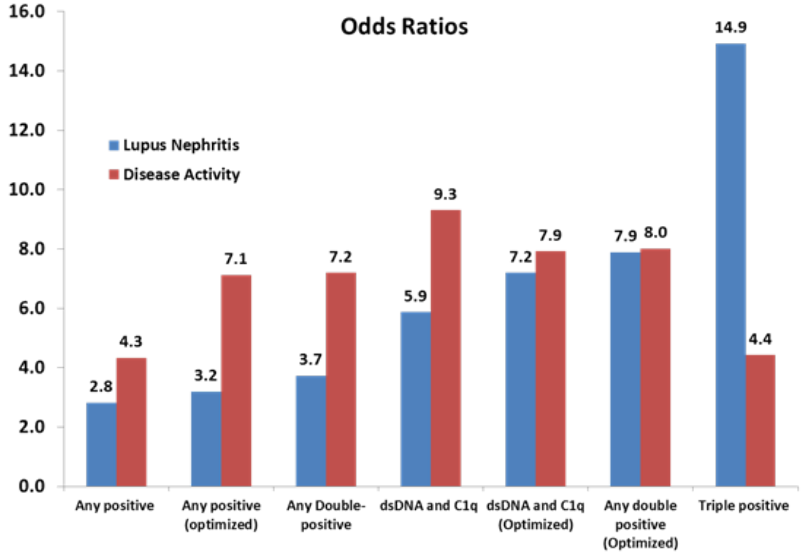
Background/Purpose: The clinical complications and symptoms of systemic lupus erythematosus (SLE) can vary widely with the individual and appropriate management is critically dependent upon the proper assessment of disease activity and organ damage. Although antibodies such as anti-dsDNA have been shown to correlate with disease activity and the likelihood of nephritis in lupus patients, the additive effect of combined biomarkers is not widely implemented. Using a cohort of well characterized SLE patients, this study investigated the utility of developing an SLE assessment model using a combination of biomarkers, namely anti-dsDNA, anti-C1q, and anti-Ku antibodies.

Methods: Samples from 261 SLE patients from Linköping University (Sweden) were tested using chemiluminescent immunoassays (CIA) for anti-dsDNA and anti-Ku (research use only) antibodies as well as by anti-C1q ELISA (all methods Inova Diagnostics, San Diego, USA). Of these 261 SLE patients, 69 (26.4%) had lupus nephritis (LN) at the time of the blood draw, or had the history of LN. The SLE disease activity index-2K (SLEDAI) scores were available for all patients and a cut-off >4 was used to define active disease (50/261, 19.2% active). The data were statistically evaluated using Analyse-it software (Version 3.90.1; Leeds, UK). The multi-parametric analysis was performed at both the manufacturer's cut-off for the methods as well as optimized cut-off points based on likelihood plots to increase the odds ratio.

Results: In the total cohort, all three antibodies (dsDNA, C1q, and Ku) demonstrated markedly higher prevalence and quantitatively higher antibody levels in active SLE patients versus inactive patients and in LN patient versus non-LN patients (see table).

	Anti-dsDNA		Anti-C1q		Anti-Ku	
	Antibody titer level	Antibody prevalence	Antibody titer level	Antibody prevalence	Antibody titer level	Antibody prevalence
Active *vs.* Inactive	$p<0.0001$	$p<0.0001$ Odds ratio = 4.2	$p<0.0001$	$p<0.0001$ Odds ratio = 6.9	$p=0.0012$	$p=0.3343$ Odds ratio = 1.8
LN *vs.* non-LN	$p<0.0001$	$p=0.0002$ Odds ratio = 2.9	$p<0.0001$	$p<0.0001$ Odds ratio = 4.4	$p=0.0213$	$p=0.1625$ Odds ratio = 2.1

When multi-parametric analysis was performed by combining biomarker results, the likelihood of nephritis and patients with active disease increased with dual positivity and triple positivity (see figure).



Conclusion: This study demonstrates the utility of a multi-parametric model approach using biomarkers for assessing SLE patients for more active and severe disease, especially for patients that may develop lupus nephritis. Furthermore, the results hold promise for the benefit of combined autoantibody profiling for the clinical management of patients.

Development and Initial Validation of a Novel Lupus Disease Activity Index to Account for Glucocorticoids: Sledai-2K Glucocorticoids Index (SGI)

Zahi Touma[1], Dafna D Gladman[2], Jiandong Su[3] and Murray Urowitz[1], [1]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is challenging to describe disease activity in SLE in the context of multiple levels of glucocorticoids (GC) treatment. We aim to develop and validate a new index, SLEDAI-2K Glucocorticoids Index (SGI), to accurately describe disease activity while accounting for GC doses.

Methods: The first 2 phases focused on to the development of the index. Phase 1: identification of scenarios of real patients seen prospectively in a longitudinal cohort at the centre in the last 20 years. Phase 2: derivation of an equation that explains the association between SLEDAI-2K and GC dose while using physician global assessment (Likert scale [LS] 0-7) as the gold standard. Phase 3 was to validate the new index, SGI, against SLEDAI-2K in a cohort of active patients on standard of care treatment. ***Phase 1*** Scenarios were identified using 2 data sampling approaches. First, the top 13 most common organ involvement combinations were identified. From each of these combinations, random scenarios with a wide spectrum of GC doses were selected. Second, patients in the entire database were grouped into 7 categories based on the GC dose [5, 10, 15, 20, 30, 50 and 60 mg/day] and 10 patients were selected randomly from each category. Scenarios included information on patients' SLEDAI-2K score, organ involvement combination and GC dose. ***Phase 2*** 3 rheumatologists ranked disease activity with LS. The sample size calculation was on the assumption of reliability with ICC ≥0.80 and required a minimum of 46 scenarios. ***Phase 3*** An independent cohort was used for the validation. We hypothesized that in patients with improvement and worsening (SLEDAI-2K decrease ≥4 and increase >4 respectively), the change in SLEDAI-2K and SGI scores will move in the same direction.

Results: **1-**The first approach yielded 29577 visits in 1400 patients and 51 scenarios. The second approach yielded 18178 visits in 1086 patients and 80 scenarios. **2-** 131 scenarios were summarized and ranked by 3 rheumatologists leading to 393 records. A perfect agreement in LS was achieved; ICC (2, k) of 0.89 (95% CI: 0.83, 0.89). A quadratic linear regression model relating GC and SLEDAI-2K was structured in this equation: SGI score =SLEDAI-2K score + [3.65 + 0.29 * GC – 0.0027 (GC * GC)]. The weight score of GC doses was derived and represented in table 1. For instance, SLEDAI-2K of 6 on 10 mg of GC provides SGI of 9. The application of SGI is illustrated in table 1. **3-** Concurrent Construct Validity: Of the 158 patients studied, 109 patients improved, 38 remained unchanged, and 11 worsened at 9-12 months follow up. At follow up SLEDAI-2K and SGI correlated highly (r= 0.87) and changed in the same direction in patients with improvement and worsening proving the validity of SGI.

Conclusion: We developed and validated a novel lupus disease activity index, SGI, that describes disease activity while accounting for GC dose.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To date, there is no generally accepted definition for remission in SLE, thus a possible goal in the treat-to-target strategy might be low disease activity. Lupus Low Disease Activity State (LLDAS) is a consensus-based definition of minimally acceptable disease activity in SLE patients (1). This definition has been initially tested for criterion validity in a multi-ethnic cohort of patients showing that it is associated with improved patient outcomes.
The aims of this study are: i) to evaluate what proportion of patients fulfils the definition of LLDAS in a monocentric cohort of Caucasian SLE patients; ii) to evaluate the effect of LLDAS attainment on damage accrual over a period of 5 years.

Methods: This is a retrospective analysis of data prospectively collected in a longitudinal observational cohort of SLE patients established in our centre in 2011; patients fulfilling the 1997 ACR classification criteria who attended the last visit from January 2016 and May 2016 were enrolled in the study. Among patients regularly followed from 2012 and 2016, those with at least one visit per year and
complete clinical and serological data available were included in this analysis. The definition of LLDAS was applied to each patient for each visit; organ damage was calculated with the SLICC/DI score (SDI) at study entry and at last observation.

Results: One hundred and six patients were eligible for the study (96.2% females, mean age at last visit 47.1±13, mean disease duration at last visit 17.5±9.3 years). At last observation the mean SELENA-SLEDAI score was 2.7 ±2.5;
84 patients (79.2%) were on treatment for SLE (glucocorticoids and/or immunosuppressants and/or biologics), 22 (20.7%) were off treatment or were taking only antimalarials drugs. According with all the items of the definition, at last observation LLDAS was present in 83 patients (73%); among these, 22 patients (20.8%) maintained a stable LLDAS during the 4.5 years of follow-up (LLDAS fulfilled for all visits). Twenty-seven patients (25.4%) accrued organ damage during the follow-up; in the cohort as a whole the mean increase in SDI was 0.3 (±0.6) resulting in a mean final SDI of 1.2 (±1.7). Patients who maintained LLDAS were younger ($p<0.02$), had a lower disease activity score at study entry ($p<0.001$) and were more likely GC-free at last observation ($p=0.005$). No differences in term of major organ involvement were present in LLDAS versus non-LLDAS patients. Patients who maintained LLDAS accrued less organ damage (ΔSLICC=0.27 vs 0.33) but this difference did not reach statistical significance.

Conclusion: In our cohort, a high percentage of patients fulfils the proposed definitions for LLDA at last visit but only a minority maintained this state for all the follow-up period. A minimally acceptable
disease activity state is an achievable target in clinical practice; it is associated with a successful GC tapering and, probably, better long-term outcomes. Reference:

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Robust, certified, and traceable reference material for autoantibody testing is vital for the validity of results obtained in the clinical laboratory. International standards for qualitative and quantitative immunologic assays are traditionally based on large batches of serum/plasma obtained from a single individual. However, autoantibodies from one single individual may not appropriately represent the vast heterogeneity of autoantibodies observed in human species. Autoantibodies to the 70/75kDa Lens Epithelium-Derived Growth Factor (LEDGF) yield a characteristic nuclear dense fine speckled (DFS) pattern on the ANA assay on HEp-2 cells. Anti-DFS70/LEDGF75 antibodies must be appropriately identified because they virtually rule out the diagnosis of systemic autoimmune rheumatic diseases. Herein we propose pooling up samples from hundreds of individuals with the characteristic DFS pattern at high titer and specific anti-DFS70/LEDGF75 reactivity. This approach should provide a reference reagent that better represents the heterogeneity within human species regarding anti-DFS70 autoantibodies.

Methods: Serum samples with the characteristic DFS pattern at titer ≥1/640 were sequentially selected in the laboratory ANA practice and kept at -80^{o}C. Validation of samples and pools included agreement on the characteristic ANA DFS pattern by 3 independent examiners and demonstration of the typical 75kDa band on western blot and moderate/strong anti-DFS70 reactivity in 2 independent methods [ELISA (cut-off>1.0) and chemiluminescent assay (CLIA; cut-off>20)]. A progressive pooling strategy included the formation of PENTA pools (5 validated samples), ICOSA pools (4 validated PENTA), SEMI-FINAL pools (3-5 validated ICOSA) and the FINAL POOL (8 validated SEMI-FINAL). The FINAL POOL was serially diluted in fetal bovine serum (FBS) to verify the linearity and increase the volume adjusting to moderate reactivity.

Results: The 760 validated samples (CLIA median 337.7U; 26.1–3,547.0) yielded 152 validated PENTA (CLIA:

420.6U; 60.4-3,518; ELISA: 5.5U; 2.8-6.8). The 152 PENTA yielded 38 validated ICOSA (CLIA: 407.2U; 77.5-1,823.3; ELISA: 5.5U; 3.7-6.7), 8 SEMI-FINAL pools (ELISA 5.2U; 3.8-6.2) and FINAL pool (ELISA 5.1U). Intermediary pools and the FINAL pool exhibited the characteristic DFS pattern and a clear-cut 75kDa band in WB. Serial dilution in FBS resulted in a linear decreasing reactivity in all methodological platforms.

Conclusion: This proof-of-concept study indicates that pooling samples from hundreds of individuals with high titer anti-DFS70 reactivity preserves the original reactivity of individual samples encompassed, as judged by the ANA, CLIA, ELISA, and WB assays. The present anti-DFS70 standard will integrate the panel of ANA standards of the Autoantibody Standardization Committee affiliated with the International Union of Immunology Societies (IUIS), to be distributed by the Centers for Disease Control. The extrapolation of this model to other autoantibody specificities must be validated by appropriate studies.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Background/Purpose: Randomized controlled trials (RCTs) in SLE identify specific populations of interest for eligibility, but still vary in the recruited populations. These differences may include the baseline disease activity level, laboratory findings, baseline treatment medication use, and racial mix. Previously presented data highlight regional differences in SLE populations which in turn may influence treatment responses. This study analyzed the demographics and baseline disease characteristics of randomized SLE patients across three different RCTs conducted through our organization.

Methods: We evaluated combined screening data from three recently enrolled SLE RCTs post hoc. Eligibility criteria were targeted at the enrollment of patients with active SLE meeting ACR classification criteria (SELENA-SLEDAI ≥8 for two studies of ~700 and 850 patients each, and SLEDAI-2K ≥6 for the third study of ~300 patients). Two studies were globally recruited, one was regional. Patients with varying degrees of severely active lupus nephritis or neuropsychiatric SLE were excluded. Differences between each combination of two study populations were evaluated via a two-tailed t-test for disease duration, corticosteroid use, immunosuppressant use, complement and anti-dsDNA status.

Results: Of the 1854 randomized patients, 50.1% were Asian; 38.8%, white; and 5.7%, black; and 93.4% were female. Details regarding treatment medications (corticosteroids, immunosuppressants, antimalarials), SLEDAI scores (total, clinical); anti-dsDNA, ANA, and C3/C4 status are presented in Table 1 and regarding subjects meeting each SLEDAI criterion in Table 2. Mycophenolate (20.0%) was the most common immunosuppressant used, followed by azathioprine

(15.8%) and then methotrexate (9.5%). Differences existed between each study population at the $p<0.001$ level for the percentage of subjects on corticosteroids, on immunosuppressants (except for a nonsignificant difference between the two global studies); with hypocomplementemia, with elevated anti-dsDNA titers or with both.

Conclusion: SLE patients enrolled in RCTs, despite having similar levels of disease required by the SLEDAI, varied in critical baseline laboratory characteristics and standard of care medications. These differences may have resulted from variables such as study size and regional aspects, e.g., racial mix, standard of care; and may impact treatment responses. Further differences in disease activity by region and race are being evaluated. Understanding such differences may influence the design of SLE RCTs moving forward.

Table 1. Screening Characteristics of All Randomized SLE Subjects

Characteristic	**Results (N=1854)**
Age, years, mean (SD)	36.0 (11.7)
Disease duration, years, mean (SD)	6.2 (6.2)
Positive ANA (≥1:80 titer or equivalent), %	97.4
Elevated anti-dsDNA ≥30 IU/mL, %	70.8
Hypocomplementemia (low C3 and/or C4), %	55.5
Elevated anti-dsDNA and hypocomplementemia, %	47.5
Oral corticosteroids, %	90.3
Oral corticosteroids ≥10 mg prednisone equivalent, %	43.3
Oral corticosteroid dose, mg, mean (SD) in subjects using corticosteroids (prednisone equivalent)	14.2 (9.3)
Antimalarials, %	70.1
Immunosuppressants, %	54.3
Corticosteroids and immunosuppressants, %	50.9
Corticosteroids, antimalarials and immunosuppressants, %	33.0
No corticosteroids, antimalarials or immunosuppressants, %	1.2
SLEDAI score ≥8, %	95.3
SLEDAI score>10, %	37.6
Clinical SLEDAI score ≥6, %	84.7
SLEDAI ≥8 and Clinical SLEDAI score ≥6, %	82.6
Proteinuria >1g/day, %	18.3
SD=standard deviation

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster I: Clinical Trial Design and Current Therapies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Oxidized Phospholipids, Lipoprotein (a) and Glycosphingolipid Associated B- 1,4 Galactosyltransferase in a Johns Hopkins cohort of patients with Systemic Lupus Erythematosus.

Background/Purpose: Systemic lupus erythematosus(SLE) is an autoimmune disease wherein the patient's immune system attacks apparently healthy tissue. These patients develop atherosclerotic plaques,and have high rates of coronary events mostly in premenopausal women. Chronic inflammation, lipid oxidation, and production of reactive oxygen species may attribute to atherosclerosis in these patients but this relationship has not been tested. We have previously shown that oxidized phospholipids(Ox-PC) could activate B-1,4galactosyltransferase to generate a glycosphingolipid, lactosylceramide which in turn, produces reactive oxygen species in vascular cells implicated in cell proliferation, angiogenesis, and migration-hallmarks in the pathophysiology of atherosclerosis.

Methods: SLE patients form the Johns Hopkins University cohort were assessed for disease activity using the Physician Global Assessment, the SELDA, and organ involvement assessments (the SLICC/ACR Damage index). Further, laboratory tests were condcuted to ascertain organ damage, and cardiovascular risk factors. Hopkins institutional board approval was obtained for this study. The SLE patients serum(N=50) were 50% Caucasian and 40% African American women with mean age of 38. Control serum(N=50) was obtianed from 90% Caucasian and 10% African American women with the mean age of 38. Serum levels of Ox-PC per apoB-100particle (Ox-PC-apoB) was measured by ELISA using a murine monoclonal antibody EO6,which binds to the phosphorylcholine group of oxidized phospholipids but not to native phospholpipids. By the use of apoB antibody an equal number of apoB particles in serum were captured first and then Ox-PC level was measured. The serum levels of lipoprotein a(Lp(a) and B-1,4galactosyltransferase(B-1,4GalT-V) were also measured by ELISA using corresponding antibody raised against these antigens.

Results: We observed that there were more Ox-PC molecules per apoB protein in the serum of SLE patients as compared to control serum. This was highly statistically significant($p<0.0001$). Since Lp(a) on apoB protein is the major carrier of OX-PC,it was not surprising to observe that the level of Lp(a) were also significantly increased in SLE serum ($p< 0.0001$). An unexpected finding was that the B-1,4GalT-V mass was also increased ($p<0.0001$) in SLE serum relative to control serum.

Conclusion: This study demonstrates that increased level of Ox-PC,Lp(a) and B-1,4GalT-V predict the pro-atherogenic and pro-inflammatory potential of these biomarkers in SLE.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a complex and highly heterogeneous disease with multi-organ involvement. Accurate tools for disease sub-classification are lacking. In most patients, skin and subcutaneous tissue are affected, and circulating immune cells are activated. We performed what is to our knowledge the first RNA-Seq on simultaneously obtained skin, intradermal white adipose tissue, and peripheral blood mononuclear cells (PBMCs) from patients with well-characterized SSc.

Methods: We obtained PBMCs and skin biopsies from healthy controls and individuals with limited cutaneous systemic sclerosis (lcSSc), diffuse cutaneous systemic sclerosis (dcSSc), and scleroderma sine scleroderma (SSS). Intradermal adipose tissue was separated from skin. Patients were followed longitudinally, and PBMCs and skin were obtained serially with repeat clinical phenotyping. We then performed stranded, total RNA-Seq for transcriptome profiling.

Results: We found increased expression of *COMP*, *THY1*, and *IGFBP4* in SSc skin biopsies with resolution to the specific differentially expressed (DE) gene isoform. In contrast, we detected a marked decreased expression of *SPAG17*, part of the ciliary axoneme central pair complex, in SSc skin. A limited set of DE genes can perfectly separate SSc from control skin. Genes with lower expression in SSc skin were enriched for the selenocysteine synthesis pathway. On the other hand, genes with increased expression in SSc skin were substantially enriched for both extracellular matrix and immune response pathways, and in particular interferon signaling. Microbial species on the skin can also be detected using *de novo* assembly. Remarkably, we found that number of DE genes and magnitude of their changes in PBMCs from SSc vs. controls was modest compared to differences detected in the skin. This dataset allows us to correlate skin scores with the transcriptome profiles of different tissues simultaneously obtained from the same individual.

Conclusion: In this initial RNA-Seq of simultaneously obtained skin, intradermal adipose tissue, and PBMCs, novel patterns of gene expression differences can be revealed that could not be recognized by earlier microarray-based transcriptome approaches. It is unclear at this time whether the matrix & immune activation signatures in the skin samples represent different SSc types, or different stages of SSc evolution. Ideally this technique could be applied to further serial biopsies to observe SSc evolution over time. Broad transcriptome profiling has excellent potential for unsupervised classification of different SSc types for further study and correlation with clinical phenotypes.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Limited cutaneous SSc (lcSSc) is characterised by less extensive skin fibrosis but patients can develop major internal organ complications and vascular manifestations. Gene expression analysis of SSc biopsies has been used to define molecular subsets of the disease and provide mechanistic insight into pathobiology. Clinically uninvolved skin in the diffuse cutaneous subset has closely replicated gene expression signatures compared with biopsies from clinically involved skin and a number of vasoactive genes have been identified this way. We have investigated the gene expression abnormalities in the more prevalent lcSSc subset through detailed transcriptional analysis of skin biopsies taken from uninvolved forearm skin.

Methods: Total RNA was extracted from skin biopsies from 15 patients with SSc fulfilling 2013 EULAR/ACR classification criteria with the limited subset of disease and 8 healthy controls (HC). Demographic, clinical and serological parameters were representative of the recruitment cohort but purposefully broad. Gene expression profiling was performed on a DNA oligonucleotide microarray chip. Differentially expressed genes (DEG) were identified using Significance Analysis of Microarrays (SAM). Functional enrichment analysis of gene signatures was done via g:Profiler.

Results: There were 218 DEG between lcSSc and HC samples (False Discovery Rate<10%). 181/218 DEG were upregulated in lcSSc samples. Hierarchical clustering of DEG suggested the presence of 2 separate groups of lcSSc samples: ‘limited 1’ and ‘limited 2’. The ‘limited 1’ group (13 samples, 10 unique patients) showed upregulation of genes involved in *cell adhesion*, *cardiovascular system* (CVS) *development* (Figure 1) and *extracellular matrix* as well as *immune* and *inflammatory response*. The CVS development signature was of particular interest as its genes showed very strong enrichment in *response to wounding*, *response to TGF-β* and *kinase cascade*. Neither ‘limited 2’ group (6 samples, 5 unique patients) nor HC samples showed functional enrichment. There were no significant differences in demographic or clinical parameters between these two groups including the presence of significant microvascular involvement and hallmark antibody reactivities.

Conclusion: Our study suggests the presence of molecular subsets in lcSSc that overlap with other clinical and serological features based on gene expression profiling of biopsies from uninvolved skin. This may reflect important differences in pathogenesis within these patient groups. We identify differential expression of a subset of genes that relate to CVS and are enriched in fibrotic signalling. This may shed light on underlying mechanisms of vascular disease in SSc. The enrichment in profibrotic profile is striking and suggests that dysregulated gene expression may contribute to vasculopathy and fibrosis in different disease subsets.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously investigated the interplay between TGFβ, BMP, VEGF and endothelin in SSc using the TβRIIΔk-fib strain, a transgenic mouse model in which there is balanced upregulation of TGFβ signalling. The pivotal role of endothelin within this multifaceted pathology was confirmed using macitentan, a licensed endothelin receptor antagonist of proven efficacy, to prevent and treat pulmonary hypertension in this model. We have extended these studies to examine whether cellular pathways targeted by modern therapies currently undergoing clinical trials in SSc are altered in this model of constitutive skin fibrosis and pulmonary vasculopathy.

Methods: RNA was isolated from cultured skin and lung fibroblasts and aortic smooth muscle cells (SMCs) explanted from adult transgenic and wildtype littermate control mice and subjected to gene expression analysis using the Illumina microarray platform (n=3 each group). Arrays were analysed for differential expression of genes involved in inflammatory, vascular and fibrotic cellular pathway components targeted by therapeutic agents undergoing multicentre clinical trial evaluation in SSc. Differential expression was defined as a 2-fold average change from wildtype with $p<0.05$.

Results: There were between 50 and 400 differentially expressed genes from the cell lines described. These gene lists were then examined to identify genes involved in the nitric oxide synthase pathway and downstream mediators (riociguat); IL-6 receptor and downstream pathways (tocilizumab) and PDGFR, FGFR and VEGFR axes (nintedanib). Several genes involved in nitric oxide metabolism were altered in lung fibroblasts, including NOS2 (inducible nitric oxide synthase), PTGIS (prostaglandin I2 synthase) and GUCY1A3 (guanylate cyclase isoform alpha 3). Genes also involved in vasoconstriction were differentially expressed in SMCs, including upregulation of multiple phosphodiesterases and PTGS-1 (prostaglandin endoperoxide synthase 1; COX-1). IL-6 gene expression was upregulated in transgenic skin and lung fibroblasts, as was STAT1, STAT3 (fold change 36:1, $p<0.004$ in skin fibroblasts) and JAK1 expression. In contrast, gp130, STAT3 and PIAS3 (protein inhibitor of STAT3) were all downregulated in SMCs. Pathways related to the mechanism of action of nintedanib are more complex since several of these downstream mediators form the non-canonical signalling pathways of TGFβ and are known to be altered in this strain. We identified multiple genes involved in these axes, for instance, upregulation of PDGFRA (fold change 137:1, $p<0.02$), FGF10, FGFR1 and downregulation of Ras and related proteins in SMCs.

Conclusion: Identification of multiple alterations in pathways targeted by potential therapeutics for SSc underpins the utility of this strain in pre-clinical investigation of candidate treatments and demonstrates the importance of selecting the most appropriate model for in vivo assessment of emerging molecular therapies in SSc. Pathways involved in vasoconstriction and inflammation are altered in relevant tissues in this TGFβ dependent strain. It is validated as a platform for experimental therapeutic studies particularly in pulmonary complications of SSc.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by fibrosis of skin and multiple organs. Morbidity and mortality are high and pathogenesis is poorly understood. Previous global gene expression studies have shown skin gene profiles with fibrotic as well as inflammatory signatures. Available treatment options are mainly based on suppression of inflammation and are only partially effective. Understanding the basis of the development and progression of SSc is therefore important to lead to deeper understanding of the disease process and to investigate better treatment options. In the current study, we aimed to identify gene expression changes in coding and non-coding RNAs in skin tissue of SSc patients as compared to healthy individuals, with a specific focus on anti-sense RNAs.

Methods: Skin biopsy-derived RNA from fourteen SSc patients and six healthy individuals was sequenced using ion-torrent next generation sequencing technology. Both protein-coding and non-coding genes annotated in Gencode V7 (GRCh38, Ensemble 83) were analysed. Validation of differentially expressed genes was performed by reverse transcriptase qPCR, comparison with a public microarray RNA dataset and validation in an independent SSc skin RNA-sequencing dataset. We focussed on non-coding RNAs and more specifically the dysregulation of non-coding antisense RNAs and their sense-stranded counterpart genes.

Results: We found 619 genes that are consistently differentially expressed and overlapped with a previously published microarray-based study. More than 95% of genes showed the same directionality of expression. Overall we find an enrichment of induced genes in immunological, cell adhesion and keratin related processes. Further analyses of specific genesets revealed induced expression of 80% of the keratin genes and an induction of genes associated with interferon and alternatively activated macrophage gene signatures. Analysis of non-coding RNAs reveals 676 deregulated non-coding genes of which a majority are classified as antisense genes. Antisense genes have shown regulatory roles on gene expression of often sense-stranded genes and for 62 differentially expressed antisense genes a coding sense gene was identified. Interestingly, a significant proportion of these sense genes (26 out of 62) were also deregulated in patients suggesting a link within these sense-antisense gene pairs which might have a role in the underlying mechanisms contributing to the disease.

Conclusion: Our data highlight significant differences between anti-sense non-coding genes expressed in SSc tissue as compared to healthy individuals. To our knowledge, our data provide for the first time evidence for the role of anti-sense genes in the regulation of differential gene expression in SSc patient-derived tissue.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: While a hallmark of systemic sclerosis (SSc) is skin fibrosis, internal organ involvement is the primary cause of mortality. Pulmonary Arterial Hypertension (PAH), Interstitial Lung Disease (ILD) and gastrointestinal dysfunction are common in these patients. Here we tested the hypothesis, generated from meta-analysis of ten different SSc datasets, that any single SSc patient would have the same molecular signatures across multiple organ systems, consistent with the systemic nature of the disease. Asking the question, "if a patient shows an inflammatory signature in skin, do they show that same signature in esophagus, fundus, duodenum, lung or blood?" To test this, we performed RNA-seq on biopsy samples for up to four different tissues from each patient.

Methods: All patients met 2013 ACR/EULAR criteria for SSc. Biopsy samples were collected from skin, esophagus, fundus, duodenum, lung and blood from 12 SSc patients. Additional tissues, from our current cohort and other SSc patients, are continuing to be collected. Lung biopsies lacked at least two paired tissues and so were excluded from current analyses. Only patients from whom at least skin, esophagus and fundus were collected were analyzed, resulting in 9/12 patients used for the analysis. 4/9 patients also had duodenum analyzed. RNA was sequenced by 75bp paired-end RNA-seq at >80 million reads per sample and aligned to the reference genome. Bioinformatic analyses were performed to determine if intrinsic gene expression subset signatures found in one tissue, were found in other tissues of the same patient.

Results: Tissue of origin showed the most robust signal with each tissue having distinct, tissue-specific gene expression signatures. Batch biases from library preparation were not significant ($p = 0.979$). Analysis of skin and esophagus from the same patient was able to recapitulate the previously defined inflammatory intrinsic gene expression subset. The fibroproliferative subset was most clearly observed in skin (n = 4/9 patients). Furthermore, for the first time, the inflammatory subset was found in the fundus (n = 5/9) and duodenum (n = 2/4) of SSc patients. 5/9 patients showed concordant intrinsic assignment across three tissues, one of whom showed concordance across all four tissues, possibly because all four tissues were collected on the same date.

Conclusion: This is the first molecular analysis of biopsies from multiple organs within an individual SSc patient. Our data suggests that molecular subsets in SSc are reproducible across organs within the same patient. We cannot rule out the possibility that pathogenic mechanisms of disease activity and progression are discordant in time in each organ, consistent with clinical observation. Further analysis of the skin, esophagus, fundus and duodenum coupled with lung and blood will provide additional insights into the progression of this systemic disease.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Genome-wide association studies (GWASs) have revolutionized our understanding of the genetic component of complex autoimmune diseases (ADs) by the identification of thousands of susceptibility loci associated with autoimmunity. The vast majority of these loci are shared risk factors for at least two or more ADs, pointing to a common genetic background underlying autoimmune processes. One approach that has been developed for the identification of common loci is to perform a combined-phenotype GWAS, that is, to combine genome-wide genotype data from two autoimmune diseases. In the present study we applied this strategy to systematically search for new common loci for systemic sclerosis (SSc) and rheumatoid arthritis (RA), two complex traits that share clinical and immunological features, and a considerable proportion of its genetic background.

Methods: The complete set of individuals enrolled for this study comprised a total of 8,830 SSc patients, 16,870 RA patients and 43,393 controls of European ancestry. First, we performed a meta-analysis combining GWAS datasets of SSc and RA using a strategy that allowed identification of loci with both same-direction and opposing-direction allelic effects. Those SNPs that showed a P-value < 5 x 10-^{6} in the combined-phenotype analysis and nominal significance in the GWA study for each disease (P-value < 0.05) were followed-up in independent SSc and RA case-control replication cohorts. Subsequently, we performed a meta-analysis of the initial GWAS screening and replication stages. Association tests were performed by the means of logistic regression. Meta-analyses were performed with inverse-variance method based on population specific logistic regression results.

Results: The cross-disease meta-analysis of the GWAS datasets identified several loci with nominal association signals (P-value < 5 x 10-^{6}), which also showed evidence of association in the disease-specific GWAS scan. These loci included several genomic regions not previously reported as shared loci, besides risk factors associated with both diseases in previous studies. The follow-up of the putatively new SSc-RA loci identified IRF4 as a shared risk factor for these two diseases ($P_{combined}$ = 3.29 x 10-12). In addition, the analysis of the biological relevance of the known SSc-RA shared loci pointed to the type I interferon and the interleukin 12 signaling pathways as the main common etiopathogenic factors.

Conclusion: The present study has identified a novel shared locus, *IRF4*, for SSc and RA. The identification of these pleiotropic autoimmunity loci may point to common pathogenic pathways, which ultimately may represent a clinical advantage, thus providing support for drug repositioning.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Single Nucleotide polymorphisms within the HLA region have been strongly associated with the occurrence of SSc and sclGVHD. However, specific studies on the amino acidic sequences of the HLA antigen presenting regions are scanty. Such approach has been very informative in predicting severity of rheumatoid arthritis (Shared Epitope). The aim of our study was to explore the presence of HLA class II functional motifs associated with severe skin fibrosis in SSc and sclGVHD (shared epitopes of fibrosis). The study was designed with a discovery cohort analysed by 4-digit HLA class II typing and a validation cohort of imputated HLA typing from GWAS data of 1000 SSc patients and controls. Here we present the results of the discovery cohort.

Methods: The discovery cohort comprised 70 SSc patients (15 with diffuse (dSSc) and 55 with limited (lSSc) subset) fulfilling 2013 ACR classification criteria and 43 sclGVHD patients with severe skin fibrosis involving >50 % of body surface area recruited from the observational clinical trial on chronic GVHD (04-C-0281). Four-digit HLA class II typing and β chain hypervariable region amino acidic sequence alignment was performed for HLA-DP and HLA-DR alleles in all patients. The obtained sequences were compared between sclGVHD patients and SSc patients with severe skin fibrosis characterized by maximum modified Rodnan skin score ≥ 25 (fibrotic phenotype group) and lSSc controls (non-fibrotic phenotype group). For the qualitative analysis amino acids were classified according the polarity, charge and hydrophobicity.

Results: Prevalence of hydrophobic and non-polar side chains was higher in patients with fibrotic phenotype compared to patients with non-fibrotic phenotype at position 26 of HLA–DQ β chain ($p = 0.047$) and lower at position 11 of HLA- DP β chain ($p = 0.026$). Comparison between two groups showed a lower prevalence of the following amino acidic motifs in patients with fibrotic phenotype compared with those with non-fibrotic phenotype: VVDE at positions 8,36,55 and 56 of HLA-DP β chain and FD at positions 67 and 70 of HLA-DR β chain ($p = 0.013$ and 0.0007, respectively). They were defined as non-permissive for fibrosis. More importantly "non-permissive" amino acids F and D at positions 67 and 70 of HLA-DR β chain were present in at least one copy in 75% of patients with non-fibrotic phenotype vs 40% of the patients with fibrotic phenotype ($p=0.0004$). Similarly, a second non permissive sequence VVDE at positions 8,36,55 and 56 of HLA-DP β chain was present in 53% of patients in the non-fibrotic group vs only 29% of the fibrotic group ($p=0.018$).

Conclusion: This is the first study which describes common sequences (shared epitopes), codified by three of the most important genes associated with SSc that seem to display a protective effect against severe fibrotic involvement in SSc and sclGVHD. We identified two non-permissive motifs within the hypervariable regions of β chains of HLA – DP, HLA – DQ and HLA – DR molecules that warrant validation in the large imputation cohort. Validation of these findings will be crucial to stratify patients diagnosed with SSc or candidate to bone marrow transplant for their risk of severe fibrosis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibrosis in systemic sclerosis (SSc), as well as a wide variety of other fibrotic diseases, is largely driven by myofibroblasts. Myofibroblasts are known to selectively produce high amounts of collagen and are found in the deep reticular dermis of patients with diffuse cutaneous SSc (dcSSc). However, our understanding of myofibroblast biology has been limited to mixed cultures of myofibroblasts due to the lack of a unique marker for their selection.

Methods: Skin biopsies from a patient with dcSSc and a healthy control were enzymatically digested and cells sorted into individual wells of a 96 well plate. Libraries were prepared according to the SmartSeq2 protocol and RNAseq performed. Data from individual cells was deconvoluted by barcode and aligned using Tophat. Transcripts were quantified using the Cufflinks. Cuffnorm files were mean centered, normalized, clustered by complete linkage using Cluster 3.0, and visualized using Java Treeview. T-distributed stochastic neighbor embedding (t-SNE) was implemented in R using the Sincell Bioconductor package

Results: Clustering showed different cell types in the dcSSc skin that were easily identified through known markers: keratinocytes, endothelial cells, macrophages, T cells and B cells. In addition, a group of cells was found that expressed smooth muscle actin (SMA/ACT2 gene) and type 1 collagen. On the basis of previously described marker genes and clustering, these cells could be divided into three well-defined groups: pericytes, smooth muscle cells and a third cell type. This third cell type uniquely expressed high levels of integrin alpha 8 (ITGA8), an integrin previously associated with myofibroblasts in mice. This cell type also uniquely expressed a series of other genes including Disintegrin and metalloproteinase domain-containing protein 12 (ADAM12). Mice deleted of cells expressing ADAM12 show severely blunted fibrosis in murine models. t-SNE analysis supported the cell groupings, showing a discrete cellular grouping for the ACTA2/ITGA11/ADAM12-expressing cells. Immunohistochemical staining revealed that several of the unique gene markers associated with the third SMA-expressing cell type co-stained with SMA, staining deep reticular myofibroblasts, and confirming the myofibroblast identity of these cells. The unique markers on these cells correlated closely with the modified Rodnan skin score.

Conclusion: Myofibroblasts have a unique transcriptome profile that provides new insights into the function of these cells. The high correlation between transcriptome markers expressed by these cells with the MRSS supports the key importance of dermal myofibroblasts in SSc skin fibrosis.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is characterized by multi-organ involvement and clinical heterogeneity. “Big data” approaches have yielded powerful tools to infer tissue-specific pathobiology. Large amounts of SSc gene expression data have been generated from different tissues and patient samples with distinct SSc clinical pathology. We performed an integrative meta-analysis of ten different SSc gene expression datasets that identified common disease drivers and tissue-specific distinctions in macrophage (MØ) phenotypes.

Methods: We developed and employed a novel data mining procedure that identified conserved coexpression patterns between ten datasets from four different tissues (skin, lung, esophagus, blood) with multiple clinical manifestations (pulmonary arterial hypertension [PAH], PF, limited and diffuse subtypes). We identified genes and processes that were conserved across all solid tissues and were highly expressed in pulmonary manifestations of SSc. We used these modules to query tissue-specific gene-gene interaction networks and analyzed the resulting lung- and skin-specific networks to infer common and tissue-specific fibrotic and inflammatory pathways.

Results: We identified a common gene signature indicative of an immune fibrotic process (IFP) composed of alternatively activated MØs that contribute to the extracellular matrix (ECM) remodeling processes. This signature was found in PAH and PF in lung, as well as the inflammatory molecular subsets in skin and esophagus. Analysis of the tissue-specific networks revealed a coupling of inflammatory and ECM processes in solid tissues that was absent in PBMC samples. We then rigorously contrasted the lung- and skin-specific gene interaction networks to identify a distinct lung resident MØ signature (LR-MØ) associated with lipid stimulation and alternative activation. Distinct MØ alternative activation transcriptional programs were observed in SSc-PF lung and SSc inflammatory skin.

Conclusion: We find evidence for alternatively activated MØs in multiple SSc tissues. However, there are subtle differences in the MØ transcriptional programs detected in skin and lung uncovered through multi-network systems analyses. In particular, different microenvironments likely provide distinct stimuli to infiltrating MØs that determine the pro-fibrotic character of these cells. This work suggests that the plasticity of this lineage is central to the divergence of fibrotic processes in multiple SSc-affected tissues and is a central component of an immune-fibrotic process driving disease.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Impaired angiogenesis in SSc is a crucial component of disease pathology that occurs in spite of upregulation of VEGF and other proangiogenic factors. MicroRNA-126 (miR-126) is expressed mainly in MVECs throughout the capillaries. MiR-126 regulates angiogenic signaling and responses to VEGF by direct repression of negative regulators of VEGF signalling pathway, including the Sprouty-related protein-1 (Spred1), and phosphoinositol-3 kinase regulatory subunit 2 (PIK3R2). In this study we investigated the expression levels of miR-126 and VEGF responses in SSc and control MVECs.

Methods: <span'arial','sans-serif';">MVECs were isolated from involved SSc skin and matched healthy subjects. The expression of miR-126 was measured by qPCR. The expression levels of VEGF inhibitors Spred1 and PIK3R2 were examined by qPCR and western analysis. The angiogenic potentials of MVECs were tested in a matrigel-based tube formation assay and in scratch test migration assay. <span'arial','sans-serif';">The expression of miR-126 was inhibited in control-MVECs by transfecting cells with has-miR-126 inhibitor and enhanced in SSc-MVECs by transfecting cells with has-miR-126 Mimic.

Results: miR-126 expression levels in SSc-MVECs and exosomes were significantly down regulated by over 10 folds in SSc-MVECs and 5 folds in SSc-exosomes (1.2 x10^7 miR-126 molecules/1million RNU44 molecules in control-MVECs and 8x10^5 in SSc-MVECs). Increased mRNA expression levels of Spred1 (2.5 folds ±0.2) and PIK3R2 (3.4±0.3 folds) in SSc-MVECs were noted by qPCR and confirmed by western analysis. Addition of VEGF (50ng/ml) to control-MVECs resulted in robust tube formation with and average branch length of (246.83±28.69 um) whereas diminished responses were seen in SSc-MVECs (88.58±15.46uM). Addition of VEGF enhanced control-MVECs migration and resulted in 50% wound closure in 6 hours, while this response was significantly diminished in SSc-MVECs (5%). Control-MVECs transfected with miR-126 inhibitor repressed miR-126 expression levels by 78% for up to 96 hours as measured by qPCR. This was associated with significant upregulation of mRNA and protein expression levels of Spred1 and PIK3R2 and reduced angiogenic capacity to levels comparable to that of SSc-MVECs. has-miR-126 Mimic transfection to SSc-MVECs resulted in upregulation of miR-126 expression, reduced expression of Spred1 and PIK3R2, and enhanced angiogenic potentials to levels comparable to control-MVECs.

Conclusion: <span'arial','sans-serif';">The data demonstrate impaired angiogenic potential of SSc-MVECs and diminished response to VEGF that was associated with significant down regulation of miR-126 in SSc-MVECs. Inhibition of miR-126 in control-MVECs resulted in impaired responses to VEGF, whereas forced expression of miR-126 in SSc-MVECs upregulated VEGV responses and normalized the angiogenic potential of SSc-MVECs. The data suggest that down regulation of miR-126 play a major role in impaired angiogenesis potential of SSc-MVECs.

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a complex autoimmune disease involving the immune system, vasculature and extracellular matrix [1]. Dysregulation of the Wnt pathway has been implicated in the development of fibrosis in SSc and is proposed to contribute to a failure to maintain tissue homeostasis and appropriate immune response [2]. The objective of this research study was to explore the role of altered microRNA expression in the skin of affected individuals and their role in the dysregulation of Wnt pathway in the development of fibrosis in black South African SSc patients with early, diffuse disease (dcSSc).

Methods: Skin biopsies from eight black South African patients with dcSSc who fulfilled the 1987 ACR classification criteria, samples from both the forearm (affected skin) and the back (unaffected skin), and eight ethnically matched healthy control skin samples were examined. sRNA sequencing libraries were prepared for 50bp single-end sequencing on the Illumina HiSeq machine. The alignment software used was TopHat and Cufflinks [3], with downstream analyses done using mirDeep and SMARTAR [4]. Count data was analysed using DESeq2 [5]. Differential expression was considered significant if the adjusted p-value was <0.05 (Benjamini–Hochberg rule). For this study both TargetScan and miRanda were used to identify the Wnt pathway gene targets of the significantly differentially expressed miRNAs.

Results: The sRNA-seq data showed differential expression of 31 miRNAs that target the Wnt pathway genes, including miR-335 and miR-204 that are important regulators of normal tissue development. Ten miRNAs were differentially expressed only in the affected SSc skin samples when compared to controls. One of these miRNAs, miR-194- 5p was predicted to target 6 Wnt pathway genes, *CCND2, EP300, FRZB, MMP7, PRICKLE1* and *WIF1*. Another, miR-326 was predicted to target five of the Wnt pathway genes, *WNT5A, LEF1, NKD1, TCF7L1* and *WIF1*.Other significantly differentially expressed miRNAs included miR-15a-5p, miR-15b-5p, miR-375, miR-18b-5p and miR20b-5p, all of which are predicted to target Wnt pathway genes and have previously associated with fibrosis, autoimmunity or SSc. Table 1 summarises the main miRNA differential expression data. Experimental evidence suggests that perfect seed-region paring of the miRNA with the target mRNA is not necessarily a reliable predictor for miRNA interactions and could explain why some of the sites predicted *in-silico* are non-functional [6] and why validation of the outcome pf differential miRNA expression is essential.

Conclusion: This study revealed a number of miRNAs were differentially expressed between SSc patients and controls indicating that epigenetic changes play an important role in the pathogenesis, progression and clinical features of the disease. These changes may be triggered by environmental changes and in the context of a disease susceptible genotype. This is consistent with the multifactorial nature of scleroderma. Thedifferentially expressed miRNAs are predicted to target genes within the Wnt pathway and could result in dysregulated gene expression disrupting the Wnt pathway. This highlights the potential for these miRNAs to be investigated as biomarkers of SSc and as potential novel targets for therapeutic intervention. **References:**

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: MicroRNAs (miRs) are a class of small, noncoding RNAs that regulate many biological processes. Some microRNAs are involved in skin fibrosis. Here, we aimed to analyze the differential expression and regulation of miR-125b and its pathophysiological role in systemic sclerosis (SSc).

Methods: Low density array was run on pooled RNA from 3 SSc and 3 healthy controls' fibroblasts. Further validation was performed by qPCR on RNA derived from cultured fibroblasts as well as from whole skin biopsies. Fibroblasts were stimulated with pro-inflammatory cytokines such as TGFβ, IL-1β, -4, -13, -17A, and PDGF. In order to identify downstream effects of miR-125b, knockdown with anti-miR-125b (or scrambled controls) in healthy controls' (HC) fibroblasts was performed to mimic the condition of SSc patients. RNA was isolated from healthy fibroblasts (n=4) after 24 hours of knockdown and was proceeded to deep sequencing using Ilumina HiSeq2000. After bioinformatic analysis, validation of the sequencing data was performed with qPCR on the RNA of the same as well as additional HC fibroblasts. Apoptosis was assessed by Caspase-Glo 3/7 assay.

Results: Screening presented miR-125b as one of the candidate miRs differently expressed in SSc. That was further validated by qPCR in primary dermal fibroblasts (SSc patients = 11, HC = 8), where it was downregulated by 47% (median 53%, first quartile 33%, third quartile 70%; $p<0.01$). Additionally, miR expression was measured in skin biopsies of both SSc patients (n=4) and HC (n=5). In patients' samples, miR-125b was downregulated by 35.5% (median 64.5%, first quartile 60.5%, third quartile 77.5%; $p<0.05$). To localize the expression of miR-125b, we separately measured the expression in dermis and epidermis of paraffin fixed tissues. In both cases, expression of miR-125b was downregulated. MiR-125b expression appeared to be independent from main pro-inflammatory cytokines action. RNA sequencing identified > 3500 differentially expressed genes with $p<0.05$. More than half of the highly expressed genes with at least 15% change were predicted targets of miR-125b by TargetScan and MiRWalk, indicating successful functional inhibition of miR-125b. Bioinformatic analysis revealed extracellular matrix organization and apoptosis regulation as the two main clusters of differentially expressed genes. Among them, BAK1 and BMF are participants of the BCL2 apoptosis pathway and predicted targets of miR-125b. Consistent with the sequencing results, qPCR showed upregulation of these genes after knockdown of miR-125b. Interestingly, BCL2 which by itself is an anti-apoptotic factor and also a target of miR-125b, was not changed after knockdown. This indicates that physiological miR-125b expression prevents cells form apoptosis. Accordingly, miR-125b knockdown resulted in 70% more apoptosis compared to either untreated cells or scrambled controls.

Conclusion: This is the first time microRNA-125b is shown to be differently expressed in SSc skin and primary dermal fibroblasts. Its downregulation increases apoptosis and might be a potential compensatory mechanism to prevent fibrosis.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare multisystem connective tissue disease characterized by skin and internal organs fibrosis and vascular abnormalities, along with the presence of autoantibodies. Basophils, which have long been associated with allergy and parasitic infections, are now identified as having the ability to promote fibrosis, stimulate B cells and increase autoantibodies production. Herein we investigated the potential role of basophils in SSc.

Methods: Peripheral basophils from patients with SSc who did not receive glucocorticoids or immunosuppressants and healthy controls (HC) were analyzed using flow cytometry and basophil activation test. The impact of the KU812F basophil cell line on both B cells and fibroblasts isolated from SSc patients were assessed using flow cytometry and xCelligence assay.

Results: Sixty-five consecutive SSc patients and 38 HC were recruited. The proportion of CD203c-positive basophils was higher in SSc patients than in HC (37.5 % [24.3 – 59.0] vs 25.6% [13.6 – 41.7]; $p < 0.001$). Compared to HC, basophils from SSc patients had higher mean fluorescence intensity (MFI) quantifications of CD154 (854 [541 – 1334] vs 485 [147 – 871]; $p < 0.05$) and intracellular B cell activating factor (1551 [1001 – 4373] vs 857 [722 – 1498]; $p < 0.05$). Activated KU812F basophils were able to decrease the proportion of CD95-positive B cells (10.5% [8.4 – 12.6 vs 14.8% [14.4 – 21.5]; $p < 0.05$), to increase the production of interleukine-6 (21.2% [16.5 – 29.9] vs 14.9 [12.3– 16.7]; $p < 0.05$) and transforming growth factor-β (5.6% [4.7 – 7.2] vs 4.1 [2.6– 5.4]; $p < 0.05$) producing B cells and to enhance the proliferation of fibroblasts from patients with SSc. Lastly, the expression of CRTH2 on basophils correlated with patients' disease characteristics and was able to discriminate those with or without pulmonary hypertension (PAH). Indeed, CRTH2 MFI quantification among basophils positively correlated with patients' diffusing capacity of the lungs for carbon monoxide ($r = 0.60$, $p < 0.05$), negatively correlated with patients' modified Rodnan skin score ($r = - 0.77$, $p < 0.01$) and was lower in SSc patients with PAH than in SSc patients without PAH (31476 [30213 – 31633] vs 59576 [41312 – 67788]; $p < 0.001$).

Conclusion: Peripheral basophils are activated and are able to simulate both B cells and fibroblasts in patients with SSc, suggesting a key role of basophils in the pathophysiology of SSc.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease, which is characterized by inflammation, fibrosis and vasculopathy in multiple organs, mainly in the lung, heart and skin. Neurotrophins (NTs) are a family of proteins promoting neuron growth and survival; however their profibrotic and proangiogenic actions were recently discovered in fibroblasts and endothelial cells. Elevated number of monocytes and their activation state has been already reported in SSc, but detailed roles of monocytes in multiorgan fibrogenesis in SSc remain unclear. We aimed to determine the contribution and the role of circulating monocytes in the onset and progression of multiorgan fibrosis in SSc. Additionally, we investigated the involvement of neurotrophin-3 (NT-3) and neurotrophins receptors in the fibrogenesis in SSc.

Methods: Endomyocardial biopsies from SSc patients and healthy controls were screened by immunohistochemistry. $CD14^+$ monocytes isolated from peripheral blood of SSc patients and healthy donors were differentiated towards the myofibroblast phenotype by stimulation with TGFβ1, IL-4, IL-10 and IL-13. In addition, $CD14^+$ monocytes were co-cultured with dermal fibroblasts originated from SSc patients

and healthy subjects, and with adult cardiac fibroblasts. After 7 days, myofibroblast gene expression and cytokine secretion profiles were evaluated by qPCR, Western blot, protein array and ELISA. Healthy and SSc dermal or cardiac fibroblasts were stimulated with NT-3 and induction of profibrotic genes was analysed by qPCR and immunofluorescence.

Results: Myocardium of SSc patients revealed the presence of CD45-expressing infiltrates, extended collagen I deposition and the presence of CD14-expressing elongated cells in the fibrotic tissue. Stimulated monocytes acquired myofibroblast-like phenotype with increased expression of collagen I ($p<0.0001$), fibronectin ($p<0.05$), and α smooth muscle actin (α-SMA) in comparison to untreated cells. Similarly, $CD14^+$ monocytes exposed to dermal or cardiac fibroblasts acquired spindle shape and expressed higher levels of profibrotic genes. The process of monocyte to myofibroblast differentiation employed TGFβ/SMAD signalling. Blocking of the TGFBR1 receptor and canonical SMAD-dependent pathway with inhibitors resulted in the abrogation of extracellular matrix secretion by monocytes. $CD14^+$ monocytes from SSc patients were characterised by higher secretion of CXCL10 ($p<0.001$), CCL20, CCL22, Leukemia Inhibitory Factor (LIF) and NT-3. SSc fibroblasts revealed higher expression of TrkB and $p75^{NTR}$ receptors. Moreover, elevated level of α-SMA was observed in SSc fibroblasts after stimulation with NT-3.

Conclusion: Here we demonstrated the capability of peripheral blood monocytes to differentiate towards the functional myofibroblast phenotype, indicating these cells as one of the potential sources of pathological tissue myofibroblasts in SSc. Additionally, SSc monocytes secreted NT-3, which induced fibroblast to myofibroblast differentiation. Further studies of TGFβ induced NT-3 expression in monocytes and its effects on fibroblast to myofibroblast differentiation might lead to novel treatment strategies.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a remarkably heterogeneous autoimmune disease, for which effective disease-modifying therapies are still lacking. The most widely used classification divides SSc into two major subsets diffuse cutaneous (dcSSc) and limited (lcSSc) SSc by the extent and severity of skin fibrosis. However, not all patients fit into these subsets. This has created great interest to examine disease heterogeneity at the molecular level to uncover unrecognized SSc subtypes that may differ with regard to clinical manifestations, prognosis or therapy response. In large-scale “omics”-type autoantibody (AAB) profiling studies we have recently identified novel SSc-associated autoantigens. Here, we describe the development of a 20 marker multiplexed AAB assay and explored its utility for SSc patient subgroup analysis.

Methods: A Luminex bead-based AAB assay was designed by combining 8 connective tissue disease (anti-centromere, anti-Scl70, U1-snRNP, SSB, Ro52, Ro60, SmB, anti-ribosomal P) antigens with 12 novel antigens (including BICD2, JMJD3/KDM6B, and PPP1R2). Novel AAB targets were previously detected in SSc patients with a p-value <0.05 (Mann-Whitney-U-test) and frequency >15%. AAB reactivity was analysed in 100 SSc patients (dcSSc: n=32, lcSSc: n=50, SSc overlap: n=9, other: n=9). The mean modified Rodnan skin score (MRSS), mean disease duration (month), and mean age (years) of the SSc cohort was 10.51, 162.5 and 56.94, respectively. To analyze the individual-level patient similarity of AAB reactivity, the total number of AABs reactive in each patient was calculated and referenced to the number of all available antigens in percent. Hierarchical cluster analysis of marker co-prevalence and patient signature overlap was performed.

Results: Based on their AAB reactivity pattern, the SSc sample cohort can be decomposed into four main clusters. Cluster 1 includes 87% of all lcSSc patients characterized by an extended AAB repertoire (including BICD2, KDM6B and PPP1R2), MRSS below the average and longer disease duration. Cluster 2 includes 56% lcSSc and 26 % dcSSc patients characterized by MRSS above the average and anti-U1-snRNP antibodies. Cluster 3 includes SSc-overlap, lcSSc and dcSSc with higher MRSS compared to Cluster 1 and 2 and variable AAB profile. Cluster 4 includes mainly dcSSc patients with anti-Scl70 AAB and highest number of patients with MRSS above the average (83%).

Conclusion: The multiplexed analysis of AABs in SSc enables defining an AAB reactivity score and patient clusters. This might support to subclassify SSc beyond lcSSc and dSSc.

The Regulatory B Cells Ameliorate Skin Sclerosis, Lung Fibrosis, and Autoimmunity Via an Anti-Oxidative Effect in Systemic Sclerosis Model Mice

Ayumi Yoshizaki, Takemichi Fukasawa, Satoshi Ebata, Kouki Nakamura, Takashi Yamashita, Ryosuke Saigusa, Yohei Ichimura, Takehiro Takahashi, Takashi Taniguchi, Asano Yoshihide and Shinichi Sato, Dermatology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease characterized by vascular damage, excessive deposition of extracellular matrix, and fibrosis in the several organs, including skin and lung, on an autoimmune background. Although the pathogenesis of SSc remains unknown, it has been proposed that oxidative stress play an important role in disease development. Many previous studies have confirmed that production of free radicals is enhanced in human SSc patients, due to ischemia and reperfusion injury following Raynaud's phenomenon, an initial clinical manifestation. Recent studies indicated that specific B cell subsets can negatively regulate T cell immune responses, and have been termed regulatory B cells. Human and mouse regulatory Bcells with the ability to express the inhibitory cytokine interleukin (IL)-10 have been identified. Although rare, regulatory B cells are potent negative regulators of antigen-specific inflammation and T cell dependent autoimmune diseases in mice. However, how IL-10 producing regulatory B cells regulate antigen-specific immune responses in vivo without inducing systemic immunosuppression is unknown. In this study, we focused on the effect of antigen-specific regulatory B cells on oxidative stress.

Methods: In this study, bleomycin (BLM)-induced SSc model mice were used. CD5+ and CD1dhi regulatory B cells were obtained from BLM or PBS treated mice respectively and adoptively transferred to BLM-induced SSc mice. To assess the effect of regulatory B cells, serum levels of 8-isoprostane, a marker of oxidative stress, were measured. Furthermore, we assessed skin and lung fibrosis histologically. Protein and mRNA levels of profibrogenic cytokines, such as IL-4, IL-6, and IL-17, were measured using ELISA and real-time RT-PCR.

Results: The regulatory B cells reduced skin and lung fibrosis and serum levels of profibrogenic cytokines in BLM-induced SSc model mice. Especially, serum levels of 8-isoprostane were decreased by adoptively transferred ex vivo-induced regulatory B cells compared with PBS injection. In addition, regulatory B cells significantly inhibited free radical production from inflammatory cells cultured with BLM. Interestingly, the regulatory B cells obtained from BLM-treated mice had more inhibitory effects than those from PBS-treated mice.

Conclusion: These results suggest that the regulatory B cells inhibited free radical production from inflammatory cells, results in ameliorating the disease manifestations of SSc. These inhibitory effects of regulatory B cells may exert via the antigen-specific manner. Although further studies are needed, the autoantigen-specific regulatory B cell can be a novel therapeutic tool for treatment for SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate clinical associations of our recently discovered systemic sclerosis-specific auto-antigen BICD2 in clinically well characterized systemic sclerosis (SSc) cohorts from two tertiary referral centers.

Methods: Serum samples were obtained from the biobanks of the Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, and Department of Dermatology, University of Cologne, Cologne. The analysis included samples collected from patients suffering from SSc (n=302) systemic lupus erythematosus (n=39), Sjogren's syndrome (n=11), rheumatoid arthritis (n=20), myositis (n=20) and healthy volunteers (n=99). Clinical annotation data, including age, gender, disease duration, MRSS, detailed information on organ involvement making up to a total of either >50 or >100 clinical data points (depending on the site) was available for more than 80% of all SSc serum samples included in this study. All samples were analyzed on the novel Multilisa BICD2 (CE), an ELISA for the semi-quantitative detection of anti-BICD2 antibodies in human serum or plasma.

Results: We found anti-BICD2 with a prevalence of 28% and 32% in the groups of SSc patients of the respective cohort, and only in 4.2% in cohorts with other rheumatic diseases or healthy controls (OR=8.702). Anti-BICD2 autoantibodies were present in a subgroup of SSc patients where skin fibrosis was either from the limited cutaneous subtype (p=0.0002) or restricted to sclerodactyly (p=0.0037). Within this line, anti-BICD2 autoantibodies showed a significantly higher titer in patients with moderate skin involvement reflected by low MRSS-stages (p=0.001). Analysis of pulmonary involvement revealed elevated anti-BICD2 titers in the group of patients *not* suffering from lung fibrosis measured by high resolution computer tomography (HCRT) (p=0.0001). Of note, the highest a-BICD2 values were observed in the group of patients having a residual transfer capability of 61-80% (DLCO stage 1 of 4). Anti-BICD2 autoantibodies were also found to be more prominent in the group of patients having a disease duration of more than 3 years.

Conclusion: In this study, we were able to further confirm the diagnostic value and high specificity of the newly discovered BICD2 autoantigen. Anti-BICD2 autoantibodies were found to be elevated in patients suffering from limited SSc, and anti-BICD2 reactivity was found to be related to clinical observations of a moderate course of disease.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: While B cell signaling is thought to be important in the pathogenesis of systemic sclerosis (SSc), the experience with B cell targeting therapies in SSc clinical trials has been mixed. Belimumab is a monoclonal antibody that inhibits B cell survival. We investigated gene expression changes of skin biopsy specimens of patients with early diffuse cutaneous (dc) SSc treated in the context of a randomized controlled pilot trial of belimumab versus placebo in patients on background mycophenolate mofetil (MMF) therapy (NCT01670565).

Methods: Biopsies of lesional forearm skin were obtained from 18 patients prior to randomization and after 52 weeks of treatment with belimumab or placebo. Patients were defined as improvers if they had a modified Rodnan Skin Score improvement ≥20% post-treatment. Using this criterion, 7/9 patients in the belimumab/MMF group were improvers, and 3/9 in the placebo/MMF group were improvers. Expression data from skin biopsies were analyzed for differentially expressed genes ($p \leq 0.05$, paired/unpaired t-test) which were investigated for functional enrichment via g:Profiler ($p \leq 0.05$, corrected for multiple testing). Differentially expressed pathways were determined genome-wide using Gene Set Enrichment Analysis (False Discovery Rate ≤5%).

Results: In the belimumab/MMF group, clinical improvers showed downregulation of genes involved in *B cell mediated immunity*, *extracellular matrix (ECM), collagen formation* and *response to TGF*-β. Decreased pathways included *IL4/IL6 signaling* as well as *B cell signaling*, *ECM, TGF*-β and *PDGF signaling* (Figure 1). Comparison between baseline samples of improvers and non-improvers showed that patients who improved were characterized by the increased baseline expression of *ECM* and *TGF*-β *signaling* genes and pathways. In the improvers from placebo/MMF group, we observed decreased expression of genes and pathways involved in *TCR signaling*, e.g. *T cell activation* and *T cell aggregation*, consistent with the mechanism of MMF as well as *Toll-like receptor signaling*. In both treatment arms, non-improvers were characterized by a small number of differentially expressed genes with no functional enrichment, consistent with the lack of clinical response.

Conclusion: Decrease in *B cell signaling* genes and pathways was observed only in patients with improved skin score in belimumab/MMF but not placebo/MMF group. While attributable to the pharmacologic effect of the drug, this was not seen in patients who did not improve. Improvers from belimumab/MMF group showed high baseline expression and significant post-treatment decrease of fibrotic genes and pathways i.e. *ECM, TGF*-β and *PDGF signaling*. This finding suggests that treatment effect may be influencing the interplay between immune activation and fibrosis linked to clinical manifestations of SSc such as skin fibrosis.

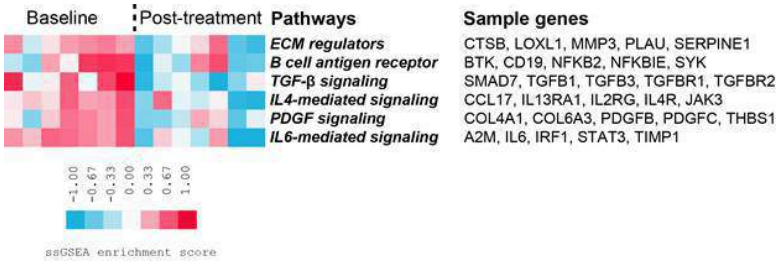

Figure 1. Sample pathways downregulated in improvers from belimumab/MMF group (GSEA FDR≤5%)

RNA and Protein Cargo of Exosomes Isolated from Serum of Systemic Sclerosis Patients Induce a Profibrotic Phenotype in Cultured Normal Human Dermal Fibroblasts: A Potential Mechanism for the Initiation and Progression of a Profibrotic

Phenotype in SSc

Peter J. Wermuth, Kellan R. Carney, Sonsoles Piera-Velazquez and Sergio A. Jimenez, Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Exosomes are lipid bilayer-bound microvesicles that contain various macromolecules including numerous microRNA (miRNA) and proteins. Exosomes mediate intercellular communication by fusing and releasing their macromolecular content into target cells. The mechanism of the establishment and progression of a profibrotic phenotype in Systemic Sclerosis (SSc) is not currently well understood. Here, we characterized the miRNA content of exosomes isolated from the serum of SSc patients and analyzed the ability of exosomal RNA and protein components to induce a profibrotic phenotype in normal human dermal fibroblasts *in vitro*.

Methods: Exosomes were isolated from serum from normal individuals and from patients with either limited cutaneous or diffuse cutaneous SSc employing a highly specific polymer precipitation procedure. The isolated exosomes were characterized by Nanosight Particle Tracking Analysis and transmission electron microscopy and the levels of nine pro-fibrotic and nineteen antifibrotic miRNA were assessed by semiquantitative real time PCR. Cultured normal human dermal fibroblasts were incubated with untreated exosomes isolated from the serum of SSc patients or normal donors or with isolated exosomes previously treated with Triton X-100, or with RNAseA, or proteinase K, alone or in combination with Triton X-100 to selectively deplete miRNAs or proteins, respectively. The expression levels of several profibrotic genes in the dermal fibroblasts treated with exosomes isolated from serum of normal individuals or SSc patients were assessed.

Results: Nanosight particle tracking analysis and transmission electron microscopy confirmed the isolation of microvesicles in the size range expected for exosomes and an exosome protein array verified that the isolated particles contained exosome-specific proteins and were not contaminated by Golgi-associated proteins. The content of six antifibrotic miRNAs was decreased whereas the content of three profibrotic miRNAs was increased in serum exosomes from both groups of SSc patients compared to normal serum exosomes. Furthermore, the levels of four miRNA were significantly different between the two SSc clinical subsets. Untreated exosomes isolated from the serum of patients with limited or diffuse SSc induced the expression of profibrotic genes in cultured normal human dermal fibroblasts whereas the establishment of this profibrotic phenotype could be partially abrogated by treatment of the exosomes with either RNAse A or proteinase K.

Conclusion: The content of profibrotic/antifibrotic miRNA of serum exosomes from SSc patients is different from that of normal serum exosomes and displays an overall profibrotic phenotype. SSc patient-derived exosomes can induce a profibrotic phenotype in target cultured normal dermal fibroblasts. The induction of this profibrotic phenotype is mediated by both the RNA and protein content of the exosomes. Since exosomes are involved in intercellular communication these observations suggest a mechanism for transmission of a profibrotic molecular program to normal target cells leading to the extension of the fibrotic process to non-affected tissues. The Role of Endothelin 1 in Activation of Vascular Smooth Muscle Cells in Systemic Sclerosis; Increased Cell Proliferation and Resistance to Apoptosis Mediated By Endotehlin B Receptors

Shadia Nada[1], Yongqing Wang[1,2], **Nezam Altorok**[1] and Bashar Kahaleh[1], [1]Medicine/Rheumatology, University of Toledo, Toledo, OH, [2]Medicine, University of Toledo, Toledo, OH

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune connective tissue disease characterized by activation of the immune system, vascular dysfunction and tissue fibrosis. Vascular dysfunction in SSc is one of the most prominent features of the disease that manifest by Raynaud's phenomenon in the early stages and by proliferative vasculopathy that affect all involved organs and progress throughout the disease course. Endothelin 1 (ET-1) is overexpressed in SSc as illustrated by elevated circulating levels and increased tissue expression in involved organs. We previously reported increased proliferative capacity of SSc- vascular smooth muscle cells (vSMCs) in association with resistance to apoptosis in comparison to control cells. In this study, we sought to examine the role of ET-1 and its signaling pathways in the generation of the activated vSMCs phenotype.

Methods: We isolated vSMCs from 4mm punch skin biopsies from 3 patients with SSc and 3 healthy controls. We evaluated the expression levels of *EDN1, EDNRA* and *EDNRB,* which encodes for ET-1, Endothelin Receptor A (ERA) and ERB, respectively, in vSMCs from SSc patients and controls. We treated vSMCs with ET-1, in the presence or absence of selective ETA antagonist (BQ123), selective ETB antagonist (BQ788) or dual ETA+B antagonist (PD145065). Under these conditions, we examined the effects of ET-1 on cell proliferation using BrdU assay, viability by MTT assay and apoptosis by Tunel assay.

Results: SSc-vSMCs overexpressed *EDN1* compared to control vSMCs (120 fold). Furthermore, and compared to control-vSMCs, *EDRA* expression levels were significantly increased in SSc-vSMCs while *EDNRB* expression levels were lower than control values. At baseline, SSc-vSMCs exhibited 1.8-fold increase in cell proliferation compared to control vSMCs (P= 0.0031). Upon treating control-vSMCs with 10nM ET-1, we demonstrate increased vSMCs proliferation by 1.6 folds (P= 0.03) in association with decreased cell apoptosis by 36%. The addition of selective ETB antagonist (BQ788) or dual ETA+B antagonist (PD145065) reduced vSMCs proliferation by 72% and 69%, respectively (P<0.05), but we did not find significant effect for selective ETA antagonist (PD156707) on cell proliferation (P>0.05). Moreover, BQ788 and PD145065 increased apoptosis of vSMCs. We did not see this effect using the selective ETA antagonist.

Conclusion: We provide an experimental evidence for increased proliferation, viability and decreased apoptosis of vSMCs by ET-1 *in vitro*, and we demonstrate that this effect is mediated by ETB receptors. Selective ETB and non-selective ETA+B receptor antagonists have a theoretical advantage over selective ETA antagonists in reducing the effect of ET-1 on proliferation of cells in tunica media, and that ET-1 have an important role in the development of vascular remodeling in SSc.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In systemic sclerosis (SSc) patients, skin fibrosis is accompanied by involution of dermal white adipose tissue

(dWAT), a prominent source of adiponectin (APN). We hypothesize that impaired APN activity due to loss of dWAT underlies the progression and persistence of skin fibrosis in SSc. To tests our hypothesis, we investigated APN pathway deregulation in SSc and used transgenic mice and APN-mimetic peptides.

Methods: APN pathway activation was evaluated in SSc skin biopsies using expression microarray and immunohistochemistry. Experimental skin and peritoneal fibrosis was investigated in ΔGLY-APN transgenic mice.

Results: Interrogating skin biopsy transcriptome data, we found that a subset of SSc patients showed reduced APN pathway activation ($p=0.04$), representing a novel molecular subset of SSc. Moreover, SSc skin biopsies ($n=20$) had significantly reduced levels of phospho-AMP protein kinase in dermal myofibroblasts compared to healthy controls ($p=0.01$), indicating attenuation of local APN signaling. To assess the effect of systemic APN, fibrosis was induced in ΔGLY-APN transgenic mice. A 2-3-fold increase in levels of circulating APN in these mice was associated with significantly attenuated skin fibrosis induced by bleomycin as well as by constitutively-active TGF-ß. Moreover, transgenic mice showed partial preservation of dWAT during early-stage fibrogenesis, and reduced influx of macrophages. Attenuation of skin fibrosis was accompanied by evidence of defective focal adhesion assembly in dermal cells. Levels of circulating APN in these mice were negatively correlated with dermal thickness ($r=-0.747$, $p<0.001$) and collagen content ($r=-0.586$, $p<0.001$). Chronic treatment of C57BL6/J mice with short APN mimetic peptides prevented and reversed experimentally-induced dermal fibrosis. ΔGLY-APN mice also showed robust protection from chlorexidine gluconate-induced peritoneal fibrosis ($p=0.05$) and myofibroblast accumulation ($p=0.02$). Cell fate-mapping studies showed that >65% of myofibroblasts within fibrotic peritoneal tissue derived from APN-positive progenitor cells resident in the mesothelial sub-lining.

Conclusion: Our results implicate defective APN production and activity in skin fibrosis in a subset of patients with SSc. APN protected mice from experimental skin and peritoneal fibrosis, and circulating levels correlated with dermal thickness. Myofibroblasts within fibrotic tissue largely derive from adipocytic lineage cells resident in the dWAT (skin) or peritoneal mesothelium. These findings suggest that restoring normal APN signaling and normal adipogenesis represent innovative therapeutic approaches to SSc.

EZH2 Modulates Angiogenesis and Fibrosis in Scleroderma

Pei-Suen Tsou, Patrick Coit, Dinesh Khanna and Amr H Sawalha, Division of Rheumatology, University of Michigan, Ann Arbor, MI
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Scleroderma (SSc) is a complex disease that involves activation of the immune system, vascular complications, and tissue fibrosis. Although the pathogenesis of this disease is largely unknown, epigenetic dysregulation has been implicated to play a role. In this study, we focused on the histone methyltransferase enhancer of zeste homolog 2 (EZH2), which is the catalytic component of the polycomb repressor complex 2. It mediates trimethylation of lysine 27 of histone 3, which acts as a repressive epigenetic mark. It has been reported that EZH2 regulates angiogenesis, and it is also involved in fibrosis. We hypothesize that EZH2 contributes to impaired angiogenesis and enhanced fibrosis in SSc.

Methods: Dermal endothelial cells (ECs) and fibroblasts were isolated from biopsies from healthy subjects or patients with diffuse cutaneous SSc. EZH2, collagen 1a1 (Col1a1), α-smooth muscle actin (ACTA2), fos-related antigen 2 (Fra2), and peroxisome proliferator-activated receptor gamma (PPARG) expression were determined by qPCR. EZH2 expression was also determined by Western blotting. EZH2 was overexpressed using an EZH2 vector. Inhibition of EZH2 was achieved by using EZH2 inhibitor DZNep (0.2μM-5μM) or EZH2 siRNA. Angiogenesis was assessed by an *in vitro* Matrigel tube formation assay. The scratch wound assay was used to evaluate fibroblast migration. A paired t-test was used to compare differences between groups, and a p-value of <0.05 was considered significant. Genome-wide DNA methylation status was evaluated using the Illumina Infinium Methylation EPIC BeadChip Array and the Illumina GenomeStudio platform was used to analyze the methylation data.

Results: The expression of EZH2 was significantly elevated in both SSc ECs and fibroblasts compared to healthy controls. To evaluate the effect of EZH2 on EC angiogenesis, EZH2 was overexpressed in normal ECs. This led to a significant decrease in tube formation on

Matrigel compared to sham-transfected cells. In contrast, silencing of EZH2 in SSc ECs restored normal angiogenesis. In normal fibroblasts, overexpression of EZH2 led to increase in Col1a1 and Fra2 mRNA expression. In contrast, SSc fibroblasts treated with DZNep showed a dose-dependent reduction in Cola1a and Fra2 mRNA expression, suggesting that inhibiting EZH2 attenuates profibrotic potential in SSc fibroblasts. In addition, we observed a dose-dependent reduction in mRNA expression of the myofibroblast marker ACTA2 in SSc fibroblasts treated with DZNep, but this did not reach statistical significance. The antifibrotic PPARG decreased at lower doses of DZNep but increased significantly at the highest dose (5μM) compared to untreated SSc fibroblasts. In the scratch wound assay, EZH2-overexpressing normal fibroblasts showed an increase in cell migration while DZNep-treated SSc fibroblasts showed wider wound width at 48 hours post-injury compared to untreated SSc fibroblasts. Genome-wide DNA methylation changes after manipulation of EZH2 expression were used to identify additional EZH2-regulated targets, which will help to further mechanistically understand the angiogenic and fibrotic effects of EZH2 in SSc.

Conclusion: Our results uncovered an important role for EZH2 in SSc. EZH2 is overexpressed in SSc ECs and fibroblasts, and this overexpression is profibrotic and results in impaired angiogenesis in this diseases. Targeting EZH2 or EZH2-regulated genes may open new therapeutic avenues for patients with SSc.

IL-31 Is an Inflammatory Pro-Fibrotic Factor Elevated in a Subset of Scleroderma Patients with Severe Pruritus

Bahja Ahmed Abdi[1], Sara Zafar[2], Zeinab Taki[3], Nikita Arumalla[4], Shiwen Xu[5], Christopher Denton[4], David Abraham[4] and Richard J. Stratton[6], [1]Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, University College London, London, United Kingdom, [2]Centre of Rheumatology and Connective Tissue Disease, University College London, London, United Kingdom, [3]Department of Rheumatology and Connective Tissue Diseases, University College London, London, United Kingdom, [4]Division of Medicine, Centre for Rheumatology and Connective Tissue Disease, University College London, London, United Kingdom, [5]Division of Medicine, Centre for Rheumatology and Connective tissue disease, University College London, London, United Kingdom, [6]Centre for Rheumatology and Connective Tissue Disease, University College London, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune rheumatic disease associated with fibroblast activation in the skin and visceral organs. In SSc, refractory pruritus is a common symptom in a subgroup of patients. IL-31, a Th2 cell derived cytokine, is implicated in causing pruritus in conditions including atopic dermatitis and T cell lymphoma. T-lymphocyte-derived factors provide a possible mechanistic link between autoimmune inflammation and the fibrosis reported in SSc. In this study we measured IL-31 levels in SSc tissue fluid and plasma, and sought correlation with itch severity and clinical parameters. In addition, recombinant IL-31 was investigated for its capacity to influence fibroblast and mesenchymal stem cell (MSC) activity.

Methods: Dermal blister fluid (BF) was obtained by a suction blister method from the involved skin of SSc patients or matched site of healthy controls synchronous to plasma sampling (SSc n=28, controls n=15) and IL-31 measured by ELISA. SSc and control fibroblasts lysates, MSC lysates, and tissue biopsied from involved skin lesions or control samples were analysed by qPCR for IL-31 receptor expression. Normal skin fibroblasts as well as MSCs were cultured and treated with IL-31 and phenotypic changes were assayed by protein assays, and next generation sequencing. Dermal fibroblast and MSC migration was assessed through scratch wound assay.

Results: IL-31 levels were higher in dermal blister fluid from SSc patients compared to controls (99.4pg/ml in SSc vs 2.3pg/ml in controls, $p<0.0003$) as well as in plasma samples (1370 vs 196pg/ml, $p<0.01$). Dermal BF IL-31 levels correlated strongly with itch severity ($R=0.72$, $p<0.0038$) and elevated BF IL-31 was characteristic of a subgroup of mainly diffuse cutaneous SSc patients with severe pruritus. SSc fibroblasts showed a higher IL-31 receptor mRNA expression compared to healthy controls (relative copy number 6.4 and 1.4 respectively, $p<0.01$), whereas the epidermal tissue extracts showed a non-significant increase in SSc (18.4 vs 8.2 respectively, p=ns). Treating fibroblasts with IL-31 led to induction of type I collagen but not CTGF, and promoted fibroblast and MSC migration dependent on

the PI3kinase pathway. Furthermore, recombinant IL-31 induced major changes in gene expression profile of both fibroblasts and MSCs.

Conclusion: We have shown that an increased expression of IL-31 correlates with severe itch in SSc patients. IL-31 receptor was expressed in SSc fibroblasts and epidermal tissues at increased levels, and recombinant IL-31 protein induced major phenotypic changes in fibroblasts and MSCs. IL-31 may link T-cell autoimmune responses to fibroblast and fibroblast precursor activation in SSc. Blocking IL-31 therapeutically may provide effective treatment in a subgroup of SSc patients identified clinically by severe pruritus.

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Mixed Connective Tissue Disease (MCTD) is a chronic, immune-mediated disorder defined by the combined presence of serum anti-ribonucleoprotein (RNP) antibodies and selected clinical features of Systemic Sclerosis, Systemic Lupus Erythematosus, Rheumatoid Arthritis and Polymyositis. The prevalence of Interstitial Lung Disease (ILD) in MCTD has been variously reported by previous studies [1]. It is considered to be a major complication in MCTD patients, yet knowledge is scarce regarding the long term progression of ILD in established MCTD.

Methods: Baseline and follow up high-resolution computed tomography (HRCT) of the lungs were systematically reviewed in 113 MCTD patients from the previously described nationwide Norwegian cohort [2]. Patients were included in the cohort if they had a clinical diagnosis of MCTD verified by a rheumatologist; positive serum anti-RNP antibody test and fulfilment of at least one of the following criteria sets: the modified Sharp's criteria, the Alarcón-Segovia criteria and the Kasukawa critera. The presence of fibrosis was evaluated according to the CT criteria of ILD recommended by The Nomenclature Committee of the Fleischner Society. The extent of fibrosis was determined in 10 HRCT sections and expressed as % of total lung volume.

Results: The mean (SD) time between baseline and follow up lung HRCT in the 113 patients was 7.0 (1.8) years. Mean (SD) disease duration at baseline was 10.0 (8.1) years. Pulmonary fibrosis was present at baseline in 36.3% and at follow-up in 38.0% of the patients. Median (IQR) extent of fibrosis % of total lung volume was 4.0 (7.3) at baseline and 6.3 (14.0) at follow up. There were only two new cases of pulmonary fibrosis at follow up resulting in an incidence proportion of 2.8%. Progression of fibrosis from baseline to follow-up was evident in 20 patients (17.7%). In these 20 patients the median (IQR) annual pulmonary fibrosis progression rate was 0.9 (1.4) % of total lung volume. Univariable logistic regression revealed that no prior arthritis at baseline was predictive of progressive lung disease.

Conclusion: Pulmonary fibrosis is present in a substantial portion of MCTD patients. These results suggest that pulmonary fibrosis generally appears early in the disease and the progression of pulmonary fibrosis years after diagnosis is generally mild and non- or slowly progressive. However a subset of MCTD patients has deteriorating progressive pulmonary fibrosis. The absence of arthritis was found to be a predictor of progressive pulmonary fibrosis.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Pomalidomide (POM) is an IMiD compound, structurally similar to thalidomide. POM binds to cereblon and facilitates Ikaros and Aiolos degradation, resulting in immunomodulation of myeloid and lymphocyte cell responses. POM exhibits anti-fibrotic activity in preclinical models of dermal fibrosis. To examine the effect of POM on systemic sclerosis with interstitial lung disease [SSC-ILD], the safety and efficacy of POM on forced vital capacity (FVC), modified Rodnan Skin Score (mRSS), and gastrointestinal symptomatology as measured by the University of California, Los Angeles (UCLA) Scleroderma Clinical Trial Consortium Gastrointestinal Tract (SCTC GIT) 2.0 instrument total score compared to placebo in subjects with SSC-ILD was assessed over 52 weeks of treatment (NCT01559129).

Methods: 23 SSC-ILD adult subjects were randomized 1:1 POM:placebo (PBO) with 22 subjects dosed. Subjects were required to have a diagnosis of SSc based on the American College of Rheumatology (ACR) 1980 criteria with onset of the first non Raynaud's manifestation of SSc within 7 years of screening. Diffusion lung capacity for carbon monoxide (DLco) ≥ 35% and ≤ 80% was required at screening along with abnormalities on high resolution computed tomography (HRCT) consistent with SSc lung involvement. Subjects were required to meet at least one of the following 2 pulmonary-related criteria to be eligible: (1)FVC readings ≥ 45% and < 70% at Screening and Baseline (Visit 2); or (2) FVC readings ≥ 70% and ≤ 80% at Screening and Baseline with a documented history of either or both: (a) A ≥ 5% decrease in FVC in the 24-month period prior to Baseline; (b) An HRCT fibrosis score > 20%. Subjects received either 1 mg POM capsule PO QD or placebo.

Results: The mean change from Baseline in predicted FVC% at Week 52 was -5.2 and -2.8 in the POM and PBO arms, respectively; for the mRSS at Week 52 was -2.7 and -3.7 in the POM and PBO arms, respectively; and for the UCLA SCTC GIT 2.0 instrument total score at Week 52 was 0.1 and 0.0 in the POM and PBO arms, respectively. In both groups there was deterioration in FVC and improvement in mRSS, and the observed changes in all three co-primary efficacy endpoints favored placebo. Overall treatment emergent adverse events (TEAEs) were comparable across both treatment arms. The most frequently reported TEAEs (in ≥ 3 subjects) in the POM arm were constipation and arthralgia. There were no deaths in the study. Severe, serious, or TEAEs leading to discontinuation in the POM arm occurred in four (40%) of the 10 subjects each. In the PBO arm, severe and serious TEAEs were each reported in one (8.3%) of the 12 subjects.

Conclusion: In this study, POM was well tolerated with an AE profile consistent with the known safety for POM use in other diseases. The study did not meet its primary endpoints of improvement in FVC, mRSS, nor for the UCLA SCTC GIT 2.0 total score at Week 52. The study

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Compared with placebo, treatment with cyclophosphamide (CYC) improved lung function and dyspnea in patients with systemic sclerosis-related interstitial lung disease (SSc-ILD).[1] While treatment with mycophenolate (MMF) is also associated with improvements in lung function,[2] no studies have directly compared mycophenolate with placebo for the treatment of SSc-ILD.

Methods: Participants enrolled in the placebo arm (N=79) of Scleroderma Lung Study (SLS) I and the MMF arm of SLS II (N=69) were included in these analyses. SLS I randomized participants to oral CYC versus placebo for 1 year, while SLS II randomized participants to MMF for 2 years versus oral CYC for 1 year followed by 1 year of placebo. Eligibility criteria for SLS I and II were nearly identical. The primary outcome was FVC%-predicted and key secondary outcomes included the DLCO%-predicted and quantitative radiographic extent of ILD. FVC and DLCO were measured every 3 months. Because radiographic imaging outcomes were evaluated at 12 and 24 months for SLS I and SLS II, respectively, we could not directly compare these outcomes. Mixed models were created to evaluate the treatment effect on the course of the FVC, DLCO, and patient-reported outcomes, over 12-months while controlling for baseline disease severity.

Results: SLS II participants assigned to MMF had similar baseline characteristics compared with SLS I participants assigned to placebo in terms of gender (65% vs. 70%), disease duration (mean [SD] years: 2.6 [1.7] vs. 3.1 [1.8]), SSc subtype (62% vs. 57% diffuse), and FVC%-predicted (mean [SD]: 66.5 [8.3] vs. 68.6 [13]), respectively. SLS II MMF patients were slightly older (mean [SD] years: 52.6 [9.7] vs. 48.1 [12.4]; P=0.015) and had a higher DLCO%-predicted (mean [SD]: 54.0 [11.1] vs. 46.2 [13.3]; P=0.0002) than SLS I placebo participants. After adjusting for baseline quantitative lung fibrosis in the zone of maximum involvement (QLF-ZM) and baseline FVC%-predicted, treatment with MMF was associated with an improved course of FVC%-predicted over 12 months (P=0.0008; Table 1a). Treatment with MMF was also associated with an improved course of DLCO%-predicted over 12 months (P=0.038; Table 1b), after adjusting for baseline QLF-ZM and baseline DLCO%-predicted.

Conclusion: Although there are inherent limitations in comparing participants from two different trials, the baseline characteristics of the SLS I and SLS II participants were relatively similar. Compared with placebo, treatment with MMF was associated with improved course of the FVC and DLCO over 12 months in patients with SSc-ILD, and this treatment effect appeared more robust than the treatment effect reported in SLS I comparing CYC with placebo. These results further substantiate the use of MMF for the treatment of SSc-ILD.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pneumoproteins are attractive biomarker candidates in systemic sclerosis (SSc) related interstitial lung disease (ILD) because they are easily obtainable and lung-specific. KL-6 and CCL-18 (PARC) have been previously reported as predictive biomarkers. Our goal was to determine the predictive significance of these two pneumoproteins for forced vital capacity % (FVC) decline within the first year of follow-up in patients with early SSc-ILD, in order to inform individualized care in routine clinical practice and facilitate enrichment strategies in clinical trials.

Methods: GENISOS (Genetics versus ENvironment In Scleroderma Outcome Study) cohort patients who had ILD verified by imaging and available pulmonary function tests at enrollment plus 12-18 months thereafter, were included in this study. All patients had disease duration ≤ 5 years at enrollment. FVC, expressed as percentage of predicted value was used as surrogate for severity of ILD. Annualized percent change in FVC at one year follow up was calculated using the formula ((FVC% PFT1 – FVC%PFT0)/FVC%PFT0)/(timePFT1-timePFT0). Baseline demographic, clinical variables and two pneumoproteins, KL-6 and CCL-18 were investigated. KL-6 and CCL-18 were measured by commercially available, validated ELISA kits. Linear regression with baseline clinical and demographic variables as independent variables was performed in univariable and multivariable models.

Results: A total of 84 patients with SSc-ILD were included, 19 were male, 19 African-American, and 46 had diffuse disease. Mean disease duration was 2.3 years. Rate of FVC% predicted change over time ranged from -0.23 to 0.38, indicating a highly variable course. Baseline KL-6 levels were higher in patients than in controls (p<0.0001, see Figure 1a). Baseline higher KL-6 levels (as a continuous variable) were predictive of a faster rate of FVC% decline at the one year follow-up (b=-0.03, *p*=0.04). Upon categorizing KL-6 using a cut-off of 1273 u/mL based on the optimal cut-off previously determined by a Japanese study (Kuwana M et al, J Rheumatol, in press), the predictive significance of KL-6 remained in both the univariate (p=0.01, see Figure 1b) and multivariable analyses after accounting for African-American race, disease duration, age, and treatment with immunosuppressive agents (b=-0.06, *p*=0.03). Twenty nine (34.5%) patients had KL-6 levels equal or above 1273 u/mL. Although CCL-18 was higher in patients than controls (<0.0001), its levels did not predict rate of FVC decline (p=0.4).

Conclusion: KL-6 but not CCl-18 is predictive of early SSc-ILD progression. In this study, we also validated the proposed cut-off of 1273 for KL-6 in an independent cohort. KL-6 is a promising pneumoprotein that can inform individualized clinical care and contribute to enrichment strategies in clinical trials of SSc-ILD.

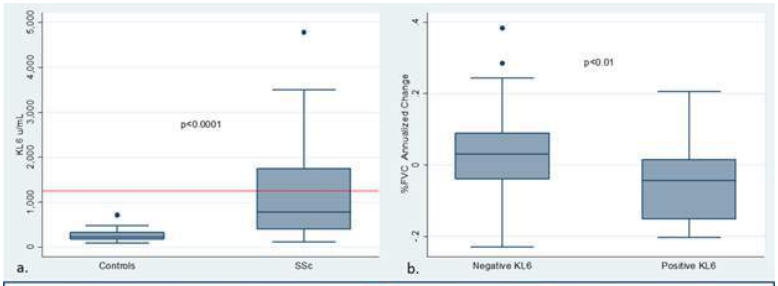

Figure 1. a) KL-6 levels (u/mL) in SSc patients versus controls (— = 1273 cut-off). b) %FVC annualized change in KL-6 positive versus negative patients based on a cut-off of 1273 u/mL. Lower values in %FVC change correspond to a faster FVC decline.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary hypertension (PH) is the leading cause of scleroderma related deaths and is often detected late in the disease course. Early identification of patients with PH will lead to earlier treatment and may improve survival. The purpose of this study is to evaluate if a positive EE predicts future development of PH in a high-risk cohort of scleroderma patients.

Methods: This study included 100 scleroderma patients with features placing them at increased risk for pulmonary hypertension, including dyspnea on exertion, DLCO <60% of predicted, FVC <60% of predicted, FVC%/DLCO% >1.6, or resting right ventricular systolic pressure (RVSP) 30-50 mm Hg. In this prospective cohort study, all patients had baseline EE performed by the standard Bruce stress echocardiogram protocol with re-measurement of RVSP within 1 minute of stopping exercise. A positive EE was defined as an increase of at least 20 mmHg in the RVSP with exercise. All patients had at least one repeat echocardiogram at least one year after baseline EE. Patients were followed per standard of care and right heart catheterization (RHC) was performed in patients with a positive EE result or if PH was suspected based on symptoms. Time to follow up was defined as months to the development of resting PH, or in patients who did not develop PH, months from initial EE to the last echocardiogram.

Results: In our patient population, 12 patients were excluded as they did not have a repeat echocardiogram and 3 additional patients were excluded as they were being treated for exercise PH at the time of EE. Table 1 shows in the remaining cohort, 43 patients had a positive EE and 42 patients had a negative EE. There were no clinical demographic differences or differences in cardiopulmonary parameters between groups. In the positive EE cohort, 10 patients (23%) developed resting PH on RHC, a mean of 4 years after EE (4 with pulmonary arterial hypertension (PAH), 5 with pulmonary venous hypertension (PVH), and 1 with pulmonary hypertension associated with lung fibrosis (PH-ILD), whereas in the negative EE group, only 3 (7%) patients developed pulmonary hypertension (1 PAH, 2 PVH) (p=0.039). Of the remaining 33 patients with positive EE who did not develop resting PH, most (51%) patients continued to have a positive EE, with a mean of 5.3 years of follow up. This included 18 patients who had exercise induced pulmonary hypertension as documented on RHC, but who did not develop worsening symptoms, or changes on the echocardiogram over time.

Conclusion: While a positive EE does predict the future development of resting PH, it is not necessarily PAH, even in high-risk scleroderma patients. PVH also is associated with a positive EE. Many patients with a positive EE may have a persistently positive exercise echocardiogram without progression to resting pulmonary hypertension. A persistently negative EE may identify patients at low risk for future PH. Table 1:

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies of severe gastrointestinal (GI) disease in systemic sclerosis (SSc) are limited by small, selected samples composed largely of subjects with prevalent disease. We undertook this study to examine the morbidity and mortality associated with severe GI disease in SSc in a large, unselected inception cohort.

Methods: A retrospective cohort of subjects with < 3 years of disease duration and without severe GI disease at baseline study visit was identified from the Canadian Scleroderma Research Group registry. Severe GI disease was defined using a previously published definition (Steen and Medsger, A and R 2000) as follows: malabsorption, hyperalimentation, pseudo-obstruction, or either antibiotics for bacterial overgrowth or esophageal stricture requiring dilatation with ≥10% associated weight loss. Subjects who developed severe GI disease during follow-up were compared to those who did not using descriptive statistics. Morbidity was assessed with the Medical Trust Short Form 36 (SF-36) physical (PCS) and mental (MCS) component summary scores. Mortality rates between subjects with and without severe GI disease were compared by dividing the number of deaths per person-years of observation in each group.

Results: Data was available for 306 subjects with < 3 years of disease duration; of these, 21 (7%) had severe GI disease at baseline study visit. Severe GI disease over a mean follow-up time of 3.8 years developed in an additional 18% (50/285) of subjects: 84% female, mean age 53 years, mean disease duration at baseline 1.6 years and proportion with limited/diffuse cutaneous SSc 54%/46%. Subjects who developed severe GI disease were more likely to have digital ulcers (52.0% vs 35.7%, p=0.03) and worse skin scores (15.7 ± 12.0 vs 12.1±10.9, p=0.003) at baseline study visit. Physical health status was more impaired at baseline in subjects with compared to without severe GI disease (SF-36 PCS 35.4 ± 11.3 vs 39.0 ± 10.9, p=0.05). There were no difference in mental health status between the 2 groups at baseline (SF-35 MCS 47.1 ± 11.3 vs 48.6 ± 12.2, p=0.30). There were 10 deaths in 137 person-years of observation among those with, compared to 21 in 1040 person-years of observation among those without severe GI disease, for a mortality rate of 3.7.

Conclusion: Severe GI disease was common in this inception cohort, affecting approximately 25% of subjects within the first 5 years of disease. It was associated with considerable impairment in physical health status and a striking increase in the risk of mortality. Baseline predictors of severe GI disease included markers of more severe vasculopathy and fibrosis. These findings provide compelling evidence to identify interventions that target selected pathophysiological pathways to reduce the burden of severe GI disease in SSc.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is the leading cause of systemic sclerosis (SSc) related mortality. We sought to determine survival, predictors of mortality, and health related quality of life (HRQoL) of PAH in a large SSc cohort followed from the time of PAH diagnosis in the modern era of PAH-specific vasodilator therapy.

Methods:

Patients enrolled in a SSc longitudinal cohort between 2009 - 2015 were included. Group 1 PAH was diagnosed on right heart catheterization (RHC) (mPAP ≥25 and PAWP <15 mmHg). Other causes of pulmonary hypertension were excluded. Summary statistics, chi-square tests and survival methods were used to determine survival rates and identify predictors of mortality. HRQoL was measured using the Medical Outcomes Study Short Form 36 (SF-36).

Results: Among 132 SSc-PAH patients, 84.9% were female and 68.9% had limited disease subtype. The mean (±SD) age at diagnosis of PAH was 62.3 (±10.5) years and disease duration at PAH diagnosis was 14.1 (±11.9) years. Over a median (IQR) follow-up of 3.7 (1.6-5.8) years, 60 (45.5%) patients died, with a median survival time from PAH diagnosis of 3.7 years. The standardized mortality ratio for patients with SSc-PAH compared with the general population was 5.8 (95%CI 4.3-7.8). The years of life lost with SSc-PAH was 15.22 years (95%CI 12.3-18.1). Kaplan-Meier survival curves (Figure 1) showed a survival advantage with combination PAH therapy and anticoagulation. Older age at PAH diagnosis (p=0.03), coexistence of mild ILD (p=0.01), worse WHO functional class (p=0.03), higher mean pulmonary arterial pressure at PAH diagnosis (p=0.001) and presence of digital ulcers (p=0.01) during follow-up were predictive of PAH mortality (Table 1). Combination therapy together with anticoagulation provided the most significant survival advantage, with a 72% reduction in mortality compared with pulmonary vasodilator monotherapy without anticoagulation (Figure 1). Patients with SSc-PAH had consistently poorer HRQoL scores in all domains of the SF-36 form except mental health than the general population.

Conclusion: Despite advanced therapy, the median survival in SSc PAH is less than 4 years. The addition of anticoagulation to standard combination therapy is associated with a significant survival advantage, pointing to mechanisms involving endothelial abnormalities and small vessel thrombosis in the pathogenesis of PAH.

Table 1. Independent predictors of mortality in SSc-PAH determined by multivariable hazard regression analysis

Characteristic	Hazard Ratio (95% CI)	p-value

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Markers for early identification of progressive interstitial lung disease (ILD) in systemic sclerosis (SSc) are in demand. The proto-typical inflammatory chemokine CCL2 has been linked to lung fibrosis in SSc. Here, we aimed to: (i) To explore CCL2 in two independent SSc cohorts, including serum from a large and unselected SSc cohort and lung homogenates at time of lung transplant from patients with SSc-ILD. (ii) To assess associations between CCL2 in sera and lung fibrosis, lung function and survival. (iii) Determine cellular origin of CCL2 and its receptor CCR2 in lung tissue from SSc patients.

Methods: Sera from the Oslo University Hospital (OUH) SSc cohort and healthy controls were analysed for CCL2 at baseline by enzyme immunoassay. High CCL2 (>0.66 ng/ml) was defined using mean value +2SD in control sera as cut-off. Paired clinical data, pulmonary function tests and the extent of fibrosis on HRCT images were obtained at baseline and follow-up. Lung tissue was collected at the time of lung transplantation from SSc and donor lungs at the UCLA. Concentrations of CCL2 in lung homogenates were determined by Luminex technology and expression of CCL2 and CCR2 in SSc tissue were assessed by immunohistochemistry (IHC).

Results: CCL2 was elevated in sera from the OUH cohort (n=298) compared to healthy controls (n=100): 0.65 ng/ml (SD 0.80) versus 0.42 ng/ml (0.54), p=0.008. High serum CCL2 was identified in 79/298 SSc patients (27%). Extent of fibrosis, FVC% and DLCO% differed significantly between high and low CCL2 subsets (Table 1), as well as the total lung fibrosis progression rate (3.4% (SD 9.2) and 1.1% (SD 4.2, p=0.041). In multivariate analyses, CCL2 was associated with severe lung fibrosis >20% (OR 2.5, 95%CI 1.04-6.08, p=0.041), total fibrosis progression >5% (OR 2.7, 95%CI 1.14-6.19, p=0.024) and annual fibrosis progression >2.5% (OR 5.2, 95%CI 1.6-16.5), p=0.005). CCL2 was associated with increased mortality (HR 1.8 95%CI 1.02-3.27, p=0.043). Survival analyses showed that patients with high CCL2 had reduced 5- and 10-year cumulative survival compared to cases with low CCL2 (89% and 77%, compared to 95% and 88%, p=0.02). In the UCLA cohort, CCL2 was elevated in lung homogenates (n=12) compared to donor lungs (n=12) (0.61 ng/ml (SD 0.48) and 0.17 ng/ml (SD 0.23), p=0.007). IHC demonstrated a CCL2 co-localization with reactive type II pneumocytes, alveolar macrophages and infiltrating mononuclear cells. CCR2 was predominantly expressed on infiltrating mononuclear cells and on alveolar macrophages.

Conclusion: We have demonstrated an association between elevated levels of CCL2 and lung fibrosis progression, severe lung fibrosis and survival in SSc. Within the lungs, CCL2 is predominately co-localized with infiltrating mononuclear cells. The results reinforce the notion that high CCL2 may serve as a marker for progressive ILD in SSc and may potentially also represent a target for therapy in this disorder.

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Extensive skin disease and renal crisis are hallmarks of anti-RNA polymerase III (RNAP) positive systemic sclerosis (SSc), while data on lung and heart involvement are conflicting. Here, the aims were to perform time-course analyses of interstitial lung disease (ILD) and pulmonary hypertension (PH) in the RNAP subset in a prospective unselected SSc cohort with longitudinal follow up data and use the other auto-antibody subsets as comparators. <>

Methods: The study cohort included 276 SSc patients from the observational Oslo University Hospital cohort with complete data on (A) SSc-related auto-antibodies, (B) paired, serial analyses of lung function and extent of fibrosis by lung HRCT at baseline and follow-up, and (C) PH verified by right heart catheterization. All patients in the SSc cohort met the 2013 ACR/EULAR classification criteria.

Results: RNAP was positive in 33/276 patients (12%), of which 79% had diffuse cutaneous SSc. Patients with RNAP had higher modified Rodnan Skin Score, developed more frequently scleroderma renal crisis and gastric antral vascular ectasia than anti-Topoisomerase 1 (ATA) and anti-centromere antibody (ACA) positive patients. Pulmonary findings in the RNAP subset were heterogeneous; 49% had no signs of ILD, while 33.3% had moderate fibrosis (1-20% fibrosis) and 18.2% had severe fibrosis at follow up (>20% fibrosis); (Figure 1

and 2). The annual fibrosis progression rate was higher in RNAP (1.2% SD 2.0) compared to ATA (0.5%, SD 5.0) and ACA (0.7%, SD 1.4) but did not reach statistical significance. Forced Vital Capacity at follow up was <80% in 39% of the RNAP subset; comparable to the anti-topoisomerase subset (ATA: 47%), but higher than anti-centromere (ACA: 13%). The accumulated frequency of PH in the RNAP subset (12 %) was lower than in ACA (18 %). The 5- and 10 year survival rates in RNAP cases were 93% and 78%, respectively. The survival of RNAP positive patients was comparable to the ATA and ACA subsets, but significantly higher than in the ANA negative patient subset.

Conclusion: In this cohort, the RNAP subset was marked by cardiopulmonary heterogeneity with progression to extensive ILD in 18 %, and PH development in 12 %. These data indicate that cardiopulmonary risk stratification early in the disease course is particularly important in RNAP positive SSc.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of premature mortality in systemic sclerosis (SSc). Immunosuppression is used for treatment of established disease. However, little is known about whether immunosuppression might prevent ILD in SSc. The aim of this study was to determine if, in SSc patients without ILD, immunosuppression (given for other manifestations) was associated with a lower risk of new onset SSc-ILD.

Methods: A retrospective cohort of 887 SSc patients without ILD at baseline was studied, using data from the Canadian Scleroderma Research Group registry. The primary exposure of interest was immunosuppression with methotrexate, cyclophosphamide, mycophenolate and/or azathioprine. The primary outcome variable was new onset ILD defined using a published algorithm (Steele, ACR 2012). Time to primary outcome was compared between exposed and unexposed subjects, modeled as a time-dependent exposure variable, using an unadjusted Kaplan-Meier model and a marginal structural model incorporating inverse probability of treatment weights (IPTW) to account for confounding. Weights were constructed using variables most likely to influence a decision to initiate immunosuppression, namely age, sex, ethnicity, disease duration, anti-centromere, anti-topoisomerase I, and anti-RNA polymerase III status, modified Rodnan skin scores, C-reactive protein levels, forced vital capacity, presence of inflammatory arthritis, presence of inflammatory myositis, and exposure to immunosuppressive therapy in the past. Subjects were censored at the visit when ILD was first recorded, or time of death, permanent study drop-out or last study visit. Both robust asymptotic and non-parametric bootstrap confidence intervals were constructed.

Results: The study included 218 subjects exposed to immunosuppression at baseline or during follow up and 669 unexposed subjects. Baseline characteristics of exposed and unexposed subjects are presented in Table 1. In unadjusted Kaplan Meier analysis, the observed risk of ILD was higher in exposed compared to unexposed subjects (log rank $p < .0001$), consistent with confounding. However, in a multivariate analysis incorporating IPTW, subjects exposed to immunosuppression had a lower estimated risk of developing ILD compared to unexposed subjects: weighted hazard ratio (HR) 0.50 (95% CI 0.28, 0.90, $p=0.021$), and, after bootstrapping, 0.50 (95% CI 0.17, 0.99).

Conclusion: To our knowledge, this is the first study to demonstrate a role for immunosuppression in preventing SSc-ILD in an observational cohort using modern causal statistical methods. In subjects perceived to be at increased risk for developing ILD, there may be value in initiating immunosuppression early, as this may alter disease course and potentially outcomes. Table 1. Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Skin ulcers in SSc are a major clinical challenge and there are various un-validated definitions of skin ulcers utilized in SSc-related clinical trials. We wanted to better delineate a precise definition for skin ulcers in SSc to be used in clinical trials. Objective: To conduct a systematic literature review (SLR) regarding definitions of skin ulcers. The results were used to develop a consensus definition for SSc-skin ulcers.

Methods: A systematic literature search for SSc-skin ulcer definitions was conducted in PubMed, Web of Science, and Cochrane for articles published from inception to January 1st, 2016. For better generalizability we included related autoimmune diseases where skin ulcers are seen: SLE, RA and vasculitis. Diabetic ulcers were also included as more data is available when defining diabetic ulcers. Inclusion criteria were: studies reporting a definition of skin ulcer, adults, English language, skin ulcer as a study outcome, diseases as outlined above. Exclusions included: not in humans, pressure ulcers, reviews and case reports <10 pts. PRISMA recommendations were followed where applicable. The extracted definitions were categorized into relevant descriptive terms (Table 1) and formed the basis for a consensus definition. SSc experts discussed the definitions using a nominal process and voted for the pertinent definition terms, during the Scleroderma World Congress (SWC). A consensus was attained when agreement was > 70%. Photographs of 11 SSc skin lesions were evaluated before and after definition development to examine the face validity and general feasibility of the definition and to allow further refinement of the definition.

Results: A total of 3464 publications were screened in abstract and title and 446 articles were fully evaluated. Of these, 66 met eligibility criteria and skin ulcer definitions were extracted. Twelve SSc experts (11 rheumatologists, 1 dermatologist) from North America (n=6) and Europe (n=6) discussed, refined and voted on the consensus definition. Descriptive terms and mitigating factors (site, size etc.) were used to develop our new definition and exclusions were decided for its utilization in clinical trials. *The preliminary SWC consensus-derived definition of SSc- skin ulcer for clinical trials is: " Loss of epidermal covering with a break in the basement membrane (which separates dermis from epidermis). It appears clinically as visible blood vessels, fibrin, granulation tissue and/or underlying deeper structures (e.g. muscle, ligament, fat) or as it would appear on debridement"*

Conclusion: Using an SLR and a modified nominal technique, a preliminary consensus-based definition of SSc-skin ulcers was developed. Further validation steps are warranted.

Definition categories	Number of times used
Loss of Epidermis	11
Loss of Epidermis and Dermis(full thickness)	34
With Depth	4
Denuded	4
Unclear/non-specific (as follows):	27
• Ischemic necrotic ulcer	
• Open sore, loss of tissue	
• Open wound	
• Skin break	
• Necrotic lesions

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is one of the leading causes of mortality in patients with systemic sclerosis (SSc). Active screening detects SSc-PAH earlier and may improve survival. Our objective was to evaluate the predictive accuracy of 2012 Australian Scleroderma Interest Group (ASIG) and 2013 DETECT when applied to all patients with SSc with suspected pulmonary hypertension (PH) versus application to only those patients with SSc with suspected PH who met the published inclusion/exclusion criteria for ASIG and DETECT (Table 1).

Methods: Subjects with a diagnosis of SSc based on 2013 ACR/EULAR classification criteria with suspected PH based on the 2013

recommendations for screening and detection of connective tissue disease (CTD)-associated PAH undergoing right heart catheterization (RHC) were evaluated (Khanna et al. Arth Rheum. 2013). Those with non-PH or PAH on RHC had ASIG and DETECT applied. Contingency table analysis was used to evaluate sensitivity, specificity, negative predictive value (NPV), and positive predictive value (PPV).

Results: Approximately 281 subjects underwent screening for PH, and out of those 281 subjects, 113 subjects underwent RHC based on 2013 recommendations for CTD-PAH or clinical opinion of the referring physician (Figure 1). The prevalence of PAH was 17% (Figure 1). DETECT and ASIG performed similarly with 100% sensitivity and NPV in subjects who met and who did not meet the inclusion/exclusion criteria for ASIG or DETECT (Table 2). However, only approximately 10% of subjects met the original published inclusion/exclusion criteria. The most common reason for not meeting the inclusion/exclusion criteria was a higher DLco value; during ASIG application, 36 subjects did not have a DLco < 50 % predicted and during DETECT application, 29 subjects did not have a DLco < 60 % predicted.

Conclusion: In a well-defined SSc- PH cohort, ASIG and DETECT work well as screening tools when applied to a broad population of subjects with SSc. If only the published inclusion/exclusion criteria for ASIG AND DETECT are used, a large proportion of subjects (87 to 88%) with suspected PH would have been missed.

Table 1. Inclusion/Exclusion Criteria for ASIG and DETECT

ASIG	
Inclusion	RVSP ≥ 40 mmHg. DLCO < 50% predicted with FVC > 85% predicted.[1]
Exclusion	FVC < 40% predicted. Abnormal LV systolic or diastolic function. Abnormal LA size. No TR jet. Estimated GFR < 30ml/min.[1]
DETECT	
Inclusion	Disease duration > 3 years. DLco < 60 % predicted.[2]
Exclusion	PH diagnosis prior to RHC. FVC < 40 % predicted. Left heart disease. Advanced PH therapy. Renal insufficiency. Pregnancy.[2]

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Although anti-centromere antibodies (ACA) typically associate with limited cutaneous subset of systemic sclerosis (lcSSc) this reactivity is also seen in some cases with diffuse skin disease (dcSSc). Since both antibody specificity and disease subset may influence clinical features and organ manifestation, we explored the impact of ACA on outcome in dcSSc, as it has previously been reported protective for renal crisis (RC) and interstitial lung disease (ILD). Objectives: We describe clinical characteristics of dcSSc patients with ACA positivity (ACA+diffuse), and compare with ACA positive lcSSc (ACA+limited) and ACA negative dcSSc (non-ACA diffuse).

Methods: First, we identified all ACA positive systemic sclerosis cases in our cohort (n=1313). Those with dcSSc (n=36, 2.7%) were compared with representative groups of consecutive patients ACA+limited (n=160) and consecutive patients non-ACA diffuse (n=260). Long-term survival and frequency of major organ based complications were compared.

Results: The peak modified Rodnan skin score (mRSS) was not significantly different between the dcSSc subgroups with or without ACA (respectively 24.0±9.9 vs 27.4±10.4, p=0.07), but peak mRSS occurred later in disease in ACA+diffuse (88.8±77.2 vs 30.7±33.1 months, p<0.001). Survival in ACA+ was similar for both subsets with survival rates at 5, 10 and 15 years of 96%, 84% and 73% in ACA+limited and 94%, 80% and 72% in ACA+diffuse. Comparing with ACA+diffuse, non-ACA diffuse had significantly lower survival of 85%, 72% and 55% at 5, 10 and 15 years respectively (p=0.002). ACA+diffuse had higher incidence of ILD than ACA+limited (p=0.018), but significantly lower than non-ACA diffuse (p=0.003). Non-ACA diffuse developed ILD mostly in the first 5 years from disease onset, while in ACA+diffuse it occurred later in disease course. During follow-up at 5 years, 15% of ACA+diffuse developed ILD (3% - ACA+limited; 36% - non-ACA diffuse), and at 15 years, 26% had ILD (5% - ACA+limited; 49% - non-ACA diffuse). More patients had pulmonary hypertension (PH) in ACA+diffuse (27.8%), than in the other groups (12.5% - ACA+limited; 11.9% - non-ACA diffuse), though this was mainly due to their longer follow-up. Cumulative incidence of PH in ACA+diffuse was not different from the other groups (at 5 years: 8% - ACA+diffuse, 6% - ACA+limited, 6% - non-ACA diffuse; at 15 years: 24%, 20% and 18% respectively). Similarly, cardiac involvement was more frequent in ACA+diffuse (8.3%) vs 1.9% in ACA+limited and 6.5% in non-ACA diffuse, but differences were not significant adjusting for time of follow-up. In contrast, incidence of RC was higher in non-ACA diffuse (13.9%), affecting only 2 patients in ACA+diffuse (5.6%) and none in ACA+limited.

Conclusion: Although uncommon, ACA+diffuse has a distinct clinical phenotype. These patients have more insidious onset of skin and major organ involvement, which may allow early therapeutic intervention. We confirm that even in dcSSC, ACA appears protective for organ-based complications, namely ILD and RC, and associates with a better survival than expected in dcSSc. Therefore, ACA or factors determining its development, may act as a phenotype modifier in dcSSc.

A Normal Pulmonary Diffusion Capacity Is Rare in Pulmonary Artery Hypertension in Systemic Sclerosis

Rebecca Overbury[1], Tracy M. Frech[2], Maureen Murtaugh[3], Virginia D. Steen[4] and PHAROS investigators, [1]Internal Medicine and Pediatrics, University of Utah, Salt Lake City, UT, [2]Division of Rheumatology, University of Utah, Salt Lake City, UT, [3]University of Utah, Salt Lake, UT, [4]Rheumatology, Georgetown University Medical Center, Washington, DC

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS) cohort is a prospective longitudinal study of patients with systemic sclerosis (SSc) who are at risk for developing pulmonary arterial hypertension (PAH) or who have already been diagnosed with pulmonary hypertension (PH). Although PAH in SSc is usually associated with a very low diffusing capacity for carbon monoxide (DLCO) we identified some patients with a normal DLCO. The purpose of this study was to look at the subset of PAH patients with a normal DLCO defined as ³ 70% predicted at the time of diagnosis of PAH compared to those with expected low DLCO defined as < 70%. We compared demographics, BNP level, pulmonary function tests (PFT), echocardiogram, and right heart catheterization findings in these groups.

Methods: Entry criteria into PHAROS for SSc patients with Group 1 PAH were a right heart catheterization (RHC) with a mean pulmonary artery pressure (mPAP) ≥ 25 mmHg and a pulmonary capillary wedge pressure (PCWP) ≤ 15 mmHg. We examined demographics (age, gender and ethnicity), echocardiogram variables (presence of pericardial effusion and left atrial size), PFT (FVC, FEV1/FVC, FVC%/DLCO%), BNP levels (<100 versus 100 pg/mL) and RHC findings and outcomes in PAH patients who had DLCO % predicted recorded near the time of RHC. We used Fisher's exact test to examine associations between two categorical variables and Kolmogorov-Smirnov test for continuous variables. Significance was assigned at $p < 0.05$.

Results: In the PAH patients (n=202), only 11 patients (5.4%) had a normal DLCO of > 70% (mean 78%) versus 191 patients (94.6%) who had a low DLCO <70% (mean 39%). There was no difference in demographics, other PFT results, echocardiogram findings, or RHC features between the normal DLCO and the low DLCO patients, The left atrium in the normal DLCO patients was slightly larger at 4.1cm than in the low DLCO group (3.7cm), but it was not statistically different, and the PCWP were the same on RHC. There were no differences in survival between these two groups. Finally, on follow up testing in10 of these11 patients, seven had subsequently developed a low DLCO.

Conclusion: Only 5% of this large cohort of SSc-PAH patients had a normal DLCO >70% predicted at the time of diagnosis. The majority of these fell below normal values on follow up testing. There were no identified differences in these patients to suggest why they maintained a normal DLCO compared to the vast majority of SSc –PAH with abnormal low DLCO. Although a low DLCO is almost always seen in SSc patients with PAH, PHAROS data suggests that in rare situations, a patient may develop PAH with a preserved DLCO.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Calcinosis cutis is a debilitating complication of systemic sclerosis (SSc) affecting one quarter of patients. Repetitive trauma may be involved in the pathogenesis of calcinosis, and a prior single-center study found that the thumbs were most commonly affected, supporting this hypothesis. We sought to confirm this finding and to characterize the complications associated with calcinosis in a multi-center, international cohort of SSc patients.

Methods: We established a prospective cohort specifically to study calcinosis in SSc. We have to date enrolled 233 consecutive SSc patients who fulfill 2013 revised ACR/EULAR criteria at 9 centers within the United States, Canada, Australia, and Mexico. We performed a thorough physical exam of the entire body to assess for the presence of calcinosis, and collected detailed information on associated features. Calcinosis was defined as radiological or physical exam evidence of subcutaneous calcium deposition, or a clear history of extruded calcium.

Results: Our cohort was 88% female, and racial distribution was 64% Caucasian, 29% Hispanic, and 4% Asian. 55% had limited cutaneous disease. Mean disease duration from first non-Raynaud phenomenon (RP) symptom was 11.1 ± 9.3 years. Calcinosis was present in 90 patients (39%). Calcinosis developed 8.4 ± 9.0 years after first non-RP symptom. From 31 patients who had x-rays of the hands available, 21 (68%) had only radiographically detectable calcinotic lesions. The most common location of calcinosis was the hands (71%), followed by the elbows (19%), and the arms and/or forearms (16%). Within the hands, calcinosis most commonly affected the thumbs with decreasing frequency moving from the thumb to the little finger (50% thumbs, 37% index, 34% middle, 22% ring, and 18% in the little finger). Within patients with calcinosis of the hands, 25% had only right hand involvement, 11% had only left hand involvement, and 64% had bilateral hand involvement. 87% patients had multiple calcinotic lesions, and the median number of lesions was 2.5 per patient (range 1-13). 21% of patients had lesions >1 cm. The most common complications from calcinosis were tenderness (34%) and spontaneous extrusion of calcinosis through the skin (27%). Ulceration and infection were more rare (8% and 3% respectively). In patients with calcinotic lesions >1 cm, ulceration was more frequent (21% vs. 4%, p=0.015).

Conclusion: The majority of SSc patients with calcinosis presents with multiple, sub-centimeter lesions affecting the hands, most frequently in the right hand and in the thumb. Assuming that the dominant hand and the thumb are exposed to the most trauma, our study supports a role for trauma in the pathogenesis of calcinosis in SSc. Ulceration and infection are rare complications, but patients with larger lesions are more likely to suffer from ulceration of calcinosis.

SESSION INFORMATION
Session Date: Sunday, November 13, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Skin fibrosis is the hallmark of SSc and may lead to significantly reduced quality of life in ways that may not be directly proportional to the area and severity of skin involvement such as that captured by the modified Rodnan skin score (mRSS). We developed a patient reported outcome instrument (PRO) to assess specifically the skin-related quality of life in patients with SSc for use in routine practice and clinical trials.

Methods: We conducted 3 focus groups (N=12) with SSc participants on how their skin condition affected their lives. Analysis of transcripts resulted in themes, which were conceptually encapsulated into four constructs: physical symptoms, physical limitations, emotional effects and social effects. 56 items for the Scleroderma Skin PRO (SSPRO) were created or adapted from existing PROs to assess each of these constructs. Input from an expert panel as well as cognitive interviews with 10 SSc participants led to removal of items with 22 remaining. The 22-item SSPRO was administered to 140 participants who also completed other PROs and rated their global skin severity. An mRSS and a global disease severity rating were also completed by a physician. Psychometric analysis included test-retest reliability, internal consistency, construct validity, exploratory and confirmatory factor analyses.

Results: Participants (N=140) primarily had lcSSc (67.1%), were female (82.1%) and Caucasian (92.9%) with mean age of 53.4 years and disease duration of 6.4 years. Mean mRSS was 9.3 (SD 10.8). Self-reported skin severity was mild (45%), moderate (48.5%), and severe (5.7%). Factor analysis supported 4 underlying factors in the SSPRO corresponding to the 4 hypothesized constructs. Removal of 4/22 items that contributed most to cross loading resulted in acceptable fit statistics in a confirmatory analysis. Test-retest reliability was moderate to high (ICC = 0.61–0.83) and internal consistency (CronbachÕs alpha = 0.89-0.96) was high. SSPRO correlated strongly with other patient reported measures suggesting construct validity, and less well with physician assessed outcomes (Table). SSPRO scores were also able to discriminate between participant-reported skin severity levels (Figure), as well as between limited and diffuse disease providing further evidence of construct validity.

Conclusion: SSPRO has been developed with extensive patient input and demonstrates reliability as well as face and construct validity. It is complementary to existing measures of SSc skin involvement with emphasis on the patientÕs experience. Further research is needed to assess its sensitivity to change.

Table. Association of SSPRO with other outcome measures

Outcome Measure*	Pearson's Correlation Coefficient†
mRSS	0.38
Cochin Hand Function Scale	0.73
Skindex-29	0.88
HAQ-DI	0.59
SHAQ VAS Intestinal	0.36

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease with pulmonary involvement seen in 75% of patients and esophageal involvement in 90% of the patients. Pulmonary disease has overtaken renal disease as the leading cause of death. There is conflicting evidence about the association between esophageal dysmotility and lung involvement. We aimed to evaluate the relationship between esophageal dysmotility and lung disease by correlating the results of Esophageal transit time (ETT) with pulmonary function test (PFT).

Methods: Charts of SSc patients fulfilling 2013 ACR/EULAR classification criteria seen in Rheumatology from 2004 to 2015 were reviewed. Patients demographics, laboratory, results of ETT, High resolution CT (HRCT) of lung and PFT were collected at baseline, years 1, 3, 5 and 10. Patients were divided based on their initial ETT findings. Using the linear mixed effects model, we tested the effect of ETT status on forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCo) and estimated the progression rates in two groups. We adjusted for relevant covariates such as disease sub type, smoking, obesity and medications.

Results: 130 patients were identified with either LcSSC (109) or diffuse SSc (21). ETT was normal in 67(52%) and abnormal in 63(48%) patients. At baseline, years 1,3,5 and 10, the mean DLCo was significantly different between the groups while the mean FVC was not. An error bar graph indicating mean and standard error of mean at each year is provided for each outcome. Abnormal ETT group have a significantly worse progression of DLCo, both in unadjusted (p=0.023) and adjusted (p=0.019) models but FVC progression was significantly worse in adjusted (p=0.018) model only. The estimated progression rates per year are provided in Table 1a. The effect of ETT status on FVC is statistically insignificant for both unadjusted (p= 0.1608 and adjusted (p= 0.133) but significant for DLCo (unadjusted p= 0.0004, adjusted p=0.0175). The means and 95% confidence intervals for the two groups are provided in Table 1b. Patients with baseline abnormal HRCT had significantly lower DLCo but did not have worse progression rate.

Conclusion: Our results show that presence of abnormal ETT correlates with reduced mean DLCo and worsening of FVC and DLCo over a period of 10 years. Presence of abnormal HRCT at baseline did not indicate progression of FVC or DLCo. Larger prospective studies need to be done to find a causal relationship. References: 1. SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Severe gastrointestinal (GI) disease is associated with considerable morbidity and high mortality in systemic sclerosis (SSc). There are no known preventative treatments. We wished to test the hypothesis that exposure to immunosuppression (for skin, lung, joint or muscle condition) in early disease could modify the risk of severe GI disease in SSc.

Methods: Subjects with < 3 years of disease duration (since the onset of the first non-RaynaudÕs disease manifestation) and without severe GI disease at baseline study visit were identified from the Canadian Scleroderma Research Group registry. Severe GI disease was defined using a previously published definition (Steen and Medsger, A and R 2000) as follows: malabsorption, hyperalimentation, pseudo-obstruction, or either antibiotics for bacterial overgrowth or esophageal stricture requiring dilatation with >10% associated weight loss. A retrospective cohort study was performed with immunosuppression to methotrexate, azathioprine, mycophenolate and/or cyclophosphamide as the exposure of interest and severe GI disease as the outcome. Descriptive statistics were used to compare the baseline characteristics of the subjects, according to exposure status. The risk of severe GI disease in exposed versus unexposed subjects was estimated using a Cox proportional hazard model, with exposure to immunosuppression modeled as a time-dependent variable and including inverse probability of treatment weights (IPTW) to account for confounding. The model was adjusted for potential demographic and disease-related confounders.

Results: This study included 285 subjects, 84% female, mean age 53 years old, mean disease duration at baseline 1.6 years, proportion limited/diffuse cutaneous SSc 54%/46%. During a mean follow-up time of 3.8 years, 152 (53%) subjects were exposed to immunosuppression and 133 (47%) were not. In univariate analyses, subjects exposed to immunosuppression were more likely to have diffuse disease (62.5% vs 26.3%, $p<0.001$), interstitial lung disease (37.8% vs 18.9%, $p<0.001$), inflammatory myositis (14.6% vs. 1%, $p<0.001$) and worse skin scores (16.5 ± 11.2 vs 8.4±9.5, $p<0.001$) at baseline study visit. In a multivariate Cox proportional hazard analysis modeling immunosuppression as a time-dependent variable and incorporating IPTW, exposure to immunosuppression did not modify the risk of developing severe GI disease: hazard ratio 0.71, 95% confidence interval 0.32, 1.58 (Table).

Conclusion: Contrary to our hypothesis, exposure to immunosuppression did not prevent severe GI disease. Further research is required to identify effective prevention and treatment interventions for severe GI disease in SSc.

Table 1. Cox proportional hazard model to identify predictors of severe GI disease in SSc, including exposure to immunosuppression (IS) modeled as a time-dependent variable and inverse probability of treatment weights (IPTW)

	Hazard Ratio	95% confidence interval		P values
Exposure vs non exposure (time-dependent)	0.71	0.32	1.58	0.397
Exposure to IS prior to baseline visit	1.43	0.30	6.85	0.654
Disease duration	0.97	0.55	1.72	0.970
Caucasian	1.60	0.49	5.23	0.437
Antibodies				
Anticentromere vs others	0.39	0.15	1.00	0.049
Antitopoisomere vs others	0.59	0.21	1.61	0.298
Anti-RNA polymerase vs others	0.71	0.24	2.15	0.549
Modified Rodnan Skin Score	1.02	0.98	1.06	0.367
C-reactive protein (log)	1.24	0.92	1.67	0.167
Interstitial lung disease	0.95	0.39	2.30	0.910
Digital ulcers	0.93	0.49	1.79	0.836
Inflammatory arthritis	1.38	0.60	3.16	0.448
Inflammatory myositis	1.25	0.29	5.47	0.769

Time Trends In Incidence And Mortality Of Systemic Sclerosis In Denmark From 1995-2011: A Nationwide Cohort Study

Background/Purpose: Epidemiological studies have documented an increasing incidence of several autoimmune disorders over the last few decades, but little is known about the temporal trends of systemic sclerosis (SSc). We aimed to improve our understanding of the epidemiology of SSc by evaluating over time the incidence and mortality in a registry-based nationwide analysis.

Methods: Using the Danish National Patient Registry (NPR) we identified all persons aged ≥ 18 with a first-time diagnosis of SSc (International Classification of Diseases 10th edition code M34 except for M34.2) between 1995 and 2011. Incidence rates (per million person-years) and first-year 1-year mortality rates (per 100 person-years) associated with SSc were calculated. Confidence intervals were

estimated under the assumption of a Poisson distribution. Age- and sex-adjusted Cox regression models were used to investigate the association of SSc with mortality, compared with the background population.

Results: Within the total Danish population (spanning from 4.939.465 individuals in 1995 to 5.419.512 persons in 2011), the total number of unique SSc cases increased from 117 in 1995 to 267 in 2011. The mean age of onset remained unchanged throughout the study period; 54.2 years (range: 22.6- 85.6) in 1995 and 55.1 years (range: 18.5-98.6) in 2011. The proportion of women fell from 82% in 1995 to 75% in 2011. The incidence rate per 1,000,000 showed an increasing trend from 23.7 (95% CI 19.8-28.4) in 1995 to 49.3 [95% CI 43.7-55.5) in 2011. Similar trends were observed when stratified by sex and various age groups. The all-cause 1-year mortality rate per 100 person-years showed a decreasing trend from 18.5 (95% CI 11.8-29.0) in 1995 to 7.0 (95% CI 4.4-11.1) in 2011. The age and sex-adjusted hazard ratio compared with the background population fell from 16.4 (95% CI 10.5-25.6) in 1995 to 8.2 (95% CI 5.2-13.0) in 2011, respectively.

Conclusion: Our data show that the incidence of SSc was increasing and 1-year mortality rates falling during the study period. Mechanisms underlying our findings remain to be determined, but it cannot be excluded that the increasing incidence estimates may in part be explained by increased physician awareness and more sensitive ascertainment methods identifying earlier and less severe cases of SSc. This could possibly also explain a higher survival rate associated with SSc in recent years. Further studies are needed to investigate the mechanisms underlying our findings and furthermore outcomes on 5- and 10-year survival.

Low Nucleoside Triphosphate Pyrophosphohydrolase Activity Contributes to Pathologic Mineralization in Systemic Sclerosis

Yue Ding[1], Supraja Yeturi[1], Claudia Gohr[1], Mary Ellen Csuka[1] and Ann K. Rosenthal[2,3], [1]Medicine, Medical College of Wisconsin, Milwaukee, WI, [2]Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI, [3]Medicine, Clement J. Zablocki VA Medical Center, Milwaukee, WI

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcinosis is a major source of morbidity in patients with systemic sclerosis (SS). In addition, increased coronary calcification has been reported in patients with SS and other inflammatory diseases. The etiology of pathologic calcification in SS is unclear. Circulating levels of inflammatory cytokines, including interleukins, are elevated in SS patients compared to controls. IL-1β can induce calcification in vitro. The mechanism of this effect was recently shown to involve modulation of nucleoside triphosphate

pyrophosphohydrolase (NTPPPH) activity. This critical ecto-enzyme hydrolyzes extracellular ATP to produce pyrophosphate (PPi). PPi functions as a potent inhibitor of calcification. Thus, low levels of NTPPPH reduce PPi levels and permit increased mineralization. We sought to test the hypothesis that circulating NTPPPH enzyme activity levels are reduced in SS patients.

Methods: After obtaining informed consent, 20 ml of blood was collected from 42 well-characterized SS patients and 17 healthy controls with similar mean age and gender. For completeness, we measured serum activity levels of three enzymes involved in PPi metabolism. PPi is generated from ATP through the action of NTPPPH. PPi is degraded by alkaline phosphatase (Alk Phos) to Pi. 5'- nucleotidase (5'NT) drives PPi production by metabolizing AMP to adenosine and Pi. **Specific activities of Alk Phos (Sigma) and 5'NT (BQ Kits) were measured per manufacturers' directions and** NTPPPH activity levels were measured with a colorimetric assay.

Results: Characteristics of the patients are shown in table 1. The mean values of PPi-metabolizing enzyme activity levels in sera of patients with SS are shown in the scatter plots in figure 1. NTPPPH levels were significantly lower (p= <0.0001) in SS patients compared to controls. There were no significant differences in levels of Alk Phos (p=0.11) and 5'NT (p=0.181).

Conclusion: NTPPPH activity levels are significantly lower in patients with SS compared to controls, leading to lower PPi levels and more pathologic calcification. This work provides additional support for the important connection between inflammation and mineralization, and identifies NTPPPH enzymes as potential targets for novel therapies for SS-associated calcification. Table 1. SS patient characteristics

Patient Characteristics

Aminaphtone Treatment Increases Skin Blood Perfusion and Related Clinical Symptoms in Patients Affected By Raynaud's Phenomenon: A Pilot Study Based on Laser Speckle Contrast Analysis

Barbara Ruaro, Sabrina Paolino, Carmen Pizzorni, Maurizio Cutolo and Alberto Sulli, Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, Genova, Italy

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Sunday, November 13, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Aminaphtone is an oral vasoactive drug used to treat microvascular impairement since 30 years, and recently suggested to down-regulate endothelin-1 production by endothelial cells, and to improve Raynaud's phenomenon (RP) symptoms (1-3). Laser speckle contrast analysis (LASCA) is a validated technique to measure skin blood perfusion (4,5). The aim of this longitudinal study was to evaluate skin blood perfusion changes and clinical symptoms during aminaphtone treatment in patients affected by RP.

Methods: Thirty-seven patients with active RP were enrolled during routine clinical assessment in November 2015: 10 primary (PRP) and 27 secondary RP (SRP) to systemic sclerosis. Aminaphtone was administered as clinical practice 75 mg twice daily (off label) in addiction to current treatments (patients were on stable drug regimen from at least two months, and they did not modify it during follow-up). Blood perfusion was measured by LASCA as perfusion units (PU) at baseline (T0), after one (T1), four (T4) and twelve weeks (T12) of treatment, at the level of fingertips, periungual areas, dorsum and palm of hands, tip of noise, zygoma, forehead, and perioral regions. Raynaud condition score (RCS) and both Raynaud's attack frequency and duration were also assessed at the same times. Statistical analysis was performed by non-parametric tests.

Results: A progressive statistically significant increase of blood perfusion was observed from T0 to T12 in all skin areas as in PRP as in SRP patients (median PU at T0, T1, T4, T12 respectively: fingertips 52, 86, 92, 104 for PRP, and 53, 91, 102, 107 for SRP; periungual areas 50, 74, 90, 91 for PRP, and 42, 80, 90, 91 for SRP; dorsum of hands 42, 59, 69, 75 for PRP, and 33, 66, 74, 78 for SRP; palm of hands 54, 76, 87, 101 for PRP, and 57, 88, 98, 97 for SRP; whole face 120, 125, 142, 150 for PRP, and 127, 128, 144, 148 for SRP; $p<0.001$ for all). In particular, all patients treated with aminaphtone showed an increase of blood perfusion from T0 to T1, and 28 out of 35 patients from T1 to T12 had a further increase of blood perfusion. A progressive statistically significant decrease of RCS (median at T0, T1, T4, T12: 7, 5, 4, 4 for PRP, and 8, 6, 4, 3 for SRP; $p<0.0001$), Raynaud frequency (median at T0, T1, T4, T12: 2, 2, 1, 1 for PRP, and 2, 2, 1, 1 for SRP attacks/day; $p<0.0001$) and duration (median at T0, T1, T4, T12: 20, 20, 10, 7 for PRP, and 20, 20, 10, 4 for SRP minutes; $p<0.0001$) was also observed from T0 to T12. The results were similar for both primary and secondary RP. Two patients had to stop the drug due to headache, and one patient was lost during follow-up.

Conclusion: This study demonstrates that aminaphtone treatment increases in short-time skin blood perfusion, as well as seems to ameliorate RP symptoms. A randomized clinical trial including larger number of control subjects need to confirm these results and to assess the possible role of aminaphtone in the treatment/prevention of systemic sclerosis related clinical complicantions. **References.** 1. Forced vital capacity predicts outcome in scleroderma associated interstitial lung disease with concomitant pulmonary hypertension: Data from the PHAROS registry

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in scleroderma and is often accompanied by secondary pulmonary hypertension (Group 3 PH). The objectives of this study were to characterize the Group 3 PH population of PHAROS, compare them to those with Group 1 PH (pulmonary arterial hypertension), and identify specific variables with prognostic significance.

Methods: PHAROS is a prospective multi-center registry of scleroderma patients at high risk for, or with definite PH based on right heart catheterization (RHC) within six months of enrollment. In this study, we included those considered by PHAROS investigators to have Group 3 PH as defined by the presence of moderately-severe ILD (as determined by a forced vital capacity [FVC] < 65% predicted and/or significant ILD by chest computed tomography scan) along with RHC-confirmed mean pulmonary artery pressure of ≥ 25 mmHg and pulmonary capillary wedge pressure < 15 mmHg and compared them to PHAROS subjects considered to have Group 1 PH (pulmonary arterial hypertension). Baseline demographics and clinical characteristics at the time of RHC were assessed, and univariate analyses (STATA, version 14.0) were performed to identify variables predictive of outcome.

Results: Sixty-three Group 3 PH patients were identified. Baseline demographics and clinical characteristics are displayed in the Table. Patients with Group 3 PH were more likely to be African-American, have diffuse skin involvement, anti-Scl70 positivity and more severe impairment on pulmonary function testing, but with better cardiac hemodynamics. With a median follow-up period of 913 days (interquartile range 383, 2158), 41% of the Group 3 PH cohort expired; with ILD progression as the most frequent cause of death (12 of 26, 46%). The 5-year survival was similarly poor for both groups: Group 1 PH 58% vs. Group 3 PH 61%. On univariate analysis of Group 3 PH patients, the only variable associated with survival time, was FVC (HR 0.967, 95% CI: 0.939-0.997; p=0.03): the lower the FVC, the higher the risk of death.

Conclusion: Moderate-severe ILD with concomitant PH is associated with a poor prognosis and the degree of physiologic restriction, as measured by FVC, is associated with worse survival time.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Bardoxolone methyl (BARD), an activator of the transcription factor Nrf2, and inhibitor of NF-kB, targets dysfunctional inflammatory, metabolic, and bioenergetic pathways. In an initial analysis of 24 patients enrolled in a Phase 2 study of BARD in WHO Group I pulmonary hypertension (PAH) patients receiving one or more background PAH therapies, a statistically significant 22 m increase in 6-minute walk distance (6MWD) compared to placebo was seen after 16 weeks of treatment[1]. A subset of six participants enrolled with connective tissue disease-associated PAH (CTD-PAH) demonstrated numerically larger changes in 6MWD than those with other forms of PAH. The current analysis reports longer-term safety and efficacy data for patients in the initial report through 32 weeks total weeks of treatment (16 weeks of blinded treatment followed by 16 weeks of treatment during the open-label extension) of the ongoing LARIAT study.

Methods: WHO Group 1 PAH patients (n = 24) were randomized in a 1:3 ratio to receive once-daily placebo or bardoxolone methyl at doses of 2.5, 5, or 10 mg for 16 weeks. Participants who completed the 16-week treatment period were eligible to continue in an open-label extension study and received BARD individually adjusted up to a maximum once-daily dose of 10 mg. The primary efficacy variable, 6MWD, was measured at baseline and at Weeks 4, 8, 12, 16, 20, and 32. Investigators and participants remain blinded to their initial treatment assignment.

Results: Overall, 18 (75%) subjects (14 bardoxolone methyl, 4 placebo) entered the extension study and completed Week 32 of the study at doses of 2.5 mg (n = 5), 5 mg (n = 5), and 10 mg (n = 4). The previously reported gain in 6MWD was sustained through 32 weeks of extended treatment with BARD. BARD-treated participants with CTD-PAH (n = 6/14) had similar sustained increases in 6MWD through Week 32. Additionally, the metabolic effects at Week 16 observed with BARD (decreased weight and creatine kinase) were sustained through Week 32. Fewer adverse events were reported during the extension study than during the first 16 weeks of treatment. The most frequently reported adverse events that occurred in >10% of patients treated with BARD during the extension study were fatigue, arthralgia, muscle spasms, nausea, and sinus congestion.

Conclusion: Bardoxolone methyl was well tolerated in patients with PAH and led to sustained improvements in 6MWD for up to 32 weeks without evidence of attenuation. References:

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a connective tissue disease that is often complicated by secondary interstitial lung disease (SSc-ILD). Due to its high morbidity and mortality, there is an on-going effort to find a specific therapy for SSc-ILD. The standard of therapy in recent years has been an immunosuppressive therapy (IST) with cyclophosphamide (CYC). Although increasing data suggest the efficacy of mycophenolate mofetil (MMF) and other ISTs, there have been very few randomized controlled trials (RTCs) to show their efficacy. In this study we will analyze the current standard of therapy in SSc-ILD in SSc centers that participated in the DeSScipher Project on SSc-ILD.

Methods: 1,447 adult SSc patients, who participated in the DeSScipher Project, met the ACR/EULAR 2013 classification criteria and had a diagnosis of SSC-ILD proven by chest X-ray or computed tomography were included in our study. Clinical parameters, medical therapies and lung function were assessed at baseline and 12 +/- 3 months later.

Results: Out of the 1,447 patients included in the study, 781 patients (54%) received ISTs. Of those only 95 patients (12%) received CYC, either as monotherapy (47, 6%) or as combination therapy (48, 6%) (combination therapy referring to any additional IST excluding glucocorticoids (GCs) < 8 mg/day or anti-malaria agents). MMF was more prevalent with 239 patients (31%), 169 (22%) on monotherapy and 70 (9%) on combination therapy. Newer therapies such as rituximab (RTX) were less frequent with 50 (6%) patients, 14 (2%) on monotherapy and 36 (5%) on combination therapy. For Tocilizumab (TOC) we found 19 (2%) patients in total, 6 (1%) on monotherapy and 13 (1%) on combination therapy. Out of the patients with SSc-ILD receiving IST there was a total of 239 (31%) patients receiving IST combination therapy. Comparing patients receiving CYC +/- other IST to patients receiving MMF, RTX or TOC either as monotherapy or as combination therapy, they are similar in age (53.7±12.7 yrs vs. 54.2±12.8 yrs in CYC), but have shorter disease duration regarding SSc (5.9±6.9 yrs in CYC vs. 8.7±6.9 yrs, $p<0.001$) and ILD (3.3±5.7 yrs in CYC vs. 5.9±7.8 yrs, $p<0.001$), similar FVC (80.8±21.4% in CYC vs. 83.1±21.5%) and higher mRSS (13.3 in CYC vs. 8.9±8.7, $p<0.001$). Interestingly, over the course of 1 year +/- 3 months patients on any combination therapy showed slightly better results in terms of FVC and mRSS compared to patients on monotherapy (ΔFVC 2.3% vs. 1.5%; ΔmRSS -1.7 vs. -0.9).

Conclusion: This study highlights the heterogeneity of ISTs in current clinical practice for the treatment of SSc-ILD. There is a high prevalence of immunosuppressive combination therapies that are not supported by any RTCs. Such combination therapy seems to have a beneficial effect on both FVC and mRSS. However, the difference is below a clinically meaningful improvement of 5% FVC. Also, these data have to be interpreted with caution, because groups are not yet adjusted for baseline characteristics.

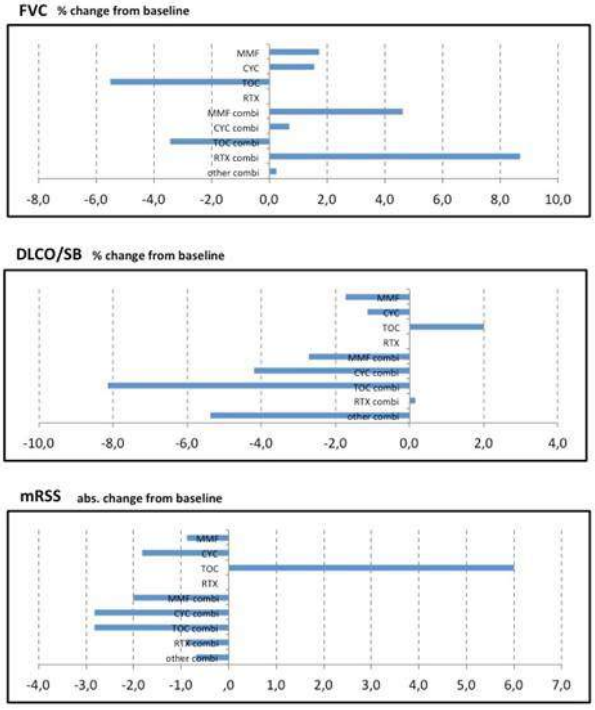

Table 1 Comparing outcomes in lung function parameters (mean changes in FVC and DLCO/SB) and skin involvement (mean changes in mRSS) after 1 year ± 3 months of IST in 141 SSc-ILD patients enrolled in the DeSScipher Project.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiac involvement is a main cause of mortality in systemic sclerosis, although reported prevalence of cardiac involvement is low and detection of cardiac involvement remains challenging. Speckle-tracking strain analysis of echocardiographic images can detect subtle myocardial dysfunction in systemic sclerosis patients. **Objectives:** This study evaluated: 1. changes in cardiac performance over time including echocardiographic myocardial speckle tracking strain analysis in a large cohort of systemic sclerosis

patients, not selected for disease severity, and 2. baseline characteristics associated with deterioration of cardiac function.

Methods: 235 systemic sclerosis patients (197 female, 52±14 years), all fulfilling ACR 2013 or Leroy 2001 criteria for systemic sclerosis, were evaluated at baseline and follow-up (2.3 years, interquartile range 1.3-3.8), including complete physical examination and screening for organ involvement with at least high resolution computed tomography of the thorax, pulmonary function test, cardiopulmonary exercise test, electrocardiography and echocardiography.

Results: Left ventricular ejection fraction did not change significantly (62%±7 vs 61%±8,p=0.148) while global longitudinal strain decreased significantly (-21%±2 vs -19%±2, p<0.001). 39 patients showed progression of left ventricular dysfunction as defined by ≥15% decline in longitudinal strain. These patients showed significant worsening of left ventricular diastolic function and Tricuspid Annular Plane Systolic Excursion (TAPSE ; 22mm±4 versus 19mm±4, p=0.003) and 6% developed pulmonary hypertension. Multivariate analysis showed that at baseline proximal muscle weakness (Odds Ratio: 3.7; interquartile range:1.3–10.4), diffusing capacity of carbon monoxide (Odds Ratio: 0.97 [0.95–1.00]) and Left ventricular diastolic dysfunction (Odds Ratio: 2.25 [1.02–4.95]) were associated with progression of left ventricular dysfunction as reflected by strain analysis.

Conclusion: In this large cohort of systemic sclerosis patients, decline of left ventricular function was detected by speckle tracking strain analysis, and increase of percentage of patients with diastolic dysfunction. At baseline, proximal muscle weakness, diffusing capacity of carbon monoxide, and left ventricular diastolic function may identify patients at higher risk for deterioration of cardiac function and in need of closer cardiac monitoring by means of annual repeated echocardiography. Table 1. Echocardiographic parameters at baseline and follow-up; n= 235 Abbreviations: LEVF= Left Ventricular Ejection Fraction; GLS= Global Longitudinal Strain; LV= Left Ventricular; sPAP= systolic Pulmonary Arterial Pressure; PAH= Pulmonary Arterial Hypertension; TAPSE = Tricuspid Annular Plane Systolic Excursion; PE= pericardial effusion

	Baseline	Follow-up	P value
LEVF%, mean (SD)	62 (7)	61 (8)	0.148
