Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a rare form of childhood autoimmune myositis that presents with proximal muscle weakness and heliotrope rash. B cells are strongly implicated in the pathogenesis of the disease and can generate myositis specific antibodies, that are associated with clinical subgroups. We propose that B cells may also contribute to the disease by producing pro-inflammatory cytokines, triggered by type I interferons.

Methods: Samples and data were collected from children with JDM recruited to the UK JDM Cohort and Biomarker Study. Peripheral blood mononuclear cells (PBMC) samples from JDM patients before treatment and on treatment were selected for analysis. PBMC from child healthy controls (CHC) (n=25) and JDM patients (n=61) were incubated in the presence of phorbol 12-myristate 13-acetate (PMA), Ionomycin and Golgi Plug for 4hrs and cytokine expression was analysed by flow cytometry. PBMC and sorted B cells were also stimulated for 48hr with R848 (TLR7/8) and assessed for intracellular IL-6 and IL-10 by flow cytometry and protein levels were measured by ELISA. PBMC were stained *ex-vivo* to look at B cell subset frequency and Ki67 expression. Differences between groups were analysed using paired/unpaired t tests or one-way ANOVA (Prism 6 software).

Results: B cell frequency was significantly higher in pre-treatment JDM patients compared to CHC samples (mean frequency of total PBMC 25.72% Vs. 22.69% (ns) (£6 months treatment) or 16.26% in CHC; $p<0.01$). This difference was most marked in the immature B cell subset (mean frequency of total B cells 36.05% Vs. 3.66% (£6 months on treatment) or 12.4% in CHC; $p<0.01$). The immature B cell subset was more proliferative before treatment (mean Ki-67% of 17.63% Vs. 8.86% (>6 months on treatment) or 7.18% in CHC; $p<0.01$). Whole transcriptome RNA sequencing of B cells from paired pre and on treatment patient samples showed an upregulation of the type I interferon signature. Of particular interest Toll-like receptor 7 (TLR7) was up-regulated in B cells from patients' pre-treatment. When B cells were stimulated with TLR7 agonist (R848) there was reduced expression of IL-10 detected by ELISA from JDM compared to CHC samples (10.61pg/ml Vs. 75.01pg/ml (mean values)). However, IL-6 expression responded the same in JDM compared to CHC (486.18pg/ml Vs. 414.29pg/ml (mean values)).

Conclusion: We have identified a subset of immature B cells that are expanded, more proliferative and express both IL-6 and IL-10 in pre-treatment patients. The up-regulated type I interferon signature in JDM could contribute to the expansion of immature B cells with an imbalance of IL-6 and IL-10 production.

Session Date: Tuesday, November 15, 2016

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: IL-6 has been considered a biomarker of disease activity in GCA and a potential therapeutic target. However, the functional role of IL-6 in GCA has not been explored. IL-6 has important roles in B cell homeostasis and Th17 differentiation as well as in driving the acute–phase response which underlines systemic symptoms in GCA. Blocking IL-6 receptor with tocilizumab (TCZ) has shown efficacy in maintaining remission in case series of refractory patients with GCA and in a recently published randomized clinical trial (Villiger PM *et al* Lancet 2016). We hypothesized that TCZ may disturb B cell homeostasis and interfere with tertiary lymphoid organ (TLO) formation. To explore TLO formation in GCA arteries and to investigate the impact of IL-6R blockade with TCZ on TLO markers in ex-vivo cultured arteries from patients with GCA.

Methods: Formation of TLO was explored in temporal artery biopsies from patients with GCA by immunofluorescence using CD20 (B cell marker) and CD21 (follicular dendritic cell marker). Expression of TLO markers CXCL13, LTα and LTβ was assessed by quantitative real-time PCR in temporal artery biopsies from 13 patients with GCA and 13 control individuals. To investigate the effect of TCZ, temporal arteries from 13 GCA patients and 8 controls were cultured on 3D matrix (Matrigel) with or without TCZ (purchased from Roche) at 10mg/ml or IgG isotype control at the same concentration. After 5-day culture, expression of CXCL13, LTα and LTβ was assessed by quantitative RT-PCR. Other pro-inflammatory (IL-1b) survival (BCL-6, BAFF) or remodeling (TGFb) molecules relevant to GCA pathogenesis were also assessed.

Results: B cell clusters intermingled with follicular dendritic cells were identified in temporal artery biopsies from patients with GCA, particularly in the adventitial layer. mRNA expression of CXCL13 (16.93 vs 7.10 relative units, p=0.001), LTα (16,82 vs 6.18, p=0.0001) and LTβ (16.75 vs 9.54, p=0.014) was significantly higher in temporal arteries from GCA patients compared to healthy controls. After 5-day culture, TCZ selectively induced a significantly decrease in CXCL13 mRNA expression in cultured arteries (p=0.023). No significant changes in LTα , LTβ, IL-1β, BCL-6, BAFF or TGFβ expression were observed upon TCZ treatment.

Conclusion: Treatment with TCZ elicits a significant and selective reduction of CXCL13 expression in temporal artery lesions from patients with GCA. Disruption of B cell homeostasis may partially account for the therapeutic effects of TCZ in patients with GCA. Supported by SAF 2014/57708-R

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a fibroinflammatory disorder of uncertain etiology. Recognition of this disease as a distinct entity stemmed from investigation into autoimmune pancreatitis (AIP), which was ultimately found to be part of a larger, systemic process. Prior studies on AIP have revealed 8 associated autoantigens including carbonic anhydrase (CA) isoforms 1, 2 and 4, lactoferrin (LAF), trypsin (PRSS2), trypsin inhibitor (SPINK1), E3 ubiquitin protein ligase (UBR2) and amylase-2A (AMY). While many AIP patients have IgG4-RD, these studies did not exclude type 2 AIP (non-IgG4 related), did not include patients with other manifestations of IgG4-RD and did not fully explore the B cell response. Our aim was to examine these autoantigens among a large and diverse cohort of systemic IgG4-RD patients.

Methods: Six of these autoantigens were commercially available in a recombinant form (CA-1, CA-2, CA-4, LAF, PRSS2, SPINK1). IgG4-RD patients (n = 100) were recruited between January 2012 and June 2016 and plasma samples frozen at -20°C until use. All samples had active disease at the time of collection. Disease controls (n = 25) included ANCA-associated vasculitis, rheumatoid arthritis and systemic lupus erythematosus. Healthy donors (n = 40) were used as negative controls. All proteins were studied by ELISA using a series of secondary antibodies (IgG, IgG1, IgG2, IgG3, and IgG4). Our cohort was powered to evaluate the correlation between autoantibody positivity and the presence of salivary gland, lymph node, pancreatic, lacrimal gland, lung, and retroperitoneal involvement.

Results: Our IgG4-RD cohort consisted of over 26 different organ manifestations including 47% with salivary gland, 28% lymph node, 21% pancreatic, 20% lacrimal gland, 20% lung and 20% retroperitoneal involvement. 77% had biopsy-proven disease while the remaining 22% had compelling clinical phenotypes with elevated serum IgG4 concentrations. 72% of the cohort had elevated serum IgG4 concentrations and 35%, elevated IgG1 concentrations. Overall, we observed a positive B cell autoantibody response in 26% of our IgG4-RD cohort. Each autoantigen was individually seen at a lower frequency, in the range of 5-10% of the cohort. 60% of the disease control cohort (15 of 25) showed a response to at least 1 of the 6 autoantigens. The predominant autoantibody subclass was of IgG1 (61%) closely followed by IgG4 (58%). IgG2 and IgG3 were also seen but at

a much lower frequencies (8% and 33%, respectively). Autoantibodies of each subclass correlated to serum elevations of that subclass. Taken as a group, the presence of one or more of these autoantibodies did not correlate to salivary gland, lymph node, pancreatic, lacrimal gland, lung, or retroperitoneal involvement.

Conclusion: Autoantibodies previously reported in association with AIP were observed among a large cohort of systemic IgG4-RD patients. The presence of these autoantibodies did not correlate to pancreatic involvement nor were they specific for IgG4-RD. This finding of promiscuous autoreactivity likely represents a breach in tolerance in IgG4-RD providing support for an autoimmune etiology to this disease.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: B cell development in the bone marrow is followed by specification into several functional subsets in the spleen, including marginal zone B (MZB) cells or follicular cells (FO). Both subsets have been shown to contribute to autoimmune phenotypes by secretion of autoantibodies, such as dsDNA in systemic lupus erythematosus (SLE). Recently, microRNAs, short non-coding RNAs, have been shown to influence a myriad of aspects in immune cell development, including B cell development. Recent work has demonstrated that deficiency of the NFkB feedback regulator, miR-146a, led to a range of hematopoietic phenotypes, but B cell phenotypes have not been extensively characterized. Here, we have found that autoimmune lupus-prone miR-146a deficient mice demonstrate a reduction in MZB cells that likely represents a developmental block, while displaying a corresponding increase in FO cells.

Methods: We use high-throughput sequencing and comparative analysis of developmental stage-specific transcriptomes to characterize this defect.

Results: We determined that the differentiation of MZB cells was impaired due to a miR-146a-dependent decrease in Notch signaling. Further, we discovered that the cell-fate regulator protein, Numb, is a direct target of miR-146a, and that its derepression in miR-146a-deficent B-cells likely underlies the decrease in Notch

signaling.

Conclusion: Collectively, we describe a new role for the function of miR-146a in regulating marginal zone B cell development, which may ultimately contribute to autoimmune and/or inflammatory phenotypes.

Targeting Mir-155 in Rheumatoid Arthritis B Cells Reduces Antibody Production

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Better understanding of epigenetic regulatory mechanisms in RA pathogenesis will facilitate the development of new biomarkers or therapeutic strategies. MicroRNAs are post-transcriptional regulators that co-ordinate cell activation by fine-tuning multiple intracellular pathways. We recently observed that microRNA-155 is up-regulated in RA B cells, particularly in anti-citrullinated protein antibodies (ACPA) positive RA patients. Herein, we examined the role of endogenous miR-155 in RA B cell function. **Materials and**

Methods: Peripheral blood (PB) was obtained from healthy controls (HC) and RA patients (2010 ACR/EULAR classification criteria). To asses endogenous levels of miR-155 in B cells subsets; $CD19^{+}$ B cell from both groups (n=6 each) were stained with antibodies against na•ve and memory subsets specific markers (CD27, CD38, IgD and IgM) and sorted with FACSAriaIII followed by quantitative RT-PCR with miR-155 and U6 (housekeeping) specific primers. miR-155 *in situ* hybridisation combined with CD20 staining was performed on

RA synovial tissues (n=5). $CD19^+$ B cells of ACPA positive RA patients (n=5-6) were transfected with miR-155 inhibitors (miR-155I) or control inhibitor (CI). 48h later, quantitative RT-PCR was performed to identify transcription factors that regulate the B cell transcriptome and are under control of miR-155 (*PAX5*, *PRDM1*, *PU.1* and *IRF4)*. To evaluate antibody production (IgG and IgG-ACPA), $CD19^+$ cells of $ACPA^+$ RA patients (n=5) were transfected with miR-155 inhibitor or a control; and cultured in the presence of BAFF (20 ng/ml) and IL-6 (30 ng/ml) or were stimulated with a plate bound CD40 ligand (2 µg/ml), BAFF (100 ng/ml), IL-21 (50 ng/ml) and anti-IgM (5µg/ml). Each condition was performed in 14 replicates. Supernatants were assessed for the presence of total IgG and IgG-ACPA using standard or immune scan ELISA, respectively.

Results: Analysis of the expression of miR-155 in B cell subsets: na•ve, $CD27^-IgD^+$; pre-switched memory, $CD27^+IgD^+$; post-switched memory, $CD27^+IgD^-$; and double negative memory cells ($CD27^-IgD^-$) revealed that the double negative memory B cell population expressed the highest levels of miR-155, which was significantly higher in $ACPA^+$RA compared to HC B cells (Figure 1). Furthermore, CD20 cells in ectopic follicular structures in RA synovium expressed high levels of miR-155. Functional studies revealed that inhibition of endogenous miR-155 in RA B cells led to the de-repression of *PU.1* but did not impact *PAX5*, *PRDM1* and *IRF4* levels (Figure 2A). This was associated with the substantial reduction in BCR crosslinking induced antibody production by RA B cells (Figure 2B).

Conclusion: Our study demonstrates that antibody production by RA B cells is controlled by the miR-155-PU1 pathway. We propose that an inhibitor of miR-155 could be used to simultaneously treat both myeloid and lymphoid synovial phenotypes increasing the current response rate of RA patients.

Session Date: Tuesday, November 15, 2016

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin 1 beta (IL1B) is a multifunctional cytokine that is highly expressed in rheumatoid arthritis (RA) and drives pro-inflammatory pathways via interleukin 1 receptor 1 (IL1R1)-mediated signaling. IL1B-specific receptor, IL1r2 is a decoy receptor that can sequester IL1B and acts as an anti-inflammatory factor. We investigated how an arthritis-specific epigenetic event is connected with the suppressed expression of anti-inflammatory IL1r2. The main goal of the current study is to explore gene regulatory pathways are involved in arthritis.

Methods: Disease-associated DNA methylation profiles analyses were conducted by methylated CpG island recovery assay (MIRA-chip) in arthritic B cells. Gene expression changes were investigated by microarray platforms and quantitative real-time polymerase chain reaction (RT-qPCR). Targeted gene silencing was carried out by electroporation of gene-specific shRNA expressing plasmids, and gene expression changes were monitored using RT–qPCR and Western blotting. Transient transfection studies were used for functional characterization of IL1r2 promoter.

Results: The promoter region of Zbtb38 transcription factor encoding gene was differentially methylated in B cells isolated from arthritic mice, which hypomethylation resulted in high expression of Zbtb38. Zbtb38 directly regulates IL1r2 gene expression and initiates its silencing in arthritic B cells. AhR transcription factor is also intimately involved in transcriptional regulation of IL1r2 and acts against Zbtb38. The fine balance of these two transcription factors can define the actual expression status of IL1r2 gene.

Conclusion: Zbtb38 forms a molecular bridge between an arthritis-associated epigenetic alteration (i.e., de novo DNA hypomethylation in Zbtb38 promoter) and transcriptional silencing of IL1r2 gene in arthritic B cells. In this context, Zbtb38 works as a potent repressor that turns off an anti-inflammatory pathway and significantly contributes to pathogenesis of arthritis.

Immunoprofiling of Bruton's Tyrosine Kinase (Btk)/Tec Family Kinase Inhibitors Indicate Activities Beyond Btk in Immunocyte Function

Jolanta Kosek[1], Lori Capone[2], Mary Adams[1], Eun Mi Hur[1], Peter H. Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: CC-292, CC-90008, and ibrutinib are covalent Btk/Tec family kinase inhibitors that block Btk activity by binding with high affinity to the adenosine triphosphate (ATP) binding site of Btk and forming a covalent bond with cysteine 384 in the target Btk protein, providing rapid, complete, and prolonged inhibition of Btk activity. The objective of this study is to provide an immunoprofile of covalent modifiers of Btk that may impact the therapeutic opportunities of this class of compounds by assessing their impact on B-cells, T-cells, NK cells, monocytes, osteoclasts, dendritic cells, and basophils.

Methods: B cell function was measured by BCR signaling and induced proliferation, plasmablast differentiation, IgG and IL-6 production, and surface expression of activation markers (CD86, CD40, CD54, and CD69). T cell function was measured by proliferation, cytokine production and CD8 T cell degranulation after TCR stimulation. NK function was measured by degranulation after exposure to K562 cells. Monocyte/macrophage activity was assessed by Fcγ Receptor-mediated TNFα production and basophil activity was measured by FcεR-mediated degranulation. Effects on osteoclastogenesis and TLR9 activation were measured in osteoclasts and dendritic cells, respectively.

Results: The three Btk inhibitors tested here had both similarities and differences in the net activities observed on immunocyte function. All three inhibitors blocked Btk-mediated PLCγ2 phosphorylation in B-cells, FCεR-mediated degranulation in basophils, and osteoclastogenesis and bone degrading activity in myeloid-derived osteoclasts. Differences were observed in B-cell function depending on the stimulus. BCR-induced proliferation was inhibited by CC-292 and ibrutinib, but only weakly for CC-90008. Similarly, CC-292 and ibrutinib blocked BCR-induced ERK1/2 phosphorylation, but CC-90008 had no effect. Conversely ibrutinib was not active in assays where CC-292 and CC-9008 were active, including IL-6 production, plasmablast differentiation, and IgG secretion. CC-90008 and ibrutinib, but not CC-292 were potent inhibitors of T-cell proliferation. Yet, all three inhibited T-cell cytokine production and degranulation. In monocyte FCγR-mediated TNFα production, TLR9-mediated mDC activation, and NK degranulation, CC292 and ibrutinib showed inhibitory activity, but none was observed for CC-90008.

Conclusion: The data gathered from the immunophenotyping of CC-292, CC-90008 and ibrutinib identified

differential functional impact on various immunocyte functions, within and beyond the original identification of B-cell activities regulated by Btk. Clinical inflammatory disease indications for these Btk inhibitors would therefore need to be differentially assessed to match the relative importance of particular disease mechanisms to the differential activities beyond Btk. B-cell antibody production, T-cell proliferation and cytokine production, NK cell function, and myeloid and osteoclast function vary significantly among the three inhibitors with the only common features being basophil degranulation and osteoclast function.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), synovial fibroblasts (SF) are one main contributor of joint destruction since they resist apoptosis and secrete pro-inflammatory cytokines and matrix degrading enzymes. Therefore, they are key players in directing immune responses in direct interaction with other cell types, like B cells. TNF superfamily members, like B cell activating factor of the TNF family (BAFF) are important B cell function modulators and survival factors and are produced by synovial fibroblasts under certain conditions. Since better understanding of B cell – fibroblast interaction will lead to potential new treatment targets, we started to characterize this interplay.

Methods: Osteoarthritis (OA, n=5) and RA (n=5) synovial fibroblasts (SF) were co-cultured in passage 3-6 with B cells. Following a preincubation period of 48h with different inflammatory mediators (TNF, IL-1, IFN-γ) or B cell stimulating factors (BAFF, CpG), B cells were added to SF cultures and incubated for another 48h period. To determine B cell survival, we used AnnexinV/PI costain in FACS. AnnexinV/PI double negative B cells (living) are given as percentage of total B cells. To specifically block the action of BAFF, we used Belimumab.

Results: The presence of SF increased B cell survival from 5.2% to 55.3% ($p<0.001$). RA SF as compared to

OA SF showed similar capacity to increase B cell survival as compared to OA SF. However, conditioned media from RA SF showed increased capacity to enhance B cell survival as compared to OA SF supernatants (RA: 15.7% vs. OA: 11.1%, p=0.04). SF preincubation with INF-γ (survival 70.8%, p=0.015), IL-1 (survival 71.5%, p=0.018), or CpG (survival 87.7%, p=0.0002) further increased survival of B cells as compared to unstimulated SF. IFN-γ (0.1-50 ng/ml) induced BAFF from SF in a concentration dependent manner (ANOVA p<0.01). RA and OA SF showed the same response to INF-γ. Blocking BAFF by adding Belimumab (10µg/ml) decreased IFN induced survival to control values (survival 52.03%, p=0.58). Belimumab, INF-γ, or IL-1 in B cell only cultures had no effect on survival, respectively. After preincubation of SF with BAFF (0.1-10ng/ml), B cell survival was increased in a concentration dependent manner (ANOVA p<0.01, max. survival 78.7% with BAFF 10ng/ml) and inhibited in the presence of Belimumab (survival 64.9%, p=0.08).

Conclusion: B cell survival is increased in the presence of RA an OA SF in a similar manner, although RA SF spontaneously produce more soluble B cell survival factors as compared to OA SF. Preincubating fibroblasts with BAFF, IFN-γ, IL-1, or CpG affects fibroblast function to further increase B cell survival. INF-γ- and BAFF-induced SF mediated increase in B cell survival can be blocked by Belimumab. Therefore, strategies to interfere with BAFF directly in the joint might lead to decreased B cell survival and reduced inflammation.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is the most frequent form of autoimmune arthritis with a prevalence of almost 1% worldwide. Anti-citrullinated protein antibodies (ACPA) are the most specific biomarker for rheumatoid arthritis (RA)(1). Although therapies designed to deplete B cells, which are the precursor to antibody-secreting cells, are effective in the treatment of RA(2), they only modestly affect ACPA and having no effect on antibodies to recall antigens in serum of treated patients(3). This suggests that autoreactive B cells may contribute to RA pathophysiology by additional mechanisms independent of terminal differentiation toward ACPA-producing plasma cells. Unfortunately, the lack of tools has prevented reliable identification of citrullinated protein (CP)-reactive B cells. Our objective was to develop a novel tool to characterize and model the function of (low-frequency) autoreactive B cells in RA.

Methods: B-cell clones from either blood or synovial fluid of CCP2+ RA patients were immortalized by a technique previously described for obtaining clones for recall antigens(4). ELISA and FACS were used to identify CCP2-reactive clones and to further characterize surface marker and cytokine expression. BCR-signaling competence was tested by calcium flux, and antigen internalization was visualized on Amnis Imagestream. Global gene expression profiles were interrogated by RNA sequencing.

Results: We have identified three unique B-cell clones from two RA patients that can secrete antibodies with specific binding to CCP2 yet show no reactivity to the control arginine variant. While clones generated through this method can secrete soluble antibody, they retain surface immunoglobulin expression, mobilize calcium in response to citrullinated protein antigen and can internalize their antigen. Finally, these clones have a unique surface profile of costimulatory molecules and can secrete both pro- and anti-inflammatory cytokines.

Conclusion: We present here the application of a unique cloning method to establish autoreactive human B-cell clones in RA. We propose that this technique can also be used for other autoimmune diseases with described autoantigen reactivity and that these B cells can be in turn utilized for the identification of autoreactive T cells recognizing novel autoantigen epitopes.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Malondialdehyde (MDA) is a naturally occurring reactive aldehyde that arises during apoptosis or as a consequence of elevated reactive oxygen species and lipid peroxidation. Free MDA can post-translationally modify lysine residues in a protein carbonylation process that generates neo-epitopes that can be recognized by autoantibodies.

Methods: Serum IgG anti-MDA levels were compared in 71 healthy controls, 30 OA, and 283 SLE and 162 RA patients, identified by ACR criteria. IgG anti-MDA was measured by sandwich ELISA using MDA-modified BSA. After flow cytometry sorting of RA synovial memory B cells, and single cell Ab-gene PCR, 114 mAbs were expressed and tested for MDA-reactivity. Analyses used the 2-sided Mann-Whitney test or Spearman correlation.

Results: In sera, IgG anti-MDA was significantly increased in SLE (17±21 RU/ml, $p<0.0001$) and RA patients (13±11 RU/ml, $p<0.0001$), compared to controls (5±3 RU/ml). In SLE, IgG anti-MDA correlated with disease activity by SELENA-SLEDAI ($p<0.0001$, $R=0.34$, $n=219$). Levels were also significantly higher in SLE patients with active disease (SLEDAI≥6, 18.9±17.3 RU/ml, $p=0.001$) than with low disease activity (SLEDAI<6, 11.5±16.6). In RA patients, IgG anti-MDA correlated with DAS28-ESR ($p<0.0001$, $R=0.35$, $n=157$). Compared to RA patients with low disease activity (DAS28<3.2, 6±3), levels were significantly increased in RA with moderate activity (DAS28 3.2-5.1, 12±11 RU/ml, $p=0.005$) and high activity (DAS28>5.1, 15±12 RU/ml, $p=0.001$). In DMARD naïve RA ($n=62$), IgG anti-MDA also correlated with serum TNFα ($p=0.002$, $R=0.39$), IL-6 ($p=0.03$, $R=0.27$), and CRP levels ($p=0.003$, $R=0.37$). In RA synovial mAbs, we identified four clones (3.5%) that recognized MDA-modified epitopes. The most reactive clone, 1276:01F04, showed high specific binding to MDA but was non-reactive with carbamylated or 4-HNE-modifications. Specificity was confirmed in antigen-competition studies with MDA or MDA acetaldehyde (MAA) protein adducts. This mAb also bound MDA-modified human fibrinogen and albumin. No cross-reactivity with citrullinated epitopes was detected, and mAbs with ACPA or RF reactivity did not bind MDA. Notably, 1276:01F04 originated from an IgG1-bearing B cell that was encoded by near germline variable genes (VH4-39, 1 R-mutation in HCDR3; VL1-51, 2 S-mutations in FR1).

Conclusion: IgM binding to MDA-adducts may be common in health from birth and are part of the natural

antibody pool. Yet, IgG anti-MDA are associated with inflammatory conditions including increased disease activity in autoimmune patients. Importantly, MDA-autoreactive B cells could also be isolated from RA synovium, the site of disease. Further studies are merited to investigate the potential pathogenic properties of IgG anti-MDA B-cells/autoantibodies.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibodies that target carbamylated proteins (anti-CarP) have been implicated in rheumatoid arthritis and are known to associate with joint damage. Furthermore, these autoantibodies can be found years before the onset of RA and the presence of anti-CarP antibodies in arthralgia patients associates with RA development. Although a large amount of clinical data is now available in relation to the occurrence of anti-CarP antibodies, little is known about their characteristics, such as their ability to react against multiple antigens and their capacities to be cross-reactive.

Methods: We investigated the reactivity of anti-CarP antibodies in serum samples from 160 RA patients (according to the ACR 1987 criteria) and 40 healthy controls using ELISA (enzyme-linked immunosorbent assay).Five different antigens, foetal calf serum, human serum albumin, bovine myelin basic protein, H1 histones and human prothrombin were selected and used in carbamylated and non-modified form. Cross-reactivity within serum samples was investigated using inhibition studies.

Results: The sera of RA samples are able to recognize a large diversity of carbamylated proteins, with positivity ranging between 39% and 58%. The recognition pattern that is observed is quite diverse, but 24% of the RA patients were able to recognize all 5 carbamylated antigens, while this occurred in none of the control samples. Furthermore, the amount of antigens that can be recognized correlates with the anti-CarP antibody levels. As for cross-reactivity, we observe that antibody binding to one carbamylated protein can often be inhibited by any of the other carbamylated proteins, but not by its non-carbamylated counterpart, indicating the cross-reactive nature of anti-CarP antibodies towards several carbamylated proteins. Interestingly, while anti-

CarP antibodies seem to be highly cross-reactive towards different carbamylated antigens, the cross-reactivity towards citrullinated proteins is limited.

Conclusion: These data suggest that anti-CarP antibodies areable to recognize many different carbamylated proteins. An anti-CarP antibody response initiated by one carbamylated protein may therefore result in recognition of several carbamylated proteins in RA patients.

Exposure to Carbamylated Self- and Non-Self-Proteins Can Lead to a Break-of -Tolerance and the Induction of Autoimmunity

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies are an important hallmark of Rheumatoid Arthritis (RA). Approximately 50% of RA patients harbor anti-carbamylated protein (CarP) antibodies. These autoantibodies target proteins that are modified through a posttranslational modification named carbamylation or homocitrullination. It has been postulated that posttranslational modifications can play a role in the breach of tolerance towards self-antigens. These anti-carbamylated protein (CarP) antibodies can recognize both carbamylated foreign- and self-proteins. It is currently unknown whether carbamylated foreign-proteins can evoke an anti-CarP autoimmune response or whether this can only be facilitated through carbamylation of self-proteins. Therefore we studied whether carbamylation of self- and foreign-proteins can drive loss of B-cell tolerance to carbamylated proteins.

Methods: Mice were immunized with carbamylated- or non-modified (auto)antigens and analyzed for autoantibody responses. Anti-CarP hybridomas were sequenced using single cell PCR-based antibody cloning technology. Mass spectrometry was used to identify carbamylated self-proteins in rheumatic joint tissue. Serum reactivity towards Ca-human serum albumin and Ca-FCS was determined for 100 RA-patients of the Leiden

Early Arthritis Cohort and 40 healthy subjects.

Results: Immunization with carbamylated self-proteins (Albumin) resulted in a potent anti-CarP antibody response against both carbamylated foreign- and self-proteins. Likewise, immunization with carbamylated foreign-proteins (OVA) induced a strong anti-CarP response against both carbamylated foreign- and self-proteins. Similar to serum anti-CarP antibodies, murine monoclonal anti-CarP antibodies were highly specific and cross-reactive to multiple carbamylated (auto)antigens. Although citrulline greatly resembles homocitrulline residues in structure, anti-CarP antibodies differ in antigen recognition profile from ACPA as they are able to discriminate between citrullinated and homocitrullinated forms of the same protein. Interestingly, we were able to identify carbamylated-albumin, in RA synovial tissue, indicating that albumin is present in carbamylated form locally in the inflamed joint. Moreover, we detected antibody responses against carbamylated-human albumin were observed in 38% of early RA patients from the Leiden Early Arthritis Clinic.

Conclusion: These results show that not only carbamylated self-, but also carbamylated non-self-proteins can lead to a breach of B-cell tolerance leading to B-cell responses against carbamylated self-proteins. These results indicate that auto-reactive B-cells to carbamylated proteins as well as it is underlying T-cell response could find its origin in the exposure to carbamylated foreign-proteins.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a complex inflammatory disorder in which autoantibodies play a prominent role. Several types of autoantibodies, including rheumatoid factors (RFs) - primarily IgM antibodies binding to the Fc-domain of IgG- and anti-citrullinated protein antibodies (ACPAs) have predictive value for RA onset and severity. Interestingly, the combined presence of both types of antibodies is a better marker for a more severe disease than the presence of only RFs or only ACPAs. While pathogenic properties of both RF and ACPA in isolation have been studied in detail, few studies have investigated the combination.

Methods: In this study, we investigated the interactions between RFs and ACPAs using well-defined recombinant monoclonal RFs and ACPAs in a biosensor system (IBIS). Monoclonal ACPAs (100nM) with or without 25nM monoclonal IgM-RFs were flowed over sensor-spots to which six different citrullinated peptides or their arginine controls were coupled. Changes in refractive index caused by binding of molecules were measured and plotted as response units against flowing time in sensorgrams.

Results: We observed that interactions between ACPAs and citrullinated peptide targets were substantially enhanced by the presence of hexameric RF (Figure 1A). The observed increase in RU was mathematically greater than could be explained by a 1:1 or even a 1:2 interaction between ACPAs and RF. This suggests that the RFs enhance the binding of ACPAs to their targets by crosslinking them (Figure 1B). These results could be replicated using RF and ACPA from RA patients' serum. RF+ ACPA+ sera treated with Dithiothreitol (DTT) to reduce the IgM-RF showed a decreased binding of ACPAs to the citrullinated peptide targets.

Conclusion: We hypothesize that RFs may contribute to pathogenesis in RA by potentiating immune complex formation of ACPAs.

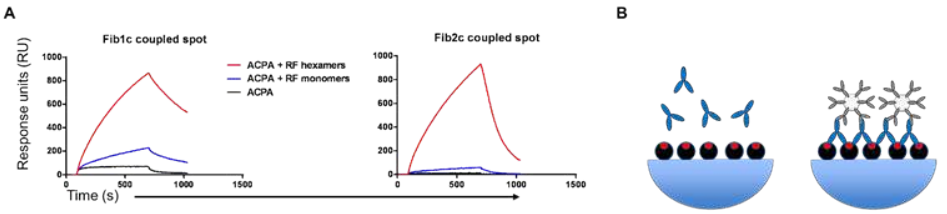

Fig. 1: (A) Interactions between ACPAs and citrullinated peptide targets (Fib1c, Fib2c) spotted on the sensor were substantially enhanced by the presence of hexameric RF. Conditions with only RF showed no binding. (B) Interpretation of A: ACPAs alone have a low affinity interaction with their targets. Hexameric RFs binding to ACPAs form higher avidity immune complexes, crosslinking ACPAs onto their citrullinated targets.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: With the advent of B cell targeted therapies the modulation of memory B cells seems to be a prime target. Human peripheral memory B cells can be distinguished by the phenotypic expression of CD27 and IgD defining three major B cell subpopulations: CD27+IgD+ pre-switch, CD27+IgD- post-switch and CD27-IgD- double negative memory B cells. We analyzed these different memory populations in RA and under IL6-R blockade.

Methods: B cells were phenotypically analyzed from RA patients at baseline, week 12 and week 24 under tocilizumab (TCZ) treatment. Memory B cell subsets were defined by CD27 and IgD and were further analyzed by color flow cytometry for surface staining of CD95, intracellular ki-67 and CXCR3 expression.

Results: The phenotypically analyzed profile in RA patients (n=60) and healthy donors (n=20) revealed that the memory B cells are activated and have higher expression of CXCR3. Surface and intracellular staining of B cells showed a significantly higher percentage of CD95 (p=0.01), ki-67 (p=0.04) and CXCR3 (p= 0.03) expression in RA. CD95 & ki-67 expressions were highest in post-switch memory B cells while CXCR3 expression was highest in pre-switch. The expressions of ki-67, CD95 and CXCR3 were significantly reduced during IL-6R blockade (Tocilizumab) therapy at week 12 & 24 in all B cell subsets.

Conclusion: Our data suggests that the three major peripheral memory B cell populations, pre-, post-switch and double negative B cells are activated in RA with enhanced CD95, Ki-67 and CXCR3 expressions compared to healthy individuals. These higher expressions in all memory B cell subsets can be reduced by IL-6R inhibition in vivo.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Repeat treatment with rituximab (RTX) predisposes some patients with rheumatoid arthritis (RA) to develop low levels of serum immunoglobulins (Igs). Understanding B cell function in relation to preserving immunity and a sustained clinical response is thus essential. We have investigated the relationships between B cell phenotype and *in vitro* function in patients RTX-naïve and in those maintaining normal serum Igs (IgM>0.4g/L and IgG>7g/L) or developing low Igs after RTX.

Methods: Serum and peripheral blood mononuclear cells (PBMC) were collected from 56 RA patients (12 pre- and 34 post-RTX). Flow cytometry (% and Mean Fluorescence intensity–MFI) was used to determine naïve and memory B cell subsets (IgD/CD27) and additionally BAFFR, CD32, CD5 and IgM. Post-RTX all patients had evidence of IgD+CD27- naïve B cell reconstitution (>25%) after a period of sustained depletion (<5 CD19+B cells/ml). Serum Igs were analysed in relation to phenotypes, BAFF and soluble CD23 (sCD23; released on differentiation to CD27+ status; normal range 1024-5025pg/ml). PBMC were cultured for 7 days with T cell dependent (TD) (anti-IgM+anti-CD40+IL4+IL21) and T cell independent (TI) (CpG+IL2) stimuli. Classes of Igs, sCD23 and anti-cyclic citrullinated peptides (anti-CCP) were measured in supernatants.

Results: After a median 5 cycles of RTX, 17 patients had normal serum Igs and 17 had developed either low IgM (n=11) or IgG (n=9) or both (n=3). Significant differences between low and normal Igs groups were noted in disease duration (median 25 vs 15 years, p=0.005) and sCD23 levels (median 908 vs 3702pg/ml, p=0.002). Median number and % CD19+B cells, RTX cycles, time from last cycle and serum BAFF were similar. Patients with low Igs also had lower %BAFFR+ pre-switch B cells (IgD+CD27+;p=0.008), higher %CD32B+ switched B cells (IgD-CD27+;p=0.02) and a negative correlation of serum IgM levels and %CD32B+ switched B cells (R^2=0.44;p=0.004). *In vitro,* IgM, IgG or IgA and sCD23 production (normalized for B cell count) was similar between groups. IgM-CCP was only produced after TD and TI stimulus but IgG-CCP was produced spontaneously in all cultures. Significantly higher levels of both IgM- and IgG-CCP antibodies were detected in supernatants from low Ig group.

Conclusion: In patients developing low serum Igs, defective B cell maturation to memory phenotype was suggested by significantly lower levels of serum sCD23. Low serum Igs were also associated with possible reduced BAFFR-mediated anti-apoptotic signaling in IgD+CD27+ B cells and a greater %CD32B+ on memory B cells, resulting in higher thresholds for differentiation to Ig production. In *vitro,* however, similar amounts of Ig were present in cultures from those with normal or low serum Igs, suggesting a lack of underlying, intrinsic B cell defects. The lack of efficient B cell differentiation in individual patients with low Igs may relate to B cell interactions with immune complexes or with different T cell subsets, possibly resulting from disturbances in RTX-induced germinal centre structure. Our results further suggest increased selection and/or survival properties of autoreactive B cells in patients with low serum total Igs evident in a more robust production of anti-CCP antibodies.

Session Title: B Cell Biology and Targets in Autoimmune Disease - Poster II: Rheumatoid Arthritis and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab (RTX) has shown clinical efficacy but up to 40 % of RTX treated rheumatoid arthritis (RA) patients are poor responders (Ann Rheum Dis. 2005 Feb;64(2):246-52) and the commonly used RA biomarkers (*RF/ACPA)* are poor predictors for therapy response. Others reported associations between BAFF/BLyS levels, Fcg RIII and IL-6 genotype, interferon type I signatures and Epstein-Barr virus genome in bone marrow and clinical outcome (Arthritis Res Ther. 2012 Apr 27;14(2)). In this study the autoantibody repertoire analysed on protein macorarrays from RA patients under RTX treatment was correlation to clinical DAS28 response.

Methods: Screening of RA sera was conducted on 37.830 unique human proteins on protein marcoarrays (http://www.engine-gmbh.de) with sera taken before and 24 weeks after treatment. The autoantibody response of different immunoglobulin classes IgD, IgA, and IgG was recorded and bioinformatically evaluated. Response was determined according to DAS28 criteria. DAS 28 scores in the responder group before treatment was from 5.4 – 7.8 and in the non-responder group 5,6 – 6,8. We analyzed 26 RA patient sera (9 responder, 7 non-responder and 10 patients with blinded response classification) investigated the data of found autoantigens *in silico*and by hierarchical clustering.

Results: : In the cohort of 26 patients 1292 different autoantigens (IgD,IgA,IgG) were detected. Using protein array we investigated clusters of autoantigen responses that disappeared or developed during RTX treatment of RA patients. Post treatment developing responses against new autoantigens can be correlated to mRNA tissue expression data and were interestingly found organ-specifically expressed. RA autoantigenic patterns before and 6 month after RTX treatment were patient-specific and no relevant autoantigenic cluster was found that was shared between patients or associated with response. However, RTX reduced the repertoire of autoantibodies after 24 weeks of treatment in the tested RA patient cohort on average by 60%. RA patients which do not respond

are generating on average 63% new autoantibodies. In good responders to RTX only 5,5% (+/-3%) new autoantibodies can be detected. The IgA and IgG autoantibody repertoire in the serum after 24 weeks of RTX treatment is reduced (IgA: 41%, IgG :31%) in good responders whereas it is increased (IgA: 1,3%, IgG: 24%) in non responders to RTX

Conclusion: RA patients present highly individual autoantibody profiles before and after RTX treatment, which do not reveal antigen-specific patterns for outcome prediction. However, after 6 month of RTX treatment the autoantibody repertoire in all good responding RA patients is reduced and non responders to RTX change their autoantibody repertoire directed against new but patient specific antigens. The fast rebuilding of functional B cells might be a underlying mechanistic difference between responders and non-responders to rituximab.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA), characterized by progressive destruction of articular cartilage, is the most common form of human arthritis. Wogonin is a naturally occurring flavonoid found in root extract of *Scutellaria baicalensis,* and it has been shown to exhibit diverse biological activities. Here, we evaluated the potential anti-inflammatory and chondroprotective effects of Wogonin in IL-1β stimulated human OA chondrocytes.

Methods: Primary human OA chondrocytes were isolated by enzymatic digestion of the cartilage obtained from OA patients who underwent total knee arthroplasty at Crystal Clinic, Akron, Ohio. Effect of Wogonin on IL-1β-induced mRNA and protein expression of iNOS, COX2, IL-6, MMP-3, MMP-9, MMP-13, ADAMTS4, ACAN and COL2A1 was examined by Taqman Gene expression assays and immunoblotting, respectively. Estimation of NO in culture supernatant was done using Griess assay. PGE_2 in culture supernatant was quantified by ELISA. Protein levels of nuclear factor (erythroid-derived 2)-like 2 (Nrf2), heme-oxygenase-1 (HO-1), and the total protein levels and phosphorylation of MAPKs were assayed by immunoblotting. siRNA mediated knockdown

was used to deplete target protein. Cellular uptake of Wogonin in OA chondrocytes was quantified by MRM analysis using mass-spectrometry.

Results: Wogonin completely suppressed the IL-1β-induced mRNA and protein expression of COX2, IL-6, iNOS, MMP-3, MMP-9, MMP-13, and ADAMTS-4 in human OA chondrocytes. Further, Wogonin significantly inhibited the NO and PGE_2 production in IL-1β-stimulated human OA chondrocytes. Interestingly, Wogonin treatment increased the expression of type II collagen (COL2A1) and aggrecan (ACAN) in IL-1β-treated OA chondrocytes. Wogonin modulated the expression of IL-1β-induced phosphorylation of MAPKs (ERK1/2, JNK, and P38) in OA chondrocytes. Additionally, Wogonin activated redox sensitive transcription factor Nrf2, which has been shown to possess major chondroprotective role. Further, Wogonin upregulated the expression of Nrf2-dependent cytoprotective gene HO-1 in human OA chondrocytes. Inhibition of activity or knockdown of HO-1 expression abrogated the chondroprotective effect of Wogonin in IL-1β-stimulated human OA chondrocytes. Cellular uptake studies showed that Wogonin levels increased in a time dependent manner indicating the absence of metabolism of Wogonin in human OA chondrocytes. These data indicate that increased intracellular accumulation in due course of time activate Nrf2/HO-1 axis that may be responsible for the observed anti-inflammatory and chondroprotective activity of Wogonin under pathological conditions.

Conclusion: The present study suggests that Wogonin could be an effective chondroprotective and anti-inflammatory agent as it switched the chondrocyte gene expression from catabolic towards anabolic response and this effect was mediated, at least in part by the activation of Nrf2 and upregulation of HO-1 expression in OA chondrocytes.

Session Date: Tuesday, November 15, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Degenerative Disc Disease (DDD), one of the main causes of low back pain, is characterized by degeneration of intervertebral disc, nucleus pulposus (NP), and cartilage matrix, resulting in decreased disc height and function. Treatment of DDD is limited to analgesics or surgery aimed at relieving symptoms, and no current therapy can reverse disc degeneration. Wnt signaling plays an important role in DDD by regulating the proliferation and differentiation of resident NP cells. SM04690, a novel, small-molecule, Wnt

pathway inhibitor was evaluated in a series of preclinical studies to determine its potential to induce proliferation and differentiation of primary NP cells, thereby promoting disc healing.

Methods: Wnt pathway inhibition was measured using a cell-based reporter assay. *In vitro* proliferation of NP cells from rat coccygeal discs, treated with vehicle or various concentrations of SM04690 for 5 days was measured by cell doubling index (CDI= cell number/initial cell number/days). Differentiation of NP cells into "chondrocyte-like" NP cells with vehicle or SM04690 treatment for 12 days was measured by Alcian blue staining and absorbance based quantification. Pharmacokinetics were evaluated by intradiscal injection in rats and rabbits, followed by analysis of compound concentrations in the disc and plasma. *In vivo* efficacy was evaluated in a rat coccygeal intervertebral disc "needle puncture" model using radiographic measurement of disk height index (DHI = disk height/vertebral height), and histological scoring (total 4-16) of Safranin O-stained sections for integrity of annulus fibrosus (AF), border between AF and NP, cellularity, and matrix of NP.

Results: SM04690 demonstrated potent (EC_{50} =11nM) and selective inhibition of Wnt signaling. *In vitro* proliferation measured as CDI was ~2-fold higher in cells treated with SM04690 compared to vehicle ($P<0.05$). Cells treated with SM4690 also showed significantly increased Alcian blue absorbance, indicating differentiation to "chondrocyte-like" cells ($P<0.01$). Single intradiscal injection of SM04690 resulted in disc concentrations >EC50 for >180 days, with minimal systemic exposure or toxicity, measured as behavioral, health, gross morphology, and microscopic adverse changes. In the rat DDD model, SM04690 treatment increased Safranin O-stained cartilage matrix (Figure A), thereby resulting in significantly increased radiographically measured % DHI ($P<0.05$; Figure B), and decreased histology scores ($P<0.05$; Figure C) vs. vehicle control.

Conclusion: SM04690, a small molecule Wnt pathway inhibitor promoted proliferation and differentiation of NP cells *in vitro*. In a rat model of DDD, SM04690 regenerated NP cells and cartilage matrix, and improved disc height, health, and shape compared to vehicle, with minimal plasma exposure or systemic toxicity. These results suggested that SM04690 has potential as a treatment for DDD.

Figure 1. SM04690 stimulated differentiation of NP cells and improved disc height and health in a rat model of DDD.

Background/Purpose: Osteoarthritis (OA) of spine (facet joints, FJ) is one of the major causes of severe low back pain and disability worldwide. However, specific mechanisms associated with facet cartilage degeneration during FJ OA are largely unknown. For the first time, in this study we investigated the role of microRNAs (miRNAs) in the pathophysiology of facet cartilage degeneration during FJ OA.

Methods: Based on MRI and histopathology, we first established and validated a patient cohort (Group 1 patients [control group]: normal or mild facet cartilage degeneration and Group 2 patients [FJ OA group]: moderate to severe facet cartilage degeneration). Using this cohort, we screened 2,100 miRNAs using miRNA-array analysis and differentially regulated miRNAs were further tested by qPCR analysis. Human FJ OA chondrocytes were cultured and transfected with miRNA mimics/inhibitors (or control mimic/inhibitor) to determine the effect of miRNA enhancement/inhibition on the expression of catabolic/inflammatory/anabolic/apoptosis markers. Signaling pathways modulated by miRNAs were also identified using mirDIP/pathDIP. Furthermore, we injected the miR-181a-5p mimic into FJs of rats to see the effect *in vivo*.

Results: Out of 2,100 miRNAs, we specifically identified 2 miRNAs (miR-181a-5p and miR-4454) that were significantly up-regulated in FJ OA cartilage compared to control facet cartilage and exhibited significant correlation with MRI grading. Further, we treated FJ OA chondrocytes with miR-181a-5p or miR-4454 or control mimic/inhibitor and showed that treatment with both miR-181a-5p or miR-4454 mimic significantly elevated the expression of inflammatory/catabolic/apoptosis markers and reduced expression of type II collagen;

inhibition of these two miRNAs was able to reverse these destructive effects in IL-1β treated cells. Our study further identified that IL-1β mediated activation of NF-κB signaling upregulated miR-181a-5p and miR-4454 expression to sustain NF-κB activation in part through zinc finger protein 440 siRNA (si*ZNF440*)-mediated phosphorylation of Ser536 NF-κB-p65 and reduction of IκB expression, resulting in a positive feedback loop that can sustain NF-κB-p65 activity. Finally, by injecting miR-181a-5p mimic in rat FJs, we observed a FJ OA phenotype in facet cartilage associated with enhanced catabolic activity and chondrocyte apoptosis *in vivo*.

Conclusion: Using clinical, *in vitro* functional and *in vivo* studies, we for the first time have identified miR-181a-5p and miR-4454 as mediators of facet cartilage degeneration.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a chronic and debilitating disease of the articulating joints in every population. Micro-RNAs are ~22 nucleotides long non-coding single stranded RNAs that mostly regulate post-transcriptional gene expression. In order to dissect the role of novel miRNAs in OA pathogenesis we exploited the next generation sequencing technology and comprehensively profiled the miRNAs expression in OA chondrocytes.

Methods: Chondrocytes were prepared by the enzymatic digestion of discarded human cartilage from donors who underwent total knee arthroplasty due to OA. Total RNA directly from the cartilage or from chondrocytes was prepared using Trizol and miRNeasy Mini kit respectively. RNA purity, integrity and NGS library integrity was verified using Agilent 2100 Bioanalyzer. The small RNA library was prepared using a kit (Illumina). Cluster generation and sequencing was performed on MiSeq system. The small RNA sequencing reads were aligned to genomic reference (hg19) and novel miRNA sequences were extracted from NGS data using Strand NGS software. miRNA targets were identified using open web bioinformatics program Diana Tools. Expression of mature miRNAs was quantified using individual miScript Primer Assay. Expression of KiSS1 and other OA related catabolic and anabolic genes was quantified using TaqMan Assays and of proteins by Western blotting. Chondrocytes were transfected with siRNAs, control miRNA, miR-N105 mimic or inhibitor using Amaxa Nucleofactor System.

Results: We analyzed the 95% of the ~20 million reads from the miRNA-Seq which passed the quality filter using the Strand NGS Software and identified 15 miRNAs as potential novel miRNAs. Based on differential expression and abundance novel miRNA miR-N105 was selected for further analysis. Expression of miR-N105 was downregulated upon IL-1β treatment in chondrocytes in a time dependent manner. Interestingly expression of miR-N105 was significantly low in damaged cartilage compared to the expression levels detected in the smooth cartilage of the same patients (n=8). Diana Tool predicted KiSS1 (KiSS-1 metastasis-suppressor) as a potential target of miR-N105. Expression of KiSS1 was 4 fold induced in OA chondrocytes upon IL-1β treatment. In the damaged cartilage expression of KiSS1 was significantly higher compared to the smooth cartilage. Overexpression of miR-N105 inhibited the IL-1β induced expression of KiSS1 which was rescued upon transfection of miR-N105 inhibitor suggesting KiSS1 is a bona fide target of miR-N105. siRNA-mediated knockdown of KiSS1 or its inhibition by overexpression of miR-N105 enhanced the expression of ACAN and reduced the expression levels of ADAMTS4 and ADAMTS5 in IL-1β-stimulated OA chondrocytes. Importantly,

overexpression of KiSS1 inhibited the ACAN expression but significantly enhanced the expression of ADAMTS4 and ADAMTS5 in IL-1β-stimulated OA chondrocytes.

Conclusion: We identified a novel miRNA-N105 that was differentially expressed in smooth and damaged OA cartilage, and validated KiSS1 mRNA as its target in OA chondrocytes. Our data also identifies for the first time KiSS1 as an important regulator of genes associated with the pathogenesis of OA.

Follistatin-like Protein 1 Is a Potent Regulator of Articular Chondrocytes in Osteoarthritis

Yury Chaly, Bruce Hostager, Sonja Smith and Raphael Hirsch, Stead Family Department of Pediatrics, University of Iowa Carver College of Medicine, Iowa City, IA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is the most common degenerative disease of the joints, affecting nearly 30 million Americans. It is characterized by a change in chondrocyte phenotype. The default route of chondrocyte differentiation is terminal differentiation, hypertrophy, apoptosis, and bone formation. In healthy articular cartilage, this default route is somehow blocked to obtain permanent cartilage. In OA, this block is lifted resulting in chondrocyte terminal differentiation characterized by a decrease in production of extracellular matrix proteins (type 2 collagen and aggrecan) and an increase in production of type 10 collagen, matrix metalloproteinase 13 (MMP13), and the transcription factor Runx2. Follistatin-like protein 1 (FSTL-1) is a protein produced by articular chondrocytes. Its expression is decreased in OA. Homozygous FSTL1 knockout (KO) mice display hypocellular cartilage as well as extensive skeletal defects. We therefore sought to determine whether loss of FSTL-1 in OA contributes to disease and whether increasing FSTL-1 expression will slow or reverse OA.

Methods: FSTL-1 expression in OA and healthy human cartilage was evaluated by immunofluorescence. Cartilage was evaluated in sectioned knee joints from FSTL-1 KO mice by staining with safranin-O. In vitro experiments were performed with human articular chondrocytes immortalized with the human telomerase gene and HPV oncogenes E6 and E7. The cells were transduced with a lentivirus encoding human FSTL-1 shRNA, or with an adenovirus encoding FSTL-1. Quantitative gene expression analysis was performed using real-time PCR for MMP13, aggrecan, collagens type 2 (COL2A) and type 10 (COL10A). Protein extracts from chondrocyte pellets were analyzed for Sox9 and phospho (p)-Smad3 by Western blotting.

Results: FSTL-1 expression was reduced in the OA chondrocytes. In FSTL-1 KO mice, a marked reduction in

articular cartilage cellularity, cartilage thickness, and matrix proteoglycan content was observed at 12 months of age. Downregulation of FSTL-1 expression in TGFβ-stimulated human chondrocyte pellet cultures led to abnormally small pellets with reduced proteoglycan content. The chondrocytes displayed an OA-like phenotype characterized by increased MMP13, COL10A, Runx2, and reduced Sox9, COL2A, aggrecan, and p-Smad3 expression. Transduction of chondrocytes with an FSTL-1 transgene led to a substantial increase in expression of COL2A.

Conclusion: These studies demonstrate that FSTL-1 plays a critical role in maintaining healthy cartilage by blocking the default route of chondrocyte terminal differentiation. Furthermore, we have shown that restoring FSTL-1 expression in chondrocytes can reverse changes observed in OA.

Session Date: Tuesday, November 15, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The ELR+ CXC chemokine CXCL6 is produced by healthy articular chondrocytes and retained within the cartilage matrix via interactions with heparan sulphate proteoglycans. There, it signals via CXCR2 to promote maintenance of articular cartilage homeostasis, particularly during conditions of physiological challenge, which was indicated by increased cartilage degradation in $CXCR2^{-/-}$mice following destabilization of the medial meniscus. The transient receptor potential channel 6 (TRPC6) mechanosensitive ion channel was demonstrated to be a specific mediator of CXCR2 driven cell migration. This project aims to investigate whether TRPC6 activity is required for CXCR2-mediated cartilage homeostasis.

Methods: Costal chondrocytes were isolated from $CXCR2^{-/-}$ mice, $TRPC6^{-/-}$mice and their wild type (WT) littermates and expanded under standard conditions. Chondrocyte TRPC channel and phenotypic gene expression was assessed using real time RT-PCR, Western blot and immunohistochemistry. Sulfated proteoglycan content of chondrocyte micromasses was measured using Alcian blue staining and spectrophotometric quantification. CXCR2 was activated using murine CXCL6 whilst TRPC6 was specifically activated using hyp9, a stabilized

derivative of the TRPC6-selective activator hyperforin. Calcium mobilization in chondrocytes was measured using a fura-2 calcium influx assay. AKT phosphorylation was analyzed by Western blot.

Results: TRPC6 mRNA and protein was detected in WT murine chondrocytes. $TRPC6^{-/-}$ and $CXCR2^{-/-}$ chondrocytes expressed lower levels of the chondrocyte differentiation markers SOX9 and type II collagen in comparison to WT controls, accompanied by less AKT phosphorylation. $TRPC6^{-/-}$ chondrocyte micromass cultures produced significantly less sulfated proteoglycans in comparison to WT. CXCL6 treatment of WT chondrocytes resulted in increased intracellular calcium mobilization and AKT phosphorylation, which was not observed in CXCL6 treated $TRPC6^{-/-}$cells. In vitro activation of TRPC6 using hyp9 led to increased AKT phosphorylation and resulted in a significant increase in SOX9 and type II collagen mRNA expression, together with a decrease in type X collagen mRNA expression.

Conclusion: TRPC6 is required for chondrocyte phenotypic stability and for CXCL6-induced calcium influx and AKT phosphorylation. In vitro TRPC6 activation is sufficient to increase the key chondrocyte phenotypic marker gene expression in murine chondrocytes, indicating that TRPC6 may be an ideal pharmacological target for reducing the loss of chondrocyte phenotypic stability and cartilage degradation during osteoarthritis.

Aggrecan Degradation Is Not Just Aggrecan Degradation:a Study of the Neo-Epitopes Tege and Args Released from Cartilage upon Aggrecanase Activity

Anne Sofie Siebuhr[1], Yi He[2], Yunyun Lou[2], Sabine Hoielt[3], Morten Asser Karsdal[1] and **Anne C. Bay-Jensen**[1], [1]Rheumatology, Nordic Bioscience, Herlev, Denmark, [2]Rheumatology, Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [3]Rheumatology, Nordic Bioscience, Biomarkers and Research, 2730, Denmark
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

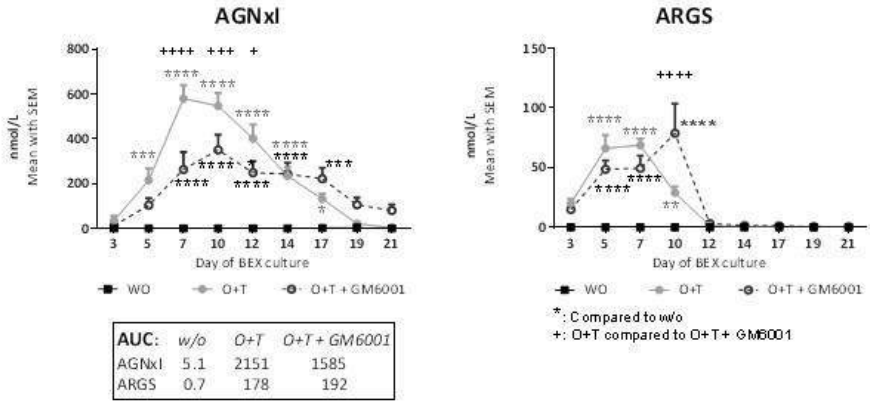
Background/Purpose: Cartilage degradation is a hallmark of arthritic disease. The main constituents of cartilage is aggrecan and type II collagen. Previous studies have shown that aggrecan degradation is prior to type II collagen degradation and that only aggrecanase degradation but not matrix metalloproteinases (MMP) degradation of aggrecan was reversible. It is therefore essential to have biomarkers that can detect reversible and irreversible aggrecan degradation to identify the condition of the cartilage. Of the well-known aggrecanase degradation site at NITEGE(373)-(374)ARGS, ARGS is released by only aggrecanse, but NITEGE is retained in the aggrecan molecule and in theory needs additional aggrecan degradation to be released. The numbers indicate the aggrecanase cleavage site. The aim was to investigate the profile of two neo-epitope biomarkers of

aggrecanase degraded aggrecan at NITEGE(373)-(374)ARGS in a bovine cartilage explants model.

Methods: Catabolic stimulated (oncostatin M and TNF-a; O+T) bovine cartilage explants were treated with or without the generic MMP inhibitor, GM6001. Explants without catabolic stimulation was used as negative control. In the culture supernatant two biomarkers investigating aggrecanase degraded aggrecan was measured. The AGNxI competitive ELISA detects the NITEGE^{373} neo-epitope and the ARGS sandwich ELISA detects the ^{374}ARGSVI neo-epitope. Statistical differences between groups were tested by two-way ANOVA.

Results: The AGNxI level was significantly increased compared to w/o from day 5 to day 17. GM6001 significantly lowered the release of AGNxI compared to O+T alone at day 7 ($p<0.0001$), day 10 ($p=0.0007$) and 12 ($p=0.01$). In addition, GM6001 shifted the release to 2days later in the culture period, as the AGNxI level was first significantly increased compared to w/o at day 7 to day 17, where the level was higher than O+T, but non-significant. The ARGS level was significantly increased at day 5, 10 and 12 for both O+T and O+T + GM6001 compared to w/o. At day 10 the ARGS level was higher in O+T + GM6001 than O+T ($p<0.0001$).

Conclusion: The prolonged release of AGNxI and the significantly lowered level of AGNxI with the MMP-inhibitor, suggest that the AGNxI release is somewhat dependent of MMP activity. In contrast, the ARGS release seems not to be MMP-dependent as there was a significant increase in O+T with the MMP-inhibitor compared to w/o and the peak was pronounced. In summary, aggrecan degradation is not just aggrecan degradation and different neo-epitopes have different importance in cartilage degradation.



AUC:	w/o	O+T	O+T + GM6001
AGNxI	5.1	2151	1585

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) and inflammatory subtypes of osteoarthritis (iOA) are degenerative joint diseases with an inflammatory component allowing for potential anti-inflammatory treatment benefit. A number of different signaling pathways have been associated with the inflammation-driven degradation of the extracellular matrix (ECM), and targeted in drug development with varying clinical results.

A better understanding of the signaling pathways and how their modulation affect ECM remodeling may therefore help in selecting novel anti-inflammatory treatments for iOA and RA.

The aim of this study was to investigate the differential effect of the anti-inflammatory inhibitors SB203580 (p38 inhibitor) and Tofacitinib (Jak inhibitor) on cartilage turnover driven by two different cytokines, IL-1α and TNF-α.

Methods:

Full depth cartilage ex vivo cultures were cultured for 3 weeks stimulated with either OSM [10 ng/ml] and TNF-α[2 ng/ml] [O+T] or IL-1α [10 ng/mL] alone, together with SB203580 or Tofacitinib at 3 μM, 1 μM and 0.3 μM. Untreated explants (w/o) were included as negative control. The cartilage ECM turnover was assessed by measuring the tissue fingerprint biomarkers C2M and AGNx1 in the conditioned medium with ELISA.

Results:

Aggrecanase mediated degradation of aggrecan was measured by AGNx1. The JAK inhibitor Tofacitinib significantly inhibited the release of AGNx1 in a dose dependent manner in both O+T and IL-1α stimulated cartilage, while the p38 inhibitor SB203580 had no effect. The degradation of type II collagen was measured by the MMP-mediated degradation of type II collagen (C2M) (Fig 1). Tofacitinib significantly inhibited C2M release in O+T and IL-1α stimulated cultures (Fig. 1d). SB203580 significantly inhibited C2M in O+T stimulated conditions in a dose dependent manner (Fig 1c). In contrast, SB203580 failed to inhibit C2M release in IL-1α stimulated conditions (Fig. 1c).

Conclusion:

The two inhibitors tested here had a positive effect on the degradation of type II collagen; however, for the p38 inhibitor only in a TNF-α driven setting. Furthermore, only the JAK inhibitor was able to inhibit aggrecan degradation, while the p38 inhibitor failed to do so in both TNF-α and IL-1α stimulated conditions. These findings suggest that anti-inflammatory effects tested ex vivo are dependent on type of cytokine activation, and, thus, indicate that signaling pathways driving inflammatory joint diseases needs to be given consideration when assessing the effect of potential anti-inflammatory treatments.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Chondrocytes in growth plate is known to respond to hydrostatic loading by increasing Indian hedgehog (Ihh) signaling, and that the primary cilium is required for this mechano-biological signal transduction to occur. Dicam (dual Ig domain containing cell adhesion molecule) was originally cloned from human chondrocyte cell-line, HCS-2/8 cells, but the role during endochondral bone formation and osteoarthritis has not been elucidated. This study reveals that Dicam has a novel function as a modulator of primary cilia-mediated Ihh signaling in chondrocytes.

Methods: Primary chondrocytes and tibia were isolated from limbs of C57BL/6 embryo (E15.5) and used in vitro study. Cartilage-specific Dicam transgenic (Col2-DICAM-Tg) mice were constructed and the phenotype of E15.5 long bone was compared with their wild type-littermates.

Results: Dicam mainly expressed in resting and proliferating chondrocytes in growth plate and it was increased by Pthrp and BMP2 in primary chondrocytes. Gain-of function study with Col2-Dicam-Tg revealed that Dicam increased length of long bones. Col2-Dicam-Tg showed an increased expression of chondrogenic, Col2a1 and proliferating marker, PCNA in immunostaining analysis. In addition, early and late hypertrophic chondrocyte marker, Col10a1 and MMP13, respectively, also increased in Col2-Dicam-Tg compared to wild-type. To elucidate a molecular mechanism of Dicam, we checked the major signaling targets in chondrogenesis, which showed an increased expression of Hhip and Zfp521, the target molecule of Ihh and Pthrp signaling, respectively. Other Ihh signaling molecules such as Ptch1, Gli2, and Gli3 and Ihh itself were also increased by Dicam overexpression in primary chondrocytes. Mechanistically, Dicam was localized to primary cilia of chondrocytes and increased a number of primary cilia and their assembly molecule, IFT88/polaris. Both knock-down of IFT88/polaris and hedgehog signaling antagonist, cyclopamine, attenuated the Dicam-mediated increase of length in primary tibia organ culture.

Conclusion: Dicam was localized to primary cilia and increased proliferation and hypertrophic differentiation of chondrocytes through Ihh signaling resulting in an increase of bone length In Vivo.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Due to exogenous stresses chondrocytes mitochondrial dysfunction is known to occur in osteoarthritis (OA) and amplifies the inflammatory cytokine induced cartilage degradation. Autophagy is an evolutionarily conserved mechanism that plays a central role in mitochondrial quality control. Here we investigated (a) whether IL-1β induce mitochondrial damage; and (b) whether the damaged mitochondria are cleared by autophagy in human OA chondrocytes under pathological conditions.

Methods: Primary human OA chondrocytes were isolated by enzymatic digestion of the undamaged cartilage obtained from OA patients who underwent total knee arthroplasty at Crystal Clinic, Akron, Ohio. Chondrocytes were treated with IL-1β (5ng/ml) followed by total RNA isolation for qPCR or lysate preparation for Western blotting. Mitochondrial damage and dysfunction was determined by JC-1 staining of chondrocytes followed by flow cytometry. Mitochondrial ROS levels as an indicator of mitochondrial damage and dysfunction were determined by MitoSOX red dye assay. Rapamycin was used to activate autophagy in OA chondrocytes and autophagic flux was confirmed by immunoblotting and immunofluorescence staining of LC3 protein. siRNA mediated knockdown of ATG5 or small inhibitors 3MA, Bafilomycin A1, chloroquine and ammonium chloride were used to inhibit autophagy in OA chondrocytes. Targeting of mitochondria by mitophagy was assessed by colocalization of mitochondria with parkin or p62 or LC3 protein or lysosomes. siRNA mediated knockdown of PARK2 was used to block mitophagy. Activation of Parkin and ubiquitination of Mfn1 and Mfn2 was assessed by immunoblotting.

Results: OA chondrocytes treated with IL-1β showed increased expression of COX-2, iNOS, IL6 and MMPs and decreased expression of COL2A1 and aggrecan. IL-1β treated OA chondrocytes also had decreased mitochondrial potential and several fold higher mitochondrial ROS production compared to controls and concomitant enhanced autophagic flux evidenced by increased LC3-II formation. Immunofluorescence staining of endogenous LC3 as well as of transiently overexpressed LC3-GFP protein also demonstrated increased autophagic flux in OA chondrocytes with damaged mitochondria. Autophagy inhibition augmented the IL-1β induced mitochondrial dysfunction, ROS production and OA like gene expression and apoptosis in OA chondrocytes while autophagy activation by rapamycin blocked the mitochondrial dysfunction and OA like gene expression. Immunofluorescence staining of mitochondria (using Mitotracker red) and of parkin or p62 protein or LC3 protein and lysosomes showed increased colocalization in IL-1β treated OA chondrocytes indicating active mitophagy. siRNA mediated knockdown of PARK2 blocked mitophagy and clearance of mitofusins and damaged mitochondria resulting in enhanced mitochondrial dysfunction and OA like gene expression in IL-1b-stimulated OA chondrocytes.

Conclusion: Our data directly demonstrate a link between the diminished autophagy and sustenance of mitochondrial dysfunction in OA and highlight the importance of the development of strategies to activate autophagy for better management of OA.

Extracellular Adenosine Deficiency Plays a Role in the Pathogenesis of

Osteoarthritis (OA) and Adenosine Replacement Prevents Post-Traumatic Osteoarthritis

Carmen Corciulo[1], Matin Lendhey[2], Tuere Wilder[1], Oran Kennedy[2] and Bruce Cronstein[3], [1]Department of Medicine, Division of Rheumatology, NYU School of Medicine, New York, NY, [2]Department of Orthopaedic Surgery, NYU-School of Medicine, New York, NY, [3]Medicine, Division of Rheumatology, NYU School of Medicine, New York, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Extracellular adenosine is highly regulated and plays an important homeostatic role via occupancy of cell surface receptors (A1R, A2AR, A2BR, A3R). Mice lacking A2AR develop spontaneous OA and A2AR-deficient chondrocytes express MMPs and Col10, suggesting a homeostatic role for adenosine/A2AR in cartilage. We tested whether diminished extracellular adenosine (generated from ATP by CD73 and/or CD39) contributes to OA and whether adenosine replacement ameliorates OA.

Methods: Chondrocytes were harvested from neonatal mice. ATP in chondrocytes and supernates was measured by luciferase-mediated bioluminescence, adenosine by HPLC and mRNA by RT-PCR. Modified OARSI scoring was carried out on safranin O-stained sections of knees from 1 yr old CD73KO mice. Post-traumatic OA was induced by application of mechanical load on rat tibia (14 wk old). Liposomal suspensions (100µl) +/- adenosine (10mg/Kg) +/- A2A, A2B or A3 receptor antagonists (1 mg/Kg, 5-6 rats/group) were injected every 10d for 56d.

Results: Treatment of rat tibial explants with IL-1β (5 ng/ml) markedly reduced ATP and adenosine release (38±17% of control, $p<0.05$, n=3; 76±7% of control, $p<0.01$; n=5, respectively). Moreover, applying a physiologic load increased adenosine release from untreated (199±27% of control, $p<0.001$, n=5) but not IL-1β treated explants (77±6%, $p<0.01$ vs control, n= 5). IL-1β–treated chondrocytes have reduced expression of ATP transporters pannexin-1 and ankh as well as CD73 (45±15%, 13±5%, 37±17%, $p<0.05$ of control, n=3, respectively). Mice lacking CD73 have mild OA (modified OARSI 1.5±0.4, $p<0.05$ vs. WT, n=5), consistent with findings in CD73-deficient patients (Arthritis Rheumatol. 2015; 67 (10)). Replacing adenosine by intraarticular injection of adenosine-liposomes reduced knee swelling and prevented OA changes in a rat model (Fig. 1 and 2) compared to saline or empty liposomes. An A2AR antagonist, but not A2BR or A3R antagonists, reversed these effects (Fig. 2).

Conclusion: Endogenous adenosine production from ATP maintains cartilage homeostasis; inflammation/injury reduces ATP release and adenosine production contributing to cartilage destruction. Adenosine replacement prevents OA development and may be useful to treat OA. Fig. 1

Unloading Results in Rapid Loss of TGFβ Signaling in Cartilage: Role of Loading-Induced TGF-B Signaling in Maintenance of Articular Chondrocyte Phenotype?

Arjan van Caam[1], Wojciech Madej[2], Esmeralda Blaney Davidson[1], Pieter Buma[2] and Peter M. van der Kraan[1], [1]Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands, [2]Orthopaedic Research Lab, Radboud university medical center, Nijmegen, Netherlands

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Absence of joint loading leads to cartilage atrophy and degeneration for unknown reason. We hypothesized that *in vivo* chondrocytes are exposed to permanent, loading mediated, TGFβ signaling and that loss of loading will result in rapid loss of protective TGFβ signalling. Additionally, we investigated the effects of inflammation on this loading mediated TGFβ signalling.

Methods : Bovine metacarpophalangeal joints were obtained from a local abattoir. TGFβ/Smad2/3P signaling was monitored by immunohistochemistry for phosphorylated-Smad2 (Smad2P) and by gene expression analysis using qPCR. A physiological load of 3 MPa (1 Hz) for 30 min was used for loading experiments. Sulfated glycosaminoglycan (GAG) levels were measured using DMB. Conditioned medium (OAS-CM), obtained from synovial biopsies of OA patients, was used to study inflammation.

Results: Active TGFβ signaling was abundantly present throughout all layers of freshly loaded cartilage. However, after unloading this signalling diminished rapidly and showed significant reduction after 2 hours. Compressive loading of articular cartilage resulted in swift restoration of Smad2P levels as well as potent up-regulation of Smad2/3P dependent gene expression including *Tgfb1*, and its receptor *ALK5*. Importantly, this process was repeatable, but could be inhibited by the ALK4/5/7 inhibitor SB-505124, indicating TGFβ or Activin signaling as the driver. However, loading effects could be mimicked by exogenous rhTGFβ1(1 or 10 ng/ml), but not by exogenous rhActivin A (1or 10 ng/ml). Unloading of explants for 2 weeks resulted in profound GAG loss and increased chondrocyte hypertrophy (*Col10a1*). Remarkably, neither repeated loading nor exogenous TGFβ1 counteracted GAG loss, but repeated loading did inhibit the elevation of *Col10a1* expression as effective as exogenous TGF-β. Strikingly, OAS-CM inhibited loading-induced expression of *ALK5* and down regulated expression of *Tgfbr2*, the essential type II receptor for TGFβ signaling, and this was reflected in reduced expression of loading-induced Smad2/3P dependent genes

Conclusion: Our data strongly indicate that, *in vivo*, articular cartilage has enduring TGFβ signalling when regularly loaded, but which is inhibited in inflammatory conditions. This loading- induced TGFβ signalling has an important role in maintenance of chondrocyte phenotype but not of cartilage GAG content. Based on these results and our earlier findings we suggest that loading-induced TGF-β signalling is crucial to maintain articular cartilage functioning and that this protective system can be impaired under inflammatory conditions.

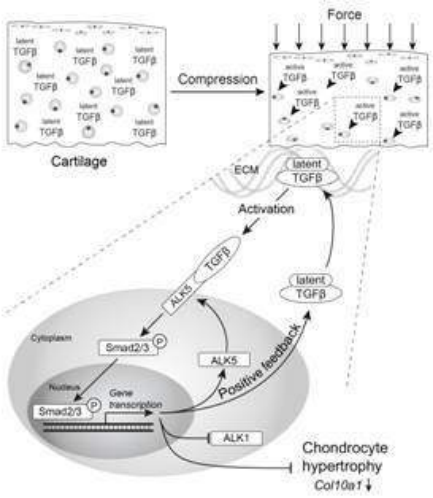

Figure 1: Loading induced Smad2/3P activates a positive feedback loop by inducing expression of its own activating receptor: ALK5, and (inactive) TGFβ1, which after production will bind to the ECM and return the system to its original stage.

Transient Receptor Potential Ankyrin 1 (TRPA1) Is Functionally Expressed in Primary Human Osteoarthritic Chondrocytes and Mediates Cartilage Destruction and Joint Pain in the Mia-Model of Osteoarthritis

Elina Nummenmaa[1], Lauri J Moilanen[1], Mari Hämäläinen[1], Erja-Leena Paukkeri[1], Riina Nieminen[1], Teemu Moilanen[2], Katriina Vuolteenaho[1] and **Eeva Moilanen**[1], [1]The Immunopharmacology Research Group, University of Tampere School of Medicine and Tampere University Hospital, Tampere, Finland, [2]Coxa Hospital for Joint Replacement, Tampere, Finland

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Transient receptor potential ankyrin 1 (TRPA1) is a membrane associated cation channel, which is widely expressed in neuronal cells and known to be involved in nociception and neurogenic inflammation. More recently, TRPA1 has also been found to be expressed in some non-neuronal cells, such as

keratinocytes and synoviocytes, but the functional roles of non-neuronal expression remain to be studied. TRPA1 has previously been shown to be up-regulated and activated by agents formed endogenously in inflammatory and hypoxic conditions characteristic to human and MIA-model of osteoarthritis (OA). We hypothesized that TRPA1 is expressed and functional in human OA chondrocytes and mediates cartilage destruction and joint pain in MIA-induced experimental OA.

Methods: Expression of TRPA1 in primary human OA chondrocytes was assessed by quantitative RT-PCR and Western Blot analysis. The functionality of the TRPA1 channel was assessed by Ca^{2+}-influx measurements. Production of MMP-1, MMP-3, MMP-13, IL-6 and PGE_2 subsequent to TRPA1 activation were measured by immunoassay. Wild type and TRPA1 knock-out mice were used in mouse cartilage culture experiments. To induce experimental OA, MIA was injected into mouse knee joint either at lower (37.5ug) or higher (500 ug) dose, and contralateral knee was injected with the vehicle. Joint pain was estimated by weight-bearing test at baseline and thereafter weekly. The animals were sacrificed four weeks after the MIA injections and histological changes in the knee joints were assessed according to the OARSI guidelines. The responses between wild type (WT) and TRPA1 deficient (knock-out, KO) mice were compared.

Results: Remarkably, TRPA1 was found to be expressed and inducible by IL-1β in primary human OA chondrocytes. The TRPA1 channel was found to be functional, as stimulation with the TRPA1 agonist AITC caused an increase in Ca^{2+}-influx, which was attenuated by the TRPA1 antagonist HC-030031. Pharmacological inhibition of TRPA1 with the selective antagonist HC-030031 downregulated the production of MMP-1, MMP-3, MMP-13, IL-6 and PGE_2 in primary human OA chondrocytes. Furthermore, genetic depletion of TRPA1 downregulated the production of MMP-3, IL-6 and PGE_2 in murine cartilage explants. Both doses of MIA caused spontaneous joint pain in WT mice as shown in weight-bearing test. However, in TRPA1 deficient mice no response was seen following the lower dose of MIA, and the response after the higher dose of MIA was clearly attenuated. Also, the higher dose of MIA caused cartilage changes typical for OA in the WT mice. Interestingly, the TRPA1 deficient mice did not develop such destructive joint changes following MIA injections.

Conclusion: The TRPA1 cation channel was found to be functionally expressed in primary human OA chondrocytes and to mediate inflammatory and catabolic effects, which are both original findings. Further, in MIA-induced experimental OA TRPA1 was found to contribute to the development of cartilage changes and joint pain. The inflammatory and hypoxic environment in the OA joint is conducive to enhance the expression and activation of TRPA1. The results reveal TRPA1 as a potential mediator and drug target in osteoarthritis.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous findings indicated that autophagy is defective in Aging and Osteoarthritis (OA). Autophagy is essential to maintain chondrocyte homeostasis by regulating the intracellular macromolecule and organelle turnover. However, the specific targets that regulate this homeostatic mechanism are still unknown. *The objective of study is to identify relevant targets regulating autophagy in Aging and OA.*

Methods: Human chondrocytes were transfected with siRNA for Atg5 (100 nM, 72 hours), an important autophagy marker, to block the autophagy pathway. To identify the key proteins associated to defective autophagy, we performed quantitative proteomics analysis using iTRAQ labeling coupled with on-line 2D LC/MS/MS. Protein identification and quantification were performed using Protein Pilot Software v 4.0. Each MS/MS spectrum was searched in the Uniprot/Swissprot database for *Homo sapiens*. Human chondrocytes, human cartilage from healthy, aged and OA human patients and mouse knee joints from young and old mice were employed. To evaluate the role of Lamin A/C overexpression on autophagy pathway in human chondrocytes, CRISPR-Cas9 technology was used.

Results: 487 different proteins were identified in response to defective autophagy in human chondrocytes. 24 targets were significantly altered ($p<0.05$) between siCtrl and siAtg5 (11 were decreased and 13 increased). Cytoskeleton organization, collagen catabolism, oxidative stress, and aging pathways are associated with chondrocytes with deficient autophagy. Taking into account the key role of autophagy in the regulation of aging and OA, we focused on Prelamin A/C. Prelamin A/C is a nuclear protein implicated in premature cell senescence that was found upregulated ($p < 0.05$). Autophagy proteins Atg5 and LC3, as well as Lamin A/C were evaluated in human chondrocytes. The results indicated a reduction in autophagy expression, accompanied with an increase in Lamin A/C. Furthermore, in aging and OA human cartilage, autophagy markers were reduced while Lamin A/C expression was increased. Histological analysis of mouse knee joints from young and old mice revealed a reduction in LC3 expression, as well as an increase in Lamin A/C expression. Importantly, *in vitro* premature aging model by genetic deletion of Zinc Metalloproteinase 24 (Zmpste24) via CRISPR-Cas9, showed a Lamin A/C overexpression, accompanied by a reduction of LC3 in human chondrocytes, suggesting that autophagy loss-of-function is intimately correlated with increased premature senescence in human chondrocytes.

Conclusion: Proteomic analysis has revealed features of premature senescence when autophagy is disrupted in chondrocytes. Lamin A/C, a nuclear protein contributing to structural integrity to the nucleus and matrix was identified as candidate target for regulating cartilage function under defective autophagy, such as aging and OA. These results support the hypothesis that autophagy is decreased with aging. Therefore, targeting Lamin A/C a promising strategy to find novel therapeutics for cartilage aging and OA.

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a degenerative joint disease, leading to pain and functional limitation. Although OA is a most common form of musculoskeletal disease, the pathogenesis still remains to be determined. This study was aimed to investigate the characteristics of cartilage derived from OA-iPSCs.

Methods: Dermal fibroblasts were obtained from one patient with early onset OA (age=31) and a healthy sibling without OA under informed consent. OA-iPSCs and control-iPSCs were reprogrammed from dermal fibroblasts, and differentiated into chondrocytes using outgrowth cells extending from embryoid bodies. The expression of cartilage specific markers was determined by immunohistochemical staining and reverse transcription-polymerase chain reaction (RT-PCR). To simulate the inflammatory condition of OA, chondrocytes differentiated from iPSCs were cultured in the presence of interleukin-1α.

Results: Dermal fibroblasts of OA patient and a healthy sibling were successfully reprogrammed into iPSCs. Pluripotency of OA-iPSCs and control-iPSCs was confirmed by immunohistochemical staining and RT-PCR for Nanog, Oct4, Fox2, and other pluripotent markers. All iPSCs were efficiently differentiated into cartilaginous pellet, which exhibit the chondrocyte-specific markers. Cartilage from OA-iPSCs showed an impaired mechanical integrity with porous structures. The expression of collagen type II were significantly decreased in OA-iPSC-cartilage, compared to control-iPSC-cartilage. Treatment of IL-1α enhanced the loss of cartilage, and the expression of matrix metalloproteinases and inflammatory molecules, in OA-iPSC-cartilage.

Conclusion: This study presented the impaired function of cartilage differentiated from OA patient derived iPSCs, and the simulation of cartilage damage in inflammatory condition of OA. Disease modeling of OA using patient-derived iPSCs would provide the better understanding for OA pathogenesis.

Bone Replaces Cartilage In Non-Weight Bearing Regions Of Immobilized Knees

Background/Purpose:

Osteoarthritis causes pain, restricts joint range of motion, reduces function, is highly prevalent worldwide and contributes to an ever-increasing burden on global health care costs[1]. Joint immobility damages articular tissues including cartilage, and has been used as an experimental model for OA[2, 3]. Various immobilization models in animals have been used including use of straps/slings, splints/casts, or rigid external fixation with or without weight-bearing on the immobilized joint, a crucial factor in articular homeostasis[4]. Therefore, the pathophysiology of immobility-related cartilage alterations and hence directions for treatment would still benefit from new data. This study examined the effect of knee joint immobilization in flexion on tibial epiphysis articular cartilage, comparing weight-bearing and non-weight-bearing regions.

Methods:

Eleven rat knees were rigidly immobilized for 32 weeks at 135° of flexion. Contralateral limbs served as controls. The medial tibial epiphysis on histological sagittal sections was divided into non-weight-bearing (anterior) and weight-bearing (middle, posterior) regions on digital images. We quantified cartilage thickness and glycosaminoglycan (GAG) staining intensity using safranin O, as well as the distribution of collagen I and II using picrosirius red under polarized light. We evaluated osteoblast activity and the presence of mesenchymal stem cells (MSCs) using immunohistochemistry to osteocalcin and overlapping CD90 and CD73 staining on serial sections, respectively.

Results:

Immobilized mean cartilage thickness was reduced in the anterior region but increased in the posterior region (92±68µm, 235±56µm respectively, Figure 1A top) compared to contralateral (154±49µm, $p=0.022$; 186±48µm, $p<0.001$, respectively, Figure 1A bottom). GAG cartilage staining area was 2±4% in the anterior region of

immobilized knees compared to 28±12% contralaterally (p=0.003). Immobilized knees had decreased collagen II staining area (11±9% vs 36±12%, p=0.006) and increased collagen I staining area (61±20% vs 43±12%, p=0.033) in the anterior cartilage region (Figure 1B top). Osteocalcin (Figure 1C) and MSC staining (Figure 1D) were decreased in immobilized knees (p=0.003 and p=0.036 for CD90 only, respectively) with no significant inter-regional differences.

Conclusion:

After 32 weeks of knee immobilization, the non-weight-bearing region of the tibia articular cartilage was thinner, lost GAG, and was replaced by bone. Long-duration immobility may share pathophysiologic features with OA and should be intervened upon in earlier stages.

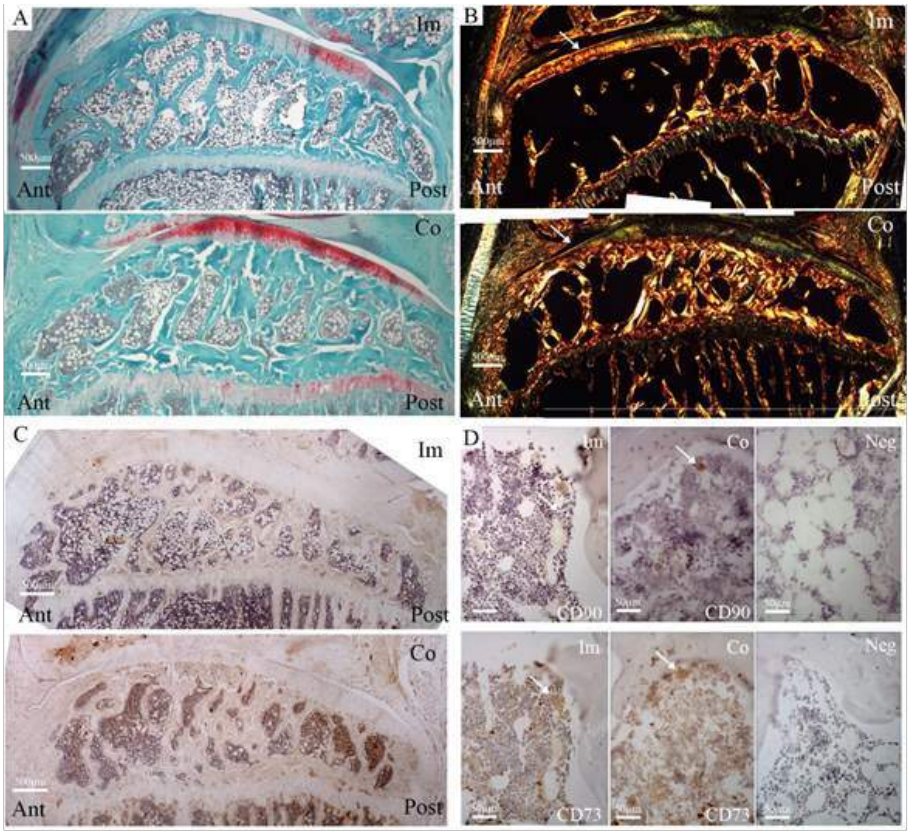

Figure 1. Cartilage changes following immobilization. (A) Digital reconstruction of tibial epiphysis and articular surface from immobilized (top) and contralateral (bottom) rat knee sections. Staining is with safranin-O. (B) Tibial epiphysis and articular surface from immobilized (top) and contralateral (bottom) rat knee sections. Staining is with picro sirius red under polarized light where collagen I appears red or yellow and collagen II appears green. Arrows identify different collagen colouration in the anterior region of the joint between the immobilized knee joint and the contralateral. (C) Immunohistochemistry: osteocalcin distribution. (D) Immunohistochemistry: CD90 (above) and CD73 (below) staining in adjacent serial sections of immobilized and contralateral rat knees as well as corresponding negative control. Background staining is with hematoxylin. Ant = anterior region; Co = contralateral; Im = immobilized; Neg = negative control; Post = posterior region.

Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a disease characterized by pain and tissue destruction, in some cases concomitant with inflammation. The link between pain and tissue destruction is yet unknown, and there is a lack objective quantifiable parameters. Collagens are the main structural proteins of the joint extracellular matrix. The degradation of especially type I (connective tissue), II (cartilage), III (synovium) and IV (basement membrane) collagens have been shown to be elevated in OA. So we investigated whether biomarkers reflecting collagen degradation were associated with knee OA representing with different pain and inflammatory phenotypes.

Methods: 111 knee OA patients, 62% women, from NYUHJD progression cohort study with varying degree of OA were included: mean (SD) age, 62 (10); mean(SD) BMI, 27(4); NSAID users, 23%; radiographic OA (KL≥2) 68%; and bilateral knee OA; 87%. Pain was assessed by VAS_{pain} and WOMAC at baseline (BL) at a 2-year follow-up (FU) visit. Median (IQR) were 39 (13-69) and 37 (13-52) for BL VAS_{pain} and $WOMAC_{pain}$. 4 BL serum biomarkers of type I, II, III and IV collagen degradation (C1M, C2M, C3M, C4M), and the 2 inflammatory biomarkers CRPM and hsCRP, were assessed. Data were log2 transformed. Associations between BL biomarkers, BL pain and change (CHG) pain scores were assessed by multivariate linear model including gender, age, BMI, $KL_{signal\ knee}$, bilateral knee OA and NSAID use. Patients with cont. mild/moderate pain had a BL VASpain<54 and FU VASpain<30, cont. moderate/severe pain had VASpain>30 at baseline and FU, and transitional severe pain had either VASpain_BL<30 and VASpain_FU>54 or VASpain_BL>54 and VASpain_FU<30 (ref). Patients with; low biochemical disease activity index (bDAI) low in CRPM (<12nM) moderate bDAI were high in CRPM but low in hsCRP (<5), and high bDAI (flare) were high in CRPM and hsCRP.

Results: ***BL association between pain and biomarkers*** C2M (β -17.9, p<0.0001) and $KL_{signal\ knee}$ (β -5.4, p=0.0031) were significantly associated with WOMAC pain. C2M (β -12.4, p=0.0033), C3M (β -19.9, p=0.059), age (β -0.84, p<0.0018), $KL_{signal\ knee}$ (β 8.9, p=0.0021) and bilateral knee OA (β -12.2, p=0.087) were associated with VAS_{pain}. ***Association between BL biomarkers and CHG pain*** C2M (β 13.3, p=0.0016), age (β 0.5, p=0.029) and bilateral OA (β -12.0, p=0.043) were significantly associated with delta $WOMAC_{pain}$. Only age, BMI and NSAID use was associated with CHG VAS_{pain}. ***Association between pain phenotypes and BL biomarkers*** Patients with cont. mild/moderate pain had significantly higher C2M compared patients with transitional severe pain (p=0.0014) and cont. moderate/severe pain (p=0.04). ***Biomarker, BL pain and CHG pain in patients w. inflammatory OA*** Patient with low bDAI had lower $WOMAC_{pain}$ (p<0.05) and VAS_{pain}(p<0.1). C1M was higher (p<0.05) in the flare group compared to the low and moderate bDAI groups. C3M was higher (p<0.05) in the moderate bDAI group than the low DAI group.

Conclusion: Different collagen degradation products are linked differentially to different phenotypes. Cartilage degradation (C2M) was consistently linked to CHG pain phenotypes, whereas it was not associated with an inflammatory phenotype. In contrast, C1M and C3M were linked to inflammatory and flared OA.

Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: CD14, though expressed by multiple cell types, is highly expressed by monocytes and macrophages. It forms a complex with Toll-like receptors (TLRs), particularly TLR-2 and TLR-4, thereby facilitating innate inflammatory responses. Elevated expression of CD14 has been associated with joint space narrowing and symptoms in patients with OA (Daghestani et al. 2015). Previous work from our lab has shown that soluble CD14 is present in synovial fluid from patients with knee OA, and sensitizes fibroblast like synoviocytes (FLS) to respond to TLR ligands. The purpose of the current study was to test whether deficiency of CD14 modulates development of structural and functional features of disease using a murine knee OA model

Methods: CD14 deficient mice ($CD14^{-/-}$) and C57BL/6J congenic controls (WT) were obtained through Jackson Laboratory. 10-12 week old male mice from both strains were subjected to de-stabilization of medial meniscus (DMM), sham surgery or left unoperated. Six and nineteen weeks post-surgery were chosen as early and advanced time points in this model. Groups of 5-9 mice at each timepoint were sacrificed and knee joint histopathology evaluated using the modified OARSI score (Miller RE et al. 2016). As a surrogate for joint pain, changes in spontaneous activity were investigated longitudinally (every 4 weeks, up to 16 weeks) after DMM surgery in the two strains, using the LABORAS® Laboratory animal behavior observation registration and analysis system (Metris B.V., Hoofdorp, The Netherlands).

Results: $CD14^{-/-}$ mice showed similar degrees of cartilage erosion (Mean score ±SEM, 4.667±1.38) as WT controls (4.6±0.6, $p>0.9999$) at 6 weeks post-DMM. However, by 19 weeks post-DMM, cartilage erosion was significantly reduced in the CD14 knockouts (6.0±0.46) in contrast to their WT counterparts (13.44±2.5, $p<0.0001$). By contrast at 19 weeks post-DMM, both strains displayed similar osteophytosis (WT: 104.4±23.16; $CD14^{-/-}$: 138.8±22.48, $p=0.15$). Analysis of spontaneous activity indicated significant decreases in climbing activity by WT mice at 4 and 8 weeks post-DMM (~84% lesser than baseline). The CD14 deficient mice in contrast maintained climbing activity through the course of 16 weeks after DMM surgery. Furthermore, $CD14^{-/-}$ mice initiated significantly greater number of climbs each hour at 8, 12 and 16 weeks post-DMM as compared to baseline ($p\leq0.004$), and their WT counterparts ($p\geq0.11$).

Conclusion: Deficiency of CD14 expression significantly diminished progression of cartilage erosion observed

in the advanced phase, and protected the mice from early climbing deficits described in this model. No significant protection from osteophytosis was observed. These findings indicate that CD14-mediated mechanisms may be targets to ameliorate symptoms and prevent progression of structural disease. Loss of CD14 appears to affect structural and functional outcomes in this model through different mechanisms over different timelines. Further studies are needed to characterize the cell types involved and the specific mechanisms of action for suitable therapeutic targeting of OA progression.

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone histomorphometry can define OA changes in rodents and in Antigen-Induced arthritis in rats. We previously found that pain from inflammatory monoarthritis in mouse knees correlated with bone histomorphometry measures. In order to determine whether these changes were due to pain or due to inflammation, we used micro CT to correlate pain behaviors with histomorphometric bone changes in knees from mice with collagenase induced non-inflammatory monoarthritis with and without analgesia with intra-articular (IA) vanilloids and botulinum toxin.

Methods: Chronic non-inflammatory arthritis was produced by IA injection of 10 µl collagenase (COL) (10IU) into the left knee of C57BL6 male mice 4 weeks prior to pain behavior testing using evoked pain scores (EPS) and an automated dynamic weight bearing (ADWB) device. EPS was a tally of fights and vocalizations/min with knee palpation at 15.6 psi. Percent weight and time on each limb was measured with ADWB apparatus (Bioseb, Vitrolles, France). IA vanilloids resiniferatoxin (RTX) and capsaicin (CAP) (10µl each of 0.001%RTX, or 0.01% CAP) were given 7 days prior to pain testing. IA botulinum toxin A (BTX) (10µl 0.02 IU) was injected 3 days before testing. Knees were imaged on a micro-CT scanner (micro-CT40; ScanCo Medical AG, Bassersdorf, Switzerland). Subchondral trabecular bone volume fraction (BV/TV), trabecular thickness (Tb.Th in µm), trabecular spacing (Tb.S in µm), and number (Th.N/mm) were calculated from coronal slices using the ScanCo bone trabecular morphometry program.<span">

Results: Arthritis pain behavior was low in naïve mice - EPS (0.57) and ADWB proportions for weight (40.9%) and time (97.4%) were normal. IA COL arthritis significantly increased EPS (4.0) but had very little effect on ADWB for weight (39.7%) and time (98.0%). Forepaw compensatory weight bearing increased only from 9.3% in naïve mice to 10.9% in COL arthritic mice. In selected mice with COL arthritis in contrast to inflammatory monoarthritis, there was no significant correlation between pain as measured by EPS or ADWB and any measure of bone histomorphometry. There was no significant difference in bone volume, trabecular number, thickness or spacing between naïve and arthritic mice. IA neurotoxin treatment of COL arthritis with either BTX or Vanilloids (RTX or CAP) did not have a consistent effect on bone histomorphometry.

Conclusion: IA COL induced monoarthritis increased EPS in mice but had little effect on spontaneous pain as measured by ADWB. MicroCT did not find significant changes in BV/TV proportion, Tb.Th or Tb.Sp in COL non-inflammatory arthritis. IA neurotoxin treatments with BTX, RTX and CAP did not affect subchondral bone. These findings are not consistent with other findings in OA rodent models or our previous results with chronic inflammatory arthritis. These results suggest that pain alone is not sufficient to produce changes in bone histomorphometry. It may be that offloading is more important and that 4 weeks is not long enough to cause gait offloading in this model. We have noted increased offloading in this model after 6 weeks. It will be important to study whether offloading with additional chronicity will change bone morphometry.

Transcriptional Analysis of Synovial Tissue Reveals Sustained Inflammatory Chemokine Expression Despite Minimal Histopathologic Change in the Destabilization of Medial Meniscus Model of Murine Knee Osteoarthritis

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The destabilization of medial meniscus (DMM) model of instability-induced OA replicates disease-related tissue pathology (including cartilage erosion, osteophytosis) and pain-related joint dysfunction, making it a useful model to investigate OA pathogenesis. Synovial inflammation characterized histopathologically, although common in OA, is not a prominent feature in this model leading some to suggest lack of significant synovial involvement. The aim of the current study was to determine if molecular analysis of synovium post-DMM could identify changes in synovial activity not otherwise revealed by histopathology.

Methods: 10-12 week old male C56BL/6J (WT) mice were subjected to DMM surgery of the right knee. Six weeks (early OA) and nineteen weeks (advanced OA) after surgery, groups of 5 mice were sacrificed and joints evaluated by histopathology for synovial hyperplasia. Hyperplasia was scored on a scale of 0-3 based on lining cell layers in three anatomic locations: superior to the medial meniscus (S.M.M), inferior to the medial meniscus (I.M.M) and in the medial peri-patellar (M.P.P) region. For molecular analysis, anterior synovial tissues were harvested at 1, 2, 4, 8 and 16 weeks post-DMM, and tissues from 3-5 mice were pooled per sample, RNA was isolated, and mRNA quantified using QX200^{TM} Droplet Digital^{TM} PCR System (BioRad, Hercules, CA). Expression of CD68 (monocytes/ macrophages), CD3δ, (T lymphocytes), and specific chemokines (CCL19 and CCL21, upregulated in OA patients) were expressed relative to TATA box binding protein (TBP)

Results: Evaluation of synovial hyperplasia showed mild or no hyperplasia (score≤1) at 6 weeks (Mean±SEM at S.M.M: 1±0.32, I.M.M: 0.33±0.33, M.P.P: 0.8±0.2) and 19 weeks (S.M.M: 0.5±0.29, I.M.M: 0.5±0.29, M.P.P.: 0.4±0.25) post-DMM. Furthermore, synovial hyperplasia post-DMM was not increased significantly compared to un-operated or sham-operated controls. In contrast, CD68 mRNA expression significantly increased early and peaked at 4 weeks post DMM surgery (21.61±3.03, $p<0.0001$) as compared to unoperated controls (2.72±1.47). No significant variation in expression of CD3d or CCL19 was detected over the time course. However, analysis of CCL21 expression indicated significantly elevated and sustained expression starting 2 weeks post-DMM (17.82±1.55), which continued to increase up to 16 weeks (34.1±3.79) post-DMM.

Conclusion: The current study suggests that molecular changes indicative of synovial inflammation are detectable in the DMM model of OA, despite minimal changes in synovial hyperplasia. Increased CD68 expression suggests an early increase in macrophages, along with a progressive increase in chemokine (CCL21) expression up to 16 weeks. The significance of these expression patterns to disease development has yet to be determined. A more comprehensive evaluation of synovial activation and its relationship with disease features, will be the focus of future studies to better understand how molecular and cellular activation within the synovial microenvironment may promote disease.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The contribution of metabolic changes induced by high fat diet (HFD) to OA is poorly understood. We sought to determine if diet regulates longitudinal changes to metabolic factors that contribute to OA.

Methods: Mice were fed normal chow diet until 9 weeks of age and then placed onto HFD or lean diet (LD) for 18 weeks, followed by resumption of normal chow, and evaluated longitudinally up to 12 months of age. Some mice were subjected to surgically-induced OA at the end of special diet. Plasma and knee joints were collected at each time points.

Results: We determined that HFD significantly increased fasting blood glucose levels, body weight, BMI and leptin levels as compared to LD fed mice. Histopathological analysis using OARSI scoring clearly showed that HFD fed mice exhibited accelerated spontaneous OA at 9 months of age as well as acceleration in the surgically induced OA at 10 and 20 wks post surgery in comparison to LD fed mice. Of the 170 metabolites analysed in blood plasma at each time point, lysophosphatidyl choline analogues (lysoPCaC20:4, lysoPCaC17:0, lysoPCaC18:0) and one phosphatidyl choline analogue (PCaaC36:2) were increased longitudinally in the HFD fed mice. Our ongoing studies are now evaluating if these LysoPC metabolomics signatures are responsible for initiating and accelerating cartilage degradative process observed in HFD fed mice and if we may predict the osteoarthritis severity by using some biomarkers as well as the involvement of the leptin-driven pathway.

Conclusion: We identified that high fat diet induces and maintains selective metabolic changes and increases OA progression in both spontaneous and surgically induced OA. We anticipate that these identified metabolomics signatures are involved in OA pathogenesis during obesity and therapeutic modulation of leptin pathway may help to attenuate or reverse OA pathologies.

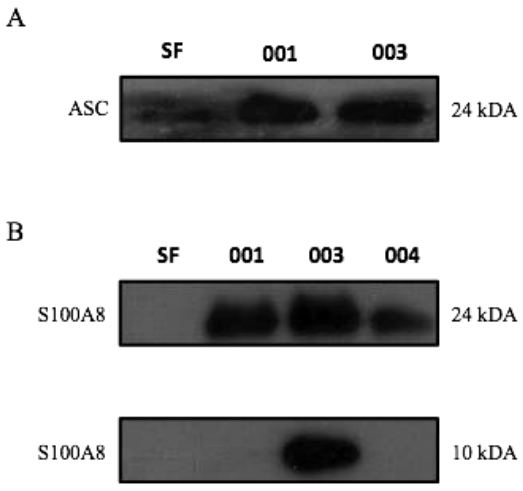
Session Date: Tuesday, November 15, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Exosomes are biologically active microvesicles derived from the endosomal membrane system understood to play a significant role in a wide range of inflammatory diseases. Exosomes both initiate and propagate inflammation through a number of mechanisms including antigen presentation and by serving as cargo vessels for damage-associated molecular patterns (DAMPs) and cytokines. In RA, synovial fluid (SF)-derived microparticles modulate chemokine and cytokine release in cultured synoviocytes. However, SF-derived microvesicles in osteoarthritis (OA) remain largely unexplored. Tumour-derived exosomes express a number of proteins known to contribute to metastasis and tissue remodelling which are conserved across OA pathogenesis including matrix metalloproteinases (MMP) and the damage-associated molecular pattern molecule (DAMP), S100A8. These proteins contribute to synovial inflammation, cartilage degradation and subchondral bone turnover in OA, We therefore sought to **1)** isolate exosomes from the SF of patients with OA **2)** determine whether these exosomes expressed any factors known to potentiate OA, including MMPs and S100 proteins and **3)** assess the functional effects of isolated SF-derived exosomes on primary human macrophages.

Methods: Exosomes were isolated from SF using an Exo-Spin isolation kit. Western immunoblotting was carried out on both exosomes and neat SF isolated from patients with OA. Primary human macrophages were treated with exosomes for 24 hours and expression of S100A8, S100A12 and RANK was analyzed by quantitative PCR (qPCR). Cytokine production by macrophages in response to exosomes was assessed by ELISA. $CD14^+$ monocytes were treated with M-CSF and exosomes or neat synovial fluid in the presence or absence of RANKL for 14 days and then stained for TRAP to analyse the ability of exosomes to drive osteoclast differentiation.

Results: Western blot analysis revealed robust expression of MMP-1 and S100A8 in exosomes from OA SF (N=3 donors) (Fig). The inflammasome adaptor protein, ASC, was also similarly detected in both exosomes and neat SF. SF-derived exosomes (25 μg/ml) upregulated S100A8 and S100A12 in human macrophages by approximately 16 to 20-fold by qPCR, while a 50-fold increase in RANK expression was observed. SF-derived exosomes were also shown to induce a 7-fold increase in IL-6 release from primary macrophages. Finally, both SF-exosomes and neat SF from OA patients promoted the differentiation of osteoclast precursor cells.

Conclusion: Based on these studies we propose that synovial fluid-derived exosomes could aggravate OA via 1) synovial inflammation through up-regulation of DAMPs, MMP and cytokines and 2) subchondral bone remodelling through promotion of osteoclastogenesis and increased expression of RANK in haematopoeitic



cells.

Terminal Uridylyl Transferase ZCCHC6-dependent Generation Of miRNA Diversity In Primary Human Chondrocytes

Background/Purpose: MicroRNAs (miRNAs) are a group of small, noncoding RNAs that post-transcriptionally regulate gene expression. miRNAs play important roles in chondrocyte function and in the development of osteoarthritis. We characterized the dynamic repertoire of the chondrocyte miRNAs and isomiRs by deep sequencing analysis in chondrocytes isolated from normal subjects as well as OA patients in response to the treatment with inflammatory cytokine IL-1b. We also tested the role of TUT7/ZCCHC6 in non-template addition of nucleotides at the ends of specific miRNAs in human chondrocytes.

Methods: Joint cartilage samples were obtained from normal subjects at autopsy and OA patients who underwent joint arthroplasty at the Crystal Clinic, Akron, OH. Primary human chondrocytes were prepared by sequential digestion of the cartilage pieces by pronase (1 mg/ml) for 2 hrs and collagenase A (1 mg/ml) for 16 hrs. Cells were serum starved overnight followed by treatment with IL-1b (2 ng/ml) for different durations (2 hrs, 12 hrs and 24 hrs). Expression of TUT7/ZCCHC6 was knocked down using ON-TARGETplus SMARTpool (GE Dharmacon). Total RNA was prepared using miRNeasy kit (Qiagen) and libraries for sequencing were prepared using True seq small RNA library preparation kit (Illumina). Next generation sequencing was performed on Illumina MiSeq sequencer. Data were analyzed using CLC genomics suite version 8 (Qiagen).

Results: There was a modest difference in the expression of miRNAs in normal and OA chondrocytes in the presence or absence of IL-1b. We found a number of miRNAs that showed a wide range of sequence modifications including nucleotide additions and deletions at 5' and 3' ends; and nucleotide substitutions. Some modifications resulted in seed shifts. Interestingly, miR-140-3p, an important miRNA involved in chondrocyte function, was found to have the highest number of modifications (Figure 1). Many of these modifications have been shown to impart a change in the miRNAs' ability to regulate gene expression. Knockdown of TUT7/ZCCHC6 resulted in a significant change in the isomiR profile in human chondrocytes demonstrating that TUT7/ZCCHC6 contributes to the miRNA complexity in human chondrocytes.

Conclusion: Together, these results reveal a complex repertoire of miRNAs and isomiRs in primary human chondrocytes and their dynamic changes in response to IL-1b treatment. Here we also show the role of TUT7/ZCCHC6 in generating the miRNA diversity in human chondrocytes. These findings will help us better understand miRNA-mediated control of gene expression in the pathogenesis of OA. This work was supported in part by USPHS/NIH grants (RO1 AT007373, RO1 AT005520, RO1 AR067056, R21 AR064890) and funds from North East Ohio Medical University to TMH.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Biology and Pathology of Bone and Joint - Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Effective treatments for Osteoarthritis (OA) are not available. In aging-related diseases, including OA, failure of cellular homeostasis mechanisms, such as autophagy can cause extracellular matrix destruction and cell death. Chondrocytes are essential for the maintenance of cartilage integrity. With aging, chondrocyte function is diminished, contributing to a cellular senescence phenotype often observed in OA chondrocytes. In addition, a defect in autophagy is observed in both aging and cartilage degeneration. *The objective of this study was to identify anti-senescence and pro-autophagy molecules by a cell-based high-throughput screening (HTS) in human chondrocytes.*

Methods: To induce cellular senescence or reduced autophagy, immortalized human chondrocytes (TC28a2) were seeded (3000 cells/well) in 384 well plates, and treated with IL-6 (10 ng/ml) for 72 or 18 hours, respectively. Then, chondrocytes were incubated with Prestwick Chemical Library (1120 approved drugs with chemical and pharmacological diversity, as well as bioavailability and safety in humans) at 10 μM for 48 hours. To identify anti-senescence hits, nuclei was stained with Hoechst 33342 (10 μM), while β–galactosidase subcellular structures was stained by using Imagene Green C12FDG substrate (10 μM). To evaluate autophagic flux, a reporter cell line was generated by lentiviral transfection of pBABE-mCherry-EGFP-LC3 plasmid in TC28a2 chondrocytes. Plates were imaged by using Operetta® High Content Screening (HCS) system in non-confocal mode using the 20x WD objective. For each well, 4 fields and 4 planes of bright field, Hoechst and fluorescein channels were obtained. Relative intensity of C12FDG in cytoplasm and number of autophagosomes/autolysosomes per area of cytoplasm were determined to quantitate β–galactosidase activity and autophagy flux respectively. For compound validation, senescence markers, autophagic flux and apoptosis were evaluated.

Results: A primary screening was performed to identify anti-senescence compounds by measurement of senescence-associated β-galactosidase activity. 308 compounds with anti-senescence effects were identified. The anti-senescence hits were analyzed by monitorizing autophagic flux. 42 compounds with both anti-senescence and pro-autophagy effects were selected. Then, 2 compounds were selected for further validation. These compounds significantly reduced senescence ($p < 0.01$) and increased autophagic flux ($p < 0.01$) in response to IL-6. Furthermore, they conferred protection against cell death by apoptosis in human chondrocytes.

Conclusion: These observations provide a unique opportunity to study cartilage aging with the objective to explore the therapeutic potential of pharmacological prevention of chondrocyte senescence and autophagy as a

strategy to slow or reverse aging-associated changes, prevent the onset of OA and provide benefits for its clinical management.

Session Date: Tuesday, November 15, 2016

Session Title: Biology and Pathology of Bone and Joint - Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) involves thinning cartilage and increased subchondral bone. Amongst many cellular processes, inflammation has been associated with OA. Wnt signaling plays a role in mediating inflammation. SM04690, a novel, small-molecule Wnt pathway inhibitor that has previously been shown to regenerate and protect cartilage in an animal model of OA, was evaluated in a series of preclinical studies to determine its potential to inhibit inflammation.

Methods: Wnt pathway inhibition was measured using a cell-based reporter assay. Anti-inflammatory activity was evaluated by measuring TNF-α and IL-6 secretion using ELISA in synovial fibroblasts stimulated with IL1b, THP-1 monocyte cells stimulated with lipopolysaccharides (LPS), and peripheral blood mononuclear cells (PBMCs) stimulated with anti-CD3/anti-CD28. A panel of pro- and anti-inflammatory cytokines (TNF-α, IL-1α, IL-1β, IL-2, IL-6, IL-8, IL-17A, IL-17F, IFNγ, and PGE2) was evaluated by ELISA, T and B cell proliferation by flow cytometry in PBMCs, and T and B cell co-cultures stimulated with super-antigen or LPS, compared to vehicle or benchmark steroids (Cyclosporin A and Prednisolone). The effect of SM04690 on the LPS-induced expression and phosphorylation of NFkB in THP-1 cells was evaluated by qPCR and Western Blot.

Results: SM04690 demonstrated potent (EC_{50} =11nM) and selective inhibition of Wnt signaling. SM04690 inhibited IL-1b-induced TNF-α and IL-6 secretion in synovial fibroblasts (EC_{50} =30nM; Figure A). SM04690 also inhibited LPS and anti-CD3/anti-CD28-induced TNF-α and IL-6 secretion in THP-1 cells (EC_{50} =10nM), and PBMCs. SM04690 significantly inhibited ($p<0.01$, effect size >40%, no toxicity) super-antigen- and LPS-stimulated production of various pro-inflammatory cytokines (TNF-α, IL-1α, IL-1β, IL-2, IL-6, IL-8, IL-17A, IL-17F, IFNγ, PGE2), and T and B cell proliferation in PBMCs and T and B cell co-cultures (Figure B). The anti-inflammatory activity of SM04690 in these assays was comparable to or better than the activities of Cyclosporin

A and Prednisolone. Additionally, SM4690 treatment decreased LPS-induced gene expression (3-fold, $p<0.01$) and phosphorylation of NFkB in THP-1 cells (Figure C).

Conclusion: SM04690, a small molecule Wnt pathway inhibitor was a potent anti-inflammatory agent in various cell types, with inhibition of NFkB signaling *in vitro*. This anti-inflammatory activity of SM4690 may provide beneficial effects in the treatment of various diseases, including OA.

Figure. SM04690 inhibited cytokine production and NFkB expression.

Session Date: Tuesday, November 15, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The recent GWAS and subsequent studies have identified susceptible genes such as CCR1 and IL10 genes, suggesting pathological roles of macrophages in Behçet's disease (BD). The purpose of this study is to compare features of in vitro differentiated M1 and M2 macrophages from peripheral blood between BD and healthy controls (HC).

Methods:

Differentiations into M1 or M2 macrophages were induced in vitro from peripheral monocytes in presence of GM-CSF or M-CSF, respectively. Expressions of CD68, CD163, and CCR1 were determined by realtime PCR and flow cytometric analyses. For the macrophages that were treated with LPS for 24 hours, the supernatants were analyzed for cytokine profiles using beads assay.

Results:

Differentiated M1 macrophage produced higher amounts of IL-6 whereas, M2 macrophage secreted higher volume of IL-10. M2 macrophage has increased expression of CD163 protein and mRNA compared to M1 macrophage. CCR1 expression was increased in M2 macrophage compared to M1 macrophage (Figure 1). Cell surface CCR1 protein expression in M1 macrophage was significantly higher in BD patients compared to HC (Figure 2, t test). BD associated SNP (rs1518111) allele T is risk for decreased expression of IL10 mRNA in HC M2 macrophage.

Conclusion:

The data suggest that both susceptible CCR1 and IL10 genes are implicated in pathogenesis of BD. Further experiments including functional analyses are required to elucidate mechanisms how M1 or M2 macrophages are involved in pathogenesis of BD.

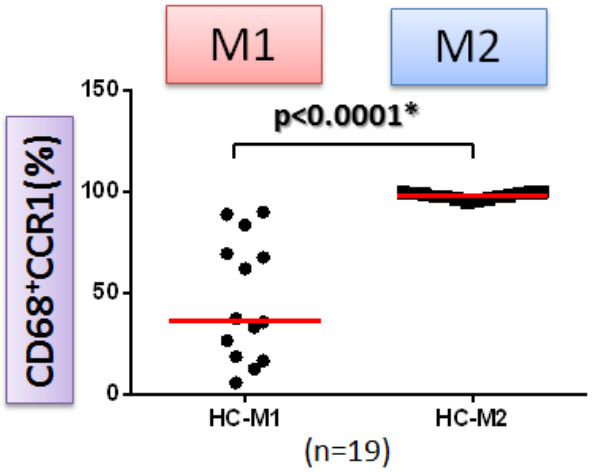

Figure 1: Difference of CCR1 expression between M1 and M2 Mϕ. Flow cytometry result showing elevated expression of CCR1 mRNA in M2 Mϕ.

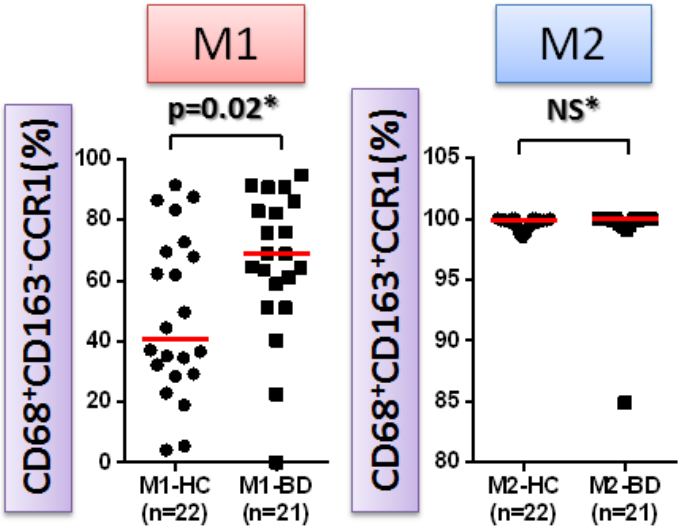

Figure 2: Difference of CCR1 expression between BD and HC. CCR1 expression in M1 Mϕ was significantly higher in flow cytometry analysis.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

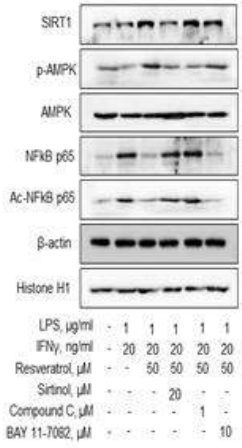
Background/Purpose: The polarization of macrophages was the expressed to M1/M2 phenotype by various

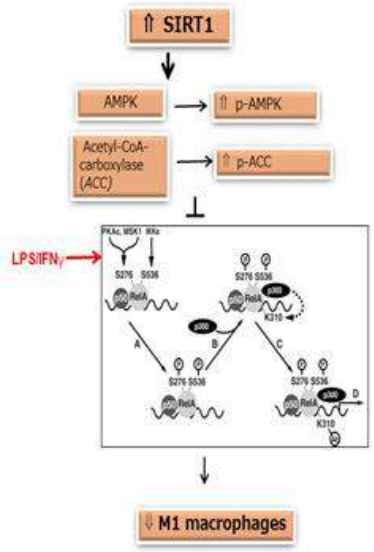
stimuli or environment signals. The M1 macrophage was pro-inflammatory phenotype and was key effector cells in the immune response of rheumatoid arthritis (RA). So, M1 macrophage influenced the inflammation of RA synovial membrane and joint destruction in RA, whereas M2 macrophage was anti-inflammatory phenotype and could down-regulate the production of proinflammatory cytokines in RA. The SIRT1 attenuated the RA inflammation via dawn-regulation of NF-¥êB signaling. However, the effect of SIRT1 on macrophages polarization remained unclear. So we aimed to check out that activated SIRT1 modulated macrophages polarization into M1 phenotype and controlled the inflammation of RA.

Methods: Monocytes from synovial fluid of RA patients, bone marrow–derived monocytes (BMDCs) from mice were studied. monocytes were cultured with M-CSF for 7days to differentiate into M0 macrophages (monocyte-derived mature macrophages M0 phenotype). M0 macrophages were incubated with LPS and IFN-gamma in order to obtain M1 macrophages. M1 macrophage markers were detected by real-time PCR.

Results: Activation of SIRT1 was achieved by Resveratrol, activated SIRT1 attenuated M1 macrophage phenotypes and pro-inflammatory cytokine expression. macrophages obtained from SIRT1-tg mice, which were overexpression of SIRT1, exhibited decreased M1 markers in association with enhanced activation of AMPK/ACC compared with macrophage from control C57BL/6 mice. In addition to SIRT1 activation, M1 polarizing signal, acetylation of NF-¥êB p65, was suppressed. In SIRT1-deficient macrophages, resveratrol fail to increase AMPK activity and to decrease the expression M1 markers owing to enhanced acetylation of NF-¥êB p65.

Conclusion:





SIRT1 maybe an important modulator of M1 macrophages polarization and increased AMPK activity, that suppressed acetylation of NF-¥êB p65 during inflammation of RA. so, modulation of SIRT1 maybe a new target in RA treatment.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-31 (IL-31) has been implicated in pruritus associated with various itchy skin diseases, including atopic dermatitis and cutaneous T cell lymphoma. While pruritus is a prominent feature in dermatomyositis (DM), there are few studies to evaluate clinical characteristics and pathogenesis of itch in DM. We examined the prevalence and severity of pruritus in patients with DM, and investigated the presence of IL-31 and IL-31 receptor in skin tissue to explain the pathomechanism of itch in DM patients.

Methods: Pruritus and disease activity of DM were evaluated by a visual analog scale (VAS) and the Cutaneous Disease and Activity Severity Index (CDASI), respectively. Gene expression of IL-31 and IL-31 receptor alpha (IL-31RA) in lesional DM skin was evaluated by qRT-PCR, and was compared with that of non-lesional DM skin, and skin tissue of cutaneous lupus erythematosus (CLE) patients and healthy controls (HC). Immunohistochemical analysis assessed IL-31 expression in skin tissue. The Spearman rank test was used to evaluate the relationship between itch intensity and disease activity, as well as itch intensity and lesional gene expression of IL-31 and IL-31RA. The Kruskal-Wallis test with Dunn's post hoc test was used to compare the difference of IL-31 and IL-31RA mRNA expression, and immunohistochemical analysis of skin IL-31 expression in DM and HC.

Results: About half of 164 patients with DM (25 male, 139 female; 61 classic DM and 103 clinically amyopathic DM; mean age ± SD 52.5 ± 14 years) had moderate to severe itch (28.66% moderate, 20.73% severe itch). Pruritus in DM was positively correlated with disease activity, with a correlation coefficient of 0.337 between VAS itch score and CDASI activity score ($p<0.01$). Skin IL-31 and IL-31RA gene expression was significantly up-regulated in DM compared to HC and CLE ($p<0.05$). IL-31 mRNA expression was positively correlated with VAS itch score ($r= 0.7619$, $p=0.03$). Immunoreactivity for IL-31 was also stronger in lesional skin of DM ($p=0.0001$).

Conclusion: In conclusion, we confirmed that itch is a prevalent symptom in many patients with DM involving the skin, and that skin IL-31 is significantly higher in DM than CLE and HC. This is the first study to suggest IL-31's crucial role in the skin for pruritus in DM.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Systemic Autoimmune Rheumatic Disease (SARD) often have a prolonged pre-clinical phase during which they are anti-nuclear antibody (ANA) positive but lack clinical symptoms. It has been proposed that progression from asymptomatic autoimmunity to clinical disease is accompanied by immunologic changes that could be used as predictors of disease development. Our objective was to identify cyto/chemokine abnormalities in ANA^+individuals who lack sufficient criteria for a diagnosis of SARD.

Methods: ANA^+ individuals who: 1) lacked clinical symptoms of SARD (ANA No Symptoms, ANS); 2) had a least one clinical symptom of SARD (Undifferentiated Connective Tissue Disease, UCTD); or 3) had a recently diagnosed steroid and immunosuppressive naïve SARD were recruited, and compared with ANA^- healthy controls (HC). The levels of 30 cyto/chemokines were measured, 29 by Luminex and one (BAFF) by ELISA. Peripheral blood interferon (IFN)-induced and BAFF gene expression was quantified by NanoString. The normalized levels of 5 ubiquitously expressed IFN-induced genes were summed to produce an IFN5 score.

Results: Cyto/chemokines were measured in plasma samples for 145 individuals (21 HC, 37 ANS, 28 UCTD, and 59 early SARD (6 SLE, 25 SjD, 25 SSc, and 3 MCTD/DM)). The plasma levels of four cyto/chemokines, IP-10, eotaxin, BAFF, and TNF-α, were significantly elevated in early SARD patients when compared to HC (Bonferroni corrected $p = 0.0001, 0.0006, 0.003, 0.033$, respectively). The levels of IP-10, eotaxin, and TNF-α were not significantly elevated in ANS and UCTD individuals as compared to HC. Although there was a trend to elevated serum BAFF levels in UCTD and ANS individuals, this only achieved statistical significance in UCTD patients ($p = 0.037$ and 0.065, respectively). However, ANS individuals had significant elevations of *BAFF* RNA in their peripheral blood ($p = 0.009$). We have previously reported that all ANA^+ subgroups (ANS, UCTD and early SARD) have significantly elevated IFN5 scores. The levels of IP-10, serum BAFF, and *BAFF* RNA

were positively correlated with IFN5 scores in ANA^+individuals, suggesting that these pro-inflammatory factors are induced by type I IFN.

Conclusion: Although elevated levels of several pro-inflammatory factors are seen in early SARD patients, these factors are not elevated in ANA^+ individuals who lack sufficient criteria for a diagnosis of SARD. Thus, elevations of pro-inflammatory factors appear to parallel progression to clinical disease.

Session Date: Tuesday, November 15, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular (CV) comorbidity is common in rheumatic diseases and includes accelerated atherosclerosis and inflammatory valvular heart disease (iVHD). KRN T cell receptor (TCR) transgenic mice congenically expressing the H-2^{g7}MHC class II molecule (K/B/g7) develop spontaneous autoimmune arthritis and provide a powerful tool for understanding the effects of chronic inflammation on the cardiovascular system. In particular, K/B/g7 mice develop iVHD with many features mirroring human pathology. By 3 weeks of age their mitral valves (MVs) uniformly demonstrate histological evidence of inflammatory infiltration. By 8 weeks, drastic MV leaflet thickening with increased collagen content and accumulation of inflammatory monocytes is apparent. Here we explored the molecular mechanisms driving iVHD in K/B/g7 mice.

Methods: Serum TNFα and IL-6 are elevated in K/B/g7 mice. Due to the established roles for these cytokines in the pathogenesis of rheumatoid arthritis and iVHD in humans, we hypothesized that they are critical mediators of iVHD in the K/B/g7 model. We used neutralizing monoclonal antibodies to test this hypothesis, treating one

cohort of K/B/g7 mice at the time of iVHD onset (4 weeks of age, initiation) and another after iVHD had been established (6 weeks of age, maintenance). The mice were given twice weekly injections of 200 μg mAb blocking TNFα, IL-6, VCAM-1, or α4β1 integrin (very late antigen 4, VLA-4) for 4 weeks. We assessed arthritis severity during the treatment period. The effect of these blocking antibodies on iVHD was determined using histological assessment and immunofluorescent staining and compared to animals that received injections of isotype control mAb.

Results: Neutralization of TNFα or IL-6 prevented iVHD progression. In both cases, this was correlated with significantly reduced expression of VCAM-1 at the blood-endothelial interface and also with significant reductions in arthritis severity. Neutralization of VCAM-1 or α4β1 did not reduce the severity of joint inflammation, but completely prevented induction of iVHD. Interestingly, when used as a treatment for established iVHD, only TNFα and VCAM-1 neutralization reduced iVHD severity, but neither significantly reduced the severity of established arthritis.

Conclusion: These studies identify a TNFα/IL-6-VCAM1-α4β1 axis as a critical driver of iVHD initiation and maintenance in K/B/g7 mice. Ongoing studies utilizing conditional gene knockouts aim to confirm the dominant inflammatory cellular element(s) recruited to the valve tissue via surface expression of α4β1. These results may inform treatment strategies for repurposing existing therapeutics (e.g. natalizumab) to treat iVHD in the setting of systemic rheumatic diseases.

Background/Purpose: Synovial fibroblast plays a key role in rheumatoid arthritis (RA), which is a chronic polyarticular inflammatory disease. SF are able to migrate long distances *in vivo* via the vasculature as previously shown in our SCID mouse migration model. In inflammatory processes, adipose tissue plays an important role as an endocrine organ. Some of its effects may be mediated by immunomodulating adipokines. RASF and endothelial cells (EC) are affected by adipokines in RA. The interaction between RASF and EC may be a crucial process in the migration of RASF through the vasculature.

Methods:

The expression of selected adhesion molecules from RASF and EC was analyzed by real-time PCR. For this purpose, primary RASF and EC were stimulated with adiponectin (10 µg/ml), visfatin (100 ng/ml) and resistin (20 ng/ml), and "therapeutically" with methotrexate (1.5 µM) and the glucocorticoids prednisolone (1 µM) and dexamethasone (1 µM).

RASF adhesion to EC was studied under flow conditions (flow rates: 18.4/30.5/60.5 ml/h) in a dynamic adhesion assay as flow conditions are required for selectins to obtain their active conformation.

Results:

Under dynamic flow condition, which simulate the blood flow *in vivo*, the adhesion of RASF to EC was increased after stimulation with visfatin (+156%/+87%/+89%) and TNF-α (+61%/+18%/+19%). On the other hand, reduced adhesion was observed after stimulation with dexamethasone (-9%/-39%/-53%) and prednisolone (-31%/-64%/-53%). In EC, TNF-α upregulated the expression of ICAM-1 (47-fold; n=9), while adiponectin decreased it (-2.9-fold; n=5). The expression of VCAM-1 was slightly decreased after stimulation with adiponectin (-1.3-fold; n=5) in EC, whereas TNF-α led to a strong upregulation (235-fold; n=7). P- Selectin was down-regulated after stimulation with TNF-α (-8.6-fold; n=7) in EC. The expression of integrin α2 was upregulated after stimulation with resistin (2.8-fold; n=7) and TNF-α (13-fold; n=6). Only TNF-α increased the expression of ICAM-1 (40-fold; n=5) in RASF, while both visfatin (2.9-fold; n=10) and TNF-α (59-fold; n=9) increased the expression of VCAM-1 in RASF.

Conclusion:

During migration of RAFS *in vivo,* the adhesion of RASF to EC most likely plays a key role. Adipokines increase the adhesion of RASF to EC under dynamic flow conditions. Migration of RASF and spreading of RA to different joint could therefore be enhanced by the influence of adipokines on adhesion molecules and their effect strengthening the adhesion of RASF to EC. Glucocorticoids caused the opposite effect, which could explain some of the protective effects observed in patients. Adipokines alter the expression of adhesion molecules and the RASF/EC interaction with the effects differing between adipokines.

Session Date: Tuesday, November 15, 2016
Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: : IL-22 is a member of IL-10 family, with both anti- inflammatory and pro- inflammatory functions, orchestrating the immune and inflammatory response.IL-22 is secreted by dendritic cells and T lymphocytes and act on non hematopoietic cells. Co-expressed IL-17A regulates the pro-inflammatory versus tissue-protective functions of IL-22. Behçet's disease (BD) is a chronic systemic inflammatory disorder at the crossroad between autoimmune and auto inflammatory syndromes. Uveitis is a sight threatening condition affects 60-80 % of the BD patients (pts).We aimed at this study to investigate the potential role of IL - 22 in uveitis associated with BD.

Methods: Serum IL-22 was detected by ELISA in 35 uveitis pts and 10 healthy controls enrolled in 4 groups ; Group 1: pts with active uveitis associated with BD(n=11),Group 2: pts with inactive uveitis associated with BD (n=12), Group 3 : pts with uveitis without apparent auto immune and /or rheumatic manifestations (n=12) and Group 4 :healthy controls (n=10).

Results: The mean serum level of IL- 22 of BD pts with active uveitis was significantly very high compared to the control (p=0.001),the mean serum level of IL – 22 of BD pts with inactive uveitis was significantly high compared to those of healthy controls (p=0.001), the mean serum levels of IL-22of BD pts with active uveits was significantly higer than those of BD pts with inactive uveitis (p=0.01), the mean serum levels of IL-22 of non Behçet's uveitis was not significantly different compared to healthy controls .Although comparing the mean serum levels of IL-22 based on site of ocular inflammation there was no statistical significance, it seems that pts of non Behçet's with posterior uveitis had higher levels of IL-22 compared to those with anterior uveitis in the same group denoting the potential role of IL 22 in vasculopathy involving the choroid plexus.

Conclusion: We could suggest that IL - 22 play an important potential role in the pathogenesis of uveitis associated with BD vasculopathy and may serve as a biomarker of disease activity.

Session Date: Tuesday, November 15, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The development of giant-cell arteritis (GCA) lesions requires amplification cascades resulting in continuous recruitment of lymphocytes and monocytes. Interferon-gamma (IFNg)- induced or up-regulated chemokines CCL-2, CXCL9, CXCL10, and CXCL11 play an important role in inflammatory cell recruitment, a process in which not only endothelial cells but also vascular smooth muscle cells (VSMC) seem to be involved (Corbera-Bellalta M et al Ann Rheum Dis 2016). CX3CL1, also known as fractalkine, and along with its unique receptor CX3CR1, are the only members of CX3C chemokine/ chemokine receptor family. CX3CL1 has two isoforms mediating different functions. The transmembrane protein form regulates cell adhesion, while the soluble one (generated by proteolytic cleavage) has chemotactic function. Soluble fractalkine is elevated in serum from patients with small-vessel vasculitis. However, expression of fractalkine and its receptor have not been explored in GCA. To explore CXCL1/CXCR1 expression in GCA lesions and in temporal artery- derived VSMC.

Methods: RNA was extracted from fresh temporal arteries of 12 GCA patients and 8 healthy controls using chloroform-isopropanol classic method. CX3CL1 mRNA expression was assessed by quantitative real-time PCR (Applied Biosystems). Fresh arteries from 1 GCA patient and 1 control were subjected to immunofluorescence using specific antibodies (Cell Signaling). VSMC obtained from cultured temporal arteries were treated with IFNg and/or TNFa for 3 days, and CX3CL1 expression by VSMC was detected by realtime PCR.

Results: CX3CL1 mRNA expression was constitutively expressed by control arteries and downregulated in GCA lesions compared with controls, probably due to VSMCs loss in the media of inflamed arteries. Consistently, immunofluorescence studies disclosed that CX3CL1 protein expression was intensively expressed by the endothelium of the GCA-involved artery and by VSMC remaining in the media. CX3CR1 was expressed by infiltrating leukocytes in GCA. As with other chemokines, CX3CL1 expression was significantly up regulated in VSMC cultured in the presence of inflammatory mediators (IFNg and TNFa). VSMC did not express CX3CR1.

Conclusion: Fractalkine and its receptor are expressed in GCA lesions. VSMCs react to the presence of inflammatory cytokines by expressing CX3CL1, highlighting a possible role of this chemokine not only in leukocyte recruitment by endothelial cells but also in leukocyte progression through the VSMC in the medial layer. Functional chemotaxis studies are ongoing to confirm this point. Supported by SAF 2014/57708-R and PIE13/00033

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Calgizzarin (S100A11) is a member of the S100 protein family that acts in different tumors via regulating number of biologic functions. Recent data suggest its association with low grade inflammation in OA. The aim of the study was to analyze the expression of S100A11 in synovial tissue, synovial fluid and serum of patients with rheumatoid arthritis (RA) and osteoarthritis (OA) and to characterize its potential association with disease activity.

Methods: S100A11 expression was analyzed in synovial tissues from patients with RA (n=6) and OA (n=6) by immunohistochemistry. Immunofluorescence staining was used to co-localize S100A11 within RA synovial tissue (n=4). Serum and synovial fluid S100A11 levels were measured by ELISA (Biovendor) in 40 patients fulfilling the American College of Rheumatology criteria for the classification of RA and in 39 subjects with OA. Disease activity score based on 28 joints (DAS28-CRP) was used to assess disease activity. For in vitro experiments, peripheral blood mononuclear cells (PBMCs) and synovial fibroblasts (SFs) were obtained from patients with RA and OA (n=6-9). Expression and protein synthesis of S100A11 and cytokines were analyzed by RT-PCR, ELISA and Western Blot.

Results: The expression of S100A11 was significantly up-regulated in the synovial lining and sublining layers ($p<0.01$) and vessels ($p<0.05$) in patients with RA compared to OA and its expression was associated with fibroblasts, T lymphocytes and macrophages. Serum (14.13 [4.26-119.8] vs. 9.50 [4.95-30.16] ng/ml; $p=0.004$) and particularly synovial fluid (195.8 [20.22-974.2] vs. 28.40 [8.20-259.80] ng/ml; $p<0.0001$) S100A11 levels were significantly increased in patients with RA compared to OA. Moreover, the levels of S100A11 were higher in synovial fluid compared to serum in both RA and OA patients ($p<0.0001$). In patients with RA, synovial fluid S100A11 correlated significantly with DAS28 ($r=0.350$, $p=0.027$), CRP ($r=0.463$, $p=0.003$), synovial fluid leukocyte count ($r=0.677$, $p<0.001$), ACPA ($r=0.424$, $p=0.006$), but not with IgM-RF ($r=0.059$, $p=0.719$). No such associations were observed in serum. In addition, S100A11 is synthetized and spontaneously secreted in higher concentrations by PBMCs ($p=0.01$) and SFs ($p=0.03$) isolated from patients with RA in comparison with OA. Extracellular S100A11 protein stimulates the production of pro-inflammatory cytokines IL-6 and TNFα in PBMCs ($p<0.05$) and SFs ($p<0.01$).

Conclusion: Our data provide the first evidence of S100A11 up-regulation and its association with inflammation and disease activity in patients with RA. Acknowledgement**:** Supported by grant 15-34065A of the Agency for Healthcare Research of the Czech Republic and MHCR 023728.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: RANTES/CCL5 (RANTES) is a C-C chemokine that binds to its receptor (CCR5) and initiates inflammatory processes in rheumatoid arthritis (RA) by facilitating leukocyte infiltration. Syndecans (also known as heparin sulfate proteoglycans, HSPGs) modulate chemokine interaction with the endothelium thereby facilitating leukocyte infiltration. However, the role of RANTES/CCL5 beyond its chemotactic activity and the role of syndecans in RANTES/CCL5 induced matrix metalloproteinase (MMP)-1 and MMP-13 expression is not yet studied. The present study was carried out to determine the role of syndecans on the RANTES/CCL5 induced MMP-1 and MMP-13 expression in human rheumatoid arthritis synovial fibroblasts (RASFs).

Methods: Human RASFs and normal SFs (NLSFs) were isolated from de-identified RA synovial tissues and healthy synovial tissues, respectively, under the IRB approved protocol. Basal cell lysates were prepared to study the expression of syndecan-1, -2, -3, and -4) was studied using qRT-PCR and Western immunoblotting methods. RASFs were treated with RANTES/CCL5 (20-100 ng/ml), IL-1β (10 ng/ml), or TNF-α (20 ng/ml) for 24 h alone or in presence of a known HSPG inhibitor, Heparinase III (0.5 U/ml). Effect of RANTES/CCL5 on MMP-1 and MMP-13 expression was evaluated using qRT-PCR and ELISA methods. Conditioned media was collected and concentrated for to determine MMP-1 and MMP-13 expression using Western immunoblotting. $p<0.05$ was considered significant.

Results: Our results showed that RANTES/CCL5 significantly induced MMP-1 and MMP-13 mRNA and protein expression ($p<0.05$). Since syndecans influence inflammatory processes by interacting with chemokines, we compared the basal expression levels of syndecans in NLSFs and RASFs. Our qRT-PCR results showed that the expression of syndecan-2 (~320%) and syndecan-4 (~80%) was significantly higher in RASFs when compared to NLSFs ($p<0.05$). No significant changes were observed in syndecan-1 and syndecan-3 expression

in RASFs compared to NLSFs. Furthermore, Western immunoblotting results confirmed that RASFs showed an increase in expression of syndecan-2 (~300 %) and syndecan-4 (~290 %) with ($p<0.05$) with no significant change in syndecan-1 and syndecan-3 expression compared to NLSFs. In addition, further stimulation of RASFs with RANTES/CCL5, IL-1β, or TNF-α for 24 h resulted in a selective induction in syndecan-2 and syndecan-4 expression ($p<0.01$) compared to the non-stimulated control. RANTES/CCL5, IL-1β, or TNF-α stimulation did not alter syndecan-1 and syndecan-3 expression in RASFs. To study whether RANTES/CCL5 induced MMP-1 and MMP-13 expression is modulated by syndecans in RASFs, we evaluated the effect of Heparinase III (HSPG inhibitor) on the ability of RANTES/CCL5 to induce MMP-1 and MMP-13 expression in RASFs. Analysis of the conditioned media showed that pretreatment with Heparinase III significantly reduced the ability of RANTES/CCL5 to induce MMP-1 and MMP-13 protein expression in RASFs ($p<0.05$).

Conclusion: Human RASFs express higher levels of syndecan-2 and syndecan-4 compared to NLSFs. In general, syndecans may also contribute to the process of tissue destruction in RA by mediating RANTES/CCL5-induced MMP-1 and MMP-13 expression in RASFs.

Novel Pathogenic Functions of IL-11 on RA Joint Fibroblasts and Endothelial Cells

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease affecting 2.5 millions of Americans. Several cytokines are involved in RA pathogenesis and may serve as potential therapeutic targets. IL-11, a member of the IL-6 family of cytokines, plays important roles in a number of physiological functions. However, pathological overexpression of IL-11 in autoimmune diseases, including RA, has also been described. Despite its overexpression in RA joint, data from studies describing the role of IL-11 in RA are controversial. In phase I/II studies, treatment with IL-11 did not affect disease activity, while others established that patients in remission had lower serum IL-11 levels that correlated with disease activity score (DAS)28 improvement. To address these controversies, we sought to elucidate the expression pattern, and functional role of IL-11 and IL-11R in RA synovitis.

Methods:

IL-11 and IL-11Ra expressions were determined in RA tissues and cells (RA subjects meet the 1987 Revised Criteria for RA Classification) using immunohistochemistry and ELISA. IL-11 effector functions on RA fibroblasts and endothelial cells were studied using scratch assay and endothelial cell migration and tube formation.

Results: We found that IL-11 levels were significantly higher in RA synovial fluid (SF) compared to osteoarthritis (OA) SF (47 fold) and plasma from RA (19 fold), OA (75 fold) and normal (NL) (18 fold) volunteers. The expression of IL-11 was significantly elevated (2 fold) in the sublining endothelial cells of RA relative to NL synovial tissues (STs). In addition, the expression of IL-11 was higher (2.5 fold) in the lining fibroblasts of RA compared to OA STs. Both histology and Western blot analysis demonstrated that IL-11Ra is expressed in RA ST fibroblasts and endothelial cells but not in NL or RA macrophages. IL-11 expression was enhanced in RA ST fibroblasts primarily by IL-1b; however, expression in endothelial and RA monocytes and macrophages was only promoted by RA SF. Employing RA fibroblasts based scratch assay, we observed that IL-11 could dose dependently promote RA fibroblast proliferation through IL-11Ra starting at 100 ng/ml, as the proliferative effect was abrogated in the presence of IL-11Ra-Fc chimeric protein. In addition, IL-11 induced synovial fibroblasts to release IL-8 and VEGF which contributed to endothelial cell transmigration and tube formation. Furthermore, IL-11, starting at a dose of 1 ng/ml, induced endothelial cell migration (13-75 fold) and tube formation (19 fold) indicating that IL-11 can contribute to angiogenesis at a physiologically relevant concentration (up to 3.7 ng/ml is expressed in RA SF). The addition of the soluble IL-11Ra-Fc chimeric protein reduced the IL-11 induced endothelial cell migration by 50% and abrogated the tube formation driven by RA SF suggesting that the IL-11 pro-angiogenic effect is mediated through IL-11Ra.

Conclusion: The binding of IL-11 to IL-11Ra on RA fibroblasts and endothelial cells promoted cell proliferation and angiogenesis respectively. Therefore, our study suggests that IL-11 may be responsible for synovial fibroblast hyperplasia and it further potentiates disease severity by increasing the invasion of blood vessels into the RA pannus.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although elevated IL-6 and its soluble receptor (sIL6R) have been found in the serum and synovium of arthritic patients, the molecular mechanisms by which it contributes to the pathogenesis of rheumatoid arthritis (RA) is not fully understood. Fibroblast-like synoviocytes (FLS) are one of the key players in the chronic inflammation of RA. Despite the knowledge provided by different studies, it is not fully resolved how cytokines present in the inflammatory environment of the RA synovium and particularly IL-6, synergize and contribute to the establishment of the rheumatoid arthritis synovial fibroblast (RASF) inflammatory phenotype.

Methods: Total RNA was extracted from 8 HSF lines and 5 RASF stimulated with either TNF-α (20ng/ml), IL-6 and sIL-6R (20ng/ml each) or in combination for 24h were used for this study. The cRNA from 4 HSF lines stimulated with either TNF-α or IL-6 and sIL-6R was hybridized in Affymetrix GeneChip® PrimeView™ Human Gene Expression Array platform containing a total of 49,395 probe sets. The microarray data analysis was performed by using Expression Console and Transcriptome Analysis Console (TAC) software (Affymetrix). Additionally, differentially expressed genes were analyzed to identify potential functional pathways using the Database for Annotation, Visualization and Integrated Discovery (DAVID). Validation of microarray data as well as synergy and priming experiments were performed by quantitative RT-PCR using specific primers.

Results: Using microarray analysis we identified genes differentially regulated (≥2 folds vs control) by the trans-signal activation of IL-6 (522 genes) and TNF-α (2640 genes) in FLS cells in culture. Interestingly, we found a significant overlap between TNF-a and IL-6/sIL-6R regulated genes. Almost 55% (287 genes) of total IL-6/sIL-6R regulated genes are common to those of TNF-a. Simultaneous induction of FLS cells with both factors synergistically stimulated the expression of selected common genes as MCP-1 and IL-6 genes, in contrast to CCL5 or IL-8 which are only activated by TNF-a in our cellular system. These data suggest that the crosstalk between TNF-a and IL-6/sIL-6R controls specific group of genes. Furthermore, stimulation of RASF cells with both inflammatory factors further enhanced the expression of these genes up to 10 fold compared to non-pathological FLS. In addition, priming experiments stimulating FLS cells with either TNF-a or IL-6/sIL-6R, followed by induction with the counterpart factor at different time-points, demonstrated that the synergistic effect requires the constant presence of both factors. These data suggest that the mechanism of crosstalk between TNF-a and IL-6/sIL-6R more likely occurs through regulation of signaling and/or transcriptional mediators rather than at a post-transcriptional level.

Conclusion: Our study suggests that despite the differential IL-6 and TNF-a intracellular signaling, there is significant overlap between the transcriptional response induced by both factors. In addition, a potent synergistic effect was confirmed for some target genes, pointing to a relevant interaction of both cytokines in the RASF pro-inflammatory effector response.

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Iinterleukin(IL)-6 and tumor necrosis factor(TNF)-α play important roles in the pathogenesis of RA, however, it remains unclear how they affect or modulate the cell cycle of Rheumatoid Arthritis Fibroblast-Like Synoviocyte (RA-FLS). Cyclins, Cyclin-Dependent Kinases (CDKs) and CDK inhibitors (CDKIs) co-operate to regulate the cell cycle, and several conditions such as replicative senescence, irradiation, low serum culture and high cellular density culture are reported to induce the expression of CDKIs, including INK4 family and Cip/Kip family, resulting in inhibiting the growth of RA-FLS (Rheumatoid Arthritis Fibroblast-Like Synoviocyte) (1). In this study, we investigated the expression of Cell Cycle regulators under stimulations of IL-6 and TNF-α.

Methods: Under stimulations of IL-6/ soluble IL-6 receptor (100 ng/ml) or TNF-α (10ng/ml), total RNA and protein were extracted from RA-FLS to analyze expressions of CDK inhibitors($p16^{INK4a}$, $p21^{Cip1}$ and $p27^{Kip1}$) by real-time PCR, and Cyclin D1 by Western Blot, respectively.

Results: Expressions of $p16^{INK4a}$ was decreased by IL-6 stimulation and $p27^{Kip1}$ was increased by TNF-α, whereas $p21^{Cip1}$ was not changed. The expression of Cyclin D1 was increased by both of IL-6 and TNF-α.

Conclusion: In RA-FLS, IL-6 and TNF-α modulate the expression of $p16^{INK4a}$, $p27^{Kip1}$ genes, and induce the expression of Cyclin D1. Our results suggest IL-6 and TNF-α co-operate to drive the G1 to S phase transition in the cell cycle of RA-FLS. **Reference:** 1. Ken Taniguchi et al. *nature medicine* 1999 Jul;5(7):760-7.

Share the Fate: Fibroblast-like Synoviocyte Cell-to-Cell Organelle Transfer Is Directed By the Inflammatory Microenvironment

Ruth Byrne[1], Isabel Olmos Calvo[2], Thomas Karonitsch[3], Felix Kartnig[4], Johannes Holinka[5], Günter Steiner[6], Peter Ertl[7], Josef Smolen[8] and **Hans Peter Kiener**[9], [1]Rheumatology, Internal Medicine III, Medical University of Vienna, Vienna, Austria, [2]Nanotechnology, Austrian Institute for Technology, Vienna, Austria, [3]Internal Medicine III, Vienna Medical University, Vienna, Austria, [4]Department of Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria, [5]Department of Orthopaedics, Medical University of Vienna, Vienna, Austria, [6]Internal Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria, [7]Vienna University of Technology, Vienna, Austria, [8]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [9]Division of Rheumatology, Medical University of Vienna, Vienna, Austria

Session Title: Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Fibroblast-like synoviocytes (FLS) form a complex tissue network via long-distance intercellular connections with wide intercellular matrix spaces. The adaptive synovial tissue response to inflammation likely depends upon the concerted activity of FLS. Using an in-vitro synovial organ culture system, we explore mechanisms of FLS directional cell-cell cooperation.

Methods: Human FLS were prepared from synovial tissues obtained as discarded specimens following joint arthroplasty. Cells were labeled with cell tracker dyes or specific organelle dyes and cultured in spherical matrigel micromasses. For selected experiments, micromasses were challenged with TNF or IFN-gamma. Data was acquired by confocal live cell imaging. Analysis of the resulting 4D movies was done using Imaris® software.

Results: To examine whether FLS transfer cytoplasmic cargo, we labeled 50% of FLS with green cell tracker dye and the other 50 % with Mitotracker. Over time, red labeled organelles accumulated in green labeled cells with a transfer rate of 10 % of newly affected cells/day. Confocal live cell imaging revealed that FLS indeed use their long-distance intercellular connections for transfer of organelles. When micromasses were stimulated with TNF (10 ng/ml) the transfer rate increased by 2-fold when compared to control. By contrast, IFN-gamma-stimulation (100 U/ml) resulted in decreased organelle transfer. The combined treatment of micromasses with TNF and IFN-gamma, however, increased the transfer rate to a level beyond stimulation with TNF alone.

Conclusion: Our experiments suggest transfer of cytoplasmic cargo, including organelles such as mitochondria between FLS. As transfer is distinctly regulated by the cytokine milieu, organelle transfer seems to be part of the adaptive synovial response to inflammation. These studies may provide insight into how synoviocytes orchestrate their activity. Further studies will demonstrate the significance of directional cytoplasmic cargo exchange for the function of the normal as well as the diseased synovium.

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Serum uric acid (SUA) has been shown to be a powerful endogenous antioxidant in the body. The double-edged characteristics of serum uric acid (SUA) and mixed results from previous studies have complicated determination of whether SUA plays a pulmonary-protective or pulmonary-destructive role. We hypothesized that SUA could have an important role in protecting the lung from oxidant damage and preventing a decline in pulmonary function. Therefore, we performed this study to investigate the association between SUA and spirometric values in a large sample drawn from a healthy population without overt clinical disease.

Methods: The Kangbuk Samsung Health Study was a cohort study of subjects who underwent a comprehensive annual or biennial examination at Kangbuk Samsung Hospital in Seoul, South Korea. We performed a cross-sectional study on 69,928 Koreans (30,572 men) without overt medical conditions who underwent a health examination in 2010.

Results: : The overall prevalence of hyperuricemia among Korean health screening examinees was 25.5% in males and 8.5% in females. Overall serum urate level was 5.1 ± 1.4 mg/dL in men and 5.0 ± 1.4 mg/dL in women. In sex-stratified analyses of SUA level, mean SUA level was positively associated with a quartile increase in Percent predicted forced vital capacity (FVC%) and forced expiratory volume in 1 s (FEV1%) in both genders ($P < 0.001$). FVC% and FEV1% were positively correlated with SUA in both genders (FVC %: $r = 0.361$; FEV1 %: $r = 0.314$ in males and FVC%: $r = 0.413$; FEV1%: $r = 0.382$ in females, all $P < 0.001$). Increasing levels of FEV1% and FVC% were associated with an increasing incidence of hyperuricemia in both genders, indicating that FVC% and FEV1% are predictive of hyperuricemia independently of other confounding factors. The adjusted ORs for hyperuricemia comparing quartiles 2, 3, and 4 to quartile 1 of FVC% in men were 0.876 (95% CI, 0.809-0.949), 0.631 (0.574-0.695), and 0.311 (0.278-0.349), respectively. The adjusted ORs for hyperuricemia comparing quartiles 2, 3, and 4 to quartile 1 of FEV1% in men were 0.791 (95% CI, 0.729-0.859), 0.565 (0.513-0.623), and 0.302 (0.270-0.337), respectively (P for trend <0.001). Similarly,

the adjusted ORs of hyperuricemia in women decreased significantly across quartiles 2 to 4 of FEV1% and FVC % compared with the highest quartile as the reference group (*P*for trend <0.001).

Conclusion: To the best of our knowledge, this is the first cohort study to show a significant positive association between hyperuricemia and good pulmonary function in a healthy Korean population, supporting the hypothesis that hyperuricemia might have a favorable effect on lung function. Longitudinal follow-up studies are required to confirm this positive association between SUA and lung function.

Allopurinol Use Is Associated with Lower Risk of Peripheral Vascular Disease in the US Elderly

Jasvinder A. Singh[1] and John Cleveland[2], [1]Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [2]Rheumatology, University of Alabama at Birmingham (UAB), Birmingham, AL

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is associated with higher cardiovascular disease risk. Based on our previous work, there is evidence that allopurinol use reduces the risk of myocardial infarction and cardiovascular disease in the elderly. This work attempts to assess whether allopurinol use reduces the risk of peripheral vascular disease.

Methods: We used the 2006-2012 5% random sample of Medicare beneficiaries to study the association of new allopurinol initiation and the risk of incident peripheral vascular disease, in a cohort study. Multivariable-adjusted Cox regression models adjusted for age, gender, race, and Charlson index, in addition to various cardio-protective medications (beta-blockers, ACE inhibitors, diuretics, statins). We calculated hazards ratio (HR) with 95% confidence intervals (CI).

Results: 3,167 of the 26,985 episodes of incident allopurinol use were associated with incident peripheral vascular disease (11.74% episodes). Allopurinol use was associated with reduced hazards of peripheral vascular disease, with unadjusted HR of 0.91 (95% CI, 0.84 to 0.98); multivariable-adjusted HR 0.89 (95% CI, 0.82 to 0.96) (Table 1). Compared to no allopurinol use, only the longest allopurinol use duration was associated with lower HR of peripheral vascular disease: >2 years, 0.77 (95% CI, 0.65 to 0.91). Other factors associated with higher hazard of peripheral vascular disease were: age 75-<85 and ≥85, male gender, higher Charlson index score, and the use of beta-blockers. Allopurinol dose was also significant in univariate analysis but not in the multivariate analysis (Table 2).

Conclusion: Incident allopurinol use was associated with a reduction in the risk of incident peripheral vascular disease; allopurinol dose was not. Only allopurinol use durations greater than 2 years reduced the risk of incident peripheral vascular disease. Future studies need to assess underlying mechanisms of this association and to assess risk-benefit ratio of allopurinol use for peripheral vascular disease prevention. Table 1: Univariate and multivariate adjusted hazard ratios for peripheral vascular disease based on allopurinol use.

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To examine the effect of allopurinol on the risk of incident myocardial infarction (MI) or stroke in patients with gout and diabetes

Methods: We used the 2007-2010 Multi-Payer Claims Database (MPCD) that linked health plan data from national commercial and governmental insurances, representing beneficiaries with United Healthcare, Medicare, or Medicaid coverage. In patients with gout and diabetes, we assessed whether current allopurinol use, defined as a new filled prescription for allopurinol, was associated with the risk of first Incident hospitalized MI or stroke (composite acute cardiovascular event), after which observations were censored. Multivariable-adjusted Cox proportional hazards models included demographics, cardiovascular risk factors and comorbidities; hazard ratios [HR] (95% confidence intervals [CI]) were calculated. Sensitivity analyses included additional adjustment for immune diseases and colchicine use.

Results: There were 2,053,185 person days of current allopurinol use and 1,671,583 person days of prior allopurinol use. There were 158 incident MIs or strokes in current and 151 in prior allopurinol users, respectively. Compared to previous allopurinol users, current allopurinol users had significantly lower adjusted hazard of incident stroke or MI, HR=0.67 (95% CI, 0.53, 0.84). Compared to previous allopurinol use for 0-6 months, current allopurinol use for 0-6 months was associated with significantly lower risk of incident MI or stroke, 0.61 (95% CI, 0.46, 0.81). Sensitivity analyses confirmed these findings.

Conclusion: Allopurinol use was protective against the occurence of acute cardiovascular events in patients with gout and diabetes. Future studies should explore the key mechanisms of allopurinol's potential cardio-protective effect.

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While inflammation is linked with higher blood pressure (BP) in the general population, few studies have examined this relationship in patients with elevated levels of inflammation. Previous studies suggest that elevated levels of inflammation may modify the relationship between traditional cardiovascular (CV) risk factors and CV risk. The objective of this study was to examine the relationship between inflammation and systolic BP (SBP) across a broad range of high sensitivity C-reactive protein (hsCRP) levels, in a large outpatient cohort including but not limited to patients with rheumatic conditions.

Methods : We studied all outpatients at two large tertiary care centers (Outpatient cohort), between January 1, 2009 and December 31, 2010, using data from the electronic medical records (EMR). The National Health and Nutrition Examination Survey (NHANES), a general population cohort, was studied using the same time period. Inclusion criteria for both cohorts were age>=18 years with hsCRP and BP measured on the same day. Since graphical assessment of hsCRP (common log transformed) and SBP in the outpatient cohort showed a non-linear association, we constructed a generalized additive model with penalized splines to examine the association between hsCRP and SBP. All models were adjusted for age, gender, race and use of anti-hypertensive therapy. The same method was applied to the NHANES cohort**.** We reviewed the medical records of 50 random patients in the highest hsCRP decile to determine the most frequent diagnosis.

Results : We studied 24,203 subjects from the outpatient cohort and 5,332 from NHANES (**Table**). In the outpatient cohort, we observed al non-linear relationship between hsCRP and SBP. Higher hsCRP was associated with higher SBP at hsCRP levels <7.8mg/L. At levels above 7.8 mg/L, hsCRP was inversely associated with SBP. In NHANES, we observed a linear relationship where an increase in hsCRP was associated with an increase in SBP (**Figure**). In the outpatient cohort, the most frequent diagnosis for patients in the highest decile hsCRP was inflammatory arthritis (50%), of which rheumatoid arthritis was the most common.

Conclusion : In a large outpatient cohort, we observed a positive linear relationship between hsCRP and SBP when hsCRP <7.8 mg/L. This relationship is consistent with previously published studies, and replicated in our NHANES analysis. However, at levels above hsCRP of 7.8 mg/L, there was an inverse relationship between hsCRP and SBP. These findings suggest the need for careful consideration of BP as a CV risk factor in patients with active inflammation.

Table. Characteristics of participants in the outpatient cohort and the National Health and Nutrition Examination Survey (NHANES)

Characteristic	Outpatient Cohort N=24203	NHANES N=5332
Age at measurement, years, mean (SD)	54.45 (15.52)	48.40 (18.37)
Female (%)	62.51	50.68
Ethinicity (%)		
Non-Hispanic White	80.42	48.61
Non-Hispanic Black	5.47	16.64
Others	14.21	34.75
Anti-hypertensive medication use (%)	25.36	31.08
C-reactive Protein, mg/L, median (25th, 75th)	2.20 (0.90, 6.00)	0.19 (0.08, 0.44)
Systolic Blood Pressure, mm/Hg, mean (SD)	126.76 (16.85)	122.48 (18.34)
Diastolic Blood Pressure, mm/Hg, mean (SD)	76.07 (15.40)	69.47 (11.95)

Figure. The relationship between high sensitivity C-reactive protein levels (hsCRP) and mean systolic blood pressure (SBP) with 95% confidence intervals, in the outpatient cohort and NHANES*.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoid (GC) therapy is used widely in patients with inflammatory diseases. However their effectiveness is offset by a range of potential harms. Clinicians and patients have differing views on the importance of certain side effects with GC therapy, which can lead to misunderstanding and a breakdown in doctor-patient relationships. People now readily share their thoughts and experiences of health related matters on social media such as Twitter, including information about medications and their side effects. There are now vast amounts of information within this domain that could return useful knowledge about patient reported adverse events (AEs) with their medications. The aim of this study was to detect and quantify GC-related AEs using a computerised system for automated suspected adverse drug reaction (ADR) detection from narrative text in Twitter.

Methods: All Tweets mentioning prednisolone or prednisone between 1st October 2012 and 30th June 2015 were acquired and anonymised before being processed through automated natural language processing software which mapped possible symptoms (e.g. can't sleep) to preferred terms (PTs) in the Medical Dictionary for Regulatory Activities (MedDRA®) dictionary (e.g. insomnia). Tweets were automatically categorised using a Bayesian probabilistic model based on their likelihood of containing text relating to a GC related adverse drug reaction (ADR). Tweets with high probability of containing an ADR, defined as proto-AE tweets, were further analysed to determine which AE symptoms appeared most commonly.

Results: There were 81,524 distinct tweets mentioning prednisolone or prednisone between the specified dates. 20,206 were identified as proto-AEs i.e. had a high probability of representing an ADR. Within proto-AE tweets, 26,894 unique PTs were captured. The 5 most commonly reported PTs in proto-AE tweets were 'insomnia' (8.6%), 'weight increased' (8.2%), 'non-specific reaction' (7.8%), 'increased appetite' (7.5%) and 'malaise' (4.4%) (Figure 1). The top 5 and 25 PTs accounted for 25.0% and 74.6% of all AE PTs respectively.

Conclusion: Insomnia and weight gain were the most frequently reported GC-related AEs posted on Twitter. There remains a disconnect between the frequency of these patient reported AEs and our collective knowledge about these events. Pharmacovigilance in Twitter has the potential to be a valuable, supplementary source of data for determining which drug side effects patients most commonly find troublesome

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Depression can easily go unnoticed in routine clinical care. The delay in the diagnosis

may increase the risk of chronicity, the number of visits, health care costs and deteriorates the quality of life. . The aims of our study was to estimate the prevalence of depressive symptoms in patients consulting for the first time and determine if patients with depression had different reasons for consultation and highest score in the visual analog scale (VAS) of pain than patients without depression.

Methods: A observational, prospective study was performed. We included patients who consulted for the first time in Rheumatology Service, excluding these with psychiatric treatments and rheumatic diseases. The PHQ-9 (Patient Health Questionnaire) evaluated the presence of depressive symptoms in the last two weeks. According to the score, they were classified in 4 categories: (1) major depressive syndrome, (2) other depressive disorders, (3) positive depressive symptoms and (4) negative depressive symptoms. To perform the analysis the patients were divided into those with a depressive disorder (1 and 2) and those who did not have it (3 and 4). T-test or Mann Whitney test was used as sample size distribution for continuous variables. Chi square or Fisher exact test was used as expected frequency distribution table for categorical variables. Multivariate logistic regression analysis taking depression as the dependent variable was performed.

Results: 121 patients were included in the study. 86% were women, mean age of 49±15 years. The most frequent reasons for consultations were polyarthralgia (35.5%) and back pain (13%). According PHQ-9, 37% of patients were classified in major depressive syndrome and 19% in other depressive disorders. No statistically significant differences between patients with and without a depressive disorder in terms of different reasons were found. However, patients with depressive disorders were more VAS pain (7, IQR 5-8) than patients without depression (5, IQR 4-6) and more days with pain in the week (7, IQR 5-7 vs 5, IQR 3-7), both with $p < 0.01$. Increased frequency of self-medication (61% vs 39%) and sleep disorders (63% vs 37%) among patients with depressive disorders was observed, although these differences were not statistically significant. In the multivariate analysis, the only variable that was found associated with depression was independently VAS pain (OR 1.33, CI 1.13-1.56).

Conclusion: High percentage of patients had a depressive disorder with higher frequency and pain perception. So rheumatologists should be aware of this problem in order to make a proper diagnosis, optimize the application of complementary studies, and perform a multidisciplinary approach to the patient.

Depression and the Risk of Psoriatic Arthritis among Patients with Psoriasis: A Population-based Cohort Study

Background/Purpose: The factors that contribute to the development of psoriatic arthritis (PsA) among patients with psoriasis are not well known. Individuals with psoriasis are at increased risk of developing major depressive disorder (MDD), and it has been suggested that systemic inflammation associated with immune activation to external stressors/exposures may be a possible mechanism for PsA. Our objective was to determine if MDD confers an independent risk towards the development of PsA among patients with psoriasis.

Methods: Newly diagnosed cases of psoriasis were identified in adults from The Health Improvement Network (THIN) database between 1987 and 2012. The exposure was incident diagnosis of MDD among those with psoriasis. The primary outcome was development of PsA. Cox proportional-hazards models were used to estimate the hazard ratio for the development of PsA. Age, sex, medical comorbidities, socioeconomic status, obesity status, smoking status, alcohol use and psoriasis severity (defined by use of therapies intended for moderate-severe psoriasis) were assessed as effect modifiers and confounders.

Results: In total, 73,447 cases of incident psoriasis were identified, of which 5216 (7.1%) developed MDD. Those that developed MDD were more likely to be younger, female, current smokers, with at least one comorbidity, socially deprived and with moderate-severe psoriasis, and less likely to be obese or alcohol users, (all p-values <0.0001). Among all psoriasis patients, 1466 (2.0%) developed PsA during the observation period. There was no evidence for effect modification by any of the covariates (p=0.368). Individuals with psoriasis who developed MDD were at significantly greater risk of subsequently developing PsA (HR 1.55, 95%CI 1.27–1.90, p<0.0001) compared to those who did not develop MDD, when adjustments were made for age and sex. This association remained significant after adjusting for all covariates (HR 1.34, 95%CI 1.02–1.75, p=0.034) (Table 1, Figure 1).

Conclusion: MDD significantly increased the risk of developing PsA among individuals with psoriasis. Heightened attention to screening for and managing MDD in patients with psoriasis may reduce PsA incidence.

Financial and Commercial Disclosures: This study was supported by a CIHR-Leo Pharma Studentship in Psoriatic Disease through the Canadian Association of Psoriasis Patients. Funding sources played no role in study design, analysis or abstract preparation.

Conflicts of Interest: None of the authors have any conflicts of interest.

Table 1. Hazard ratios for the risk of psoriatic arthritis associated with depression among patients with psoriasis are shown in unadjusted and adjusted models.

Model	**Hazard Ratio (95% CI)**	***P*-value**
Unadjusted Model		
Depression	1.56 (1.28 to 1.90)	<0.0001
Age and Sex Adjusted Model		
Depression	1.55 (1.27 to 1.90)	<0.0001
Age	0.81 (0.73 to 0.90)	<0.0001
Sex	1.15 (1.04 to 1.28)	0.006
Multivariable Adjusted Model		
Depression	1.34 (1.02 to 1.75)	0.034
Age	0.66 (0.58 to 0.76)	<0.0001
Sex	1.23 (1.08 to 1.40)	0.002
Obesity Status	1.63 (1.42 to 1.88)	<0.0001
Smoking Status	0.90 (0.82 to 0.99)	0.028
Alcohol Use	0.98 (0.82 to 1.16)	0.788
Charlson Comorbidity Index	0.90 (0.82 to 0.99)	0.034
Townsend Deprivation Index	0.99 (0.94 to 1.04)	0.648
Psoriasis Severity	1.86 (1.62 to 2.14)	<0.0001

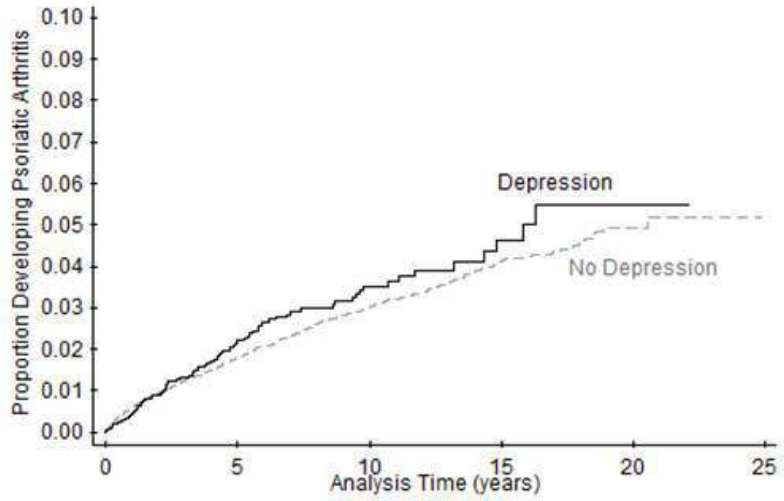

Figure 1. Kaplan-Meier failure curves are shown to estimate the proportion of psoriasis patients who developed psoriatic arthritis based on exposure to depression (black) or no exposure to depression (dotted grey).

Natural language processing to rapidly identify potential signals for adverse events using electronic medical record data: example of arthralgias and vedolizumab

Background/Purpose:

In our rheumatology practice, we noted an increased number of referrals for debilitating joint pain in inflammatory bowel disease (IBD) patients who received vedolizumab. Vedolizumab is a humanized monoclonal antibody targeting a4b7 integrin in the intestinal mucosa, FDA approved in 2014. The objective of this study was to assess for a potential link between arthralgias and subjects who received vedolizumab. Since joint symptoms are uncommonly coded by gastroenterologists, we hypothesized that applying natural language processing (NLP) to extract information from narrative notes, would detect an association that would not be observed using ICD9 codes alone.

Methods: We studied 10,742 IBD patients from a published and validated electronic medical record cohort from 2 large tertiary care centers. Vedolizumab users were identified by electronic prescriptions for infusions. Information on arthralgia was obtained using ³1 ICD9 codes for 'arthralgia' (719.4x), at any point during follow-up. We also processed notes for the concept arthralgia + subconcepts, e.g. ankle pain, with NLP arthralgia defined as ³1 mention of the concept 'arthralgia'. To determine the performance characteristics of ICD9 and NLP for arthralgia, we randomly selected 100 subjects to establish gold standard cases of arthralgia. We tested the association between vedolizumab use and arthralgia by constructing logistic regression models adjusted by the potential confounders age, sex, IBD follow-up time and IBD treatments (**Table 1**).

Results: We studied 10,742 subjects of which 3.5% received vedolizumab; clinical characteristics in **Table 1**. Compared to medical record review, NLP had a higher accuracy for arthralgia: PPV 0.90 vs 0.78 using ICD9 codes (**Table 2**). Using NLP, the prevalence of arthralgia was higher among IBD patients who received vedolizumab (77.1%) compared to those who did not (49.1%). After adjusting for potential confounders, there was no association between vedolizumab and the ICD9 code for arthralgia (OR 0.96, 95%CI 0.73-1.25). In contrast, we observed a significant association between vedolizumab and NLP for arthralgia after adjustment (OR 1.72, 95% CI 1.32-2.29).

Conclusion: Using NLP, we confirmed the clinical observation of an increased prevalence of arthralgias among patients who received vedolizumab. This signal would not have been detected using ICD9 codes alone. This study provided preliminary data for a potential association and future studies are needed to determine the exact timing of joint symptoms in relation to vedolizumab.

Table 1. Characteristics of IBD patients who did and did not receive vedolizumab.

	IBD cohort (no vedolizumab) N=10,366	Vedolizumab N=376
Age, mean (SD)	47.1(18.8)	41.7(14.8)
IBD follow-up time in months, mean (SD)	53.7(56.9)	84.6(69.3)
Female (%)	53.4%	58.5%
IBD treatments, ever/never use (%)		
TNFi use	11.7%	72.1%
Immunomodulator*	13.7%	76.6%
5-Aminosalicylic acid**	4.0%	44.7%

*Immunomodulator= azathioprine, methotrexate, 6-mercaptopurine

**5-Aminosalicylic acid= basalazide, mesalamine, olsalazine, sulfasalazine

Table 2. Performance characteristics of classifying arthralgia in patients using ICD9 codes compared to NLP.

	ICD9 for arthralgia		NLP for arthralgia	
		95% CI		95% CI
Positive predictive value (PPV)	0.79	0.59-0.92	0.9	0.76-0.97
Negative predictive value (NPV)	0.71	0.59-0.81	0.88	0.77-0.95
Sensitivity	0.52	0.36-0.68	0.83	0.69-0.93
Specificity	0.89	0.78-0.96	0.93	0.82-0.98

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Hashimoto´s thyroiditis (HT) are frequently seen by rheumatologists due to rheumatic complain that do not fit into diagnostic criteria for a definite arthropathy. The purpose of this study was to establish the prevalence and associated factors of undifferentiated inflammatory arthropathy (UIA) in a sample of Hispanic patients with Hashimoto's thyroiditis (HT).

Methods: Cross-sectional study in consecutive patients with HT from the outpatient clinic of the Endocrinology Division of the University Hospital. Diagnosis was based on the presence of anti-thyroid peroxidase antibodies (N=76) or typical ultrasonographic findings (N=25).

Results: One hundred one patients were evaluated by two rheumatologists (EJGC, LMVH). Ninety six percent

were female and the median age was 50.01 years. We excluded six patients from the study (five who met the American College of Rheumatology 1987 criteria for RA and one who met the Assessment of SpondyloArthritis international Society criteria for SpA). Overall, 73.27% referred arthralgias and 36.30% axial inflammatory pain. ANA were positive in 54.46%, RF in 12.87%, and ACPA in 2.97% of patients. Twenty five percent of patients met criteria for undifferentiated inflammatory arthropathy (UIA). The following features distinguished HT patients with UIA versus HT patients without UIA: peripheral arthralgias (100.00% vs. 58.60, $p < 0.0001$), xerostomy (64.00% vs. 34.30%, $p = 0.0200$), xerophtalmy (64.00% vs. 40.00%, $p = 0.0330$), myalgia (96.00% vs. 50.00%, $p < 0.0001$), Raynaud phenomenon (32.00% vs. 8.60%, $p = 0.0100$) and axial inflammatory manifestations (68.00% vs. 24,30%, $p = 0,0001$). The independent risk factors for UIA were the presence of myalgia (OR = 15.04; 95% CI: 1.83 – 123.41) and axial inflammatory manifestations (OR = 4.20; 95% CI: 1.37 – 12.87). RF and ACPA were positive in 3 and 1 patients with UIA; and in 7 and 1 patients without UIA, respectively (NS). There was no correlation between thyroid function levels and UIA, and no laboratory tests showed clinical utility as predictors of UIA in patients with HT.

Conclusion: One out of four patients with HT of our sample had UIA. Risk factors for the development of UIA were the presence of myalgia and axial inflammatory manifestations. UIA is a common manifestation in patients with HT. Therefore, HT should be considered in the differential diagnosis of patients with inflammatory joint symptoms.

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a progressive, debilitating condition. It is estimated that

between 25 and 35% of patients with psoriasis may develop psoriatic arthritis during the course of the disease. In these patients the psoriasis precedes the onset of PsA by an average of 10 years, so it is very important that dermatologists should be able to recognise the signs and symptoms of this in order to start the diagnostic process. The EARP (Early ARthritis for Psoriatic patients) questionnaire is a detection tool for PsA in psoriatic patients, which has good psychometric properties in its original Italian version that had not yet been validated for the Spanish population.

Methods: Observational, cross-sectional, multicentre study. A dermatologist and a rheumatologist participated at each centre. The dermatologist included patients between 18 and 85 years of age who had been diagnosed with psoriasis and who were not seeing a rheumatologist and did not have any other dermatological conditions. Basic sociodemographic and clinical variables were recorded. The patients answered the EARP questionnaire and a question about their health status. The rheumatologist then performed a physical examination of the same patients with additional analytical/radiological tests, if deemed necessary according to clinical practice, to conclude whether PsA was present/absent. The study was approved by the Independent Ethics Committee of Hospital de la Santa Creu i Sant Pau de Barcelona.

Results: 377 patients were included with a mean age (SD) of 48.1 (14.3) years, 56% male. 35.4% had completed secondary education and 42.5% were employed. A cut-off point of ≥4 points in the EARP questionnaire indicated a diagnosis of PsA. The EARP questionnaire was feasible (1.6% non-response) with good internal consistency (Cronbach's α=0.776) and good construct validity, as there was a statistically significant correlation between the CASPAR criteria (p=0.01) and the rheumatologist's diagnosis (p<0.01). The EARP questionnaire presented a sensitivity of 84.4% and a specificity of 62.9%, with a higher percentage of false positives than false negatives (37.1%;15.6%) (Table 2). No statistically significant sociodemographic differences were found between the patients who were and were not diagnosed with PsA by the rheumatologist.

Conclusion: The Spanish version of the EARP questionnaire is a valid tool for the early detection of PsA symptoms by dermatologists when assessing patients who are susceptible to this condition.

Session Title: Epidemiology and Public Health - Poster III

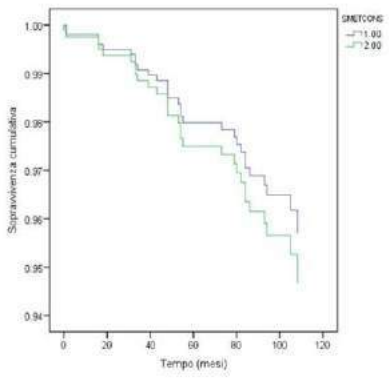
Session Type: ACR Poster Session C

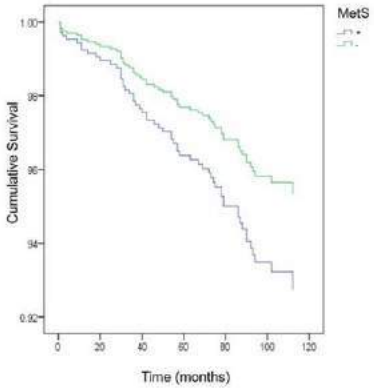
Session Time: 9:00AM-11:00AM

Background/Purpose: all-cause and cardiovascular mortality and cardiovascular morbidity are reportedly increased in rheumatic diseases, both inflammatory and non-inflammatory. Few studies, however have addressed the impact of metabolic syndrome (MetS) on mortality and cardiovascular morbidity (ASCVD, death, stroke, Myocardial infarction, peripheral arterial disease) in rheumatic diseases.

Methods: MetS was defined according the 2009 Consensus criteria (1), as the presence of at least among 3 among increased abdominal circumference (AC: M ≥ 94 cm; F ≥ 80 cm) , elevated blood pressure (BP: ≥130/85), triglycerides (TG ≥150 mg/dL), glucose (GLU: ≥100 mg/dL), or reduced HDL-Cholesterol (HDL M<40 F<50 mg/dL). The original population consisted of 1234 non-selected rheumatic patients without a history of major cardiovascular. 259 patients were eventually excluded from data analysis, because of lack of follow-up (N=252) or evidence of cardiovascular events before inclusion in the study (N=7). Of the remaining 975 patients (M 217; F 758), complete data were available for 849 patients; Mets variables were missing in < 5% of patient (AC 2.15%; BP 2.36%; GLU 3.79%; HDL 4.52%; TG 3.90%). According to current practice (2), missing data were imputed by multiple imputation, using the multivariate imputation by chained equation algorithm (3). Survival and ASCVD event risk were evaluated by Kaplan-Meier and Cox proportional hazard models. Statistical computations were performed with SPSS and R softwares.

Results: The mean duration of follow-up was 7.38 years (0-1 – 11.67), totalling 7195 patient-year. 219 (22.5%) were affected by non inflammatory diseases, 260 (26.7%) by RA, 152 (15.6%) by psoriatic arthritis/SpA, and 344 (35.3%) by CTD or vasculitis. In the whole population, 63 deaths and 115 ASCVD events in 58 patients were observed, with no significant differences between MetS + (N=330) and MetS- (N=645) patients. In the Cox Model, Mets was not correlated with the risk of death (HR 0.996 95% CI 0.577-1.721, p = 0.989), or ASCVD (HR 1.514, 95% CI 0.876-2.617, p = 0.138). For both all-cause mortality and ASCVD, age (HR 1.103, 95% CI 1.073-1.134, and HR 1.983 95% CI 1.095-3.591 respectively) and male sex (HR 1.943, 95% CI 1.066-3.541 and HR 1.046 95% CI 1.021-1.072 respectively) were correlated with the outcome.





Conclusion: In our population patients affected by non-selected rheumatic diseases, metabolic syndrome did not influence all-cause deaths and atherosclerotic cardiovascular events. These data seem to confirm previous observations showing that factors other than traditional risk factors have a major impact on cardiovascular mortality and morbidity in rheumatic diseases. **References**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: EULAR recommendations for cardiovascular disease (CVD) risk management in inflammatory joint diseases (IJD) advocates annual CVD risk assessments to reduce the increased CVD risk. Knowledge of the prevalent CVD risk factors in different diagnoses may enable tailoring of efficient CVD preventive strategies. Our aims were: I) Evaluate prevalence of CVD risk factors in IJD patients and 10-year risk for fatal CVD according to the systemic coronary risk evaluation (SCORE). II) Investigate CVD risk factor distribution across IJD entities and age groups.

Methods: In the nationwide NOrwegian Collaboration on Atherosclerosis in patients with Rheumatic joint diseases (NOCAR) project, annual CVD risk assessment is implemented. IJD patients ≥30 years of age are eligible for inclusion. Recorded CVD risk factors include non-fasting lipids, blood pressure (BP), self-reported CVD risk variables and established CVD. SCORE estimates were compared across IJD diagnoses for males and females individually, using analysis of variance, stratified by decennial age. Number of CVD risk factors, determined by presence of diabetes, hypertension, family history of premature CVD, hyperlipidemia (total cholesterol >8 mmol/L and/or low-density lipoprotein cholesterol> 6 mmol/L), current smoking or obesity (body mass index>30kg/m^2), was counted for each patient. Frequency of CVD risk factors for was estimated and compared across the four major entities, using logistic regression (age and sex adjusted).

Results: Of 2647 patients included (rheumatoid arthritis [RA]: n=1696, ankylosing spondylitis [AS]: n=445, psoriatic arthritis [PsA]: n=376 and other spondyloarthritides [SpA]: n=130), 58% were females and the median (inter-quartile range [IQR]) age and disease duration were 57.4 (46.8-66.8) and 8.0 (3.8-15.9) years, respectively. Median (IQR) crude SCORE estimate was 2.2% (0.5-4.3) and comparable across diagnoses, apart from male AS patients having lower SCORE estimates (p=0.01). CVD risk factor prevalence were comparable across individual IJD diagnoses, except PsA patients who had significantly (p=0.01) more CVD risk factors in the oldest age groups.The percentage with at least one CVD risk factor and mean number of risk factors was 45 % and 0.6 in individuals < 40 years, increasing to 66% and 1.1 and 84% and 1.5 in age groups 40-60 and >60 years, respectively (Figure). In detail, CVD risk factor rates were: family history of premature CVD: 18%, established CVD: 10%, current smoking: 20%, hypertension: 53%, obesity: 18%, diabetes: 7%, hyperlipidemia: 1%. PsA patients were significantly more likely to be obese (p=0.001), hyperlipidemics (p<0.05), diabetics (p<0.001), hypertensive (p<0.0001), and were less frequently smokers (p=0.04).

Conclusion: A high rate of CVD risk factors was present even in young patients. Apart from PsA, the prevalence of CVD risk factors was uniformly distributed across all IJD entities.

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Compared with cardiovascular (CV) risk in rheumatoid arthritis (RA), precise CV risk in psoriatic arthritis (PsA) and psoriasis is less established, particularly the relative contribution of traditional CV risk factors versus systemic inflammation. The objective of this study is to compare the incidence of Major Adverse Cardiac Events (MACE) among patients with RA, PsA and psoriasis with population controls adjusting for traditional CV risk factors, systemic inflammation, and Disease Modifying Anti-Rheumatic Drug s(DMARDs).

Methods: Using linked, routinely collected health data from 1999 to 2013 in Wales UK, available from the Secure Anonymised Information Linkage (SAIL) databank, which includes general practitioner, and hospital datasets, the incidence of a MACE was investigated in individuals with RA (n=8,650), PsA (n=2,128), psoriasis (n=24,630) and population controls (n= 1,187,706), while controlling for traditional CV risk factors, systemic inflammation (measured by erythrocyte sedimentation rate (ESR)), and DMARDs.

Results: Demographic details and incidence of MACE are listed in Table 1. After controlling for traditional risk factors, CV risk was significantly increased for individuals with RA (HR: 1.2, 95% CI: 1.0-1.3, p=0.038) and psoriasis (HR: 1.1, 95% CI: 1.0-1.3, p=0.025) but not for PsA (HR: 1.0, 95% CI: 0.7-1.5, p=0.887). ESR was significantly higher in patients with RA compared with patients with psoriasis, PsA and controls. ESR was associated with increased in CV risk in RA but not psoriasis or PsA. No interaction between DMARDs and MACE occurrence was observed. **Table 1: Baseline Characteristics AND INCIDENCE OF MACE** ControlRAPsAPsoriasis(n=1187706)(n=8650)(n=2128)(n=24630)Age at diagnosis (SD)50 (17.2)59.6 (14.6)50.3 (13.1)51.4 (16.2)Male49%32%47%49%Baseline BMI (SD)25.5 (5.1)26.8 (5.5)27.8 (5.9)26.5 (5.4) Hyperlipidemia 7.30% 13.90% 12.60% 11.40% Diabetes 7.80% 14.10% 13.10% 11.90% Hypertension21.60% 39.70% 33.30% 29.90% Smoker21.20% 24.60% 21.90% 27.90% MACE Incidence rate per 1000PY (95% CI)4.5 (4.5 to 4.6)9.6 (8.8 to 10.5)2.9 (2.2 to 3.9)5.3 (5.0 to 5.7)

Conclusion: In addition to traditional CV risk factors, there is an increased incidence of CV disease for RA and psoriasis, but not for PsA. This demonstrates the varying mediators of CV risk across the conditions and highlights the need for different CV risk reduction strategies for specific diseases.

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with the presence of psoriasis. Both conditions are influenced by lifestyle factors such as alcohol consumption, smoking and obesity. Furthermore, there is evidence that PsA is associated with an increased risk of cardiovascular disease (CVD) compared to the general population. The aim of this study was i) to compare lifestyle factors between individuals with PsA, psoriasis and a control group and ii) to assess the relationship between these inflammatory diseases and CVD outcomes.

Methods:

UK Biobank recruited 502,664 people aged 40-70 years in the UK between 2006 and 2010. Cross-sectional data on lifestyle, sociodemographics, and health and medical history were collected at the assessment visit by questionnaire and interview by a research nurse. Participants were asked if they have ever been diagnosed by a physician with PsA, psoriasis or any other disease. Lifestyle factors including alcohol (current or past intake) and smoking status (ever or never) were recorded and height and weight measured to calculate BMI. In this cross-sectional study, the frequency of these factors was compared between PsA, psoriasis and healthy controls using logistic or linear regression analyses depending on the outcome, adjusting for age and gender. Comparison between disease groups was performed by linear combinations of coefficients post estimation. Three CVD outcomes: heart attack, angina and hypertension, were tested for association with disease group using logistic regression including BMI, smoking, alcohol, age and gender as covariates. Odds ratios (OR) and β coefficients are reported with 95% confidence intervals (CI).

Results:

A total of 476,626 participants were included; 862 participants with PsA, 4,761 participants with psoriasis and 471,003 control participants (Table). Compared with the control group; both the PsA and psoriasis groups had higher BMI (β 1.43 (95% CI 1.11-1.75) and 0.72 (0.58-0.85) respectively), the psoriasis group smoked more (OR 1.63 (1.54-1.72)) and the PsA group had a lower rate of current drinkers (OR 0.68 (0.55-0.85)). Comparing between disease groups; the PsA group had a higher BMI (β 0.69 (0.32-1.06)) and lower rates of both ever smoking and current alcohol consumption (OR 0.70 (0.61-0.81) and 0.65 (0.51-0.83) respectively). Finally, hypertension was more prevalent in PsA compared to the control and psoriasis cohorts (OR 1.71 (1.48-1.97) and 1.55 (1.33-1.82) respectively).

Conclusion: Using a large population based cohort we have shown that self-reported rates of hypertension are significantly higher in patients with PsA compared with psoriasis independently of known CVD risk factors. The results contribute to our understanding of the lower quality of life reported by patients with PsA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies have suggested that the chronic inflammatory nature of rheumatic conditions (rheumatoid arthritis (RA) and psoriatic arthritis (PsA)) as well as psoriasis (PsO) may predispose patients to cardiovascular (CV) disease and metabolic disorders. However, the individual impact of RA, PsA, PsO, and their treatments, on traditional CV risk factors - hypertension, diabetes mellitus (DM), hyperlipidemia, and obesity - is not well understood.

Methods: Patients with RA, PsA, and PsO with visits between January 1, 2002 and June 30, 2014 were identified (and included in three separate cohorts) in MarketScan, a large US employer-based claims database. The index date was defined as the date of RA, PsA or PsO diagnosis, and patients were required to be continuously enrolled for 12 months prior to the index date. Four cohorts were defined for each of the three diagnoses based on treatment (or lack thereof) during follow-up. The four cohorts were 1) TNF inhibitor (TNFi) monotherapy, 2) non-biologic (nb)DMARD monotherapy, 3) TNFi + any other nbDMARD combination therapy, and 4) No DMARD treatment. The treatment cohorts were followed from the date treatment was initiated after the index date until disenrollment, end of study period, switching medications to qualify for a different treatment

cohort, or until the last available day supply of any medication in the designated treatment cohort. The primary outcome was the first occurrence of the CV risk factors during the follow-up period. Incidence rates (IR) per 1,000 patient-years (PY) with 95% confidence intervals (CI) were calculated. Incidence outcomes were age- and sex-standardized to the MarketScan general population.

Results: We identified 126,820 patients with RA, 18,924 with PsA, and 28,788 with PsO. Mean age at index date was similar for both PsO and PsA patients (50 yrs), but RA patients were older (56 yrs). Mean follow-up time ranged from 2.4 years to 3.0 years. Among RA patients, incidence rates of the 4 CV outcomes were fairly consistent between DMARD treated and non-treated patients, with numerically lower rates for hyperlipidemia and obesity. In PsO patients, monotherapy cohorts had higher rates of all outcomes than those not receiving any DMARDs. In PsA patients, rates of hypertension, diabetes and obesity were similar among all treatment groups, whereas hyperlipidemia displayed numerically higher rates among the DMARD treated cohorts (Table 1).

Conclusion: Impact of treatment on CV risk factors is not consistent across disease states or the CV risk factors. When treating patients there needs to be consideration for both the underlying disease states, and the CV risk factor of interest. The results highlight the importance of close monitoring and careful management of CV risk factors in patients with RA, PsA and PsO.

Patient Reported Disease Activity and Efficacy of Biologic Therapy in Patients with Psoriatic Arthritis. an Observational Study of 107 Patients of the Estonian Society for Rheumatology Biologic Therapy Register during 2008-2014

Sandra Tälli[1], Marika Tammaru[2] and Kati Otsa[1], [1]East-Tallinn Central Hospital, Department of Rheumatology, MD, Tallinn, Estonia, [2]East-Tallinn Central Hospital, MD, PhD, Tallinn, Estonia

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis is a heterogenous disease that can effectively be treated with biologic therapy. The treatment outcome is affected by difference in disease expression and patients population. The aim of this study was to evaluate the patient reported outcome of the therapy and the disease activity in the perspective of gender differences.

Methods: Data on patients with psoriatic arthritis were extracted from the Estonian Society for Rheumatology Biologic Therapy Register from 2008 to 2014. Demographic, clinical and disease activity measurements were evaluated at the initiation of the biologic therapy and at patients last recorded registry entry during the observational period. The association of gender and patient reported outcome measures and objective disease acitivity measures were assessed with Wilcoxon rank-sum test, linear regression was used to adapt for potential confounders.

Results: Among 107 patients (mean age 44.8 (standard deviation, ±12.4) years, mean stay in register 32.3 (±24.8) months, mean number of registry entries 5.4 (±2.8)) 53.3% were females. At the initiation of biologic therapy, female patients had more active disease by both subjective (visual analogue scale (VAS) value of pain, female vs male means 60.2 vs 47.7, p=0.0365; HAQ-DI 1.65 vs 0.70, p=0.0023) and objective disease activity measures (DAS28 5.2 vs 4.0, p=0.0071; BASDAI 6.8 vs 5.4, p=0.0423). Female patients had more active disease also at the last recorded visit (VAS pain 30.8 vs 17.6, p=0.0022; VAS global assessment 30.5 vs 16.2, p=0.0007; HAQ-DI 1.0573 vs 0.44, p=0.0085; DAS28 3.1 vs 1.8, p=0.0001; BASDAI 3.5 vs 2.2, p=0.0084). The differences persisted after adjustment for age, time in the register and change in the biologic therapy. During the treatment period all the objective and subjective disease activity measures improved without a gender difference with an exeption of HAQ-DI which showed bigger change in female patients (-1.00 vs -0.24, p= 0.0148).

Conclusion: Previous studies have shown that men have higher objective disease activity and are more likely to develop structural damage whereas women have higher activity in patient reported outcomes (1). In this study female patients were susceptible to more active disease regarding most aspects of psoriatic arthritis. However further studies are needed to evaluate the relationship to the disease expression or other manifestations of the disease and female gender. In this population there was no gender difference in treatment efficacy by objective measures. 1. Eder et al. Ann Rheum Dis 2013;72:578-582

Effect of Anti-Rheumatic Treatment on Selenium Levels in Rheumatoid Arthritis, Psoriatic Arthritis and Ankylosing Spondylitis

Gia Deyab[1], Ingrid Hokstad[2], Milada Cvancarova Småstuen[3], Stefan Agewall[4], Jon Elling Whist[5] and **Ivana Hollan**[5,6,7,8], [1]Department of Medical Biochemistry, Innlandet Hospital Trust, Lillehammer, Norway, [2]Lillehammer Hospitat for Rheumatic Diseases, Lillehammer, Norway, [3]Institution of health care - Health science PhD program, Oslo and Akershus University College, Oslo, Norway, [4]University of Oslo, Oslo, Norway, [5]Innlandet Hospital Trust, Lillehammer, Norway, [6]Brigham and Women's Hospital, Boston, MA, [7]Harvard Medical School, Boston, MA, [8]Lillehammer Hospital for Rheumatic Diseases, Lillahammer, Norway

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The cause of the increased cardiovascular risk in inflammatory rheumatic diseases (IRDs) is still unclear. Intriguingly, selenium-deficiency, which might be caused by poor diet or inflammation, has been proposed to contribute to development of cardiovascular disease (CVD), and selenium supplementation has been reported to decrease CV risk. Moreover, decreased selenium-levels are likely to promote inflammation.

The aim of this study was to compare serum selenium (s-Se) levels in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS), and to evaluate if these levels are influenced by methotrexate (MTX) and/or anti-tumor necrosis factor treatment (anti-TNF). Furthermore, to assess if s-Se levels are associated with markers of disease activity and endothelial function (EF).

Methods:

From the biobank of PSARA study, we examined samples from 131 IRD patients starting with either MTX or anti-TNF with or without MTX (anti-TNF±MTX) due to high active disease. s-Se (atomic absorption spectroscopy), EF (finger plethysmography) and serologic inflammatory biomarkers were evaluated at baseline and after 6 weeks and 6 months of therapy.

Results: The baseline median s-Se levels in the total IRD group (72µg/L) were within the reference range 50-120 µg/L. The s-Se levels increased in all groups after 6 weeks and 6 months of therapy, but the differences from baseline were not statistically significant. Changes in s-Se were significantly related to changes in CRP and ESR (both p=0.001 at 6 weeks and p=0.033 and p=0.035 at 6 months, respectively), but not to changes in EF. There were no statistically significant differences neither in s-Se baseline levels nor in changes in s-Se between baseline and follow up between RA , AS and PsA . In patients treated with MTX, s-Se levels increased after 6 weeks (p=0.012) and 6 months of therapy (p=0.038). In patients treated with anti-TNF±MTX, there were no changes in s-Se levels during the follow-up.

Conclusion: IRD patients had s-Se levels within the normal range. The s-Se levels increased after 6 weeks and 6 months of anti-rheumatic therapy, but the differences were statistically significant only in patients treated with MTX monotherapy (not in those treated with anti-TNF). Thus, larger and longer studies are needed to determine if anti-rheumatic treatment, in particular MTX, might influence CV risk through increasing s-Se levels (either due to its anti-inflammatory effect or other effects).

Comparisons of Patients Prescribed Biosimilars or BIO-Originators for Autoimmune Diseases in Germany

Sumesh Kachroo[1], Christopher Black[1], Emma Sullivan[2], John Waller[2] and James Piercy[2], [1]CORE, Merck & Co., Inc., Kenilworth, NJ, [2]Adelphi Real World, Manchester, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare the characteristics of patients who receive biosimilars against patients receiving bio-originators.

Methods: The Adelphi Biosimilars Programme 2016 is a cross-sectional survey of German rheumatologists who prescribe biosimilars. For a sample of their RA, AxSpA and PsA first line biosimilar or bio-originator patients, initiated since 2015 (the introduction of biosimilars in Germany), rheumatologists reported patient characteristics including: demographics, insurance coverage, clinical status and treatment history. Physicians were asked to describe a typical biosimilar patient in comparison to a bio-originator patient.

Results: No differences were observed in age, gender, ethnicity, BMI and employment status between biosimilar patients (n=100) and bio-originator patients (n=52). Patients initiated on bio-originators were more likely to have private health coverage (13%) than biosimilar patients (8%). 8% of biosimilar patients were 'deteriorating rapidly' at therapy initiation but this was 21% in bio-originator patients. Biosimilar patients were using non-advanced therapies (e.g. DMARD) for 11.6 months longer than bio-originator patients. Rheumatologist responses suggested there is no 'typical' biosimilar patient from a clinical/demographic perspective, though 28% stated it was cost difference that motivates them to prescribe to a specific patient.

Conclusion: The data shows that biosimilars are initiated in patients who are clinically less severe than bio-originator patients and that they also spend more time on alternative non-biologic therapies before biologic initiation. This suggests that when a more severe patient is being treated physician are more likely to choose are more well-known bio-originator. Physicians did not describe a 'typical' patient in terms of clinical characteristics and stated that it was cost reasons that would drive them to prescribe biosimilars in most patients, suggesting that payer pressure is influencing prescribing decisions.

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) treatment options are based on the use of DMARDs and NSAID but their use may vary widely, despite international recommendations and guidelines. We aimed at determining the prevalence of comorbidities and prescription patterns of synthetic DMARDs, NSAIDs, and other drugs in a real-life cohort of patients and to determine if sex influences the use and retention rates of therapeutic options.

Methods: We performed a retrospective cohort analysis of administrative health databases of Lombardia region (>10 million population) through the RECORD study of the Italian Society of Rheumatology. PsA and comorbidities were identified using specific copayment exemptions (045.696.0 for PsA) from January 1st 2005 to December 31st 2015 and then linked to DMARD, NSAID, steroid, and other prescriptions. The influence of sex on prescriptions and retention rates was evaluated using Cox regression analyses and the results presented as hazard ratios (HR) and 95% confidence intervals (95%CI).

Results: We identified 8,981 PsA cases (**Table 1**) and the prescribed DMARDs, NSAIDs and steroids are reported in **Table 2**. Among clinical features, most comorbidities were found in significantly different proportions in men and women. Of note, 0.8% of patients had a diagnosis of depression while 20.5% received anti-depressants (both being more frequent in women). Methotrexate (MTX) was used in 59% of patients, almost equally in its oral and parenteral formulation, with the latter most commonly prescribed at 10 mg weekly dose. MTX was most frequently prescribed to men, while sulfasalazine and hydroxychloroquine (HCQ) to women. Of note, women received more steroids while men received more NSAIDs. A higher risk for MTX discontinuation was found in women (HR1.06,95%CI1-1.1,p-value0.047), who retained HCQ more commonly (HR0.83,95%CI0.72-0.96, p-value0.012); no differences were observed for other DMARDs retention rates.

Conclusion: In our real-life cohort of patients with PsA anti-depressants are largely used, especially in women. Among DMARDs, MTX is most frequently prescribed but appears to be largely used in its oral formulation and at low dose. Off-label treatments for PsA such as HCQ and steroids are used more frequently in women. In general terms, women and men with PsA have different comorbidities and may underlie different treatment choices. **Table 1.**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Classification criteria lacking specificity cause inclusion of many false positives in settings with low prevalence of disease. The ASAS axial spondyloarthritis (axSpA) criteria have 84% specificity. If the prevalence of axSpA among chronic back pain (CBP) patients is 5% one expects 3.6 false positively labeled persons for each true axSpA patient. Back pain is a key issue in the classification of axSpA. Our aim is to assess the specificity of spinal pain features to obtain better performance of the ASAS criteria.

Methods: We assessed (1) low back pain or stiffness; (2) thoracic inter-scapular back pain or stiffness; (3) frontal chest pain or discomfort by analyzing data from two earlier studies.[1,2] *Inflammatory* back pain (IBP) is defined as 4 or 5 Calin criteria: onset of back discomfort ≤ age 40; insidious onset; persistence for ≥ 3 months; morning stiffness; improvement with exercises. In the *first* study[1], 739 apparently healthy leisure time sportsmen (orienteers) completed a detailed questionnaire on spinal and chest pain features. AxSpA is assumed to be absent in this group. The *seco*nd study[2] (a Swiss family study on AS) enabled assessing specificity of chest and back pain features in B27- first degree relatives of 275 B27+ AS patients. All (both B27+ and B27-) participants underwent clinical exam, full HLA-typing, radiography of SI joints and completed questionnaires, including chest and spinal pain features. Pelvic x-rays were blindly read, twice by each of 2 investigators. They agreed in 95.6% (kappa 66.4).

Results: The table shows the specificities for the sportsmen. The 3 pain syndromes were highly associated ($p<0.001$). Low back pain *ever* is age related. The specificity in the age groups 10-19, 20-29, 30-39, 40-49, 50-59 year are 70.1%, 46.3%, 52.1%, 42.8%, and 37.1% respectively. Altogether 24.1% of back pain *ever* can be classified as chronic IBP. The specificity of diagnostic spinal x-rays is 67.5%. Radiographs were done in 25% (6/24) in people with IBP < 3 months duration, but in 67 % (40/60) of people with ≥ 3 months IBP. Specificity was 99.1% for not using analgesics because of back pain ≤ last 6 months. The likelihood ratio for having had a diagnostic spinal radiograph is 2.2 (46/84:67/264) if chronic IBP is present compared to absent. Specificity was very high (99.1%) for not using analgesics because of back pain ≤ last 6 months. AS or sacroiliitis was found in 20/274 (7.3%) B27+ relatives. Sacroiliitis was never observed in B27- relatives with IBP. Of note B27+ relatives *without sacroiliitis* have more often chest pain and IBP than B27- relatives suggesting axSpA or spondylitic disease in B27+ relatives.[2] The specificities for the B27- relatives are shown in the table.

Conclusion: Better knowledge of specificity of spinal pain syndromes may help improving performance of classification criteria for axSpA. Chest pain and use of analgesics seem promising candidate variables.

Spinal Pain Syndrome	Orienteers[1] % specificity (n=739)	B27- Relatives % specificity (n=248)	B27- Relatives % positive (n=248)	B27+ SI-Relatives % positive (n=248)

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Given conflicting evidence regarding statin use and the relationship with musculoskeletal

conditions, and the rising disability and societal/personal repercussions associated with both osteoarthritis (OA) and back pain, understanding predisposing exposures (including medication related) deserve further attention. The objective of this study was to examine the association between statin use and the risk of being diagnosed with non-traumatic arthropathies, back disorders, and use-related injury in a propensity score-matched cohort with long-term follow-up.

Methods: This was a retrospective cohort study using clinical, administrative, and pharmacy data from 10/2003-3/2012 from patients enrolled in the military health care system in the San Antonio Multimarket region. Two treatment groups were defined: statin-users (those who newly received statins for ≥120 days) and non-users (included patients before initiating statins or never used statins). We excluded prevalent statin users, patients who had < 2 years of baseline period, or <1 medical encounter at followup period. A propensity score-matched cohort was generated to match statin-users and non-users using 115 variables (including personal history, social history, family history, healthcare utilization, baseline period start date, followup duration, comorbidities, Charlson comorbidity index, use of various classes of medications, and undergoing invasive and noninvasive cardiovascular procedures during the baseline period). Outcomes assessed included ICD-9 diagnoses codes for validated AHRQ disease categories of: non-traumatic arthropathies (ex. OA), back disorders (ex. intervertebral disc disorders), and use-related injury (ex. sprains and strains). As primary analysis (for space consideration we do not include the secondary and sensitivity analyses), we examined odds ratios of outcomes in statin-users and nonusers in the propensity score-matched cohort using conditional logistic regression analysis.

Results: A total of 60,455 patients were identified. We propensity score-matched 6728 non-users with 6728 statin-users (52 years of age, ~47% women). Statin users had a higher odds of non-traumatic arthropathies (odds ratio (OR) 1.17; 95%CI 1.09-1.25), back disorders (OR 1.27; 95%CI 1.19-1.36), and use related injury (OR 1.11; 95%CI 1.03-1.19).

Conclusion: Statin use was associated with a significant increase risk of non-traumatic arthropathies, back disorders, and use-related injury. These data challenge several existing studies implicating a protective effect of statins on musculoskeletal conditions. Our results provide additional motivation to further investigate the overall impact of statin therapy on musculoskeletal health, specifically if prescribed for primary prevention in physically active individuals.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Football is the world's most popular team sport. However, whether professional footballers have a higher prevalence of knee injury and subsequently, knee pain (KP), radiographic knee osteoarthritis (RKOA) and total knee replacement (TKR) than the general population remains largely unknown. We therefore undertook a population-based study comparing ex-professional footballers and the general population to (1) determine the prevalence of KP, RKOA and TKR; and (2) investigate the specific risk factors associated with these three conditions. This is the second part of the project, aiming to determine the specific risk factors that are associated with KP, RKOA and TKR within footballers.

Methods: A case control study was undertaken in footballers, where cases were defined as footballers with KP, RKOA or TKR and controls were those without these outcomes. A questionnaire survey was undertaken in 4775 retired professional footballers in the UK, via Football Clubs and organisations (including the Professional Footballers Association). 1207 footballers (25.3%) responded to the survey and 472 additionally agreed to undergo standardised bilateral knee radiographs. Potential risk factors were collected through the questionnaire. KP was defined as pain in or around the knees for most days of the last month. RKOA was assessed via weight-bearing semi-flexed posterior-anterior and 30° flexion skyline views and graded using the Kellgren-Lawrence (KL) system (RKOA defined as KL$\geq$3) and the Nottingham Line Drawing Atlas (NLDA). TKR was a self-reported measure, confirmed in some by x-ray. Significant risk factors for each outcome were determined using multivariate logistic regression and reported as odds ratio (OR) with 95% confidence interval (CI).

Results: The prevalence of KP in footballers was 52.2%, which is twice as common as the general population (25.2% reported in Study Part 1 abstract). Knee injury and its subsequent investigations/interventions (exploratory and/or corrective surgery) and management (intra-articular knee injections) were associated with KP. While a number of other significant risk factors were identified for KP, very few were identified for RKOA and none for TKR (Table 1).

Risk Factors	**Odds Ratio**, OR (95% Confidence Interval, CI)		
	KP	RKOA	TKR
BMI (≥25kg)	1.07 (1.04 – 1.10) ‡	0.95 (0.50 – 1.82)	0.92 (0.60 – 1.41)
Digit (2D:4D) Ratio	1.34 (1.05 – 1.72) *	1.00 (1.00 – 1.00)	1.02 (0.70 – 1.50)
Familial Knee OA	1.85 (1.37 – 2.51) ‡	0.74 (0.39 – 1.40)	0.80 (0.49 – 1.29)
Familial Hip OA	1.50 (1.06 – 2.11) *	0.68 (0.31 – 1.51)	1.04 (0.62 – 1.75)
Familial Hand OA	1.63 (1.18 – 2.25) †	0.48 (0.22 – 1.06)	1.04 (0.64 – 1.69)
Familial Knee Replacement	1.21 (0.87 – 1.71)	0.87 (0.43 – 1.77)	0.66 (0.62 – 1.20)
Constitutional Malalignment	1.28 (0.93 – 1.76)	0.87 (0.39 – 1.96)	1.13 (0.69 – 1.82)
Joint Injury	4.22 (3.26 – 5.48) ‡	1.71 (0.91 – 3.20)	1.14 (0.78 – 1.68)
Surgical Intervention #	4.19 (3.23 – 5.43) ‡	3.08 (1.50 – 6.31) †	0.97 (0.66 – 1.41)
Injections	2.55 (2.01 – 3.25) ‡	1.81 (1.06 – 3.07) *	0.87 (0.60 – 1.25)

Table 1 #surgical intervention, which includes exploratory, corrective and/or lesser surgery. OR adjusted for age and BMI; *p<0.05, †p<0.01, ‡p<0.001

Conclusion: Knee injuries, together with subsequent investigations (specifically exploratory and interventional arthroscopy) and management (specifically intra-articular knee injections), were strongly associated with risk of later KP and RKOA. Football organisations need to be mindful of these data and apply strategies to minimise the risk of knee injury (and subsequent investigation and management) in professional football players.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Traumatic knee injuries, such as injuries to the anterior cruciate ligament (ACL) and menisci, are associated with early onset osteoarthritis (OA). Our understanding of the pathobiology underlying this association is limited, and detailed studies of knee injury populations are needed. This longitudinal study examined the association between knee injury and function, pain, and OA in a cohort of military officers. The precipitating effect of injury on OA has not previously been studied in this population, which has a high rate of knee injury.

Methods: We assessed pain, function, and OA in military officers with a prior history of ACL/meniscal injuries (knee injury subcohort) and compared them to a group of injury-free participants (injury-free subcohort). Both subcohorts were drawn from an existing cohort of 6452 military officers enrolled between 2004 and 2008, when participants were matriculating cadets at the U.S. Air Force Academy, U.S. Military Academy, or U.S. Naval Academy. The knee injury subcohort had ACL or meniscal injuries prior to, or during, their 4-year academy career (n=106). The injury-free subcohort was site-matched from the same source cohort and had no history of ACL/meniscal injuries (n=108). Injury status was verified via re-administration of injury history questionnaire (all injuries) and clinical record review (post-matriculation injuries). Both groups completed a questionnaire between 08/11/15 and 05/10/16 that assessed physician-diagnosed OA, patient-reported knee outcomes (Knee injury and OA Outcome Score, or KOOS), and a single-item measure for knee pain, aching, or stiffness (5-point Likert scale) in the past 30 days. Data were analyzed using descriptive statistics and log-binomial regression models. KOOS scores were scaled (0=extreme deficit, 100=no deficit).

Results: Mean age was 27.7 years (injured: 27.7 years; non-injured 27.7 years) and 38% were women (injured: 34%; non-injured: 42%). Mean weight was 77.4 kg and body mass index was 25.1 kg/m^2. Mean time from first ACL/meniscal injury to follow-up assessment was 8.5 years. Among the subjects with a history of ACL/meniscal injuries, nearly one in ten (10/108) had been diagnosed with knee OA. In comparison, none of the non-injured (0/106) had been diagnosed with knee OA (p=0.0357). ACL/meniscal injury subjects had clinically-relevant deficits on KOOS symptoms, sports/recreation (SR) and quality of life (QOL) scales (mean differences: -7.1, -7.6 and -10.5 respectively, all p<0.0001). Deficits on KOOS pain and activities of daily living scales were smaller and not clinically-relevant (mean differences: -4.3 and -2.6 respectively, both p<0.01). Over one-third of ACL/meniscal injury subjects endorsed (moderate/severe) the single-item question about knee pain, aching, or stiffness in the past 30 days (39/108), compared to 11% of non-injured (12/106, p=0.0001).

Conclusion: By the midpoint of their military careers, officers with a history of ACL/meniscal injury have deficits in knee-related QOL and physically-vigorous knee function (KOOS SR). Their OA prevalence (10% by age 28) is concerning given their youth and the physically-demanding nature of their profession.

Session Time: 9:00AM-11:00AM

High Dietary Fiber Intake is Associated with a Lower Likelihood of Severe Knee Pain Trajectory

Background/Purpose: Dietary fiber has been found to reduce systemic inflammation and body weight, both of which are linked with joint pain in knee osteoarthritis (OA). In this study, we assessed the association between fiber intake and knee pain trajectories over time.

Methods: In the Osteoarthritis Initiative of 4,796 participants with or at risk of knee OA, dietary fiber intake was estimated using a validated food frequency questionnaire at baseline and sex-specific quartiles of dietary fiber were created. Knee pain score was assessed using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) at baseline and annually for 8 years, and ranged from 0 (no pain) to 20 (worst pain). Group-based trajectory modeling was used to identify distinct WOMAC pain patterns with knee replacement (KR) cases censored at time of surgery. We used multivariable polytomous regression to assess dietary fiber and pain trajectories.

Results: Of the 4,075 participants (8,150 knees) remaining at year 8, baseline age [mean (SD)] was 61.3 (9.1) years and BMI was 28.6 (4.8) kg/m^2. During the 8-year course, 4.9% of the subjects underwent KR. We identified four distinct pain trajectories with the mean posterior probabilities ≥0.87 (**Figure**). None of the trajectories suggested substantial worsening of pain over time. Compared with the group of no pain, participants who had higher dietary total fiber had a lower likelihood of being in the severe pain group (p-trend<0.08) with those at the highest quartile having a statistically significant 29% lower likelihood of being in this group (**Table**).

Similar results were found for grain fiber with severe pain trajectory (p-trend<0.01). Results were similar among those with radiographic OA defined by Kellgren-Lawrence grade ≥2 at baseline or when selecting the more painful knee based on WOMAC score. Because improvement in pain was noted between baseline and month 12 for all trajectories, we examined the relation of fiber intake and WOMAC trajectories starting at month 12, and the results did not change materially.

Conclusion: Our study suggests that higher dietary total or grain fiber was inversely related to a pain trajectory characterized by severe pain over 8 years.

Table

	Dietary total fiber			
	Quartile (Q)1 [Lowest]	Q2 vs. Q1	Q3 vs. Q1	Q4 [Highest] vs. Q1
Median (IQR) (g/day)	8.6 (6.4,11.3)	12.5 (9.9, 15.5)	15.1 (12.4, 18.9)	20.6 (16.2, 26.3)
Pain trajectory groups				
No pain (n=2,848)	% 22.4	24.3	25.9	27.3

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Estimating the proportion of the population with severe OA is useful for health service planning. To calculate the proportion of the population with mild, moderate or severe OA, the Global Burden of Disease 2010 Study (GBD2010) used published WOMAC scores. From this, the proportion of the population in high income countries with mild OA was estimated as 71%, moderate 27% and severe 2%. Lay descriptions of levels of severity of OA were developed for GBD2010. If these are accurate measures of disease severity, these descriptions would be useful additions to population-based health questionnaires or brief assessments in clinical practice. The aim of this study is to validate lay descriptions of mild, moderate and severe OA and determine the proportion of a cohort within each category.

Methods: The descriptions were presented to the KHOALA cohort comprising OA knee and hip prevalent cases recruited as a representative sample of French patients with clinical and radiographic OA. Participants indicated which description they felt best described their condition. An additional level of "No pain or disability" was added for this cohort. Mild OA was described as "Has pain in the leg, which causes some difficulty running, walking long distances, and getting up and down" Moderate OA: "Has moderate pain in the leg, which makes the person limp, and causes some difficulty walking, standing, lifting and carrying heavy things, getting up and down and sleeping" Severe OA: "Has severe pain in the leg, which makes the person limp and causes a lot of difficulty walking, standing, lifting and carrying heavy things, getting up and down, and sleeping" Participants also completed WOMAC, EQ5D, EUROQOL VAS and walking times.

Results: Currently, 307 participants have completed the questionnaire with results shown in the table below. There was a significant trend for the WOMAC, EQ5D, EUROQOL and Maximal walking time to decline as the self-reported level of severity moved from none through mild and moderate to severe. The lay descriptions show significant convergent and divergent validity with the standardized measures used.

Conclusion: These preliminary results suggest that the lay descriptions are understandable by participants in this cohort. Those who rated their condition as consistent with the severe description also scored worse on the measures of pain and function. 14% classified themselves as having severe OA, in contrast to GBD2010, where

only 2% were classified as severe OA. The burden of OA may in fact be greater than reported in GBD2010 as the proportion of the population living with more severe disease may have been underestimated. Further assessment is being undertaken with a larger sample of the KHOALA cohort. These lay descriptions may be useful as a brief starting point for discussions in clinical care, or a contribution to the assessment of severity of OA.

	No pain/ Difficulty Mean (sd)	Mild Mean (sd)	Moderate Mean (sd)	Severe Mean (sd)	P value
n	49	135	80	43	
% of total	16.0	44.0	26.1	14.0

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: With the growing development of new technologies in clinical research, an electronic version of the OsteoArthritis Knee and Hip Quality Of Life (OAKHQOL), the e-OAKHQOL, has been formulated. This study aims to assess the validity of the e-OAKHQOL questionnaire and analyze whether the answers were affected by the form of administration (electronic versus paper).

Methods:

Two samples of patients with knee osteoarthritis (ACR criteria) were constituted. The first was composed of subjects, recruited by their general practitioner and who could choose to respond to the electronic or paper version. The second included subjects who responded to the paper version and were matched with respondents to the electronic version in the first sample. The OAKHQOL questionnaire contains 43 items, 3 of them are independent, and describes health-related quality of life (HRQoL) in 5 dimensions: physical activity, mental health, pain, social functioning and social support. A total score is normalized to a score from 0 (worst HRQoL) to 100 (best HRQoL). Two complementary analytical methods were used, the classical test theory (CTT) and a Rasch measurement model for item response theory (partial credit model).

Results: The electronic form was preferred by 471 (89.7%) patients. Among them, 345 were matched to the respondents of the paper version. The percentage of missing responses was lower in electronic than paper form (1.6% versus 2.0%, p = 0.01). The confirmatory factor analysis showed that the 4 or 5-factor models best fit with the data, although the CFI value was slightly below 0.9 (RMSEA value was below 0.08 as expected for model with good fit). Discrimination was good for the physical activity, mental health and pain dimensions. Rasch analysis revealed four items with underfitting. Internal consistency was excellent for dimensions Physical Activities (PSI = 0.96) and mental health (PSI = 0.93) but were slightly less than 0.85 for the other dimensions. No meaningful differential item functioning was detected for the mode of instrument administration, gender, age, educational level, low-back pain and BMI.

Conclusion:

Analysis with CTT and Rasch measurement of the e-OAKHQOL questionnaire revealed the good measurement properties of the five dimensions, so it may be a valuable alternative to the paper form. The instrument may offer many advantages in research and routine clinical practice such as immediate availability of the patient's score and better collection of data.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Physical activity guidelines for adults stipulate at least 150 minutes/week moderate-to-vigorous (MV) intensity physical activity acquired in bouts lasting 10 minutes or more (MV-bout). But, 2 in 5 adults with lower-extremity conditions not only fail to meet guidelines, they are physically inactive, not performing a single 10 minute MV-bout session of MV activity in a week. The objective of this study is to identify evidence-based thresholds related to improved low function or sustained high function (improved/high) among adults with lower limb joint symptoms.

Methods: Adults with symptomatic (pain/aching/stiffness) lower extremity joints from an Osteoarthritis Initiative accelerometer substudy had gait speed (n=1476) and self-reported SF-12 physical component score (PCS) function (n=1629) assessed two years apart. Year2 function compared to baseline assessed as improving to a better or remaining in the best (i.e., maintaining high) 2-year function quintile. Alternative physical activity metrics (sedentary, light intensity activity, total MV activity, and non-sedentary minutes/week) were evaluated against the legacy MV-bout metric to predict improved/high function using the area under the receiver operating curve (AUC). Classification tree analysis identified minimum threshold levels.

Results: Two years later 34% of adults (aged 40-83) had improved/high gait speed and 38% had improved/high SF-12 PCS function. Only total weekly MV activity was a stronger significant predictor of improved/high function (greater AUC) than the legacy MV-bout metric for both gait speed and SF-12 function and the only predictor selected by classification tree analyses (Figure 1). Meeting the 45 total MV minute/week threshold increased the relative risk (RR) for improved/high function (gait speed RR 1.8, 95% CI: 1.6 to 2.1; self-reported physical function RR 1.4, 95% CI: 1.3 to 1.6) compared to less active adults. Thresholds were consistent across sex, BMI, knee OA status and age.

Conclusion: Meeting an evidence-based threshold of 45 total MV minutes/week increased the likelihood of function preservation in high functioning persons and improvement in those with functional limitations among adults having lower limb joint symptoms. This threshold is a less demanding goal than the current guidelines in two ways. First, all time spent in MV activities contributes to attaining the 45 minute goal in contrast to the legacy MV-bout threshold which is only met through activity acquired in bouts lasting at least 10 minutes. Second, 45 minutes/week may be a more feasible goal than the current 150 minutes/week minimum. This evidence-based threshold represents an intermediate goal towards achieving the current physical activity guideline for adults with lower limb symptoms.

Prevalence and Trends in Prescribed Opioid Use Among US Adults with Arthritis, 2008-2013, Medical Expenditure Panel Survey

Jennifer M. Hootman[1], Miriam Cisternas[2], Louise Murphy[3] and Jan Losby[4], [1]Centers for Disease Control and Prevention, Kennesaw, GA, [2]MCG Data Services, Carlsbad, CA, [3]Division of Population Health, Centers for Disease and Control, Atlanta, GA, [4]Division of Unintential Injury Prevention, Centers for Disease Control and Prevention, Atlanta, GA

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: <span">Since 1999, overuse deaths from opioids in the US has quadrupled with

prescription use driving the epidemic. From 1999 to 2014, more than 165,000 persons died from overdose related to opioid pain medication in the United States. The 2012 American College of Rheumatology Osteoarthritis treatment guidelines provide limited guidance, using the GRADE evidence rating system, on opioid prescribing: opioids are conditionally not recommended for hand OA and there is no recommendation for knee and hip OA. National US population-based estimates of prescribed opioid use among adults with arthritis are unknown; therefore, we examined prevalence of and trends in use (2008-2013) among adults with and without arthritis; among those with arthritis, we estimated prevalence of use across selected socio-demographic characteristics.

Methods: <span">We analyzed 2008 to 2013 Medical Expenditure Panel Survey (MEPS) data. MEPS is annual survey designed to represent the US civilian non-institutionalized population. For each year, we categorized respondents as using prescribed opioids if they reported filling ≥ 1 narcotic analgesics prescription during that year. We categorized respondents as having arthritis if they reported ≥ 1 of ICD-9-CM 274, 710, 712 – 716, 719, and 729.

Results: <span">In 2013, 36.6 million (15.4%) US adults filled an opioid prescription and US adults with arthritis comprised approximately half (53%) of all US adults taking prescribed opioids. Prevalence among those with and without arthritis was 29.3% (95% confidence interval [CI] =27.4-31.1) and 9.9% (95% CI=9.3-10.4), respectively. From 2008 to 2013, prescribed opioid use prevalence (age-standardized) rose by 4 percentage points (4.4 million) among adults with arthritis (2008=24.7%; 95% CI=23.3-26.3; 2013=28.6%; 95% CI=26.5-30.8) but remained constant among adults without arthritis (Figure). Adults with arthritis with the highest prescribed opioid prevalence were those who were publicly insured only (37.8%), had < high school education (33.7%), some college/associate degree (32.2%), high school graduate (31.9%), or were non-Hispanic Blacks (31.8%). <span">

Conclusion: <span"><span">In 2013, US adults with arthritis represented more than half of prescribed opioid users in the general population of US adults with nearly 1 in 3 US adults with arthritis filling an opioid prescription. Using the US Centers for Disease Control and Prevention March 2016 opioid prescribing guideline for managing chronic pain may reduce high prescribing for this population and optimize pain management care while improving patient safety. The arthritis population may also benefit from attention to strategies outlined in the recent National Pain Strategy and greater use of evidence-based, non-pharmaceutical methods of reducing joint pain for arthritis, such as greater physical activity and non-opioid pharmacologic therapies. <span">

Analgesic Use and Subsequent Risk of Falls in Participants with or at Risk of Knee Osteoarthritis

Wei-Hsuan Lo-Ciganic[1], Lysbeth Floden[2], Erin L. Ashbeck[3], Lili Zhou[1] and C. Kent Kwoh[3,4], [1]Department of Pharmacy, Practice and Science, University of Arizona, College of Pharmacy, Tucson, AZ, [2]Department Pharmacy, Practice and Science, University of Arizona, College of Pharmacy, Tucson, AZ, [3]The University of Arizona Arthritis Center, Tucson, AZ, [4]Rheumatology, University of Arizona, College of Medicine, Tucson, AZ
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Analgesics including opioids, nonsteroidal anti-inflammatory drugs (NSAIDs), antidepressants, and nutraceuticals are commonly used for pain relief in osteoarthritis (OA). Although it has been reported that opioids and some antidepressants may increase the risk of falls, results from studies assessing the association between analgesic use and falls are mixed. Prior studies were limited by focusing on a single fall as the outcome, and lack of adjusting for pain severity, concurrent use of other medications associated with falls (e.g., anticholinergics), and other potential confounders. Our objective was to assess the association between type of analgesic use and subsequent risk of falls among participants with or at risk of knee OA.

Methods: We performed a longitudinal analysis with 4 years of follow-up (n=4,511) from the Osteoarthritis Initiative (OAI) cohort study. Analgesic use was identified through medication inventory and/or questionnaires. We grouped patients into 6 exclusive subgroups based on annually assessed analgesic use in the following hierarchical order of potency: (1) opioids, (2) antidepressants, (3) prescription NSAIDs, (4) over-the counter (OTC) NSAIDs/aspirin and other pain medications, (5) nutraceuticals, and (6) no analgesic use. We used multivariate logistic regression with generalized estimating equations to estimate the effect of analgesic use on the subsequent risk of any fall and recurrent falls in the following year, adjusted for sociodemographics, health status/behavior (e.g., pain severity, concurrent use of other medications related to falls), and access-to-care factors.

Results: Overall analgesic use decreased from 64.8% at baseline to 52.8% at the 4-year follow-up visit. In contrast, opioid use increased from 2.9% to 3.5% over this same time period. In each annual follow-up period, approximately 33% of participants self-reported at least one occurrence of a fall and 15% reported recurrent falls (i.e.≥ 2). Compared to those without any analgesic use, participants in the opioid and antidepressant groups had modest increased odds of both any fall (opioids: adjusted OR [aOR]: 1.37, 95% CI 1.08-1.74; antidepressants: aOR=1.27, 95% CI: 1.09-1.48) and recurrent falls (opioids: aOR: 1.34, 95% CI 1.00-1.80; antidepressants: aOR=1.34, 95% CI: 1.10-1.64; **Table 1**). Participants in the OTC NSAIDs/other pain medications group had a 24% higher odds of recurrent falls.

Conclusion: Opioids and antidepressants were associated with a modest increased risk of both any fall and recurrent falls after adjustment for pain severity and other potential confounders, among participants with or at risk of knee OA. Clinical management of pain with opioids and antidepressants among those at risk of falling warrants caution. Future research is needed to exmine and better understand the association between risk of falls and the use of OTC NSAIDs/other pain medications.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Vitamin D is implicated in bone homeostasis and its deficiency is associated with a progressive bone loss and fragility fractures. Our aim was to characterize vitamin D levels in Portuguese post-menopausal woman and evaluate its association with prevalent osteoporotic vertebral fractures (VF) and vertebral bone mineral density (BMD).

Methods: The present study was conducted under the scope of EpiReumaPt cross-sectional, population-based study. The study population was women ≥ 65years-old from EpiReumaPt (882 participants representative of Portuguese postmenopausal women). 25- hydroxyvitamin D serum levels were determined and Vitamin D insufficiency was defined as <30ng/ml and Vitamin D deficiency as <10ng/ml. Clinical Risk factors for fractures and OP treatment were assessed. Ten-year risk of fractures was calculated using FRAX tool. VF were evaluated by CT Scan and classified using the Genant method. Vertebral BMD was performed and osteoporosis was defined using the t-score cut-offs of the World Health Organization. Prevalence estimates were computed as weighted proportions for take into account the sampling design. Multivariate regression models were used to assess the association of vitamin D levels and VF and BMD. Age, body mass index, NUTS II, seasons and glomerular filtration rate were considered as possible confounders.

Results: Vitamin D insufficiency was present in 38.4% of Portuguese postmenopausal women and 14.2% had vitamin D deficiency. The prevalence of osteoporosis was 15% and of VF was 11.7% among Portuguese postmenopausal women. Regarding clinical risk factors 49.1% of postmenopausal women reported having at least one previous fragility fracture independently of the localization. The mean10-year risk for a major fracture was 9.9 ± 9.5 % and for hip fracture was 4.4 ± 7.2%. A significant number of postmenopausal women had ≥10% of 10- year risk for major fracture (38.2 %) and of postmenopausal women had ≥3 % of 10-year risk for hip fracture (7.9 %). Only, 53% of the OP postmenopausal women were under treatment. Vitamin D deficiency was independently associated with prevalent VF (OR=15.9; 95%CI 1.93,130.55; p= 0.010) but not with vertebral BMD (β= -0.016; 95%IC -0.178, 0.146; p=0.848). Vitamin D insufficiency was not significantly associated with VF or with BMD.

Conclusion: Portugal is a sunny country of Southern Europe**,** levels of vitamin D are below the recommended levels for a large proportion of post-menopausal Portuguese women and this fact is associated with vertebral fragility fractures. Vitamin D supplementation recommendations should be reviewed and public health policies should address this issue.

Association Between Extent of Symptomatic Joint Involvement in Osteoarthritis and Comorbid Lung Disease in Patients Scheduled for Joint-Replacement Surgery

Anthony V. Perruccio[1,2,3], Rajiv Gandhi[4], J. Denise Power[5,6] and Elizabeth M. Badley[7], [1]The Arthritis Program, University Health Network, Toronto, ON, Canada, [2]Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, [3]Health Care & Outcomes Research, Krembil Research Institute, University Health Network, Toronto, ON, Canada, [4]University Health Network, Arthritis Program, Toronto, ON, Canada, [5]Arthritis Program, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [6]Dalla Lana School of Public Health, Toronto, ON, Canada, [7]Toronto Western Research Institute, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - ARHP Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Comorbidity is highly prevalent in osteoarthritis (OA), although the origin of this is not well understood. The presence of multi-joint symptoms in OA, and noted associations between obesity and OA in non-weight bearing joints, suggests a likely systemic component. Lung disease has also has been associated with obesity and other systemic factors. Our purpose is to investigate the association between the extent of symptomatic joint involvement in patients with OA and prevalent lung disease.

Methods: Patients with end-stage hip and knee OA were recruited from an orthopaedic clinic in 2010-2012. Patient questionnaires captured symptomatic joints, comorbidities (lung disease, heart disease, diabetes, and high blood pressure), BMI (calculated from reported height and weight), smoking status, functional limitations (Western Ontario McMaster University OA Index physical function subscale) and demographic characteristics. Bivariate analysis tested trends in lung disease prevalence by symptomatic joint count categories (1; 2-4; and 5+). Logistic regression analyses evaluated the association between symptomatic joint count (continuous) and lung disease, adjusting for other assessed study measures.

Results: Study sample: 913 individuals scheduled for joint replacement surgery (469 knees and 444 hips). Mean age was 64 years, 44% male. Lung disease was reported by 9.5%. Mean symptomatic joint count was 4.4 (range: 1-20); almost 40% reported ≥5 symptomatic joints. Comparing individuals reporting lung disease with those who did not, those reporting lung disease had significantly higher mean BMI (mean ± SD: 33.2 ± 8.0 vs 29.4 ± 6.2); more previous/current smokers 41.4% vs 23.6%, greater comorbidity (significantly more with heart disease, diabetes, and high blood pressure), and greater symptomatic joint count (mean ± SD: 6.2 ± 4.4 vs 4.2 ± 3.2). A statistically significant increasing trend in lung disease prevalence was observed with joint count categories (1; 2-4; 5+). Logistic regression showed, adjusted for study covariates, each numerical increase in symptomatic joint count was associated with a 7% (OR: 1.07, 95% CI: 1.01, 1.14) increased odds of reporting lung disease. Other independent predictors of lung disease were previous/current smoker (OR: 2.64, 95% CI: 1.32, 4, 5.26), reporting diabetes (OR: 2.37, 95% CI: 1.28, 4.40) and having functional limitations (OR: 1.03, 95% CI: 1.01, 1.06). Females were significantly more likely to report lung disease (OR: 2.40, 95% CI: 1.34, 4.28). There were no significant associations with BMI, high blood pressure or surgical hip or knee group.

Conclusion: Findings suggest that having multi-joint symptoms in OA may increase the probability of concurrent lung disease. This raises questions for OA research including the nature of possible underlying mechanisms.

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While rheumatoid arthritis is associated with a number of different lung conditions, the relationship with osteoarthritis, overwhelmingly the most frequent type of arthritis in the population, has been less well studied. Objective: to examine whether arthritis is associated with an increased likelihood of reporting asthma and/or COPD.

Methods: Data from the 2011- 2012 Canadian Community Health Survey, a representative survey of the household population, restricting analyses to the population age >= 35 years (n=88,734). Participants were asked about specific long term health conditions diagnosed by a health professional, including arthritis (excluding fibromyalgia), asthma, and COPD (specifically chronic bronchitis, emphysema or chronic obstructive pulmonary disease). Multinominal logistic regression was used to examine associations between lung conditions (none, asthma only, COPD only, both asthma and COPD) and arthritis, controlling for covariates: age, sex, education, household income, smoking status (never, former, current), body mass index (BMI: underweight, normal, overweight, obese), and mean number of other chronic conditions (out of 9). Sensitivity analysis: a) analyses were restricted to those reporting OA; b) analyses were stratified by BMI categories given the strong association of obesity and arthritis and the possibility of metabolic/inflammatory pathways.

Results: People with arthritis (23 % of the population) more frequently reported lung conditions than those without, respectively asthma only 8.2% vs 5.5%, COPD only 5.4% vs 2.0%, and asthma+COPD 3.4% vs 0.8%. Compared to those without, people with arthritis, were more likely to be current or former smokers (70.3% vs 57.0%), to be obese (26.8% vs 16.7%) and have more other chronic conditions (mean 1.5 vs 0.5). In regression analyses arthritis was significantly associated with all lung conditions: OR (95%CI): asthma only 1.48 (1.26, 1.73); COPD only 1.60 (1.34, 1.91); asthma+COPD 1.98 (1.65, 2.37). The odds of all lung conditions were significantly higher for females. Being a current or former smoker was significantly associated with COPD, but not with asthma. Obesity and the number of other chronic conditions were significant risk factors for reporting all

lung conditions. Sensitivity analyses: results were unchanged when restricted to OA. Analyses stratified by BMI categories gave similar results.

Conclusion: This population-based study confirms a relationship between arthritis and lung diseases, and adds to the scant previous literature. The increased odds of reporting lung diseases by people with arthritis raises questions as to the mechanism. The consistency of the association over BMI categories suggests pathways other than those mediated by metabolic/inflammatory factors. The findings also suggest that recommendations for the management of arthritis should consider the potential implications of having lung disease, for example, for physical activity.

Session Title: Epidemiology and Public Health - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Severe joint pain (SJP) from arthritis may reflect insufficiently managed pain, and SJP can limit an individual's ability to perform basic functions. We determined the prevalence of SJP among adults with doctor-diagnosed arthritis, overall and by various sociodemographic and health characteristics in 2014, and examined whether the absolute number and age-standardized prevalence of SJP changed for the years 2002, 2003, 2006, 2009, and 2014.

Methods: We used data from the National Health Interview Survey, an annual, nationally representative, in-person interview survey of health status and behaviors of the noninstitutionalized civilian U.S. population. Unweighted sample sizes and final response rates were 31,044 (74.3%) in 2002; 30,852 (74.2%) in 2003; 24,275 (70.8%) in 2006; 27,731 (65.4%) in 2009; and 36,697 (58.9%) in 2014. Adults were defined as having doctor-diagnosed arthritis if they answered "yes" to "Have you ever been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" Respondents assessed their joint pain on a scale of 0 to 10 in the past 30 days, "where 0 is no pain or aching and 10 is pain and aching as bad as it can be." Severe joint pain was defined as a 7 to 10. Prevalence estimates were age-standardized to the projected U.S. 2000 population (the US public health standard): differences were statistically significant if 95% confidence intervals (CIs) did not overlap.

Results: The age-standardized prevalence of SJP did not differ significantly by year (Figure 1). In 2014, over one third of adults with arthritis had SJP (37.4%) with the highest age-standardized prevalence of SJP among those who had serious psychological distress (66.7%), were unable to work or disabled (61.5%), or identified as non-Hispanic blacks (58.1%). The estimated number of adults with arthritis and SJP increased significantly from 2002 (10.5 million, 95% CI: 9.9-11.1 million) to 2014 (14.6 million, 95% CI: 13.8-15.4 million) (Figure 2).

Conclusion: The prevalence of SJP in the past 30 days remained high (range: 35.3-37.5%) and stable from 2002-2014, but absolute numbers continue to grow and in 2014, was almost 15 million. This is likely due to the aging of the population. Increased dissemination of evidence-based physical activity interventions shown to reduce joint pain in adults with arthritis is needed. National efforts to improve generic pain management (e.g., the 2016 National Pain Strategy) may also help.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - ARHP Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Depression is one of the most common mental disorders in the United States, affecting 15.7 million adults. It frequently co-occurs with other chronic conditions (e.g., arthritis), particularly in middle age and older adults. Despite the considerable evidence that physical activity reduces symptoms and adverse effects of arthritis and depression, physical inactivity is highly prevalent among those with these conditions. The study purpose was to estimate the 2013 prevalence of: 1) arthritis among adults with self-reported depression; 2) physical inactivity among adults with depression by arthritis status.

Methods: The Behavioral Risk Factor Surveillance System (BRFSS) is an annual state-based random-digit dialed telephone survey of the civilian, noninstitutionalized US population aged >18 years. Doctor-diagnosed arthritis was defined as a 'yes' to: "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus or fibromyalgia?" Self-reported depression was defined as a 'yes' to: "Ever told you have a depressive disorder, including depression, major depression, dysthymia, or minor depression?" Physical activity level was assessed using 6 questions on frequency and duration of participation in activities of moderate and vigorous intensity. Persons reporting no participation in either moderate or vigorous physical activity were classified as physically inactive. The 2013 BRFSS (n= 491,773) weighted median response and cooperation rates were 45.9% and 65.7%, respectively. Calculation of percentages and 95% confidence intervals (CI) accounted for the NHIS' multistage, complex sample design. Percentages were age-standardized using the 2000 US projected adult population provided by the US National Center for Health Statistics.

Results: In 2013, 42.8% (95% CI=42.2-43.5; 18.5 million) of US adults with self-reported depression also had arthritis. Compared to adults with neither condition (25.9%; CI=25.6-26.3), adults with depression only (35.9%; CI=35.2-36.5), arthritis only (35.3%; CI=34.5-36.2), and both depression and arthritis (41.6%; CI=40.3-42.9) had significantly higher prevalence of physical inactivity (Figure).

Conclusion: Depression and arthritis frequently co-occur and the combination is associated with high prevalence of physical inactivity, a missed opportunity to engage in a proven non-pharmaceutical self-management strategy for both conditions. Through universal screening of patients with arthritis for depression,

health care providers may identify a treatable barrier to increasing physical activity.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) patients are known to have sleep disturbances. Quality of sleep may affect quality of life, but this association has not been systematically evaluated. The aim of this study was to examine the distribution and association of quality of sleep and quality of life among patients diagnosed with SLE.

Methods: SLE outpatients at three rheumatology centers in Western Japan were included in this cross-sectional study. The consented participants completed Japanese versions of the following questionnaires: the Pittsburgh Sleep Quality Index (PSQI), the 12 item Short Form Health Survey (SF-12), and the Lupus Patient-Reported Outcome tool (LupusPRO). Clinical information, including the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), was obtained from medical records. Correlation coefficients (r) were used to measure the associations between the PSQI and the other factors. Stability of quality of sleep was examined by administering the PSQI at baseline (T1) and 2 weeks later (T2).

Results: The study included 205 SLE patients. The mean age was 47.8±13.6 years (mean SLE duration: 15.0±8.8 years) and >90% were female. The mean SLEDAI score was 3.9±3.7. The majority of the participants (62.9%) had sleep disturbances (PSQI<6.0). Neither the overall PSQI, nor the subcategories were associated with duration of SLE, prednisolone dosage, or SLEDAI. Total PSQI score was weakly associated with all of the SF-12 subcategories (range of r: −0.26–0.39) and showed weak to moderate associations with the LupusPRO subcategories (r: −0.51–0.22), except for “medication”, “procreation”, and “satisfaction with care” (all r<0.20). Analysis of the seven PSQI subcategories revealed that “daytime dysfunction” was weakly to moderately associated with all of the SF-12 subcategories (r: −0.27–0.47) and all of the LupusPRO subcategories (r: −0.59–0.20), except for “procreation” and “satisfaction with care”. However, “sleep duration” was not associated with any of the SF-12 or LupusPRO subcategories. “Sleep efficiency” was weakly associated with “physical health”, “physical function”, and “pain“ in the SF-12 and LupusPRO. “Sleep quality” and “sleep disturbances” were weakly associated with “pain” and the “emotional” and “mental” subcategories in the SF-12 and LupusPRO. The analysis of the stability of sleep quality, revealed a correlation coefficient of 0.79 for the total PSQI scores at T1 and T2. Among the seven PSQI subcategories, the T1 and T2 measurements of “sleep efficiency” and “sleep disturbance” were moderately associated (0.54 and 0.61, respectively), and those for “use of sleep medication” and “sleep latency” were strongly associated (>0.8).

Conclusion: We found that quality of sleep, especially “sleep efficiency”, was poor for the majority of patients in the sample. Quality of sleep was associated with various aspects of quality of life, especially pain, vitality, and emotional health. Management of pain and emotional health may be important for improving quality of sleep in SLE patients.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fear of movement is associated with increased pain, decreased physical function, decreased activity, and negative psychological symptoms. Little is known about fear of movement in the context of osteoarthritis. This study examined the frequency of and factors associated with fear of movement among patients with symptomatic knee osteoarthritis (sxKOA), using the new Brief Fear of Movement (BFOM) measure.

Methods: This cross-sectional study is a secondary analysis of data from a randomized exercise trial among patients with sxKOA. Participants (n=350) were recruited from an academic medical center, the community, and an ongoing cohort study. Participants (mean age = 65.3 ± 10.9; 71.7% female; 26.3% nonwhite) had sxKOA based on a physician diagnosis and/or a prior radiograph. The BFOM scale contains 6 items using a 4-point scale ranging from "strongly agree" to "strongly disagree." We examined relationships of BFOM with: age, sex, race (white vs. nonwhite), education (bachelor's degree or higher vs. up to a bachelor's degree), Knee Injury and Osteoarthritis Outcome Score (KOOS) pain and activities of daily living (ADL) subscales, knee symptom duration, depressive symptoms (PHQ-8), falls in the prior 12 months, history of knee injury, family history of knee problems, self-efficacy for exercise (SEE), and unilateral balance test. We created a 3-level ordinal variable, which grouped participants based on agreement ("agree" or "strongly agree') with 0, 1-2, or 3+ items on the BFOM scale. General linear models with trend tests were used to compare participant characteristics across the 3 BFOM categories. A proportional odds logistic regression model with backward selection was used to examine multivariable associations of participant characteristics with the ordinal BFOM variable.

Results: The majority of participants (76%) agreed with at least 1 item on the BFOM scale, and 36% endorsed 3+ items, suggesting high fear of movement. In bivariate analyses, the following were significantly associated ($p<0.05$) with the ordinal BFOM variable: age, KOOS pain, KOOS ADL, PHQ-8, and SEE (Table). In the multivariable model (for which the proportional odds assumption was met), the following remained after backward selection: age (odds ratio (OR) = 0.74 per 10-point increase, 95% confidence interval (CI) = 0.60 – 0.97), KOOS ADL (OR = 0.66 per 10-point increase, 95% CI = 0.54 - 0.90), PHQ-8 (OR = 1.11, 95%CI = 1.04 – 1.20), and SEE (OR = 0.99, 95%CI = 0.97 – 1.00).

Conclusion: Among patients with sxKOA, there was a high frequency of fear of movement, which can negatively impact physical activity, an important component of osteoarthritis management. Psychological variables were significantly associated with BFOM, suggesting that behavioral and psychological interventions may decrease fear of movement and improve clinical outcomes in individuals with sxKOA.

Table. Bivariate Associations of Participant Characteristics with Fear of Movement, N=350.				
	Agree with none (n=81, 23.1%)	Agree with 1 to 2 (n=142, 40.6%)	Agree with 3 to 6 (n=127, 36.3%)	Trend p-value

Abstract Number: 2194

The Association Between Arthritis and Carpal Tunnel Syndrome:

National Health Interview Survey, 2010

Nancy A. Baker, Department of Occupational Therapy, University of Pittsburgh, Pittsburgh, PA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - ARHP Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Carpal tunnel syndrome (CTS) is associated with high-repetition, forceful jobs. Additionally, non-occupational factors, such as arthritis, have been associated with CTS. There is conflicting evidence about the association between arthritis and CTS[1], probably due to studies with small samples, obtained from medical clinics rather than the general population, and "work-related" CTS populations. We used data from the 2010 National Health Information Survey (NHIS), representative of the U.S. civilian non-institutionalized population, to determine the risk for CTS for people with arthritis after controlling for occupational and non-occupational factors.

Methods: We analyzed adults (age 18-65). CTS cases were defined as "Have you EVER been told by a doctor or other health professional that you have a condition affecting the wrist and hand called carpal tunnel syndrome?" Arthritis and diabetes were self-reported in a similar fashion. Obesity was those with Body Mass Index (BMI) ≥30, and smoking as those who never or ever smoked. To identify occupational type, respondents were categorized in five major Standard Occupational Classification System categories (SOC): 1) Management, professional, and related; 2) Sales and office; 3) Service; 4) Natural resources, construction and maintenance; and 5) Production, transportation, and material moving, each of which represent progressively greater exposure to high-repetition, forceful jobs. We completed a logistical regression using appropriate NHIS weights: Step 1 included age, sex, race/ethnicity, education, and employment status; Step 2 the SOC; Step 3 arthritis and other co-morbidities. NHIS weights were applied to all analyses.

Results: Of our sample of 22,012 adults, 7.5% (95%CI: 7.0, 7.9) had CTS. Older adults and females were more likely to report CTS, while Hispanic/Non-Hispanic Other were less likely than Non-Hispanic Whites (See Table 1). Only respondents working in Production were significantly more likely to report CTS than those in Management (OR 1.4: (95% CI 1.1, 1.8) (Table 1). Diabetes, obesity, and smoking were all independent risk factors for CTS, with odds ratios ranging from 1.3 to 1.5. The arthritis odds ratio was 3.1 (95%CI 2.7, 3.5).

Table 1: Multivariable adjusted odds ratios (OR) with 95% confidence intervals (95% CI) for adults with and without CTS: NHIS 2010

Variable	OR (95% CI)
Age: 35-65 (referent: 18-34)	3.2 (2.6, 3.9)
Sex: Female (referent: Male)	2.6 (2.2, 3.0)
Race/ethnicity (referent: Non-Hispanic White)	
Hispanic	0.7 (0.6, 0.9)
Non-Hispanic Black	1.0 (0.8, 1.2)
Non-Hispanic Other	0.6 (0.4, 0.9)
Education: > College (referent: <College)	1.0 (0.9, 1.2)
Employment: Employed (referent: Not employed)	0.9 (0.8, 1.0)
SOC category: (referent: Management)	
Sales and office	1.2 (1.0, 1.4)
Service	1.1 (0.9, 1.4)
Natural resources, construction and maintenance	1.2 (0.9, 1.6)
Production, transportation, and material moving	1.4 (1.1, 1.8)
Arthritis: arthritis (referent: no arthritis)	3.1 (2.7, 3.5)
Diabetes: diabetes (referent: no diabetes)	1.5 (1.2, 1.8)
Obesity: BMI >30 (referent: BMI ≤30)	1.3 (1.2, 1.5)
Smoke: ever smoked (referent: never smoked)	1.4 (1.2, 1.6)

Conclusion: Respondents with arthritis were 3 times more likely to report CTS than those without arthritis, and were at similar risk as older adults. Non-occupational factors such as diabetes, obesity and smoking are as likely to be risk factors for CTS as jobs that require high repetition and forceful hand exertions. While both occupation and non-occupational factors are important risk factors for CTS, arthritis is one of the prime risk factor for CTS in the general population. References: 1. Burger MC, et al. Non-Occupational Risk Factors for Carpal Tunnel Syndrome: A Review. Women's Health Bull. 2016;3(2):e34820.

Conceptualizing the Life Course in the Employment Experiences of Working-Aged Adults with Arthritis: A Qualitative Study

Arif Jetha[1,2], Julie Bowring[1], Catherine Connelly[2], Sean Tucker[3], Kathleen Martin Ginis[4] and Monique A.M. Gignac[5,6], [1]Institute for Work & Health, Toronto, ON, Canada, [2]DeGroote School of Business, McMaster University, Hamilton, ON, Canada, [3]University of Regina, Regina, SK, Canada, [4]Department of Kinesiology, McMaster University, Hamilton, ON, Canada, [5]Instititue for Work and Health, Toronto, ON, Canada, [6]Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - ARHP Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Research consistently finds that arthritis contributes to work disability. Yet, few studies have examined how employment experiences differ across the life course. This study examines the concept of the life course and its impact on the employment experiences of young, middle-aged and older adults with arthritis.

Methods: A series of focus groups and interviews with young (ages 18 to 34 years, n = 7), middle-aged (ages 35 to 54 years, n = 13) and older adults (>55 years, n = 25) living with arthritis were conducted. Participants were asked about aging with arthritis and ways in which their life circumstances, disease characteristics and career progress changed over time and affected their involvement in paid work. Two investigators independently coded data and incongruences were discussed. A modified grounded theory approach was used to inductively build a conceptual framework of the life course.

Results: The life course was made up of three interconnected domains that included life phase (i.e., changing social roles and responsibilities), career stage/job tenure (i.e., duration of employment and seniority in a job) and disease course (i.e., short- and long-term changes to arthritis symptoms). Life course domains and their impact on work experiences tended to differ based on the calendar age of the participant. Young adults described having to spend more energy transitioning into stable employment and a fear of worsening symptoms. Attributed to an early career phase, young adults were more reluctant to request workplace accommodations. Middle-aged adults discussed how their arthritis disrupted roles outside of work (e.g., parenting and marriage). Being in the mid-career stage and having greater job tenure offered more opportunities to access accommodations and benefits. For both young and middle-aged adults, having arthritis at a non-normative time of life created a barrier to disclosing the details of their condition and asking for help. In contrast, older adults talked about their life phase as being a time where they weighed the decision to retire against continuing to work. Related to a longer disease duration and greater job tenure, older adults discussed a toolbox of strategies they used to manage their arthritis and employment. When compared to the younger age groups, older adults were more likely to acknowledge that an arthritis diagnosis was part of aging and they were more comfortable talking to others about their limitations and requesting support.

Conclusion: Life course differences existed when comparing the employment experiences of young, middle-aged and older adults with arthritis, and should be considered in the development of work disability prevention policies and programs. Future research should also be conducted to identify opportunities for measuring life course domains in population health studies.

Trajectories and Predictors of Fear-Avoidance in Persons With Rheumatoid Arthritis. A Longitudinal Observational Study

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory disease with symptoms such as pain, severe fatigue, depression and activity limitation. Pain and activity limitation are known to increase the risk of developing fear-avoidance behavior but their associations with physical activity are not fully verified. RA is a chronic disease that people have to live with for many years but knowledge on how fear-avoidance develops over time is still scarce. The aim of the study was to identify and describe groups with different trajectories of fear-avoidance beliefs over 2 years and to identify predictors for each trajectory in people with RA.

Methods: A sample of 2569 people with RA (mean age 58, 77% women) was identified via the Swedish Rheumatology Quality Registers. They responded, at baseline and at 1-year and 2-year follow-ups, to a valid questionnaire on demographics (age, gender, number of children and adults in household, education, income) health-enhancing physical activity (HEPA, current and maintained), disease-related factors (co-morbidity, perceived health, pain, fatigue, activity limitation) and psychosocial matters (fear-avoidance beliefs, anxiety/depression and self-efficacy for exercise). Data were analyzed with k-means longitudinal cluster analysis to identify trajectories of fear-avoidance beliefs and multinomial logistic regression to identify predictors of each trajectory.

Results: Three stable trajectories of fear-avoidance beliefs were identified from the cluster analysis; one with low (n = 1060) fear-avoidance beliefs, one with moderate (n = 1043) and one with high (n = 466). Predictors of stable high fear-avoidance beliefs, compared to low or moderate levels, were male gender, below average

income, current physical activity below HEPA levels and high activity limitation. Additional predictors of high fear-avoidance beliefs compared to low were below-university education, high pain, moderate activity limitation and low self-efficacy for exercise (Table 1).

Conclusion: There are 3 stable trajectories of fear-avoidance behavior in people with RA. The strongest modifiable predictors of persistently high fear-avoidance beliefs are more pronounced activity limitation, pain, below HEPA levels and low self-efficacy for exercise. These factors are important to identify at an early stage in people with RA in order to develop strategies to prevent high fear-avoidance behavior. Table 1. Baseline predictors of trajectories with high (n = 466) vs low (n = 1060) and moderate (n = 1043) fear/avoidance beliefs. Odds ratios (OR) and 95% confidence intervals (CI). Bold figures indicate significant predictors ($p < 0.01$).

Session Title: Epidemiology and Public Health - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: People with knee osteoarthritis (OA) are thought to be less physically active than those without OA. This includes time in moderate-to-vigorous physical activity (MVPA), a critical level of intensity associated with numerous health benefits, and walking, the most common type of physical activity in older adults. However, little empirical data exists to support these trends. The purpose of this study was to compare objectively measured physical activity and walking among people with symptomatic knee OA (SxOA) with people from the US population of the same sex and similar age. We hypothesized that those with SxOA will be less active than the US population.

Methods: We used data from the Osteoarthritis Initiative (OAI), a large prospective cohort study of knee OA (n=486), and the National Health and Nutrition Examination Survey (NHANES), a nationally representative sample from the United States (n=1455). Physical activity was measured in both cohorts with an accelerometer-enabled monitor worn for ≥ 10 hours/day for ≥ 4 days (NHANES – Actigraph 7124; OAI – Actigraph GT1M). Data were collected in OAI from 2008-2010, and in NHANES from 2005-2006. SxOA was defined as those with Kellgren–Lawrence grade ≥ 2 and knee pain on most of the last 30 days. MVPA was defined as ≥ 2020 activity counts/min. We also classified those who walked ≥10 minutes/week at ≥80 steps/min to reflect purposeful walking. Within age- and sex-specific strata, we compared mean time in MVPA between cohorts with independent t-tests and calculated the likelihood that people with SxOA walked purposefully ≥10 min/day compared with the US population using odds ratios (OR).

Results: Within age- and sex-specific strata, physical activity levels were generally similar ($p>0.05$) among people with SxOA and the general US population. People with SxOA spend on average 4-29 minutes in MVPA, while the US population spent 2-26 minutes in MVPA (Figure 1)**.** The proportion of people who walked at least 10 min/day was 8-60% for those with SxOA and 10-54% in the US population (Table 1). The odds of walking at least 10 minutes/day was similar for individuals with SxOA relative to the US population.

Conclusion: Strikingly low levels of physical activity were observed in both people with SxOA and people in the general US population. The presence of pain and OA is not likely a primary reason for low levels of physical activity among people with SxOA. **Figure 1.** Mean minutes per day (± 95% CI) in MVPA for the US population (NHANES) and people with SxOA (OAI SxOA).

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - ARHP Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Reports of associations of hypermobility and osteoarthritis (OA) vary widely**.** One possible cause for this lack of agreement may be different impacts of hypermobility by joint site. No prior cohort study has examined this association at the foot. This cross-sectional analysis assessed joint hypermobility with foot OA and symptoms in a large community-based cohort.

Methods: Of the 863 community-based participants with complete foot radiographs (2012-15), 848 had Beighton data (joint hypermobility; 2003-2010). Beighton criteria assessed the ability to do: passive dorsiflexion fifth finger ≥ 90 degrees, passive apposition thumb to forearm, elbow hyperextension ≥10 degrees, knee hyperextension ≥10 degrees, and palms on floor during forward trunk flexion with knees extended. One point was given for each completed maneuver (total score: 0 [unable to do any maneuver] to 9 [all maneuvers done]). Joint hypermobility was defined as Beighton score ≥4; the knee maneuver alone also was examined specifically due to the biomechanical connection of the knee and foot/ankle. Standing anteroposterior and lateral foot x-rays were read with the LaTrobe atlas to measure osteophytes (OST, 0-3) and joint space narrowing (JSN, 0-3) at five joint sites: first metatarsophalangeal, first cuneo-metatarsal, second cuneo-metatarsal, navicular-first cuneiform, and talonavicular. A joint with a score ≥2 OST or JSN was considered to have radiographic OA (rOA). Foot rOA was defined as ≥1 joint with rOA within the same foot. Foot symptoms (yes/no) was based on response to: "On most days of any one month in the last 12 months did you have pain, aching or stiffness in your left/right foot?" Separate logistic regression person-based models were used to estimate associations of foot rOA, site rOA, and symptoms with hypermobility, adjusting for covariates of age, sex, race (Caucasian vs. African American), body mass index (BMI), and history of foot injury. Pairwise interactions between hypermobility and each covariate were examined (<0.10 considered significant).

Results: This sample was 68% women and 33% African American (mean age=71 years, mean BMI=31 kg/m^2). Joint hypermobility was present in 59 participants (7%); 189 (22%) participants had foot rOA, and 176 (21%) had foot symptoms. The adjusted odds of talonavicular rOA and foot symptoms were 3.0 and 2.4 times higher, respectively, among participants able vs. unable to perform the knee maneuver but based on small numbers. While no association was seen for foot rOA and hypermobility, non-significant increased estimates suggested possible relationships with specific foot joints and with foot symptoms (Table). No statistical interactions of hypermobility by covariates were observed.

Conclusion: Joint hypermobility may be related to rOA of specific foot joints and with foot symptoms. Future longitudinal studies will clarify the influence of hypermobility on the incidence and progression of foot OA and

symptoms.

Table. Adjusted* odds ratios (OR) and 95% confidence intervals (CI) for association of foot outcomes with Beighton Criteria.

Peri-Aortic Adipose Tissue Volume Is Directly Associated with Fat Accumulation in Adjacent Trunk Muscles Independent of Other Fat Depots: The Framingham Study

Session Title: Epidemiology and Public Health - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Age-related accumulation of muscular fat and loss of muscle mass contribute to impaired

muscle function and consequent mobility impairment in older adults. These muscle changes may result from excess ectopic fat accumulation, which produces inflammatory cytokines that promote differentiation of muscle satellite cells into adipocytes versus myoblasts. It is unknown whether this muscle-fat cross-talk occurs primarily via systemic effects of circulating cytokines, or through paracrine effects between adjacent compartments. Our objective was to determine the association of peri-aortic adipose tissue (PAAT) volume with size and fat content of adjacent trunk muscles among 948 participants (56% women) in the community-based Framingham Study.

Methods: Multidetector CT abdominal imaging measured PAAT volume (cm^3), as well as cross-sectional area (mm^2) and attenuation (HU), a marker of fat content, of the erector spinae, transversospinalis, and trapezius muscles at the T7 and T8 levels. Cross-sectional area and attenuation of each muscle was averaged for the left and right sides, and across vertebral levels. Linear regression was used to calculate coefficients (β) estimating the associations of PAAT volume with muscle cross-sectional area and attenuation, adjusting for sex, age, height, body mass index (BMI) and self-reported physical activity (Framingham Physical Activity Index). Models were further adjusted for abdominal visceral (VAT) and subcutaneous adipose tissue (SAT) volumes (cm^3), measured from the same CT images, to determine if PAAT associations were independent of abdominal fat depots.

Results: Mean age was 58 years (range 45-81), mean BMI was 28 kg/m^2 (range 18-53). While there was no association with muscle cross sectional area (β=-0.96, P=0.37), PAAT was inversely associated with muscle attenuation (β=-0.31, P<0.0001), indicating greater muscle fat content with increasing PAAT. The association remained after further adjustment for VAT (β for PAAT=-0.21, P<0.0001) and SAT (β for PAAT=-0.33, P<0.0001). Results were similar when stratified by sex and categorizing PAAT as quartiles.

Conclusion: We found that increased fat surrounding the aorta was associated with greater fat content in nearby trunk muscles, independent of overall obesity and specific abdominal fat depot volumes. PAAT was not, however, associated with trunk muscle size. Our findings suggest that age-related fat accumulation in skeletal muscle may result mainly from local paracrine effects of adjacent fat depots. Cross-talk between neighboring fat and muscle is a potential novel target for therapies aiming to prevent or restore loss of muscle function.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Epidemiology and Public Health - ARHP Poster

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia symptomatology results in a low functional capacity[1], limiting the daily activities and the quality of life of the patients[2]. Walking for commuting is a healthy behaviour which might be one of the sources for increasing the physical activity in women[3,4]. We aimed to examine the association between active commuting and objectively measured physical activity in women with fibromyalgia.

Methods: A total of 486 fibromyalgia women who meet the 1990 American College of Rheumatology Fibromyalgia criteria were enrolled in this cross-sectional study. Mode of commuting was assessed with a mode of commuting questionnaire[5]. Physical activity was measured by accelerometry during 7 complete days. One way analysis of covariance was performed between active (i.e. walk or cycling) and passive commuters (i.e. users of cars, motorbikes and bus). Linear regression analyses were conducted to further examine the relationships between mode of commuting and physical activity in separates models. All analyses were conducted separately in two age groups, i.e.: <51 (young group) and ≥51 (older group)[6]. Age, algometer score and accelerometry wear time were used as confounders.

Results: Active commuters from both age groups spent less time in sedentary activities (all $p<0.001$), greater time in all physical activity intensities (all $p\leq0.001$; except vigorous, $p<0.05$), and registered a higher amount of steps ($p\leq0.001$) than passive commuters. The results of the linear regression analysis showed, in the younger group, a positive and significant association between active commuting and moderate, moderate to vigorous physical activity, total physical activity and steps count (all $p\leq0.01$). Active commuting was negatively and significantly associated with sedentary time ($p=0.008$). No association between active commuting and accelerometry outcomes were observed in the older group.

Conclusion: Findings of the current study suggest that, in fibromyalgia women, commuting actively is associated with less time in sedentary activities, greater levels of physical activity and a higher amount step counts. A public health strategy for increasing the physical activity levels in this population might be to promote walking to reach the daily destinations (i.e., work, supermarket…). Self-Reported Breathlessness on Exertion Is Associated with Poor Outcomes Among Women with Systemic Lupus Erythematosus (SLE)

Patricia P. Katz[1], Sofia Pedro[2], Robert S. Katz[3], Frederick Wolfe[4] and Kaleb Michaud[5],
[1]Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]Rush University Medical Center, Chicago, IL, [4]National Data Bank, Wichita, KS, [5]University of Nebraska Medical Center, Omaha, NE
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Epidemiology and Public Health - ARHP Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Breathlessness is often considered as a predictor of functional outcomes in pulmonary disease, but has not been examined in SLE.

Methods: Data were from the National Data Bank for Rheumatic Diseases (NDB), for which participants complete questionnaires every 6 months. Only women with SLE who completed one of the most recent completed questionnaires were included (n = 278). Breathlessness was assessed with the Medical Research Council questionnaire (Table 1). Outcomes examined were self-reported lupus status (Systemic Lupus Activity Questionnaire, SLAQ[1]), assessment of lupus activity (rating from 0 [not active] – 100 [very active]), global assessment of health status (rating from 0 [doing very well] – 10 [doing very poorly]), and self-reported assessments of pain, fatigue, and sleep problems, each rated 0 – 10 with higher ratings reflecting worse symptoms. ANOVAs and multivariate linear regression analyses estimated the relationship of breathlessness on outcomes. Multivariate analyses controlled for age, low education, low income, body mass index (BMI), duration of SLE, self-reported disease damage (Brief Inventory of Lupus Damage, BILD[2]), Rheumatic Disease Comorbidity Index (RDCI)[3], current or former smoking, and self-reported chronic obstructive pulmonary disease (COPD) or asthma.

Results: Mean age was 58 ± 13 years, 22% had education ≤ high school, and 47% had low income. Mean disease duration was 21 ± 12 years, mean BMI was 29 ± 8, and mean score on the RDCI was 2.7 ± 1.8. 5% were current smokers, 41% were former smokers, and 7% had self-reported COPD. In both unadjusted and unadjusted analyses, breathlessness ratings were associated with worse outcomes on each measure (Table 2).

Conclusion: Breathlessness was associated with worse patient-reported outcomes among this group of women with SLE, even after controlling for disease status, smoking, and self-reported COPD. While self-reports of breathlessness are often used to assess pulmonary functioning, these items may also indicate poor cardiorespiratory fitness. [1] Karlson EW, et al. *Lupus* 2003; 12:280. [2] Yazdany J, et al. *Arthritis Care Res* 2011; 63:1170 [3] England BR, et al. *Arthritis Care Res* 2015; 6: 865

Table 1. MRC categories and frequencies	
	% (n)
Group 0: Only get breathless with strenuous exercise	39.8 (98)
Group 1: Get short of breath when hurrying on a level or up a slight hill	25.6 (63)
Group 2: Walk slower than people of the same age on the level because of breathlessness or have to stop for breath when walking at my own pace on the level	14.2 (35)
Group 3: Have to stop for breath after walking 100 yards or after a few minutes on the level	20.2 (50)
Group 4: Too breathless to leave the house	0.8 (2)
• Groups 3 and 4 were combined for analysis. • Respondents were instructed not to answer items if activity problems were due to other physical problems	

Table 2. Association of breathlessness ratings with outcomes					
	Group 0	Group 1	Group 2	Group 3/4	p-value*
SLAQ	8.3 ± 6.1	10.4 ± 6.3	13.5 ± 6.8	14.9 ± 7.8	.05
Lupus activity rating	21.1 ± 24.0	28.0 ± 22.9	38.1 ± 29.4	45.1 ± 30.6	.009
Global health status rating	2.5 ± 2.3	3.6 ± 2.3	4.9 ± 2.3	5.7 ± 2.7	<.0001
Pain	2.5 ± 2.6	4.0 ± 2.5	5.2 ± 2.8	5.5 ± 2.7	.005
Fatigue	3.5 ± 2.9	4.4 ± 2.7	6.4 ± 2.7	6.8 ± 2.5	<.0001
Sleep	3.1 ± 2.9	4.1 ± 3.0	5.3 ± 3.4	5.8 ± 3.0	.008
* p-value from multiple linear regression controlling for age, education, income, BMI, smoking (current or former), SLE duration, SLE damage (BILD score), comorbidity index (RDCI), and self-reported COPD (chronic obstructive pulmonary disease, emphysema, or chronic bronchitis) or asthma

Comparison of New and Old American College of Rheumatology Classification Criterion for Diagnosis of Fibromyalgia

Kenrin Shi[1], Kenji Miki[2] and Masao Yukioka[3], [1]Department of Orthopaedic Surgery, Yukioka Hospital, Osaka, Japan, [2]Center for Pain Management, Osaka University Hospital, Suita, Japan, [3]Orthopaedic Surgery, Yukioka hospital, Osaka, Japan

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

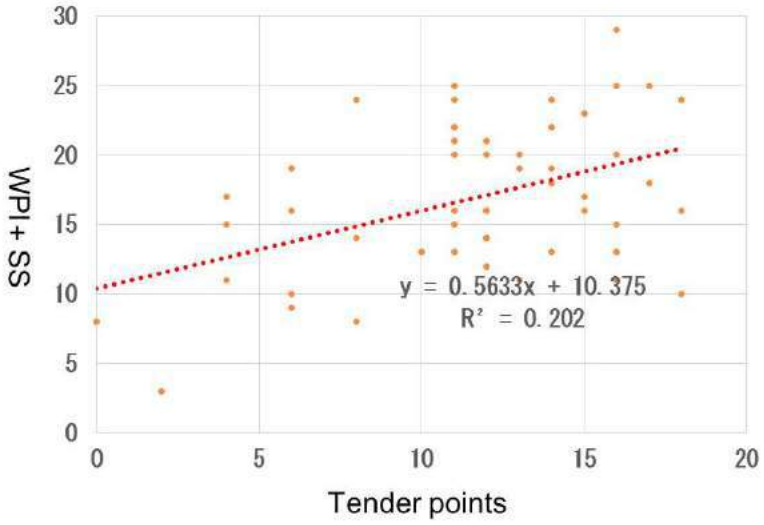
Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is a chronic disease characterized by severe, long lasting pain that spreads widely in almost whole body. The cause of the disease is still unknown, and no efficient treatment has yet been established. It is well known that the severity of pain as well as accompanying symptoms can often be influenced either by psychological or by social factors, which support the recognition of the disease as one of functional somatic disorders.

Methods: American College of Rheumatology (ACR) revised the classification criteria for diagnosis of FM in 2010, after 20 years of clinical use of the old one that had been published in 1990. Old criteria simply classifies patients as FM by number of tender points (11 or more, out of 18 in total), whereas new one considers not only the extent of widespread pain but also the severity of pain and many accompanying symptoms. In this study, comparison between the new and old criterion was performed in total 61 patients with FM or doubtful FM (male 11, female 50, average age 54.0 years, average duration from onset 4.5 years).

Results: Tender points by 1990 criteria was 12.0 in average (min 0, max 18), with 42 patients out of 56 presenting 11 or more, who were diagnosed as FM. Average Widespread Pain Index (WPI) and Symptom Severity (SS) by 2010 criteria scored 10.9 (min 2, max 18) and 6.1 (min 1, max 12), respectively, resulting 38 out of 59 were diagnosed as FM (WPI>7, SS>5 or 3<WPI<6, SS>9). Sum of the two scores in new criteria, WPI and SS, was 16.8 in average (min 3, max 29), and demonstrated positive correlation with tender points in old criteria (r=0.45). However, diagnoses by the two criterion did not always coincide.

Conclusion: Despite of overall accordance between two criterions, the diagnosis did not always coincide. Interestingly, the positivity of tender points in old criteria as well as that of widespread pain in new one demonstrated significant differences by the locus. Moreover, the positivity of accompanying symptoms in new criteria (41 in total) demonstrated significant differences from each other. All these differences may suggest that pain and tender locus as well as accompanying symptoms could be weighed either more or less, not equally as they are, depending the influence in diagnosis. Physicians should apply these criterion flexibly.



Correlation of two ACR classification criterion for diagnosis of fibromyalgia.
Tender points in old criteria (1990) and WPI+SS in new criteria (2010) demonstrated positive correlation. WPI, widespread pain index; SS, symptom severity.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Abstract:

Background/Purpose: the association between Fibromyalgia Syndrome (FMS) and childhood maltreatment and adversity has frequently been proposed but limited data exists regarding the trans-cultural nature of this association, based on retrospective self-report analysis. Moreover, the differences between FMS and other chronic rheumatic disorders such as rheumatoid arthritis have not been extensively analyzed.

Methods: 75 Israeli FMS patients and 23 Rheumatoid Arthritis (RA) patients were compared. Childhood maltreatment was assessed by the Childhood Maltreatment Questionnaire (CTQ) and potential depressive and anxiety disorder were assessed by the Patient Health Questionnaire PHQ-4. FMS severity was assessed by use of the Widespread Pain Index (WPI), the Symptom Severity Score (SSS) and the Fibromyalgia Impact Questionnaire (FIQ). Potential posttraumatic stress disorder (PTSD) was diagnosed according to the Diagnostic and Statistical Manual of Mental Disorders IV-TR symptom criteria by the Posttraumatic Diagnostic Scale (PDS). RA severity was assessed by the RA Disease Activity Index (RADAI). Health status was assessed by the Short Form 36 health survey (SF-36).

Results: Similar to previous reports in other countries, high levels of self-reported childhood adversity were reported by Israeli FMS patients. PTSD was significantly more common among FMS patients compared with RA patients, as well as reports of childhood emotional abuse, physical and emotional neglect. The OR for PTSD among FMS patients compared with RA patients, when controlling for anxiety and depression, was 4.9 with 95% CI 1.02-23.6. ($p<0.05$). Reports of physical and sexual abuse did not significantly differ between FMS and RA patients and no significant difference was found regarding rates of "severe" and "very severe" childhood trauma between the groups. Levels of depression and anxiety were significantly higher among FMS patients compared with RA patients. FMS patients demonstrated significantly lower scores regarding energy/fatigue, emotional wellbeing, and social functioning compared with RA patients.

Conclusion: The study demonstrated the cross cultural association between FMS and childhood maltreatment, including neglect and emotional abuse as well as PTSD. Significant differences were demonstrated between FMS patients and patients suffering from RA, a model of an inflammatory chronic rheumatic disease.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The current study is an innovative exploratory investigation, aiming at identifying differences in personality profiles within FMS and CFS patients.

Methods: 344 participants (309 female, 35 male) reported suffering from FMS and/or CFS and consented to participate in the study. Participants were recruited at an Israeli FM/CFS patient meeting held in May 2013, and through an announcement posted on several social networks. Participants were asked to complete a research questionnaire, which included FMS criteria and severity scales, and measures of personality, emotional functioning, positivity, social support and subjective assessment of general health. 204 participants completed the research questionnaire (40.7% attrition rate).

Results: A cluster analysis produced two distinct clusters, which differed significantly on psychological variables, but did not differ on demographic variables or illness severity. As compared to cluster number 2 (N=107), participants classified into cluster number 1 (N=97) showed a less adaptive pattern, with higher levels of Harm Avoidance and Alexithymia; higher prevalence of Type D personality; and lower levels of Persistence, Reward Dependence, Cooperation, Self-Directedness, social support and positivity.

Conclusion: The significant pattern of results indicates at least two distinct personality profiles of FM and CFS patients. Findings from this research may help improve the evaluation and treatment of FM and CFS patients, based on each patient's unique needs, psychological resources and weaknesses, as proposed by the current trend of personalized medicine.

Cognitive Functioning in Fibromyalgia: The Central Role of Effort

Jacob Ablin[1], Tamar Bar On –Kalfon[2], Gilad Gal[3] and Ran Shorer[2], [1]Rheumatology, Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel, [2]Rheumatology, Tel Aviv Sourasky medical center, Tel Aviv, Israel, [3]School of Behavioral Sciences, Tel Aviv-Jaffa Academic College, Tel Aviv, Israel

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia syndrome (FMS) patients demonstrate deficits in tests of attention, executive functioning and verbal memory. We assessed the role of effort in the cognitive impairment in FMS patients, alongside common symptoms of pain, fatigue and depression.

Methods: 50 FMS patients underwent a computerized cognitive assessment battery including memory, executive function, attention and information processing speed (NeuroTrax Corp.). Age and education standardized scores

were computed. Effort was assessed by the Test of Memory Malingering (TOMM). FMS symptoms were assessed by the Fibromyalgia Impact Questionnaire (FIQ), Widespread Pain Index (WPI) and Symptom Severity Scale (SSS), a Visual Analogue Scale (VAS) of clinical pain and the Beck depression inventory (BDI-2).

Results: FMS patients showed impaired performance on the memory, attention and information processing speed domains. According to the TOMM, sub-optimal effort was shown by 16% of patients. TOMM scores were not associated with pain, fatigue or depression. After controlling for effort, no significant impairment was found in memory scores; however attention and information processing speed scores remained significantly low. Multiple regressions analysis, performed in order to evaluate the contribution of effort, pain, fatigue and depression, found effort to be the only significant variable accounting for variance of cognitive scores on all domains.

Conclusion: The findings confirm impaired attention and processing speed in FMS patients, independent of effort level. Nonetheless, the findings point to a general and strong effect of effort on neuropsychological performance in FMS patients, especially in the domain of memory, emphasizes the importance of effort testing in this population.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Brazilian registry on fibromyalgia syndrome (EpiFibro) included 810 patients who satisfied the American College of Rheumatology Classification Criteria for Fibromyalgia (ACR1990) at the time

of diagnosis. Objectives – 1. Describe treatment modalities for Brazilian Patients; 2. Describe treatment measures in each of the modalities.

Methods: – A transversal study on a multicenter cohort of Brazilian Fibromyalgia patients. All patients fulfilled at the data entry the American College of Rheumatology Classification Criteria for Fibromyalgia. The analysis was made through descriptive statistical technique (frequency and standard deviation).

Results: Three hundred and forty two (342) entries were excluded for having incomplete forms at the treatment modalities. In relation of the therapeutic modalities, it was observed: sixty-six (66) patients are taking only medications and no non-pharmacological therapy; four hundred and fifty five (455) patients are taking some medicines; three hundred and three (303) patients are receiving some kind of health education; two hundred and six (206) patients are practicing exercises and ninety seven (97) are getting some kind of other non-pharmacological measures. The most frequent combination of modalities is medicine, health education and exercises (89). The only 2 drugs approved for fibromyalgia in Brazil are duloxetine (57 patients in use) and pregabalin (11 patients in use). Other medications with proved efficacy by literature have also being prescribed off label, such as amitriptyline (115), venlafaxine (17), fluoxetine (49), cyclobenzaprine (77), tramadol (30) and gabapentin (11). The most used medication associations are: fluoxetine and amitriptyline (88), fluoxetine and cyclobenzaprine (14), amitriptyline and cyclobenzaprine (7), tramadol and paracetamol (23). Other associations were also reported: pregabalin and duloxetine (2), pregabalin and amitriptyline (3), pregabalin and fluoxetine (5), gabapentin and duloxetine (1), gabapentin and amitriptyline (1). There were also prescribed triple associations. In relation to exercises, 108 patients practice aerobics, 26 stretching exercises and 2 strengthening exercises. The most frequent combination is aerobics and stretching exercises (48). The non-pharmacological measures most used are heated swimming pool exercises (17), relaxing techniques (10), acupuncture (10), psychotherapy (9), massage (6) and tender point infiltration (6). It has been also mentioned hypnosis, homeopathy and biofeedback.

Conclusion: The majority of Brazilian fibromyalgia patients are treated by a combination of pharmacological and non-pharmacological measures. It is prescribed approved medications for fibromyalgia, but the most prescribed drug is amitriptyline off label, probably for economic reasons. The most prescribed medicine combination is fluoxetine and amitriptyline. The most practiced exercises are the aerobics modalities and the most non-pharmacological measures are health education and exercises in heated swimming pool.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Disabling distal upper limb pain is common but relatively understudied. Fear avoidance (FA) models of disability have been empirically tested for back and lower limb pain. There is a lack of research investigating their tenability for disabling distal upper limb pain. Given the region's distinct functional demands, it is important to understand the role of psychosocial and behavioural factors in the pain-disability relationship. The aim of this study was to investigate whether any of five psychosocial or behavioural factors implicated in FA models mediated the distal upper limb pain-disability relationship: kinesiophobia, psychological distress, multiple somatic symptoms, beliefs about prognosis, change in physical activity, and change in leisure time arm use.

Methods: This observational study used data from a UK multi-centre randomized controlled trial to investigate mediators of the relationship between: 1.) Pain and disability at the time of referral; 2.) Baseline pain, and disability 26wks later. Patients referred to physiotherapy with distal upper limb pain/disability completed self-report questionnaires at baseline, 6, 13 and 26wks. Information was collected on pain intensity (11-point Numeric Rating Scale), disability (modified Disabilities of the Arm, Shoulder and Hand questionnaire), kinesiophobia (Tampa Scale for Kinesiophobia), quality of life (EQ-5D), somatic symptoms (Modified Somatic Perception questionnaire), beliefs about prognosis, physical activity and leisure time arm use. Mediation analysis included use of Baron and Kenny criteria, Sobel tests, and, for longitudinal models, analysis of covariance using data collected at three follow-up time points (baseline, 26 weeks and either 6 or 13 weeks). Models were adjusted for age, gender, diagnostic category, pain duration and history, and trial treatment group: (a) immediate physiotherapy; or normally timed physiotherapy, with (b) advice to rest; or (c) advice to remain active during a six-to-seven week waiting period. Sensitivity analyses used multiple imputation by chained equations to assess for bias due to missing data.

Results: 538 participants (54% female; mean age 49yrs, SD 14) provided data. The relationship between pain and disability at time of physiotherapy referral was partially mediated by kinesiophobia, which explained 12.6% of the total effect of pain on disability (95%CI 5.3-16.8%). Longitudinally, there was evidence that development of prognostic pessimism over the initial treatment period partially mediated the relationship between pain at time of referral and disability 26wks later (14.2% of the total effect, 95%CI 0.04%-23.4%). Sensitivity analyses using multiple imputation made only minor differences to the results, and no difference to their interpretation.

Conclusion: We have demonstrated that kinesiophobia and prognostic pessimism partially mediated the distal upper limb pain-disability relationship. While psychological distress and activity avoidance have been found to mediate the relationship in back and lower limb pain, they were not identified in this population. This would suggest that cognitive constructs may be more important treatment targets for distal upper limb pain.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II:

Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is characterized by chronic widespread pain and tenderness making it difficult to manage. Accounting for FM heterogeneity might elicit an improvement in patient treatment. Chronic diseases are a dynamic process with increasing and decreasing symptomology and clinical manifestations. Several diseases similar to FM have known chronicity trends; rheumatoid arthritis has stages indicated by disease progression, and according to the Centers for Disease Control and Prevention, three different disease courses exist. The objective of this study was to cluster patients into stages, or similar disease profiles, based on severity of FM (i.e., patient co-morbidities, regions of pain, and procedures), as well as time.

Methods: We identified 2,529 FM patients with a total of 79,570 clinical visits between January 1999 and February 2014 from an administrative claims data. Patients were clustered based on similarity of co-morbidities (symptom severity), region of pain (widespread pain), and procedures (treatment intensity) by implementing a sequence of unsupervised and supervised learning techniques. Text analysis and a review of physician notes were conducted to obtain secondary conditions and diseases to assist in the understanding of stage classification.

Results: There were four parent stages of FM identified and labeled: 1) regional FM with classic symptoms; 2) generalized FM with increasing widespread pain and some additional symptoms; 3) FM with advanced and associated conditions, increasing widespread pain, increased sleep disturbances, and chemical sensitivity; and 4) secondary FM reactive to disease. Approximately 45% of patient observations were reclassified when the constraints of time were lifted. Most notably, the rate of stage misclassification dramatically reduced from 11.2% to 4.4% when patients were reclassified based on exponential increases in disease severity as opposed to time. These findings lend support that FM stages are more characterized by disease severity and are less time-dependent.

Conclusion: Generally, patients increase in their symptom severity and region of pain by stage. Parallels are beginning to emerge between the different stages and presentations of underlying conditions. General clustering seems to be occurring but requires more research. Nonetheless, this work makes a case for the presence of FM stages in which important clinical ramifications exist that may lead to a more precise treatment approach for FM patients.

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: As in other chronic diseases, adherence to the treatment regimen of patients with fibromyalgia (FM) is low (between 30 and 80%), depending on the definition of adherence and the methodology used to measure it. This study aims to determine the level of adherence to drug therapy in patients with FM and identify factors associated with non-compliance to therapy.

Methods: an analytical and cross-sectional study was conducted. Patients with FM were included considering the classification criteria (ACR 1990) for both those who were receiving drugs for the treatment for their disease and those who attended the outpatient clinic. For the assessment of adherence, the questionnaires CQR (Compliance Questionnaire on Rheumatology) were used, to assess anxiety GAD-7 (Generalized Anxiety Disorder), to assess depression PHQ-9 (Patient Helth Questionnaire) and to assess the impact disease of the S-FIQ (Spanish Fibromyalgia Impact Questionnaire) were used.

Results: 78 patients were surveyed (70 women). The mean age was 47,3 years. 41% (32 patients) were adherent (CQR> 80). 41% (19) of the nonadherent had severe depression according to the PHQ-9 vs 6% (2) of those which if adhered. 67% (31) of the nonadherent had severe anxiety by questionnaire GAD-7 vs the 16% (5) of which adhered. It was also observed that 87% (40) of nonadherent had low quality of life measured by the S-FIQ (S-FIQ >50%) questionnaire vs. a 50% (16) of the adherent members who had good quality of life. The three cases showed a statistically significant association with non-adherence to drug treatment.

Conclusion: it was observed that less than half of FM patients were adherent to drug treatment. Factors associated with nonadherence were depression, anxiety and reduced quality of life.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously shown that, among patients awaiting physiotherapy for distal upper limb pain/disability, advice to remain active is associated with greater functional recovery compared to advice to rest. In low back pain, studies of stratified care have shown that matching patients to optimal interventions reduces costs of treatment, and can help individuals return to work. In contrast, few studies have examined whether patients benefit from a stratified approach to distal upper limb pain management. Thus, the aim of the current study was to investigate whether pre-specified patient characteristics (baseline pain intensity, pain duration, gender, employment status, pain history, and diagnostic category) modified the effect of advice, among patients referred for physiotherapy with distal upper limb pain.

Methods: This observational study used data from a UK multi-centre randomized controlled trial. Participants underwent a clinical examination and completed questionnaires before trial randomisation to either (a) advice to rest; or (b) advice to remain active, at the start of the six-to-seven week waiting time for physiotherapy. Follow-up questionnaires were mailed 6, 13 and 26 weeks later. Questionnaire items asked about pain intensity (11-point Numeric Rating Scale), employment status, pain duration and pain-related disability, using the modified

Disabilities of the Arm, Shoulder and Hand questionnaire (mDASH). A difference of 1 unit on the mDASH equates to 1 additional functional limitation and was therefore interpreted as clinically meaningful change. The interaction between advice group and the 6 pre-defined factors on change in disability at 6, 13 and 26 weeks was quantified using linear regression, controlling for the level of disability at the time of referral.

Results: 282 participants with complete follow-up data were included in this analysis (57% female; mean age 50yrs, SD 14). There was a significant interaction between gender and treatment effect at 26 weeks (p=0.011). Males who received advice to remain active had greater functional improvement than males advised to rest, a difference that was both statistically significant and clinically meaningful (mDASH improvement 1.47, p=0.003). In contrast, among females, active advice was not associated with an improvement in outcome (mDASH improvement -0.17, p=0.68). This sex-treatment interaction was evident from 6-week follow-up (mDASH improvement in men, compared to women, among those advised to remain active: 1.11, p=0.05). No other factors were identified as effect modifiers.

Conclusion: Of six patient characteristics investigated as possible effect modifiers of advice for distal upper limb pain, only gender was identified to be of statistical significance and clinical importance. Active advice, previously found to be more effective overall, was particularly effective in males. It should be noted that the trial was not powered specifically to look at interactions and that this secondary data analysis was hypothesis-generating. The mechanisms driving the gender effect require further study before the introduction of stratified management approaches in distal upper limb pain can be supported.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Idiopathic adhesive capsulitis is described as a frozen shoulder with severe and global

range-of-motion loss of unknown etiology. On the other hand, the most common cause of shoulder pain is impingement syndrome. The aim of our study was to investigate of clinical and radiological features of adhesive capsulitis and shoulder impingement syndrome according to functional outcomes.

Methods: One hundred and fifty patients with adhesive capsulitis and shoulder impingement syndrome enrolled. The demographic characteristics of the patients were examined. Magnetic resonance imaging (MRI) and routine blood test results were recorded. Constant Shoulder Score (CSS), Shoulder Disability Questionnaire (SDQ) and Visual Analog Scale (VAS) were used to measure pain and functional status. Statistical analysis was made using NCSS (Number Cruncher Statistical System) 2007 Statistical Software (Utah, USA).

Results were evaluated considering the significance level $p< 0.05$. **Results:** The mean age of the patients was 54.57±6.20 years (min:36; max: 66; median: 55) out of 150 patients, 96 were women and 54 were men. Seventy-five patients had adhesive capsulitis and Seventy-five patients had shoulder impingement syndrome. There was no statistically significant difference between the two groups with respect to descriptive characteristics of the patients ($p>0.05$). Hypertension (HT), diabetes mellitus (DM) and hyperlipidemia were significantly higher were detected in patients with adhesive capsulitis ($p <0.05$). No significant was noted difference in terms of thyroid disease, and cardiac disease between the groups ($p> 0.05$). The functional disturbance and disability evaluated by CSS and SDQ were significantly higher in patients with adhesive capsulitis ($p<0.05$). According to the radiological findings, partial rupture and effusion were significantly higher in patients with shoulder impingement syndrome ($p<0.05$). No significant difference was determined between the groups according to the presence of labral tear or total rupture in MRI results ($p>0.05$). No difference was noted CSS and SDQ scores according to presence of partial rupture in both groups ($p>0.05$).

Conclusion: In present study, the radiological findings may not be associated with severe pain or poor functional status. DM, HT and accompanying hyperlipidemia were risk factors for adhesive capsulitis. Comorbid diseases should be kept in mind. It is important to identify high-risk patients to prevent and to arrange the treatment strategies.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To estimate the prevalence of secondary fibromyalgia (FM) in patients with RA and its effect on the disease activity score (DAS28) in a tertiary care teaching hospital.

Methods: Patients aged above 18 years who had been diagnosed with rheumatoid arthritis (RA) as per the ACR/EULAR criteria 2010 were included in the study. Fibromyalgia (FM) was diagnosed using the ACR 1990 criteria. Patients with incomplete clinical data and above 75 years were excluded. Laboratory and clinical findings were entered in a structured format. DAS28 was assessed using ESR and supplemented with CRP, only if ESR was not available. Statistical analyses were performed using SPSS v16 software. The study was approved by the Institutional Ethics Committee of PGIMER, Chandigarh.

Results: A total of 371 subjects were recruited with a mean age of 46 (±12.3) years. The study population followed normal distribution in age with a median of 46 years and mode of 45 years. The male to female ratio was 1:5.4. The prevalence of FM was 18.1% amongst RA patients (67/372). In patients with secondary FM 92.5% were female compared to 82.6% without FM. 65.7% patients with FM had a disease duration of greater than 5 years compared to 46.9% patients without FM. 71.6% of patients with FM had high disease severity compared with only 43.9% patients without FM. The average DAS28 score was significantly higher [($p<0.001$); 95% CI: 1.2 - 3.7] in patients with secondary FM (5.68±1.49) compared to those without FM (4.92±1.62). In sub-analyses of independent variables of DAS28, tender joint counts were significantly higher [($p<0.001$); 95% CI: 3 – 8.8] in patients with FM (17.90) as compared to RA patients without FM (11.98). Also, the patients' global health scores were worse [$p<0.001$; 95% CI: 5.5 - 21.6] in RA patients with FM. Swollen joint count and ESR values were comparable in both the groups.

Conclusion: The present study reports that 18.1% of the RA patients had associated FM. TJC and GH of patients are affected by the co-existing FM. The study advocates the development of new outcome measures that are more objective and depend upon reliable laboratory biomarkers/ultrasound evidence of synovitis for assessing the disease activity of RA patients.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secondary fibromyalgia (FM) is seen 15-20% of patients with rheumatoid arthritis (RA) (1), systemic lupus erythematosus (SLE) (2), osteoarthritis (OA), and other rheumatic diseases. New formal ACR criteria for FM are available (3), but not used in most routine care, largely because it is not feasible for patients with different diagnoses to complete different questionnaires in busy clinical settings. Scores on a Multidimensional Health Assessment Questionnaire/routine assessment of patient index data (MDHAQ /RAPID3) may provide clues to FM (4, 5). We analyzed MDHAQ/RAPID3 scores in patients with RA or OA, who had or did not have secondary FM, to develop a simple index to identify patients with secondary FM comparable to ACR FM Criteria.

Methods: All patients with all diagnoses at one academic center complete an MDHAQ/RAPID3 at all visits before seeing the rheumatologist. Nine MDHAQ measures were studied: 1. a 0-10 physical function (FN) scale; 2. pain (PN) and 3. patient global estimate (PATGL) on 0-10 visual analog scales (VAS) (compiled into a 0-30 RAPID3); 4. sleep quality; 5. anxiety; 6. depression; 7. 0-10 fatigue VAS; 8. 0-48 RADAI self-report of painful joints; 9. 60 item symptom checklist. Patients in this study also completed a widespread pain questionnaire to assess ACR FM Criteria (6), and the rheumatologist assigned a diagnosis of FM independent of any questionnaire results. The 9 MDHAQ measures were analyzed in patients with primary RA or OA for frequencies and area under receiver-operating-characteristic (ROC) curves for secondary FM according to ACR FM Criteria or clinical criteria, to develop a simple FM index for optimal discrimination of secondary FM vs no secondary FM.

Results: 84 patients with OA or RA were studied; 58 did not have secondary FM by ACR criteria or clinical diagnosis, 16 had FM by both criteria, 6 had FM only by clinical criteria, and 4 only by ACR criteria. Agreement between clinical and ACR Criteria was substantial (kappa 0.68, $p<0.001$) (6), and only data for ACR Criteria are presented. Patients who had secondary FM had higher mean scores on all 9 MDHAQ scales studied and ROC areas>0.80. A simple MDHAQ 0-3 FM index involves allocating one point each for pain≥6/10, RADAI≥16/48, and symptom checklist≥16/60. A score of 2/3 on the MDHAQ FM index classified identically 90% of patients with FM by ACR Criteria.

Conclusion: A simple 0-3 MDHAQ-FM index based on pain, RADAI self-report joint count, and symptom checklist provides 90% agreement with the new ACR FM criteria. The MDHAQ is feasible in busy clinical settings, as the same questionnaire can provide important clinical information in all patients with all diagnoses, and appears useful to identify secondary FM.

	Cut-off point, sensitivity, and specificity for MDHAQ item and the composite FM in the Liverpool Hospital Australia dataset (N = 84). FM diagnosis by ACR criteria				
	Cut-off point	**ROC Area**	**Sensitivity**	**Specificity**	**Correctly classified**
Symptom checklist (0-60)	≥ 16	0.98	77.3%	83.9%	82.1%
RADAI (0-48)	≥ 16	0.90	84.2%	80.8%	81.7%
MDHAQ-PAIN (0-10)	≥ 6	0.88	86.4%	75.8%	78.6%

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia is a complex disorder with strong psychological and pain components and is best managed with multidisciplinary therapies. Previous studies have suggested that Tai Chi is an integrated mind-body approach that enhances both physical and mental health and may be an effective treatment for fibromyalgia. It is unknown however whether Tai Chi is better than aerobic exercise, a common treatment for this population, and if so whether the effectiveness of Tai Chi depends on its duration and intensity.

Methods: We conducted a 52-week, single-blind, randomized trial of Tai Chi vs. aerobic exercise for fibromyalgia (ACR 1990 and 2010 diagnostic criteria). Participants were randomized to 1 of 4 Tai Chi intervention groups: 12 or 24 weeks of Tai Chi once or twice per week, or an aerobic exercise intervention held twice per week for 24 weeks. The primary endpoint was change in the Revised Fibromyalgia Impact Questionnaire (FIQR) score at 24 weeks. Secondary endpoints included change in patient global assessments, the Hospital Anxiety and Depression scale (HADS), depression (Beck II), sleep quality (PSQI), arthritis self-efficacy scale (ASES-8), and 6-minute walk tests and health-related quality of life (SF-36 PCS and SF-36 MCS). The comparative efficacy of the five treatments was determined using longitudinal regression based on the intent-to-treat principal using evaluations made at 0, 12, 24 and 52 weeks. We report treatment contrasts at 24 weeks focusing on comparisons of: 1) Aerobic Exercise vs. average of four Tai Chi groups; 2) average of 12 week Tai Chi vs 24 week Tai Chi; and 3) average of once per week Tai Chi vs. twice per week Tai Chi.

Results: The mean age of subjects was 51.8y (SD 12.4), mean disease duration 8.8y (7.5), mean BMI 30.0 kg/m^2 (SD 6.7), 93% were female, and 61% were white. Treatment groups did not differ in baseline outcome expectation. All Tai Chi groups (averaged across the 4 groups), compared to aerobic exercise showed statistically significant improvements in FIQR ($p=0.03$), patient global assessment ($p=0.005$), anxiety and depression ($p=0.006$), and self-efficacy ($p=0.0004$). Significant improvements for most but not all outcomes favor 24 week vs. 12 weeks, compared to aerobic exercise **(Table 1).** Participants in Tai Chi groups had significantly higher class attendance than the Aerobic Exercise group (54-63% vs 35%), $p<0.0001$). No serious adverse events were observed.

Conclusion: Tai Chi significantly reduced the symptom severity of fibromyalgia and was more effective than aerobic exercise for a variety of physical and mental health outcomes among a general population of individuals with fibromyalgia. The higher attendance rate in Tai Chi could also indicate that it is a preferable intervention in this patient population, though further study is warranted. Tai Chi should be considered as an important non-pharmacologic treatment option in patients with Fibromyalgia.

Table 1: Change in Outcomes from baseline to 24 weeks by groups (4 Tai Chi groups vs. Aerobic Exercise)						
Outcome	**Aerobic Exercise**	**Tai Chi 1x12 weeks**	**Tai Chi 2x12 weeks**	**Tai Chi 1x24 weeks**	**Tai Chi 2x24 weeks**	**P-value (Tai Chi vs Aerobic Exercise at 24 weeks**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Both the revised 2010 FM criteria (Wolfe et al.) and the 2013 FM criteria (Bennett et al.), rely on counting the number of pain locations plus a certain number of symptoms as presumptive evidence for the patient having widespread pain. However, little is known about how these criteria operate in the primary setting.

Methods: A descriptive cross sectional study assessed adults being seen in2 primary care clinics. Data sources included chart review, history, physical exam and patient-completed surveys.

Results: Altogether 357 patients were studied (all female, age 50 ± 16.3 years). Chart review revealed that 50 patients carried a diagnosis of FM in their medical record. However, only 17 patients fulfilled the 2013 FM diagnostic criteria. A comparison of the 2 diagnostic groups is shown in the following table:

Test	Clinician diagnosed FM (n=50)	Criteria diagnosed FM (n=17)	P Value
Number of pain locations	12.7±7.86	15 ± 4.1± 4.09	<0.001
SIQR symptom score	32.7±9.4	36.1± 8.6	0.17
BP pain threshold	132.3±51.5	122.1±18.4	0.47
Total SIQR score	66.7±18.4	62.5 ± 18.4	0.41
SIQR function	50.2±20.10	52.7±20.10	0.67
SIQR pain	6.5± 1.97	7.1 ± 2.01	0.26
SIQR tenderness	6.8±32.86	7.9±2.49	0.13
SIQR sleep	6.5±3.67	8.1 ± 2.35	0.99
Environmental sensitivity	6.8±3.21	7.5±3.06	0.42
“I have a persistent deep aching pain over most of my body.”	7.9±2.59	9.1 ± 1.13	<0.01

Conclusion: These results show that clinician diagnosed and criteria diagnosed patients were very similar in most descriptive variables. The 2013 criteria are based on a pain locations score >16 and a SIQR symptom score of>21. It is seen that the symptoms score does not account for the difference in diagnosis, but the number of pain locations was significantly less in the clinician diagnosed FM. Thus it appears that there is a group of “fibromyalgia like” patients that differ from 2013 criteria patients only in the number of pain locations. This raises 3 questions: 1. What should we call the clinic diagnosed patients who are symptomatically similar but differ from criteria diagnosed patients only in the number of pain locations? 2. Is the number of pain locations representative of the concept of widespread pain? 3. Would the concept of widespread pain be better defined by a question, such as seen in the last row?

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Caffeine's action as an NSAID adjuvant are well understood, yet little clinical research has explored its effects on opioid analgesia. We present data from a large sample of fibromyalgia patients assessing the effect of caffeine use in the presence and absence of opioid analgesics.

Methods: 962 patients (67% female) presenting to a tertiary pain clinic and meeting the 2011 American College of Rheumatology (ACR) survey criteria for fibromyalgia were included. Patients completed the Brief Pain Inventory (BPI), Hospital Anxiety and Depression Survey (HADS), PROMIS fatigue measure, pain catastrophizing scale, and Oswestry Disability Index (ODI). Consumption of caffeinated beverages and opioid analgesics was assessed using a dichotomous item: patients indicated "yes" or "no" to daily consumption. General linear models were used to determine effect of caffeine use on independent measures. Gender and smoking status differed in univariate analysis and were controlled for as covariates. Adjusted mean differences (x) (standard error) are reported. Analyses were performed with SPSS 22.

Results: 568 (59%) patients were on current opioid therapy (66% female) and 394 (41%) were not (67% female). In patients on opioid therapy, caffeine consumers had significantly lower pain severity [$F= 4.3$, $p= .04$, $x= .33(.16)$], pain interference [$F= 8.1$, $p< .001$, $x= 0.5(0.2)$], fatigue [$F= 14.2$, $p< .001$, $x= 2.5(0.7)$], depression [$F= 5.2$, $p= .01$, $x= 1.0(0.4)$], catastrophizing [$F= 11.0$, $p< .001$, $x= 3.8(1.2)$] and disability [$F= 12.9$, $p< .001$, $x= 3.3(0.9)$] compared to non-caffeine consumers. Anxiety did not differ between caffeine groups. In the opioid negative group, caffeine consumers reported significantly less fatigue than non-consumers [$F= 5.3$, $p= .02$, $x= 2.0(0.9)$]. No other measures differed significantly between caffeine consumers and non-consumers in patients not on opioid therapy.

Conclusion: Fibromyalgia patients on opioid therapy that also use caffeine reported significantly lower symptoms compared to patients that do not consume caffeine. However, in patients not on opioid therapy, caffeine consumers don't share the same benefits seen in subjects on opioid therapy. These results suggest that consumption of caffeine in conjunction with opioid analgesics could possibly provide therapeutic benefits not seen with opioids or caffeine alone. Further research is needed to assess caffeine's adjuvant effects on opioid analgesics in chronic pain.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - Poster II: Clinical Focus

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We compared treatment outcomes between newly diagnosed versus formerly diagnosed patients seen in the brief interdisciplinary fibromyalgia treatment program (FTP). The FTP includes diagnostic evaluation as well as treatment, focused on cognitive behavioral therapy.

Methods: We studied 978 fibromyalgia who underwent the FTP and met the 1990 ACR clinical criteria for fibromyalgia. We abstracted the patients' diagnosis information from electronic medical record. All the 978 patients completed the Fibromyalgia Impact Questionnaire (FIQ) and the Short Form-36 Health Status Questionnaire (SF-36) at baseline.

Results: Five hundreds thirty-five patients (55%) received diagnosis of fibromyalgia when seen in FTP and were defined as newly diagnosed group. The rest, 443 patients (45%), were previously diagnosed with fibromyalgia and were confirmed to have fibromyalgia at the FTP, were defined as formerly diagnosed group. It had been 3.6 (9.2 SD) years for those formerly diagnosed patients had their fibromylgia diagnosed before they seen in FTP. Those formerly diagnosed patients were more likely to be older, and to have higher BMI and longer duration of fibromyalgia symptoms compared to early diagnosed patients. After adjusting for these differences, no differences were found in the FIQ total score, FIQ subscales, and all the SF-36 subscores between newly and formerly diagnosed patients. After treatment, 313 patients (58.5%) in newly diagnosed group and 224 patients (50.3%) in formerly diagnosed group completed the 6-12 month follow-up questionnaires, and both groups tended to improve excepted for the FIQ depression subscale and SF-36 general health perceptions and role emotional subscores; however, the formerly diagnosed patients had significantly less improvement in the FIQ subscales in work missed days (P=0.04).

Conclusion: In our clinic sample, included both newly and formerly diagnosed patient with over ½ being newly diagnosed, there was no differences on symptom severity and quality of live between newly and formerly

diagnosed fibromyalgia patients. Both groups benefited from the FTP similarly. Brief, interdisciplinary FTP could both benefit incident and prevalent fibromyalgia patients; moreover, these newly diagnosed patients might miss less work days after treatment. Further studies are needed to verify our results and to demonstrate the mechanisms underneath this phenomenon.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The highest prevalence of severe fatigue in rheumatic diseases is observed in FM[1]. Physical fitness and subjective well-being have been suggested as resilience resources that can help to deal with FM symptomatology[2,3]. The present study aimed to examine: (i) the independent association of overall physical fitness and subjective well-being with fatigue, and (ii) the combined association of overall physical fitness and subjective well-being components with fatigue in FM.

Methods: We used data from the al-Ándalus project, which is a population-based cross-sectional study. A total of 420 women with FM, who met the 1990 ACR FM criteria, were included in the present study. Fatigue was assessed with Multidimentional Fatigue Inventory. Physical fitness was measured with the Senior Fitness Test battery. The scores of each physical fitness test were transformed to standardized *z*-scores ([value-mean]/standard deviation) to compute an overall physical fitness score. Subjective well-being was assessed with two questionnaires: the Positive and Negative Affect Schedule (for positive affect and negative affect) and Satisfaction with Life Scale (for satisfaction with life).

Results: Based on preliminary analyses to identify potential confounders, all analyses of the present study were adjusted by age and body fat percentage. All partial correlations between overall physical fitness, positive affect, negative affect, and satisfaction with life and fatigue dimensions were significant (all, $p \leq .004$). Linear regression models showed that: (i) overall physical fitness was independently associated with general fatigue and physical fatigue (both, $p < .001$), (ii) positive affect was independently associated with lower scores at all fatigue dimensions (all, $p < .001$), (iii) negative affect was independently associated with reduced motivation and mental

fatigue (p<.001 and p=.01, respectively), and (iv) satisfaction with life was independently associated with mental fatigue (p=.046). Analyses of covariance showed statistically significant combined associations of overall physical fitness and positive affect with general and physical fatigue (all, p<.001).

Conclusion: Findings of the present study highlight the significance of the association of physical fitness and positive affect with fatigue of women with FM. Further research, using longitudinal data, testing the causality of the present findings is required. **References**: [1]Overman, CL et al., *Clin Rheumatol*. 2016;35(2):409-15. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

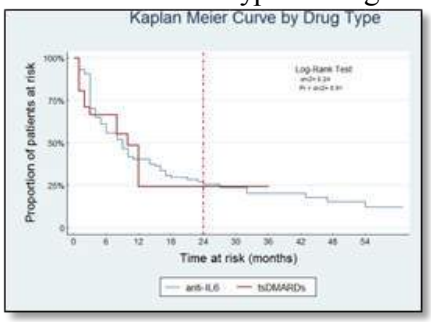
Session Time: 9:00AM-11:00AM

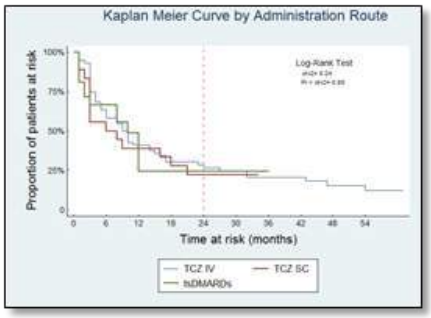
Background/Purpose: The treatment of rheumatoid arthritis (RA) has evolved continuously. The introduction of non-conventional DMARDs, which include biologic and targeted synthetic DMARDs (tsDMARDs), has been a breakthrough. Although there is plenty information on when to initiate these drugs, data on when to stop them is scant. The objective of this study was to assess the length of remission and relapse rate in patients with RA who had to discontinue tocilizumab (TCZ) or tsDMARDs (tofacitinib or baricitinib) due to the completion of extended long-term clinical trials, and to compare the survival curves of disease remission.

Methods: A prospective cohort study of RA patients in remission (DAS28 < 2.6, 0 swollen joints) assembled at the time of their last dose of either tocilizumab (subcutaneous [SC] or intravenous [IV]), tofacitinib or baricitinib. Patients were followed every 8 weeks through a COPCORD questionnaire and every 4 months by an in-office assessment. Doses of methotrexate were not changed. Patients were instructed to contact our center should any RA-related symptoms occur. The primary endpoint was relapse, defined as the presence of ≥1 swollen joints. Kaplan-

Meier curves were calculated per type of drug (TCZ and tsDMARDs) and per route of administration (PO, SC and IV). A log-rank test was used to assess differences among survival curves and Cox regression was used to evaluate variables as predictors of relapse. Significance was set at $p<0.05$.

Results: Ninety-nine patients were analyzed, 88% female, with a mean age of 47±13 years. Sixty patients were treated with TCZ-IV, 18 with TCZ-SC and 21 with tsDMARDs. During the follow-up of 165 person-years, 27 patients (27%) maintained remission. The median time until relapse was 9 months. No significant differences were found between the type of drug or the administration route. No variables were identified as relapse predictors.





Conclusion: Long-term remission is possible in a proportion of patients after suspending a non-conventional DMARD. This effect has been previously reported with multiple biologic agents but not with tsDMARDs. Further studies are required to establish algorithms on the discontinuation of non-conventional DMARDs after achieving remission.

Real-World Cost of Treating Inadequate Responders to Anti-Tumor Necrosis Factor Therapy

A Nadkarni[1] and M Brouillette[2], [1]Bristol-Myers Squibb, Princeton, NJ, [2]Truven Health Analytics, Bethesda, MD
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: RA patients (pts) receiving anti-TNF therapy may have an inadequate response (IR) to 1st-line treatment. Among pts for whom treatment fails, little is known about associated treatment costs or the proportion with an IR to a 2nd-line anti-TNF. We quantified the RA-related healthcare cost of treating pts with an IR to an anti-TNF using an adaptation of a published administrative claims-based algorithm to identify IR. We examined the probability of IR to 1st- and 2nd-line anti-TNF biologics, and assessed RA-related healthcare costs among pts with an IR to 1st- or 2nd-line treatments.

Methods: This was a retrospective, observational cohort study based on administrative claims data. Adults (aged ≥18 yrs) with RA initiating an anti-TNF between 1-1-2009 and 12-31-2013 were included. Pts were required to have continuous insurance enrollment for 12 mths before initiating an anti-TNF, and no treatment with any biologics during this period. Pts who experienced an IR to 1st-line anti-TNF and were treated with a 2nd-line anti-TNF were analyzed as a sub-sample. Variable-length follow-up was measured for both the 1st- and 2nd-line treatments, beginning with initiation of an anti-TNF and continuing until one of the following: use of a biologic other than the initiated anti-TNF, disenrollment from health insurance or reaching the study end date of 12-31-2013. IR was defined as a composite of discontinuation or switch of the initiated anti-TNF, anti-TNF dose escalation, initiation of a new non-biologic DMARD, new/increased oral glucocorticoid (OGC) use/dose or receiving ≥2 injections of glucocorticoid (IGC). Kaplan–Meier analysis was used to calculate probability of IR over time. RA-related healthcare utilization and costs were expressed in per-pt per-month (PPPM) units and corresponded to medical claims with an International Classification of Diseases, Ninth Revision, Clinical Modification diagnosis code for RA, the initiated anti-TNF and non-biologic DMARDs.

Results: A total of 26,785 pts met our inclusion criteria for the 1st-line analysis; 4638 for the 2nd-line analysis. Mean follow-up time was 525 days for 1st line and 383 days for 2nd line; Kaplan–Meier-estimated probabilities of IR were 67% at 6 mths, 82% at 12 mths and 91% at 24 mths for 1st line; 77%, 89% and 95% at 6, 12 and 24 mths for 2nd line. In both lines, the primary reason for IR was discontinuation of initiated anti-TNF (52–61% of pts), followed by: 2+ IGC (30–33%); switch of initiated anti-TNF (23–34%); initiation of a new non-biologic DMARD (14–27%); anti-TNF dose escalation (15–19%); new/increased OGC use/dose (13–15%). Average RA-related PPPM costs were $3883 (SD $10,697) for pts with an IR to 1st-line therapy and $6831 (SD $32,849) for pts with an IR to 2nd-line therapy.

Conclusion: In this retrospective study using real-world data, a high proportion of pts with RA experienced an event indicative of IR to 1st- or 2nd-line anti-TNF treatment. The RA-related healthcare costs of treating pts with IR were substantial.[1]

Economic Burden of Rheumatoid Arthritis Is Higher for ACPA-Positive Patients

J Shafrin[1], N Hou[1], MG Tebeka[1], L Rosenblatt[2], K Price[2], C Patel[3] and K Michaud[4], [1]Precision Health Economics, Los Angeles, CA, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Bristol-Myers Squibb, Princeton, NY, [4]University of Nebraska Medical Center, Omaha, NE

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) have emerged as promising serological biomarkers of rapidly progressing RA and are associated with more severe disease and joint damage. ACPA testing has been increasingly used as a routine tool for RA diagnosis. Furthermore, treatment efficacy has been shown to vary by ACPA-positive (+) status.[1] However, little is known about the economic burden of patients with RA who are ACPA+.

Methods: IMS PharMetrics Plus health insurance claims and electronic medical record (EMR) data from 2010 to 2015 were used to identify patients with incident RA. Patients were ≥18 years of age, had ≥1 inpatient or ≥2 outpatient claims reporting an RA diagnosis code (International Classification of Disease, Ninth Revision, code 714.0), and had an anti-cyclic citrullinated peptide (anti-CCP, a surrogate of ACPA) antibody test within 6 months of diagnosis. Incident patients were defined as those who had no claims with an RA diagnosis code in the 6 months before the first observed RA diagnosis. The primary outcome of interest was RA-related medical expenditure, defined as the sum of payer- and patient-paid amounts for all claims with an RA diagnosis code. Secondary outcomes included healthcare utilization metrics such as treatment with a DMARD and physician visits. Generalized linear regression models were used for each outcome, with ACPA+ status (anti-CCP ≥20 U/mL), age, sex and Charlson co-morbidity index as explanatory variables.

Results: Of 647,171 patients diagnosed with RA, 89,296 were incident cases meeting inclusion criteria and 47% (n=42,285) had an anti-CCP test. Restricting the sample to 9747 patients with a linked EMR, 859 reported an ACPA test result. Of these, 25% (n=212) were ACPA+ and 26% (n=219) were male. Compared with ACPA-negative (–) patients, adjusted results showed that ACPA+ patients were more likely to use either conventional (71.2 vs 49.6%, $p<0.001$) or biologic (20.3 vs 11.8%, $p<0.001$) DMARDs during the first year after diagnosis, and had more physician visits (5.57 vs 3.91 times/year, $p<0.001$). The annual RA-associated total expenditure was $7940 for ACPA+ and $5243 for ACPA– patients (Δ=$2697, p=0.002; Figure 1). Medical expenditure (i.e. excluding prescription drug costs) was $4380 for ACPA+ and $3427 for ACPA– patients (Δ=$954, p=0.168).

Conclusion: Patients with RA who are ACPA+ have a higher RA-related economic burden than patients who are ACPA–. Providers may consider utilizing the results of anti-CCP testing to inform treatment decisions in this higher-cost population of patients with RA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The goal of this study was to validate a claims-based statistical model to predict disease activity measured by the 28-joint count Disease Activity Score (DAS28) in a population of Veteran patients enrolled in the VARA registry.

Methods: VARA enrolled Veterans were included in the study if they had a healthcare encounter during the 365-days prior to their DAS28 score and were without diagnoses of cancer, organ transplantation, or other autoimmune diseases. Models using claims data were developed to predict the first DAS28 fulfilling these criteria. Three models were developed based on initial selection of variables for analyses. All variables included in the model were required to have a prevalence in the population ³1%. The 1st model started with 253 variables believed to be associated with disease activity (all clinical predictors). The 2nd model leveraged hierarchical classification systems for pharmacy, procedure and diagnostic codes along with the clinically derived variables for high-dimensional variable selection of 1,275 possible predictors (all predictors). The 3rd approach pre-screened all predictors with a significant bivariate association with the DAS28 resulting in 279 predictors (pre-screening). Models were also compared for patients with <5 years of RA disease to those ³5 years of RA disease. The least absolute shrinkage and selection operator (LASSO) with 5-fold cross-validation was used for variable selection and model development. The classification accuracy was examined for 4 disease activity categories: remission (<2.6), low (2.6-3.1), moderate (3.2-5.1) and high (>5.1) activity.

Results: There were 1,582 Veterans who fulfilled inclusion criteria. The adjusted r-square for the 3 models tested ranged from 0.221-0.223 (Table 1). The number of predictors in the final models were 32 for the clinical predictors, 45 for all predictors and 46 among pre-screened. The adjusted r-square for models based on patients with <5 years (n=429) of RA disease were slightly better than for patients with ³5 years (n=1056) of RA disease. Correct Classification ranged from 40% to 41% for the three models.

Conclusion: The multiple models tested found many predictors with significant unique correlation with the DAS28. Nevertheless, the overall model performance revealed similar results and showed relatively weak overall predictive accuracy in measuring disease activity when using DAS28 as the dependent variables. The models performed poorly at predicting patients with remission and high disease activity making the overall correct classification rate <50% for all models. Duration of disease did not have a large impact on model performance. Future research should investigate additional strategies to collect disease activity measures directly from medical records and allow inclusion of additional laboratory and other clinical data.

Table 1: Model Validation by Initial Set of Predictor Variables

Variable Sets			All Clinical Predictors	All Predictors	Pre-screening
Potential Predictors			253	1275	279
Potential Predictors with ≥ 1% prevalence (i.e., predictors put in model)			175	567	230
Predictors in final model			32	45	46

Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have higher healthcare utilization (HCU) and costs than patients without RA[1]. Evidence is mixed as to the impact of biologic treatment on HCU. The purpose of this study was to evaluate HCU before and after etanercept (ETN) initiation.

Methods: We conducted a retrospective cohort study using claims data. Adult RA patients newly exposed to ETN from January 1, 2010 through December 31, 2013 were included. Patients were required to have at least 1 inpatient or outpatient claim for RA (ICD-9-CM 714.0) in the primary position, and at least 1 ETN medication claim; the earliest ETN claim served as index date. Patients were excluded if they had exposure to a biologic DMARD or had a claim for psoriasis, psoriatic arthritis, ankylosing spondylitis, or juvenile idiopathic arthritis. The proportion of days covered (PDC) was calculated and used as a measure of ETN compliance. The primary outcome was the change in HCU (both overall and RA-related) in the year before and after ETN initiation. McNemar's test and paired t-test were used to determine statistical significance for dichotomous and continuous variables, respectively. To compare the HCU across ETN compliance groups, F-test and Chi-square test were used for categorical and continuous variables, respectively.

Results: We identified 6,737 ETN initiators. The mean age was 49.8 years and 77.3% were female. Frequency of medication use for oral corticosteroids, opioid analgesics, NSAIDS and NB-DMARDS decreased significantly from the pre-index to post-index period (Table 1). There was a significant decrease in overall outpatient services, ED visits and hospitalizations from the pre-index to post-index period (data not shown). In the post-index period, there was a statistically significant decrease in HCU factors with increasing ETN compliance (Table 2).

Conclusion: Health care utilization, including medication use, outpatient services and inpatient admissions decreased after ETN initiation. Patients who were the most compliant with their medication experienced significantly lower utilization than non-compliant patients. The reduction in HCU is consistent with a reduction in disease activity as shown in clinical trials of ETN.[2]

Session Time: 9:00AM-11:00AM

Title: Above-Label Dosing with Biologics in Treatment-Naïve and Treatment-Experienced Patients with Moderate-to-Severe Psoriatic Arthritis **Authors:** S. Schwartzman*[1], Y. Li[2], H. Zhou[3], V. Herrera[2], J. Palmer[2]
Affiliations: [1]Hospital for Special Surgery, New York, NY, US; [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, US; [3]KMK Consulting Inc., Morristown, NJ, US

Background/Purpose: Moderate-to-severe psoriatic arthritis (PsA) patients may be treated with biologics. Limited evidence is available about biologic utilization patterns outside approved doses. This study described the extent of dosing for etanercept (ETA), adalimumab (ADA), certolizumab (CER), golimumab (GOL), and ustekinumab (UST) among moderate-to-severe PsA patients who were biologic naïve versus (vs) previously treated with biologics.

Methods: Adult PsA patients in the MarketScan® claims database were identified between 01/01/2011–12/31/2013 (identification period), with a 1-year follow-up and 3-month look-forward period (post-index period) ending 3/31/2015. Patients included had ≥1 PsA diagnosis using International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) code 696.0 and ≥1 pharmacy claim for ETA, ADA, CER, GOL, or UST during the identification period. Patients were considered treatment-naive if they had no prior biologic use or treatment-experienced if they had previous use of any biologic in the 6 months before the index date. Excluded patients had any other autoimmune disease indicated for treatment with biologics of interest. Intravenous biologic therapy was not evaluated due to lack of available data in MarketScan databases. Mean days of above-label use (daily maintenance dose ≥10% higher than indication), below-label use (daily maintenance dose ≤10% less than indication), and on-label use (daily maintenance dose ±10% than indication) per patient were described and stratified by treatment-naïve vs treatment-experienced patients.

Results: This study identified 4245 PsA patients receiving biologic therapy: ETA (n=2342), ADA (n=1788), and GOL (n=115), respectively. Patients on CER (n=0) or UST (n=14) were not included due to small sample size and because both agents were only approved for PsA in late 2013. The majority of patients were male (~50-60%), with a mean age of ~50 years of age, and from the South of the United States. Across all three biologic patient cohorts examined, the majority of PsA patients were treatment-experienced, with ETA showing the highest proportion of patients with prior biologic use (67%), followed by GOL (57%) and ADA (56%) (Table 1). Treatment-experienced patients on ADA had greater mean days of above-label use compared to those naive to treatment (47 vs 19 days); however, treatment-experienced patients on ETA and GOL had fewer days of above-label use on average compared to naïve counterparts (ETA: 16 vs 20 days; GOL: 9 vs 16 days). **Table 1. Mean days of above-label, on-label, and below-label use per patient per year**

	ETA (n=2342)	ADA (n=1788)	GOL (n=115)
Total number of patients, n (%)			
Naïve	783 (33.4)	791 (44.2)	49 (42.6)
Experienced	1559 (66.6)	997 (55.8)	66 (57.4)
Total days on treatment, n			
Naïve	299	306	304
Experienced	291	299	309
Average days of above-label use, mean (SD)			
Naïve	20 (61)	19 (54)	16 (67)
Experienced	16 (60)	47 (107)	9 (49)
Average days of on-label use, mean (SD)			
Naïve	277 (99)	286 (86)	288 (77)
Experienced	271 (101)	251 (123)	300 (77)
Average days of below-label use, mean (SD)			
Naïve	3 (24)	1 (14)	0 (0)
Experienced	4 (33)	0 (9)	0 (0)

Conclusion: Above-label use was observed in PsA patients treated with ETA, ADA, and GOL; Prior biologic use seems to be a factor in above-label use of ADA versus other biologic cohorts.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease requiring continuous therapy to reach low disease activity targets and to delay its long-term health effects. We investigated predictors of adherence with biologic therapy and healthcare costs among patients with RA in the first and second year after first biologic initiation.

Methods: <span">Patients with RA initiating a first (index) biologic between January 1, 2009 and December 31, 2012 and with 2 years of continuous enrollment were identified in the IMS PharMetrics Plus commercial claims database.Based on Year 1 data, we classified patients as 'effectively' or 'non-effectively' treated using a validated algorithm that considers six criteria of adherence, treatment changes, or steroid use. Adherence on index agent was defined by proportion of days covered (PDC) >80%. Logistic regression models assessed predictors of adherence at Years 1 and 2 using demographic, clinical and pre-index cost characteristics that were statistically significant in univariate analysis. Inverse probability of treatment weighted structural models were used to estimate total and RA-related healthcare costs in Year 2, controlling for baseline characteristics and effective/non-effective treatment in Year 1.

Results: <span">Of the 10,374 eligible patients, 76.1% were female, median age was 51 years, and 77.9% used a non-biologic disease-modifying antirheumatic drug (DMARD) in 12 months pre-index. In Year 1, 29.7% were considered effectively treated.Among all patients, 46.0% and 33.6% were adherent over the entire one and two year periods, respectively. Patients using the infused agents, infliximab and abatacept, had the highest adherence (63.7%, 48.0) in Year 1, with infliximab users more adherent (47.0%) over 2 years. Adherence across the four subcutaneous agents was highest for adalimumab and etanercept. Adherence was more likely in older patients, males, and those with prior DMARD use over both time periods (Table). Additional predictors of adherence in both years were index drug, region and payer type. Higher total healthcare costs during Year 2 were predicted by effective treatment in Year 1, choice of index drug, greater patient age at index, prior use of glucocorticoids, and greater comorbidity burden ($p<0.05$). Effective treatment in Year 1, patient age at index, geographic region, and index year were significant predictors ($p<0.05$) of RA-related healthcare costs in Year 2.

Conclusion: <span">Adherence in both time periods varied by drug, prior DMARD use, and demographic factors with several of these being significant predictors in Year 1 and 2.Year 2 total and RA-related health care costs were predicted by common variables of older age and effective treatment in Year 1. <span">

Table. Predictors of 1- and 2-Year Adherence (PDC > 80%) With Biologic Therapy		
Independent Variable	**1 Year Adherence OR (95% CI)**	**2 Year Adherence OR (95% CI)**

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Authors: S. Schwartzman*[1], Y. Li[2], H. Zhou[3], V. Herrera[2], J. Palmer[2] **Affiliations:** [1]Hospital for Special Surgery, New York, NY, US; [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, US; [3]KMK Consulting Inc., Morristown, NJ, US

Background/Purpose: Disease control among patients with moderate-to-severe psoriatic arthritis (PsA) may involve above-label dosing of biologic drugs; limited information is available about the economic impact of above-label dosing. We examined the costs associated with above-label dosing among patients with moderate-to-severe PsA receiving etanercept (ETA), adalimumab (ADA), certolizumab (CER), golimumab (GOL), and ustekinumab (UST).

Methods: Adult PsA patients in the MarketScan® Commercial Claims databases were identified between 01/01/2011–03/31/2013 (identification period) and followed-up for 1 year, with a 3-month look-forward period (post-index period) ending in 3/31/2015. Patients had ≥1 PsA diagnosis using International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) code 696.0, ≥1 pharmacy claim for ETA, ADA, CER, GOL, or UST during the identification period. Intravenous therapy was not evaluated due to lack of available data in MarketScan databases. Patients who switched to a different biologic following the use of their initial biologic or had any autoimmune disease for which one of the studied biologics of interest could potentially be used were excluded. Above-label use was defined as a daily maintenance dose ≥10% higher than indicated in the label. Each cohort and its total healthcare costs associated with above-label use were divided into 3 categorizes: <30, 30-179 and ≥180 days, respectively.

Results: This study identified 4245 PsA patients on ETA (n=2342), ADA (n=1788), and GOL (n=115). Patients on CER (n=0) or UST (n=14) were not included due to small sample size and because both agents were approved for PsA in late 2013. Ninety percent of the ETA, 85% of the ADA, and 96% of the GOL patient cohorts had at least 30 days of above-label use. Five and a half percent (5.5%) of the ETA, 5.4% of the ADA, and 1.7% of the GOL patient cohorts had at least 30-179 days of above-label use whereas 4% of the ETA, 9.6% of the ADA, and 2.6% of the GOL patient cohorts had ≥180 days above-label use. In the post-index period, the mean total all-cause healthcare costs (medical and pharmacy) were increased in the biologic patient cohorts with more above-label use (ETA cohort: $30,625 <30 days vs. $55,359 ≥180 days; ADA cohort: $31,620 <30 days vs. $54,176 ≥180 days; GOL cohort: $37,224 <30 days vs. $47,993 ≥180 days, respectively). Within the above-label use categories, ETA and ADA showed increased costs associated with increased duration of above-label dosing in annual mean total all-cause healthcare costs per patient (ETA: $10,561 <30 days; $16,213 30-179 days; $25,167 ≥180 days; ADA: $13,446 <30 days; $17,623 30-179 days; $16,251 ≥180 days); The observations for patients treated with GOL are limited by the small sample size.

Table 1. Patient Demographic and Total Healthcare Costs Associated with Above-label Use of ETA, ADA and GOL

	<30 days Above-label Use			30-179 days Above-label Us			≥180 days Above-label Use		
	ETA (n=2118)	ADA (n=1520)	GOL (n=110)	ETA (n=129)	ADA (n=97)	GOL (n=2)	ETA (n=95)	ADA (n=171)	GOL (n=3)

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To determine total and subspecialty physician encounters, emergency room (ER) visits and hospitalizations in an incident cohort of rheumatoid arthritis (RA) cases and matched control patients over 13 years.

Methods: A retrospective cohort study was performed utilizing administrative health care data from approximately 1 million people with access to universal healthcare. Using ICD-9 and ICD-10 diagnostic codes, 7 RA case definitions were used. Each case was matched by age and gender to 4 randomly selected controls. Data included physician billings, ER visits and hospital discharges over 13 years.

Results: The number of incident RA cases varied from 3,460 to 27,657 depending upon the case definition. The mean (SD) age was 56.0 (17.8) years and the proportion of females was 68%. Using a single representative case definition for RA, the utilization of different services in the index year and after 13 years of follow-up is summarized in Table 1. All encounters with physicians and services by RA patients were significantly higher than controls ($p<0.0001$ for all) and were highest in the index year, declining thereafter. Over 13 years the reduction in utilization varied by service from 78% (Rheumatologists; $p<0.0001$), 54.7% (Internal medicine; $p<0.0001$), 17.1% (primary care physicians; $p<0.0001$), 9.2% (other physicians; $p<0.0001$), 30.2% (ER visits; $p<0.01$) and 63% (hospitalizations; $p<0.0001$). **Table 1: Utilization of physician and clinical services by RA patients and controls**

Clinical service	Encounters/year in index year		Encounters/year after 13 years	
	RA cases	Controls	RA cases	Controls
All physicians	17.26	6.35	12.88	7.82
Rheumatologists	2.40	0.01	0.53	0.02
General internists	0.74	0.19	0.33	0.16
Other physicians	3.98	1.52	3.61	2.21
Primary care physicians	10.14	4.64	8.41	5.43
Emergency room visits	0.58	0.27	0.40	0.25
Hospitalizations	1.40	0.30	0.52	0.35

Conclusion: In RA patients, health care utilization is highest in the first year following the diagnosis which is also the time of maximal involvement by rheumatologists. Utilization declines over time and encounters with patient's primary care and other physician groups predominate.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Repository corticotropin injection (RCI) may produce anti-inflammatory and immune-modulatory effects. This study examined the demographics of those who used RCI and the trends in medication use, specifically prednisone, after RCI initiation.

Methods: This retrospective analysis of the Symphony Health Solutions Patient Transactional Dataset from 2008 to 2015 included patients with at least 1 claim for RA, SLE, or DM/PM, and any use of RCI. Patients with claims for non-rheumatologic conditions that may also be treated by RCI, namely, multiple sclerosis and proteinuria, were excluded. Demographics, patterns of RCI use, and concomitant medications (corticosteroids [CS], biologics, NSAIDs, and DMARDs) were reported. Patients were followed for concomitant medication use from 2 years prior to and 1 year after RCI initiation. Paired two-tailed t-test was used to calculate the *p* values for the use of each drug class before/after RCI initiation**.**

Results: Out of 2.7 million rheumatologic patients in the database over 6 years, there were 2,749 patients who used RCI - 1269 RA patients, 874 SLE patients, and 606 with DM/PM (**Table 1**). SLE patients were younger than RA and DM/PM patients, and most of the patients were female for all 3 conditions. Majority of patients received 80U of RCI twice weekly. The study identified 504 RA, 322 SLE, and 222 DM/PM patients with sufficient follow up time to evaluate concomitant medication use. For all 3 conditions, the proportions of patients who used any CS were significantly lower after RCI initiation: reduced from 67% pre-index to 54% post-index for RA, from 73% to 58% for SLE, and from 76% to 58% for DM/PM ($p < 0.05$ for all comparisons, **Figure 1**). Proportions of patients on biologics and DMARDs were also significantly lowered after RCI initiation. In **Figure 2**, among patients who had taken CS consistently 24 weeks before RCI initiation, dose reductions were statistically significant for RA (28%), and trended lower without statistical significance for SLE (25%) and DM/PM (25%). Limitation of the retrospective analysis include uncertainties in diagnosis, medication use, and factors influencing medication changes.

Conclusion: This claims-based study of patients with RA, SLE, and DM/PM indicated that RCI use may be associated with significant reductions in CS requirements.

Table 1. Patient Characteristics

Patient Characteristics	RA	SLE	DM/PM
Number of patients on RCI	1269	874	606
Age, Mean (Years)	59.1	48.1	55.5
Female	78%	89%	70%
RCI dose of 80U twice weekly	58%	57%	68%
RCI dose of 200U weekly	12%	15%	16%
RCI duration, Mean (Days)	115.7	129.2	157.1

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Multiple biologic DMARDs (bDMARDs) are approved in the US for the treatment of RA. Previous studies have indicated significant clinical inertia in moving patients who have failed conventional DMARDs (cDMARDs) to bDMARDs. We sought to identify factors associated with bDMARD use.

Methods : The data for this analysis were obtained from the 2015 online RA community survey "Rheumatoid Arthritis in America". The survey was administered by Health Union between August 6, 2015 and Sep. 12, 2015. Subjects self-identified as having RA and were recruited from RheumatoidArthritis.net subscribers, email and social media (N=3149). Patients aged 18 years or older at RA diagnosis, living in the US, and naïve to clinical trials (N=2735) were included in this analysis. Survey variables included demographics; financial status; disease onset and disease status; patient reported outcomes; RA therapy; provider/practice characteristics; patient knowledge, attitudes, perceptions of RA (disease, therapy, and care), patient behaviors; and medication history. A regression tree partitioning algorithm was used as the primary analysis to systematically identify subgroups of patients where bDMARD use was substantially different from the overall population. As a secondary analysis, logistic regression with stepwise selection was also performed.

Results : Patients were mostly women (96%), Caucasian (87.9%), mean age was 51.5 years, and mean time since diagnosis of 7.3 years. Overall, 72.6% of patients had signs and symptoms that suggested their RA disease was not controlled and 38.2% were naïve to bDMARDs. Ever use of a bDMARD was higher in uncontrolled patients (vs. patients who had evidence of disease control); this observation was consistent across disease duration (Figure). Of 47 subgroup variables used in the regression tree algorithm, three variables were associated with bDMARD use and met the stringent selection criteria (consistency, internal/external validity): (1) time since RA diagnosis (≥2 years); (2) expected annual out of pocket spending (≥$2000); and (3) preferred medication route of administration (prefer injection/infusion). The stepwise logistic regression retained 18 variables including the three variables identified by regression tree analysis. Of the remaining 15 variables, odds ratios for ever use of bDMARDs greater than 2.0 were observed among patients who were uninsured, were treated by a rheumatologist, had moderate/severe disease at symptom onset or currently, and prior use of cDMARDs.

Conclusion : In this online community of RA patients, 72.6% did not have disease in control and 38.2% had never used a biologic. bDMARD use varied considerably among patient subgroups, particularly by time since RA diagnosis, expected annual out-of-pocket spending, and preferred medication route of administration.

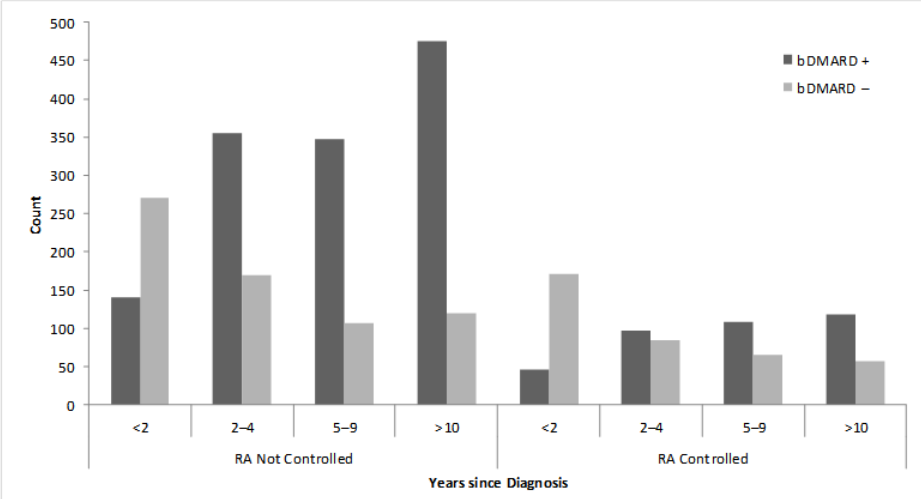

Figure. Ever use of bDMARDs by disease status and years since diagnosis (n=2735).

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Medications used to manage RA vary in efficacy, safety, and convenience of use. A better understanding of patient preferences of these attributes is key to understanding patient barriers to effective therapeutic management. The objective of this study was to evaluate US patient views of RA medication attributes.

Methods: The data for this analysis were obtained from the 2015 online RA community survey "Rheumatoid Arthritis in America". The survey was administered by Health Union between August 6, 2015 and Sep. 12, 2015. Subjects self-identified as having RA and were recruited from RheumatoidArthritis.net subscribers, email and

social media (N=3149). Patients aged 18 years or older at RA diagnosis, living in the US, and naïve to clinical trials (N=2735) were included in this analysis. Within the survey, patients ranked eight attributes—reduce the severity of flares, injection, infusion, proven safety record, reduce the number of flares, minimal side effects, pill, and rapid reduction of RA symptoms—assuming equal insurance and cost-effectiveness from 1 (most important) to 8 (least important). This ranking and patient preference for drug administration route were analyzed for all subjects and by age (<45, 45–64, ≥65 years old), gender, race (Caucasian, yes/no), RA disease severity (mild, moderate, and severe), and use of bDMARDs using ANOVA for continuous variables and Chi-square tests for categorical variables.

Results: Patients ranked "rapid reduction of RA symptoms" at mean (SD): 3.0 (1.8) over "minimal side effects" 3.4 (1.8); "proven safety record" 3.5 (2.0); "reduces the severity of flares" 3.5 (1.6); number of flares 3.6 (1.6); and taken as a pill 5.5 (1.9), injection 6.5 (1.7), or infusion 7.0 (1.7). For drug formulation, the majority (70%) of RA patients surveyed preferred oral medication to injection with preloaded pen (15%), injection with syringe (9%), or infusion (6%), with difference in preference by disease severity and history of bDMARD use (Figure).

Conclusion: Rapid reduction of symptoms was rated the most important attribute of RA medications, assuming equal insurance and cost-effectiveness. Oral was the preferred route of administration, with more severe (vs. less severe) and bDMARD-current (vs. bDMARD-prior/never) patients having a greater preference for non-oral. A better understanding of patient medication preference should help identify patient barriers to effective management of RA. **Figure 1**. Subgroup analysis of drug formulation preference by current disease severity (n=2100) and history of bDMARD use (n=2735).

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept (ABA), a T cell co-stimulation inhibitor, was initially approved by the European Medicine Agency (EMA) for patients with rheumatoid arthritis (RA) who had failed ≥ 1 tumor necrosis factor inhibitor (TNFi), and was available in Europe in 2008. Thereafter EMA also approved ABA for patients failing methotrexate (biologic-naïve patients): this was available in Europe after 2011.These different RA target populations might lead to a change in the RA population treated with ABA over time. Our objective is to analyze differences in the baseline characteristics of RA patients treated with ABA according to calendar year

Methods: All patients from the BIOBADASER 2.0 register with a diagnosis of RA and treated with ABA from January 2008 to December 2014 were selected and divided according to calendar year: 2008-2011 and 2012-2014. Variables analyzed: age; gender; disease duration; number of previous biological agents; disease activity at initiation of biological drug, measured by the DAS-28 score; concomitant treatment with glucocorticoids and synthetic DMARDs; baseline comorbidities (ischemic heart disease, malignancy, diabetes, chronic obstructive pulmonary disease, heart failure and hepatitis B infection); and ABA treatment duration

Results: From January 2008 to December 2014, 252 RA patients treated with ABA were included in the BIOBADASER 2.0 register. Baseline characteristics and distribution by calendar year are shown in Table 1. At baseline, patients treated with abatacept between 2008-2011 had significantly higher basal activity [DAS28 (5.18 (1.46) vs 4.74 (1.57); p 0.037], longer time on ABA [13.44 (12.1) m vs 7.59 (9.1) m; p= 0.039], and fewer patients with ischemic heart disease [1 (0.6%) vs 4 (4.6%), p=0.031], compared with patients treated between 2012-2014. No differences in other parameters were found

Conclusion: Abatacept treatment pattern has not been changed over the time and is being used in patients who failed ≥ 1 biological agent. Initially, patients treated with abatacept had significantly higher baseline DAS28, and a longer time on biological treatment, probably reflecting disease management in Spain **Table 1. Differences in basal characteristics and presence of comorbidities of patients treated with abatacept according to calendar year**

Years		2008-2011	2012-2014	p

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: This study examined treatment patterns in a rheumatology patient (pt) population initially prescribed innovator infliximab (IFX) that either switched to biosimilar infliximab (CT-P13) or continued on IFX following availability of CT-P13 in the Turkish healthcare system.

Methods: Adult pts with ≥1 diagnosis code (ICD-10-CM M05.X; M06.X) for rheumatoid arthritis (RA) and a prescription for IFX were identified in a national Turkish health care database during the study period (01DEC2010-01DEC2015). Eligible pts were those who continued on IFX (Continuers cohort; CC) or switched from IFX to CT-P13 (Switchers cohort; SC) during the identification period; had continuous medical/pharmacy benefit enrollment ≥12 months before and ≥6 months after the index date (date of switch for SC and a random IFX prescription date for CC); had a prescription claim for IFX within 16 weeks of the index date during the baseline period. Demographics, concomitant disease, medications, and treatment patterns (dose, refill interval, discontinuation, and switch) were summarized. A confirmed discontinuation was defined as a switch to another biologic medication or the absence of an index biologic claim for ≥120 days without censoring. Patient weight was unavailable in the dataset.

Results: Key results are shown in the Table and Figure. A total of 3018 pts met study criteria. The majority (95%; n=2870; CC) continued on IFX and had a mean age of 44 years; 46% were female and mean follow up of 12 months. A total of 148 pts (5%) switched to CT-P13 (SC) and had mean age of 44 years; 51% female and mean follow up of 9 months. Approximately 40% of pts in each cohort had a concomitant diagnosis for ankylosing spondylitis (AS; Table). Other concomitant diseases and medications appeared balanced between cohorts. In the CC, pts had an average of 4.7 infusions at a mean dose of 4.4 vials approximately every 10 weeks. In the SC, pts had an average of 2.6 infusions at a mean dose of 3.6 vials approximately every 10 weeks. Therapy discontinuation occurred in 38% in the CC; average time to any discontinuation or censoring of IFX was 256 days (Table). In the SC, CT-P13 discontinuation was observed in 82%; average time to any discontinuation or censoring of CT-P13 was 124 days; 74% of SC switched to another biologic with 94% of these returning to IFX.

Conclusion: This study shows switching from IFX to CT-P13 was infrequent. However, in those switching to CT-P13, a high percentage (82%) of CT-P13 discontinuation was observed and the majority returned to IFX. Further studies are needed to understand the reasons for these observations.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a crystal deposition disease and the most prevalent inflammatory arthritis in the United States (US). Maintaining gout control has been associated with reduced healthcare resource utilization and healthcare costs, with uncontrolled gout (serum uric acid [sUA] >6 mg/dl or ≥1 flare in past year) incurring >1.3 times the costs compared to controlled gout (sUA <6 mg/dl and no flares in past year).[1] The long-term impacts of uncontrolled gout, including economic consequences, have not been well summarized. A systematic literature review was conducted to clarify the economic value of controlling gout with treatment in the US.

Methods: A search of published literature from Jan 2006 to Jan 2016 was conducted in PubMed, EMBASE, MEDLINE In-Process, the Cochrane Collaboration, and other non-indexed citations. Three independent researchers reviewed the results using predetermined inclusion and exclusion criteria. Preliminary inclusion criteria were: 1) gout disease focus; 2) reported disease burden or treatment outcomes; 3) English language. Non-human studies, opinion-based reviews, and case-reports were excluded.

Results: We identified 178 studies meeting eligibility criteria. All studies reporting longitudinal epidemiology data indicated an increased prevalence of gout over time, ranging from 1.1% in 1959–1962 to 3.7% in 2009–2010. Of the 178 studies, 13 were found in which primary analyses of healthcare costs in patients with gout were conducted (**Table**). Classification of gout in US-focused retrospective claims database analyses were largely based on an incident population, which underestimates the true economic burden. Cost estimates for gout treatment in the US range from $7.7 billion for gout-specific costs to ≥$20 billion for total costs. Overall, the data show a substantial cost of care associated with uncontrolled gout that increases with disease severity and comorbidities, such as end-stage renal disease.

Conclusion: In the US, uncontrolled gout results in a significant economic burden that is higher in patients with more severe disease. Uncontrolled gout is associated with higher economic costs than controlled gout; furthermore, controlled gout has been associated with lower healthcare costs and protection against comorbidities. This study

was sponsored by AstraZeneca.

Comparison of Assessment and Management of RA and Other Rheumatic Diseases By Rheumatologists in Private Practices or an Academic Medical Center

Anna Coleman[1], Herbert Lindsley[2] and Jo Wick[3], [1]Rheumatology, University of Kansas Medical Center, Kansas City, KS, [2]Internal Medicine, University of Kansas Medical Center, Kansas City, KS, [3]Biostatistics, University of Kansas Medical Center, Kansas City, KS

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Since 80% of rheumatologists practice outside the university setting, training projects for rheumatoid arthritis (RA) may benefit from an improved understanding of RA management and care in private practice (PP). The aim of this study was to determine whether similarities and differences exist in the delivery of care and treatment of RA and other rheumatic diseases in PP and academic settings.

Methods: 18 rheumatology clinicians were observed by a second year medical student: 9 in PP and 9 at an academic medical center (UNV). Observational data (without chart review) were collected, including patient demographics, rheumatologic diagnoses, general physical exam, joint exam, and therapy. Clinicians were interviewed to survey therapeutic approaches to RA.

Results: Of 195 total patient visits, 83 (43%) were at UNV and 112 (57%) at PP. New patients represented 25% of UNV visits and 18% of PP visits. Visit length for new patients averaged 44 minutes at UNV and 29 minutes at PP. Established RA patients represented 38% of UNV visits and 22% of PP visits. Visit length for established RA patients averaged 33 minutes at UNV and 17 minutes at PP (Figure 1). For inspection, auscultation and joint palpation of established RA patients, the weighted point value averaged 2.4 points at UNV and 2.7 points at PP. UNV physicians were found to use Biologics 17% more frequently compared to PP physicians (Figure 2). Rank order of the top five diagnoses for UNV was RA, OA, fibromyalgia, Sjogrens, and gout. For PP the rank order was RA, OA, gout, psoriatic arthritis, and fibromyalgia.

Conclusion: Average visit length for established RA patients differed between UNV and PP groups, with visits being 48% shorter in PP settings. Patient populations also differed, with new patient visits representing a greater proportion of UNV visits. The elevated frequency of biologic prescription in the UNV group suggests a difference in treatment approaches. In contrast, complexity of established RA patient physical exams (detail points) was similar between the two groups. Diagnostic frequency of common rheumatologic diseases was also similar.

The Paucity of the Evidence Base for American College of Rheumatology Practice Guidelines

Ali Duarte-Garcia[1], Richard Zamore[2] and John B. Wong[2], [1]Medicine, Tufts Medical Center, Boston, MA, [2]Tufts Medical Center, Boston, MA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The American College of Rheumatology (ACR) practice guidelines establish U.S. and international treatment recommendations and hence performance measures and research priorities, so we sought to characterize the quality of evidence, the strength of recommendations and their relationship in the ACR guidelines.

Methods: For consistency (because ACR guidelines as of March 2016 used 3 different evidence grading systems), two independent reviewers applied the American College of Cardiology (ACC)/ American Heart Association (AHA) grading system to evaluate the quality (level) of evidence and class (benefit to harm or strength) of ACR treatment recommendations. To give each guideline equal weight, we reported results as medians and interquartile ranges (IQR) of the percentages of recommendations by level and class within each guideline.

Results: In the 8 guidelines (Glucocorticoid Induced Osteoporosis (GIOP); Juvenile Idiopathic Arthritis (JIA); Gout; Lupus Nephritis (LN); Osteoarthritis (OA); Spondyloarthritis (SpA); Polymyalgia Rheumatica (PMR); Rheumatoid Arthritis (RA)) involving 403 (range 10-102) recommendations, 23% (IQR 12-30%) were supported by level A (high) quality evidence; 18% (IQR 15-20%) level B (moderate); and 50% level C (IQR 46-70%) (low) (Table 1). In the 4 guidelines that reported the strength of 143 recommendations, 26% (IQR 21-31%) were class I (high benefit to harm ratio); 62% (IQR 58-64%) class II (moderate to low benefit to harm); and 16% (IQR 13-19%) class III (harm exceeds benefit) (Table 2). Overall, only 10% (IQR 7-12%) of recommendations (mean 9% of 143 recommendations) had both level A evidence and class I strength of recommendation. Of the level A and class I recommendations, the majority involved OA. Similarly, only 6% (IQR 2-12%) of recommendations (mean 9% of 143 recommendations) had both level B evidence and class I strength of recommendation. Most recommendations were level C and class II (median 30%, IQR 21-41%%, mean 32%). At the extremes, OA (58%) and GIOP (35%) had the most level A recommendations, and JIA (2%) and PMR (10%) had the least. Conversely, level C evidence comprised 86% of JIA recommendations, 70% of RA and 70% of LN.

Conclusion: The ACR clinical practice guidelines consist primarily of low-level evidence with moderate to low strength of recommendation. Few recommendations are both strong and supported by high-level evidence, emphasizing the need to expand the evidence base. _

Table 1. Guideline recommendations by Level (Quality) of evidence

Guideline	A	B	C
GIOP	35% (13/37)	19% (7/37)	46% (17/37)
JIA	2% (2/102)	12% (12/102)	86% (88/102)
Gout	21% (18.5/88)	31% (27/88)	48% (42/88)
LN	24% (8/33)	6% (2/33)	70% (23/33)
OA	58% (35/60)	17% (10/60)	25% (15/60)
SpA	29% (11/38)	20% (7.5/38)	51% (19.5/38)
PMR	10% 1/10	45% (4.5/10)	45% (4.5/10)
RA	13% 4.5/35	17% (6/35)	69% (24/35)
Mean	24%	21%	55%
Median (IQR)	23% (12-30%)	18% (15-23%)	50% (46-70%)

Table 2. Guideline Recommendations by Class (Strength) of recommendations

Guideline	I	II	III
OA	22% (13/60)	62% (37/60)	17% (10/60)
SpA	18% (7/38)	66% (25/38)	16% (6/38)
PMR	10% (3/10)	45% (4.5/10)	25% (2.5/10)
RA	34% (12/35)	63% (22/35)	3% (1/35)
Mean	26%	59%	15%
Median (IQR)	26% (21-31%)	62% (58-64%)	16% (13-19%)

Utilization Patterns of Subcutaneously Administered Biologic Medications within a Sample of Rheumatoid Arthritis Patients

Joseph Tkacz[1], Brenna Brady[2], Lorie A. Ellis[3] and Roxanne Meyer[4], [1]Health Analytics, Columbia, MD, [2]Health Analytics, LLC, Columbia, MD, [3]Health Economics & Outcomes Research, Janssen Scientific Affairs, LLC, Horsham, PA, [4]Janssen Scientific Affairs, Horsham, PA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adherence to medication is crucial to the maximum therapeutic benefit of biologic treatment. The plethora of currently approved biologic agents makes comparison of the various medications more difficult, particularly when drug dosing and administration schedules vary. This study used administrative claims to investigate real world utilization and adherence patterns of subcutaneous (subQ) biologic treatment in a population of patients with RA.

Methods: The earliest incident adalimumab (ADA), certolizumab (CER), etanercept (ETA), and golimumab (GLM) biologic cycles of treatment were identified in the Truven MarketScan® and Optum Clinformatics™ research databases for adult patients with an RA diagnosis (ICD-9: 714.xx) between 2009 – 2013. Members were required to have ≥ two index biologic fills, and continuous eligibility for at least 6 months prior to biologic initiation. Members were followed until the end of their treatment, eligibility was lost, or the end of the data was reached. Utilization measures included biologic placement, treatment gaps measured as the number of days between expected refill dates, dose escalation, defined as any appearance of a twofold increase in dose from the starting dose, and medication adherence assessed by the proportion of days' covered (PDC). Members with 80% of the days in their treatment period covered by the index medication were categorized as adherent. One-way ANOVA and chi-square tests of equality of proportions were conducted to assess group differences.

Results: Modal monthly calculated dosages were in line with recommended prescribing guidelines for all four treatments (Table 1). GLM and CER were significantly less likely to be administered as a first line biologic compared to ADA and ETA; however GLM members were more likely to be adherent (*p*s < 0.05). ADA and GLM members displayed the greatest refill consistency within the Truven database as evidenced by lower gaps between refills (*p*s < 0.05). Consistent with the label, ADA cycles were more likely to show a dose escalation (*ps* < 0.001). Nearly two-thirds of all treatment cycles persisted for ≥ 6 months, with the greatest proportion from the ETA group across both databases. ($p < 0.001$).

Conclusion: Significant differences in biologic utilization patterns were observed among the four treatment

groups. ADA and ETA were the most common first line biologics, though GLM cycles were associated with greater refill consistency and levels of adherence. These findings have implications for healthcare decision makers interested in quality improvement or optimization of adherence in patients treated with subcutaneous biologic therapies.

Injectable Corticosteroid Use in Musculoskeletal Care Specialties

Gurjit S. Kaeley[1], Myint Thway[1] and Sunita Dodani[2], [1]Rheumatology, University of Florida College of Medicine, Jacksonville, Jacksonville, FL, [2]Epidemiology, University of Florida, College of Medicine & College of Public Health and Health Professions, Gainesville, Jacksonville, FL

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Injectable corticosteroids (IC) are widely used for joint and soft tissue injections. Although four main types of preparations are available, there is sparse evidence and consensus for the selection and utilization of ICs. Using national outpatient Medicare data, we studied the utilization of IC preparations amongst musculoskeletal (MSK) care specialists.

Methods: A retrospective secondary analysis of Medicare physician and other supplier Public Use Files from 2014 were used for assessing injectable corticosteroids' utilization. Non-duplicative billing claims for ten preparations of IC were calculated by MSK provider specialty and by State. MSK provider specialties were grouped into six groups that billed the majority of the services as shown in Table 1. Number of services submitted were standardized with Prednisone 5 mg to reflect unique doses. Cost per standardized service was then calculated. For national trends, injectable corticosteroids were aggregated to five main classes. Descriptive analysis was conducted using R-Studio (Version 0.98.1102) and Tableau (Version 9.3).

Results: Amongst the most commonly used ICs, methylprednisolone 40mg and 80mg preparations were cheapest and most commonly used preparations (Table 1). Triamcinolone 10mg and betamethasone preparations were the next most commonly utilized. Amongst these, betamethasone was more expensive and least used by Radiology and Rheumatology. Triamcinolone 1mg was the most expensive and was utilized mainly by the Pain Management. Moreover, Dexamethasone being the least expensive was also heavily utilized by the Pain Management. Hydrocortisone and triamcinolone diacetate were least utilized. Among MSK providers, Orthopedists had the highest utilization of IC, and Radiologists the least (Figure 1). In other words, Orthopedists showed the highest service counts as well as payments for IC use. When compared with other MSK specialties in the Top 10 states for national trends (Figure 2), Orthopedists were the dominant providers for total billing in these states, but Pain Management followed by Rheumatology had the most number of services per provider. In contrast to number of standardized service units, the highest payments were for betamethasone, methylprednisolone, and triamcinolone injectable corticosteroids.

Conclusion: This study highlights the disproportionate spending on certain types of injectable corticosteroids by MSK providers with no clear guidelines on their use. Variations between MSK providers in injectable corticosteroids types and dosage bespeak the need for additional research aimed at establishing uniform injectable corticosteroid use guidelines. There is a need for further trials investigating the comparative efficacy of different injectable corticosteroids with specific outcome measures to facilitate a more evidence-based practice.

Glucocorticoids in Early Rheumatoid Arthritis Management, Friend or Foe?

Diederik Decock[1], Rene Westhovens[1,2], Veerle Stouten[1], Kristien Van der Elst[2,3], Johan Joly[2], Patrick Verschueren[1,2] and CareRA Study Group, [1]KU Leuven Department of Development and Regeneration, Skeletal Biology and Engineering Research Center, Leuven, Belgium, [2]Rheumatology, University Hospitals Leuven, Leuven, Belgium, [3]KU Leuven, Department of Public Health and Primary Care, Skeletal Biology and Engineering Research Center, Leuven, Belgium

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The Care in early Rheumatoid Arthritis (CareRA) trial compares different combinations of csDMARDs with remission induction glucocorticoid (GC) schemes starting at high or moderate dosages in a treat to target approach. Efficacy results after 52 weeks showed high rates of DAS28(CRP) remission reaching >60%. However, many physicians are still reluctant to use such regimens in practice for fear of side effects. This study explores the risk-benefit balance of GC-based intensive treatment strategies.

Methods: DMARD unexperienced Early Rheumatoid Arthritis (ERA) patients were stratified into a high- or low-risk arm based on classical prognostic markers. High risk patients were randomized to COBRA Classic (Methotrexate (MTX) + Sulphasalazine + prednisone stepdown from 60mg), COBRA Slim (MTX + prednisone stepdown from 30mg) or COBRA Avant-Garde (MTX + Leflunomide + prednisone stepdown from 30mg). Low risk patients were randomized to MTX Tight Step Up (MTX-TSU) without oral GCs or COBRA Slim. Prednisone was tapered down over 6 weeks to 7.5mg in Classic and 5mg in the other COBRA arms. Oral GCs were stopped at week 34. DMARD monotherapy was aimed for in all strategies. Demographics and disease parameters were routinely registered. All patients attending the week 52 visit in CareRA were analyzed. Remission, low disease activity, obesity and arterial hypertension were defined as DAS28(CRP)<2.6, DAS28(CRP)≤3.2, BMI ≥30 kg/m² and systolic/diastolic blood pressure ≥140/90 mmHg. This analysis describes trial effectiveness, effects of treatment on BMI and blood pressure, and safety events of interest.

Results: Of the 379 patients included in our trial, 349 (91.3%) attended week 52. Remission and low disease activity were achieved in 227/349 (65.6%) and 278 (80.3%) patients respectively, with 236 (68.2%) patients on MTX monotherapy. The therapeutic strategy could be followed per protocol by 263 (75.4%) patients. Of patients not able to follow the protocol 26 (7.4%) were using biologicals and 18 (5.2%) GCs. Table 1 gives detailed information per treatment strategy. BMI changed 0.0 ±3.2 kg/m^2 after 52 treatment weeks. The proportion of obese patients did not rise between baseline and week 52 (20.1% vs 20.3%). Systolic and diastolic blood pressure changed -0.9 ±15.8 mmHg and -0.4 ±10.6 mmHg respectively, without a significant change in the proportion of hypertensive patients (10.7% vs 6.1%). The only difference between treatments arms in either risk groups was a BMI decrease in Avant-Garde compared to Classic and Slim between baseline and week 52 (p=0.01). Diabetes and glucose intolerance were reported only once, in Cobra Slim and Classic respectively. Hyperglycaemia was reported once in Classic, Avant-Garde and MTX-TSU. Glycosuria was reported in 1 Avant-Garde patient. No differences between groups were observed in infection rate. Most common were respiratory infections.

Conclusion: Intensive treatment strategies using short-term glucocorticoids for remission induction show a favourable risk-benefit ratio after 1 year, with only a small proportion of patients requiring biologics and no need for prolonged GC use in ERA.

REAL-Life Cost of UK Healthcare Resource for Patients with Rheumatoid Arthritis, Comparing High and Low/Remission Disease States

Bruce Kirkham[1], Estee Chan[2], Alexandra Vincent[2] and Alison Elliott[3], [1]Rheumatology, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom, [2]Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom, [3]Market Access Directorate, Roche Products LTD UK, Welwyn Garden City, United Kingdom
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) has differing therapeutic outcomes, with resulting differences in function and quality of life. Little is known about the effects of disease activity states on costs of routine care of people with RA. We quantified the real medical costs of treating patients with RA who were in a high DAS28 state (HDAS) versus low DAS28 or remission (LDAS), in a Guys & St Thomas' NHS Foundation Trust (GSTT) and Roche Products Ltd collaborative project.

Methods: The GSTT RA Centre database of 1,700 patients with RA, was used to generate two groups of 60 patients with high DAS28 (DAS28>5.1) scores and low DAS/remission, matched in terms of age, sex and duration of disease. Patients with co-morbidities such as significant chronic medical conditions, cancer and fibromyalgia were excluded to ensure comparable groups. Health Assessment Questionnaire (HAQ-DI) and EQ-5D values were compared. All medical costs incurred at GSTT from August 2013 to September 2015 were collated, including drug costs, inpatient and outpatient procedures and investigations.

Results: The mean and range for average HAQ-DI and EQ-5D respectively was 1.78 (0.15-2.92) and 0.286 (0.691 – [-0.239]) for the HDAS group and 0.70 (0-2.31) and 0.714 (1-0.258) for the LDAS group, both significantly different. Total GSTT pharmaceutical costs were £390,904, with biologic drug costs of £377,507 for HDAS patients and £324,805, with biologic drug costs of £321,401, for LDAS patients. 17 people in the HDAS group took concomitant prednisolone compared to 5 in the LDAS group. Total costs for the HDAS group were £733.984.02 ($1,078,957) vs £483,755.97 ($711,121) for the LDAS group, a difference of £250,228.05 ($367,835). Costs for patients living near our centre to those living at a distance did not differ significantly indicating that much of their hospital care took place at GSTT. The annual GSTT cost per patient increment of HDAS RA vs LDAS RA was £2085 ($3,066). These costs do not capture non-GSTT healthcare costs.

Conclusion: This study describes 'real world' hospital costs of treating patients with rheumatoid arthritis who have different disease activity, with minimal co-morbidity differences, treated by the same team. Poor function and quality of life for those people in high disease activity despite higher use of concomitant steroids and similar biologic drug use, shows the challenging nature of their RA. The data further support strategies to treat early and effectively by demonstrating that patients with low disease activity has a lower cost impact on the Trust and improved function and quality of life scores.

The "Financial Toxicity" of Therapy in Patients with Rheumatoid

Arthritis

Gary Craig[1,2], Keith Knapp[1,2], Karen Ferguson[2] and Sergio Schwartzman[3], [1]Arthritis Northwest PLLC., Spokane, WA, [2]Discus Analytics LLC., Spokane, WA, [3]Rheumatology, Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In the pre-biologic era, major costs faced by patients with RA included hospitalization and joint replacement. Biologic agent development has led to increasing outpatient costs. The effects of this from a patient's perspective have not been thoroughly explored although modeling exists in the oncology literature[1]. The purpose is to present patients' perspective of how medical costs impact their view of financial burden in rheumatologic care.

Methods: In this retrospective cross-sectional study, the US Rheumatology database JointMan® was utilized. Patients complete a financial impact form at every visit. Patients respond on a Likkert scale to the question, "How much of an impact does the cost of your medical care received from our office have on your life financially?" Response options: intolerable, severe, moderate, mild or none. Percentages of each response category were calculated for the time periods: 4/20/15–6/15/15, 10/20/2015–12/15/20, and 4/20/15–6/15/2016. Patients were also asked whether their financial situation would cause them to skip visits, postpone a visit, have difficulty paying for a visit or medication, cut dosage of medications, skip doses of medications, or fail to fill a medication.

Results: Of the 12554 responses, the mean patient age was 58, 73.11% female; 90.94% Caucasian. All patients had Medicare or private insurance; none were uninsured.

Response	Response Count	Percentage
Intolerable	31	0.25%
Severe	384	3.06%
Moderate	1997	15.91%
Mild	3132	24.95%
None	7010	55.84%

Global distribution of all responses

A two-sided T-Test comparing the "none" category for the April 2016 time point to all other categories combined revealed a statistically significant relationship $t=21.87$ ($p<0.0001$).

	Apr-15	Oct-15	Apr-16
No Impact	46.76	53.23	63.83
Some Level Of Impact	48.29	51.71	36.16

Conclusion: Surprisingly, there was an increasing trend in the "none" category indicating no perceived financial impact. Potential explanations include that this analysis was mostly from one large rheumatology practice where all patients surveyed were insured. In this population health insurers recognize the importance of biologics and were more likely to approve therapy. Competitive financial strategies are employed by pharmaceutical companies offering multiple or substantial co-pay assistance. ACR guidelines for treatment pathways are published including recommendations for biologic therapy which may aid insurance coverage.

Abstract Number: 2249

Comparison of Discontinuation Rates Among Patients with RA Initiating Biologics

Sofia Pedro[1] and Kaleb Michaud[1,2], [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]University of Nebraska Medical Center, Omaha, NE

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: While difficult to directly compare effectiveness of biologics in observational settings, drug discontinuation can be a useful substitute. We compared the discontinuation rates of individual and groups of biologics, by mechanism of action, mode of delivery, previous biologic use, line of treatment, and concomitant MTX and/or prednisone.

Methods: Using a large US-wide observational cohort, the National Data Bank for Rheumatic Diseases (NDB), we characterized patients with RA who initiated a biologic from 2005 through 2015. For simplicity, we included tofacitinib as a non-TNF (NTNF) biologic. Baseline characteristics were assessed by each biologic and by grouped mechanism of action. Discontinuation, described using Kaplan-Meier survival curves, was defined as either stopping the drug or adding another DMARD. Sensitivity analyses defined discontinuation only as stopping the drug. Discontinuation rates were further analyzed by stratifying several factors: route of administration (SC *vs* PO *vs* IV), line of treatment (1st, 2nd, 3rd+), prior use of biologics (TNF or NTNF) and concomitant use of MTX and/or prednisone.

Results: A total of 2458 patients initiated a TNF and 1349 a NTNF, representing 6326.5 and 2987.5 patients-years of follow-up, respectively. Overall, median survival (IQR) was 1.5 (0.5-3.0) for TNFs and 2 (1- 3.5) for NTNFs, or 4 (2-9) and 4 (2-7.5) in sensitivity analysis. Figure illustrates individual biologic survival curves by mechanism of action. Grouping by route of administration, the median survival was for PO of 3.0 (2-6) years and did not differ between IV and SC (1.5 (0.5 – 2.5) years). When considering later lines of treatment, the rates of discontinuation were similar with median survival (IQR) of TNF *vs* NTNF: 1st line 3.5 (1-9.5) *vs* 2.5 (1-5.5), 2nd line 4 (1.5 -9.5) *vs* . (5.5-.) and 3rd+ line of treatment 3.5 (2-8) *vs* 3 (1-5). Stratifying by prior use of TNF, the survival was longer for TNF vs. NTNF 1.5 (1-3.5) *vs* 0.5 (0.5 -0.5) years, but the reverse occurred with prior use of NTNF, 1 (0.5 -1.5) vs. 2 (1.-3.5) years. For both groups, discontinuation rates were lower with no concomitant MTX, TNF 8.5 (3.5-.) vs. NTNF 6 (3.5 -.).

Conclusion: As more medication options became available over the past decade, discontinuation rates of biologics for patients with RA have increased and have become more similar. Surprisingly we found rates to decrease when biologics were taken without MTX, an area for further investigation.

A Real World View of Rheumatoid Arthritis Patients Treated with Advanced Therapies: Comparing Patient Profiles and Outcomes

Laurent Chanroux and Fara Mboge, Therapy Watch, Research Partnership, London, United Kingdom
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Advanced therapies including bDMARDs and tofacitinib have been shown to help control disease progression in rheumatoid arthritis (RA) and reduce joint damage. The aim of our research is to better understand if certain patient types may be more suitable for specific treatment options and assess if any of these achieve significantly different outcomes in RA patients.

Methods: We used data collected as part of an online treatment survey conducted among a panel of rheumatologists between June 2014 and January 2016 in the USA. We reviewed and analysed a total of 4,044 patient forms reported by 206 physicians. Physicians were sampled to provide a mix of practice types and regions that would be representative of the universe of treaters. The record forms collected were split into 3 patient groups, group 1 = those treated with an TNF-inhibitor biologic (etanercept, adalimumab, infliximab, certolizumab pegol, golimumab), group 2 = those treated with a non-TNF biologic (abatacept, rituximab, tocilizumab) and group 3 = those treated with the JAK-inhibitor, tofacitinib. We analysed demographic data for these patients along with their current DAS, joint count, HAQ score and perceived disease severity to assess their response to therapy over time.

Results: On average, non-TNF biologic patients are older than TNF-inhibitor (TNFi) and tofacitinib patients (53.9 years old vs. 50.0 and 51.2, respectively) and more likely to be female (75%, $p < 0.05$). In addition, they more commonly suffer from comorbid conditions (83%) particularly when compared with TNFi patients (73%). TNFi patients are significantly more likely to be on their 1st ever biologic (86%) compared to non-TNF and tofacitinib patients (41% and 53%, respectively) and have been on their current treatment for longer on average (32 months vs. 23 for non-TNF and 11 for tofacitinib patients). TNFi patients have on average been diagnosed for the shortest amount of time (64 months vs. 72 and 84 for tofacitinib and non-TNF patients) and experienced the shortest delay between diagnosis and 1st biologic initiation (28 months vs. 46 and 40 for tofacitinib and non-TNF patients). A significantly larger proportion of TNFi patients is considered to have mild RA (69%) vs. non-TNF and tofacitinib patients which are more likely to suffer from moderate to severe disease. TNFi patients are more frequently deemed to be in full remission (34%) and are more likely to have a DAS28 < 2.6 (54%) while non-TNF and tofacitinib are significantly more likely to have a DAS28 between 3.2 and 5.1. However, there were no significant differences in the mean DAS28 and HAQ scores reported for patients in all 3 groups and limited differences in their mean joint counts. There were significant differences in the proportion of patients that were deemed to have severe RA at diagnosis in each group (35% for non-TNF patients, 29 for tofacitinib patients and 23% for TNFi patients) and accounting for these differences in severity at diagnosis we saw reduced differences in the proportion of patients currently in remission in each treatment group. Nevertheless, TNFi and tofacitinib patients are significantly more likely to be employed full time (51% and 48%, respectively) vs. non-TNF patients (40%) while a smaller percentage of TNFi patients are unable to work due to their RA (5%) when compared to non-TNF and tofacitinib patients (both 9%).

Conclusion: While there are significant differences in the demographics and treatment flow of patients treated with TNFi, non-TNF biologic and tofacitinib, it is unclear whether treatment choices are based on specific patient profiles or treatment guidelines and non-clinical factors. In addition, while each drug group achieved a reduction in the proportion of patients with severe disease and a considerable proportion of patients with low disease activity or remission, it is unclear whether better outcomes are consistently achieved with one treatment option vs. another. Additional research is needed to better ascertain if differences in perceived outcomes are real and what factors are truly driving them.

[4] Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA

[5] Novartis Pharma AG, Basel, Switzerland

Background/Purpose: The cost per responder analysis attempts to quantify the relative value of the two comparator drugs by assessing how the two agents compare in terms of cost per treatment outcome. The objective of this analysis was to estimate and compare the long-term cost per responder based on the Assessment of Spondyloarthritis International Society (ASAS) outcomes following 52 weeks of treatment of ankylosing spondylitis (AS) with the anti-IL-17A antibody Secukinumab relative to the anti-TNF antibody Adalimumab.

Methods: The cost per responder for each treatment namely Secukinumab and Adalimumab was estimated by dividing the drug acquisition cost for the course of treatment with its response rate. Drug costs were estimated on the basis of the official US drug acquisition costs and the number of doses required for 52 weeks. Long-term response rates were estimated using a matching-adjusted indirect comparison (MAIC) technique based on the data from MEASURE 2 and ATLAS clinical trials of Secukinumab and Adalimumab, respectively. MAIC analysis matched the age, gender distribution, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), C-reactive protein (CRP) and TNF-naive proportion at the baseline. A sensitivity analyses was also conducted by varying the choice of baseline characteristics (all above except BASDAI) used in MAIC analysis.

Results: MAIC analysis showed that ASAS (20, 40 and 5/6) response rates were significantly higher for Secukinumab compared to Adalimumab at 52 weeks. ASAS 20, ASAS 40 and ASAS 5/6 response rates were 80% vs 65%, 61% vs 47%, 72% vs 55% for Secukinumab vs Adalimumab, respectively (**Figure 1A**). The cost per ASAS 20 responder was $77,271 vs $74,946, cost per ASAS40 responder was $101,333 vs $104,202, whereas, costs per ASAS 5/6 responder was $86,194 vs $88,675 for Secukinumab vs Adalimumab, respectively (**Figure 1B**). While the costs per ASAS (40 and 5/6) responders were about 3% lower for Secukinumab compared to Adalimumab, the cost per ASAS 20 responders for Secukinumab was about 3% higher than that of Adalimumab at 52 weeks. Sensitivity analyses for ASAS response rates and cost per responder showed similar results, confirming the robustness of our main analysis.

Conclusion: The long-term cost per responder for ASAS (40 and 5/6) outcomes over 52-week treatment period were lower for Secukinumab compared to Adalimumab in AS patients. These findings indicate that Secukinumab represents a cost-efficient treatment choice for the treatment of AS patients in the US. **Keywords:** Adalimumab, Ankylosing spondylitis, Cost per responder, Matching-adjusted indirect comparison, Secukinumab

Figure 1: Predicted response rate (A) and cost per responder (B) analysis of ASAS (20, 40 and 5/6) for Secukinumab vs Adalimumab for the treatment of ankylosing spondylitis at 52 weeks in principal analysis

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Health Services Research - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) treatment comes at a high price, with both direct costs related to healthcare resource utilization and indirect ones related to decreased work productivity. Previous studies have attempted to estimate the annual medical costs of SLE patients in the United States using available Medicare datasets. This study was initiated to estimate health care costs to payers for SLE treatment at a major U.S. academic institution.

Methods: This is a retrospective cohort study evaluating healthcare utilization for patients with SLE treated at Columbia University Medical Center/NewYork-Presbyterian Hospital between January 2000 and September 2014, using electronic medical record (EMR) data from the Clinical Data Warehouse. The control groups are represented by patients with rheumatoid arthritis (RA) and patients with renal transplants. Patients with SLE, RA, or renal transplant were identified using diagnostic codes from the International Classification of Diseases, Ninth Revision (ICD-9). Data on diagnosis-related group (DRG) weighting was obtained from www.cms.gov; base rates for emergency and hospital visits were obtained from www.health.ny.gov.

Results: 4,800 hospitalized patients with SLE were identified based on one ICD-9 code for lupus. The diagnosis of SLE using these criteria was validated based on review of 134 charts; this method of identifying SLE cases in the Data Warehouse had a positive predictive value (PPV) of 0.66 for diagnosing SLE. A total of 5,642 patients with renal transplant, and 7,273 with RA were also identified. Reimbursement from payers for hospital admissions and ER visits were estimated from the DRG weights and base rates. The DRG provides a weighting system based on the severity of the average patient. For SLE and RA alone, the respective weight is 0.7882 and 0.7337; with a comorbid condition, it is 1.1645 and 1.2287. For SLE with a major comorbid condition, it is 2.4409, while the renal transplant weight is 3.154 regardless of comorbidities or severity.

	SLE	Renal Transplant	RA
Unique Patients (N)	4,800	5,642	7,273
ED Visit (N)	20,178	18,426	31,718
Average ED Visits/patient	4.20	3.27	4.36
Reimbursement for ED visit ($)	155.57	622.54	144.82
Total Reimbursement for ED Visits ($ x 10^6)	3.14	11.47	4.59
Hospital Admissions (N)	10,464	23,518	16,255
Hospital Admissions/patient	2.18	4.17	2.23
Reimbursement per Hospital Admission ($)	23,830	30,800	10,960
Total Reimbursement Hospital Admissions ($ x 10^6)	249.39	724.25	178.21

Conclusion: These data suggest that the cost to payers, health insurance companies, for hospital-based care for SLE (252.53 mil $) is higher than that for RA (182.8 mil $) despite the much higher prevalence of RA. However, the true cost of a lupus patient to the admitting hospital—especially a hospital that provides tertiary and quaternary care—can be much higher than what is reimbursed; it is likely closer to the cost of a transplant patient, as patients with moderate/severe SLE are treated with the same immunosuppressants as transplant recipients and are at risk for the same co-morbidities. In sum, these data suggest that SLE care in hospitals is expensive for health insurers. Further efforts should be made to improve outpatient management in order to reduce excessive use of emergency room resources, as has been done with the renal transplant population. Additionally, hospitals and providers should lobby for a revision of the DRG weights for SLE.

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune-mediated rheumatic disease (IMRD) including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS), are severe and disabling chronic diseases in rheumatology. Biotherapies such as subcutaneous tumor necrosis factor-alpha inhibitors (SC-TNFis) have transformed the management of rheumatoïd diseases. Very few studies have assessed the persistence to all four SC- TNFis for IMRD in a European setting. The objective of this study was to describe treatment persistence in a real-world setting, among patients diagnosed with IRMD, initiating treatment with an SC-TNFi in France and who were naïve of biotherapies (subcutaneous and intravenous) in the last 18 months.

Methods: The *Système National d'Information Inter-régime* [French national health insurance scheme information-sharing system] (SNIIR-AM) database lists all outpatient and inpatient healthcare consumption for individuals covered by the general health insurance scheme. Using French claims data, patients were included through Long Term Disease (LTD) status and hospital admission, based on ICD-10 codes. Identification of RA was based on M05, M06, M08.0, M08.2, M08.4 and M13 ICD-10 codes. For AS, identification was based on M08.1, M08.8, M08.9, M45 and M46 to M14 ICD-10 codes, and identification of PsA was based on M07 and M09 ICD-10 codes. Patients were then identified through filled prescription for adalimumab (ADA), etanercept (ETA), certolizumab pegol (CZP) and golimumab (GLM) between 06/01/2012 and 12/31/2013. Persistence was estimated using Kaplan Meier analysis.

Results: A total of 4,750 patients with RA were identified, 5,735 with AS and 1,244 with PsA. For the overall cohort of IMRD naïves patients, comparisons over 12 months showed that persistence was different between the four SC-TNFis, with persistence rates of 59.1% for CZP, 56.4% for ETA, 57.2% for ADA and 60.2% for GLM ($p=0.0004$). For RA cohort ($p<0.0983$) persistence rates were 60.3% for CMZ, 60.9% for ETA, 62.2 % for ADA

and 63.8% for GLM. For AS ($p<0.0001$) persistence rates were 52.7% for ETA, 54.6% for ADA and 58.9 % for GLM. For PsA, persistence rates were 52.5% for ETA, 57.8% for ADA and 55.9 % for GLM ($p=0.2014$). For AS and PsA analysis sample size of CMZ cohort were too small to estimate Kaplan-Meier curves.

Conclusion: Persistence rates observed in naïves patients varied according to SC-TNFis with significant difference for the overall and the AS cohorts. Those results seem correspond with others results published recently in the literature

Patient Adherence with Biologic Therapy in Rheumatoid Arthritis: A Real-World Review of Compliance

Laurent Chanroux, Fara Mboge and Denise Baldock, Therapy Watch, Research Partnership, London, United Kingdom

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Health Services Research - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic agents (bDMARDs) have been shown to help control disease progression in rheumatoid arthritis (RA) and reduce joint damage. The aim of our research is to better understand patient compliance to guide the development of strategies to combat poor adherence.

Methods: We used data collected as part of an online patient survey conducted among 500 Rheumatoid Arthritis (RA) patients in December 2015 in 5 EU countries (France, Germany, Italy, Spain, UK). We focused our research on 197 patients treated with a biologic, 111 of which missed a dose in treatment within the previous 6 months. We analysed the route of administration of their treatment to assess the influence of intravenous infusions (IV) versus subcutaneous injections (SC). We also explored whether any correlation existed between patients' adherence to therapy and their relationship with the doctor they would normally see for their RA.

Results: 56.3% of our patients reported missing a dose of their biologic in the previous 6 months and on average these patients missed 2.8 doses during this period. Reasons cited for missing their dose include: "I felt better and didn't think I needed it" (29%), "I felt worse and didn't want it" (22%), "I didn't think it was helping" (17%) and other less common reasons such as infection, other types of sickness or surgery. Patients treated with SC biologics account for 55.3% of our sample and 54.1% of these patients reported being non-compliant with treatment in the period analysed, missing on average 2.8 doses. Although we had previously hypothesized that adherence may be higher among patients receiving an IV biologic, 58.0% of IV patients reported being non-compliant with treatment with a mean of 2.7 missed doses. Interestingly 38% of IV patients cited feeling better and thinking they did not need treatment, whereas 20% of SC patients reported feeling worse and not wanting to take their injection treatment. We

then looked at assessing whether the route of administration had an effect on patient's compliance to treatment using Pearson correlation analysis however, our findings deduced no significant relationship between both data sets. Further analysis looked at whether the relationship with the primary health care professional (HCP) had any possible influence on the outcome of compliance, however once again a Pearson correlation analysis found no significant link when non-compliant patients scored their relationship based on specific statements describing their relationship with the doctor they normally see for their RA.

Conclusion: Our research shows that a significant proportion of biologic patients miss one or more doses of their prescribed biologic over a 6 month period despite the benefits and cost of these therapies. Additional research is needed to optimise patient engagement with their disease and the healthcare providers they interact with to ensure improved long-term compliance with therapy.

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoinflammatory disorders (AD) are characterized by recurrent fevers associated with systemic symptoms involving joints, skin, muscles, and eyes in the absence of adaptive immune responses. Profound dysregulations in various innate immune pathways including the inflammasome-mediated IL-1 signaling are characteristic of these syndromes. While previous studies have revealed that neutrophils may play critical roles in driving the inflammatory process in AD, whether specific neutrophil subsets and neutrophil processes play distinct pathogenic roles in these diseases remains to be characterized.

Methods: We examined the presence of distinct proinflammatory neutrophil subsets in AD and assessed their pathogenic potential. Blood was obtained from healthy controls and from patients with Familial Mediterranean Fever (FMF), Pyogenic Arthritis, Pyoderma gangrenosum, and Acne (PAPA) syndrome, Cryopyrin Associated Periodic Syndromes (CAPS), Tumor necrosis factor receptor-associated periodic syndrome (TRAPS), Autoinflammation-PLCG2-associated antibody deficiency-immune dysregulation (APLAID), and mutation negative AD. Normal density granulocytes (NDGs) were isolated by dextran sedimentation and PBMCs were isolated by Ficoll gradient. Presence of low-density granulocytes (LDGs) was assessed by a negative selection magnetic bead procedure from the PBMC fraction. The capacity of NDGs and LDGs to synthesize neutrophil extracellular traps (NETs) spontaneously was assessed by fluorescence microscopy.

Results: LDGs were classified as $CD15^{+}/CD14^{lo}$ or $CD10^{+}/CD14^{lo}$ and were detected, to varying extents, in all auto-inflammatory samples tested. Compared to healthy control NDGs and autologous NDGs, LDGs from AD patients displayed an enhanced ability to spontaneously form NETs. The proinflammatory cytokine IL-1β was externalized in NETs from NDGs and LDGs from AD patients. NDGs and LDGs from AD patients displayed distinct mRNA expression profile for inflammasome-related proteins and nucleic acid-sensing TLRs.

Conclusion: Collectively, these preliminary results suggest that LDGs are present in AD, may represent a potential source for IL-1β production and contribute to tissue damage and disease manifestations.

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Many genetically defined autoinflammatory diseases (AID) are caused by innate immune dysregulation and present with “neutrophilic dermatoses”. This study systematically assesses immune-cell infiltrates, and interferon (IFN) scores in skin biopsies of 2 IFN-mediated AID: STING-Associated Vasculopathy with onset in Infancy (SAVI) and Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated Temperature (CANDLE) and 2 IL-1-mediated AID, Neonatal-onset Multisystem Inflammatory Disease (NOMID) and Deficiency of IL-1 Receptor Antagonist (DIRA). We hypothesize that histopathologic and immunologic

features present in skin lesions can distinguish IFN- from IL-1-mediated disorders.

Methods: Tissue from skin lesions of patients with NOMID (n=4), DIRA (n=4), SAVI (n=3), CANDLE (n=5) and other interferonopathies (UIFN) (n=7) were stained with H&E. Immunohistochemistry with antibodies to Myeloperoxidase (MPO/Neutrophil), CD163 (macrophage), CD123 (plasmacytoid dendritic cell (pDC)), CD3 (T cell), CD19 (B cells) was performed. The presence of Neutrophil extracellular traps (NETs, citrullinated histone H4) and IFN-inducible protein (Mx1) were assessed by immunofluorescence. An RNA IFN score was obtained. Inflammatory cells in skin regions were semi-quantitatively scored: 0=absent, 1=scant, 2=moderate or 3=abundant.

Results:

Clinically, NOMID patients present with urticaria, DIRA with pustulosis, CANDLE with nodular rashes and SAVI with acral violaceous vasculitic plaques. Histochemically, dense MPO+ cells within intraepidermal microabscesses were seen only in DIRA. In CANDLE, MPO+ and CD163+ cells were noted predominantly in the deep dermis and sucutis. SAVI had intravascular thrombi, fibrinoid necrosis of vascular wall with abundant perivascular MPO+ and CD163+ cells. Nuclear debris was seen in SAVI and CANDLE. Mild CD123+ cells were seen in dermis and perivascular areas in SAVI and CANDLE; but not in DIRA and rarely in one NOMID sample. CD3+ cells were seen predominantly in dermis and perivascular areas in SAVI, and in periadnexal areas in CANDLE. Dermal CD19+ cells were noted only in a patient with long-standing SAVI. The presence of NETs was evident in NOMID, DIRA and CANDLE, but not in SAVI. SAVI and CANDLE samples have positive Mx-1 staining and high IFN-response gene scores, but not in NOMID and DIRA.

Conclusion: A distinct histologic pattern of neutrophil and macrophage infiltration characterizes SAVI, CANDLE, NOMID and DIRA skin biopsies, while Mx-1 staining and the IFN score distinguish IFN- and IL-1 mediated AID. Thus, the histologic and immunologic assessment of skin biopsies may guide the diagnosis and identify dysregulated immune pathways in AID. Furthermore the skin can serve as a tissue model to evaluate molecular pathways that lead to the skin manifestations in genetically defined and undefined inflammatory diseases.

Abstract Number: 2257

Regulation of Mitochondrial Proton Gradient Is Critical for NLRP3 Inflammasome Activation

Jehad H. Edwan, Raphaela Goldbach-Mansky and Robert A. Colbert, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Self-activating mutations in NLRP3 cause a spectrum of autoinflammatory diseases known

as cryopyrin-associated periodic syndromes (CAPS). NLRP3 is a key component of a multiprotein complex known as the inflammasome that mediates the maturation of the proinflammatory cytokine IL-1β, and can induce rapid cell death in a process known as pyronecrosis. Although several models for inflammasome activation have been proposed the precise molecular mechanism, as well as the role of NRLP3 mutations, remains to be elucidated. Emerging evidence suggests that mitochondria are involved in inflammasome activation. ATP is produced from ADP in the presence of a proton gradient across the mitochondrial membrane by ATP synthase (F(1)F(0) ATP synthase). F-type ATPases consist of two structural domains, F(1) - containing the extramembraneous catalytic core, and F(0) - containing the membrane proton channel. ATP5O appears to be part of the connector linking these two components and it confers sensitivity to oligomycin induced increase in the proton gradient. Here we asked whether regulation of mitochondrial membrane potential by ATP50 and oligomycin plays a role in NLRP3 inflammasome activation.

Methods: ATP5O expression was knocked down in THP-1 cells. Cells were stimulated with LPS followed by oligomycin and ATP. IL-1β release and intracellular IL-1β were measured with a flow-based assay. Supernatants were incubated with IL-1β-capture beads, added back to fixed and permeabilized cells, and both were stained with antibodies against IL-1β, then evaluated by flow cytometry. Viability of non-fixed cells was evaluated with 7AAD staining. LPS stimulated cells were also evaluated by immunofluorescence and western blot analysis.

Results: By flow analysis we provide evidence that an increase in the proton gradient induced by oligomycin results in a significant increase in ATP induced inflammasome activation, while knockdown of ATP5O, results in a significant reduction in inflammasome activation. Decreasing the proton gradient with FCCP and 2DG significantly inhibits inflammasome activation, suggesting a requirement for an increased proton gradient across the mitochondrial membrane. Using confocal microscopy of BMDM from NLRP3 knockout mice to visualize pyronecrosis, we provide evidence that this process is NLRP3 dependent.

Conclusion: These data suggest a previously unrecognized role for ATP5O in regulating mitochondrial membrane potential, which can regulate NLRP3 inflammasome activation. These results point toward mitochondrial membrane potential as a novel therapeutic target for NLRP3-mediated inflammatory diseases.

Role of NLRP12 on Disease Severity in Autoimmune Arthritis

Ryan Lupo and Peng Liu, Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Nucleotide-binding oligomerization domain (NOD)-like receptors (NLRs) are cytoplasmic sensors that response to danger signals released by invading pathogen or self-damaged

tissues. NLRP12 is a member of the NLR protein family and classified as a negative regulator of inflammation and autoimmune response. However, the role of NLRP12 for autoimmune arthritis has not been explored. To investigate the NLRP12 effect on rheumatoid arthritis (RA), we decided to study whether NLRP12 deficiency would have an impact on disease outcome using the RA model of collagen-induced arthritis (CIA).

Methods: C57BL/6 *Nlrp12*$^{-/-}$ mice were obtained from Dr. Jenny Ting's laboratory and backcrossed onto DBA/1J background for eleven generations. These mice and wild type (WT) mice were induced with CIA. Arthritis development was monitored for 45 days, and joint samples were harvested for histological analysis and RT-PCR detection of cytokine production in the joints.

Results: We found that *Nlrp12*$^{-/-}$ mice show reduced clinical scores and diminished paw swelling compared to WT mice throughout disease development. Histological joint sections of *Nlrp12*$^{-/-}$ mice show a decrease in immune cell infiltration to the synovial membrane and space, reduced cartilage damage, and less bone erosion. Then we examined the cytokine expression in the joints of *Nlrp12*$^{-/-}$ mice and found that the proinflammatory cytokines IL-1beta and IL-6 were substantially reduced compared to WT mice, whereas TNFalpha and IL-17 expressions remain similar between *Nlrp12*$^{-/-}$ mice and WT mice.

Conclusion: Our results indicate that NLRP12 deficiency reduces autoimmune arthritis in the CIA model by decreased inflammation and proinflammatory cytokines in the joints. Further studies are needed to identify the innate immune cells and the molecular pathways in which NLRP12 functions in autoimmune arthritis as they could lead to potential therapeutic targets for patients with RA.

Session Title: Innate Immunity and Rheumatic Disease - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Acute gout is a highly common and painful form of inflammatory arthritis, occurring mainly in men above the age of 50. The recurring flares of arthritis are elicited by monosodium urate (MSU) crystal deposits in the joints that, in the presence of a secondary stimulus, can induce synergistic cytokine production. Sodium butyrate can inhibit MSU-induced cytokine production via broad inhibition of class I histone deacetylases

(HDACs)[1], which includes HDAC1, -2, -3, and -8. HDACs could therefore be an important target for new therapies against gout. Our aim is to further pinpoint the HDAC(s) involved in MSU-induced cytokine production.

Methods: Primary peripheral blood mononuclear cells were isolated from healthy donors. The cells were pre-incubated with a highly specific HDAC1/2 inhibitor, Romidepsin, or other metabolic inhibitors and stimulated with a combination of palmitic acid (C16.0) and MSU crystals. Cytokine levels were measured by ELISA, transcription was measured with qPCR. *In vivo* effects of Romidepsin were assessed in C57Bl/6 mice. The mice received 2 intraperitoneal doses of Romidepsin, after which we injected them intra-articularly with a MSU crystals and a TLR2 ligand. Joint swelling was assessed macroscopically, IL-6 and KC were measured in the synovium, and total joints were sent for histology.

Results: Romidepsin potently inhibited C16.0+MSU-induced inflammatory cytokines in healthy volunteers. It furthermore induced transcription of PTEN, a negative regulator of PI3K/Akt signaling, and CPT1A, a β-oxidation enzyme that is down-regulated by Akt. Additionally, inhibiting glycolysis with 2-deoxy-D-glucose decreased C16.0+MSU-induced cytokine production, and inhibition of β-oxidation with etomoxir increased it. *In vivo*, Romidepsin potently inhibits macroscopic joint swelling already at a dose of 0.03 mg/kg. IL-6 and KC were not significantly reduced in the synovium. We are still awaiting the histology results.

Conclusion: These results suggest that Romidepsin inhibits MSU-induced cytokine production by restoring cellular energy homeostasis, possibly by inhibiting Akt signaling. In a relevant mouse model for gout, Romidepsin significantly inhibits macroscopic joint swelling. With these results, we provide a rationale for HDAC1/2 inhibition as a potent anti-inflammatory treatment which may have beneficial effects in acute gout.

Session Title: Innate Immunity and Rheumatic Disease - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Lubricin/proteoglycan-4 (PRG4) is a mucinous glycoprotein secreted by synovial fibroblast and superficial zone chondrocyte. PRG4 has a homeostatic multifaceted role in the joint including boundary lubrication, friction lowering of apposed cartilage surfaces and prevention of synovial overgrowth. PRG4 is abundant in the synovial fluid (SF) and its levels are reduced in SF from patients with inflammatory arthropathies[3]. In animal models of post-traumatic osteoarthritis (OA) and inflammatory arthritis, PRG4 expression is reduced in cartilage and synovium. PRG4 intra-articular treatment retards progression of cartilage degeneration in preclinical post-traumatic osteoarthritis. Recent studies have suggested that PRG4 may have anti-inflammatory properties. Musculoskeletal ultrasound studies have highlighted the deposition of MSU-crystals onto the superficial margin of cartilage defined by US OMERACT definition as the Òdouble contourÓ sign and its deposition contributes to abnormal joint homeostasis. The objective of this study was to evaluate the anti-inflammatory properties of PRG4 in MSU in acute gout inflammation

Methods: Synovial fluid (SF) aspirates from normal and patients with acute gout flares were used to evaluate the activation TLR2 and TLR4 on HEK cells. Activation of TLR2 and TLR4 on HEK cells was assessed by immunoprecipitation of PRG4 from gout SF. We evaluated the impact of recombinant human PRG4 (rhPRG4) on MSU-induced release of interleukin-1 beta (IL-1b), tumor necrosis factor alpha (TNF-a), interleukin-8 (IL-8) by human monocytic cell line, THP-1 using ELISA, immunohistochemistry, and western-blot analysis. We also evaluated the role rhPRG4 in inhibiting the NLRP3 inflammasome in THP-1 cells.

Results: Using TLR-HEK cells systems, we found that synovial fluid from acute gout (n=5) activated primarily through TLR2 rather than TLR4. Normal synovial fluid did not result in either TLR2 and TLR4 activation. Gout SF treatment resulted in a significant higher TLR2 activation compared to normal SF ($p<0.001$). Removal of PRG4 from gout SF by immunoprecipitation with a monoclonal anti-PRG4 antibody resulted in higher TLR2-HEK activation compared to gout SF and untreated controls. In a dose dependent manner, rhPRG4 significantly inhibited IL-1b, TNF-a and IL-8 production by human monocytic cell line, THP-1 in response to MSU using ELISA, western blot analysis and immunohistochemistry. Immunohistochemistry of NLRP3 showed a dose dependent inhibition by rhPRG4 comparable to its inhibition by colchicine.

Conclusion: PRG4 is a mucinous glycoprotein secreted by synovial fibroblasts and superficial zone chondrocytes which retards progression MSU-crystal induced arthritis by binding to TLR2 and this binding mediates a novel anti-inflammatory role for PRG4 in joint homeostasis. Our findings provide a better understanding of the molecular mechanism(s) of PRG4 in MSU-crystal induced arthritis with important implications in the development of novel biological strategies in gout.

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory diseases such as rheumatoid arthritis (RA) are associated with oxidative stress as a result of elevated levels of reactive oxygen species (ROS). Oxidative stress leads to the formation of malondialdehyde (MDA) and acetaldehyde (AA), both of which react to form malondialdehyde-acetaldehyde (MAA) protein adducts. Our previous *in vitro* experiments have demonstrated that methotrexate (MTX) significantly decreases MAA-adduction of proteins (human albumin). Furthermore, the ROS generated by the reaction of MDA+AA to form MAA-adducted proteins are directly scavenged by MTX. However, the biological relevance of MTX's ability to scavenge ROS and inhibit the generation of MAA-adducted proteins remains unclear. Therefore, we tested the hypothesis that MTX inhibits intracellular redox signaling as well as the formation of MAA-adducted proteins.

Methods: To test our hypothesis, we examined the activation of a well-described redox-sensitive intracellular signaling pathway in which nuclear factor erythroid 2-related factor (NRF2), a redox-sensitive transcription factor, is stabilized and translocates to the nucleus. In the nucleus, NRF2 binds to antioxidant response elements (ARE) by utilizing a NRF2/ARE Luciferase reporter cell line in which luciferase expression is under control NRF2. Cells were incubated with vehicle, Human Serum Albumin (ALB), AA, MDA, MDA+AA (unbound), MAA-Alb for 24 hours at 37^{o}C in the absence or presence of MTX (2μM). In addition, to further evaluate the scavenging of ROS by MTX, tert-butylhydroquinone (TBHQ, 5 mM), a known inducer of NRF2, in the presence of MTX was added to NRF2/ARE cells and incubated for 24 hours. NRF2 activation was quantified by measuring the amount of luciferase via luminescence the cell line produced in response to various stimuli.

Results: As shown in Figure 1. MDA+AA significantly ($p<0.001$) increased NRF2 activation compared to cells treated with vehicle or Alb controls and MTX significantly attenuated ($p<0.001$) this redox-sensitive response. NRF2 activation with AA, MDA, or MAA-Alb in isolation demonstrated no increase in NRF activation. Furthermore, as a positive control MTX significantly ($p<0.001$) inhibited the well-characterized TBHQ-dependent activation of NRF2 by almost 3-fold.

Conclusion: This study demonstrates that when MDA+AA are mixed in the culture, a biologically relevant redox-sensitive signaling pathway is induced, that activates NRF2. Interestingly, the MAA-adduct (MAA-Alb) is unable to activate NRF2, indicating the response is activated through the metabolites of ROS. Furthermore, the ability of MTX to inhibit this redox-dependent cellular response corroborates our previous observation that MTX scavenges ROS. Together, these data strongly indicate a novel mechanism of MTX and suggest a new therapeutic benefit of MTX, which is its antioxidant potential.

Session Date: Tuesday, November 15, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In the early phase of rheumatoid arthritis (RA), PGE_2 recruits different immune cells from the blood stream into target tissues. Via the EP4 receptor, PGE_2 acts as a cytokine amplifier (e.g. triggers IL-6 expression in macrophages) and induces the expansion of inflammatory T helper 17 (Th17) cells by increasing the activity of IL-23/IL-17 axis. These mechanisms play a pivotal role in the development of autoimmunity. [2]

Interestingly, in a mouse model of collagen antibody-induced arthritis (CAIA), EP4 knockout mice were resistant to the development of experimental arthritis.[3] These findings strongly suggest that EP4 receptor antagonists may potentially act as novel early DMARDs. CR6086, a selective antagonist of EP4 receptor, was previously found to improve or resolve disease features in the rat and mouse CIA model of RA.[4,5] In this study we present a pharmacological characterization of CR6086, and provide evidence for its immunomodulatory effects on *in vitro* models of IL-23 and IL-17 release from human cells.

Methods: We assessed first the functional effect of CR6086 on the human EP4 receptor by measuring the levels of PGE2-stimulated cyclic adenosine monophosphate (cAMP) production in stably transfected HEK293 cells, and on human THP1 cells differentiated with PMA to macrophages. Different models of immune cell differentiation and expansion were used, and the effect of CR6086 was evaluated by ELISA on IL-23 release from human dendritic cells, and on IL-17 release from human Th17 cells.

Results: CR6086 showed high affinity for the human EP4 receptor with a Ki = 16.6 nM, and strong inhibitory effect on PGE2-stimulated cAMP levels, with an IC_{50} of 22nM and 58nM in stably transfected HEK293 cells, and in THP1 differentiated macrophages, respectively. The analysis of the immunomodulatory potential for CR6086 was made by analyzing the release of selected cytokines (i.e. IL-23 and IL-17, Table 1) related with the activation and progression of the immune response in the RA pathology. We found that CR6086 dose-dependently reduced IL-23 release in activated human dendritic cells, and inhibited IL-17 release in activated human Th17 cells. In both the cell models CR6086 appeared more effective than naproxen.

Conclusion: CR6086 is a new potent EP4 receptor antagonist with immunomodulatory potential. In fact, it significantly reduced the release of IL-23 and IL-17, two cytokines important for the activation of the immune response during the early phases of RA. Session Title: Innate Immunity and Rheumatic Disease - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease largely driven by immune complexes and their interaction with FcγRs present on macrophages within the synovium. In RA joint destruction has been associated with an increased lipid oxidation and an altered lipid profile. Apolipoprotein E (Apo E) is an important regulator of LDL levels and its absence strongly elevates LDL in the serum. In the present study we investigated the role of Apo E in inflammation and joint destruction during antigen-induced arthritis (AIA).

Methods: Experimental arthritis (AIA) was induced by injection of 60 µg mBSA into the right knee joint of and wild type (WT) control mice previously immunized with mBSA/CFA. Joint swelling was measured by uptake of ^{99m} Technecium (^{99m}Tc) and expressed as a ratio of the uptake in the right (injected) and left (non injected) knee joint. Humoral immunity (mBSA antibody titer) was measured by ELISA. WT BM-MΦ were stimulated for 24 hours *in vitro* with or without 50µg/ml oxLDL and the mRNA expression of the FcγRs was measured by qPCR. Joint inflammation and bone erosion were measured by histological analysis using an arbitrary scale from 0 to 3. TRAP$^+$cells were determined using immunohistochemistry.

Results: Apo E$^{-/-}$ mice showed significantly less joint swelling at day 1, 3 and 7 after AIA induction compared to WT controls (21%, 17%, 18% lower, respectively). Serum mBSA antibody levels (total IgG, IgG1, IgG2a and IgG2b) are comparable between the two immunized mouse strains. LDL serum levels were significantly higher in arthritic Apo E$^{-/-}$ mice and LDL/oxLDL was found within synovial macrophages. At day 21, histology of the knee joints showed less infiltration of inflammatory cells within synovium and joint cavity (22 % and 44% lower, respectively) in the ApoE$^{-/-}$ mice compared to WT controls. WT BM-MΦ stimulated with oxLDL displayed a significant down-regulation of mRNA levels of FcγR I and FcγR II when compared to their non stimulated controls (1,7 and 2,3 fold change, respectively). Joint destruction was significantly reduced in the Apo E$^{-/-}$ mice, as indicated by the reduction of chondrocyte death (32% reduction) and bone erosion (25% reduction from 1.5±0.2 to 1.1 ±0.1). In line with that, ApoE$^{-/-}$ mice showed a reduction of the number of osteoclasts present at the area of resorption within the arthritic knee joints (36% lower from 20±4 osteoclasts/section in WT mice to 12±5 in ApoE$^{-/-}$mice), as measured by image analysis of TRAP staining.

Conclusion: Apo E regulates inflammation and joint destruction during AIA by regulating LDL(oxLDL) levels and macrophage FcγRs expression within the synovium.

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity is associated with the development and progression of osteoarthritis (OA). Although the mechanisms involved in this association are poorly understood, it is well appreciated that obesity-induced changes in adipose tissue could affect whole body metabolism and inflammatory responses through secreted mediators. The infrapatellar fat pad (IFP) is an adipose tissue depot in the knee joint. Due to its intracapsular and extrasynovial localization, it is conceivable that the IFP could contribute to the pathophysiology of OA through release of soluble mediators. However, it is still unclear whether and how the IFP is affected by obesity. Therefore, we set-out to investigate whether obesity-related changes described in other adipose tissue depots can also be found in IFP.

Methods: IFP volume was determined in 83 knee OA patients with MRI using sagittal T1 and T2-weighted images. IFP and subcutaneous adipose tissue (SCAT) were obtained from 76 knee OA patients, all undergoing joint replacement surgery (total N=129: 69% women, mean age 65 years, mean (SD) body mass index (BMI) 29.7 kg/m^2 (5.31)). IFP volume was measured by manual segmentation of the IFP boundaries on section-by-section sagittal T1-weighted images, using the software program OsiriX. Sagittal T2-weighted images were used to distinguish and compare between IFP and non-IFP structures. The software program OsiriX measured the IFP volume by making a 3D-model of the drawn contours. Crown-like structures (CLS) were determined using immunohistochemistry. Adipocyte size was determined by light microscopy and histology. Stromal vascular fraction (SVF) cells were characterized by flow cytometry.

Results: The IFP volume determined by MRI associated with gender ($B = 0.610$, $p < 0.001$) and height ($B = 0.692$, $p < 0.001$), but not with BMI. The mean volume of IFP adipocytes was 271 pL and was not correlated with BMI; in contrast, SCAT adipocytes were larger (551 pL) and did correlate with BMI ($r = 0.38$, $p = 0.004$). Few CLS were observed in IFP, with no differences between overweight/obese and lean individuals. Moreover, obesity was not associated with higher infiltrating immune cell numbers in IFP. Likewise, the percentage of CD3, CD4, CD8 or CD14 positive cells did not correlate with obesity. Extensive characterization of IFP macrophages revealed that CD206 and CD163, usually associated with an anti-inflammatory phenotype, were the most abundantly expressed surface markers on macrophages (81% and 41 % respectively), but macrophages produced predominantly IL-6 and TNFα, and little IL-10. Interestingly, $CD163^+$ macrophages had an activated and pro-inflammatory phenotype.

Conclusion: In conclusion, we did not find obesity-related changes in IFP regarding IFP volume, adipocyte size and volume, CLS, number and phenotype of infiltrating cells, although we did found obesity-related changes in SCAT. This indicates that IFP is affected differently by obesity than other fat depots such as SCAT and visceral adipose tissue, suggesting that IFP might have a different function than the standard fat depots.

Session Date: Tuesday, November 15, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Neutrophil extracellular traps (NETs) play an important role in the pathogenesis of ANCA-associated vasculitis (AAV). Sera of MPO-ANCA or PR3-ANCA positive patients can induce NETs In vitro. The present study aimed to investigate whether NET induction could serve as a biomarker in MPO- and PR3-positive AAV patients.

Methods: Healthy neutrophils were stimulated with 10% serum from 62 GPA patients, 37 MPA patients and 18 healthy subjects. NETs were stained with Sytox and imaged by automated 3D confocal laser scanning microscopy and quantified with digital image analysis. NET-inducing capacity was defined as the fold increase of quantified NETs relative to healthy control. To investigate NET induction by ANCA autoantibodies, IgG was isolated from sera using protein G agarose beads after which depletion of IgG in the flow through was confirmed with ELISA.

Results: Both GPA and MPA samples showed significantly higher NET-inducing capacity (fold change mean ±SEM for GPA 40±7.4, $p<0.0001$ and for MPA 153.2±44.9, $p<0.01$). MPA sera had a significantly higher NET-inducing capacity than GPA ($p<0.0001$). In 14 AAV patients who had seroconverted, we observed that the NET-

inducing capacity returned to levels of healthy controls (1.40±0.42, p=0.37). However, we found no correlation of NET-inducing capacity with titers of MPO and PR3 antibodies (r=0.17, p=0.35 for MPO and r=-0.04, p=0.79 for PR3). To further determine whether NET release was mediated by ANCA autoantibodies, we isolated MPO-ANCA IgG and PR3-ANCA IgG from 5 different sera. These purified IgG antibodies did not show NET-inducing capacity (1.40±0.33, p=0.45). In contrast, corresponding IgG-depleted sera had similar NET-inducing capacity as whole sera (12.91±4.5 for IgG-depleted sera and 18.88±7.26 for whole sera, p=0.51).

Conclusion: These data show that NET release in AAV patients is independent of MPO-ANCA or PR3-ANCA. Therefore, these data indicate that NET release might be a novel biomarker of AAV that is independent of ANCA autoantibodies. Our data supports the hypothesis that NETs are a source of autoantigens for the production of ANCA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The melanocortins (MCs) are endogenous peptides (including ACTH, α-MSH and γ-MSH), which bind 5 G protein-coupled receptors (MCRs 1 through 5) with varying affinity. They exert anti-inflammatory effects primarily via MCR3, and also MCR1 and possibly other MCRs. ACTH is unique among MCs in stimulating adrenal corticosteroid production via MCR2. It is rapidly effective and has been used to treat acute gout and several other inflammatory conditions, but can be associated with some corticosteroid-related toxicities. Our objective was to generate novel ACTH-containing MC fusion peptides that maximize anti-inflammatory activity in part through MCR3 while reducing corticosteroid induction.

Methods: A series of peptides containing ACTH linked to other MCs were chemically synthesized, and selectivity for each MCR was evaluated using CHO cells transfected with individual MCRs. Anti-inflammatory activity was

evaluated in the mouse air pouch model of acute gout. Peptides were administered via sc injection (doses: 3, 10, 30 nmoles [nm]) at 1 hr before (pre-Rx) or 1 hr after (post-Rx) urate crystal injection into the pouch. The pouch was lavaged 4 hrs after crystal injection, and neutrophils and other inflammatory mediators were quantified. Plasma corticosterone levels were measured at 60 min in healthy mice.

Results: AQB-565, a 47aa peptide containing $ACTH_{1-24}$ and NDP-MSH (a more potent analog of α-MSH) fused with a 10aa linker, showed an 11-fold more potent agonist of MCR3 than ACTH (Table). It also showed ~20-fold greater activity on MCR4 and MCR5 relative to ACTH.

Selectivity and Potency of AQB-565 and ACTH on Individual Melanocortin Receptors

MCR	MCR1	MCR2	MCR3	MCR4	MCR5
AQB-565 EC_{50} (nM)	0.39	0.21	0.80	1.8	9.6
$ACTH_{1-24}$ EC_{50} (nM)	0.34	0.13	7.3	34	190
Relative Potency (AQB-565 *vs.* ACTH)	Similar	Similar	9x	19x	20x

Serial dilutions of peptide were incubated with CHO-MCR cells for 30 minutes, cyclic AMP levels were determined by LANCE assay. Eleven concentrations of each peptide were tested in triplicate, data were fit to a 4-paramater curve, and receptor activation was expressed as half-maximal effective concentration (EC_{50}). Relative potency is expressed as: ACTH EC50/AQB-565 EC50.

AQB-565 was more potent than ACTH (all data expressed as percent relative to control). Pre-Rx with AQB-565 significantly reduced neutrophil influx compared to ACTH at 3 nm (78±23% *vs.* 5±42%, p<.001) with no significant difference at 10 nm (92±7% *vs.* 82±18%) or 30 nm (92±4% *vs.* 89±11%). Pre-Rx with AQB-565 significantly reduced IL-1β levels compared to ACTH at 3 nm (39±21% *vs.* 10±19%, p<0.0001) and 10 nm (60±13% *vs.* 46±16%, p<.05) with no significant difference at 30 nm (76±7% *vs.* 61±9%). AQB-565 (3 nm) reduced accumulation of cytokines and chemokines in the air pouch exudate: TNFα (-55%), IL-6 (-84%), IL-17 (-60%), GM-CSF (-37%), MCP-1 (-46%), MIP-1β (-53%), and KC (-84%). Treatment with AQB-565 decreased mouse corticosterone levels by 40% (p=0.05) at similarly effective doses to ACTH. AQB-565 was also effective when given post-Rx with decreases of 85±15% and 46±26% of neutrophils and IL-1β levels, respectively.

Conclusion: The fusion of the MCs NDP-MSH and ACTH creates a molecule (AQB-565) reflecting a strategy of targeted MCR modulation with greater anti-inflammatory effects in an *in vivo* model of acute gout and decreased adrenal steroidogenesis. This novel compound has promise as a potential therapeutic for acute gout and possibly multiple additional inflammatory conditions.

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) remains a cornerstone of treatment in multiple forms of inflammatory arthritis, lupus and vasculitis. The anti-inflammatory effects of MTX are more likely to result from an increase in intracellular and extracellular adenosine concentration, which are produced after inhibition of the enzyme AICAR transformylase by MTX, which converts the nucleotide analog AICAR (5-aminoimidazole-4-carboxamide ribonucleotide), also known as ZMP to formyl-AICAR, resulting in the accumulation of this metabolite. Another function of AICAR is the activation of the AMP-dependent kinase (AMPK). AMPK is a highly conserved trimeric protein kinase complex that exists in essentially all eukaryotic cells and is a crucial cellular energy sensor. In mammals, AMPK is activated by an increasing cellular ADP/ATP ratio secondary to metabolic stress (glucose deprivation, hypoxia, and ischemia) or accelerate ATP consumption. Once activated by decreased intracellular energy status, AMPK will promote ATP production by switching on catabolic and turning off anabolic biosynthetic pathways. We hypothesize that AMPK activation mediates a major portion of the anti-inflammatory effects of MTX and that this may account for the efficacy of MTX in rheumatic diseases. A better understanding of the molecular targets of methotrexate may allow the development of novel anti-inflammatory drugs.

Methods: We investigated the role of the anti-inflammatory effect of methotrexate via AMPK in human monocytes-derived macrophages (MDM) and mouse bone marrow-derived macrophages (BMDM) along with AICAR and A769662 (well knows as AMPK activators) and compound C, a selective ATP-competitive inhibitor of AMPK**.** AMPK phosphorylation and total AMPK were measured by Western blotting. Cells were then stimulated with LPS or TNF-α, and *production of* pro-inflammatory cytokines were measured in the supernatant using a Luminex multiplex assay technique. We also generated AMPKα1 deficient macrophages in order to test if these are resistant to the anti-inflammatory effects of MTX.

Results: MTX induced AMPK phosphorylation in a time and dose-dependent manner, with effects comparable to the synthetic AMPK activator A769662 and AICAR both in hMDM and BMDM. MTX-induced AMPK activation was associated with a reduction in the production of pro-inflammatory cytokines (IL-6, IL-1 β, and TNF-α) in response to LPS and TNF stimulation. Compound C is able to partially reverse the effects of MTX on LPS and TNF -induced cytokine production, suggesting that AMPK activation is responsible for these anti-inflammatory effects. Folic acid is not able to revert the MTX activation of AMPK in hMDM and BMDM.

Conclusion: Methotrexate is able to induce AMPK activation in both human and mouse macrophages, and suppress pro-inflammatory cytokines in a manner dependent on AMPK activity. These results have been confirmed genetically in macrophages deficient in AMPK subunits and models of chronic inflammation and diseases such as serum transfer arthritis. Our findings raise the possibility that some anti-inflammatory effects of MTX are mediated by AMPK, suggest that AMPK may be a target for the action of current ‘antimetabolite’ anti-inflammatory agents and a target for the development of new anti-inflammatory drugs.

Fructose Amplifies Inflammatory Potential in Human Monocytic Cells Via Reduction of AMP-Activated Protein Kinase Activity

Xihua Cao[1], Jeffrey N. Miner[2], Robert Terkeltaub[3,4] and **Ru Liu-Bryan**[1,4], [1]VA Medical Center, San Diego, CA, [2]Discovery Biology, Ardea Biosciences, Inc., San Diego, CA, [3]Rheumatology, VA Medical Center, San Diego, CA, [4]Medicine-Rheumatology, University of California, San Diego, La Jolla, CA

Session Title: Innate Immunity and Rheumatic Disease - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: High dietary content of fructose (in table sugar, sweetened sodas, energy beverages, and fruit juices) is a substantial risk factor for both hyperuricemia and developing gout. Fructose is well recognized to elevate serum uric acid via increased hepatic uric acid production through ATP consumption needed to metabolize fructose. Specifically, fructose metabolism in multiple cell types can lead to ATP depletion, and generation of AMP, and also of uric acid through xanthine oxidase (XO). The objective of this study was to test the hypothesis that fructose is pro-inflammatory *in vitro* in human monocyte-macrophage lineage cells, which play a major role in initiating and regulating the gout inflammation cascade. In doing so, we examined the roles of fructose stimulated uric acid generation. Soluble uric acid decreases hepatocyte activity of AMP-activated protein kinase (AMPK), a constitutive master inhibitor of inflammatory responses to urate crystals. AMPK tissue activity is decreased in obesity and diabetes.

Methods: Human monocytic THP-1 cells were cultured in RPMI media (1% FCS) containing 5 mM glucose for 24 hours. Fructose (5 or 15 mM) was then added to the media, and cells were cultured for additional 48 hours. For controls, glucose (2, 5 or 15 mM) was used instead of fructose. In some cases, febuxostat (xanthine oxidease inhibitor, 1 μM)) was added 30 min before addition of fructose. To determine the effect on fructose on inflammatory potential of THP-1 cells, twenty-four hours after addition of fructose, the cells were treated with LPS (1μg/ml) for another 24 hours. Expression of total AMPKα, Thr172 phosphorylated AMPKα indicative of AMPK activation, and expression of AMP deaminase 1 (AMPD1) were examined by Western blot analysis. Inflammatory cytokine and chemokine IL-1β and CXCL8, respectively, were measured by ELISA.

Results: Decreased phosphorylation of AMPKα, correlated with increased expression of AMPD1, were observed in THP-1 cells in response to fructose, but not glucose, at 5 and 15 mM concentrations. In addition, these effects were inhibited by febuxostat, suggesting dependence of endogenous uric acid generation. In comparison, fructose at 2 mM concentration had no effect on phosphorylation of AMPKa and expression of AMPD1. Moreover, inflammatory potential of THP-1 cells was enhanced by fructose, evidenced by significantly increased LPS-induced expression of IL-1β and CXCL8 (by ~30% and 20%, respectively).

Conclusion: Excessive dietary fructose can increase peripheral monocyte inflammatory potential by reducing AMPK activity, in association with endogenously cell-generated uric acid. These observations may contribute to the marked increase in risk of developing gouty arthritis in those with high dietary fructose.

Proteinaceous Amorphous Calcium Carbonates As a Novel Family of Crystals in Synovial Fluid from Symptomatic Joints

Bolan Li[1], **Nora Singer**[2,3] and Ozan Akkus[3,4], [1]Mechanical and Aerospace Engineering, Case Western Reserve University, Cleveland, OH, [2]Medicine and Pediatrics, MetroHealth System, Cleveland, OH, [3]Case Western Reserve University School of Medicine, Cleveland, OH, [4]University Hospitals Case Medical Center, Cleveland, OH

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There are many types of particulate matter in synovial fluid, and specific identification of these particles are challenging. We assessed synovial fluid samples from arthropathic joints and identified that crystals displaying Maltese-cross pattern under polarized light microscopy. We are first to report that such crystals are actually proteinaceous amorphous calcium carbonate crystals (PACC).

Methods: 174 symptomatic synovial fluid (SF) samples were included in this study, which were collected as discarded SF for joints aspirated for clinical care. Polarized light microscopy and alizarin red S staining were used to screen SF samples. Chemically specific techniques including Raman microspectroscopy (μRS) and scanning electron microscopy (SEM) coupled with energy dispersive x-ray (EDX) analyses were used to characterize crystals with Maltese-cross patterned birefringence.

Results: Maltese-cross birefringent crystals were present in 5.7% (10 of 174 SF) of symptomatic joints and positively stained with alizarin red S. Raman spectrum of these crystals was similar to those of sodium carbonate and calcium carbonate in bands 700 – 750 cm^{-1} and 1070 – 1090 cm^{-1}. Raman microspectroscopy (μRS) and SEM/EDX analyses showed absence of phosphate groups, excluding the possible crystals' association with basic calcium phosphates. The molar ratio (1:3.68) between calcium and oxygen in these crystals was close to the ratio in calcium carbonate ($CaCO_3$, 1:3). These crystals dissolved with protein digesting enzymes. As a result, we term these crystals "proteinaceous calcium carbonate crystals (PCCD)".

Conclusion: Theses data provide chemically specific evidence that birefringent particles displaying Maltese-cross birefringence patterns are an amorphous form of calcium carbonate that also include a proteinaceous phase. Our findings counter the prior notion that such crystals are lipids (based on birefringence) or basic calcium phosphates (based on alizarin red S staining). These crystals were observed in symptomatic joints, occurred at a frequency comparable to that observed for calcium pyrophosphate (CPPD) crystals, and their presence was initially overlooked by clinical microscopic observation. This study should elevate the consciousness of clinical microscopists in considering PACC as a crystal species involved in joint arthropathy.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Calcium pyrophosphate crystals including monoclinic and triclinic dihydrate phases (m- and t-CPPD) are found in 40% of end-stage osteoarthritis (OA) patients. Frequently asymptomatic, it can give rise to synovitis contributing to OA lesion worsening. Microcrystal inflammation is orchestrated by macrophage interleukin (IL)-1β secretion which required a 2-step process: synthesis of precursor form proIL-1β and its cleavage to mature IL-1β by active caspase 1 depending on the NLRP3 (*NOD-like receptor family, pyrin domain containing 3*) inflammasome activation. Several pathways can be entailed in inflammasome activation in response to danger signals: ATP-dependent potassium (K^+) efflux, reactive oxygen species (ROS) production, or mitochondrial disruption. We have previously demonstrated that m- and t-CPPD differentially induced NLRP3 protein expression and IL-1β production but intracellular mechanism leading to NLRP3 inflammasome activation is not clearly defined.

Methods: Human THP-1 or THP-1 ρ° cells (treated with ethidium bromide), and bone marrow-derived macrophages (BMDM) from wild type (wt) or P2X7 receptor knock-out (*p2x7r*$^{-/-}$) mice were primed before stimulation with synthetic m- and t-CPPD crystals in presence or absence of K^+-enriched media (KCl 50mM – to block K^+ efflux), N-acetyl-L-cystein (NAC 50mM – an intracellular ROS scavenger) or oxidized ATP (oxATP 200µM – an antagonist of ATP receptor). IL-1β and extracellular ATP (ATP_e) concentrations were measured in cell culture supernatants whereas intracellular ROS production and mitochondrial membrane potential were evaluated using fluorescent probes (DFDA and JC-1, respectively).

Results: First, we observed that CPPD stimulation induced a *de novo*ROS production combined with a stronger mitochondrial membrane depolarization following m-CPPD than t-CPPD crystal stimulation. This latter effect and IL-1β production were inhibited in presence of NAC. Moreover, we showed a drastic inhibition of IL-1β maturation process in THP-1 ρ° cells which have a mitochondrial ROS production deficiency. Second, K^+-enriched media on one hand inhibited CPPD-mediated IL-1β production by THP-1 cells and on the other hand

restored basal levels of ROS and mitochondrial membrane potential. Finally, we found that m- and t-CPPD crystals differentially brought on an ATP release and that IL-1β production was partially inhibited by oxATP. However, although ATP_e can trigger K^+ efflux through P2X7 receptor opening, we observed a similar or only a weak decreased IL-1β production between wt and *p2x7r*$^{-/-}$ BMDM after t-CPPD and m-CPPD stimulation respectively. In contrast, IL-1β production is completely abrogated in presence of KCl as well wt as *p2x7r*$^{-/-}$ BMDM.

Conclusion: We demonstrated that K^+ efflux triggered by CPPD crystals is the first signal leading to mitochondrial ROS production and disruption which are considered as intracellular danger signal required for NLRP3 activation and IL-1β production. Interestingly, K^+ efflux is partially dependent on P2X7 receptor through ATP release but the main K^+ channel has to be defined.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chondrocalcinosis is characterized by calcium pyrophosphate dihydrate (CPPD) deposition in articular cartilage. It can occur as a rare autosomal dominant disorder with florid early-onset osteoarthritis (OA). Two observed gene mutations are: ANKH [1] (progressive ankylosis; on chromosome 5p) and TNFRSF11B [2] (coding for osteoprotegerin (OPG), on chromosome 8q). ANKH mutations apparently affect extracellular pyrophosphate (PPi) levels by altering its transporter function. OPG, a decoy receptor, regulates bone remodeling by binding receptor activator nuclear factor Kappa beta ligand (RANKL), preventing osteoclast bone resorption. Any alteration in the bone remodeling process, may alter bone mineral density. We report a US family with gain-of-function mutation in TNFRSF11B coding for OPG that is potentially related to this family's severe

OPG-CPPD phenotype. Previously, only 1 family with the same OPG gene mutation has been described in the literature (Ramos et al, 2015). The purpose of this study is to screen 3 generations of affected members of a US family of Italian/German ancestry with early-onset autosomal dominant OA and radiographic chondrocalcinosis for mutations in ANKH or TNFRSF11B.

Methods: Subjects were identified by proband's rheumatologist. Clinical presentations, similar to the proband were noted in 6 out of 10 male family members over 3 consecutive generations. Genetic testing was performed on peripheral blood and buccal swab samples from proband and 2 other affected family members, in accordance with institutional guidelines for human subjects with written informed consent and IRB approval. DNA isolated from samples was amplified for ANKH and TNRSF11B by PCR using gene-specific primers and subjected to dideoxy sequencing of PCR products. Patient sequences were compared to control samples and sequence anomalies were confirmed by antisense sequencing of the PCR products.

Results: The proband, a 43 year old male patient, presented at age 31, with progressive polyarticular crippling arthritis resulting in pain and disability. His knee X-rays showed advanced loss of joint space. X-rays of his wrists, elbows and ankles also revealed severe arthropathy and extensive chondrocalcinosis, strongly suggestive of CPPD disease. Arthrocentesis and synovial fluid analysis was deferred due to absence of significant joint effusions. Diagnostic work up for primary metabolic disorders associated with CPPD was negative. Genetic testing of proband and 2 affected family members identified a read-through mutation of the termination codon (A=>T; Stop402Leu) in TNFRSF11B. Studies performed by Ramos et al show that the mutant-OPG has enhanced capacity to inhibit osteoclastogenesis. Hence, this mutation is potentially linked to this family's severe OA-CPPD phenotype.

Conclusion: We have identified a second family with a read-through, gain of function mutation (Stop402Leu) in TNFRSF11B gene coding for OPG that is likely related to their OA/CPPD phenotype. While it is not yet clear how mutations in OPG may give rise to the CPPD phenotype, targeted inhibition of OPG binding to RANKL may become a therapeutic approach to prevent and/or treat pathological joint chondrocalcinosis.

Session Date: Tuesday, November 15, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Diuretic use is strongly associated with development of hyperuricaemia and gout. Genetic variation in the renal uric acid transporters *SLC2A9* (encoding GLUT9) and *SLC22A11* (encoding OAT4) has been reported to interact with diuretic use to increase the risk of developing gout at a population level. The aim of this study was to determine whether variation in *SLC2A9* or *SLC22A11* influences renal handling of uric acid in response to frusemide.

Methods: Following an overnight fast and one week of a low salt diet, healthy participants (n=100) aged 18-50 years attended a study visit with intake of a single oral 40mg tablet of frusemide. Blood and urine samples were obtained for urate, sodium, potassium, creatinine, prior to frusemide and then 30, 60, 120, and 180 minutes after frusemide. The *SLC2A9* SNP *rs11942223* and *SLC22A11* SNP *rs2078267* were genotyped and data were analysed based on the presence or absence of the gout-protective allele. The primary endpoint was change in fractional excretion of uric acid (FEUA) and secondary endpoint was change in serum urate.

Results: Oral intake of 40 mg frusemide led to a marked diuresis (mean (SD) urine volume 2162 (717) ml over 180 minutes) and increase in fractional excretion of both sodium (FENa) and potassium (FEK) over the 180 minute study period (P<0.001 for all). Following intake of frusemide, FEUA initially increased (mean (SD) change from baseline +1.9 (3.0) % at 60 minutes, P<0.001) and then decreased (mean (SD) change from baseline -1.5 (2.1) % at 180 minutes, P<0.001). A very small increase in serum urate was observed over the study period (mean (SD) change from baseline +0.12 (0.17) mg/dL at 180 minutes, P<0.001). At both 60 and 180 minute time-points, change in FENa predicted change in FEUA, independent of urine volume (standardized β for both time-points >0.46, P<0.001). The presence of the protective alleles for *SLC2A9* and *SLC22A11* did not significantly alter the FEUA or serum urate responses to the frusemide load (Figure).

Conclusion: Intake of frusemide leads to a biphasic FEUA response, with initial increase and subsequent reduction in FEUA. Our data do not support the hypothesis that genetic variation in *SLC2A9* or *SLC22A11* influences acute changes in renal handling of uric acid in response to frusemide intake. **Figure:** Mean (95% CI) change from baseline in FEUA and serum urate based on presence of A. *SLC2A9* protective allele and B. *SLC22A11* protective allele. Sex, ethnicity and age adjusted P values are shown.

Background/Purpose: Serum uric acid is an important biomarker for gout disease and kidney function. Genome-wide association study (GWAS) meta-analyses have identified 28 loci in European and Japanese population samples. Combined analysis of these summary data across populations offers the opportunity to discover new serum uric acid (SUA) associations through greater sample size and power, and trans-ancestral analyses provide the opportunity for fine-mapping associations with greater resolution given differing linkage disequilibrium patterns between populations.

Methods: Summary statistics from European (N=110,238) (PMID 23263486) and East Asian (N=21,268) (PMID 22797727) meta-analyses were obtained. We used ImpG v1.0 (PMID 24990607) to impute the results into 1000 Genomes phase 3 variants, and performed sample-size weighted z-score meta-analysis. LD-independent variants with $P_{META} < 5x10\text{-}8$, not in LD ($r2<0.1$) with previously identified regions, were considered novel SUA loci. We used functional partitioned LD score regression (PMID 26414678) on all associated loci in the European GWAS to identify SNP-heritability enriched tissue-specific regulatory regions, for use as functional priors in PAINTOR (PMID 26189819) fine mapping analyses to identify putative causal variants.

Results: Trans-ancestral meta-analysis of European and East Asian GWAS revealed nine new SUA-associated loci ($P_{META} < 5x10^{-8}$). Three of the new loci are located in the 11q12.3-13.2 region near the established SLC22A11/12 association. Additional novel loci are located near the FGF5, LNC00603, HLA-DQB1, B4GALT1, BICC1 and USP2 genes. Tissue-focused functional partitioning of SNP-heritability indicated the strongest enrichments of kidney, GI and liver tissues ($P<10^{-7}$), among other significant tissues (Figure 1). Trans-ancestral meta-analysis and functional fine-mapping decreases the numbers of SNPs in causal variant credible sets, and for example pinpoints the rs17632159 SNP as likely causal (posterior $P>0.9$) at the TMEM171/174 locus.

Conclusion: Meta-analysis of existing GWAS increases power and leads to the identification of nine new loci associated with serum uric acid levels. Increased resolution in trans-ancestral GWAS, with functional annotation

enrichments, improves fine-mapping of serum urate GWAS loci.

Evidence of Phospho-Degron Regulating Expression of Urate Secretory Transporter ABCG2

Alexis Hofherr[1], Meng Li[2], Michael Kottgen[1] and **Owen M. Woodward**[2], [1]Nephrology, University of Freiburg Medical Center, Freiburg, Germany, [2]Physiology, University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: ABCG2 is a high capacity urate secretory transporter of the renal proximal tubule. The common Q141K ABCG2 mutation causes gout in humans through an increased instability of the nucleotide-binding domain leading to enhanced degradation and reduced function.

Methods: Typical biochemical and cell biological techniques

Results: Here, we found ABCG2 protein rescued from degradation with the proteasome inhibitor MG-132 is

phosphorylated; raising the possibility that a phospho-degron regulates ABCG2 trafficking and expression. An *in silico*analysis of ABCG2 revealed a limited number of predicted phosphorylation sites, including S195, a serine conserved in the mammalian lineage. The upstream RXRXS represents a target motif for AKT1 and PKA, which both co-immunoprecipitated with ABCG2. Specifically, endogenous AKT1 pulled down both over expressed ABCG2 in HEK293 cells as well as endogenous ABCG2 in mouse kidney lysate. AKT1 and ABCG2 transcript co-localize in the proximal S2 segment of the mammalian nephron and inhibiting the AKT1 kinase cascade with PI3K inhibitor LY294002, or with growth factor receptor (RTK) inhibitor Vandetanib, dramatically up-regulated ABCG2 expression. Conversely, activating the AKT1 cascade with FBS down-regulated ABCG2 expression. Replacement of the S195 residue with a phosphomimetic aspartic acid resulted in significant reduction in ABCG2 expression, localization of ABCG2 to peri-nuclear compartments, and significant sensitivity to MG-132; confirming the S195 residue as a phospho-degron. Finally, a non-phosphorylatable S195A substitution led to the complete rescue of the Q141K gout mutant protein expression and trafficking.

Conclusion: Modeled ABCG2 structure indicates phosphorylation of the S195 residue may only be possible when the nucleotide-binding domains are separated, suggesting the S195 phospho-degron may be part of a novel regulatory mechanism for function and trafficking in ABC transporters. Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of gout in New Zealand Polynesian (Māori and Pacific) populations is approximately twice that of the New Zealand European population, with a younger average age of onset and more severe symptoms. We aimed to undertake a genome-wide association study of gout in Polynesian people. Additionally, we assessed the differences in genetic susceptibility to gout between Eastern and Western Polynesian individuals to further identify regions involved in gout risk.

Methods: Polynesian individuals with clinically-ascertained gout (n_{gout} = 929) or with no history of gout ($n_{control}$ = 861) were recruited. This cohort was divided into Eastern (New Zealand and Cook Island Māori; n_{gout} = 566, $n_{control}$ = 605) and Western Polynesian (Samoan, Tongan, Tokelauan and Niuean; n_{gout} = 363, $n_{control}$ = 256) based on self-reported ancestry and principal component clusters. Genotyping across the Infinium CoreExome chip and logistic regression analyses adjusted for sex and age were conducted. Differential effect of each variant in the two cohorts was compared using Cochran's Q-test during meta-analysis, in order to identify heterogeneous effects. Genome-wide significant association was set at $P < 5.0x10^{-8}$ and suggestive association at $P < 1.0x10^{-5}$.

Results: The only genome-wide significant result in the combined Polynesian cohort was at *ABCG2* (*rs2231142*: OR = 2.31, $P = 9.7x10^{-14}$). The Western Polynesian cohort showed a genome-wide significant effect for *rs2231142* (OR = 2.65, $P = 1.4x10^{-11}$), but the Eastern Polynesian cohort did not (OR = 1.87, $P = 5.2x10^{-4}$). These results were not significantly different ($P_Q = 0.13$). Two other variants in the *ABCG2* locus (*rs6857847* and *rs3737488*) had significant Q-test p-values ($P_Q = 5.1x10^{-8}$ and $2.8x10^{-8}$), with strong protective effects in Western Polynesian (OR = 0.47, $P = 2.0x10^{-7}$; and OR = 0.47, $P = 1.36x10^{-7}$), but weak susceptibility effects in Eastern Polynesian people (OR = 1.22, $P = 4.3x10^{-2}$; and OR = 1.23, $P = 3.5x10^{-2}$). A variant on Chromosome 18 (*rs4939827*) also produced a genome-wide significant Q-test p-value ($P_Q = 1.5x10^{-8}$). This variant had a suggestively significant protective effect in Western Polynesian (OR = 0.53, $P = 7.4x10^{-6}$) and a non-significant susceptibility effect in Eastern Polynesian individuals (OR = 1.38, $P = 5.0x10^{-4}$).

Conclusion: Genome-wide association analysis of Polynesian cohorts revealed a significant effect at *ABCG2* in the Western Polynesian, but not Eastern Polynesian, cohort. There was a genome-wide significant difference in effect at *rs4939827*, within an intron of *SMAD7*, a gene that has been associated with inflammatory bowel disease, colorectal cancer, and chronic kidney disease and that is involved in the regulation of TGF-beta signalling.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The ABCG2 Q141K (*rs2231142*) variant is an established cause of hyperuricaemia in Europeans. Although the effect size of *ABCG2 rs2231142* on serum urate levels is ~60% that of *SLC2A9,* the effect size of *ABCG2* on gout is consistently greater than that of *SLC2A9*[1,2]. We tested the hypothesis that *ABCG2* plays a role in gout additional to causing hyperuricemia by testing for association of *rs2231142* with gout using asymptomatic hyperuricemic controls. *SLC2A9 rs11942223* was included for comparison.

Methods: There were 1,672 European gout cases and 15,367 controls and 1,197 New Zealand Polynesian (Māori and Pacific Island) gout cases and 1,371 controls. The Polynesian sample set was divided into Eastern (EP) and Western Polynesian (WP). Association testing was done using logistic regression with multivariate adjusting for confounding variables, including highest recorded serum urate in analyses with gout cases.

Results: In the European sample set, the 141K allele was strongly associated with asymptomatic hyperuricemia compared with normouricemic controls (OR=1.55, P=4.3x10^{-18}) and with gout compared with asymptomatic hyperuricemia controls (OR=1.83, P=2.6x10^{-14}). In the Polynesian sample sets, the 141K variant was not associated with asymptomatic hyperuricemia compared with normouricemic controls (WP: OR=1.22, P=0.35; EP: OR=0.99, P=0.97) whereas there was a strong risk effect for gout compared with asymptomatic hyperuricemia (WP: OR=2.35, P=3.9x10^{-5}; EP: OR=2.15, P=0.010). For *SLC2A9 rs11942223,* there was no positive association with gout compared with asymptomatic hyperuricemia controls in any of the ancestral sample sets (Europeans: OR=0.82, P=0.022; WP: OR=0.81, P=0.69 and EP: OR=1.39, P=0.41).

Conclusion: These data are consistent with a role for *ABCG2* 141K in gout pathogenesis when hyperuricemia is established, potentially through formation of monosodium urate crystals and/or regulation of the inflammatory response to deposited crystals. In Polynesian people *ABCG2* 141K does not play a role in determining hyperuricemia. 1. Kottgen et al. *Nat Genet* 2013;45:145-54. 2. Phipps-Green et al. *Ann Rheum Dis* 2016;75:124-30.

Exon Sequencing Reveals a Significant Burden of Non-Synonymous Variants in Both SLC22A11 (OAT4) and SLC22A12 (URAT1) in European Hyperuricemic Individuals

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Common variants within the uric acid transporter genes *SLC22A11* (OAT4) and *SLC22A12* (URAT1) have been associated with hyperuricaemia and gout in multiple populations, but these associations have been with intronic or intergenic variants with no obvious causal role in protein function. This research aimed to characterise the exonic sequences of *SLC22A11* and *SLC22A12* in European and Polynesian individuals and assess whether rare non-synonymous variants in these genes are causal of hyperuricemia.

Methods: The exonic regions of *SLC22A11* and *SLC22A12* were sequenced in 422 individuals with hyperuricemia or gout (Polynesian = 227, European = 195) and 386 individuals without hyperuricemia or gout (Polynesian = 213, European = 173). All non-synonymous variants were identified and analysed using burden testing methods. SIFT, Polyphen-2, and PROVEAN were used to predict the effect of these non-synonymous variants on protein function.

Results: Eighteen non-synonymous variants were identified in *SLC22A11* and *SLC22A12*, of these sixteen were missense (*SLC22A11* = 9, *SLC22A12* = 7) and two were nonsense (*SLC22A11* = 1, *SLC22A12* = 1). The nonsense variant in *SLC22A11* was found in one Māori woman and three European men, all with high serum urate levels (average = 8.55 mg/dL), whilst the *SLC22A12* nonsense variant was found in a Tongan man with a normal serum urate level of 5.04 mg/dL. Burden analyses of all non-synonymous variants in the European cohort produced a significant burden of risk variants ($P = 0.02$) in *SLC22A11*, and a significant burden of protective variants in *SLC22A12* ($P = 0.01$). The same effect was not seen in the Polynesian cohort ($P = 0.29$ and 0.73, respectively). Prediction of the functional effects of each of the missense variants suggests only three of the nine *SLC22A11* variants, but six of the seven *SLC22A12* variants, modify protein function.

Conclusion: Rare non-synonymous variants in both *SLC22A12* and *SLC22A11* significantly associate with hyperuricemia in European individuals. Our data confirm the protective effect of rare genetic variants in *SLC22A12*, encoding the uric acid transporter URAT1. This is the first time rare genetic variants in *SLC22A11* have been implicated in causing hyperuricemia, and our findings challenge current understanding of OAT4 (SLC22A11) as a transporter that mediates renal uric acid reabsorption. Notably, the vast majority of missense variants in other solute transporters are neutral or loss-of-function[1]. 1. Leabman et al. *Proc Natl Acad Sci U S A* 2003;100:5896-901.

Session Date: Tuesday, November 15, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Accurate case-definition is important for epidemiological studies of gout. However, in multipurpose cohort studies frequently used for genome wide association studies, limited information is usually available for gout case-definition. Many different combinations of available data have been used to identify gout cases in large genetic epidemiological studies. The aim of this study was to determine the most precise case-definition of gout from the limited items available in multipurpose cohorts for use in for population-based genetic studies.

Methods: Data from the UK Biobank were analysed. Data (including genome-wide genotypes) were available for 105,421 European participants aged 40 to 69 years without kidney disease. Gout definitions and combinations of these definitions were identified from previous epidemiological studies. Self-report of gout was defined by reporting of gout diagnosis by the participant at the time of study interview. Hospital diagnosis of gout was defined by either primary or secondary hospital discharge coding for gout (ICD10 M10 including subcodes). Urate lowering therapy (ULT) use was defined by self-report of allopurinol, febuxostat, or sulphinpyrazone use, without leukemia or lymphoma (ICD10 C81-C96). Winnard-defined gout was defined by hospital diagnosis or gout specific medication (ULT or colchicine)[1]. Logistic regression was performed genome-wide using plink2 adjusted for age, sex, waist circumference, and waist circumference to height ratio.

Results : There were 2066 (2.0%) gout cases defined by self-report of gout, 1652 (1.6%) defined by ULT use, 382 (0.4%) defined by hospital diagnosis, 2295 (2.2%) defined by self-report of gout or ULT use, and 1861 (1.8%) gout cases defined by Winnard-definition. For the originally reported 10 hyperuricaemia SNPs[2], association with gout at genome-wide significance (P<5x10-8) was observed for 5 SNPs (*ABCG2, SLC2A9, GCKR, SLC17A3* and *SLC22A12*) using the definition of self-report of gout and the definition of self-report of gout or ULT use, 4 SNPs (*ABCG2, SLC2A9, GCKR,* and *SLC17A3*) using the Winnard definition, 3 SNPs (*ABCG2, SLC2A9,* and *GCKR*) using the ULT use definition, and 2 SNPs (*ABCG2* and *SLC2A9)* using the hospital diagnosis definition (Table). The definitions of self-report of gout or ULT use, and self-report of gout alone had greatest precision for all analyses.

Conclusion: Of existing definitions that use routinely collected data, case definitions that include self-report of gout have the greatest precision for detecting genome wide significant associations in epidemiological studies of gout. **References:** 1. Winnard et al Rheumatology 2012, 2. Kottgen et al Nature Genetics 2013.

Table: Odds ratios [95% CI] and P values for originally reported 10 hyperuricaemia SNPs (Kottgen et al. 2013) using different gout definitions. Data are adjusted by age, sex, waist circumference and waist to height ratio.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Observational studies have reported that hyperuricemia may be protective in the development of osteoporosis. Serum urate concentrations positively correlate with bone density, and higher serum urate concentrations are associated with reduced risk of fragility fractures. The mechanisms of this bone-urate relationship are currently unexplained. The aim of this laboratory study was to examine whether soluble urate directly influences function of bone cells to promote bone formation.

Methods: For all assays, we examined the effects of soluble urate at physiological temperature and pH, at a range of urate concentrations consistent with those observed in humans (0 (control), 0.10, 0.20, 0.30, 0.40, 0.50, 0.60, 0.70 mmol/L). The effects of soluble urate on osteoclast development and function were examined using the RAW264.7 cell line osteoclastogenesis assay, a murine bone marrow osteoclastogenesis assay, a human peripheral blood osteoclastogenesis assay and a rat mature osteoclast assay. The early osteoblast-like MC3T3 cell line was used to examine the effects of soluble urate on cell viability (using MTT and alamarBlue assays), mineralisation, and gene expression for osteoblast differentiation markers. The MLO-Y4 osteocyte line was used to determine the effects of soluble urate on osteocyte viability and expression of genes implicated in osteocyte function.

Results: Addition of soluble urate in the RAW264.7 osteoclastogenesis assay led to small increases in osteoclast

formation (ANOVA p=0.018, Figure). However, no significant effects on osteoclast number or activity were observed in the murine bone marrow assay, human peripheral blood osteoclastogenesis assay or rat mature osteoclast assay. In the MC3T3 osteoblast assays, soluble urate did not alter cell viability, mineralisation, or gene expression of markers including type 1 collagen, osteocalcin or osteoprotegerin. Similarly, in MLO-Y4 osteocyte assays, soluble urate did not alter cell viability or gene expression of RANKL, E11 or connexin-43.

Conclusion: Soluble urate at physiological concentrations does not promote anabolic bone formation pathways in *in vitro* bone cell assays. These data do not support the concept that the observed positive association between serum urate and bone density is due to direct effects of urate on bone. **Figure:** RAW264.7 osteoclastogenesis assays (showing pooled data from six biological repeats), demonstrating that higher concentrations of soluble urate leads to small increases in osteoclast formation. Dunnett multiple comparison test compared with control (no added urate) *p<0.05.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone erosion in gout is strongly associated with tophi; lesions comprising of inflammatory cells surrounding collections of monosodium urate (MSU) crystals. Osteocytes are the most abundant cell population within bone and are important regulators of bone remodeling. The aim of this study was

to investigate the direct effects of MSU crystals and indirect effects of MSU crystal-induced inflammation on osteocyte function.

Methods: For direct *in vitro* assays, MSU crystals were added to MLO-Y4 osteocyte-like cells cultured in type I collagen gels (3D) for 1h, 6h and 24h. For indirect *in vitro* assays, RAW264.7 macrophage-like cells were cultured with or without MSU crystals (0.5mg/mL) for 24h and supernatants were harvested and filtered for conditioned media preparation. The conditioned media (40%) was then added to the 3D MLO-Y4 cultures for 1h, 6h and 24h. All changes in MLO-Y4 gene expression were examined using real-time PCR and analyzed using two-way ANOVA with *post hoc* Sidak's tests. The relationship between osteocytes, MSU crystals and macrophages in erosive gout was examined by polarizing light microscopy and CD68 immunohistochemistry in joint samples obtained from cadaveric donors with crystal-proven gout.

Results: In the direct *in vitro* assays, culture with MSU crystals alone did not alter the expression of osteocyte-related genes or inflammatory mediator gene expression ($P>0.1$ for all). In contrast, addition of conditioned media from MSU crystal-exposed RAW264.7 cells to MLO-Y4 cultures led to a ~2-4-fold increase in expression of E11 and connexin43 at the 6h and 24h time-points compared to control conditioned media ($P<0.0001$). RANKL expression was also increased at 6h and 24h ($P<0001$, Figure) and OPG expression was reduced at the 6h time-point by ~2-fold ($P=0.007$). In addition, expression of inflammatory genes was upregulated, including TNF-a (~4-fold at 1h), IL-1b (~5-fold at 6h and 24h), IL-8 (>500-fold at all time-points), IL-11 (>200-fold at 6h and 24h), IL-6 and cyclooxygenase-2 (Figure) ($P\leq0.001$ for all)**.** In histological analysis of cadaveric joint samples affected by gout, numerous CD68+ macrophages and MSU crystals were identified in proximity to osteocytes within bone.

Conclusion: MSU crystals do not directly influence osteocyte-related gene expression. However, interactions between MSU crystals and immune cells in the joint may promote osteocyte expression of pro-resorptive and inflammatory mediators, which can have important consequences for local bone remodeling. These indirect effects on osteocyte function may contribute to bone erosion in gout.

Figure: Mean (SEM) changes in relative expression levels of RANKL, COX-2 and IL-6 in MLO-Y4 cells cultured with 40% conditioned media from MSU crystal-exposed RAW264.7 cells or control RAW264.7 cells (no MSU). *Post hoc* Sidak's test, *p<0.05, **p<0.01 and ***p<0.001 vs control conditioned media.

Session Date: Tuesday, November 15, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown that abnormal loads induce meniscus cell damage and matrix degradation both in-vivo and in-vitro[1,2]. Monosodium urate (MSU) crystal is considered a Òdanger signalÓ as it activates the innate immunity[3]. Presence of MSU in synovial fluid is associated with the worst osteoarthritis (OA) pathology and disease progression[4]. Mineralization is dependent on the ratio of Phosphate/Pyrophosphate (Pi/PPi) that is influenced by manifold factors including Ank, Enpp1 and Alp respectively[5]. The objective of this study was to investigate the effect of increasing concentrations of MSU crystals on chondrocyte function, differentiation, and mineralization.

Methods: Primary chondrogenic cell line (ATDC5) was cultured in a 1:1 mixture of DMEM/F12 medium containing 10% FBS, Insulin-Transferrin-Selenium and incubated with increasing concentrations of endotoxin-free MSU crystals at increasing concentrations (0.01, 0.025, 0.05 and 0.1 mg/ml) for 4, 7, and 14 days respectively. Purification of total cellular RNA for real time PCR was prepared from ATDC5 cells at different time points. Real-time quantitative PCR and immunohistochemistry were performed on specific extracellular matrix genes, metalloproteinases, and specific mineralization genes such as Ankh, Enpp1 and Alp. Alcian-blue and Alizarin red S staining was performed at selected time point of ATDC5 cells exposed to different MSU concentrations.

Results: MSU crystals have a negative effect in the function and differentiation of ATDC5 chondrogenic cell lines. The ability of chondrocyte to produce matrix protein assessed by relative mRNA expression of aggrecan and type II collagen was reduced in chondrocytes following culture with MSU crystals and correlated with Alcian-blue staining. The expression of Type X collagen and MMP-13 in monolayer and pellet cultures was increased following culture with MSU crystals and correlated with Alizarin red staining. The expression of genes involved in extracellular PPi metabolism such as Ankh and Epp1 were increased after prolonged exposure to MSU crystals (1-way ANOVA $p<0.05$) while Alp remained unchanged (Figure 1). The expression of Ankh, Enpp1 and Alkp was confirmed by western blotting ($p<0.05$) and was associated with changes in the extracellular Pi/PPi ratio.

Conclusion: Long-term culture of MSU crystals with chondrogenic cell line ATDC5 impairs the function and differentiation of chondrocytes with increased hypertrophy and mineralization. Our findings lend additional support to the potential involvement of the innate immune system in OA pathology and progression by accelerating chondrocyte hypertrophy. **Figure 1.** Increase in Ankh, PC-1 gene expression compared to Alp in ATDC5 14 day pellet cultures exposed to 0.1 mg/ml MSU.

Background/Purpose: Transferrin and its cell-surface receptor regulate iron uptake and ferritin sequesters free iron and acts as a store for excess iron. Ferritin has been positively associated with serum urate in the National Health and Nutrition Examination Survey III [1]. There have been observational and interventional studies suggesting a role for iron as a trigger for gout flares, which may be due to pro-inflammatory activities associated with iron [2]. Consistent with this, genetic variation in the transferrin receptor has been associated with gout and with an increased likelihood of self-report of an iron-rich food as a trigger of flares [3]. This observational study aimed to replicate the association of serum ferritin with serum urate (SU) and to test for association of serum ferritin with gout.

Methods: Association with gout was assessed in European (100 cases, 60 controls) and Polynesian (100 cases, 60 controls) male individuals from New Zealand (NZ) and a mixture of Latino, African American and European (33

cases, 60 controls) individuals from the United States (US). People with liver damage/ disease were excluded. For the SU association analysis, 180 participants without gout from NZ and the US and an additional 1,260 participants from the Jackson Heart Study (JHS) were used. Participants taking diuretic medication, or who had kidney disease or gout or first-degree relatives with gout were excluded from the SU analysis. Multiple regression analyses adjusted for age, sex (where relevant) and body mass index were done using R v3.3.0. Self-reported grandparental ancestry (for Polynesian) and C-reactive protein level (for JHS and US) were also included as covariates in the various analyses. Beta and OR statistics are expressed per 10 ng/mL increase in ferritin.

Results: Serum ferritin was positively associated with gout in NZ Polynesian [OR=1.031, *P*=4.4E-03] and US [OR=1.214, *P*=6.9E-05] participants but not NZ Europeans [OR=0.997, *P*=0.84] (Table). A positive association of ferritin with urate was observed in both NZ Polynesian [ß=0.081 µmol/L, *P*=1.1E-03] and US [ß=0.29 µmol/L, *P*=4.3E-06] individuals but not in NZ Europeans [ß=0.052 µmol/L, *P*=0.33]. A positive association of serum ferritin with SU was found in both males (ß=0.046 µmol/L, *P*=9.3E-03) and females (ß=0.081 µmol/L, *P*=1.6E-03) in the JHS.

Conclusion: The association of ferritin with SU and gout was independent of C-reactive protein level, suggesting that the relationship is not due to the elevation of ferritin in inflammation [4] and consistent with a direct role for iron metabolism in the control of SU and gout. This is supported by the previous report of association of the transferrin receptor with gout. 1. Ghio et al. *Free Radic Res*. 2005;39:337-42. 2. Facchini. *Rheumatology*. 2003;42:1550-55. 3. Session Time: 9:00AM-11:00AM

Background/Purpose: Monosodium urate (MSU) crystals are known to activate inflammatory pathways that overlap with interleukin-1β (IL-1β) signaling. The present study was carried out to determine if MSU utilizes IL-1β signaling proteins to elicit inflammatory responses.

Methods: THP-1 monocytes were converted to macrophages with phorbol myristate acetate (PMA) for 3 hours followed by stimulation with MSU crystals (25-200 μg/ml) for 0-24 hours. Whole cell extracts were prepared for the detection of cellular proteins by Western blotting method, while the conditioned media was collected for the quantitation of secreted IL-1β and TNF-α by ELISA. Molecular dynamics (MD) simulation was performed using protein preparation wizard of Schrodinger suit 2014.3 on TAK1-TAB1 protein with a tautomeric form of MSU as a ligand. Recombinant human TAK1 protein was used for *in vitro* kinase assay. For *in vivo* evaluation, C57BL/6J mice were administered (5Z)-7-Oxozeaenol (an inhibitor of TAK1; 5 mg/kg, p.o.) or febuxostat (5 mg/kg. p.o.) 2 hours prior to MSU injection (0.5 mg/20 μl) in the footpad. Changes in the paw circumferences were measured up to 48 hours of MSU injection.

Results: Stimulation of THP-1 macrophages with MSU (25-200 μg/ml) resulted in a dose- and time-dependent increase in IL-1β and TNF-α production ($p<0.05$). At the cellular level, MSU selectively inhibited the global expression pattern of K^{63}-linked ubiquitination without affecting K^{48}-linked ubiquitination in activated THP-1 cells. Interestingly, a rapid phosphorylation of IRAK-4 (Thr^{345}/Ser^{346}), IRAK-1 (Thr^{387}), IRAK-1 (Thr^{209}), and TAK1 ($Thr^{184/187}$) in THP-1 macrophages was observed within 5 to 15 minutes of MSU stimulation. Blockade of IL-1β secretion by Brefeldin A in THP1 macrophages had no effect on MSU-induced TAK1 activation, suggesting TAK1 as a direct target of MSU. To evaluate the importance of IL-1β signaling proteins using chemical inhibitors, we found that the inhibition of TAK1, but not IRAK-1/4 or TRAF6, completely abrogated MSU-induced IL-1β and TNF-α production in THP-1 macrophages ($p<0.01$). Furthermore, *in silico* simulation of TAK1 revealed that MSU is capable of activating TAK1 and arresting its conformational position in active state, thereby, causing sustained TAK1 kinase activation. Furthermore, *in vitro* kinase assay results also showed that MSU (100-500 μg/ml) induces autophosphorylation of TAK1 protein in a dose-dependent manner ($p<0.05$). Findings from *in vivo* studies suggest that the pretreatment of mice with (5Z)-7-Oxozeaenol significantly inhibited MSU-induced paw circumferences in mice ($p<0.01$), which was comparable to febuxostat treatment.

Conclusion: Our study shows that MSU is capable of inducing TAK1 activation in THP-1 macrophages independent of endogenous IL-1β, suggesting TAK1 as a potential therapeutic target for the treatment of gout.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gouty arthritis is a common inflammatory joint disease that arises in response to the deposition of monosodium urate (MSU) crystals in soft joints, periarticular and articular joints of individuals with hyperuricemia[1]. Studies have shown that the inflammatory response occurs when macrophages within the joint space phagocytose MSU crystals[2]. Macrophages (THP-1 monocytes or Mφ) are a functionally heterogeneous cell population that have two different phenotypes related to different stimuli: M1 (classically activated) and M2 (alternatively activated)[3]. Based on their activation status, macrophages can influence a response cascade in gout. The objective of this study was to investigate MSU-induced responses on macrophages, and M1 and M2 polarized macrophages by using cytokine array, immunohistochemistry, and Western blot analysis.

Methods: The human monocytic cell line THP-1 differentiated into macrophages using 10 ng/ml PMA. Once differentiated, macrophages were incubated with LPS and IFN-γ for classical macrophage activation (M1) or IL-4 and IL-13 for alternative activation (M2). MSU-crystals were induced 48 hours later to both M1 and M2 polarized macrophages and re-incubated. After the incubation, the impact of MSU-crystals on macrophage polarization was studied and assessed by performing cytokine array, immunohistochemistry, and Western blotting.

Results: Immunohistochemistry shows that there is a differential effect produced by MSU crystals as seen by either having a pro-stimulatory effect or an anti-inflammatory effect based on the cytokine or chemokine. Macrophages show a 2-fold increase in IL-1β, IL-8, TNF-α, IL-6, GRO, and GRO-α compared to M1 and M2. IL-10, an anti-inflammatory cytokine, increased on M2 compared to macrophages and M1. Additionally, TGF-β2 did not differ between THP-1 monocytes, M1 and M2. Osteopontin, an anionic phosphoprotein, mediates biomineralization. There was a 2 fold increase in osteopontin in M1 and M2 compared to macrophages.

Conclusion: Our results from immunohistochemistry and Western blot analysis confirm that there are significant differences between crystal activation in macrophages, M1, and M2 due to their inherent functions. Upon MSU-crystal induction, a more robust effect is seen on the macrophages compared to M1 and M2 polarized macrophages. This area of research warrants further investigation. **References** 1. Session Date: Tuesday, November 15, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment of acute gout involves the use of NSAIDs, colchicine or corticosteroids. Unfortunately, co-morbid conditions such as chronic kidney disease, peptic ulcer disease and congestive heart failure make the use of these agents dangerous or contraindicated. Therefore, there is an unmet need for new therapies in acute gout. Eicosanoids have been implicated in a vast number of inflammatory conditions, such as gout. Currently, over a hundred different eicosanoids have been identified, with many having potent bioactive signaling capacity. Monosodium uric (MSU) crystals are known to induce eicosanoid inflammatory mediators. We hypothesized that a complete study of these eicosanoid mediators might identify new therapeutic targets in acute gout.

Methods: Complete eicosanoid profiling was determined by ultra-performance liquid chromatography-electrospray ionization triple quadrupole mass spectrometric (UPLC-QTRAP/MS/MS) method, and was conducted in peritoneal lavage 7 hours after MSU (3mg) intraperitoneal injection, and in bone marrow derived macrophages (BMDM) supernatants after either MSU (0.25mg/ml) stimulation for 4 hours, or LPS (100ng/ml) for one hour plus MSU (0.25mg/ml) stimulation for 4 hrs. To test the hypothesis that selective 12/15-lipoxygenase (LOX) inhibition by intraperitoneal ML351 (50mg/kg) protects against MSU inflammation, we used two MSU crystals-induced inflammation murine models: subcutaneous air-pouch model to measure MSU crystal-induced cytokine production by ELISA and inflammatory cell accumulation 7hrs after MSU (3mg) injection; and intraarticular injection of MSU (100µg) crystals. Histopathological studies from the injected joints were carried after 7hrs.

Results: Complete eicosanoid profiling identified COX and 15 LOX eicosanoids as the mediators more abundant in BMDM after LPS/MSU stimulation. Of note, only 15 LOX eicosanoids were released after just MSU stimulation in BMDM. Interestingly, 12/15 LOX eicosanoids were highly represented in the peritoneal lavages after MSU

intraperitoneal injection. In the *in vivo*models, intra-articularly injected MSU crystals provoked a neutrophilic infiltration that was significantly reduced in joints from mice treated with ML351 inhibitor. MSU crystal-induced inflammatory cell infiltration was also significantly attenuated in mice treated with the 12/15 LOX inhibitor. Of interest, amount of IL-6 and IL-1β in the pouch were not decreased in the 12/15 LOX inhibitor group suggesting an IL-1β independent effect.

Conclusion: 12/15 LOX eicosanoids are abundant after MSU crystal stimulation, and their inhibition by ML351 decreased cellular infiltration in two models of MSU crystal induced inflammation. Therefore, selective 12/15 LOX inhibition might be an attractive potential target in acute gout flares safer than the current treatments.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a common and very painful form of arthritis triggered by deposits of monosodium urate (MSU) crystals in the joints. Lifestyle factors such as dietary intake trigger gout flares, but trauma and surgery also induce gout attacks. Systemic non-steroidal or steroidal anti-inflammatory therapies are unsuitable to treat postsurgical gout flares due to their side effects. Postsurgical gout flares typically involve previously affected joints and develop within 8 days after surgery. These features make it ideal for a local, safe prophylactic therapeutic option. Thus, we developed a prophylactic therapeutic system of activatable particles, which would release the drug of interest only under inflammation exposure, minimizing the amount of drug required to control inflammation and circumventing collateral damage to healthy tissues (Fig. 1). This pH sensitive release system of glucocorticoid-loaded microparticles could be prophylactically injected in the joint at risk.

Methods: Acetalation of dextran (AcDex, 10kDa) was determined by NMR (64%), and 3-5mM particles were formulated by electrospray. The signal of these particles is Òturned onÓ upon exposure to acidic pH, which reveals hydroxyl groups and thus increases the materialÕs hydrophilicity. After the hydrophobicity switch, drug diffuses out the polymer matrix. Dexamethasone palmitate (DXM-P) release was analyzed by LC-MS under different pH. Bone-marrow derived macrophages (BMDM) were treated prophylactically for up to 48hrs. with either free DXM-P, DXM-P loaded into AcDex particles, or DXM-P loaded into the slow-release FDA-approved

poly(lactic-co-glycolic acid; PLGA) particles and then stimulated with LPS (100ng/ml) and MSU (0.25mg/ml) overnight. Cytokine amounts were determined by ELISA in BMDM supernatants. We also used an air-pouch model of MSU-induced inflammation to test the particles. We administered either free DXM-P or DXM-P-loaded AcDex particles 24 hrs. before MSU (3mg) injection in the pouch. Cell count was determined after pouch lavage.

Results: The release of DXM-P from AcDex particles increased in lower pH, confirming their responsiveness. Prophylactic treatment *in vitro* of BMDM with DXM-P-loaded AcDex particles up to 48 hrs. before MSU stimulation, significantly reduced IL-1b, TNFα and IL-6 cytokine production compared to both free drug and slow release PLGA-particles. *In vivo*, DXM-P loaded particles significantly reduced cell infiltration in the air pouch when prophylactically injected 24 hrs. before MSU injection.

Conclusion: We have successfully developed a prophylactic option to prevent acute gout flares in post-surgical patients.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Both serum urate (sUA) and endothelial dysfunction have been associated with hypertension and cardiovascular disease. Increasing sUA level has been associated with endothelial dysfunction

and higher inflammatory markers (e.g., high sensitivity c –reactive protein [hsCRP]). To date, however, few studies have examined the relationship between sUA, endothelial dysfunction, and blood pressure (BP) including young and largely healthy individuals. **Objectives**: To determine whether there is an association between higher sUA, endothelial dysfunction as measured by flow-mediated dilation (FMD), and BP in young adults.

Methods: We conducted a cross-sectional analysis of baseline data for consecutively enrolled individuals (age 18 – 40 years). Inclusion criteria were: baseline systolic BP (SBP) ≥ 120 and <160 mmHg or diastolic BP (DBP) ≥ 80 and < 100 mmHg, and sUA ≥ 5.0 mg/dL for men or ≥ 4.0 mg/dL for women. Clinic SBP and DBP, 24- hours ambulatory BP monitoring (ABPM), hsCRP, and sUA level were obtained. Associations between sUA, endothelial dysfunction measured by FMD, and ABPM variables were evaluated using a general linear model. Adjustments for age, gender, race, and BMI were applied after significant univariate results. Data reported are mean +standard deviation (SD).

Results: There were 69 participants included in the analysis. Participants recruited had a mean age of 29.0 ± 6.9 years, 30 % were female, 43 % African-Americans, mean BMI was 29.0 ± 6.0 kg/m², and mean sUA was 5.9 ± 1.1 mg/dL (range from 3.9 to 8.5 mg/dL). We found no significant cross-sectional associations between sUA, FMD, and BP variables assessed by ABPM (Table). Participants in the upper tertile of sUA had significantly more endothelial dysfunction as measured by FMD than those in the lower tertiles (Figure). However, this difference was no longer significant after multivariable adjustment age, gender, race, and BMI.

Conclusion: In this cross-sectional analysis of young adults, there was no evidence to support an association between sUA levels and endothelial dysfunction or BP. Endothelial dysfunction or BP might be associated with changes in sUA when measured longitudinally in individuals, but not when measured cross-sectionally in populations. Larger studies will be needed to confirm these results. **Table. Cross-sectional correlation between sUA, FMD, and Ambulatory Blood Pressure parameters**

Parameters	r	p-value
sUA and FMD	**-0.19**	**0.15**
sUA and SBP	**-0.02**	**0.85**
sUA and DBP	**-0.07**	**0.61**
sUA and MAP	**-0.02**	**0.86**

sUA: serum uric acid, SBP: systolic blood pressure, DBP: diastolic blood pressure, MAP: mean arterial blood pressure, FMD: flow-mediated dilation

Inflammatory Status and Serum Uric Acid Determine High-Density Lipoprotein Cholesterol Levels in a Non-Rheumatic Population

Mariano Andrés[1], María Amparo Quintanilla[2], Eliseo Pascual[3], Pedro Morillas[2] and FAPRES study group, [1]Sección de Reumatología, Hospital General Universitario de Alicante, Alicante, Spain, [2]Servicio de Cardiología, Hospital General Universitario de Elche, Elche, Spain, [3]Departamento de Medicina Clínica, Emeritus Professor, Universidad Miguel Hernández, Alicante, Spain

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In inflammatory disorders, highest incidence of cardiovascular (CV) events paradoxically occurs at lower lipid levels [ARD.70:482], especially for high-density lipoprotein cholesterol (HDLc). Current data in general, non-inflammatory population suggest a similar but milder phenomenon [Circulation.107:391]. Serum uric acid (SUA) levels appear to determine the inflammatory status of the subjects, even in normouricemia [EHJ.27:1174]. The aim of this work was to assess whether inflammatory status and SUA associate with HDLc levels in a hypertensive population aged 65 years or older.

Methods: Analysis of the FAPRES study (cross-sectional study aimed that assessed the prevalence of atrial fibrillation in hypertensive patients aged 65 years or older). Inflammatory status was considered based on serum leukocytes. A comparison between serum lipids levels (HDLc, low-density lipoprotein-cholesterol [LDLc], total cholesterol [TCh], triglycerides [TG]) and different tertiles of leukocytes and SUA was performed using ANOVA. Correlation between leukocytes and SUA was analyzed by Pearson's coefficient. In case of significant differences, a multivariate linear regression model was built for each lipid parameter to adjust for potential confounders (age, gender, CV risk factors, renal failure, BMI, use of diuretics or statins, prior coronary disease, sinus rhythm at EKG).

Results: 860 patients were analyzed, mean aged 72.9 years (SD±5.8), 52.5% females. Leukocytes and SUA levels mildly correlated (r=0.127, p=0.001). Lower HDLc and higher TG levels were found in upper tertiles of both leukocytes and SUA, with no differences on TCh and LDLc (Table). Multivariate analysis confirmed an independent, inverse association of HDLc with both leukocytes (β=-0.001, p=0.025) and SUA (β=-1.054, p=0.037); and for TG levels, an independent, direct association was found with both leukocytes (β=+0.004, p=0.049) and SUA levels (β=+8.411, p=0.003).

Conclusion: In a hypertensive population aged 65 years or older, both inflammatory status and SUA levels showed an inverse, independent association with HDLc, following current data on patients with inflammatory disorders. Interestingly, SUA and leukocytes mildly correlated. This phenomenon might help to define a pro-atherogenic

profile on the general population.

Mean (±SD)	TCh	p	HDLc	p	LDLc	p	TG	p
- Leukocytes <5900	197.8 (±41.3)	0.15	54.3 (±13.2)	0.006	121.1 (±35.9)	0.20	115.2 (±48.6)	0.03
- Leukocytes 5900-7200	195.6 (±35.0)		53.1 (±12.7)		118.7 (±29.9)		132.7 (±88.3)	
- Leukocytes >7200	191.7 (±41.7)		50.8 (±12.6)		116.1 (±34.7)		129.0 (±54.8)	
- SUA<4.7	198.1 (±40.5)	0.32	56.6 (±13.8)	<0.001	119.6 (±36.6)	0.60	111.6 (±47.9)	0.001
- SUA 4.7-5.8	194.3 (±36.3)		54.8 (±12.9)		117.5 (±32.5)		117.5 (±47.0)	
- SUA>5.8	191.7 (±37.1)		49.7 (±10.8)		116.6 (±31.3)		135.6 (±90.7)

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies on gout and its stages as a cardiovascular (CV) risk factor are few and with contradictory results. We compared echocardiographic parameters, known as independently associated with CV risk, and the scores obtained by using the Framingham Risk Score (FRS) in order to establish the differences in CV risk between obese and non-obese patients (pts) in the individual stages of gout.

Methods: A total of 201 pts were examined cross-sectionally, divided into three groups: asymptomatic hyperuricemia (n=52), 29 males and 23 females aged 55.23±15.94 years; gouty arthritis without tophi (n=86), 71 males and 15 females aged 56.36±12.29 years and gouty tophi (n=63), 60 males and 3 females aged 58.89±11.03 years. Obesity was defined as body mass index (BMI)>30 kg/m². FRS was calculated. Pts underwent echocardiography performed by one investigator, unaware of the cases clinical data, with 2.5MHz transducer. The following parameters were measured: left atrium (LA) size, thickness of the interventricular septum (IVS) and of posterior wall (PW) of the left ventricle in end-diastolic phase, fractional shortening (FS), Sm - reflecting systolic function of the left ventricle, Em - a sensitive indicator of diastolic dysfunction and E/Em ratio - an indicator of left ventricular filling pressure. Data were analyzed by Kolmogorov-Smirnov, t-test, Mann-Whitney, ANOVA test and

multiple linear regression.

Results: In asymptomatic hyperuricemia 22 (42.3%) of the pts were obese. In this group no difference was estimated in FRS (p=0.187), FS (p=0.885), Sm (p=0.400), Em (p=0.459) and E/Em (p=0.422) between obese and non-obese pts. However, obese pts had larger LA (mean±SD; 40.68±5.22 vs 36.50±5.37 mm, p=0.007), thicker IVS (mean±SD; 12.71±1.46 vs 11.18±2.18 mm, p=0.006) and thicker PW (mean±SD; 12.41±1.66 vs 10.48±2.03 mm, p=0.002). In gouty arthritis without tophi 41 (47.7%) of the pts had obesity. FRS (p=0.238), FS (p=0.110), Sm (p=0.341), Em (p=0.430) and E/Em (p=0.887) were equal between obese and non-obese pts, but obese pts had larger LA (mean±SD; 39.66±4.36 vs 36.60±5.12 mm, p=0.004), thicker PW (mean±SD; 12.71±1.67 vs 12.05±1.89 mm, p=0.037) and tended to have thicker IVS (mean±SD; 12.74±1.50 vs 12.02±1.87 mm, p=0.054). Twenty six (41.3%) of gouty tophi were obese. Comparison between obese and non-obese gouty tophi pts showed no difference in FRS (p=0.990), FS (p=0.157), Sm (p=0.830), Em (p=0.059) and E/Em (p=0.138). Likewise, pts with obesity had larger LA (mean±SD; 42.45±5.96 vs 39.25±5.84 mm, p=0.039), thicker PW (mean±SD; 13.50±2.46 vs 12.13±1.77 mm, p=0.007) and a tendency of thicker IVS (mean±SD; 13.17±1.42 vs 12.26±2.05 mm, p=0.056). Multiple linear regression, adjusted for age, revealed that the increase of BMI was a factor for thickening of the PW in asymptomatic hyperuricemia (r^2=0.565), gouty arthritis without tophi (r^2=0.305) and gouty tophi (r^2=0.261).

Conclusion: In the three stages of gout obese subjects had more pronounced alterations in the heart morphology, although the lack of differences in the left ventricular function and in the FRS. The simultaneous use of FRS and echocardiography contribute for a more complete assessment of CV risk in gout.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a health disorder affecting many patients worldwide. Clinical gout studies showed

a high prevalence of cardiovascular diseases (CVD), raising the question whether gout is a risk factor for CVD. Our aim was to examine the prevalence of CVD in patients with crystal-proven gout compared to non-gout arthritis controls and to analyze whether disease severity is associated with CVD in gout.

Methods: From July 2011 until May 2016 patients with arthritis referred for diagnosis were consecutively included in the **Go**ut **A**rnhem-**L**iemers (GOAL) cohort. Joint fluid analysis was performed in all patients for crystal-proof of gout, controls were negative for crystals. Patients' characteristics and CVD (angina pectoris, myocardial infarction, heart failure, transient ischemic attack, cerebrovascular accident, peripheral vascular disease, heart valve abnormality, arrhythmia) were collected. In gout patients, gout disease severity factors (disease duration, attack frequency, tophi, affected joints, serum urate acid level, joint damage) were also collected. A 'case-control' analysis was performed to compare gout patients with controls for the prevalence of CVD, correcting for confounders. Within gout patients, the association between gout disease severity factors and CVD was analyzed.

Results: In total 700 crystal-proven gout patients and 276 non-gout arthritis controls were enrolled in the 'case-control' analysis. Forty-seven percent of 700 gout patients and 24% of 276 controls had one or more prevalent CVD (Table 1). Gout was strongly associated with an increased prevalence of CVD compared to controls, corrected for confounders in a multivariate regression (OR: 3.39; 95% CI, 2.37-4.84). In gout patients, disease duration ≥2 years, tophaceous gout, oligo- or polyarthritis, serum urate acid >0.55 mmol/L and joint damage were univariate risk factors for CVD (Table 2). After adding the cardiovascular risk factors in the multivariate logistic regression model, disease duration ≥2 years (OR: 2.01; 95% CI, 1.31-3.09), oligo- or polyarthritis (OR: 1.66; 95% CI, 1.03-2.66), serum urate acid >0.55mmol/L (OR: 1.73; 95% CI, 1.12-2.68) and joint damage (OR: 2.26; 95% CI, 1.38-3.69) were still independently associated with prevalent CVD.

Conclusion: After adjustment for cardiovascular risk factors, crystal-proven gout was strongly associated with an increased prevalence of CVD compared to controls. Within gout patients, disease severity (disease duration ≥2 years, oligo- or polyarthritis, serum urate acid >0.55 mmol/L and joint damage) were independently associated with prevalent CVD.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Gout and hyperuricemia have been associated with cardiovascular disease. Studies have documented the impact of serum urate levels on hypertension and that increased urate levels lead to release of myeloperoxidase from neutrophils in gout patients. Our group has described that HDL can function as anti-inflammatory HDL (protective) or pro-inflammatory HDL (piHDL –which exacerbates progression of cardiovascular disease) in RA, SLE and SSc patients. We sought to evaluate association between hyperuricemia and tophaceous urate load on biomarkers of cardiovascular disease.

Methods: Using plasma from healthy normal controls (from established SLE – piHDL comparator group) we compared plasma urate with myeloperoxidase (MPO), piHDL, and traditional cardiovascular measures (BMI, Total Cholesterol, HDL, LDL). Pro-inflammatory HDL function was determined by measuring the change in fluorescence intensity caused by oxidation of DCFH by oxidized LDL in the presence or absence of test HDL**.** Fluorescence intensity in the absence of HDL was normalized to 1.0. Values greater than 1.0 after the addition of HDL indicated piHDL. MPO levels were measured using ELISA (R&D Biosystems). In this pilot study, we also investigated the relationship between urate burden and pro-inflammatory biomarkers by estimating total body urate burden in 7 patients. Urate volume was summed across all 4 extremities using dual energy CT. Pro-inflammatory HDL was measured as described above. (At time of abstract submission, MPO not evaluated.)

Results: Among the sample of normal controls, plasma urate was correlated with MPO ($r=0.51$, $p< 0.001$). Urate levels were not correlated with piHDL, age, ethnicity or BMI. Urate levels were correlated with total cholesterol ($r= 0.30$, $p = 0.05$) and LDL ($r = 0.03$, $p < 0.05$) but not HDL or TG. Among the pilot sample of gout patients, though small sample size, piHDL was well correlated with measured urate burden, $r = 0.75$, $p = 0.05$ (and $r = 0.66$, $p = 0.10$ for log transformed variables shown below). piHDL was not associated with urate, total cholesterol, HDL or LDL.

Conclusion: Increased plasma urate levels are associated with increased MPO levels in healthy normals but not piHDL. Increased urate deposits in gout patients are associated with increased piHDL activity. These findings may represent separate intermediary pathways between hyperuricemia and urate burden and cardiovascular disease.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is an independent risk factor for cardiovascular disease (CVD). Investigators studying the relationship between gout and CVD have focused on acute coronary outcomes, with limited evidence available regarding peripheral arterial function. Using high-resolution ultrasound imaging of the brachial artery, we examined endothelial and smooth muscle arterial function in gout subjects versus healthy controls.

Methods: 34 untreated male gout subjects and 64 healthy control males were included. By enrollment criteria some gout subjects, but no healthy controls, had coronary artery disease (CAD) or diabetes, or were current smokers. Demographics and medical history were recorded. Participants underwent brachial artery flow-mediated dilation (FMD; arterial response to blood flow after transient interruption using a distal blood pressure cuff) and nitroglycerine-mediated dilation (NMD) to assess endothelium-dependent and independent arterial smooth muscle responsiveness, respectively. Dynamic ultrasound images were assessed by two independent observers, with results reported as percentage change in arterial diameter from baseline.

Results: Compared with healthy controls, gout subjects had a higher prevalence of CAD (21% vs 0%, $p<0.05$), chronic kidney disease (76% vs 0, $p<0.05$), hypertension (71% vs 22%, $p<0.05$) and hyperlipidemia (50% vs 18%, $p<0.05$), but a similar low prevalence of diabetes (6% vs 0%, $p=0.12$). 29% of gout patients were current smokers (p vs control<0.05). Gout subjects were slightly older (58.9 vs 53.2 years, $p<0.05$), and significantly more gout patients were African American (44% vs 8%). Both FMD (2.20±3.12 vs 3.56±2.50, $p=0.021$) and NMD (16.69±9.01 vs 24.51±7.18, $p=0.00002$) were significantly reduced in the gout group vs controls. Gout non-smokers, white gout patients, and gout patients lacking specific co-morbidities persisted in having decreased FMD and NMD compared with controls. Gout patients with versus without specific co-morbidities had similar degrees of impaired FMD and NMD. Analysis of the gout group showed an inverse Pearson correlation between FMD and CRP ($R=-0.42$, $p=0.017$), a trend for inverse Pearson correlation between FMD and serum urate ($R=-0.31$, $p=0.08$); but no correlation between NMD and CRP or serum urate.

Conclusion: Compared with healthy controls, patients with gout have reduced arterial function as measured by FMD and NMD. While the increased prevalence of comorbidities among gout patients may contribute to diminished arterial function, it appears to be insufficient to explain the endothelial and smooth muscle dysfunction observed. Hyperuricemia and chronic inflammation may contribute to endothelial dysfunction among gout patients, but do not appear to contribute to smooth muscle dysfunction. Whether appropriate gout therapy may improve FMD and NMD in gout patients remains to be determined.

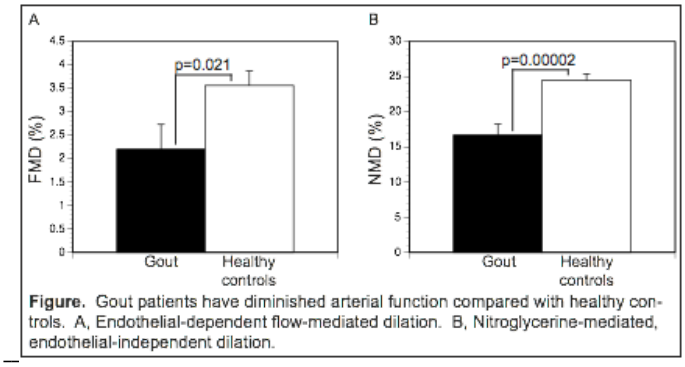

Figure. Gout patients have diminished arterial function compared with healthy controls. A, Endothelial-dependent flow-mediated dilation. B, Nitroglycerine-mediated, endothelial-independent dilation.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Elevated serum uric acid (sUA) levels, with and without gout, are associated with systemic inflammation, coronary artery disease (CAD), chronic kidney disease, and diabetes. Patients with asymptomatic hyperuricemia may have subclinical urate deposits in joints and arteries. Positron emission tomography (PET)-measured coronary flow reserve (CFR) is a senstive marker of myocardial perfusion and a quantitative predictor of clinical CAD risk. Patients with CFR <2.0 are at increased risk for major adverse cardiac events and cardiac death. We aimed to determine the association between sUA levels and CFR, insulin resistance, renal function, systemic inflammation, and subclinical urate deposits in patients with asymptomatic hyperuricemia and metabolic syndrome.

Methods: Adults aged ≥40 years with sUA levels ≥6.5 mg/dl and metabolic syndrome according to the National Cholesterol Education Program –Adult Treatment Panel III criteria were eligible. Patients with gout, nephrolithiasis, symptomatic CAD or pulmonary disease and those using xanthine oxidase inhibitors or probenecid were excluded. We assessed resting and stress induced (after adenosine infusion) myocardial blood flow (MBF) using a cardiac PET and calculated CFR from these data. We also measured sUA, IL-6, high-sensitivity c-reactive protein (hs-CRP), serum creatinine, insulin resistance by homeostatic model assessment (HOMA-IR) method, and urate deposits using dual-energy CT (DECT) of the foot and carotid arteries.

Results: We conducted an interim analysis including 18 subjects (**Table**) with the mean (SD) age of 66.0 (7.4) years and mean (SD) sUA level of 8.1 mg/dl (1.1). The mean (SD) CFR was abnormaly low at 1.9 (0.4) and the mean (SD) stress MBF was 1.5 (0.4) ml/min/g. On univariate regression analyses, sUA had no signficant association with CFR (β=-0.05, p=0.9), stress MBF (β=0.17, p=0.7), IL-6 (β=-1.14, p=0.5), serum creatinine (β=0.31, p=0.5) HOMA-IR (β=0.95, p=0.5), hs-CRP(β=-5.45, p=0.06), and eGFR (β=-0.76, p=0.15). Four patients (22.2%) were found to have urate deposits in the foot by DECT with urate volume ranging between 0.01 to 0.39 cm^3. None had urate deposits in the carotid arteries.

Conclusion: In this interim analysis of the pilot study involving patients with asymptomatic hyperuricemia, no relationship was noted between sUA and CFR and other cardiometabolic markers. However, we found urate deposits in the foot in over one-fifth of the patients. Final analyis that further determines the link bewteen sUA and cardiometabolic risk in patients with asymptomatic hyperuricemia and metabolic syndrome is underway.

Table: Summary of the study cohort (n=18)		
Demographics	Age, years	66.0 ± 7.4
	Male	4 (22.2%)
Clinical characteristics	BMI, kg/m2	35.3 ± 6.3
	Waist circumference, inches	49.2 ± 20.2
	SBP, mmHg	139.1 ± 15.6
	DBP, mmHg	71.4 ± 8.3
Laboratory characteristics	Uric acid, mg/dl	8.1 ± 1.1
	IL-6, pg/ml (ref: 0.0-15.5)	7.5 ± 8.6
	Serum creatinine, mg/dl	1.0 ± 0.2
	GFR, mL/min/1.73m^2	44.7 ± 11.9
	Fasting glucose, mg/dl (ref: 65-99)	104.9 ± 19.9
	HOMA-IR (ref <2.0)	5.9 ± 4.6
	Hs-CRP, mg/L (ref: 0.0-3.0)	12.2 ± 20.7
Cardiac PET findings	Coronary flow reserve (ref >2.0)	1.9 ± 0.4
	Myocardial blood flow at stress, mL/min/g	1.5 ± 0.4
	LV EF at rest, %	61.4 ± 10.1
DECT of the foot	Urate deposits	4 (22.2%)
DECT of the neck	Urate deposits	0 (0%)
Data are presented as Mean ± SD or N (%). BMI= body mass index, SBP=systolic blood pressure, DBP=diastolic blood pressure, IL= interleukin, GFR= glomerular filtration rate, HOMA-IR=homeostatic model assessment – insulin resistance, LV EF=left ventricular ejection fraction, PET=Positron emission tomography, DECT=dual energy CT

Session Date: Tuesday, November 15, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Blood pressure and hypertension are associated with uric acid, the end product of purine catabolism, but the underlying mechanism remainds unclear. During the final stage of purine metabolism, xanthine oxidase (XO) breaks down hypoxanthine to xanthine, and xanthine to uric acid, while reactive oxygen species (ROS) are formed. Accumulation of ROS by increased uric acid production has been suggested as a possible underlying mechanism for the association between uric acid and high blood pressure. We therefore investigated whether (i) serum uric acid concentration and/or (ii) 24h urinary uric acid excretion, as proxy for uric acid production, are associated with ambulatory blood pressure and hypertension.

Methods: Cross-sectional analyses were conducted among 2660 individuals (52% men, mean age 60.0±8.2 years; 26.7% type 2 diabetes [by design]) from The Maastricht Study. Multivariable linear and logistic regression analyses were performed to investigate the association of serum uric acid concentration and 24h urinary uric acid excretion with 24h pulse pressure (PP), 24h mean arterial pressure (MAP) and hypertension. Hypertension was defined as mean 24h systolic BP of ≥ 135 mmHg, 24h DBP ≥ 85 mmHg, and/or the use of anti-hypertensive medication. Analyses were adjusted for sex, age, glucose metabolism status, and further for treatment of diabetes and hypertension, body mass index, smoking behavior, alcohol consumption, education, and eGFR (in the logistic analyses, no adjustment for anti-hypertensive medication). Analyses exploring the role of serum uric acid were additionally adjusted for 24h urine uric acid excretion, whereas analyses exploring the role of 24h urine uric acid excretion were additionally adjusted for serum uric acid concentration and fractional excretion of uric acid (FE_{UA}).

Results: In fully adjusted analyses, serum uric acid concentration (per standard deviation [SD] of 330 μmol/L) was associated with higher MAP (β 0.50 mmHg (95% confidence [CI], 0.14 to 0.88; *P*=0.01) and positively associated with hypertension (odds ratio 1.29; CI, 1.14 to 1.46; *P*-value <0.001). Twenty-four-hour urinary uric acid excretion (per SD 141 mg/day/1.73m^2) was associated with higher MAP (β 0.85 mmHg; CI, 0.30 to 1.40; *P*--value <0.001). There was no significant association between serum and 24h urinary uric acid excretion with PP. There was no interaction for the aforementioned associations with sex or age.

Conclusion: We found evidence of associations between serum uric acid concentration with MAP and hypertension. Additionally, 24h uric acid excretion was associated with MAP. This indicates that both serum uric acid concentration and uric acid production are, independent of each other, associated with blood pressure.

Session Date: Tuesday, November 15, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyperuricemia is a known cardio-metabolic risk factor as well as risk factor for gout. Physical activity has been found to improve many other cardio-metabolic risk factors; however, the relationship between physical activity and serum uric acid levels is not well understood. It has been shown that physical activity improves insulin sensitivity, lowering fasting serum insulin levels, and that lower insulin levels improve uric acid excretion. It would follow that physical activity may be beneficial in lowering serum uric acid levels. We aimed to evaluate how objectively measured physical activity related with serum uric acid concentrations in the 2003-2004 National Health and Nutrition Examination Survey (NHANES).

Methods: As part of the 2003-2004 NHANES serum uric acid was measured via a colorimetric enzymatic assay. Physical activity was assessed with seven days of ActiGraph accelerometry (n=3475). Here we used restricted cubic splines to parametrically estimate the relationship of physical activity amounts and serum uric acid levels, while controlling for age, gender, ethnicity, alcohol use, body mass index (BMI), and renal function.

Results: We found a borderline overall relationship of physical activity amounts and serum uric acid (df=4, p=0.519) and a significant effect of the non-linear portion over and above the additional impact of linear effect (df=3, p=0.0331). This non-linear relationship between physical activity and uric acid was U-shaped: below 760 kCal/day, uric acid was inversely related to physical activity amount; above 760 kCal/day, uric acid was positively related to physical activity amount. The median physical activity amount was 403 kCal/day, with 75% of the study population averaging less than 604 kCal/day and 90% of the study population averaging less than 849 kCal/day. The mean serum uric acid of the study population was 5.36mg/dL with a standard deviation of 1.36 mg/dL. Based on this relationship, the effects of physical activity on predicted serum uric acid ranged over 0.7 mg/dL (5.5-6.2 mg/dL).

Conclusion: In a nationally representative sample of US adults, a non-linear, U-shaped, relationship between

objectively measured physical activity and serum uric acid was found. This suggests possible competing mechanisms by which physical activity influences serum uric acid at lower and higher amounts and intensities of physical activity.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of hyperuricemia and gout suggests that sex hormones play a role in the gender difference with gout. Estrogen has been thought to reduce serum uric acid levels by increasing renal urate elimination. However, studies on the relationship between testosterone and uric acid levels showed conflicting results. We performed this study to define whether anti-androgen treatment affects serum uric acid levels in men.

Methods: This retrospective study reviewed the medical records of 178 patients who underwent anti-androgen treatment for advanced prostate cancer from January 2004 to December 2013 at Seoul National University Bundang Hospital. We enrolled 92 patients with available pre- and post-treatment (3 or 6-month) uric acid levels among them. An age-matched control included 46 prostate cancer patients who underwent surgical treatment only and had available pre- and post-treatment uric acid levels. The change of serum uric acid levels was compared by generalized estimation equation (GEE) model between patients with and without anti-androgen treatment.

Results: Compared to the control group, patients with anti-androgen treatment showed a more pronounced reduction of uric acid levels at both 3 and 6 months (estimation = -0.765 at 3-month and -0.739 at 6-month after anti-androgen treatment, both p-value < 0.001, Figure 1A). After further adjusting with hemoglobin, blood urea nitrogen, serum creatinine and serum protein levels, the difference was still significant (estimation = -0.831 at 3-month and -0.766 at 6-month, both p-value < 0.001, Figure 1B). When patients were stratified according to pre-treatment uric acid level (uric acid > 7 mg/dL versus <= 7 mg/dL), patients with hyperuricemia showed a more decrease in uric acid levels at 3-month compared to those with normouricemia (estimation = -1.072, p < 0.001, Figure 2).

Conclusion: These results showed that serum uric acid levels significantly decreased after anti-androgen therapy and suggest that male sex hormone could partially explain the gender difference in gout and hyperuricemia prevalence.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased levels of serum urate (sUA) have been reported in association with hypertension, chronic kidney disease, and obesity. All these conditions are over-represented in US African Americans, who also have greater environmental risk factors for developing hyperuricemia including elevated fructose intake. Our group has previously reported that young African Americans have lower sUA concentrations than Caucasians after adjustment for clinical and demographic factors. **Objectives:** To determine whether there is a differential association between sUA and race in young adults.

Methods: We examined baseline data on consecutively enrolled individuals (age 18 – 40 years) in an interventional study aimed at lowering blood pressure (BP) through the administration of a urate-lowering therapy. African Americans were over-represented in the sample by study design. Enrollment criteria included a sUA of ≥

5.0 mg/dL for men or ≥ 4.0 mg/dL for women. After sUA means comparisons between African Americans and other races using t-test, we performed multivariable adjustments for age, sex, serum creatinine, and body mass index (BMI) in a multiple linear regression model.

Results: Sixty-nine participants recruited from Birmingham, AL were included in the analysis. Participants had a mean age (±standard deviation) of 29.0 ± 6.9 years, 30% were female, 43% were African Americans (AAs), and the mean BMI was 29.0 ± 6.0 kg/m². The mean sUA was 5.9 ± 1.1 mg/dL (range: 3.9 to 8.5 mg/dL). We found a significantly lower sUA for African Americans compared to persons of other races (5.5 ± 1.2 mg/dL vs 6.3 ± 1.0 mg/dL, p= 0.009). After multivariable analysis the difference in sUA between African Americans and other races was attenuated to non-significance (p= 0.33) due to the effects of BMI and sex. As expected, the association between sUA and sex was significant (Table).

Conclusion: In this cross-sectional analysis of young adults, African Americans had lower sUA concentrations than other races. However, in our model this difference is explained by the effect of sex differences in sUA and BMI. A potential limitation is that participants were enrolled after they met a sUA threshold so not all the ranges of sUA in a normal population are represented in this analysis. Larger studies will be needed to fully address this question. **Table. Multivariable regression model on the association between serum urate and race among young adults (n=69)**

Variable	Estimate (95% confidence interval)	p
Race (African-Americans versus other races)	-0.32 (-0.88 – 0.24)	0.3
Age (per year)	0.009 (-0.03 – 0.04)	0.6
Sex (men versus women)	1.44 (0.75 – 2.14)	<0.001
BMI (per unit of kg/m^2)	0.04 (0.01-0.08)	0.02
Serum creatinine (per milligram per deciliter)	0.42 (-1.17 - 2.03)	0.6

BMI= Body-mass index

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking has been found to be negatively correlated with serum uric acid levels by virtue of reduced production and increased consumption of endogenous anti-oxidant uric acid among smokers and has been reported to decrease incidence of gout. We looked at the question of association between active smoking and acute gout by examining this association using a large inpatient US database.

Methods: We used the Nationwide Inpatient Sample (NIS) database (largest publicly available all-payer inpatient care database in the United States) from the years 2009-2011 to identify patients aged ³ 18 years without missing information for gender and age. Current smokers among them were selected using previously validated ICD-9 code 305.1. Hospitalizations with history of smoking but not active smoker were. Patients who developed acute gout during hospitalization were identified based on ICD-9 code 274.01 marked as a secondary diagnosis. Patients with acute gout as a primary diagnosis were excluded to prevent confounding from a group that may still have been actively smoking at the time of their flare. Univariate logistic regression was used to examine the previously reported confounding factors including age, sex, diabetes, hyperlipidemia, hypertension, chronic kidney disease (CKD), early menopause/post menopause, major organ transplant, obesity and alcohol. We then constructed a multivariable logistic regression using all factors with significant associations during univariate analysis (defined as $p<0.10$). STATA version 13.0 (College Station, TX) was used for analysis to accommodate for the complex design of survey sample data (NIS).

Results: A total of 17,847,045 discharge records were used in the analysis. Both univariate (OR 0.59, CI 0.54-0.63, $p<0.0001$) and multivariate (OR 0.64, CI 0.59-0.68, $p<0.0001$) regressions showed statistically significant reduction of acute gout incidence among hospitalized patients who were current smokers but were assumed to have ceased smoking during hospital stay.

Conclusion: Active tobacco use was associated with a lower risk of acute inpatient gouty arthritis, even when controlling for conventional risk factors. More study is needed to correlate this finding with uric acid levels, and a better understanding of the mechanisms that explain this finding are necessary. Figure 1: Selection process for discharges included in analysis

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Many studies have reported that gout is associated with increased risk of cardiovascular events and mortality. However, information regarding gout disease severity is limited in these studies and it is unclear how gout impacts on mortality risk. The aim of this study was to determine mortality rates and predictors of mortality in people with recent onset of gout.

Methods: People with gout disease duration <10 years were recruited into a prospective observational study from primary and secondary care settings. Comprehensive clinical assessment was completed at baseline. Participants were prospectively followed for at least one year. Information about death was systematically collected from primary and secondary health records. Standardised mortality ratios (SMR) were calculated and risk factors for

mortality were analysed using Cox proportional hazard regression models.

Results: The mean (SD) follow-up duration was 5.1 (1.6) years (a total 1,511 patient years accrued). Of the 295 participants, 43 (14.6%) had died at the time of censorship (SMR 1.96 (95% CI 1.44, 2.62)). Of the 43 participants who died, 26 deaths (60.5%) were due to a cardiovascular cause and 17 (39.5%) were due to a non-cardiovascular cause. In Cox proportional hazards analysis, older age (70-80 years hazard ratio (HR) 5.71, 95% CI 2.02 to 16.19, *P*=0.001; 80-91 years HR 5.45, 95% CI 1.68 to 17.71, *P*=0.005), diuretic use (HR 3.09, 95% CI 1.63 to 5.87, *P*<0.001) and presence of subcutaneous tophi (HR 3.08, 95% CI 1.62 to 5.83, *P*<0.001, Figure) were independently associated with an increased risk of all-cause mortality. The presence of subcutaneous tophi was the only baseline variable independently associated with both cardiovascular cause of death (HR 2.90, 95% CI 1.29 to 6.51, *P*=0.01) and non-cardiovascular cause of death (HR 3.86, 95% CI 1.41 to 10.56, *P*=0.01).

Conclusion: People with gout disease duration <10 years have an increased risk of age/sex/ethnicity standardized death. The presence of subcutaneous tophi at baseline is an independent predictor of both cardiovascular and non-cardiovascular mortality. **Figure: Effect of tophi on all-cause mortality**. Kaplan–Meier survival plot comparing participants with tophi present at baseline with participants with no tophi at baseline for all-cause mortality. Time axis in years, unadjusted *P* value is shown.

Tophaceous Gout and the Risk of Mortality: A General Population-Based Study

Background/Purpose: A recent study based on data from a gout specialty clinic (N=706) found that patients with tophi (N=215) had a two-fold increased risk of mortality compared to those without tophi. However, no population-based data are available on the topic. We evaluated the mortality impact of tophaceous gout in a general population context.

Methods: Using an electronic medical record database representative of the UK general population, we identified tophaceous gout cases (based on physician diagnosis) and up to 5 non-tophaceous gout controls matched on sex, age, gout duration, and entry time between January 1, 1995 and December 31, 2015. We calculated mortality rates and hazard ratios (HRs) using a Cox proportional hazard model to adjust for demographics, lifestyle factors, comorbidities, medications, and healthcare use. We conducted subgroup analyses based on age (≤70 and >70) and sex.

Results: Among 618 patients with tophaceous gout (55% men, mean age=73 years), the mortality rate was 64.7 deaths/1000 person-years, whereas among 2850 matched gout patients (56% men, mean age=73 years), the corresponding mortality rate was 45.5 deaths/1000 person-years. Tophaceous gout was associated with a 60% increased risk of mortality (HR=1.60; 95% CI, 1.29-1.97) compared to those without tophi. After adjusting for covariates, these estimates remained similar (HR=1.60; 95% CI, 1.28-1.99). Those in the younger age group (≤70 years) and who were male tended to have a larger HR (**Table 1**).

Conclusion: This general population-based cohort study indicates that tophaceous gout is associated with an increased risk of death among gout patients, particularly among those who are younger (≤70) or male. Total urate burden as well as morbidity and functional decline associated with chronic tophaceous gout may explain the increased mortality.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is the most prevalent inflammatory arthritis, affecting 2.4% of adults in the UK. Recently, a link has been suggested between gout and erectile dysfunction (ED), however studies quantifying ED reporting by gout patients are lacking. The aim of this study was to determine the population level absolute and relative rates of ED reporting by patients with gout over a decade in England.

Methods: Utilising data from one of the largest English primary care consultation databases (Clinical Practice Research Datalink), we identified 9,653 men with incident gout and matched them to 38,218 controls (ratio 1:4) by age and practice. Absolute and relative rate of incident ED was calculated using Cox regression models. Absolute rates within specific time periods before and after gout diagnosis were compared to controls using Poisson regression models.

Results: Overall, the absolute rate of ED post-gout diagnosis was 193 (95% Confidence interval (CI): 184-202) per 10,000 person-years. This corresponded to a 31% (Hazard Ratio (HR) = 1.31 95%CI: 1.24-1.40) increased relative risk and 0.6% excess absolute risk compared to those without gout (Table 1). Among those prescribed urate-lowering therapy, the risk of ED was similar for cases and controls (HR=1.10 95CI: 1.01-1.19). Compared to controls, the risk of ED was also high in the year before gout diagnosis (incidence rate ratio= 1.63 95%CI 1.27-2.08). Our relative risk estimates remained broadly similar when we restricted our analyses to those with ED treated with medication.

Conclusion: We have shown a statistically significant increased risk of ED among men with gout, however, the absolute risk difference is small indicating limited influence of disease on ED. Clinicians should be aware that higher reporting of ED before gout diagnosis suggests a possible influence of hyperuricemia on arterial vasculature warranting further investigations. Overall our finding are reassuring to patients and clinicians.

Table 1: Absolute and relative rate of Erectile Dysfunction after gout diagnosis

Variable	Cases Rate[1] (95% CI)	Controls Rate (95% CI)	Hazard Ratio[2] (95% CI)	Absolute risk difference[1]
Overall Erectile Dysfunction				
All ages	192.8 (184.0-202.1)	136.2 (132.1-140.4)	1.31 (1.24-1.40)	56.6
≤34	61.4 (45.4-127.4)	34.6 (27.3-43.9)	1.20 (0.79-1.83)	26.8
35 – 44	112.4 (99.5-127.4)	76.2 (70.1-82.8)	1.18 (1.01-1.39)	36.4
45 – 54	211.7 (196.1-228.6)	146.0 (138.6-153.5)	1.28 (1.16-1.41)	65.7
55 – 64	262.8 (245.1-281.4)	186.3 (178.3-194.8)	1.37 (1.25-1.49)	76.5
Medication treated Erectile Dysfunction				
All ages	80.2 (77.1-83.5)	113.7 (107.0-120.9)	1.36 (1.26-1.47)	33.5
≤34	16.3 (11.5-23.0)	33.6 (22.4-50.9)	1.24 (0.67-2.29)	17.3
35 – 44	45.7 (41.1-51.0)	62.4 (52.8-73.6)	1.11 (0.89-1.37)	16.6
45 – 54	87.1 (81.6-92.9)	126.8 (114.8-140.0)	1.30 (1.15-1.47)	39.7
55 – 64	108.8 (102.7-115.3)	156.7 (143.2-171.5)	1.46 (1.30-1.64)	47.9

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

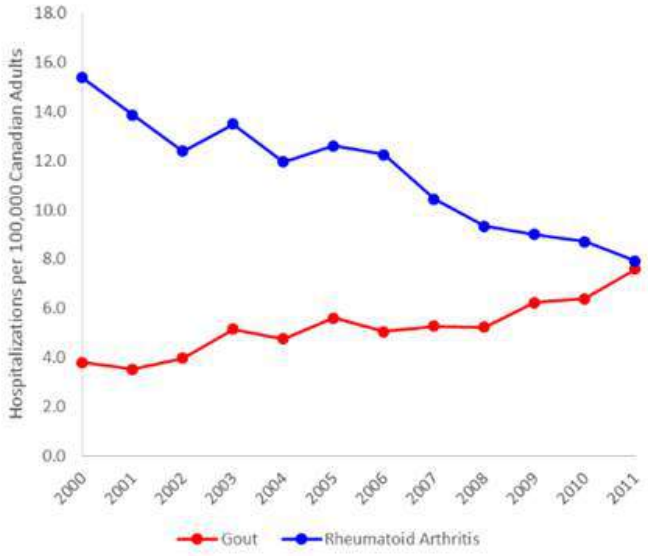
Background/Purpose: Gout and rheumatoid arthritis (RA) are the two most common forms of inflammatory arthritis worldwide. As hospitalizations for both conditions lead to substantial health resource use, contemporary inpatient trends and associated costs may provide important benchmarks of disease burden. However, relevant data are limited. We evaluated contemporary hospitalization trends for gout and RA in a Canadian general population context.

Methods: We used PopulationData BC, a population-based dataset spanning the entire Canadian province of British Columbia. We included patients at least 18 years of age who were hospitalized from 2000-2011 with a principal diagnosis of either gout (ICD-9-CM 274 or ICD-10-CA M10) or RA (ICD-9-CM 714 or ICD-10-CA M05 or M06). We calculated annual rates of hospitalizations (expressed per 100,000 Canadian adults) for gout and RA. We assessed the trend of total hip and knee replacements among study patients. We evaluated the inpatient economic burden for both conditions. Costs were inflation-adjusted to 2011 Canadian dollars. We assessed all annual trends using Poisson and linear regression models.

Results: From 2000 to 2011, the annual hospitalization rate for those with a principal diagnosis of RA declined by 49% from 15.4 to 7.9 per 100,000 Canadian adults ($p<0.001$), whereas that for gout increased by 100% (i.e., doubled) from 3.8 to 7.6 per 100,000 Canadian adults ($p<0.001$) **(Figure)**. Thus, at the beginning of the study period, hospitalizations for RA were approximately 4 times more frequent than those for gout; however, these opposing trends of the two conditions led to similar hospitalization rates by 2011 (i.e., 7.9 and 7.6 per 100,000 Canadian adults for RA and gout, respectively). Approximately 31% of hospitalizations with a principal diagnosis of RA were associated with total hip or knee replacement. From 2000 to 2011, the rate of these surgeries in patients with a principal diagnosis of RA decreased from 3.8 to 2.9 per 100,000 Canadian adults ($p=0.0097$). In contrast, less than 1% of hospitalizations with a principal diagnosis of gout were associated with total hip or knee replacement. The inflation-adjusted inpatient costs associated with a principal diagnosis of gout more than doubled

over the study period from $19,426 to $43,783 (2011 CAD) per 100,000 Canadian adults (p<0.001), whereas those for RA decreased by 40% from $103,314 to $62,348 per 100,000 Canadian adults (p=0.0023) over the same period.

Conclusion: Our findings indicate that hospitalization rates for gout have doubled over the past decade, while those for RA have decreased considerably. While these data provide an encouraging benchmark for RA care, they also highlight the critical need to improve gout management and prevention to mitigate its rising disease burden in



Canada and beyond.

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The relationship between gout and cancer remains unclear. Whereas some studies have reported possible anti-cancer benefits of uric acid and monosodium urate crystals, others have found an increased risk of cancer in gout patients. Our study aimed to clarify the relationship between gout and colon metaplasia, including cancer and polyps.

Methods: We conducted a retrospective study of patients in a VA hospital system using two distinct approaches. To obtain a historical, cross-sectional view of colon cancer prevalence, we assessed the presence of physician-coded diagnoses of colon cancer and/or polyps in gout patients, versus patients with osteoarthritis (OA) but no gout, with active records in our computerized patient record system (CPRS) between 2007 and 2008. Lung and prostate cancer prevalence were recorded for comparison. In the second approach, we included only patients with documented colonoscopy reports in CPRS, and performed a retrospective cohort study of colon cancer and polyp incidences in gout versus OA patients over a ten-year period (2001-2010). In addition, colon cancer and polyp incidences were compared between patients who had undergone screening versus diagnostic colonoscopy, those who used aspirin or NSAIDs and those who did not, and between gout patients who used allopurinol and/or colchicine and those who did not.

Results: 1287 gout patients and 1287 OA patients were included. Gout and OA patients were similar in age, ethnicity, BMI and smoking history. Gout patients had a lower physician-coded prevalence of all colonic lesions (cancer or polyp: 1.8 versus 9.6%, $p<0.001$), and a lower prevalence of colon cancer (1.0 versus 1.9%, $p<0.001$), than OA patients (Figure A). Lung and prostate cancer were similar between the two groups. Among 581 gout patients and 598 OA subjects with documented colonoscopies, the ten-year incidence of colon cancer was lower in gout patients than in patients with OA (0.8 versus 3.7%, $p=0.0008$) (Figure B). This difference in colon cancer incidence remained significant after accounting for NSAID and/or aspirin use. Among gout patients, the use of colchicine and/or allopurinol, as well as the presence or absence of concomitant of OA, did not appear to influence colon cancer prevalence. Differences in colon cancer incidence were significant between gout and OA patients undergoing diagnostic colonoscopy (0.5% in gout patients versus 4.6% in OA patients, $p<0.001$) but not those undergoing screening colonoscopy (0.9% in gout patients versus 1% in OA patients, $p=1.0$). No protective effect of gout was observed for prostate or lung cancer.

Conclusion: Patients with gout had decreased physician-reported prevalence, and colonoscopy-documented incidence of colon cancer compared to patients with OA, suggesting a possible protective effect of gout or a gout-associated clinical, epidemiological or genetic factor.

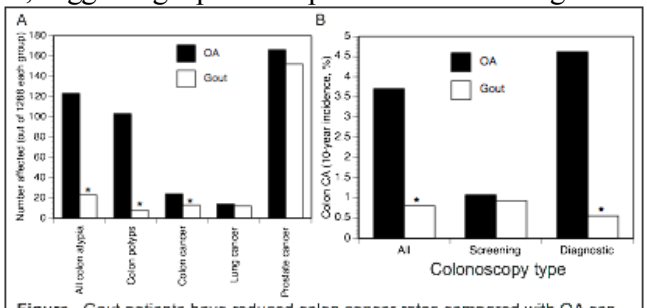

Figure. Gout patients have reduced colon cancer rates compared with OA controls. A, Prevalence based on physician documentation. B, Incidence based on colonoscopy results. *=p<0.01 compared with OA.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose : Recurrent flares of inflammatory arthritis are the central clinical feature of gout. However, methods of gout flare reporting in research settings are inconsistent and poorly defined. The aim of this study was to map patterns of gout flare and assess the concurrent validity of different methods of flare reporting by comparison with other methods of gout disease activity.

Methods: Flare diary entries from a randomised controlled trial of patients with gout were analysed. Over a four-month period, participants (n=120) completed daily flare diary entries with recording of self-report of flare, pain score (Likert scale 0-10) and medications taken for flare. The time-course domain in the 2015 ACR/EULAR gout classification criteria was used to define the time elements of a typical flare (time to maximal pain <24 hours, resolution of symptoms in ≤14 days, complete resolution between symptomatic episodes). Pain x time plots for each individual participant were inspected and analysed for six methods of flare reporting including flare count, time to first flare, number of days with self-reported flare, number of days with self-reported flares requiring medication, number of days with Gaffo-defined flare (CART approach: pain score >3 and self-report)[1], and area under the pain-time curve (AUC pain). Concurrent validity assessment included correlation analysis of these methods of reporting with other measures of gout activity measured monthly over the same time period (area under the curve (AUC) variable-time plot analysis); patient and physician global assessments, joint counts, and C-reactive protein (CRP).

Results: Inspection of individual plots showed wide variation in the severity, frequency and duration of flare (Figure), with only 55/120 (45.8%) experiencing predominantly typical flares over the four-month study period. Flare counts over time could not be reliably calculated due to difficulty determining the boundaries of individual flares for some participants. Time to first flare correlated poorly with other measures of gout activity. In contrast, all other tested methods of flare reporting significantly correlated with other measures of gout activity; AUC pain correlated most strongly with AUC CRP ($r=0.43$, $P<0.001$), and number of days of self-reported flare correlated most strongly with other measures of disease severity (AUC patient global 0.62, AUC physician global 0.62, AUC tender joint count 0.53, AUC swollen joint count 0.44, $P<0.001$ for all).

Conclusion: There is wide variation in the patterns of flare over time in individuals with gout, leading to challenges for flare reporting in clinical trials. Time-dependent reporting strategies such as the number of days in self-reported flare correlate well with other measures of gout disease severity and may provide a more accurate measure of severity of flare burden over time. **Reference:** Gaffo et al A&R 2012

Session Title: Metabolic and Crystal Arthropathies - Poster II: Epidemiology and Mechanisms of Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To date, most of the models used to identify gout cases within large administrative databases have relied solely only on administrative billing codes. The positive predictive value (PPV) of these models ranged from 33-86%. Natural language processing (NLP) is a range of computational techniques for analyzing and representing naturally occurring written or oral text for the purpose of achieving human-like language processing for a range of tasks or applications. In this study we aimed to develop and validate an algorithm that accurately identifies gout patients within the Partners biobank database using both codified data and information from clinical text notes using NLP.

Methods: To create a gold-standard training set, a training set of 200 patients was created. Two rheumatologists reviewed the electric medical records of the 200 patients and classified them as having the disease (Y), probably having the disease (P), not having the disease (N) or unable to make a classification (U). We used the clinician-reviewed classifications to train models to predict the probability of a gout diagnosis or no gout on the basis of a logistic regression classifier with the adaptive least absolute shrinkage and selection operator (LASSO) procedure to select informative variables. We constructed three separate models to predict a diagnosis of gout in our partners biobank cohort- (1) model utilizing number of gout ICD-9 codes alone (ICD-9 model), (2) model comprising all codified variables including disease complications (codified model) (3) a combined model including both codified and NLP variables (combined model).

Results: The area under the curve (AUC) for the combined model was 0.901 (95% CI 0.830-0.972), with a sensitivity of 0.936 at a positive predictive value cut-off of 0.902. The AUC of the ICD-9 model was 0.721 (95% CI 0.617-0.825), while that of the codified model was 0.879 (95% CI 0.806-0.952). Addition of NLP narrative terms to our final model resulted in improving the sensitivity to 0.936 from 0.89, at the same PPV level of 0.902, thus resulting in improved identification of gout cases by 4.12%, compared to the codified model. On review of medical records from an additional random set of 50 patients each predicted to have gout by the combined model, 44 were correctly identified as having this diagnosis through chart review resulting in a positive predictive value of 88%.

Conclusion: Including narrative concepts from natural language processing improves the accuracy of EMR case-definition for gout while simultaneously identifying more subjects compared to models using codified data alone.

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Environmental triggers such as infection are considered to be involved in pathogenesis of polymyositis (PM) and dermatomyositis (DM). This study was aimed to investigate influence of season and residential environment on development of PM/DM-associated interstitial lung disease (ILD), in association with myositis-specific autoantibodies.

Methods: This study used data recorded in a multicenter retrospective cohort of Japanese patients with PM/DM-associated ILD (JAMI cohort), which involved 44 institutions across Japan. Inclusion criteria of the JAMI cohort were adult-onset, definite or probable PM/DM including clinically amyopathic DM (CADM), ILD confirmed by imaging, and availability of serum samples at diagnosis. Demographic and clinical information was retrospectively collected by chart review, and sera were subjected to autoantibody assays; ELISA for anti-melanoma

differentiation-associated gene 5 (MDA5) and RNA immunoprecipitation for anti-aminoacyl-tRNA synthetase (ARS), including Jo-1, PL-7, PL-12, EJ, OJ, and KS. Seasonality was assessed by Roger's test in patients who developed the disease in the past 5 years. As for residential environment, we evaluated if patients' residence at disease onset was close to the major freshwater sites. The waterfront was defined as area within 1.75 km from large river, lake, or pond calculated on the Google map.

Results: Of 498 patients enrolled, anti-MDA5 and anti-ARS antibodies were detected in 212 (42%) and 165 (33%), respectively. Since one had both antibodies, 122 (24%) were regarded as the anti-MDA5/ARS-negative group. Anti-MDA5-positive patients represented a higher frequency of CADM (76% versus 24% or 30%; P <0.01 for both comparisons), and a lower cumulative survival rate at 6 months (67% versus 97% or 96%; P <0.01 for both comparisons), compared to anti-ARS-positive or anti-MDA5/ARS-negative group. Interestingly, seasonality of the disease onset was found in anti-MDA5-positive patients (P = 0.035, Figure1): more cases developed the disease in autumn/winter than in spring/summer, but not in anti-ARS-positive or anti-MDA5/ARS-negative group (P = 0.73 and 0.59, respectively). Clinical features were comparable between anti-MDA5-positive patients who developed the disease in autumn/winter and those who developed in spring/summer. The proportion of patients who resided in freshwater waterfront at disease onset was significantly higher in anti-MDA5-positive group than in anti-ARS-positive or anti-MDA5/ARS-negative group (65% versus 50% or 50%; P <0.01 for both comparisons).

Conclusion: Anti-MDA5 antibody-positive DM-associated ILD developed predominantly in autumn/winter and clustered around freshwater waterfront, suggesting roles of environmental triggers in development of the disease.

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to define the pattern of muscle involvement in patients with immune-mediated necrotizing myopathy (IMNM).

Methods: All Johns Hopkins Myositis Longitudinal Cohort subjects with an available thigh magnetic resonance imaging (tMRI) who fulfilled criteria for IMNM, dermatomyositis (DM), polymyositis (PM), clinically amyopathic DM (CADM) or inclusion body myositis (IBM) were included in the study. Fifteen muscles were assessed by tMRI for the presence or absence of edema, atrophy, fatty replacement, and fascial edema. Disease subgroups were compared using univariate and multivariate analysis. Within IMNM, patients with anti-SRP and anti-HMGCR were also compared.

Results: The study included 666 subjects (101 IMNM, 176 PM, 219 DM, 17 CADM and 153 IBM). Compared to patients with DM or PM, IMNM was characterized by a higher proportion of thigh muscles with edema, atrophy, and fatty replacement ($p<0.01$), independent of other confounding variables. Compared with anti-SRP, anti-HMGCR patients showed a lesser proportion of muscles with atrophy (-9%, $p=0.04$). In IMNM, muscle abnormalities were especially common in the lateral rotator and gluteal groups. Fascial involvement was more widespread in DM. Interestingly, fatty replacement of muscle tissue began early during the course of IMNM as well as the other muscle diseases. Although it had a negative predictive value of 93%, an optimal combination of tMRI features had only a 55% positive predictive value for diagnosing IMNM.

Conclusion: Compared to patients with DM or PM, IMNM is characterized by more widespread muscle involvement. Compared with anti-HMGCR, anti-SRP patients seem to have more severe muscle involvement.

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Due to the rarity of the entity, the literature on focal myositis (FM) fails to address important questions on its nosology, associated disorders, clinical presentation and therapeutic management. We sought to shed light on clinical, pathological, and therapeutic features of FM through the analysis of data from a large patient cohort.

Methods: We searched for confirmed cases of FM in the Lyon University Hospital's database of patients diagnosed with myositis since year 2000. FM was diagnosed as per the usual clinicopathological definition. Clinical, serological, imaging, pathological and therapeutic data were collected. When missing from the original pathological analysis, complementary immunohistochemistry was redone when possible.

Results: Of the 810 patients included in the myositis database, 36 (4.4%) had confirmed FM (22 males, 14 females, mean age=45) (Figure 1.A). The main clinical signs were focal muscular pain (78%), fever (28%) and local erythema (36%). Serum creatine kinase was usually normal (81%); conversely, serum immunological abnormalities (mild to marked inflammation as determined by ESR or CRP, autoantibodies such as anti nuclear or anti-extractable nuclear antigen, and dysglobulinemia) were found in the sera of 58% of the patients. Beyond confirming previously-reported findings, the pathological analyses also illustrated significant rates of vascularitis within the muscle (73%) and fasciitis (75%). While FM's etiopathogeny remains enigmatic, this study highlighted frequent association with immune-mediated inflammatory disease (IMID) (39%), neoplasia (19%), radiculopathy (14%) and trauma (8%) (Figure 1.B). IMID included Behcet's disease (n=5), various inflammatory rheumatic diseases (n= 5) and others. Neoplasms were solid cancers in six cases (bladder n=2, thyroid n=1, skin n=1, prostate n=1, and adenocarcinoma of unknown primary site n=1), and hemopathies in two (one had both). Contrasting with the usual perception, two-thirds of the cohort required immunosuppressive therapy. As first line, all patients received steroids. The recurrence rate was 36%. In case of refractory disease, or frequent relapses, a second line was considered with azathioprine, methotrexate, intravenous immunoglobulin or cyclophosphamide. Interestingly, when underlying disease was present, the FM clinical course was often correlated with the associated pathology evolution.

Conclusion: This study provides new clinic-pathological features to define FM. Despite of the classic view of a seldom painful and spontaneously resolving disorder, this work suggests that FM can be a serious disease and require active treatment. Moreover, these results suggest that FM patients should receive IMID and neoplasia screening.

The Predictive Risk Factors for Complication of Infection during the Treatment for Inflammatory Myopathies Complicated with Interstitial Lung Disease

Session Date: Tuesday, November 15, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is one of the predominant causes of death in polymyositis/dermatomyositis (PM/DM). We have already reported that low P_aCO_2 and interstitial lesions in more cranial zone of lungs are independent prognostic factors for ILD associated with PM/DM (PM/DM-ILD), and the most common causes of death in early stage are respiratory failure and infection. Here we investigated the predictive factors for complication of infection during treatment for PM/DM-ILD.

Methods: We retrospectively analyzed clinical features, laboratory and high-resolution computed tomography (HRCT) findings at baseline, initial therapeutic regimens, clinical outcomes, and episode of serious infection of patients with PM/DM-ILD who had received initial treatment at the two hospitals belonging

to Yokohama City University from 1993 to 2015. The lungs were horizontally divided into 4 zones (Zone A to D from more cranial area) in HRCT, and severity of ILD lesions were evaluated in each zone.
We conducted univariate and multivariate analyses to extract risk factors for death and infection.

Results: One hundred six patients (PM 19, DM 49, clinically amyopathic DM (CADM) 38) were recruited. The mean age was 55 +/- 14 years, and 77 (73%) were female. As initial therapies, oral prednisolone (PSL) was prescribed in all patients. Methylprednisolone (mPSL) pulse, intravenous cyclophosphamide (IVCY), and oral calcineurin inhibitor therapies were performed in 77 (73%), 43 (41%) and 73 (69%), respectively. Thirty-seven (35%) received combination therapy with IVCY and a calcineurin inhibitor. Forty patients (38%) had a total of 54 events of serious infection at 40 +/- 26 days from initiation of immunosuppressants. The foci of infection were seen most commonly in lung
(bacterial pneumonia 19, pulmonary suppuration 2, pneumocystis pneumonia 9, CMV infection 15, and the others 9). Lower serum albumin level ($p = 0.01$), higher serum CRP, LDH, KL-6 levels ($p = 0.01$, $p = 0.001$, $p = 0.01$, respectively), high initial dose of PSL ($p = 0.01$), mPSL pulse ($p = 0.02$), IVCY ($p <$
0.001), and combined immunosuppressants ($p = 0.04$) were extracted as risk factors for infection by univariate analyses (Table 1). There was no significant relation between severity of ILD and infection. A multivariate logistic regression analyses revealed that the high initial dosage of PSL ($p = 0.003$, hazard ratio 6.21) and higher serum LDH level ($p = 0.017$, hazard ratio 4.08) were independent risk factors for infection. Of 11 patients, who died within 6 months, four (36%) were died of infection.

Conclusion: Although rapid and intensive therapies are required for PM/DM-associated ILD, appropriate monitoring, prophylaxis and early treatment for infection are important, especially in patients who received high-dose of initial glucocorticoid and showed higher serum LDH level.

Table 1. Demographic, clinical, and laboratory features of 106 patients with PM/DM-ILD

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyositis (PM)/dermatomyositis (DM) is a chronic inflammatory disorder that affects muscle, skin and lung in various degree, and interstitial lung disease (ILD) is a major cause of death. In clinical setting, it is necessary to predict future clinical manifestations and outcomes accurately before initiation of treatment. In this study, we examined initial predictors of poor survival in patients with PM/DM-associated ILD.

Methods: This study used a database of a multicenter retrospective cohort of Japanese patients with PM/DM-associated ILD (JAMI cohort), which involved 44 institutions across Japan. Inclusion criteria of the JAMI cohort were adult-onset, definite or probable PM/DM including clinically amyopathic DM (CADM), ILD confirmed by imaging study, and availability of sera at diagnosis. Demographic features, diagnosis, clinical features, laboratory findings, high-resolution CT patterns and treatment regimens used were retrospectively collected. Serum samples were subjected to autoantibody assays; enzyme-linked immunosorbent assay for anti-melanoma differentiation-associated gene 5 (MDA5) and RNA immunoprecipitation for anti-aminoacyl-tRNA synthetase (ARS). Cumulative survival rates were calculated using the Kaplan-Meier method and equality of survival curves was tested by the Breslow test. The best model for predicting survival was searched using multivariate analysis using step-wise selection of parameters and the Cox proportional hazards regression model.

Results: This study enrolled 497 patients, including 76 (15%) with PM, 158 (32%) with classic DM, 263 (53%) with CADM (median observation period: 20 months, IQR 5-43). Autoantibody analysis revealed 209 (42%) positive for anti-MDA5 and 166 (34%) positive for anti-ARS antibodies. By univariate analysis, age at onset (>60 years), male, CADM, fever, Raynaud phenomenon, absence of muscle weakness, skin ulceration, CRP (>1 mg/dL), CK (<750 IU/L), aldolase (<17.5 IU/L), SP-D (<100 ng/mL), ferritin (>500 ng/mL), random GGA pattern on CT, SpO_2 (<95%), positive anti-MDA5, and negative anti-ARS were identified as initial parameters associated with subsequent mortality. By testing various combinations of parameters selected by univariate analysis, we propose a model consisting of independent predictors of poor survival rates (**Figure**). In terms of treatment regimens introduced, use of calcineurin inhibitors was associated with better survival rates while corticosteroid pulse therapy and intravenous immunoglobulin were associated with poor outcomes.

Conclusion: Using a large cohort of well-defined patient population, we have successfully identified independent predictors of short-term mortality in patients with PM/DM-associated ILD.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: An association between cancer and dermatomyositis (DM), referred to as cancer-associated myositis, is well recognized and clinically important. The overall cancer risk is up to 25-30% among DM patients. The high frequency of malignancies detected close to DM diagnosis suggests that DM can be a paraneoplastic syndrome, and cancer within three years of DM diagnosis is often defined as cancer associated myositis (CAM). The absence of a biomarker for CAM leads to a thorough screening for cancer in patients diagnosed with DM. Recently anti-TIF1-gamma has been discovered to be associated with cancer and DM. A meta-analysis claimed pooled sensitivity of anti-TIF1-gamma for diagnosing cancer-associated DM to be 78% (95% CI 45–94%), and specificity to be 89% (95% CI 82–93%). Thus anti-TIF1-gamma has shown promising results as a marker for CAM. However, none of the studies evaluated anti-TIF1-gamma association with cancer with or without other paraneoplastic rheumatic syndrome than DM. To clarify the specificity of anti-TIF1-gamma antibodies as a biomarker for CAM we analyzed the frequency of anti-TIF1-gamma antibodies in other cancer associated inflammatory rheumatic syndromes as well as in cancer patients and healthy controls.

Methods: Sera from patients with paraneoplastic rheumatic syndrome (n=91) (arthritis n=39, Raynaud´s n=23, other n=29) , patients with solid cancer (n=95) and healthy controls (n=80) were analyzed for the frequency of anti-TIF1-gamma IgG by ELISA using a commercially available recombinant TIF1-gamma protein as coating antigen. The cut-off value was calculated by adding 2SD to the mean OD value of 80 healthy controls.

Results: Positivity for anti-TIF1-gamma IgG was 3,3% (n=3) in patients with paraneoplastic rheumatic syndrome, 3,1% (n=3) in cancer patients and 1,3% (n=1) in healthy controls. There was no significant difference in positivity between the groups (p>0,05). Sensitivity and specificity for diagnosing cancer were 3,2% and 98,7%, and for paraneoplastic rheumatic syndromes, 3,3% and 96,84% respectively.

Conclusion: AntiTIF1-gamma antibodies are rarely present in patients with solid cancers or paraneoplastic rheumatic syndromes. This finding strengthens the approach to use anti-TIF1-gamma IgG as marker for cancer-associated DM.

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Research has indicated that cardiovascular disease is the leading cause of death in the Idiopathic Inflammatory Myopathies (IIM). Only a small number of studies have investigated the burden of cardiovascular morbidity in patients with myositis in comparison to a healthy population. Arterial stiffness, a strong predictor of cardiovascular risk, can be non-invasively quantified via the Reactive Hyperaemia Index (RHI) and the Augmentation Index (AI), unadjusted and adjusted to 75 beats per minute. A reduced RHI and a raised AI is indicative of endothelial dysfunction and increased arterial stiffness. The aim of this study was to characterise the presence of cardiovascular risk factors in an IIM population in comparison to a healthy population.

Methods: Adults with a verified IIM diagnosis were recruited. A healthy matched control cohort was also recruited. The following investigations were carried out on each patient on the same day: tobacco use assessment, brain natriuretic peptide (BNP) measurement, body composition analysis, blood pressure measurement, measurement of fasting cholesterol, triglyceride, C-reactive protein (CRP), insulin and glucose concentrations, carotid artery intima-medial thickness (CIMT) and plaque identification via ultrasound, ejection fraction measurement and valve dysfunction identification via echocardiography. Radial artery stiffness (RHI and AI) was quantified non-invasively using the endoPAT system. Ten year cardiovascular disease (CVD) risk was calculated for each patient via QRISK2. Continuous variables were compared between the two groups with the Mann-Whitney U test and categorical variables were compared with the Chi-squared test.

Results: Nineteen IIM patients with confirmed disease according to the Bohan and Peter criteria and 20 healthy controls were recruited (Table 1). A higher proportion of the IIM cases were female and were slightly younger. AI (unadjusted and adjusted to 75 bpm) was higher for the IIM cases and RHI did not differ. Previous tobacco use was similar between the two groups. Median lean fat mass and total body water was lower in the IIM cases and body mass index (BMI) was raised. Cholesterol, insulin, CRP, glucose and triglyceride measurements did not vary between the two groups. Median haemodynamic measurements (BNP, SBP, DBP, ejection fraction), CIMT and the number of identified carotid plaques and heart valve abnormalities were similar in each group. Ten year CVD risk was similar between each group.

Conclusion: This study indicates that arterial stiffness (measured as AI), a strong indicator of cardiovascular risk, is increased in IIM patients. Further, IIM is associated with increased BMI and variations in body composition. Cardiac function, atherosclerosis burden, 10 year CVD risk, cholesterol profile and insulin resistance is similar in IIM cases and controls. A further study of the cardiovascular manifestations in a larger IIM cohort is warranted.

Table 1 - Comparison of demographic and cardiovascular variables between IIM cases and controls			
	Cases n = 19	**Controls n = 20**	**p-value**
No. female (%)	15 (79)	9 (45)	0.09
Median age/years (IQR)	39 (34, 49)	42 (33, 47)	0.92
Median alcohol intake/units per week (IQR)	0 (0, 2)	3 (1, 16)	<0.01
No. current smokers (%)	5 (26)	6 (30)	1.00
Median smoking pack years (IQR)	1 (0, 7)	1 (0, 7)	0.94
Median BNP/pg/ml (IQR)	67 (50, 90)	53 (23, 91)	0.19
Median EF percentage (IQR)	58 (55, 64)	61 (59, 66)	0.17
No. with a valvular abnormality (%)	9 (47)	7 (35)	0.63
Median systolic blood pressure/mmHg (IQR)	135 (113, 144)	120 (112, 133)	0.16
Median diastolic blood pressure/mmHg (IQR)	77 (69, 83)	74 (69, 78)	0.50
Median CIMT/mm (IQR)	0.06 (0.05, 0.06)	0.06 (0.05, 0.06)	0.93
No. with plaque present (%)	1 (5)	2 (10)	1.00
Median RHI (IQR)	2.1 (1.7, 2.6)	2.1 (1.9, 2.6)	0.63
Median AI (IQR)	16.0 (-4.8, 24.0)	6 (-5.5, 14.0)	0.22
Median AI @ 75bpm (IQR)	6.5 (-10.8, 20.5)	-1.0 (-8.5, 9.5)	0.14
Median body fat % (IQR)	36.2 (27.6, 44.6)	32.4 (26.0, 36.6)	0.29
Median lean fat mass/Kg (IQR)	44.8 (42.4, 51.9)	55.4 (46.2, 61.6)	0.06
Median total body water/Kg (IQR)	33.8 (31.8, 38.6)	40.6 (33.8, 45.1)	0.13
Median body water % (IQR)	46.7 (40.5, 53.1)	49.4 (46.0, 54.1)	0.18
Median BMR/Kcal (IQR)	1432 (1330, 1690)	1707 (1440, 1871)	0.11
Median whole body impedance/Ω (IQR)	637 (584, 746)	611 (551, 678)	0.37
Median BMI/Kg/m^2 (IQR)	29.6 (23.3, 33.1)	25.8 (25.1, 31.4)	0.64
Median fasting insulin/mU/L (IQR)	6.4 (4.2, 11.3)	7.5 (5.2, 11)	0.88
Median fasting glucose/mmol/L (IQR)	4.7 (4.2, 5)	4.8 (4.5, 5)	0.62
Median total cholesterol/mmol/L (IQR)	5.1 (4.3, 5.4)	4.9 (4.3, 5.5)	0.78
Median triglyceride/mmol/L	1.2 (0.9, 1.8)	1 (0.7, 1.8)	0.37
Median HDL/mmol/L (IQR)	1.5 (1.1, 1.8)	1.4 (1.2, 1.6)	0.88
Median LDL/mmol/L	2.9 (2.4, 3.3)	2.8 (2.5, 3.3)	0.94
Median cholesterol:HDL ratio (IQR)	3.4 (3.0, 4.8)	3.3 (2.7, 4.1)	0.65
No. raised cholesterol:HDL ratio (%)	7 (37)	7 (35)	0.73
Median CRP/mg/L (IQR)	1.4 (0.5, 4.5)	1.2 (0.8, 2.2)	0.12
Mean 10 Year CVD risk percentage (SD)	4.7 (5.4)	4.2 (4.5)	0.76

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-Mi2 autoantibodies (Aabs) have been proposed to be highly specific for dermatomyositis (DM) and to be associated with a DM classical phenotype consisting of typical skin rashes and low extra-muscular features. Cancer has been estimated in about 30% of all DM patients. Patients with anti-Mi2 DM are considered having a good prognosis, possibly related to a markedly lower risk of malignancy reported in this subset. Nonetheless, there has been only a few and small cohort descriptions of this DM subgroup. Our objective was therefore to describe the phenotype of anti-Mi-2 DM in a large French cohort.

Methods: A national multicenter retrospective cohort study was performed (15 medical centers) including all patients with a clinical phenotype suggestive of DM (cutaneous manifestations and/or muscle involvement) and a positive anti-Mi2 Aabs. Medical records were retrospectively reviewed. Muscle strength was assessed using the Medical Research Council (MRC) scale and cancer-associated myositis (CAM) was defined as a cancer occurring ± 3 years of diagnosing myositis.

Results: A total of 65 patients were identified, 62% were female and mean age at diagnosis was 54 years old (yo) (±17 yo). DM skin rash was reported in 88% of patients, most frequently Gottron papules and/or sign (68%), periungueal erythema (51%) and heliotrope rash (40%). Peripheral muscle weakness was reported in 92% of patients and dysphagia was reported in 34% of patients. At diagnosis, patients displayed severe muscle weakness

(MRC 3/5, ±1/5*)* with mean CK level of 5085 UI/L (±5535 UI/L). Systematic review of muscle biopsies (n=11) showed marked inflammatory infiltrates. Strikingly, necrosis and regeneration were identified in all patients (n=11/11). C5b-9 deposition was found in all patients mainly on non-necrotic fibers but only sparsely on capillaries and without prominent capillary loss. Arthritis, Raynaud phenomenon and interstitial lung disease were reported in less than 20 % of patients**.** CAM was identified in 20% of patients and detected within one year and a half of DM diagnosis in most patients (n=11/12). All CAM patients, but one (38 yo), were diagnosed over 50 yo. There was no predominant histological subtype of malignancy (gastro-intestinal, urological, gynecological and pulmonary) and cancer was metastatic in a third of patients. Survival rate was 83% after a mean follow-up of 4.9 years from cancer diagnosis. Ninety-eight percent of patients were initially treated with corticosteroids (CS), in combination with immunosuppressant (IS) in 60% of cases. Patients treated with CS monotherapy (n=14), needed second-line agents upon follow-up in 60% of cases. In all, 53% of patients relapsed upon CS and/or IS tapering.

Conclusion: In this large French cohort, patients with anti-Mi2 DM displayed a phenotype with 3 main characteristics (i) pure DM phenotype (low overlap features) (ii) necrotizing myositis (severe weakness, high CK level and muscle fiber necrosis) and (iii) higher than expected malignancy rate.

Session Date: Tuesday, November 15, 2016

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical research is dependent on being able to recruit and enroll appropriate patients in sufficient numbers to make robust conclusions. For many diseases it can be difficult to obtain satisfactory numbers of participants, which can impact the quality of research performed. Investigators have used a variety of

advertising methods to reach potential participants for research studies. Advertising through new technology platforms offers many advantages over other types of study advertising, particularly for rare diseases. By using these platforms, very specific groups of individuals can be targeted, thus increasing the probability that a person who sees a notice for a study has the disease being investigated. The idiopathic inflammatory myopathies are a group of rare muscle disorders and we performed advertising campaigns using Facebook and Google advertising platforms for these diseases in an attempt to evaluate their relative characteristics and effectiveness.

Methods: IRB approval was obtained to use Facebook and Google advertising platforms for four NIH non-interventional studies attempting to enroll patients with juvenile or adult dermatomyositis, polymyositis, or inclusion body myositis. Targeted words and ad criteria were developed in conjunction with experts from each platform. Similar terms and criteria were picked for each platform. The advertising ran on Google from October 9th to November 18th 2015 and on Facebook from September 30th 2015 to February 17th 2016.

Results: Google ads had 1,285,733 views and Facebook ads had 335,941 views. In total, 0.54% of impressions on Google and 2.29% of impressions on Facebook led to a click of the advertisement. Google averaged about 80 cents a click and Facebook averaged 30 cents a click. Each site also collected additional advertising data about the population reached. On the Google platform 17 search terms led to 10 or more individuals clicking the advertisement and they were not the 17 terms with the highest number of impressions. With a list of 49 keywords there were 1110 distinct search terms used by end users that led to our advertisement being displayed. Facebook ads reached 191,098 individual people. The majority of individuals reached were female (175,914 female, 336 male, 127 unknown) and between the ages of 45-64 years (63% of the clicks and 55% of views). The vast majority of individuals seeing the Facebook ad did so on a mobile news feed (98% of all clicks and 97% of all views) with the rest viewing the ad on their desktop feed, third party mobile application or website, or desktop right hand column in order of frequency for views and clicks. Of the mobile devices used to access the content, 40% of clicks were on an android smartphone, 36% on an iPhone, 15% on an iPad, and 4% on an Android tablet.

Conclusion: Both Google and Facebook advertising platforms were able to reach a large audience of potential study participants for a rare disease. Each platform collects its own type of user data and differs in how ads can be targeted. Overall, Facebook was cheaper per a click, led to more absolute clicks, and had a higher percentage of individuals who saw the ad click it.

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Statin-induced autoimmune myopathy (SI-AIM) is often difficult to treat. While corticosteroids (CSs) are the mainstay induction therapy used by most clinicians for autoimmune myopathies, SI-AIM seems corticosteroid resistant. Intravenous immune globulin (IVIG) on the other hand has been used with success as part of an induction regimen or even as monotherapy (Mammen AL, NEJM, 2015). Our objective was to describe the clinical phenotype and successful treatment regimens of patients with SI-AIM but not treated with CSs.

Methods: Our study included all patients from the Université de Montréal AIM cohort (comprising four academic hospitals) with a documented anti-3-hydroxy-3-methylglutaryl-CoA reductase (anti-HMGCR) autoantibody. We selected statin-exposed patients who did not receive any CSs during the course of their treatment and performed a retrospective review of medical records. Remission was defined as a serum creatine kinase (CK) level <500 U/L whereas maintenance of remission corresponded to a CK level <500 U/L sustained for at least 6 months.

Results: From a cohort of 45 anti-HMGCR positive AIM patients, 42 were previously exposed to statins, of whom 8 patients (4 men, 4 women, mean age 59 years) were not treated with CSs and therefore selected for study. Three clinical stages of myopathy were recognized: stage 1 (serum CK elevation, normal muscle strength, normal EMG), stage 2 (CK elevation, normal strength, myopathic EMG) and stage 3 myopathy (CK elevation, proximal muscle weakness, myopathic EMG). Three out of 8 patients presented and were treated in stage 1 myopathy after a mean statin discontinuation time of 23 months (range 5-74 months). The remaining 5/8 patients presented in stage 3 myopathy. The mean time between statin cessation and treatment initiation was 5 months (range 0-10 months), with one patient improving to stage 2 myopathy upon statin discontinuation. MTX monotherapy induced remission in all 3 patients presenting in stage 1 myopathy and in 1 patient in stage 2 myopathy. The mean time to remission was 7 months (range 4-13 months). In the remaining 4 patients with stage 3 myopathy, IVIG was successfully used in 3 patients to induce remission with either MTX or MTX+AZA, whereas 1 patient responded to a MTX+AZA combination alone. The mean time to remission for stage 3 myopathy was 10 months (range 1-21 months). MTX monotherapy (n=5/6) or a MTX+AZA combination (n=1) were able to maintain remission in the 6 patients available for analysis. Thus, all 8 patients did not require CSs to achieve remission.

Conclusion: Eight patients with SI-AIM were successfully treated with immunosuppressive and/or immunomodulating agents but not with CSs. Four patients with normal strength (i.e. in stage 1 or 2) responded to MTX monotherapy. In patients with proximal muscle weakness, combination therapies with MTX+IVIG, MTX+AZA or MTX+AZA+IVIG were successfully used and thus, these approaches appear reasonable induction strategies in stage 3. Early recognition of stage 1 SI-AIM and timely treatment initiation could minimize the use of IVIG and CS therapies and consequently lead to better outcomes in these patients.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: in patients with active myositis, magnetic resonance imaging (MRI) often demonstrates muscle edema thought to represent active inflammation. An MRI-based muscle inflammatory scoring system has been validated for juvenile myositis (Rheumatology 2011; 50:2237), but to the best of our knowledge there is no such a scoring system for adult myositis. We aimed to validate an MRI-based edema score for patients with adult myositis.

Methods: twenty-one patients (9 polymyositis [PM], 12 dermatomyositis diagnosed according to Bohan and Peter criteria) were included in the study. In 8/9 patients with PM the diagnosis was confirmed by consistent histology. MRI of the thigh and pelvic floor muscles was performed on a 1.0 or 1.5T scanner using a surface coil. Edema (1= present, 0= absent) was assessed by fat-suppressed sequences in 17 thigh and pelvic floor muscles and a score (0-17) was calculated by adding the separate muscle scores by three blinded independent observers. Sensitivity to change was assessed by sign test. Muscle strength was evaluated in 12 muscle groups by manual muscle test (MMT) and graded according to the extended Medical Research Council scale (0-5). Serum creatine kinase (CK) levels were measured (U/l) and MMT performed simultaneously or within a week from the MRI study in each patient.

Results: 38 MRI scans were available from 21 patients. 10 patients had new onset of myositis. Two patients had 4 scans, 1 had 3 scans, 9 had 2 scans, and 9 had 1 scan each. The median MRI edema score was 2.7 and the interquartile range (IQR) 8.96. Inter-rater Cronbach's alpha was 0.984, while single-measure intraclass correlation coefficient (ICC) was 0.954 (95% confidence interval [CI] 0.922-0.974). Bland-Altman's plot showed no significant differences between raters. Two raters evaluated the same MRI exams on 2 different time points to determine intra-rater variability. Cronbach's alpha was 0.903 and 0.921, while single-measure ICC was 0.815 (95% CI 0.667-0.901) and 0.851 (95% CI 0.729-0.921) for rater 1 and 2, respectively. In 7 patients for whom a repeat MRI after treatment onset was available median edema score decreased from a median of 8.83 (IQR 9.18) to 0.71 (IQR 12.3) (p 0.07). MRI edema score did not correlate with serum CK levels (median 384, IQR 1317) or MMT (median 4.39, IQR 0.45) ($p>0.05$ Spearman's rho).

Conclusion: the MRI edema score presented herein is highly reproducible with good inter- and intra-rater variability and appears to be sensitive to change. The significant lack of correlation of MRI edema score with serum CK levels and MMT suggests that these measures of myositis activity may be at least partially uncoupled, suggesting that MRI score adds information on disease activity above the CK and MMT, although the small sample size hampers a confident conclusion in this regard.

Session Date: Tuesday, November 15, 2016

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The identification of myositis specific and associated autoantibodies occurring in idiopathic inflammatory myopathies (IIMs) has improved classification and prognosis determinations. With commercial availability, these autoantibodies are being ordered outside of the research setting in routine clinical practice. While these autoantibodies are reported to occur in approximately 30% of IIMs, real world positivity rates and ordering patterns have not been described. We aimed to determine the positivity rate within our tertiary health system, and the proportional ordering of the myositis panel between specialists.

Methods: We included all Duke University Health System patients who had a myositis autoantibody panel (including anti-Jo-1, PL-7, PL-12, EJ, OJ, Mi-2, SRP, PM/Scl, Ku and U2-snRNP) ordered between October 2014 and December 2015. We recorded specific autoantibody positivity for the institution and by ordering specialty. Ordering provider was classified as either adult or pediatric and grouped by provider specialty. Specialty groups included pulmonary, rheumatology, neurology, dermatology, cardiovascular, emergency medicine and general medicine.

Results: Out of 378 myositis antibody panels ordered, 79 (20.9%) returned positive (Table). Overall, 59% of positive tests were myositis specific autoantibodies. Among positive tests, anti-synthetase antibodies were the most common (29.1%) followed by anti-Mi-2 (27.8%). Of the 5 assayed, only 3 anti-synthetase antibodies were detected in this population, anti-Jo-1, anti-PL-7, and anti-PL-12. Combined, adult pulmonary, rheumatology and neurology ordered 85.7% of the antibody panels; adult pulmonary ordered the most tests (242; 64%). Positivity rates were 50% for adult cardiovascular and general pediatrics (4 panels ordered), followed by adult

rheumatology (31.7%; 13 tests). Six patients were positive for two different antibodies; anti-Mi-2 occurred in 4 of the 6. The panel was performed twice in 4 patients; in 1 patient, an initially negative panel later found anti-U2-snRNP.

Conclusion: This is the first study to determine the positivity rate of the myositis antibody panel in real-world use in a tertiary referral center. Within our multi-specialty practice, the majority of testing was performed by adult pulmonary, followed by rheumatology and neurology. Our results may reflect the presence of an active interstitial lung disease clinic. Of interest, anti-Jo-1 had a nearly equal prevalence to the other anti-synthetase antibodies in this population. Both anti-Mi-2 and anti-Ku antibodies were seen across the majority of ordering specialties, while the anti-PM/Scl antibody was primarily found by pulmonology. Overall, our test positivity rates were similar to prior reports in disease-specific populations. Further characterization of this cohort will help guide future use of this testing.

Table. Positive myositis antibody tests by provider group and autoantibody. In total, 47 MSAs were positive and 32 MAAs were positive. *Anti-synthetase antibodies.

Abstract Number: 2319

High Prevalence of Asymptomatic Vertebral Fractures in Inflammatory Myositis

Latika Gupta, Sukesh Edavalath, Ramnath Misra and Able Lawrence, Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with inflammatory myositis have increased prevalence of symptomatic fractures. Early detection of asymptomatic vertebral fractures may help in their prevention. We studied the frequency of asymptomatic vertebral fracture and its risk factors in inflammatory myositis.

Methods: Adults with inflammatory myositis were included and dorsal and lumbar spine lateral radiographs were taken. The scoring was done using Genant's semi-quantitative method. Besides demographic data, weight, height, postmenopausal status, duration of corticosteroid use, anticonvulsants, calcium supplements, and other co-morbidities like diabetes or hypothyroidism and past history of non-vertebral fracture were recorded. Bone mineral density was done using DEXA. Myositis Damage Index (MDI) was also assessed. All results are expressed in median and IQR.

Results: 100 patients (82 females) with myositis of age 35.5 (28.5-46) years and disease duration 3 (1.81-8.0) years were studied. Twenty patients were postmenopausal women. 35 patients had adult dermatomyositis (DM), 26 each had polymyositis and 26 connective tissue disease associated myositis and 13 had juvenile onset myositis. Forty-six patients had asymptomatic vertebral fractures. 19 patients had more than one fracture. Half the fractures occurred in those with disease <5 years. Of the 69 fractures, 47 (68.1%) were mild, 16 (23.2%) were moderate and 6 (8.7%) were severe. 11^{th} and 12^{th} thoracic vertebrae were most commonly affected. Of the 67 patients who underwent BMD assessment, 62.7% were osteopenic and 26.9% were osteoporotic. T scores of DEXA scan at the lower third of the radius correlated negatively with fracture number (r=-0.27 (-0.50 to -0.005), p=0.04). Gender, age, duration of disease, intake of corticosteroid or calcium, BMI, menopausal status, or MDI had no correlation with number of fractures.

Conclusion: Patients with inflammatory myositis have high prevalance of asymptomatic vertebral fractures.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Oropharyngeal dysphagia (OPD) is an ominous finding in autoimmune myositis (AIM), yet few studies have evaluated the disease subsets at higher risk for this life-threatening complication. Recent AIM classifications have identified three dominant entities: pure dermatomyositis (DM), necrotizing autoimmune myositis (NAM), and overlap myositis (OM). Pure polymyositis (PM) is uncommon and is an exclusion diagnosis. The aim of the present study was to describe, in relation to DM, NAM and OM, the clinical and laboratory characteristics associated with OPD.

Methods: A retrospective cohort of patients diagnosed with AIM between January 2001 and January 2016 was identified in two academic hospitals affiliated with the University of Montreal. All patients with objective OPD, defined by an abnormal videofluoroscopy swallow study (VFSS) and/or the need for percutaneous gastrojejunostomy (PGJ), were included. Severe dysphagia was defined as aspiration visualized on VFSS and/or the need for PGJ and/or aspiration pneumonia. The associations between OPD and various characteristics, including diagnostic subsets of AIM, clinical and laboratory features, and the presence of cancer within 3 years of AIM diagnosis, were examined.

Results: Within the total cohort of 180 patients with a diagnosis of AIM, the main subset was OM (n=94, 52.2%) and the other subsets were distributed as follows: 46 pure DM, 37 NAM, and 3 PM. Objective OPD was present in 26 patients (14.4%). An abnormal VFSS was documented in 25 patients and 9 patients had a PGJ. For this dysphagic cohort, the mean age (+/-SD) was 62.9 (+/- 10.7) years and 61.5% were women. The main diagnostic subset was pure DM (n=12, 44.4%), while 6 patients had NAM, and 8 had OM. Among the 8 OM patients, 6 had concomitant distal oesophageal dilatation on chest CT, 5 of which had scleroderma features. Each of the DM-specific autoantibodies (aAbs) (TIF, NXP2, Mi-2 and SAE) was represented among the pure DM patients, while HMGCR and SRP aAbs were only found in NAM. In OM, only one patient had Jo-1 aAbs, while RNA polymerase III, PM-Scl and U1RNP aAbs were also seen. Cancer was found in 24/180 patients and was more prevalent among the dysphagic (n=10/26, 38.5%) compared to the non-dysphagic patients (n=14/154, 9.1%) (p=0.0005). Dysphagic patients in the DM subset showed the highest rate of cancer (n=8, 66.7%). Severe OPD was identified in 11/26 patients. Six of them had DM, all with an associated cancer. Severe dysphagia was also present in 3 NAM and 3 OM. OPD was treated with methylprednisolone pulses as induction therapy in 15 patients, and IVIG in 21. Evolution of OPD was generally favorable, and complete remission was seen in 17 patients (65.4%). However, in the subset of cancer-associated pure DM, only 2 patients (25%) had resolution of OPD. Overall, 6 patients with

OPD died, of which 3 had pure DM associated with cancer.

Conclusion: Our study demonstrates that pure DM is the dominant AIM subset associated with objective OPD. Cancer is significantly more prevalent among the dysphagic patients, specifically in the pure DM subset. Based on this evidence, clinicians are urged to aggressively investigate pure DM patients with OPD for evidence of cancer.

Session Date: Tuesday, November 15, 2016

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

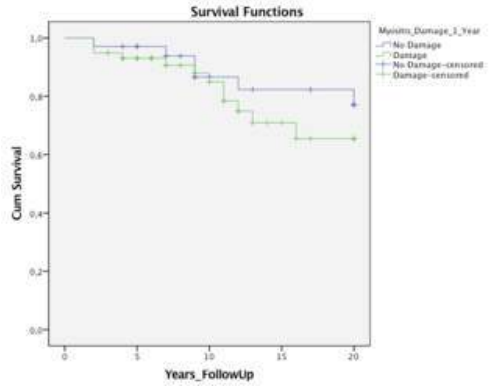
Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of rare diseases, including dermatomyositis (DM), polymyositis (PM) and juvenile dermatomyositis (JDM). Patients often need long-term treatment with corticosteroids and immunosupressive drugs, as full remission is uncommon. A method to evaluate damage accrual in these patients has been previously developed[1] and our aim was to determine if early damage in the course of the disease is predictive of mortality.

Methods : We reviewed the clinical records of 92 patients with IIM (Bohan and Peter criteria) with at least 2 years of follow up. JDM patients diagnosed before the age of 16 were excluded. The patients were evaluated according to gender, ethnicity, age at diagnosis, use of corticosteroids and immunosupressive therapy and time of follow-up. Damage captured by the Myositis Damage Index (MDI) was assessed 1 year post-diagnosis and for those who died within 20 years of diagnosis, the year and cause of death were also determined. Time to death was analysed using Cox regression and Kaplan-Meier, and patients who were lost to follow up were censored at the time of the last observation.

Results : Sixty-seven patients were female (72.8%), the mean age at diagnosis was 41.6 years (95% CI 38.5-43.81) and the mean time of follow up was 13.54 years (95% CI 11.65-15.43). Sixty-three per cent of patients were White, 22.8% Afro-Caribbean, 13% South Asian and 1.1% Black. Thirty-eight per cent had DM, 32.6% PM,

26.1% overlap syndrome and 3.3% JDM. For every 1 point increase in the MDI score at 1 year post-diagnosis, the patient was 1.486 time more likely to die; HR 1.486 (95% CI 1.096-2.016; $P = 0.011$). A Kaplan-Meier survival curve between patients with no damage (MDI score = 0) and with damage (MDI score >/= 1) also showed a difference between the 2 groups, but it was not statistically significant (graph 1).

Graph 1: Kaplan-Meier Curve with Time to Death in Damage vs No Damage at 1 Year Post-Diagnosis



The type of damage in each group is described in table 1.

Table 1 – Damage by Assessed Group

MDI Manifestations (%)	Alive (n = 74)	Dead (n = 18)
Muscular	45.9	50
Skeletal	1.4	5.6
Cutaneous	9.5	11.1
Gastrointestinal	1.4	5.6
Pulmonary	17.6	44.4
Cardiovascular	6.8	11.1
Peripheral Vascular	0	11.1
Endocrine	5.4	11.1
Ocular	0	0
Malignancy	0	5.6

Conclusion : Early damage in the course of IIM is associated with increased mortality up to 20 years after diagnosis. Further studies are necessary to establish the factors which contribute the most to this early damage.

The Clinical Significance of Curvilinear Bodies on Ultrastructural Examination of Muscle

Thomas Khoo[1], Sophia Otto[2], Barbara Koszyka[2], Caroline Smith[2], Peter Blumbergs[3], Sue Lester[4] and **Vidya Limaye**[5], [1]Medical Student, University of Adelaide, Adelaide, Australia, [2]Anatomical Pathology, SA Pathology, Adelaide, Australia, [3]Pathology, University of Adelaide, Adelaide, Australia, [4]Rheumatology, The Queen Elizabeth Hospital, Adelaide, Australia, [5]Rheumatology, Royal Adelaide Hospital, Adelaide, Australia
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) therapy for autoimmune disease may be associated with detection of curvilinear bodies (CB) on ultrastructural examination of muscle. Whilst ocular toxicity is related to cumulative HCQ dose, the clinical significance of CB is uncertain and whether their detection reflects dose-dependent toxicity is not known.

Methods: The electronic database of muscle biopsies reported in the Anatomical Pathology Laboratory, SA Pathology was searched from 2006 to the present, to identify biopsies with CB. The clinical features of these patients, including body mass index and cumulative HCQ dose were recorded. A control group of 16 patients with biopsy-proven idiopathic inflammatory myositis (IIM) who were on HCQ at the time of biopsy but who did not have histopathological evidence of CB was identified from the South Australian Myositis Database.

Results: 19 patients with CB on ultrastructural examination of muscle were identified; details were available for 18. Among patients with CB, 7/18 also had IIM. 7/10 of patients with CB who did not have IIM or MHC1/11 expression had documented proximal weakness, 7/11 had raised serum creatinine kinase (CK) levels. There was no difference in body weight (p=0.47), body mass index (p=0.93), cumulative HCQ dose (p=0.52) or cumulative dose adjusted for body weight (p=0.39) or body-mass index (p=0.32) between patients with CB and controls. Patients with CB had lower median CK levels than controls (p=0.034). Weakness was present in 12/17 patients and 12/16 controls (p=1.0). Concurrent proton-pump inhibitors were co-prescribed in 12/18 (67%) patients with CB and in 6/16 (38%) controls (p=0.17).

Conclusion: In contrast with HCQ-induced ocular toxicity, the development of CB does not appear to be related to cumulative HCQ dose or body weight. Patients with CB frequently have muscle weakness even in the absence of MHC1 expression suggesting a role for non-immune mechanisms of muscle injury. A high proportion of patients with CB are co-prescribed proton pump inhibitors raising the possibility that co-prescription of both agents may disrupt lysosomal function and adversely affect muscle function.

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In order to enable meaningful clinical care and research, accurate algorithms are needed to identify patients with dermatomyositis (DM). In this study, we aimed to evaluate DM case-finding algorithms in a large health administrative database.

Methods: 100 patients were randomly selected from the Vanderbilt Synthetic Derivative, a de-identified version of the medical record, using the International Classification of Diseases version 9 (ICD9) code for DM: 710.3. We developed 13 algorithms using combinations of frequency of ICD9 code, clinic encounter (defined as two ICD9 codes at least three months apart in one year), provider specialty (Rheumatology, Neurology, or Dermatology), use of immunosuppressant medications (prednisone alone or other immunosuppressants), Current Procedural Terminology code (for electromyogram or skin or muscle biopsy), and creatine kinase level over 600 IU/L. Diagnosis was confirmed by manual review of the de-identified chart using documented diagnosis of DM or DM sine myositis by rheumatologist, dermatologist, or neurologist as the gold standard. Age, ANA status, chart length, and number and type of Bohan and Peter (B&P) criteria were extracted from each chart. Patients with DM sine myositis or incomplete medical records were excluded from analysis of test characteristics with B&P criteria.

Results: Of the 100 patients reviewed, sixty-four were diagnosed as having DM by provider documentation and forty met threshold for diagnosis of as least "possible" DM by B&P criteria. Table 1 shows the algorithm characteristics, including positive predictive value (PPV), cohort sensitivity, and specificity in both subsets of patients. Table 2 shows characteristics of DM patients found with the algorithms. An algorithm of clinic encounter and prednisone dose of at least 20mg daily had the highest PPV and specificity in each group (PPV: 95.3, 96.8; specificity: 94.4, 97). Provider specialty and immunosuppressant medications separately had high sensitivity in each group (sensitivity > 95%).

Conclusion: An algorithm of clinic encounter with prednisone dosage of at least 20mg daily had the highest PPV. An algorithm of 3 or more instances of ICD9 code 710.3had well performing test characteristics as well, with cohort sensitivity and positive predictive value. These algorithms can be used to identify cohorts of patients with rare disease in electronic medical records or administrative database and enable further study of outcomes and

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sporadic inclusion body myositis (sIBM) represents a progressive inflammatory muscle disease, which causes severe loss in skeletal muscle mass and strength, especially in the quadriceps muscles. Loss in muscle strength has been reported as high as 15% per year in sIBM patients[1]. The impairment in muscle performance causes reductions in physical function and quality of life, eventually leading to loss of independency. Only few studies have investigated the effects of exercise training in sIBM patients and none have employed a non-exercising control group for reference. Therefore the objective of the present study was to investigate the effect of 12 wks low-intensity blood-flow restricted (BFR) training vs. the natural time course of disease progression on maximal knee extensor muscle strength in sIBM patients.

Methods: The present data are part of a larger randomized controlled trial reported in clinicaltrials.gov database (NCT02317094). Twenty-two patients diagnosed with sIBM (4 females, 18 males, 69.0±5.6 years) were tested for maximal unilateral isometric knee extensor muscle strength in both legs (mean of right and left leg is presented), using an isokinetic dynamometer (KinCom; Chattecx Corp., Chattanooga, TN, USA). Following baseline testing participants were randomized to a BFR-training group (BFR, n=11) or to a non-exercising control group (CON, n=11). The BFR group performed unilateral BFR-training for both legs (leg press, knee extension, knee flexion, dorsal flexion & plantar flexion, 3-4 sets per exercise) two times per week for 12 wks. Exercise intensity (training loads) was ~25RM and blood-flow restriction was achieved using an inflatable pneumatic cuff applied at the proximal part of the shank/thigh. Cuff pressure (110 mmHg) was maintained throughout all sets and pauses while released by the cessation of the final set of each exercise, before continuing with the next exercise.

Results: At 12 wks follow-up CON showed a significant reduction in isometric knee extensor strength compared to baseline (-9.1%, p=0.051). In comparison, analyzing patients with satisfactory training compliance (>60%, n=8) BFR showed no change in knee extensor strength (+5.7%, N.S.). Further, a group x time interaction in maximal knee extensor strength was observed from baseline to 12 wks follow-up (p=0.021).

Conclusion: By extrapolating the present data the disease-related rate of loss in knee extensor muscle function in the present sIBM patients (~30% per year) appeared to be much greater than previously reported in old healthy adults (2-4% per year). Notably, maximal knee extensor muscle strength was preserved in response to 12 wks of BFR training, although on the other hand no specific improvements were observed. These findings indicate that BFR-training may have a protective effect on skeletal muscle function in sIBM patients, preventing or delaying the loss in contractile capacity seen with progression of the disease in the present non-exercising control group.

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-HMGCR antibodies represent a characteristic serological feature of statin-exposed and statin-unexposed patients with immune mediated necrotizing myopathy (IMNM). We assessed anti-HMGCR antibodies in patients with suspected IMNM following statin exposure and patients with other autoimmune inflammatory diseases.

Methods: We evaluated the presence of anti-HMGCR autoantibodies in sera samples from 13 statin-exposed patients who were suspected of having IMNM, 38 patients with different inflammatory and autoimmune rheumatic diseases (systemic lupus erythematous, rheumatoid arthritis, ankylosing spondylitis, systemic sclerosis, polymyositis and anti-phospholipid syndrome) and 29 healthy subjects. The autoantibodies were detected by two assays: a new chemiluminescence QUANTA Flash HMGCR kit utilizing BIO-FLASH system, and QUANTA Lite®HMGCR ELISA kit.

Results: Twelve samples from patients with suspicion for IMNM were found positive for anti-HMGCR antibodies by both assays. Only one of the 13 samples that were found positive by QUANTA Flash HMGCR was negative by QUANTA Lite® HMGCR. A very good qualitative agreement was found between these two assays (kappa=0.949; P value < 0.0001; 95% CI, 0.918 - 1.0). A quantitative comparison between QUANTA Flash HMGCR and QUANTA Lite® HMGCR based on the levels of anti-HMGCR antibodies also revealed a strong correlation (Spearman's coefficient 0.846; 95% CI, 0.686 -0.928). In statin-exposed patients, the diagnosis of necrotizing myopathy was proven by muscle biopsy (10 patients underwent biopsy before and 3 patients after the detection of anti HMGCR antibodies). All samples from healthy subjects and from the disease-controlled patient cohort were negative for anti-HMGCR antibodies. Receiver operating characteristic (ROC) analysis for QUANTA Flash and QUANTA Lite® yielded area under the curve values of 0.997 and 1.0 respectively. The sensitivity and

specificity for IMNM were 100% and 100% for ELISA and 100% and 96.3% for CIA resulting in odds ratios of 1593 and 491.2 correspondingly.

Conclusion: The presence of anti-HMGCR antibodies is a useful biomarker of IMNM in statin-exposed patients. There is a good correlation between the two anti-HMGCR antibody assays evaluated in the present study.

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) associated with inflammatory myopathy (IM) has a poor prognosis and requires specific treatments. Intravenous Cyclophosphamide (CYC) is one of the main treatments for moderate to severe ILD in Europe. Recent data suggested that Rituximab (RTX) could also be effective in this context. We thus retrospectively compared the efficacy of CYC followed by classical immunosuppressive treatment (IST) *vs*. RTX in inflammatory myopathy-related ILD.

Methods: Between 2003-15, 43 patients with IM-related ILD were included either at diagnosis or during a relapse. Pulmonary progression was defined in accordance with the American Thoracic Society (ATS), including NYHA stage progression, any severe event related to the ILD, CT-scan worsening and/or pulmonary function test aggravation (FVC > 10% and DLCO > 15% decrease). Serious adverse events were recorded in both groups. Uni- and multivariate statistical analyses were performed using appropriate tests.

Results: Steroids were given to all patients and cumulative doses were similar in both groups. Twenty-eight patients received intravenous CYC (6 monthly pulses [2-12], 700mg/m2), always followed by classical IST, including azathioprine (n = 14) or mycophenolate mofetil (n = 5). Fifteen patients were included in the RTX group and received two pulses initially (1g, D1-D15); infusions were repeated every 6 months (1g, median = 2 times [1-3]). Only six patients (40%) received concomitant classical IST. Median FCV at enrolment was 55% [29-113] in CYC group *vs*. 71% [45-96] in the RTX group (p = 0.01) and median DLCO was 30% [15-66] in CYC group *vs*. 42% [21-88] in RTX group (p = 0.03). After two year, median FVC increased by 38% (p = 0.02) and median DLCO increased by 32% (p = 0.08) in the CYC group as compared to 31% (p = 0.002) and 0% (p = 0.84) in the RTX group, respectively. However, ILD progression occurred in 11 patients (39%) after two years as compared to 2 patients (13%) in the RTX group. Whereas it was similar after 6 months in both groups, the survival without pulmonary progression showed a significant advantage for RTX group at two years (p = 0.023). Multivariate analysis showed that a ≥15% DLCO decrease at six months was the only criterion predicting the pulmonary progression at two years (p = 0.03). Nine patients (32%) had serious adverse events (mostly infectious complications) in CYC group, as compared to one (7%) in the RXT group (p = 0.07).

Conclusion: Patients receiving RTX for IM-related ILD showed a better survival without pulmonary progression than those treated with CYC followed by conventional IST. The difference was more significant during the "maintenance therapy period". RTX seemed also better tolerated than CYC. The place of RTX in this context should thus be reconsidered and validated prospectively.

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: diverse forms of cardiac involvement (CI) have been described in inflammatory myopathies (IM), and is a frequent cause of death in these diseases

Methods: A multicenter retrospective study from the REMICAM registry was performed. All patients were diagnosed with IM according to Bohan and Peter criteria, followed between Jan 1980 and Dec 2014 and classified into 7 different clinical subgroups: primary dermatomyositis (DM), primary polymyositis (PM), juvenile dermatomyositis (JuvM), cancer associated myositis (CAM), overlap myositis (OM), inclusion body myositis (IBM) and necrotizing myositis (NM). CI was defined as the presence of cardiac arrhythmia (EKG +/-Holter), myocarditis and/or pericarditis (echocardiography). Descriptive statistics, univariate and multivariate analysis were performed. Kaplan Meyer curves with long-rank analysis were used for survival.

Results: : From 478 patients (74% w, 44±23 y at diagnosis, 10±8 y of follow-up, 28% PM, 22% DM, 19,9% OM, 19,2% JuvM, 8,4% CAM, 1,3% IBM, 1,3% NM), 98 (21%) presented cardiac involvement: 53 arrhythmia, 25 myocarditis and 30 pericarditis. Patients with CI were older at diagnosis (55 vs 40 y, p<.0001), and presented more frequently DM (p=.003). CI as a whole was associated with older age (p=.003), cardiovascular disease (CVD) (p<.0001), pulmonary hypertension (PH) (p=.005), and dysphagia (p=.016), less presence of calcinosis (p=.004), higher erythrocyte sedimentation rate (ESR) (p=.003). Arrhythmia was associated with older age (p=.008), CVD (p<.0001) and less calcinosis. Myocarditis was associated with pulmonary hypertension (p=.03), arterial hypertension (p=.008) and dysphagia (.001). Pericarditis was associated with CVD (p=.002), Raynaud (p=.008) and cancer (p=.03). Median survival was 16±3 and 35±10 years for patients with or without CI (p<.0001). Seven patients were lost to follow up and 47 (52%) died, mainly from CV event (32%), infection (28%), cancer (17%) and interstitial lung disease (4%).

Conclusion: Cardiac involvement appears in 20% patients with inflammatory myopathies and confers bad prognosis, with elevated mortality. Arrhythmia is associated with older age and cardiovascular disease, suggesting that other factors could influence survival, but myocarditis is associated with dysphagia, with could suggest the presence of a more severe disease.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-MDA5 Ab positive dermatomyositis (DM) is a unique subset of inflammatory myopathy characterized by non- or mild muscle weakness, skin manifestation such as palmar pustles, and high prevalence of rapidly progressive interstitial lung disease (RP-ILD) with resistance to therapies. RP-ILD determines prognosis of DM patients with anti-MDA5 Ab, and intensive immunosuppressive therapy, a combination therapy with high dose glucocorticoid (GC), cyclophosphamide (CY) and calcineurin inhibitors such as cyclosporine (CsA) is required for ILD. However, there are patients who fail to response the treatment and it is not clear what patients are resistant to intensive immunosuppressive therapy. The aim of the present study is to identify poor prognostic factors in RP-ILD in DM positive for anti-MDA5 Ab.

Methods: Retrospective analysis was performed on consecutive 15 anti-MDA5 + patients with RP-ILD among 63 inflammatory myositis who admitted our department from 2007 to 2015. RP-ILD was defined by ILD with worsening of respiratory condition and chest infiltration within 1 month. Anti-MDA Ab was measured by ELISA in our lab. All patients were treated with combination of high dose GC (pulse therapy followed by 60mg/day of predonisolone), IVCY (500-750mg every 2-4 week) and CsA (12h intravenous administration adjusted to Cmax above 1000ng/ml during infusion and Cmin 200-250 ng/ml. Imaging analysis was conducted by 3 independent investigators.

Results: Subjects were 15 patients of 8 males and 7 female with age of 57.9±10.4 year; 14 of them were amyopathic DM (DM). Eight of them died within 6 month (7 died of respiratory failure), and 7 survived by immunosuppressive therapy. Comparison of clinical features of poor and good prognosis was shown in Table 1. Serum ferritin levels before immunosuppressive therapy and increase in ferritin levels during the treatment was high in patients with poor prognosis. The numbers of lung fields with ground glass opacities (GGO) was large in the dead. New infiltrate during the therapy was frequently found in the dead. Based on these findings, we made a score to predict the prognosis; add points of 3 factors:1) if serum ferritin levels before treatment >1000ng/ml or increase in ferritin levels during therapy >2000 ng/ml: point 1, if no: 0; 2) if numbers of lung fields (rt/lt upper, middle and lower, total 6 fields) with GGO > 4: point 1, or if <3: point 0; and if lung infiltrate was improved within 2 week starting therapy: point -1, no change: 0, and worsened or new infiltrate: 1. When the score was 3 and2, 3/3 (100%) and 5/7(71%) died, respectively while all of score <2 survived.

	Survive	Death	p
number	7	8	
ADM/DM	7/0	7/1	0.33
M/F	3/4	5/3	0.44
Age	52.4+3.4	63.0+3.2	0.04
Ferritin before Treatment(ng/ml)	851+481(498)	1697+450 (1385)	
(A) Ferritin before Treatment>1000	1 (14%)	6(75%)	o.o4
Increase in Ferritin after Treatment	1125+3461(711)	6934+3238(2206)	0.31
(B) Increase in ferritin >2000	1(14%)	5(62%)	0.05
Ferritin (A) or (B)	1(14%)	6 (75%)	0.04
AaD02 (mmHg)	24.2+54.2 (21.6)	94.9+50.7(34.5)	0.35
Number of lung fields with GGO	4.0+1.6 (3)	5.8+0.3 (6)	0.03
Number of lung fields with GGO>4	3(42%)	8 (100%)	0.01
Change in lung infiltrate in 2 weeks after treatment	Improved : 4 No Change:2 Worsened :1	Improved : 6 No Change:2 Worsened :0	0.02

Conclusion: When serum ferritin levels are elevated before treatment , ferritin levels are ibncrased during therapy, many lung fields are affected by GGO and new lung infiltrate emerged during the therapy, the prognosis of ILD of DM patients with anti-MDA5 Ab is poor in spite of intensive immunosuppressive therapy.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: several data are available about the use of IvIg in the treatment of idiopathic inflammatory myopathies (IIM), but the results derive from small cohorts. The aim of our study is to evaluate the efficacy of IvIg in a monocentric cohort of patients with IIMs.

Methods: retrospective study of IIM pts treated in our unit with IvIg in the last 5 years (2gr/kg/month). We evaluated ESR, CRP, creatine kinase CK; muscle strength (manual muscle test 8 - MMT8), clinical symptoms (dysphagia, dyspnea, loss of strength) at the baseline, after 6 months and at the last follow-up. We analyzed indications to treatment, major organ involvement, previous therapies, adverse events (AE).

Results: 50 pts were enrolled (17 M, 33 F), 25 PM, 24 DM, 1 IBM; 9 (3 PM, 6 DM) were affected by paraneoplastic disease. Mean disease duration was 23.7±47 months. Indications to the treatment were: loss of strenght (all patients), dysphagia (19), lung involvement (6), DM rash (18), arthritis (2) and fever (1). IvIg were chosen for refractory disease (32 pts), neoplasia (9), recurrent infections (8), pregnancy (1). Previous treatment included corticosteroids in all patients (mean cumulative dose 5.4±7.0 grams), MTX in 17, CSA in 6, rituximab in 3, CYC in 5, AZA in 4, MMF in 5. After 6 months muscular strength improved in 26/41 patients and no patient worsen. Mean CK levels were significantly reduced from 1647±2140UI/ml to 368±662UI/ml ($p=0.023$). Mean MMT8 values increased from 56.0 to 61.6 ($p<0.001$). DM skin rash improved in 12/18 patients, dysphagia in 16/19, dyspnea in 7/10, arthritis in 2/2. At last observation 21 patients were still in IvIg treatment; patients received a mean of 29 infusions (min 1, max 164). 41 patients are still in follow up (9 died for myositis related causes); the mean follow-up duration is 66 months. Seven patients presented AE but only 2 pts stopped the treatment (1 arrhythmia, 1 heart failure). 47 patients maintained improvement of the muscular strength, 1 pt presented DM skin rash, dysphagia was still present in 12 pts but less severe compared to the baseline. MMT8 globally improved ($p<0.001$) and CK reduced ($p<0.001$).

Conclusion: IvIg is an expensive treatment, but our data confirmed their efficacy and safety particularly in refractory IIM patients. Muscular strength, dysphagia, arthritis and DM skin rash are the most responsive manifestations, particularly during the first 6 months of the therapy. On the light of these data, new perspective trials on the therapeutic approach of IIM are needed, to evaluate the best timing of IvIg treatment in IIM.

Session Title: Muscle Biology, Myositis and Myopathies - Poster II: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Inclusion body myositis (IBM) is the most common idiopathic inflammatory myopathy in patients over the age of 50. For atypical or early cases where classic histopathologic changes are lacking, imaging can play a role in identifying subclinical muscle involvement. Muscle sonography has shown an increased muscle echointensity (EI) seen in various disease states. This study was undertaken to assess the pattern of muscle involvement in IBM patients with the use of ultrasound and identify potential imaging features of the disease.

Methods: Patients seen from November 2015 to May 2016 with clinicopathologically or clinically defined IBM by European Neuromuscular center were included in the study. Seven muscle groups were imaged bilaterally for each patient (deltoids, biceps, flexor carpi ulnaris, flexor digitorum profundus, rectus femoris, tibialis anterior and gastrocnemius) using a standardized protocol. Images were coded for muscle severity qualitatively using the Heckmatt score (1 normal, 2 slightly increased muscle EI, 3 marked increase in EI with decreased bone echo, and 4 severely increased EI with no bone echo). Quantitative values for muscle echointensity were calculated for each muscle by manually segmenting each muscle through ITK-Snap and calculating average pixel intensity through MATLAB. Mean values were calculated for each muscle group.

Results: Sixteen patients were included in the study, 8 male and 8 female, all Caucasian. Average duration of disease was 11.8 years. Of the 7 muscle groups studied, the muscles showing the most severe abnormalities with a Heckmatt score of 3 or more were the gastrocnemius and flexor digitorum profundus. Quantitative assessment of echointensities similarly showed the highest values for the gastrocnemius, flexor digitorum profundus and the biceps. There was also asymmetry often seen between muscle groups of the same patient, particularly in the gastrocnemius, with a heterogeneously increased EI, often in a "popcorn pattern".

Conclusion: Muscle sonography can be a useful adjunct evaluation in patients suspected to have inclusions body myositis. Findings are a heterogenously increased echogenicity in affected muscles. Most severely affected muscle groups tended to be the gastrocnemius and flexor digitorum profundus. The presence of asymmetry between sides may also be an additional indicator of the disease.

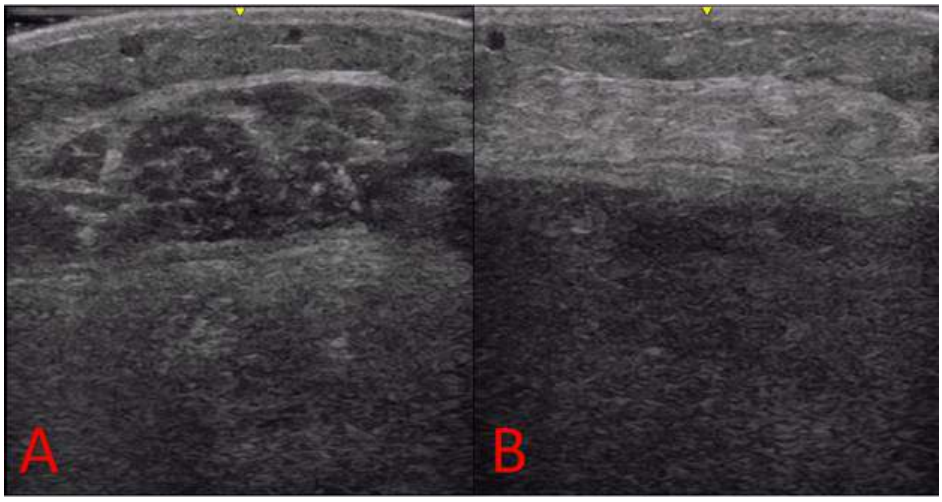

Figure 1. Asymmetry of appearance of gastrocnemius in same patient: A left, B right

Figure 2. Heterogenous increase in EI of gastrocnemius muscle ("popcorn pattern")

Muscle	Heckmatt score, mean	Echointensity, mean
Deltoids	2.58	80.2
Biceps	2.84	90.72
Flexor carpi ulnaris	2.84	78.54
Flexor Digitorum Profundus	3.37	90.73
Rectus femoris	2.93	80.35
Tibialis anterior	2.9	89.2
Gastrocnemius	3.37	91.28

Table 1. Averaged echointensities per muscle group by quantitative and qualitative assessments

Session Title: Orthopedics, Low Back Pain and Rehabilitation - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of this study was to analyze time-trends in various types of total joint arthroplasty (TJA) and assess if the proportion of the procedures performed on patients with RA has changed over time.

Methods: The Nationwide Inpatient Sample (NIS) database was queried from 2002 to 2012 to identify the number of patients per year undergoing TJA of the shoulder (TSA), elbow (TEA), knee (TKA), hip (THA), and ankle (TAA). We determined the proportion of these patients with a diagnosis of RA. Consistent with the design of the NIS, sampling weights were applied to obtain national estimates. Population-based rates of TJA were calculated using population estimates from the U.S. Census Bureau.

Results: During the study period, the overall utilization of TJA increased by 64.7% while the prevalence of comorbid RA in all TJA increased 0.1%. However, when stratified by specific joint, the prevalence of RA in patients undergoing TJA significantly decreased ($p < 0.05$) by 12% for TEA and 0.9% for TSA, decreased 4.6% ($p = 0.06$) for TAA, while there were increases of 0.2% for THA and 0.1% for TKA.

Conclusion: While the incidence of TJA is increasing nationally, the epidemiological landscape of TSA, TEA, and TAA performed in the RA population has varied. Such findings may be evidence of the successful early implementation of biological DMARD therapy and/or adoption of aggressive treatment strategies using combinations of traditional and biological DMARDs.

Session Title: Orthopedics, Low Back Pain and Rehabilitation - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Wear, osteolysis, and late aseptic loosening associated with ultrahigh-molecular-weight polyethylene components used in total hip arthroplasties (THA) have led to increased interest in metal-on-metal (MOM) prostheses. The availability of large-diameter metal femoral heads results in increased range of motion, reduced potential for femoral neck impingement on the acetabular rim. Despite the potential advantages, however, a continuing concern with MOM articulation is the release of metal ion debris locally and systemically in patients' blood and urine. These metal-metal wear-related complications include formation of pseudotumors, metalosis, and soft tissue necrosis. This study reports midterm outcome of THA with a Pinnacle (DePuy, Japan) modular MOM acetabular prosthesis.

Methods: From 2006 to 2008, primary THA, 86 primary THA (80 patients) were performed using a Pinnacle (DePuy, Japan) modular MOM acetabular prosthesis. There were 14 men and 72women with the mean age of 62.4 years. The preoperative diagnosis of most patients was osteoarthritis. Clinical hip function outcomes were evaluated using the Japanese Orthopaedic Association (JOA) hip score at preoperative and final follow-up. A perfect JOA hip score is 100 and the worst score is 0. Radiological analysis was performed at final follow-up. And the potential of MRI was examined for screening of pseudotumors following MOM THA. MRI was conducted in all hips postoperatively.

Results: Eight patients (9 hips) were lost before their 6-year follow-up. So, 77 THA (72 patients) were evaluated at mean 7.2-year follow-up (range 6-9.1 years). The mean (± SD) preoperative JOA hip score of 45.2 (± 12.2)

improved significantly to 86.5 (± 10.7) postoperatively at final follow-up. Four patients (4 hips) experienced problems with dislocation but no recurrent instability. An additional 1 patient (1 hip) was infected at 3.5-year after primary arthroplasty. The infected THA eventually led to removal of the stem and liner, and was performed one stage revision THA. Fifteen patients (17 hips) were observed in pseudotumor attributable to the MOM articulation by MRI from 2-year to 5-year after arthroplasty. Four patient (4 hips) was switched to a metal-on-polyethylene articulation from 5.1-year to 8.1-year postoperatively due to development with pain and swelling. In the 4 patients, 3 patients were observed pseudotumor and 1 patient were not observed, but all patients were diagnosed as ARMD (adverse reactions to metal debris). In 18 patients with pseudotumor and/or revision surgery, we evaluated between 14 patients with not revision surgery and 4 patients with revision surgery. At radiological analysis the mean cup angle of inclination was significant higher in the patients with revision surgery. Kaplan-Meier survivorship for the THA construct in this group was constant at 96.1% at 6 years after arthroplasty.

Conclusion: Clinical scores such as JOA score revealed excellent outcomes at mean 7.2-year follow-up. However, prevalence of pseudotumors per hip was 22.1%. The current cohort of patients will continue to be followed with special attention being paid to any potential local tissue reaction or other complications resulting from metal wear debris.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Orthopedics, Low Back Pain and Rehabilitation - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In progress of medical treatment against rheumatoid arthritis (RA) disease activity using methotrexate (MTX) and/or biologics, we often see cases that require surgical intervention for progressive ankle joint destruction and disorder. Total ankle arthroplasty (TAA) had been one of the procedures for destructive ankle joint in RA cases. In this situation, whether biologics treatment could contribute to improve the outcomes after TAA is not elucidated.

Methods: A retrospective observational study was completed for 21 cases receiving a mobile-bearing ankle prosthesis design for treatment of rheumatoid ankle from October 2010 to May 2014. Duration of the postoperative observation was between 2 and 6 years. The FINE mobile-bearing prosthesis (Teijin-Nakashima Medical Co., Ltd., Okayama, Japan) was used. Within 21 cases, 10 cases were treated with biologics (infliximab, etanercept, tocilizumab, abatacept), and 11 cases were treated with NON-biologics drugs (MTX, tacrolimus, salazosulfapyridine, bucilamine). Preoperative and postoperative score for Japanese Society of surgery of Foot (JSSF) RA foot ankle scale was evaluated. A postoperative self-administered foot evaluation questionnaire (SAFE-Q) was also administered at the final follow-up. Prosthesis sinking, appearance of radiolucent area, tilting angle between tibial and talar compornent were investigated as radiographic evaluation. These parameters were compared between bio group and NON-bio group.

Results: There was no significant difference between the two groups in disease duration (bio: 20.1±11.2 years, NON-bio: 18.2±7.7 years), age (bio: 62.9±3.0 years old, NON-bio: 67.2±1.5 years old), DAS28-CRP score (bio: 2.53±0.48, NON-bio: 2.86±0.83), and doze of administered prednisolone (bio: 1.2±2.1 mg/day, NON-bio: 2.2±2.2 mg/day). On the other hand, the proportion of cases without prednisolone administration was significantly high in bio group (bio :7/10 [70%], NON-bio: 3/11 [27%]). In both groups, JSSF score was significantly improved after surgery, and there was no significant difference in postoperative score between the two groups. In SAFE-Q score at the final follow-up, there was no significant difference between the two groups, pain and pain related index (bio: 77.9±15.3, NON-bio: 82.4±10.9), physical functioning and daily living index (bio: 53.2±25.7, NON-bio: 52.7±17.3), social functioning (bio: 57.5±35.0, NON-bio: 45.4±32.7), shoe related index (bio: 46.7±48.2, NON-bio: 59.2±29.8), general health and well-being index (bio: 60.0±34.1, NON-bio: 76.8±22.6). In radiographic findings, appearance of radiolucent area in posterior tibial component was seen in 4 cases of biologics group. Talar prosthesis sinking was seen in 3 cases of biologics group. Tilting angle between components showed no significant difference between the two groups (bio: 0.3±0.2 degrees, NON-bio: 0.2±0.25 degrees).

Conclusion: No significant difference in postoperative clinical outcomes after TAA was found between biologics treatment group and NON-biologics treatment group within 2-6 years follow-up. Control of the disease activity is firstly important, and when tight control of RA was achieved even in NON-biologics treatment cases, TAA seems to be appropriate for RA patients. However, because biologics has the ability to stop the administration of prednisolone, biologics treatment cases has theoretically an advantage for prosthesis durability from the perspective of the strength of bone mineral structure. Long term follow-up is required.

Ultrasound-Guided Facet Joint Injections through a Longitudinal Approach

Christelle Darrieutort-Laffite, Antoine Colombey, Joelle Glemarec, Yves Maugars and Benoit Le Goff, Rheumatology, Nantes University Hospital, Nantes, France

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Orthopedics, Low Back Pain and Rehabilitation - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Facet joint-mediated pain has been identified as a common cause of lumbar pain. Steroid injections are currently made to treat them, usually performed under fluoroscopy or Computed Tomography-guidance. Ultrasound (US) is also appropriate to locate facet joints and some authors showed efficacy of US-guided injections through a transversal approach. On a longitudinal view, facet joints are easy-to-identify as a series of lumps with the joint capsule appearing as a thin hypoechoic line covering the joint. Each lump corresponds to the inferior articular process of the superior vertebra overlying the superior articular process of the vertebra below it. Considering the good visibility of these joints and their capsule on the longitudinal view, we studied the feasibility of US-guided facet joint injections using a longitudinal inline approach.

Methods: Patients referred to our Rheumatology department to receive facet joint injections under fluoroscopy have been included. To realize the injection, we first located the accurate lumbar level on a longitudinal median view and facet joints have been identified placing the probe 2-3 cm away from the median line. The needle was inserted in the axis of the probe to reach the hypoechoic line corresponding to the capsule or, if not visible, the top of the lump. When we obtained the bone contact, iodinated contrast medium followed by cortivazol has been injected. Finally, we made a lumbar X-ray. The first objective was to assess the number of injections realized in front of the joint. For secondary objectives, we assessed the number of accurate arthrography, the duration of the procedure and the occurrence of adverse events. During the US examination, the visibility of the capsule and the presence of osteophytes have been collected.

Results: Thirty-eight patients have been included by two operators. We excluded four patients because of a poor visibility of the spinal structures. Mean age was 58.4 years (range, 30-82) and mean BMI was 25.2 kg/m^2 (range, 18-34). US showed osteophytes in 42% and the articular capsule was inconstantly visible (25%). One-hundred and forty-four injections have been performed and 141 X-ray analyzed. One-hundred and twenty-three injections (87%) have been correctly realized in front of the joint. However, a proper arthrography has been obtained in only 35 cases (25%). Mean procedure duration was 8.5 minutes for four injections. No complication occurred, six patients (18%) reported a transient pain exacerbation.

Conclusion: With a longitudinal inline approach, 87% of US-guided facet joint injections were realized in front of the joint. However, we obtained a correct arthrography in only 25%. The depth of the target-point, the inconstant visualization of the capsule and the obliquity of the needle probably explain this result.

Session Title: Orthopedics, Low Back Pain and Rehabilitation - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment of rheumatoid arthritis (RA) has been dramatically changed by methotrexate (MTX) and biologics. According to introduction of these effective drugs for the control of disease activity, several changes in RA have been reported, especially in large joints. For the surgical numbers of total hip arthroplasty (THA) and total knee arthroplasty (TKA) in RA, most of studies showed decreased numbers of THA and TKA. The aim of this study was to investigate recent changes of number of surgery in the cases of THA and TKA, radiological findings, laboratory data, and patients' background such as dose changes of drugs in the regional center for RA.

Methods: Between 2000 and 2015, 81 primary cases of THA and 239 primary cases of TKA were performed for RA. We analyzed the changes of the number of surgery. The age at the time of surgery, pre- and peri-operative laboratory data, such as white blood cell count (WBC), hemoglobin (Hb), and C-reactive protein (CRP) were reviewed. Also, medication with methotrexate (MTX) and corticosteroids (CS) were also carefully reviewed. In radiographic analyses of the hip, presence of acetabular protrusion and bone spur formation were evaluated. For femoral side, canal width ratio and cortical index were analyzed. For the cases of TKA, Larsen grades, preoperative femoral-tibial angle (FTA), and the appearance of bone spur were analyzed. Statistical analysis was performed using Cochran-Armitage test and linear regression analysis. The p-values less than 0.05 were considered statistically significant.

Results: The numbers of THA and TKA were significantly decreased with time ($p<0.01$, respectively). The average age at surgery showed continual increase (THA; $p<0.05$, TKA; $p<0.01$). The administration rate and averaged dose of CS were decreased with year (THA; $p<0.05$, TKA; $p<0.01$). On the other hand, although the average dose of MTX was increased with year (THA $p<0.05$, TKA $p<0.01$), the administration rate of MTX did not show any changes. The pre- and peri-surgical WBC and Hb did not show any changes with year. The averaged pre-surgical CRP decreased for THA （$p<0.05$）, but no significant difference was observed in TKA cases. Peri-surgical change of CRP did not show any changes for both group. In radiographic analyses, TKA cases did not show proportional changes in the Larsen grades. Although cases with a severe varus deformity were decreased, the mean FTA showed no changes during the period. Interestingly, we found the continual increase of the case number of RA knee with the spur formation ($p<0.01$). For THA cases, the presence of acetabular protrusion was decreased and the presence of bone spur formation around the acetabulum was increased. Although the canal width ratio did not show any changes, the cortical index were significantly increased with year ($p<0.01$).

Conclusion: In our registry, the numbers of primary THA and TKA for RA were significantly decreased during the time period. Our results may reflect increased cases of OA changes of hips and knees in RA. Tight control of the disease by effective drugs may influenced improved disease activity and prevention of joint destruction.

Splinting for Trigger Finger. Short Term Effects

V. De Cillis[1], A. Perez Davila[2], A. Bohr[3] and E. Scheines[4], [1]Occupational Therapy, Hospital de Rehabilitacion Manuel Rocca, Buenos Aires, Argentina, [2]Rheumatology, Hospital de Rehabilitación Manuel Rocca, Ciudad Autonoma de Buenos Aires, Argentina, [3]Rheumatology, Hospital Manuel Rocca, Ciudad Autonoma de Buenos Aires, Argentina, [4]Rheumatology, Hospital Manuel Rocca, Buenos Aires, Argentina
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Orthopedics, Low Back Pain and Rehabilitation - ARHP Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory processes of flexor tendons of fingers can produce pain and less (impaired) functionality. Trigger finger (stenosing tenosynovitis) is frequently seen in clinical practice. It is characterized by pain, snapping or locking when flexing the finger. The European consensus guideline for managing trigger finger suggests different interventions according to severity and duration of symptoms (orthoses/splints, corticosteroid injections, and surgical treatment.) Splinting is often indicated in order to prevent tendon friction. Among the different types of splinting, the experts recommend those that provide 0° metacarpophalangeal (MCF) blocking to avoid movement and load of the tendon through the A1 pulley. The aim of this study is to determine the short term effectiveness of splinting for trigger finger according to severity and duration of symptoms.

Methods: We included patients with Trigger finger diagnosis, type 1 to 3 according to Quinnell grading classification (mild, moderate, severe symptoms) who was under stable medication. Patients that received physiotherapy treatment and corticosteroid injections within 2 months before entry were excluded. Subjects were evaluated at admission and 30 days after using the splint with pain VAS, hand strength (jamar dynamometer), ability and dexterity (Picking up test) and global impact of hand disorders in daily activities (DASH disabilities of the arm, shoulder and hand). They were equipped with trigger finger splint providing 0° blocking of MCF to prevent sliding and tendon load through the A1 pulley. Patients used the splint for four weeks to perform daily activities.

Results: 15 patients were included (13 women and 2 men), 90% with trigger finger type 2/3 of Quinnell classification and 1 to 5 months of symptoms duration. 100% improved performance of daily activities according to DASH questionnaire. In 80% a decrease in frequency of locking, stiffness of the hand and fingers flexion were observed. We could not find changes in pain and strength parameters.

Conclusion: All the patients included improved the ability to perform daily activities after a month of splinting; and in most of the patients a decrease in the frequency of locking during finger flexion was noted. Even when these results are encouraging, it would be useful to increase the sample size and compare the splinting with other therapeutic modalities for the conservative treatment of trigger finger.

Session Date: Tuesday, November 15, 2016

Session Title: Orthopedics, Low Back Pain and Rehabilitation - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sleep disturbance is common in people who have inflammatory arthritis and can contribute to disability, symptomatology, and use of increased healthcare. Disturbed sleep is a common complaint among people with inflammatory arthritis and this consequently has an effect on their overall quality of life, in addition to their mental and physical health. Little is known regarding the current practice of Health Professionals in Rheumatology on their engagement with patients in discussing their sleep quality and disturbances therefore, it is important to investigate if there are any educational needs in this important area of practice

Methods: Objectives were to investigate the awareness of Irish Health Professionals in Rheumatology on their patients' engagement when discussing sleep quality, sleep disturbances and physical activity, among Irish people who have inflammatory arthritis. Members from the Irish Rheumatology Health Professionals Society (n=43) were invited to participate in a cross-sectional survey hosted on SurveyMonkey$^{(R)TM}$. Ethical approval was received. Descriptive statistics, Chi-square tests/Fisher's exact tests were used to analyse the data using SPSS v22

Results: Twenty eight (65%) Health Professional's responded. Results found the mean number of years qualified to be 16.93 (SD 6.82), mean number of years working in Rheumatology to be 10.07 (SD 4.04) and 40% of respondents reporting half of their patient workload coming from people who have inflammatory arthritis. Just 52% discuss sleep with their patients with 46% mentioning fatigue as their main reason when enquiring. Of those who do discuss sleep, 100% of their patients mentioned 'pain' and 'waking up in the middle of the night or early morning' as disturbances when discussing their sleep, while 67% reported 'taken prescribed or over the counter medication' to help with their sleep. There was no statistically significant association between longer years qualified, more years working with people with inflammatory arthritis or health profession, when discussing sleep. When using the Short Questionnaire to Assess Health-enhancing physical activity (SQUASH), Health Professional's were active 2,248 minutes per week. This exceeds the American College of Sports Medicines' physical activity guidelines however, is low compared to other physical activity Health Professional surveys from European countries, even-though 100% of respondents believe it is important to measure physical activity

Conclusion: Only half of Health Professional's discuss sleep with their patients with fatigue as the main reason when enquiring. Health Professional's meet the physical activity guidelines however, are less active than their European peers. There is a need to develop education and training for physiotherapists in the importance of enquiring about their patients sleep quality and disturbances and the potential impact it has on their physical activity levels. In addition, the effects of physical activity and exercise interventions on poor sleep quality and

disturbances needs to be examined so that Health Professional's are in a better position to promote health and well-being in people with Inflammatory Arthritis, in this important area of practice

Session Title: Orthopedics, Low Back Pain and Rehabilitation - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Behavioral theories suggest psychological distress reduces physical activity (PA) engagement via behavioral inhibition. Community factors such as neighborhood cohesion are also associated with PA. This study examined the association between emotional distress and PA in adults with persistent knee pain and identified whether neighborhood social cohesion moderates this relationship.

Methods : Data from 601 African American and White adults > 45 years with persistent knee pain (defined as pain, aching, stiffness on most days) enrolled in the Johnston Osteoarthritis Project (2006-2011) were analyzed. Moderate/vigorous intensity PA (MVPA), measured using the Behavioral Risk Factor Surveillance Survey (BRFSS) PA scale, was categorized into a 3-level variable according to 2008 US PA Guidelines (0-9, 10-<150, ³150 MVPA minutes/week). The Arthritis Impact Measurement Scales (AIMS 2) – Anxiety scale measured anxiety (higher scores indicate more anxiety) and SampsonÕs Neighborhood Cohesion Scale assessed social cohesion (higher scores indicate greater cohesion). Covariates included: demographics (age, gender, race, education, body mass index (BMI), employment), medical history (comorbidities, symptomatic KOA), depression (CES-D), community factors (poverty level, neighborhood walkability, safety, aesthetics), perceived helplessness, and WOMAC physical function, stiffness and pain. A generalized logit model examined associations between MVPA levels and anxiety and the interaction between perceived social cohesion and anxiety, adjusting for covariates (**Table**).

Results : ParticipantsÕ mean age was 68.9 years (SD=9), 407(67%) were Caucasian, 431 (72%) were female. 403 (67%) adults had knee pain for ³ 5 years and mean AIMS-2 anxiety score was 3.36 (SD=1.9). 222 (37%) adults engaged in < 10 minutes of MVPA/week, 138 (23%) in 10-149 minutes/week and 241 (40%) met DHHS requirements of ³ 150 min of MVPA/week. Three hundred fourteen individuals (52%) reported positive neighborhood social cohesion. Factors associated with engagement in some MVPA and meeting recommended MVPA levels were: younger age, female gender, better knee function, fewer comorbidities, less depression, longer duration of knee pain, and positive neighborhood social cohesion and aesthetics. A two-unit increase in the AIMS anxiety subscale, among individuals who perceived positive cohesion, was associated with increased odds of engaging in MVPA.

Conclusion : Neighborhood social cohesion appears to moderate the relationship between anxiety and participation in weekly MVPA. Specifically, social cohesion did not affect those engaged in high PA levels but did promote more PA among those who were anxious/tense. Recognizing the positive affect of social cohesion on anxiety and MVPA may inform counseling strategies for adults with persistent knee pain to adopt PA to manage their pain.

Table: Correlates of Weekly Physical Activity Participation in Adults with Persistent Knee Pain From Multivariate Generalized Logit Model

Session Date: Tuesday, November 15, 2016

Session Title: Orthopedics, Low Back Pain and Rehabilitation - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Total joint replacement surgery has become one of the most common elective surgical procedures. Improvements in pain and physical function following total hip arthroplasty (THA) and total knee arthroplasty (TKA) are known however less is known about changes in physical activity (PA). A recent systematic review qualitatively described changes in PA following THA and TKA but did not examine changes in pain, quality of life, and physical function. As such, the purpose of this study is to conduct a systematic review of the literature, with meta-analysis, on the change in PA after THA or TKA surgery and evaluate other factors such as changes in pain levels, physical function and quality of life that may contribute to participation in PA.

Methods: We searched three databases (Pubmed, CINAHL and Embase) for peer-reviewed, English-language cohort studies that tracked change in accelerometer measured PA in the same population from pre- to-post surgery. Two reviewers independently screened titles, abstracts, and full-texts with a third reviewer settling disagreements. Two reviewers independently abstracted demographic and outcome data relating to PA, pain, physical function and quality of life. Random-effects models were used to produce standardized mean differences (SMD) for physical activity, quality of life, pain, and physical function outcomes. Effect sizes were gauged as small (SMD=0.2), moderate (SMD=0.5) and large (SMD=0.8). Heterogeneity was measured with I^2.

Results: Eleven studies (531 total patients) published between 2002-2014 met eligibility criteria. Subjects mean ages ranged from 42.1 to 69.0 years of age, mean body mass index ranged from 23.0 to 32.6, and a majority of participants were women. Surgical area (TKA or THA) varied with THA alone (n=4 studies), TKA alone (n=5 studies), and combined either THA and TKA patients (n=2 studies). At 6 months post-surgery no significant increase in accelerometer measured PA was found when compared to pre-surgery PA (SMD=0.09; 95% CI -0.08 to 0.25; I^2=0%). A small-to-moderate significant effect was found for accelerometer measured PA at 12 months post-surgery when compared to pre-surgery PA (SMD=0.43; 95% CI 0.22 to 0.64; I^2=0%). At 6-monts post surgery large and significant effects were found for reduction in pain (SMD= -1.25 ((95% CI -1.89, -0.61)), improved quality of life (SMD=0.71 ((95% CI 0.08, 1.34)), and improved physical function (SMD=0.84 ((95% CI 0.21, 1.47)).

Conclusion: Despite large improvements in pain, physical function and quality of life, participants PA levels remained the same at 6 months and showed modest improvement at 12 months post TKA or THA. Reasons for the decreased levels of PA are unknown but may be behavioral in nature. Considering the consistency of effect demonstrated across these eleven studies future studies should seek to understand the barriers for decreased PA following TKA or THA so that future intervention studies may improve PA among this subgroup of patients.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Orthopedics, Low Back Pain and Rehabilitation - ARHP Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Standard post-operative physical therapy (PT) for total knee replacement (TKR) aims to increase knee range of motion (ROM), which is important for walking and adopting an active lifestyle, e.g., taking more steps/day, after TKR. However, it is unclear to what extent limited ROM may be a barrier to physical activity after TKR. This is important to study since ROM is a modifiable impairment that can be prioritized in PT after TKR. The purpose of this study was to evaluate the association of ROM with physical activity over the first 6 weeks of PT after TKR.

Methods: We recruited patients with a first time unilateral TKR from a local PT clinic. We excluded people with comorbidity that affected physical function other than arthritis. We quantified physical activity as steps/day using an accelerometer enabled monitor (Actigraph GT3X) worn for at least 3 days during waking hours. Knee ROM was measured by a physical therapist using a standardized approach. We classified lacking $\geq 5°$ of full knee extension as limited extension, and knee flexion $\leq 95°$ as limited flexion. We examined the difference in steps/day between those with and without limited knee ROM with physical activity each week of PT (weeks 1 to 6) using difference tests and 95% Confidence Intervals (CI).

Results: We included 26 people after TKR (age [mean± sd] 64.9 ± 9.1 years, BMI 34.5 ± 7.5 kg/m^2, 56% female) at baseline. Participants walked 1889 ± 1467 steps/day at week 1, and 3474 ± 2277 step/day at week 6. In general, there was little difference in steps/day between those with and without limited ROM. For instance, there was a non-statistically significant difference in steps/day between those with limited extension (n=20) compared with those without (n=6) (776 steps/day, 95% CI [-2185, 633.26]). In a similar fashion, there was little difference among those with limited flexion (n=7) compared with those without (538 steps/day, 95% CI[-818, 1894]). A small difference was observed at week 6 for extension. No participants had limited flexion after week 3. (Figure)

Conclusion: Our preliminary findings show little difference in physical activity among people with and without ROM limitations after TKR. Limited ROM, even at clinically significant levels, may not be a major barrier to physical activity after TKR. **Figure:** Weekly steps/day for people after TKR with and without limited knee extension/flexion during outpatient PT [sample size (n) provided above each data point].

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Orthopedics, Low Back Pain and Rehabilitation - ARHP Poster

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Physical activity monitoring studies in rheumatology initially used uniaxial accelerometers. But advanced triaxial accelerometry technology replaced uniaxial accelerometers. Uniaxial devices measure accelerations in one dimension while triaxial devices measure body accelerations in three planes of movement planes. The aim of this study is to create a crosswalk table between uniaxial and triaxial physical activity measures to facilitate comparing work from previous studies based on uniaxial devices with new studies using triaxial devices.

Methods: An Osteoarthritis Initiative subset of 185 community dwelling adults aged 45 years or older having knee osteoarthritis or knee osteoarthritis risk factors simultaneously monitored physical activity using both a uniaxial accelerometer (ActiGraph GT1M) and a triaxial accelerometer (ActiGraph GT3X) worn on the waist for 7 days. Relationship of minute-by-minute output data from the two accelerometers (uniaxial activity counts; triaxial vector magnitude counts) was evaluated using classification tree analysis (Salford Systems CART® v8.0). Data were split into learning (835,221 matched minutes/130 persons) and test (361,941 matched minutes/55 persons) sets. The learning set was used to get uniaxial cutpoints and the test set was used to test the cutpoints. Optimal classification trees (i.e., minimizing misclassification error) identified best-performing cutpoints for uniaxial activity counts to predict triaxial vector magnitude counts using least absolute deviation (LAD) splitting methods. Medians of triaxial vector magnitude counts in each terminal node were used as predicted values for that node. Mean absolute deviation (MAD), a measure of model error, was independently estimated in the test set. Data included only waking hours and excluded sleep periods at night.

Results: 185 participants included 55% with radiographic knee OA (Kellgren-Lawrence grade score ≥ 2), 10% with high pain (SF-12 bodily pain ≥ 3), and 43% with obese weight (body mass index ≥ 30 kg/m^2). Classification tree analyses identified 26 best-performing (i.e., minimum misclassification error) cutpoints for uniaxial activity counts to predict triaxial vector magnitude counts in the learning set (Table 1). MAD estimate was 302.33 in the test set using 26 optimal cutpoints from the learning set.

Conclusion: This crosswalk table between uniaxial and triaxial physical activity measures will facilitate comparisons of previous uniaxial data with future studies using newer triaxial technology in knee osteoarthritis populations.

Table 1. Uniaxial Activity Count Cutpoints and Predicted Triaxial Vector Magnitude Counts for Each Node Number

Node Number	Number of Observations	Uniaxial Activity Count Cutpoints	Predicted Triaxial Vector Magnitude Counts
1	416,933	0	0
2	80,580	1 – 23	75.85
3	37,416	24 – 45	141.16
4	32,577	46 – 75	236.51
. . .	. . .	. . .	. . .
23	732	4239 - 4742	5107.15
24	449	4743 - 5168	5580.56
25	626	5169 - 6626	6122.38
26	194	6627 or above	7756.02

Understanding Patient Barriers and Facilitators to Healthy Eating and Physical Activity before and after Knee Replacement

Christine Pellegrini[1], Gwendolyn Ledford[1], Rowland W. Chang[2] and Kenzie Cameron[3], [1]Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Institute for Public Health and Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL, [3]General Internal Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL

Session Date: Tuesday, November 15, 2016

Session Title: Orthopedics, Low Back Pain and Rehabilitation - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Knee replacement typically results in reduced pain and improved physical function, yet post-operative physical activity levels often remain unchanged. Many patients also gain weight following surgery, yet no weight management programs exist for this population. We sought to identify patient-reported barriers and facilitators to healthy eating and physical activity among patients before or after knee replacement.

Methods: Twenty patients with knee osteoarthritis between 40-79 years who had a knee replacement surgery scheduled or completed within 3 months were interviewed. Interview topics included perceived barriers and facilitators to healthy eating and physical activity, both before or after knee replacement. Interviews were coded and analyzed using constant comparative analysis.

Results: Interviews were completed by 11 pre-operative and 9 post-operative patients (overall mean 64.7±9.8 years, 45% female, 90% White, BMI 30.8±5.5 kg/m^2). The most common barriers to healthy eating identified were desire for high fat/calorie foods, overconsumption, and mood. Time-related factors (i.e., planning meals, making time to grocery shop) and portion control were identified as facilitators to healthy eating. Barriers for activity included pain, physical limitations, and lack of motivation, whereas facilitators included having motivation to improve knee symptoms/outcomes, building activity habits, and monitoring activity levels.

Conclusion: Identifying the specific barriers and facilitators influencing eating and activity behaviors provides critical insight from the patient perspective which will aid in developing a patient-centered weight loss program for knee replacement patients. Understanding these factors could guide clinician discussions encouraging weight loss pre- or post-operatively in overweight and obese knee replacement patients.

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: This Phase 2a/b trial evaluated the safety and dose effectiveness of honeybee toxin (purified *Apis mellifera*toxin) injections to improve pain and physical function in patients with osteoarthritis (OA) of the knee.

Methods: Eligible patients were ≥35 years (men and women), with OA in one or both knees (Grade 1-3) and with pain symptoms ≥4 on a visual analog scale (VAS) after medication washout. Eligible patients were randomized to histamine controls: 2.75 µg (n=4), 8.25 µg (n=3), or 27.5 µg (n=4); or to honeybee toxin: 100 µg (n=9), 300 µg (n=10) or 1000 µg (n=10). Patients received 10 intradermal injections (5 in each knee) with syringes randomly filled with control, toxin or saline depending on treatment assignment. Injection sites were randomly targeted to the OA knee because honeybee toxin has systemic effectiveness as well as local activity. Safety evaluated any significant adverse events (AEs) including immediate hypersensitivity reactions from treatment after a negative honeybee toxin skin test (50 µg). Efficacy endpoints were assessed at Predose (Day 1), and Follow-Up Visits (Day 7 and 14) for pain and physical function using subscores from the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Version LK 3.1, as well as for patient global assessment (PGA) and physician global assessment (PhGA).

Results: The majority of patients (33/40, 82.5%) reported at least one treatment-emergent adverse event (TEAE) that were primarily mild to moderate injection site reactions (discomfort, edema, induration, pain, pruritus, urticaria and warmth). All injection site reactions resolved by Day 14. There were no discontinuations or SAEs associated with the honeybee toxin doses, and there were no changes in laboratory parameters, vital signs, or electrocardiograms. At Day 7, WOMAC pain subscores showed an improvement in pain relative to control for all three honeybee toxin doses but not significantly; i.e., least square mean (LSM) difference from control: -2.23, -2.27 and 2.11, respectively, for the 100 µg, 300 µg and 1000 µg doses; p=0.2880. Physical function subscores, however, showed significant improvement versus control at Day 7: -11.27 (p=0.0374), -11.38 (p=0.0308) and -10.35 (p=0.0541), respectively, for the honeybee toxin doses. Further, at Day 7, a significant majority of all patients treated with honeybee toxin (66.5%; p=0.0177) assessed their condition (PGA) as being “very good or good” whereas 90% of patients in the control group perceived their condition as being “fair or poor.” The PhGA was generally consistent with the PGA. Regarding Day 14 efficacy assessments, most were consistent with Day 7, however, the improvements among the doses were not as significant.

Conclusion: The honeybee toxin regimens resulted in consistent improvement in pain, physical function, and global health perceptions in patients with knee OA. The safety profile raised no concerns or issues related to treatment. The results of this Phase 2 trial provide sufficient clinical evidence to justify investigating the safety and efficacy of honeybee toxin (purified *Apis mellifera* toxin) for treating patients with OA pain and inflammation in a Phase 3 trial.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adults with osteoarthritis (OA) have greater glucose concentrations and inflammation. It remains unclear if inflammation and glucose homeostasis are related to specific features of early stage OA. Bone marrow lesions (BMLs) and effusion are early features of OA that can change size in < 12 weeks and are associated with knee pain and OA progression. We explored if serum concentrations of impaired glucose homeostasis (glucose, glycated serum protein [GSP]) or inflammation (C-reactive protein; CRP) were associated with the prevalence of knee BMLs or effusion.

Methods: We conducted a cross-sectional study with baseline data from the Osteoarthritis Initiative. We selected participants who had no radiographic knee OA, were at high risk for knee OA, and had sagittal fat-suppressed knee magnetic resonance images and fasting serum. Blinded staff conducted assays for CRP, GSP, and glucose. One reader segmented BML volume using a semi-automated program (intra-tester ICC > 0.86). Two readers used a semi-automated program to segment effusion volume (intra-tester ICC > 0.84). We defined BML prevalence as a knee with a BML volume ≥ 1 cc and effusion prevalence as a knee with an effusion volume ≥ 7.5 cc. We performed separate logistic regression models for these 2 outcomes with each biomarker as a predictor, adjusting

for age, sex, body mass index (BMI), and Physical Activity Scale for the Elderly (PASE) scores. We explored interactions between the biomarkers and BMI. When a nonlinear relationship was present we performed piece-wise logistic regressions.

Results: We included 343 participants with a mean age of 59 ± 9 years, BMI of 27.9 ± 4.5 kg/m^2, PASE score of 171 ± 82, and 64% female. CRP was associated with BML prevalence (odds ratio [OR] = 1.43, 95% confidence interval [CI] = 1.09 to 1.87; Table 1). For effusion, we found an interaction between BMI and CRP: among adults with a BMI < 25 kg/m^2 there was a trend towards a positive association between CRP and effusion (OR = 1.40, 95% CI = 1.00 to 1.97), while no significant association was observed among people with a BMI ≥ 25 kg/m^2. We detected a nonlinear relationship between GSP and effusion prevalence: for GSP levels ≥ 5.5cc people with greater concentrations were more likely to have effusion, while for GSP levels < 5.5cc people with lower concentrations were more likely to have effusion (Table 2).

Conclusion: Among individuals without knee OA, CRP is related to the presence of BMLs and effusion among normal weight individuals. Abnormal GSP is associated with effusion. It will be valuable to explore if inflammation and glucose homeostasis are predictive of symptomatic knee OA.

Table 1. C-Reactive Protein (CRP) is Associated with the Prevalence of Bone Marrow Lesions (BMLs)

Predictor (continuous)	**No BML (n = 287) Mean (SD) (Reference)**	**Prevalent BML (n = 56) Mean (SD)**	**Prevalent BML Crude OR (per unit of biomarker concentration)**	**Prevalent BML Adjusted OR (per unit of biomarker concentration)**
CRP (mg/L)	3.24 (1.22)	3.67 (1.12)	**1.36 (1.05, 1.75)**	**1.43 (1.09, 1.87)**
lnGSP	5.50 (0.70)	5.43 (0.82)	0.87 (0.58, 1.32)	0.97 (0.65, 1.46)

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Varus knee thrust is an abrupt change in frontal plane alignment of the tibiofemoral joint observed during gait. Thrust has been previously linked to radiographic knee OA progression, worsening cartilage and bone marrow lesions, and knee pain. Knee thrust is a dynamic event that likely influences the entire kinematic chain of the lower limb and causes trunk lean yet the effects of thrust on the hip and ankle and the lower back are not known. As low back, hip, and ankle pain are impactful problems among older adults, and as varus thrust is potentially modifiable through gait retraining interventions, determining a relation of thrust to pain at these regions is of interest. *Our objective was to determine the effects of knee thrust on the two-year incidence of frequent ankle, hip, and low back pain in older adults with or at risk for OA.*

Methods: The Multicenter Osteoarthritis Study (MOST) is a prospective cohort study of older Americans that have or are at risk for knee OA. At the 60-month clinic exam, 60 Hz frontal plane video recordings were acquired as participants completed two self-paced walking trials over a 4.9 meter walkway. A trained reader, blinded to disease status, assessed the presence of varus thrust on a majority of steps (intra-rater $\kappa = 0.73$). Frequent ankle, hip, and low back pain was self-reported by MOST participants using a homunculus. Among participants with no pain at the 60-month exam, incident frequent pain in these regions was defined at the 84-month exam as "pain, aching, or stiffness on most days in the past 30 days." To assess the relation of thrust to incident pain, we used logistic regression adjusting for age, sex, race, BMI, and gait speed. In limb-based analyses (hip and ankle pain), generalized estimating equations accounted for two limbs from the same subject.

Results: 1375 subjects (mean age 67.3 ± 7.7; mean BMI 30.3 ± 5.7; 89.3% White; 58.7% female) contributed to the person-based analysis. 2158 knees from 1087 subjects comprised the sample for the limb-based analyses. Varus thrust was observed in 31.3% of knees. Nonsignificant results suggested that knees with thrust may have 1.30 times the odds (95% CI: 0.97, 1.73) of incident hip pain ($p = 0.08$), and that persons with thrust in at least one knee have 1.47 times the odds (95% CI: 0.96, 2.24) of incident low back pain ($p = 0.08$) compared to knees without thrust. No association was found between knee thrust and risk of incident ankle pain ($p = 0.22$) (see Table).

Conclusion: While small numbers of incident pain cases may have restricted our ability to detect significant relationships, nonsignificant findings suggest a possible association between varus thrust and two-year risk of developing frequent hip and low back pain. Further investigation into the relationship between aberrant movement at the knee and painful injury at these regions may help explain these findings.

Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Abstract:

Background/Purpose: Insufficiently active adults experience reduced quality of life. Because half of adults with arthritis are physically inactive, we evaluated the additional effect of a motivational-interviewing based lifestyle physical activity intervention when added to physician-advice-only control group on pain and physical function in adults with knee osteoarthritis or rheumatoid arthritis (RA).

Methods: Participants meeting American College of Rheumatology criteria for knee osteoarthritis or RA were randomized to physician-advise-only control or motivational-interviewing-based physical activity intervention group. For the motivational-interviewing intervention, participants met with a physical activity advocate who facilitated individualized physical activity goal setting and behavior change using motivational interviewing. Primary outcomes were pain and function evaluated by Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) for knee osteoarthritis and Health Assessment Questionnaire (HAQ) for RA at baseline, 3 months, and 6 months. Secondary outcome was accelerometer-measured moderate-to-vigorous physical activity (MVPA). Linear regression with generalized estimating equations (GEE) was used to evaluate the average intervention effect on changes in outcomes from baseline to 3 months and/or 6 months.

Results: Participants included 155 adults with knee osteoarthritis (76 intervention, 79 control) and 185 adults with RA (93 intervention, 92 control). The knee osteoarthritis participants who received the motivational-interviewing physical activity intervention had WOMAC pain score improve by 0.91 points (95% CI 0.05, 1.77), WOMAC function improve by 1.91 points (95% CI -0.66, 4.47), and their average daily physical activity increased by 22.79 minutes/day (95% CI -18.45, 64.04) more than control. For the RA intervention group, HAQ function score improved by 0.11 (95% CI -0.01, 0.22) compared to controls.

Conclusion: Motivational-interviewing-based physical activity intervention participants with knee osteoarthritis experienced significant improvement in pain compared to physician-advice-only controls. Both knee osteoarthritis and RA intervention participants demonstrated a trend towards improved physical function.

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Due to these sparse and inconsistent clinical data, our current study aims to describe the associations between serum levels of resistin, knee synovial inflammation and structural changes in patients with knee osteoarthritis (OA).

Methods: Patients (n = 200) with symptomatic knee OA (assessed according to American College of Rheumatology criteria) (mean 63.1 years, range 49-79, female 46.5%) participated in this study and all measures were performed at baseline and two years later. Serum levels of resistin were measured using enzyme-linked immunosorbent assay. Infrapatellar fat pad (IPFP) high signal intensity alteration and effusion-synovitis were measured from magnetic resonance imaging (MRI) to represent synovial inflammation. Knee structural changes such as cartilage volume, cartilage defects and bone marrow lesions (BMLs) were assessed in MRI semi-quantitatively or quantitatively. Multilevel mixed-effects liner regression or logistic regression was used in the data analyses.

Results: Serum level of resistin was not significantly associated with age, sex and BMI. It was significantly and positively associated with high signal intensity alteration within IPFP and effusion-synovitis score and volume in univariable and multivariable analyses (Table 1). Additionally, it was significantly and positively associated with total scores of tibiofemoral cartilage defects and BMLs before and after adjustment for co-variables (Table 1). The association between serum levels of resistin and tibial cartilage volume was negative but not significant in multivariable analyses. There were no significant interactions between serum resistin, sex and BMI on synovial inflammation and knee structural change.

Conclusion: Serum levels of resistin were significantly and positively associated with synovial inflammation and knee structural abnormalities, suggesting a potential role of resistin in knee OA. Table 1. The association between resistin and knee structural changes

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Whilst arthritis in other affected joints and back pain is known to lead to worse outcomes following total hip replacement surgery, these risk factors have not previously been operationalized as a musculoskeletal morbidity profile. The aim of this study was to measure the influence of other joints and spine (in four musculoskeletal morbidity grades) on the 1-year outcome of primary hip replacement.

Methods: The European Collaborative Database of Cost and Practice Patterns of Total Hip Replacement study (EUROHIP) consists of 1,327 patients receiving primary THR for osteoarthritis (OA) across 20 European orthopedic centers. The primary outcome was whether or not a patient responded to THR at 12-months as measured by the relative effect per patient (REPP score), calculated for each patient using the total WOMAC score. The primary predictor of interest was the grade of musculoskeletal morbidity (MSM). The cohort was grouped into four combinations of arthritis based on the index joint, other large joints and spine respectively: MSM grade 1 (single-joint), 2 (multi-joints), 3 (single-joint and spine), 4 (multi-joints and spine) (Table 1). Confounders adjusted for were: age, sex, body mass index, living alone, years of hip pain, ASA grade, anxiety/depression, pre-operative WOMAC subscales.

Results: 845 patients were included for this analysis with complete 12-month follow-up WOMAC scores. The mean age was 65.7 years and 55.2% were female. Increasing MSM grade was associated with worse outcomes of surgery, where the responder rates for THR were: 254 (92.4%) MSM grade 1, 272 (87.2%) MSM grade 2, 46 (80.7%) MSM grade 3, 142 (74.4%) MSM grade 4. This was confirmed in adjusted logistic regression models: MSM grade 4 vs. 1 odds ratio (OR) 0.26 95% confidence interval (CI) (0.14, 0.46); MSM grade 3 vs. 1 OR 0.32 95%CI (0.14, 0.73); MSM grade 2 vs. 1 OR 0.56 95%CI (0.32, 1.00) (Fig.1).

Conclusion: Other joints and spine measured as musculoskeletal morbidity have a strong influence on the 1-year outcome after THR. The effect size was large in comparison to other risk factors. Even so, the majority of patients in MSM grade 4 can still profit from surgery (>75% responder rate).

Table 1. Description of Musculoskeletal morbidity (MSM) grades

	Without Spine	With Spine
Index Joint	**Grade 1**	**Grade 3**
	416 (32.1%)	112 (8.6%)
Index & Other large joints	**Grade 2**	**Grade 4**
	479 (36.9%)	291 (22.4%)

Longitudinal Construct Validity for Four Patient-Reported Outcomes Measurement Information System (PROMIS) Short Forms: Physical Function, Pain Interference, Depression, and Anxiety Among Adults with Knee Osteoarthritis

Augustine C. Lee[1], Lori Lyn Price[2], Jeffrey B. Driban[1], William F. Harvey[1], Timothy E. McAlindon[3], Angie Mae Rodday[4], Hans E. Knopp[5] and Chenchen Wang[1], [1]Rheumatology, Tufts Medical Center, Boston, MA,

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-Reported Outcomes Measurement Information System (PROMIS) provides clinicians and researchers access to reliable, valid measures of health status to resolve many challenges associated with the comparability and interpretability in OA. However, for adults with OA, longitudinal construct validity, i.e. ability of a measurement instrument to detect changes over time, of PROMIS instruments is unknown. Our purpose is to evaluate the longitudinal construct validity for 4 PROMIS Short Forms: Physical Function, Pain Interference, Depression, and Anxiety among those with knee OA following the recommended guidelines of the Consensus-based Standards for the Selection of Health Measurement Instruments (COSMIN).

Methods: We performed a longitudinal analysis using the pooled, similar treatment effects that resulted from a randomized trial comparing Tai Chi with physical therapy in adults with symptomatic knee OA (ACR criteria). Participants completed questionnaires at baseline and after 12-week intervention. Longitudinal construct validity was investigated according to the COSMIN standard by testing 6 *a priori* hypotheses regarding expected Spearman's correlations between changes in PROMIS scores and changes in legacy measures (Short Form-36 subscales, WOMAC, Beck Depression, Perceived Stress, 6-minute and 20-Meter Walk Tests). After an item-by-item comparison of PROMIS short forms and legacy measures, an expert group formulated each hypothesis by including direction, strength, and rationale for expected correlation. Each PROMIS short form was assigned an overall rating of longitudinal construct validity based on its total number of confirmed hypotheses: High, 5-6 of 6 ($\geq$75%); Moderate, 3-4 of 6 (50%$\leq$ x <75%); or Poor, 0-2 of 6 (<50%).

Results: We examined 165 participants (mean age 61 years, 70% female, 53% white, 92% Kellgren/Lawrence Grade $\geq$ 2). We confirmed 5 of 6 *a priori* hypotheses (83%) for PROMIS Physical Function. For Pain Interference, Depression, and Anxiety, respectively 4 of 6 (67%), 3 of 6 (50%) and 4 of 6 (67%) hypotheses were confirmed. Therefore, PROMIS Physical Function has high longitudinal construct validity, and PROMIS Depression, Anxiety, and Pain Interference have moderate longitudinal construct validity.

Conclusion: Our results support that these 4 PROMIS short forms: Physical Function, Pain Interference, Depression, and Anxiety have the ability to detect changes over time for their intended construct among people with symptomatic knee OA. In addition, we provide an important standard of reference for clinicians and researchers to better apply or interpret these instruments in future clinical trials. Additional studies using PROMIS instruments of different domains or among cross-cultural OA populations are warranted.

Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (OA) is characterized by pain, functional impairment, disability, and joint space narrowing due to degradation of articular cartilage and bone remodeling. The Wnt signaling pathway is known to play a central role in the formation of joint tissues, and altered Wnt signaling has been associated with cartilage loss in preclinical and clinical studies.[1] SM04690 is a small molecule inhibitor of the Wnt pathway in development as a potential OA therapeutic to be administered as an intra-articular (IA) injection into the affected joint. A phase 1, first-in-human, multicenter, 24-week, single-dose-escalation, randomized controlled trial (RCT) of SM04690 was completed in subjects with moderate to severe knee OA. This report provides exploratory radiographic outcomes.

Methods: In the completed phase 1 RCT, escalation cohorts were dosed at 0.03 mg, 0.07 mg, and 0.23 mg SM04690 per 2 mL injection. A sample size of 20 subjects (randomized, 16 active: 4 placebo) per dosing cohort was selected. Subjects were administered a single IA injection into the target knee on Treatment Day 1, and participated in a follow-up period of 24 weeks. Safety, pharmacokinetics (PK), biomarker, and preliminary efficacy data were collected. To evaluate change from baseline in joint space width (JSW), X-rays of the target knee joint were taken at baseline and week 24. An exploratory analysis of change in JSW was conducted using repeated measures analysis of covariance (ANCOVA) adjusting for baseline JSW in the modified Intention-to-treat (mITT) population.

Results: Sixty-one subjects (average age 62.6 [±5.7] years, female n=41 [67%], average BMI 30.4 [±4.7] kg/m^2) were enrolled. In the mITT population at 24 weeks, the 0.07 mg cohort displayed a statistically significant change from baseline in medial JSW (0.49 mm [0.75]) as compared to placebo (-0.33 mm [0.87]) (P=0.02). No change or improvement in medial JSW was observed in 9 of 15 subjects (60%) in the 0.03 mg cohort, 12 of 15 subjects (80%) in the 0.07 mg cohort, and 6 of 11 (55%) subjects in the placebo cohort. In the 0.23 mg cohort, 9 of 16 (56%) subjects demonstrated worsening of JSW. Individual radiographic responses for the 0.07mg cohort and placebo group are presented in the Figure.

Conclusion: Exploratory radiographic outcomes from this completed phase 1 study suggested that treatment with SM04690 may have maintained or increased joint space width compared to placebo, providing proof of concept data of efficacy in the treatment of knee OA. Further evaluation studies are ongoing. References:

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: African Americans have higher prevalence and greater severity of knee osteoarthritis (OA) on radiographs compared with Caucasians. Magnetic resonance imaging (MRI)-based quantification of 3-dimensional (3D) anatomical changes of the knees may offer superior insights into potential racial differences in joint morphology compared with radiographs. Therefore, we applied this method to examine anatomical differences between African Americans and Caucasians.

Methods: We used data from the OAI, a longitudinal cohort study designed to investigate the natural history of and risk factors for knee OA. Active appearance modelling, which has excellent reliability, was used to automatically segment the knee MRI (MAGNETOM Trio, Siemens) sagittal 3D DESS-we sequence from each femur as principal components from a shape model. The OA bone shape vector is a line through the mean shape of a training set of OA and non-OA femurs, also expressed as principal components. Individual bone shapes are projected orthogonally onto the OA bone shape vector. Zero is defined as the mean non-OA shape, 1 unit is 1 SD of the non-OA shape distribution. Positive values indicate more of an OA shape. Separate vectors were prepared for males and females. We quantified the difference in 3D femur bone shape between African Americans and Caucasians, stratified by sex, using linear regression, adjusting for KL grade, age, and body mass index (BMI), using generalized estimating equations to account for the correlation between knees within the same subject.

Results: We included 1534 African American and 7319 Caucasian knees that had 3D bone shape measured at baseline. Of African Americans, 481 male and 1053 female knees were assessed. Of Caucasians, 3165 male and 1053 female knees were included. In male and female knees, the crude mean 3D bone shape vectors for the distal femur were higher for African Americans compared with Caucasians, even at KL grade 0 (**Table 1**). Significant differences in 3D bone shape were found between in African Americans and Caucasians, stratified by sex, controlling for age and BMI (**Table 2**).

Conclusion: African Americans had more overall anatomical changes of OA than Caucasians in MRI-based 3D femur bone shape, which were not due to differences in KL grade, age, or BMI. Further, African Americans had higher OA vector values, even at KL grade 0, than Caucasians, and this may explain the higher prevalence of OA in African Americans. Of note, age and BMI had only minimal effect on 3D femur bone shape change. This finding of racial differences in 3D bone shape warrants further investigation to understand the underlying mechanisms causing these differences to gain further insight into factors influencing the pathogenesis of OA.

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity, a major risk factor for knee osteoarthritis (OA), is a state of systemic inflammation through elaboration of adipokines (pro and anti-inflammatory cytokines) from adipose tissue. Whether degree of adiposity or systemic level of pro-inflammatory adipokines is associated with presence of local inflammation (synovitis) in knee OA is not known. Thus, in this study, we evaluated the cross-sectional association between total body fat mass and serum leptin (a proinflammatory adipokine) level to the presence of synovitis of the knee on MRI in community-dwelling older adults, with and without knee OA.

Methods: We included participants from the Multicenter Osteoarthritis (MOST) study, which has whole body Dual Energy X-ray (DXA) for assessment of fat mass, serum leptin assay and knee MRI (fat-suppressed (FS) fast spin-echo intermediate-weighted (IW) sequences) for evaluation of synovitis available. Sex-specific tertiles were created for total body fat mass and serum leptin from baseline visit. Person-level synovitis was defined by WORMS score >=1 on knee MRI from the same visit separately at 3 specific sites: 1) Infrapatellar fat pad; 2) Intercondylar; and 3) whole knee Effusion. A sum score of synovitis was calculated by adding the scores at the above sites. To assess the relation of fat mass tertiles and serum leptin tertiles to knee synovitis, we performed logistic regression for the site specific synovitis and linear regression for sum of synovitis score, adjusting for age, sex, education, physical activity, smoking status and body weight (proxy for loading effect). Analyses were repeated, stratified by the presence of radiographic knee OA (Kellegren-Lawrence grade ≥2) status.

Results: Among 2871 subjects, 1015 subjects developed synovitis (162 infrapatellar, 419 intercondylar and 462 effusion). We did not find an association between tertiles of fat mass or serum leptin with site specific synovitis or sum of synovitis scores (**Table 1**). Results did not change when stratified by radiographic knee OA.

Conclusion: Our results suggest that presence of knee synovitis may not be associated with obesity-related systemic inflammation. However, as our study is limited by power, larger studies are needed to comprehensively study this relation between obesity-related systemic inflammation and synovitis in knee OA as it may provide insight into the pathogenesis of knee OA.

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Preliminary investigation in this cohort supported an association between hip morphology and symptoms, however, the influence of race, gender, age, BMI and radiographic hip OA (rHOA) remains unclear.

Methods: Data are from the baseline visit of the Johnston County OA Project. Hip symptoms were assessed by: 1) patient-reported groin pain (yes/no) and 2) hip pain on internal rotation (yes/no). RHOA was defined as a Kellgren Lawrence grade of 2 or more. Standardized software (OxMorf, Oxford, UK) was used to assess hip morphology. We focused on 5 key hip morphologies (Table). Joint-based logistic regression models, stratified by sex, and employing generalized estimating equations to account for intra-person correlation, were used to estimate Odds Ratios (OR) associations between morphologic measures and symptomatic outcomes, adjusting for race, age, BMI, and side (labeled OR^1), while a second model considered the influence of baseline rHOA (labeled OR^2); interactions between rHOA and morphologic measures were considered significant at a p value of <0.1, in which case stratified analyses were performed.

Results: The analysis sample included 4530 hips from 2274 individuals, mean age 64 years, mean BMI 29kg/m^2, 30% Black, 39% male. Approximately 20% of hips had rHOA. Among women, significant associations were identified between hip symptom outcomes and increasing alpha angle, Gosvig ratio, triangular index height, and protrusio acetabula independent of race, age, and BMI. However, after adjusting for rHOA, the associations with pain on internal rotation were no longer statistically significant, and those with groin pain were seen only for hips with rHOA. Additionally, protrusio acetabula was protective for groin pain in this model (Table, left). For men, a similar statistically significant association between hip symptom outcomes and increasing alpha angle, Gosvig ratio, triangular index height, and lateral center edge angle (CEA) was noted. After adjustment for rHOA, these associations were attenuated, although significant associations remained between pain on internal rotation and increasing Gosvig ratio, triangular index height, and for CEA <=25 degrees (versus referent 25-40 degrees). For the groin pain outcome, a statistically significant association with alpha angle was present only in those with rHOA. In this model, a low CEA (<=25 degrees) was associated with greater odds of groin pain, while a high CEA (>40 degrees) was protective (Table, right).

Conclusion: Hip pain on internal rotation and groin pain were more likely with certain hip morphologies in men and women, however this association was highly dependent on baseline rHOA status. Pincer-type morphologies

(CEA>40 degrees and protrusio) appeared protective for groin pain when coupled with rHOA. One hypothesis is that the added depth and acetabular coverage could increase stability and reduce extreme range of motion, resulting in reduced symptoms.

TABLE. Associations (and corresponding 95% confidence intervals) between morphologic measures and hip symptom outcomes by sex, before (OR[1]) and after (OR[2]) adjustment for rHOA

MORPHOLOGIC MEASURES	WOMEN (n=2755 hips)				MEN (n=1775 hips)

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: For the assessment of Symptomatic Slow Acting Drugs in Osteoarthritis (SYSADOAs), regulatory Agencies request the assessment of two co-primary endpoints: pain and function. They also recommend the design of three-arm studies including the investigational drug, a placebo and an active comparator.

Methods: The CONCEPT study investigated the symptomatic effects of pharmaceutical grade Chondroitin Sulfate (CS) (800 mg/day), Celecoxib (CE) (200 mg/day) and a placebo (PL) in a double-blind, double-dummy Phase III clinical trial.

Results: 604 patients recruited in 5 European countries, with knee osteoarthritis (OA) in accordance with the ACR criteria, were followed for 182 days. In the intention to treat analysis, pain (VAS) was significantly reduced, at D182, in the CS (-52%) and in the CE (-52%) compared to PL (-42%) ($P < 0.05$ for both). No differences were observed between CS and CE. The Lequesne index, measuring pain and function, showed similar results with CS (-37%) and CE (-36%) being significantly different from PL (-28%) ($P < 0,05$ for both) and no difference between CS and CE. Similar results were observed for the Minimum Clinically Important Improvement (MCII)

and Patient Acceptable Symptoms State (PASS) at D182 for the intention to-treat and per-protocol populations. Safety analyses showed no significant differences between the three groups.

Conclusion: Pharmaceutical grade Chondroitin Sulfate, at the dose of 800 mg/day, reduced pain and improved function to the same extent as Celecoxib and significantly more than placebo, in patients with knee osteoarthritis.

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone marrow lesions (BMLs) are of high interest in osteoarthritis for their association with pain and structural progression. They are characterized on magnetic resonance (MR) images as ill-defined areas of hyper intensity on fat-suppressed, T2 weighted, and short tau inversion recovery (STIR) sequences and of intermediate or low intensity on T1 weighted sequences in comparison with normal subchondral bone. Our understanding of the underlying mechanism of action of BMLs will be increased by histopathological studies of the subchondral bone. Therefore, we performed a systematic literature review.

Methods: We searched relevant databases up to May 2016 without language restrictions for articles describing the histology of BMLs in patients with primary osteoarthritis. We identified 503 unique records that were screened independently by two authors. Based on title and abstract we excluded 463 records (agreement 96.0%, k=0.65), and for the remaining 40 records we retrieved full-text papers to assess eligibility. Finally, we included 11 articles in this review by mutual agreement. Due to heterogeneity between studies meta-analysis was not possible.

Results: All studies used specimens from total joint replacement surgery (knee n=7; hip n=4). Study size ranged from 6 to 60 patients (median 15). Studies differed in histological and radiological methods (e.g. in vivo (n=8)

versus ex vivo (n=3) imaging and imaging sequences). Most reported histological findings in BMLs were fibrosis (knee n=7; hip n=3), necrosis (knee n=4; hip n=3) and trabecular abnormalities (knee n=5; hip n=2). Bone marrow edema (n=5) was predominantly reported in hip studies (n=3), and less in knee studies (n=2). Other reported findings were: hyper vascularity or blood vessel hyperplasia (n=5), bone remodelling (n=3) and increased bone volume fraction (n=4). Two knee studies correlating topography of MR imaging with histology, compared subchondral bone with and without BMLs. Both studies demonstrated fibrosis, necrosis and trabecular abnormalities were increased in BMLs compared to control subchondral bone. In three knee studies micro-computed tomography was used showing that trabeculae of BMLs were thicker and more plate-like shaped than trabeculae in control specimens.

Conclusion: Published data summarized in this systematic review indicated that several histological features are reported in BMLs; consistently reported are fibrosis, necrosis and trabecular abnormalities. How and whether these histological features are related is not clear. However, to think of BMLs as merely reflecting increased water content within the bone marrow, is an outdated notion. Since some histological findings indicate an active process, BMLs might not only characterize disease stage, but could also help to identify those patients at high risk of structural progression. A better understanding of pathological processes underlying BMLs could potentially lead to new targets in osteoarthritis treatment.

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To demonstrate the non-inferiority of “Active” compared to “Standard” spa therapy at 6 months in symptomatic knee osteoarthritis (KOA) care.

Methods: Prospective, randomized, monocenter, non-inferiority trial with community-based recruitment of KOA patients. Inclusion criteria were: KOA according to the ACR criteria, pain VAS> 3 on a 0-10 scale, and Kellgren and Lawrence (KL) grade ≥2. "Standard" spa" comprised 18 days of standardized spa treatment, 6 days a week for 3 weeks. "Active spa" included iterative spa sessions, 3 days a week for 3 weeks, followed by a dedicated rehabilitation program, 3 days a week for 3 weeks. The primary endpoint was achievement of a minimal clinically important improvement (MCII) for pain VAS, and/or a MCII for function on WOMAC function subscale and no knee surgery, at 6 months (composite MCII). The secondary endpoints were composite MCII at 3 months and achievement of Patient Acceptable Symptoms States (PASS) for pain and function.

Results: Of 283 participants (mean age 64.3 (9.0) years, 181 (66.8%) women, 181(79.7%) bilateral OA, 151 (58.5%) KL grade III or IV), 145 were allocated to Standard spa and 138 to Active spa. Non inferiority could not be demonstrated for the primary endpoint at 6 months: difference of responders -0.01 90%CI [-0.18 to 0.02], p=0.14; number of patients achieving composite MCII: 86 (66.2%) and 66 (57.9%) in the Standard and Active spa group respectively. However, difference between the 2 groups was neither significant for the same criteria (p=0.18). At 3 months, active spa group was not inferior to standard spa group with composite MCII outcome criteria. The number of patients achieving PASS increased from baseline to 3 months and then decreased at 6 month (table). All the analyses using PASS criteria showed non-inferiority of the active spa group at six months.

		Standard spa		Active spa		Difference of responders		P
		N=145		N=138				(non -
Definition of responder		N	(%)	N	(%)		[IC 90%]	inferiority)
3 months	Composite MCII	76	(56.3)	75	(70.1)	0.14	(0.04 to 0.24)	<.0001
6 months	Composite MCII	86	(66.2)	66	(57.9)	-0.08	(-0.18 to 0.02)	0.14
Before Spa	PASS for pain	13	(9.8)	18	(15.1)	0.05	(-0.02 to 0.12)	<.0001
3 months	PASS for pain	54	(44.6)	66	(66.0)	0.21	(0.11 to 0.32)	<.0001
6 months	PASS for pain	51	(44.0)	47	(45.6)	0.02	(-0.09 to 0.13)	<.0001

Conclusion: Active spa can reasonably be proposed to patients with KOA. Such protocol could be more cost-effective while allowing benefiting spa therapy without absenteeism from work or avoiding accommodation costs for patients living close to the centre.

Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Nonsteroidal anti-inflammatory drugs (NSAIDs) are widely used in Osteoarthritic patients for their anti-inflammatory and pain-killer proprieties. Various reports suggest an increase in blood pressure of about 3-5 mmHg in relation with systemic use of NSAIDs. This effect is observed from the beginning of the treatment; however, due to his "modest" amplitude, it was largely ignored both by patients and physicians. New epidemiological data suggest that such a small increase in BP could produces in USA about 21.000 deaths per year (higher than in case of gastrointestinal deaths produced by the unprotected usage of nonselective NSAID). For the time being much less is known about the blood pressure effect of topical NSAIDs. The interest for this subject is higher as long as both systemic and topical NSAID seem to have similar therapeutic effect on superficial exposed joints (e.g. knee, wrists, elbows etc.) but different safety profile. The aim of the study was to evaluate whether or not the use of a topical NSAID (acecelofenac) in osteoarthritis affects blood pressure or pulse rate values.

Methods: 52 patients with a clear diagnostic of osteoarthritis have been evaluated, by using a continuous Automated BP Monitoring system (ABPM), before and after the utilization of topical aceclofenac. Blood pressure and pulse rate have been continuously recorded for 48 hours at baseline (24 hours without topical NSAID use) and day1 (24 hours with topical NSAID use). Same NSAID (namely aceclofenac) in same dose have been used in all cases. Subjects that received antihypertensive therapy, those receiving therapeutic regimes with potential impact on blood pressure and those that changed their concomitant medication during the study have been excluded from the analyses. Daytime (0700-2200), nighttime (2201-0659) and all-day (24h) systolic and diastolic BP along with pulse rate values have been analyzed. Difference between Baseline and Day1 have been tested by using ANOVA and Fisher exact test; a $p<0.05$ was considered significant.

Results: : No difference has been observed between baseline (no drug) and Day 1 (topical aceclofenac day) regarding diastolic BP or Heart rate (see the table). For systolic BP a statistical significant reduction between Day1 and baseline (-1.88 mmHg , sd: 5.8 mmHg) has been found. Similar results have been obtained for all-day, nighttime and daytime sub analysis.

	N	Minimum	Maximum	Mean	Std. Deviation
Sys BP Baseline	52	101.75	147.90	122.8904	10.16477
Sys BP Day 1	52	103.9	140.3	121.007	7.6768
Dia. BP Baseline	52	55.05	88.10	75.4462	6.41531
Dia. BP Day 1	52	56.4	87.1	75.390	5.9851
HR Baseline	52	60.2	95.9	78.127	6.7779
HR Day 1	52	59.3	90.3	77.313	6.2257

Conclusion: Although this study has certain limitations our data suggest that no significant increase of BP or HR are associated with topic use of NSAID (in our case Aceclofenac). Larger studies should be made to confirm the conclusion of this study. **References:** 1.Snowden S, Nelson R- The effects of nonsteroidal anti-inflammatory drugs on blood pressure in hypertensive patients. High-Fat Diet Is Associated with a Higher Incidence of Radiographic Knee OA and Progression of Knee Joint Space Narrowing: Data from the Osteoarthritis Initiative

Anna Shmagel[1], Naoko Onizuka[2], Lisa Langsetmo[3], Kristine E. Ensrud[4] and Robert Foley[5], [1]Rheumatic & Autoimmune Diseases, University of Minnesota, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, [3]University of Minnesota School of Public Health, Minneapolis, MN, [4]University of Minnesota and Minneapolis VAHS, Minneapolis, MN, Minneapolis, MN, [5]Renal Diseases and Hypertension, University of Minnesota, Minneapolis, MN

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Animal studies have shown that high-fat diet may increase the risk of osteoarthritis (OA), while other evidence suggests that dietary polyunsaturated fatty acids may be protective.

Methods: We investigated the associations between high-fat diet and radiographic OA in a well-established knee OA incidence and progression cohort (Osteoarthritis Initiative) N = 4796. Fixed flexion radiographs of bilateral knees were evaluated for Kellgren and Lawrence score (KL) and joint space narrowing (JSN) at baseline, 12, 24, 36, 48, 72, and 96 months of follow up (mean follow-up 8 years); incident radiographic OA was defined as a new KL score ≥2 in either knee, and JNS progression was defined as progression from a previous radiograph by a partial grade or more. Diet was assessed at baseline by food frequency questionnaire. Dietary fat consumption was expressed as per cent of total calorie intake and categorized in quartiles (Q1:<29.05% (referent group), Q2: 29.06-34.29%, Q3: 34.30-39.42%, Q4: >39.43%). Logistic regression was used for analyses.

Results: After adjustment for age, race, and gender, higher dietary fat consumption was associated with increased odds of incident radiographic knee OA (aOR Q2 1.14 (0.89-1.45), Q3 1.37 (1.07-1.75), and Q4 1.52 (1.20-1.94), p = 0.003) and progression of knee JSN (aOR Q2 1.15 (0.96-1.38), Q3 1.40 (1.17-1.67), and Q4 1.28 (1.07-1.54), p = 0.002). Similarly, higher consumption of poly- and monounsaturated fats as well as saturated fats was associated with incident radiographic knee OA and JSN progression. Further adjustment for BMI attenuated the associations of higher dietary fat consumption with these outcomes; for example, the aORs for incident radiographic knee OA were Q2 1.05 (0.81-1.35), Q3 1.25 (0.97-1.61), and Q4 1.28 (0.99-1.65), p = 0.15).

Conclusion: In a cohort of high risk adults, high-fat diet was associated with an increased incidence of radiographic knee OA and progression of knee JSN due in large part to greater body weight among those with higher fat consumption. Biological mechanisms underlying the relationship between high dietary fat consumption, obesity and OA should be explored in further studies.

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Safety studies have shown that risks associated with non-steroidal anti-inflammatory drugs (NSAIDs) are related to dose; however, there is little evidence regarding this dose-toxicity relationship for meloxicam, including in the United States (US). Prior studies assessing the meloxicam dose-toxicity relationship have been limited in sample size, the ability to control adequately for potential confounders and changes in dose over time, and the inclusion of a comprehensive set of adverse event outcomes. This study assessed the relationships between meloxicam dose and risks of gastrointestinal (GI), cardiovascular (CV), and renal events in a commercially insured US population.

Methods: MarketScan©claims databases (2010-14) were used to analyze the risks of GI (upper GI bleed/perforation [UGIB], uncomplicated ulcer [UU], lower GI bleed [LGIB]), CV (myocardial infarction [MI], stroke, congestive heart failure [CHF], hypertension), and renal events by meloxicam daily dose (DD) category (>7.5mg to ≤15mg [higher dose]; ≤7.5mg [lower dose]) in a cohort of adult new users of meloxicam with osteoarthritis (OA). A separate cohort was created to assess each event. Patients with prior history of GI, CV or renal disease were excluded from the cohort constructed for that event. Hazard ratios (HRs) were estimated using multivariable Cox analyses with DD as a time-dependent covariate. The models controlled for baseline patient demographics and clinical characteristics, selected a priori based on published NSAID analyses and clinical guidance.

Results: In total, 337,260 meloxicam new users (62.5% female; median age at index 59 years) met the initial study inclusion criteria. HRs and 95% confidence intervals are presented in Table 1. Increased risks of GI and CV events were associated with higher versus lower doses of meloxicam. HRs for higher dose (> 7.5 mg to ≤15mg) versus lower dose (≤ 7.5 mg) for MI (1.05), stroke (1.03), hypertension (1.07), UGIB (1.50), UU (1.18), and LGIB (1.10) were above 1.0.

Table 1. Cox Hazard Ratios for Gastrointestinal, Cardiovascular, and Renal Events Associated with Higher Versus Lower Doses of Meloxicam among Adult New Meloxicam Users with Osteoarthritis with No Observed History of the Event

Endpoint	Hazard Ratio (>7.5mg to <15mg vs ≤7.5mg)	95% Confidence Interval
MI	1.05	0.93, 1.18
Stroke	1.03	0.96, 1.11
First of MI or Stroke	1.03	0.97, 1.10
CHF	0.95	0.82, 1.10
First of MI, Stroke, or CHF	1.06	0.99, 1.13
Hypertension	1.07	1.03, 1.11
UGIB	1.50	1.20, 1.88
UU	1.18	1.02, 1.37
First of UGIB or UU	1.23	1.07, 1.40
LGIB	1.10	0.98, 1.23
First of UGIB, UU, or LGIB	1.14	1.04, 1.24
Renal Failure	0.99	0.89, 1.10

Conclusion: In this cohort study, numerically increased risks of CV and GI events were observed with higher doses versus lower doses of meloxicam among adult new users of meloxicam with OA and no prior history of the

event. Of note are increased risks of hypertension, an event of substantial clinical importance previously inadequately studied, and upper GI events. These findings support the US Food and Drug Administration (FDA) recommendation to use the lowest effective dose of NSAIDs. This study suggests the importance of studying the effect of meloxicam dose on risks of serious adverse events in a large sample, adequately adjusting for potential confounders, and treating dose as a time-dependent covariate.

The Association of Superolateral Hoffa's Fat Pad Edema and Synovitis with Structural Changes in the Patellofemoral and Tibiofemoral Joints: The Multicenter Osteoarthritis Study

Mohamed Jarraya[1], Ali Guermazi[2], David T. Felson[3], Frank Roemer[4], Michael C. Nevitt[5], James Torner[6], Cora E. Lewis[7] and Joshua Stefanik[8], [1]Mercy Catholic Medical Center, Darby, PA, [2]Boston University School of Medicine, Boston, MA, [3]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, [4]University of Erlangen-Nuremberg, Erlangen, Germany, [5]Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, [6]University of Iowa, UIowa, Iowa City, IA, [7]Preventive Medicine, University of Alabama at Birmingham, Birmingham City, AL, [8]Physical Therapy, Northeastern University, Boston, MA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the relation of superolateral HoffaÕs fat pad (SHFP) edema and Hoffa-synovitis to cartilage damage and bone marrow lesions (BMLs) in the patellofemoral (PF) and tibiofemoral (TF) joints.

Methods: The Multicenter Osteoarthritis (MOST) study is a NIH-funded longitudinal cohort study of older individuals with or at risk for knee OA. We used data from the 60-month study visit where all eligible subjects had knee MRI assessed for other structural features of knee OA. SHFP edema and Hoffa-synovitis (infrapatellar and/or intercondylar) were assessed on sagittal proton density-weighted fat-suppressed MRI images by two musculoskeletal radiologists and dichotomized into presence (>1) and absence (=0). Cartilage damage and BMLs were scored in the PF and TF joints. We used three definitions of structural damage: 1) any cartilage damage (WORMS score of ³2), 2) full-thickness cartilage damage (WORMS score 2.5, 5-6) and 3) any BML (WORMS

score of ³1). We further defined the location of PF and TF joint damage in the lateral and medial compartments. Separate logistic regression models were used to determine the relation of SHFP edema to our three definitions of structural damage in the medial and lateral PF and TF joints, adjusting for age, sex and BMI. The same models were used with HoffaÕs synovitis as the exposure instead of SHFP edema.

Results: 1041 knees were included; Mean (sd) age and BMI were 66.8 (7.5) and 29.6 (4.8), respectively; 65% were female. SHFP edema and Hoffa-synovitis was present in 12.7% and 59.3% of knees, respectively. Compared with knees without SHFP edema, knees with SHFP edema showed statistically significant increase in odds of any and full-thickness cartilage damage, and any BML in the lateral PF joint only. Compared with knees without synovitis, knees with Hoffa-synovitis showed statistically significant odds of any and full thickness damage, and BMLs in all 4 compartments (table).

Conclusion: While synovitis is a marker of whole-joint disease, SHFP edema is a surrogate of local lateral PF joint disease only. SHFP edema is likely the result of mechanical impingement and maltracking leading to local structural abnormalities like cartilage and osseous changes.

		Any Cartilage Damage		Full Thickness Cartilage Damage		BMLs	
		Medial	Lateral	Medial	Lateral	Medial	Lateral
SHFP Edema	PF Joint	1.6 (0.97-2.6)	**1.8 (1.2-2.6)**	1.3 (0.84-1.9)	**2.0 (1.3-3.0)**	1.4 (0.93-2.0)	**1.9 (1.3-2.7)**
	TF Joint	0.99 (0.67-1.5)	1.0 (0.72-1.5)	0.99 (0.63-1.6)	0.71 (0.40-1.3)	0.90 (0.61-1.3)	1.3 (0.82-2.1)
Hoffa-Synovitis	PF Joint	**2.5 (1.9-3.4)**	**2.7 (2.1-3.5)**	**2.3 (1.7-3.2)**	**2.9 (2.0-4.1)**	**1.6 (1.3-2.1)**	**2.2 (1.7-2.9)**

Association Between Osteoarthritis and Dyslipidemia: A Systematic Literature Review and Meta-Analysis

Pauline Baudart[1], Karine Louati[1], Christian Marcelli[2,3], Francis Berenbaum[1] and Jeremie Sellam[1], [1]Rheumatology dept, APHP St-Antoine hospital, Univ Paris 06, Paris, France, Paris, France, [2]Rheumatology, Caen, France, [3]Rheumatology dept, University Hospital Centre of Caen, Caen, France

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Beyond obesity-related osteoarthritis (OA), association between metabolic syndrome and OA delineates the metabolic OA phenotype. Along this line, we aimed to investigate the prevalence of dyslipidemia in OA patients and whether OA and dyslipidemia are associated.

Methods: We performed a systematic literature review from 3 electronic databases (PubMed, Embase and Cochrane) until January 2016, and abstracts of 2013-2015 meetings (ACR, EULAR, OARSI). We included cross-sectional, cohort and case control studies to assess the number of patients with OA and/or dyslipidemia. We calculated the mean (±SD) prevalence of dyslipidemia in patients with and without OA and the odds ratio (OR) (95% confidence interval (95%CI)) of having dyslipidemia among patients with OA. We used Revman V.5.3 to perform a meta-analysis. A random-effects model was used in case of high heterogeneity. Quality of the studies was assessed with STROBE score (%) and sensitivity analyses were performed.

Results: From 605 published studies, 48 were included in the analysis (29 cross-sectional, 10 cohort and 9 case-control studies). The median of STROBE quality score was 69%. Twenty-one over 30 studies showed a positive association between OA and dyslipidemia. Twelve over 18 studies with a score STROBE > 60% found a positive association. Four over 7 studies that reported an OR adjusted on age and BMI were positive too. In 14,843 patients with OA, the mean prevalence of dyslipidemia was 30.2±0.6% (mean±SD), whereas in 196,168 patients without OA, the mean prevalence was 8%±0,1%. The risk of dyslipidemia was greater in OA than non-OA patients (OR=1.98 (1.43-2.75), p<0.0001*) (Figure 1)*, especially for knee (OR=2.27 (1.33-3.89), p=0.003) and hand OA localizations (OR=2.12 (1.46-3.07), p<0.0001). Results were unchanged in sensitivity analyses (exclusion of studies with STROBE score <60% or including OA diagnosis not based on ACR criteria or Kellgren-Lawrence grading).

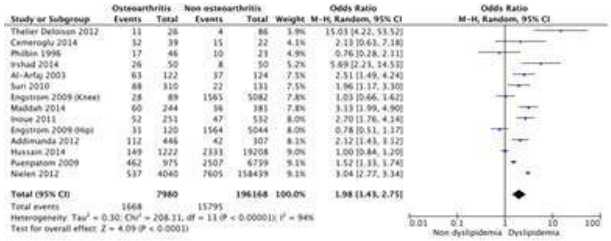

Figure 1: Forest Plot for dyslipidemia among patients with and without OA

Conclusion: OA Patients have a 2-fold increased risk for dyslipidemia, suggesting that this metabolic disturbance could be a risk factor of OA. Such a result supports the individualization of a metabolic OA phenotype.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Hand osteoarthritis (HOA) is a common and frequent cause of pain. HOA is a heterogeneous group of disorders with two main subsets including non-erosive disease and erosive, sometimes referred to as inflammatory, HOA. Few studies demonstrated inflammatory ultrasound changes and more severe clinical symptoms in patients with erosive compared with non-erosive disease, however the results are inconclusive. The aim was to evaluate progression of pain, stiffness, physical impairment and ultrasound features in patients with erosive and non-erosive HOA in a one-year longitudinal study.

Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint pain and swelling were assessed. Patients reported joint pain on 100 mm visual analogue scale (VAS). Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Radiographs of both hands were examined and erosive disease was defined by at least one erosive interphalangeal joint. Synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes. Patients were examined at baseline and one-year follow-up.

Results: Altogether, 129 patients (12 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2015. Out of these patients, 72 had erosive disease. Patients took symptomatic slow-acting drugs (SYSADOA) twice a year, non-steroidal anti-inflammatory drugs (NSAIDs) and analgesics on demand. Duration of morning stiffness ($p<0.01$) and number of clinically swollen joints ($p<0.05$) were significantly higher in patients with erosive compared with non-erosive disease at study entry. Duration of morning stiffness ($p<0.05$) become shorter in patients with erosive, but not in those with non-erosive disease, however the number of clinically swollen joints were not significantly changed at one year follow-up in both groups. According to the AUSCAN, patients with erosive compared with non-erosive disease had more pain ($p<0.05$) and stiffness ($p<0.01$) at study entry. Pain, but not stiffness, got worse ($p<0.05$) in patients with erosive compared with non-erosive disease. US-detected pathologies such as gray-scale synovitis total score ($p<0.001$), intensity of PDS ($p<0.01$) and number of osteophytes ($p<0.01$) were significantly higher in patients with erosive compared with non-erosive disease at study entry and got worse in gray-scale synovitis total score ($p<0.01$), intensity of PDS ($p<0.01$) and numerically also in number of osteophytes ($p<0.1$) at one-year follow-up. There were no significant differences in consumption of NSAIDs for OA between both groups.

Conclusion: This study shows that pain associated with US-detected synovial hypertrophy, inflammatory signs and osteophyte formation is more severe in patients with erosive HOA than in patients with non-erosive disease and is more likely to progress over one year. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To examine whether synovial changes on ultrasound (US) associate with knee pain (KP) and/or underlying structural radiographic changes of osteoarthritis (OA).

Methods: In this case-control study, participants with early KP and established KP (more than 3 years duration) were compared with participants without KP. Participants were selected from the Knee Pain and Related Health in the Community (KPIC, n=9514) survey in Nottingham, UK. Cases and controls were age and gender matched. KP was defined as pain in or around the knee on most days for at least a month. Synovial changes (effusion, hypertrophy and Power Doppler (PD) signal) were measured by the two observers (inter-observer concordance correlation was 0.8 (0.6 to 0.9) for effusion and 0.7 (0.5 to 0.9) for synovial hypertrophy). OA structural changes were measured by standardised radiographs (semi-flexed weight-bearing and flexed skyline views) using the Nottingham Line Drawing Atlas (NLDA). Odds ratio (OR) and 95% confidence interval (CI) were estimated with adjustment for age, gender, body mass index and the total NLDA scores. Multinomial logistic regression was used to handle the case control study with three groups and to estimate ORs between early KP, established KP and no KP groups. A subgroup analysis in participants with unilateral KP was performed using a multilevel generalized linear mixed regression to compare painful knees with pain-free knees within persons (a well matched case control analysis).

Results: A total of 420 participants were included of which 219 had early KP, 103 established KP and 98 no KP (mean age 60 years; 60% women). The prevalence of US effusion (≥4mm) were 24.5%, 39.8% and 62.1% in no KP, early KP and established KP. The prevalence of US hypertrophy (≥4mm) were 5.1%, 22.2% and 42.7% and the prevalence of PD signal were 0%, 3.2%, and 1.9% in these three groups. US effusion (≥4mm) increased the risk of early KP (OR 2.03, 95% CI 1.16 to 3.56) and established KP (4.75, 2.49 to 9.06). Similarly, hypertrophy (≥4mm) also increased the risk of early KP (5.63, 2.12 to 15.01) and established KP (14.24, 5.12 to 39.60). However, the association with effusion was diminished when adjusted for radiographic changes (Figure 1). In contrast, radiographic severity of OA on the NLDA was positively associated with KP, irrespective of the adjustment for the US features and other confounding factors.

Further analysis in people with unilateral KP (n=147) showed that the associations with both effusion and hypertrophy were diminished after adjusting for radiographic severity (1.02 (0.61 to 1.69) and 1.64 (0.85 to 3.17), respectively).

Conclusion: This study confirms that the association between US synovial changes and KP depends on the radiographic severity of OA, suggesting that US features reflect part of the overall structural changes occurring in OA joints and on their own are unlikely to be independent predictors of knee pain.

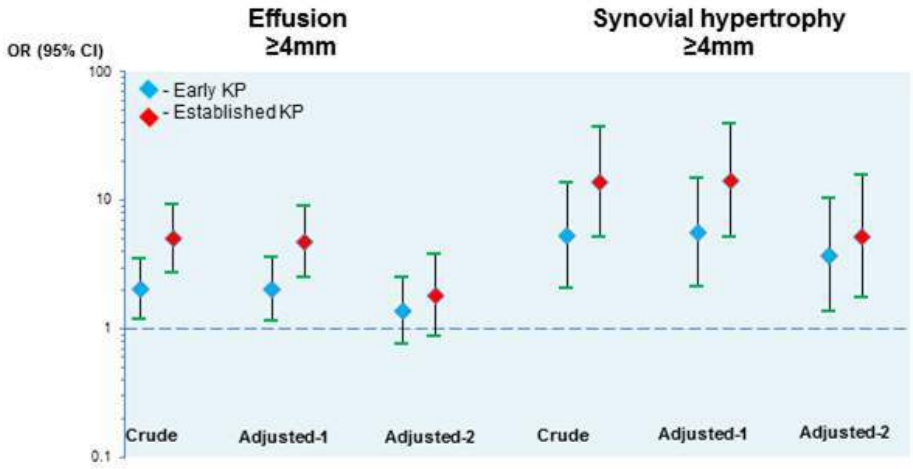

Figure 1. Association between US features and knee pain. Note that y axis is logarithmically scaled.

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Swimming is a non-weight-bearing exercise often recommended to people with knee OA because it is viewed as being less harmful to the knee despite that no epidemiologic studies have evaluated the effect of swimming on knee pain or OA. Therefore, we aimed to evaluate the relationship of a history of swimming with symptomatic knee OA in the Osteoarthritis Initiative (OAI), a community based cohort not recruited based on swimming status.

Methods: This is a cross-sectional study of OAI participants with knee x-ray readings, symptom assessments, and completed lifetime physical activity surveys where participants identified 3 most frequently performed physical activities (≥ 20 times in life) from a list of 37 for ages 12 – 18, 19 – 34, 35 – 49 and ≥50 years old. Those indicating swimming as an activity were defined as a swimmer in that time period. Any history of swimming included swimmers from all time periods. Data on number of swimming bouts performed were ascertained. Posterior-Anterior semi-flexed knee radiographs were obtained at 48-month visit and scored for Kellgren-Lawrence (KL) grade (0-4). Radiographic OA (ROA) was defined as KL ≥ 2. Frequent knee pain within a person required at least one knee with symptoms. Symptomatic radiographic OA (SOA) required that at least one knee had both ROA and frequent knee pain. Anyone with a total knee replacement was classified as having all outcomes. We performed logistic regression analyses where the predictor was any history of swimming and in the specific age ranges using dichotomous groups and groups based on tertiles of swimming bouts. The outcomes were ROA, frequent knee pain, and SOA; adjusted analyses included covariates age, sex, BMI, prior history of injury, and all other activities correlated with swimming, including walking, in the respective age ranges. Trends were tested using the Cochrane-Armitage test.

Results: The activities positively correlated with swimming were walking and other water-based activities, such as sailing.

Table 1. Characteristics of those with no history of swimming, any history of swimming, all participants, and those excluded from these analyses.					
Participant Characteristics	Non-Swimmers (n = 1575)	Swimmers (n =1062)	All Participants (n = 2637)	OAI Participants seen at 96-month visit before 9/12/12 who did not complete the historic physical activity survey (n = 699)	OAI Participants eligible for historic physical activity survey, but did not complete questionnaire (n = 618)
Age (years)	64.1 (9.0)	64.7 (8.9)	64.3 (8.9)	65.4 (8.5)	67.0 (9.4)
Sex (% Male)	48.5%	37.9%	44.2%	32.5%	38.8%
BMI (kg/m^2)	28.7 (4.8)	28.1 (4.9)	28.4 (4.9)	28.7 (5.1)	29.1 (5.2)
Frequent knee symptoms (%)*	40.1%	36.9%	39.3%	50.4%	48.5%
ROA (%)*	59.5%	53.9%	57.3%	65.7%	62.9%

		p for trend=0.4	p for trend=0.2	

***Adjusted for age, sex, BMI, all leisure physical activities that significantly correlate with swimming during the relevant time frame, and prior knee injury.**
****Results were similar with frequent knee pain and ROA as the outcomes.**

Conclusion: We did not find an increased prevalence of symptoms or ROA in people with a history of swimming compared to those without. There may be a benefit to swimming for all these outcomes which could be tempered due to confounding by indication, particularly in older age groups. In the 19-34 year old group, a younger age group, where the result is strongest, there is less likely to be reverse causation. People who swim tend to also walk and participate in other water-based leisure activities. This is the first epidemiologic study to support that swimming does not appear detrimental and may be beneficial towards knee health.

The Cross-Sectional and Longitudinal Associations Between Metabolic Syndrome and Hand Osteoarthritis – Data from the Framingham Study

Mette P. Strand[1], Tuhina Neogi[2], Jingbo Niu[2], David T. Felson[3,4] and Ida K. Haugen[5], [1]Medical Faculty, University of Oslo, Oslo, Norway, [2]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, [3]Arthritis Research UK Centre for Epidemiology, Institute of Inflammation and Repair, University of Manchester, Manchester, United Kingdom, [4]Clinical Epidemiology Unit, Boston University School of Medicine, Boston, MA, [5]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The association between osteoarthritis (OA) and metabolic syndrome (MetS) is controversial. Hand OA, and especially erosive hand OA (1), may be more strongly related to systemic risk factors, such as MetS, than OA in lower limbs. Hence, our aim was to explore the associations between hand OA and MetS in the Framingham Offspring cohort.

Methods: Hand x-rays and clinical data on MetS were available in 1090 persons between 50-75 years, of whom 785 had follow-up hand x-rays after 7 years. Baseline hand radiographs were read according to Kellgren-Lawrence (KL) scale. The longitudinal x-rays were similarly read in pairs according to KL scale and were also read for central erosions. We examined whether MetS and its components were associated with presence of radiographic hand OA (≥1 finger joint with KL grade ≥2) and erosive hand OA (≥1 finger joint with erosions) at baseline using logistic regression. Linear regression was performed with KL sum score as outcome. In longitudinal logistic regression analyses, we examined the associations between MetS and its components at baseline and

incident radiographic hand OA in persons with no hand OA at baseline. Analyses were repeated using incident erosive hand OA in persons with no erosions at baseline. Age and sex were included in all models with/without additional adjustment for body mass index (BMI).

Results: Mean (SD) age was 59.2 (6.3) years and 52% were women. At baseline, radiographic hand OA was present in n=492/1090 (45%), whereas erosive hand OA was found in n=52/785 (7%). N=492/1090 persons (45%) had MetS. In cross sectional analyses, MetS, central obesity and hypertension were associated with hand OA presence after adjusting for age and sex, but only the latter reached statistical significance (Table). No associations were found for KL sum score (data not shown) or erosive hand OA (Table). Incident hand OA and incident erosive hand OA occurred in 166/375 (44%) and 55/733 (8%), respectively. Whereas no associations were found for incident hand OA, there was a trend that MetS was associated with development of erosive OA, and a significant association was found for central obesity (Table). All associations remained similar after additional adjustment for BMI. **Table:** Associations between MetS and hand OA.

	Cross-sectional analyses OR (95% CI)*		**Longitudinal analyses OR (95% CI)***	
	Hand OA presence	**Erosive hand OA presence**	**Incident hand OA**	**Incident erosive OA**
MetS	1.23 (0.95,1.61)	0.71 (0.39,1.30)	0.78 (0.51,1.19)	1.66 (0.95,2.92)
Central obesity	1.23 (0.94,1.61)	0.69 (0.37,1.27)	1.40 (0.92,2.15)	*1.78 (1.02,3.10)*
High BP or anti-hypertensive rx	*1.41 (1.08,1.84)*	1.01 (0.56,1.83)	1.10 (0.72,1.67)	1.19 (0.67,2.11)
Diabetes or antidiabetic rx	1.14 (0.86,1.51)	0.74 (0.38,1.45)	0.89 (0.56,1.42)	1.32 (0.73,2.40)
Low HDL or lipid-lowering rx	1.09 (0.83,1.42)	0.77 (0.41,1.44)	1.23 (0.81,1.87)	1.23 (0.70,2.15)
High triglycerides	0.92 (0.69,1.23)	0.49 (0.25,0.96)	0.67 (0.43,1.05)	1.23 (0.65,2.31)
OR=odds ratio; CI=confidence interval; OA=osteoarthritis, MetS=metabolic syndrome; BP=blood pressure, HDL=high-density lipoprotein, rx=treatment. * Adjusted for age and sex.				

Conclusion: No consistent results were found between MetS and the presence and development of hand OA. A significant association was found between central obesity and incident erosions, but the lack of associations in baseline analyses suggests that this may be a chance finding. **References:** 1) Marshall M. et al. The Clinical Utility of the Bulge Sign in Evaluating Knee Osteoarthritis

Fatimah Al Eid[1], Timothy E. McAlindon[2], Ming Zhang[3] and Jeffrey Driban[3], [1]Rheumatology, Tufts Medical Center, Boston, MA, [2]Division of Rheumatology, Tufts Medical Center, Boston, MA, [3]Tufts Medical Center, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite clinicians commonly using the bulge sign test to assess presence of knee effusion, prior studies have questioned the validity of the test to detect the prevalence of knee effusion based on ultrasound imaging. It remains unknown if the bulge sign test over time is a sensitive test to detect changes in knee effusion. Hence, we evaluated the association between the bulge sign test and magnetic resonance (MR) imaging-based knee effusion volume at a single visit and change over 2 years.

Methods: We selected individuals from the Osteoarthritis Initiative (OAI) who had no radiographic knee osteoarthritis at baseline and had MR images and a clinical exam at baseline and 24-month OAI visits. We enriched the sample to include 250 individuals who had an increase in radiographic severity (Kellgren-Lawrence grade). We selected the 1 knee per person. Two readers used a semi-automated software to quantify MR-based knee effusion volume (includes synovitis and effusion; intra-tester reliability: 0.73 to 0.97). Reader 1 reviewed all segmented images to ensure consistency between readers, knees, and time. The bulge sign was performed during a standardized clinical exam. We defined an incident bulge sign as a person with a positive bulge sign at the 24-month visit but not at baseline. We used an independent-sample t-test to compare baseline effusion volume between those with and without a positive bulge sign at baseline. A second independent-test was used to compare change in effusion volume between those with an incident bulge sign and those who never had a positive bulge sign. We also used logistic regression with ROC curves to explore the optimal cutpoint for baseline effusion volume and change in effusion volume for baseline positive bulge sign and incident bulge sign, respectively.

Results are reported as mean (standard deviation). Results: At baseline of OAI visit 352 participants were eligible participants with a mean age of 59.6 (8.6) years, mean BMI of 28.4 (4.5) kg/m2, and 62% female. The 47 participants with a positive bulge sign (15.38 [12.83] cm^3) had greater knee effusion (t=-3.45, p=0.001) than those without a positive bulge sign (8.81 [6.14] cm^3). Based on an ROC curve, knee effusion volume had an area under the curve of 0.67 with an optimal cutoff between those with and without a positive bulge sign of 8.39 cm^3. At the 24-month OAI visit, the 40 (14%) participants with an incident positive bulge sign (9.85 [11.90] cm^3) had greater increases in knee effusion volume(t = -4.21, p = 0.0001) than the 251 participants without an incident positive bulge sign (1.65 [7.69] cm^3). Based on an ROC curve, change in knee effusion volume had an area under the curve of 0.70 with an optimal cutoff between those with and without a positive bulge sign of 2.06 cm^3.

Conclusion: The bulge sign test is associated with effusion volume and changes in effusion volume but may misclassify individuals with and without larger volumes of effusion or those with larger increases in knee effusion volume. Clinicians and researchers need to be aware of these properties when relying on the bulge sign test.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteophyte (OP) formation is one of the clinical features of osteoarthritis (OA), so early detection of OP formation can be of diagnostic value. OP can be visualised using magnetic resonance imaging (MRI) that are not easily visualised by conventional radiography, and at greater sensitivity than radiographs for detection of early and central OP. Although some studies have examined relationships between MRI-detected OP and clinical features of knee OA, longitudinal studies are rare. Furthermore, clinical significance of x-ray-undetectable OP is unknown. Therefore, our study aims to describe cross-sectional and longitudinal associations between MRI-detected OP and knee pain and structural changes in older adults; and to evaluate the longitudinal associations between x-ray- undetectable OP and knee pain and structural changes.

Methods: 837 participants (mean age 62 years, 50% female) were randomly selected from local community at baseline. T1- or T2-weighted fat suppressed magnetic resonance imaging (MRI) was used to assess knee OP, cartilage volume (CV), cartilage defects (CD) and bone marrow lesions (BMLs) at baseline and after 2.6 years. Knee pain was assessed by self-administered Western Ontario and McMaster Osteoarthritis (WOMAC) Index questionnaire at baseline and after 5 years. Radiographic osteoarthritis (ROA) was assessed at baseline with a standing anteroposterior semiflexed radiograph scored using the Osteoarthritis Research Society International atlas. OPs detected by MRI but not by X-ray at baseline were defined as x-ray- undetectable OP. Analyses were performed using linear regression models and log-binominal regression models.

Results: 86.6% of participants had MRI-detected OPs at baseline, while only 10% of participants had radiographic OPs. Cross-sectionally, MRI-detected OPs at medial tibiofemoral, lateral tibiofemoral and patellar compartments were significantly and site-specifically associated with a higher prevalence of CD and BMLs, and reduced CV after adjustment for common covariates (all $p<0.01$). MRI-detected OPs in whole compartment were significantly associated with higher prevalence of total knee pain ($p<0.01$). Longitudinally, baseline MRI-detected OP site-specifically predicted increases in CD and BMLs and loss of CV (all $p<0.01$) in multivariable analyses.

Compared to participants without any OP, participants with x-ray- undetectable OP and definite OP (both radiographic and MRI-detected OP) had greater CV loss and increased CD and BMLs longitudinally. Presence of x-ray- undetectable OP predicted decreases in total knee pain over 5 years, while participants with definite OP predicted increases in knee pain, after adjustment for BMLs, CD and NSAIDs usage.

Conclusion: MRI-detected OPs were associated with knee structural abnormalities and knee pain cross-sectionally and longitudinally. Although x-ray- undetectable OP is associated with knee abnormal structural changes, it predicts decreases in knee pain over time suggesting an adaptive response.

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (OA) is characterized by pain, functional impairment, disability, and joint space narrowing due to degradation of articular cartilage and bone remodeling. The Wnt signaling pathway is known to play a central role in the formation of joint tissues, and altered Wnt signaling has been associated with cartilage loss in preclinical and clinical studies.[1] SM04690 is a small molecule inhibitor of the Wnt pathway in development as a potential OA therapeutic to be administered as an intra-articular (IA) injection into the affected joint. A phase 1, first-in-human, multicenter, 24-week, single-dose-escalation, randomized controlled trial (RCT) of SM04690 was completed. It assessed safety and tolerability of SM04690 administered IA to subjects with moderate to severe OA. This report provides a breakdown of components driving the Outcome Measures in Rheumatology (OMERACT)-Osteoarthritis Research Society International (OARSI) strict responder data to further evaluate proof of concept of efficacy of SM04690.

Methods: In the completed phase 1 RCT, escalation cohorts were dosed at 0.03 mg, 0.07 mg, and 0.23 mg SM04690 per 2 mL injection, in cohorts of 20 subjects (randomized, 16 active: 4 placebo). Subjects were administered a single IA injection in the target knee on treatment day 1, and participated in a follow-up period of 24 weeks. Safety, pharmacokinetics (PK), biomarker, and preliminary efficacy data, including the Western Ontario and McMaster Universities Arthritis Index (WOMAC Likert v3.1), were collected. The percentage of OMERACT-

OARSI "strict" responders in the modified Intention-to-Treat (mITT) population were evaluated. "Strict" responders were defined as reporting either WOMAC Function subscore or WOMAC pain subscore improvement of ≥50% coupled with at least a 20-point reduction in the given subscore (scaled to [0-100]).

Results: Sixty-one subjects (average age 62.6 [±5.7] years, female n=41 [67%], average BMI 30.4 [±4.7] kg/m^2) were enrolled. Versus placebo, there were statistically more OMERACT-OARSI strict responders in the 0.07 mg cohort at week 12 (76% vs. 36%; *P*=0.04), and numerically more in the 0.03 mg cohort at week 24 (73% vs. 36%; *P*=0.07) (Figure). More subjects in the 0.07 mg cohort met both the pain and function criteria vs placebo at 12 weeks (53% vs. 36%), and 24 weeks (44% vs. 27%). Responses in the 0.23 mg cohort were 44% at week 12 and 25% at week 24.

Conclusion:

Analysis of OMERACT-OARSI strict responders in this phase 1 study provides evidence of a potential treatment effect on both OA pain and function for the novel Wnt inhibitor SM04690 compared with placebo. These data support further development in an ongoing phase 2 RCT.

Obesity and Severity of Joint Space Narrowing Are Associated with Viscosupplementation Failure in Patients with Knee Osteoarthritis. Post-Hoc Analysis of a Double-Blind, Controlled, Multicentre, Randomized Trial

Florent Eymard[1], Xavier Chevalier[2] and Thierry Conrozier[3], [1]Department of Rheumatology, APHP Henri Mondor Hospital, Paris, France, [2]Rheumatology, Hopital Henri Mondor, Créteil, France, [3]Department of Rheumatology,, Nord Franche-Comté Hospital, Belfort, France

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Viscosupplementation (VS) is still controversial. One of the key points is the lack of well-identified factors of response. We aimed to identify clinical and radiologic factors associated with lack of a relevant response according to OMERACT-OARSI criteria after intra-articular (IA) hyaluronic acid (HA) injections in symptomatic knee OA patients.

Methods: We included the 166 patients with available data from the intent-to-treat population (n=205) of the HAV-2012 trial, a controlled, multicentre, double-blind, randomised, non-inferiority trial comparing 2 HA products for symptomatic tibiofemoral OA. At inclusion, demographic, anthropometric, clinical data (patient global assessment, WOMAC, knee effusion) and radiologic data (OARSI grade, patellofemoral OA) were recorded. Patients received 3 weekly IA injections of HA. At 6-month follow-up, VS response was defined according to OMERACT-OARSI criteria.

Results: Clinical characteristics at baseline and VS effectiveness were similar between the 2 HA groups, so their data were pooled**.** The mean age was 65.2 [63.7-66.8] years; 101 (60.8%) were women; 73 (44.0%) had severe tibiofemoral space narrowing. At baseline, mean WOMAC pain and function scores were 9.8 [9.3–10.3] and 27.5 [25.7–29.4], respectively. At 6 months, 113 patients (68.1%) were considered responders. Multivariate analysis showed that obesity and radiologic severity (OARSI grade 3 vs 1-2) were significantly associated with VS failure (p=0.0001 and p=0.011, respectively). Initial pain intensity and functional severity were not associated with VS response.

Conclusion: IA injection of HA for knee OA should mainly be considered in subjects with low BMI and mild tibiofemoral space narrowing.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In a previous cross-sectional study we noted higher fatigue levels in patients with advanced lower limb OA compared with RA, and identified differences in common outcome variables and their associations with fatigue between RA and OA groups. High levels of disability and depression correlated with fatigue in both conditions. In the current longitudinal study, we re-appraised patients in the initial cohort and assessed their fatigue levels and associated disease variables 5 years after their initial assessment in order to test the stability of these influences over time.

Methods: The original study recruited 103 patients each with RA or hip/knee OA (n=206). Of these 68 OA and 72 with RA were available for re-assessment after 5 years (n=140; 68% retention). Reasons for loss to follow-up were moving out of area, death and declining to take part. All participants were assessed for pain and fatigue using 100mm VAS scales; functional disability using the HAQ- disability index; and mood using the Hospital Anxiety and Depression Scale (HADS-Anxiety and HADS-Depression). CRP was measured in all participants and BMI calculated. In the RA group, the Disease Activity Score (DAS-28) was recorded. In the OA group, pain and disability were self-reported using the WOMAC score. Changes over time in the outcomes of interest were assessed separately for OA and RA using paired t-tests. Changes were compared between OA and RA using regression models of follow-up values adjusting for baseline values of the variable in question, along with baseline age, sex, and BMI. Similar models were used to examine the impact of joint replacement within the OA group. Correlations between change scores for all outcomes were investigated separately for OA and RA using Pearson's correlation coefficients.

Results: There was no evidence for interval changes over 5 years in RA for any of the outcomes including DAS-28 scores (change +0.00; 95% CI -0.33, 0.33; p=0.989) whereas in OA significant reductions in severity for a number of outcomes were recorded in the OA group: HAQ decreased by 0.38 (95% CI 0.20, 0.55; p<0.001), WOMAC-total by 21.6 points (95% CI 16.1, 27.1; p<0.001), pain (VAS) decreased by 27.1 (95% CI 19.4, 34.9; p<0.001), HADS-Depression decreased by 2.0 (95% CI 1.1, 2.9; p<0.001). In the OA group, changes between all 15 pairs of outcomes were positively correlated (p<0.045) aside from VAS fatigue and HAQ (p=0.087). However, there were fewer significant correlations in the RA group. Among the OA group, 57 (84%) had interval hip/knee joint replacement. There was no evidence that this was associated with better follow-up HAQ, pain, or fatigue (all unadjusted and adjusted p≥0.090), but was associated with improvement on WOMAC total (14.0 points unadjusted, 95% CI 1.0, 26.9; p=0.035; 13.8 adjusted, 0.9, 26.6; p=0.036).

Conclusion: After 5 years a range of common disease outcomes were surprisingly stable in RA, but significant reductions in pain, fatigue, disability and total WOMAC score were noted in OA, although only this last measure was associated with joint replacement. The strongest correlates with fatigue over 5 years were anxiety and depression in both groups.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Erosive hand osteoarthritis (OA) is a hand OA subset with high disease burden, although effective therapies are still lacking and clinical trials are scarce. Moreover, the low sensitivity-to-change of radiographs hampers outcome measurement of structural damage in short-term trials. Therefore, we explored the effect of etanercept on several biomarkers of bone, cartilage and inflammation.

Methods: Analyses were performed in a double blind trial comparing etanercept (50mg/week for 24 weeks, followed by 25mg/week up to 1 year) to placebo (NTR 1192). Ninety patients with symptomatic erosive OA with clinical and ultrasonographic signs of inflammation in ≥1 interphalangeal joint were included. The following biomarkers were measured with ELISA at baseline, 24 and 52 weeks: C-terminal collagen crosslinks I (CTX-I) in urine, and high sensitivity C-reactive protein (hsCRP), myeloperoxidase (MPO), matrix metalloproteinase 3 (MMP3) and hyaluronic acid (HA) in serum. In some patients additional measurements at 4, 12, and 36 weeks were available. The effect of treatment on each biomarker at 24 and 52 weeks was estimated with generalised estimating equations in the intention to treat (ITT) and per protocol (PP) population, adjusting for baseline and study center. Patients fulfilling all inclusion criteria who completed the trial were included in the PP population.

Results: Biomarkers were measured in 78 patients (n=39 per group, 80.8% women, mean age 58.6 (SD 6.8), mean BMI 25.9 (SD 3.8)). Biomarker levels were comparable between groups at baseline, with large interquartile ranges (IQRs; table). Levels of hsCRP decreased slightly in both groups, but there were no between-group differences (at 24 weeks median 1.1 (IQR 0.7 to 4.2) and 1.7 (IQR 0.9 to 4.1) mg/L in placebo and etanercept group respectively). However, MMP3 levels decreased more in the etanercept group compared to placebo after 24 weeks (mean difference -1.44 ng/mL, 95% CI -2.82 to -0.05 (n=63)), although this difference was not sustained after etanercept dose reduction. No differences in the other biomarker levels were noted. PP analyses showed similar results.

Conclusion: Anti-TNF therapy reduced serum MMP3 levels, but not CTX-I, hsCRP, MPO and HA, in patients with erosive OA. The secretion of MMP3 is known to be stimulated by TNFα, and viewed as a marker of cartilage destruction. It remains unclear whether the observed decrease is merely a marker for decreased TNFα biological activity after anti-TNF, or that it is a sign of reduced cartilage damage in the etanercept group.

Table. Baseline levels of each biomarker (median (interquartile range)) and between-group differences after 24 and 52 weeks (ITT population).

	Baseline		**24 weeks**	**52 weeks**
	Placebo	**Etanercept**	*mean difference (95% CI)*	*mean difference (95% CI)*
CTX-I	7.3 (3.4, 14.6)	10.2 (4.0, 16.5)	-5.90 (-12.67 to 0.88)	-3.88 (-12.85 to 5.09)
hsCRP	1.8 (0.8, 2.8)	2.3 (1.5, 4.3)	-0.29 (-1.91 to 1.34)	0.54 (-0.50 to 1.59)
MPO	420.6 (330.1, 618.8)	358.1 (235.7, 602.9)	-28.19 (-140.30 to 83.91)	55.72 (-99.26 to 210.70)
MMP3	4.5 (1.0, 6.6)	4.9 (0.8, 6.8)	-1.44 (-2.82 to -0.05)*	-0.21 (-1.83 to 1.41)
HA	51.6 (39.2, 65.9)	47.2 (34.4, 69.6)	12.56 (-14.17 to 39.30)	18.73 (-6.17 to 43.63)

*Significantly lower in the etanercept compared to placebo group (p=0.04).
CTX-I, C-terminal collagen crosslinks I (urine, ug/L); HA, hyaluronic acid (serum, ng/mL); hsCRP, high-sensitivity C-reactive protein (serum, mg/L); MMP3, matrix metallopeptidase 3 (serum, ng/mL); MPO, myeloperoxidase (serum, ug/L).

Session Title: Osteoarthritis – Clinical Aspects - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The relationship between oxytocine (OT) and osteoarthritis (OA) is poorly studied and remains unknown. However the subchondral bone is considered as a major player in osteoarthritis, and a protective effect of OT on bone mineralization is described in recent studies. The aim of our work was to investigate a possible link between OT and OA.

Methods: we used three different approaches: i) In vitro using MSC (adipose and bone marrow derived stem cells) that were maintained as mono-layer (2D) or as pellets in three dimension (3D) in the absence or the presence of OT. RT-PCR, histological and immunohistochemical analysis were performed. ii) in vivo using a rat animal model developing OA upon anterior cruciate ligament transection (ACLT) . Twenty female Wistar rats were divided in 2 groups: one group was sham operated whereas the second was ACL transected. Half of each group received either OT (1 mg/kg/day) injections or saline buffer. Histological analysis was performed on day 28. The severity of OA lesions was assessed on a scale adapted from Mankin's score at medial part of the femur. iii) Clinical analysis using a **human cohort**. Samples issued from a hand OA cohort (ADEM). 63 OA women have been included; men were excluded because of their low number. At baseline, all subjects benefited of OT and leptin circulating levels measurements and hand X rays (Scoring systems including Kelgren and Lawrence and Verbruggen scores). The control group consists in subjects of the same age range without osteoporosis, OA or inflammatory disease.

Results: OT treatment of differentiating MSCs for 21 days induced a significant increase of agrecan, Col X and COMP mRNA levels without variation of Col 1a. Immunostaining experiments showed an improvement of Sox9 and Col II expression in the presence of OT. The histological analysis of rat knee showed no differences in the severity of lesions between the different ACLT groups. The characteristics of the women cohorts is as follow: 63 OA women age=65 (+/-11), Body Mass Index (BMI) = 24(+/-4), OT=1.4 (+/-2) and 19 control women age=63(+/-10), BMI=26(+/-5), OT=6.5(+/-7).The multivariate analysis adjusted for age, BMI and leptin levels, showed a significant lower level of OT in hand OA women ($p=0.002$, $\beta=3.4$). In univariate analysis, there was no relationship between OT blood levels and the severity of OA (Verbruggen:$p=0.7$, KL:$p=0.2$), Joint Space Narrowing ($p=0.2$) and osteophytes ($p=0.1$).

Conclusion: Our study shows an anabolic effect of OT on chondrogenesis and that OT circulating levels was significantly lower in OA patients. OT might represents an interesting player in the pathophysiology of osteoarthritis and further studies will shed some light on its mechanism of action.

Patient Preference for Display of Electronic Patient-Reported Outcomes in Osteoarthritis Clinical Trials: Wording Emphasis, Question Format, and Navigation Button Placement

Laura Khurana[1], Ellen Durand[1], Sarah Gary[1], Tony Otero[1], Chris Hall[1], Aisling Ryan[2], Christopher J. Evans[2] and **Susan Dallabrida**[1], [1]ERT, Boston, MA, [2]Endpoint Outcomes, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Osteoarthritis – Clinical Aspects - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Electronic patient-reported outcomes (ePROs) are a reliable method for collecting patient data in osteoarthritis clinical trials and offer many advantages over paper collection; however, it is essential to consider patient preference and ease of use when employing this technology. Improving the usability of ePRO in osteoarthritis clinical trials could ultimately reduce subject burden and improve subject engagement.

Methods: 104 subjects with osteoarthritis were surveyed regarding their preferences for ePRO display.

Results: When presented with options for showing emphasis in a sentence, subjects thought that underlining best drew attention to emphasized words (36%), followed by bold (35%) or capitalized (21%) lettering. Subjects were shown screens of a multi-select question formatted to read left to right (question to the left of the answers) or top to bottom (question above the answers). 39% could read and understand the screens equally. Of those with a preference, 75% preferred the top to bottom format. Subjects were shown screens of a tablet computer ePRO device with either one question per screen or several multi-select questions per screen in a matrix format. 68% preferred one question per screen; of these subjects, 58% thought it was easier to read and 45% thought it was easier to understand the question. 32% preferred multiple questions per screen; of these subjects, 50% thought it was faster to complete and 38% thought it was easier to read. Subjects were shown two screens with “back” and “next” navigation buttons at either the top or bottom of the screen. 28% thought it was equally easy to find the buttons; of those with a preference, 76% preferred them at the bottom of the screen.

Conclusion: When possible, questionnaire designers should consider these results to incorporate patient preference into the design of ePRO instruments; potentially reducing subject burden and increasing patient engagement in clinical trials.

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Canakinumab (CAN), a highly selective human anti-IL1 β monoclonal antibody, had demonstrated its efficacy and safety in patients (pts) with active systemic juvenile idiopathic arthritis (SJIA) in a comprehensive global clinical program consisting of one phase II and two phase III trials.[1,2]However, limited data was available on long-term efficacy and safety of CAN in SJIA. The study objective was to assess the long-term efficacy and safety of CAN treated SJIA pts over a 5-year (yr) follow-up observational period.

Methods: This was an open-label extension (OLE) study (NCT00891046) of SJIA pts participating in the global clinical trials of CAN.[3] Pts, 2 to <20 yrs of age at the time of enrollment in study, received subcutaneous CAN 4 mg/kg every 4 weeks. Baseline was defined as the starting point of the extension trial. Efficacy assessments were done every 3 months, including adapted pediatric response criteria (aACR), clinical inactive disease, and clinical remission on medication (continuous 12 months of clinical inactive disease). Safety assessments included adverse events (AEs) and serious AEs (SAEs).

Results: Overall, 147 pts to the OLE study had a median treatment duration of 3.2 yrs; total treatment exposure was approximately 365 pt-yrs. Of 147 pts, 100 (68%) completed 96 weeks of treatment, whereas 47 (32%) pts discontinued the study. Another 25 pts (17%) discontinued the study after Week 96. Of the 107 pts with an aACR 30 at entry to the OLE study, 61.7%, 79.4%, and 86.0% have had aACR 100, 90, and 70 responses, respectively at last assessment. At baseline, 32.7% of patients were with inactive disease which increased up to 60%-70% between Week 36 and Week 168. Clinical remission on medication was achieved in 43% pts. In total, 137 (93.2%) pts reported at least 1 AE during the 3.2 yrs median exposure in the study corresponding to 2.009 AEs/100 pt-days (733.6 AEs/100 pt-yrs) with infections (202.7 per 100 pt-yrs) being the most common AE. Overall, 47 (32.0%) pts had at least 1 SAE corresponding to 0.089 SAE/100 pt-days (32.6 SAE/100 pt-yrs) with the most common being JIA (14 pts) denoting disease flares or worsening of SJIA. Ten patients (6.8%) with a total of 12 macrophage activation syndrome (MAS) events were reported as SAE and 7 patients among them discontinued the study. No deaths were reported.

Conclusion: In patients previously treated with CAN in pivotal trials, response to treatment was sustained or improved during long-term treatment in the OLE study. Safety profile of CAN was consistent with safety findings from previous studies. References: 1. Ruperto N, et al. *N Engl J Med*. 2012;367(25):2396-406. 2. Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophage activation syndrome (MAS) is a life-threatening episode of hyperinflammation and a substantial cause of morbidity and mortality in pediatric rheumatology. It occurs most often as a complication of systemic juvenile idiopathic arthritis (SJIA). Despite highly efficacious treatments for SJIA with biologic agents blocking IL-1 and IL-6, patients remain at risk for MAS. Additionally, it is unclear whether treatment with biologic agents alters the clinical presentation of MAS.

Methods: We performed a comprehensive literature review to identify published cases of MAS in SJIA patients which occurred while being treated with biologic agents. Where necessary, authors were contacted directly to obtain further demographic, clinical or laboratory information. These accumulated cases were then compared to the large database of MAS cases collected as part of the 2016 MAS classification criteria project, which we used as a historical cohort.

Results: Together, sixteen published manuscripts or abstracts were identified, describing 138 episodes of MAS occurring while patients were treated with biologic agents. Further data collection and removal of duplicates led to 85 cases of MAS where clinical and laboratory information was available for analysis. Of these, 34 cases occurred while on canakinumab and 46 while on tocilizumab. Patients who developed MAS while treated with canakinumab had no significant differences in their reported clinical features. These patients did have a lower median white blood cell count (3.4 $x10^9$/L vs 9.9 $x10^9$/L, $p<0.0001$) and serum ferritin level (2170 ng/ml vs 5353 ng/ml, $p<0.05$) at MAS onset than the historical cohort; all other laboratory features of MAS were not significantly different. In contrast, patients who developed MAS while treated with tocilizumab were less likely to present with fever or hepatomegaly than patients in the historical cohort. In addition, patients treated with tocilizumab had significantly lower white blood cell counts (3.6 vs 9.9, $p<0.0001$), serum ferritin levels (983 vs 5353, $p<0.0001$), and less severe anemia (12.0 g/dl vs 9.8 g/dl, $p=0.01$) than patients in the historical cohort. Additionally, other laboratory features of MAS were more pronounced in patients treated with tocilizumab, with lower platelet counts (96 $x10^9$/L vs 144 $x10^9$/L, $p<0.0001$) and fibrinogen levels (113 g/l vs 267 g/l, $p<0.0001$), and higher aspartate aminotransferase levels (244 U/l vs 134 U/L, $p<0.05$). Due to these differences, the 2016 MAS classification criteria only categorized 53-55%% of tocilizumab treated patients as having MAS, compared to 76-83% of patients treated with canakinumab and 78% of the historical cohort.

Conclusion: This represents the largest reported analysis of MAS cases occurring during treatment with biologic therapy, and reveals important differences in clinical and laboratory features when MAS occurs during treatment with canakinumab and tocilizumab. Taken together, these findings support the need for increased clinical vigilance for signs of developing MAS in these patients, as well as the use of supporting laboratory features such as platelet count, AST and fibrinogen in MAS surveillance.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) is a severe autoinflammatory disease characterized by systemic features including high fevers, rash, and arthritis. SJIA can impose a high physical, psychosocial, behavioral and financial burden on patients and their families. This international, real-world study conducts a detailed analysis of the impact of the burden of SJIA by evaluating caregiver perspectives of disease burden utilizing a SJIA-specific questionnaire combined with physician data about disease severity and treatment.

Methods: SJIA treatment centers in France, Germany, Netherlands, UK and the US participated. Patients were 4-18 years with confirmed SJIA and received one of the following biologic treatments for ≥2 months: anakinra (ANA), canakinumab (CAN), or tocilizumab (TOC). Caregivers had cared for the patients for the previous ≥6 months, were >18 years, spent ≥50% of their time with the patients, and completed a SJIA-specific survey. Physicians reported disease severity and treatment through retrospective chart review. Ethics committee approvals and written informed consent were obtained. The caregiver questionnaire assessed the impact of SJIA on the practical, social and emotional aspects of caregivers' lives. Validated and tailored patient-reported outcome (PRO) measures were used: the Child Health Questionnaire-Parent Form 50 (CHQ-PF50), 36-Item Short Form

Health Survey (SF-36), and Work Productivity and Activity Impairment Questionnaire: Specific Health Problem (WPAI:SHP). Tailored questions collected data on patient function, treatment satisfaction and direct/indirect resource utilization.

Results: Sixty patients enrolled from 6/15-5/16: 12 on ANA, 24 on CAN, 24 on TOC; 45% from the US; 47% female; mean age at survey was 11.3 years. Mean age at SJIA diagnosis was 6.7 years, mean age at start of ANA, CAN, and TOC Rx was 7.4, 8.9, and 6.7 years, respectively. Caregivers were 80% female, mean age 41.4 years, and 37% reduced or stopped working due to their child's SJIA. Of the patients enrolled on CAN and TOC, 71% and 46% respectively had previously been on ANA. Baseline CHAQ, CHQ-PF50, and WPAI scores were worse in CAN and TOC than ANA patients (Table). Highest caregiver stressors were worry over long-term SJIA impact on their child (44%) and uncertainty about the future (29%). Caregivers' treatment satisfaction and resource utilization varied (Table). **Conclusion:** Treatment sequencing and PRO measures indicate ANA is used as 1st line for mild SJIA while CAN and TOC are used as 2nd/3rd line for severe SJIA. Caregivers expressed stress over the long-term impact of SJIA and fear for the future and had variable treatment satisfaction and resource utilization levels.

Table. SJIA patient and caregiver reported outcomes

		Anakinra	Canakinumab	Tocilizumab	All
CHAQ global VAS score, mean ± SD [N]		0.0 ± 0.0 [9]	1.6 ± 2.7 [17]	1.9 ± 3.1 [12]	1.3 ± 2.6, [38]
CHQ-PF50	Physical (PhS) summary[1], mean ± SD [N]	44.5 ± 7.7[12]	38.1 ± 18.4 [23]	38.7 ± 18.6 [24]	39.7 ± 18.2 [59]
	Psychosocial (PsS) summary[2], mean ± SD [N]	48.9 ± 10.8 [12]	46.8 ± 12.8 [23]	45.2 ± 10.6 [24]*	46.6 ± 11.4 [59]
WPAI	Time missed due to child's SJIA over last 7 days (hours), mean ± SD [N]	0.0 ± 0.0 [11]	3.5 ± 6.9 [17]	3.8 ± 8.2 [16]	2.8 ± 6.6 [44]
	Overall work impairment due to child's SJIA (%), mean ± SD [N]	6 ± 15 [11]	21 ± 27 [15]	16 ± 33 [14]	15 ± 27 [40]
	Activity impairment (%), mean ± SD [N]	9 ± 16 [12]	19 ± 27 [24]	20 ± 30 [24]	17 ± 26 [60]
Caregivers treatment satisfaction	Children were not stressed/ anxious about receiving treatment, % [n/N] [3]	13 [5/40]	39 [11/28]	33 [10/30]	27 [26/98]
	Never missed a treatment, % [n/N] [3]	88 [35/40]	93 [25/27]	80 [24/30]	87 [84/97]
	Thought treatment was convenient, % [n/N] [3]	21 [8/39]	68 [19/28]	33 [10/30]	38 [37/97]
Resource utilization	Direct: Visited hospital/clinic for tests, % [n/N]	67 [8/12]	67 [16/24]	71 [17/24]	68 [41/60]
	Indirect: Receive help from informal caregivers at least once a month, % [n/N]	33 [4/12]	38 [9/24]	33 [8/24]	35 [21/60]

n represents respondents with a certain response; [N] represents total respondents for a datapoint
[1]CHQ PhS normative mean score 53.0 ± 8.8 SD (standard deviation)
[2]CHQ PsS normative mean score 51.2 ± 9.1 SD
[3]Caregivers were asked about experiences with any biologic the patient had ever been on, not just the biologic they were on during the study, so the total [N] can be >60
*Clinically moderate effect size only observed between normative and TOC based on mean difference >5

Innovative Use of PK and PD to Guide Dose Selection for a Monoclonal Antibody Aimed at Neutralizing the High IFNγ Activity Present in Patients with Macrophage Activation Syndrome (MAS)

Philippe Jacqmin[1], Kathy de Graaf[2], Maria Ballabio[2], Robert Nelson[2], Zoë Johnson[2], Walter Ferlin[2], Geneviève Lapeyre[2], Fabrizio De Benedetti[3] and **Cristina de Min**[2], [1]MnS, Dinant, Belgium, [2]NovImmune S.A., Geneva, Switzerland, [3]Division of Rheumatology, Ospedale Pediatrico Bambino Gesù IRCCS, Roma, Italy, Rome, Italy

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Data from an animal model of MAS and the observed high IFNγ and IFNγ-related chemokines (CXCL9, CXCL10) levels in MAS/sJIA patients have prompted the design of a study to investigate the therapeutic role of IFNγ neutralization in patients with this disease. An ongoing study in primary HLH (pHLH) shows promising efficacy and favourable safety of NI-0501, an anti-IFNγ antibody, in the control of HLH, known to be driven by high production of IFNγ. PK and PD data of NI-0501 obtained from the ongoing clinical trial in pHLH have been used to define the NI-0501 dosing strategy to be used to investigate the role of IFNγ neutralization in MAS/sJIA patients.

Methods: In active HLH the measurable circulating IFNγ levels do not account for the total amount of the cytokine present in the body. Following the administration of NI-0501 in pHLH patients, the measurement of "total IFNγ", namely free and bound to NI-0501, is used as a surrogate for IFNγ production, revealing the high production of this cytokine, despite the relatively low "free IFNγ" levels at baseline in blood. Extrapolations from these data allowed the estimation of IFNγ production in MAS/sJIA patients, based on the levels of IFNγ-related chemokines present at baseline.

Results: The measurement of total IFNγ levels in pHLH revealed that the IFNγ concentration to be neutralized by NI-0501 was several hundreds fold higher compared to what indicated by the baseline free IFNγ level (median IFNγ at baseline <50 pg/ml; at peak 17'858 pg/ml). Total IFNγ at 48 hours post NI-0501 administration tightly correlates with IFNγ-related chemokine levels (CXCL9: r=0.6264, p=0.0008; CXCL10: r=0.6931, p=0.0001), suggesting that CXCL9 and CXCL10 concentrations are excellent markers of the presence of biologically active IFNγ. The amount of IFNγ produced in MAS/sJIA patients was then indirectly estimated on the basis of the total IFNγ concentration in pHLH patients with comparable levels of CXCL9 and CXCL10 following the administration of NI-0501. This information, coupled with modelling and simulation techniques, has allowed to i) determine the NI-0501 dose expected to neutralize rapidly the total amount of IFNγ in the majority of MAS/sJIA patients, ii) identify an appropriate frequency of NI-0501 administration to avoid unnecessary drug accumulation.

Conclusion: The methodology applied allowed a precise determination of the dosing strategy to be tested in the future trial, significantly reducing the risk of exposing patients to non-therapeutic NI-0501 doses.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The pharmacokinetics (PK) of canakinumab (CAN) and total interleukin (IL)-1β kinetics

have been well investigated in CAPS patients (pts).[1] Here we present the PK and pharmacodynamics (PD) of CAN (solution for injection-liquid in vial [LIVI]) from the randomized treatment epoch (primary analysis up to Week 16) of a Phase III study (NCT02059291) in colchicine-resistant/intolerant familial Mediterranean fever (crFMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD), and TNF receptor associated periodic syndrome (TRAPS) pts.

Methods: The study comprised 3 disease cohorts (crFMF, HIDS/MKD, and TRAPS). Each cohort followed the same study design across 4 epochs (screening epoch [up to 12 weeks], randomized treatment epoch [16 weeks], randomized withdrawal epoch [24 weeks] and open-label treatment epoch [72 weeks]). Pts (age, ≥2 years) with crFMF, HIDS/MKD, or TRAPS who had a flare during Epoch 1 were randomized (1:1) in Epoch 2 to receive subcutaneous (sc) CAN 150 mg (or 2 mg/kg for pts weighing ≤40 kg) every 4 weeks (q4w) or placebo. Blinded uptitration (up to 300 mg) was allowed for pts not resolving the index flare by Day 15. Serum samples for CAN concentrations and total IL-1β were collected at baseline (Day 1), and trough samples, at weeks 2, 4, 8, 12, and 16.

Results: In crFMF, HIDS/MKD, and TRAPS pts, the serum clearance and steady-state volume of distribution of CAN varied according to body weight, and were estimated to be 0.14±0.04 L/day and 4.96±1.35 L, respectively. The estimated half-life of CAN was 25.6±6.4 days. CAN minimal concentration at Week 16 following 150 mg sc q4w dosing was estimated to be 15.3±6.6 µg/mL. The estimated steady-state area under the serum concentration-time curve from time zero to the end of the dosing interval tau (AUC_{tau}) was 648±202 µg.day/mL. Similar results were obtained in all 3 diseases. CAN binding to circulating IL-1β was demonstrated by increase in total IL-1β following CAN dosing in all 3 diseases. In pts requiring uptitration to 300 mg, levels of total IL-1β were higher, suggesting higher production of IL-1β, and therefore the need for a higher dose.

Conclusion: This was the first study to evaluate the PK of canakinumab given in the LIVI form. The results observed in crFMF, HIDS/MKD, and TRAPS pts were similar to those observed in other indications (CAPS and SJIA) using the lyophilisate form. These data suggested that the new formulation did not affect the PK/PD of canakinumab and similar to CAPS, patients with higher levels of IL-1β require canakinumab uptitration to achieve optimal disease control. Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Open label studies have shown the efficacy of canakinumab (CAN), a fully human and highly specific anti-IL-1β monoclonal antibody, in patients (pts) with Periodic Fever Syndromes (PFS), which include colchicine-resistant Familial Mediterranean Fever (crFMF), Hyper-IgD Syndrome/Mevalonate Kinase Deficiency (HIDS/MKD) and TNF-Receptor Associated Periodic Syndrome (TRAPS). Currently, no data is available on the effect of CAN on Health-Related Quality of Life (HRQoL) in pts with PFS. The study objective was to assess the effect of CAN on HRQoL using Child Health Questionnaire-Parent Form 50 (CHQ-PF50) and Short Form-12 Health Survey (SF-12) in pts with PFS.

Methods: In this Phase 3, randomized, placebo-controlled study of CAN in pts with PFS (NCT02059291), SF-12 Physical Component Summary (PCS) and Mental Component Summary (MCS) scores were assessed in adults, whereas CHQ-PF50 Physical Summary (PhS) and Psychosocial Summary (PsS) scores were assessed in children (>5–<18 years).

Results: Of the 181 pts (63 crFMF, 72 MKD/HIDS, 46 TRAPS) randomized to CAN or placebo, 71 were adults (age ≥18 years) and 110 were children (age ≥2–<18 years). Pts who initially received placebo and did not respond were switched to CAN. Treatment with CAN was associated with an early clinically meaningful improvement in SF-12 PCS scores reported at Week (Wk) 5, which were sustained and increased to a large effect size by Wk 16 for all indications (Table). Similarly, clinically meaningful improvement in SF-12 MCS, CHQ-PF50 PhS, and CHQ-PF50 PsS scores was observed for all indications, except for PsS in HIDS/MKD and TRAPS pts.

Table: Patient reported outcomes						
Outcome measures	Mean change from baseline (n/N)#,**					
	crFMF		HIDS/MKD		TRAPS	
	Week 5	Week 16	Week 5	Week 16	Week 5	Week 16
SF-12 PCS	7.9 (29/30)	9.55 (30/31)	13.81 (15/15)	13.81 (14/14)	9.63 (16/17)	11.64 (13/14)
SF-12 MCS	4.83 (29/30)	4.27 (30/31)	6.41 (15/15)	8.14 (14/14)	5.65 (16/17)	5.51 (13/14)
CHQ-PF50 PhS	13.2 (21/24)	20.1 (18/21)	5.5 (32/34)	9.9 (27/29)	7.4 (16/18)	14.9 (13/14)
CHQ-PF50 PsS	4.1 (21/24)	7.2 (18/21)	1.8* (32/34)	5.2 (27/29)	0.9* (16/18)	1.2* (13/14)

N=total number of pts; n=pts who received at least one dose of CAN.
#An increase in mean score from baseline is an improvement.
*Minimal important difference[1,2] from baseline was not achieved.
**In the general U.S. population, mean summary scores are 50 for CHQ-PF50 and 50 for SF-12 (50.01 and 49.98, respectively for PCS and MCS).[3,4]

Conclusion: Canakinumab showed rapid improvement by Wk 5 in pt-reported outcomes in adults and children with PFS, which was sustained through Wk 16. **References**: 1. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cryopyrin-Associated Periodic Syndrome (CAPS), is a rare hereditary auto inflammatory disorder representing 3 phenotypes: familial cold auto-inflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and chronic infantile neurologic cutaneous and articular syndrome/neonatal onset multisystem inflammatory disease (CINCA/NOMID).[1] Canakinumab (CAN), a fully human anti–IL–1β monoclonal antibody, has been shown to be effective over 56 weeks in patients with CAPS aged <24 months (core study).[2] Here we report the long-term efficacy and safety of canakinumab in these patients through 152 weeks in an extension study to the core study (NCT01576367).

Methods: CAPS pts who completed the core study received 2 mg/kg subcutaneous CAN every 8 weeks, in continuation with the core study. Pts who received a dose adjustment in the core study were continued on the same dose in the extension phase. Efficacy was evaluated by investigator clinical assessment of autoinflammatory disease activity, C-reactive protein (CRP) and serum amyloid A (SAA) levels. Safety was assessed in terms of adverse events (AEs).

Results: Of 17 pts (aged ≤6 years), enrolled in the extension study, 12 (70.6%), 4 (23.5%) and 1 (5.9%) had MWS, NOMID and FCAS phenotypes, respectively. All 17 pts were complete responders; 16 (94.1%) had no flare, and 1 (5.9%) NOMID patient had a flare at the end of extension study. Physician global assessment improved over the extension study, with decline in severity from baseline of the core study to the end of extension study (EOS). The number of pts with absent autoinflammatory disease activity improved from 4 (23.5%) to 11 (64.7%); minimal activity increased from 5.9% (1 pt) to 29.4% (5 pts); mild or moderate activity decreased from 47.1% (8 pts) to 5.9% (1 pt); moderate activity decreased from 23.5% (4 pts) to 0 patients. This improvement was also observed in the assessment of skin rash; proportion of patients with no skin disease increased from 29.4% (5 pts) at baseline of core study to 94.1% (16 pts) at EOS. The mean decrease in CRP and SAA levels from core study baseline was −10.4 and −54.36 mg/L, respectively at EOS. Overall, 10 (58.8%) pts had AEs suspected to be related to CAN; the most common were diarrhea, pneumonia, rhinitis and cough (3 pts each). Eight (47.1%) pts experienced at least 1 serious AE (4 MWS and 4 NOMID pts), with pneumonia being the most common (2 [11.8%]). No deaths occurred during the study.

Conclusion: Canakinumab effectively maintained clinical and serological efficacy in CAPS pts in the extension study. No new safety findings were observed, and the safety profile of canakinumab was consistent with previous studies, which corroborates the long-term use of canakinumab in the treatment of CAPS patients. **References**: 1. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Majeed syndrome is a rare, autosomal recessive disorder that presents with early onset chronic recurrent multifocal osteomyelitis (CRMO) and microcytic congenital dyserythropoietic anaemia caused by a mutation in the *LPIN2* gene (OMIM reference #609628). Occasionally, Majeed syndrome is associated with neutrophilic dermatosis. The chronic inflammatory bone disease starting before the age of two has previously been described having a recalcitrant debilitating course resulting in permanent joint contractures and growth disturbances after years of chronic inflammation. Aim: To report the long-term effect of IL-1 inhibition in two patients with Majeed syndrome.

Methods: Whole-body MRIs were performed at presentation, after 3 months and at regular yearly intervals using T1 weighted images and short tau inversion recovery (STIR) images. Patiens: Two brothers with consanguinity of the parents were diagnosed with Majeed syndrome. *LPIN2* gene resequencing of both patients revealed a homozygous 2-bp deletion (c.1312_1313delCT) resulting in a premature stop codon (p.Leu438fs-16X). Both patients were refractory to the treatment with corticosteroids and etanercept. Demonstration of the clinical and biochemical efficacy of IL-1 inhibition by anakinra led to the treatment of both children with canakinumab.

Results: Canakinumab 4 mg/kg subcutaneously every 4-5 weeks has now been given for 5 years as monotherapy. During the past years no fever related to the CRMO has been observed. The children have been well without any clinical signs of osteomyelitis, no physical restraints, and no skin changes. The drug has been well tolerated and

without any side effects. At no time corticosteroids and NSAIDs have been given after canakinumab was initiated. Repeated whole-body MRIs showed disappearance of osteomyelytic lesions in both patients already after few months. Whole-body MRIs have been performed yearly during the past 5 years showing no signs of relapse in Sib A. Sib B had normal whole-body MRIs during the first 4 years but showed transient, subclinical osteomyelytic lesion at the ossis pubis after 4 years and a subclinical lesion at the right corpus tibiae after 5 years. Growth of height has been normal for both children growing along the 25th percentile. ESR was still moderately elevated during the first year of treatment but normalized thereafter in both children. However, within the past year the ESR has been variably elevated (from 12 to 29 mm/hr) in Sib B. During the years hemoglobin has been within normal range for both children. Erythroblasts have been slightly elevated in Sib A (0.05-0.12 x 10^9/L), but not in Sib B (<0.01 x 10^9/L).

Conclusion: Sustained effect of IL-1 inhibition by canakinumab for the treatment of Majeed syndrome is described. The drug is well tolerated and although costly, the prevention of a debilitating course of this rare, chronic disease seems to be achievable by canakinumab.

Evaluation of Intestinal Inflammation in Children with FMF

Ozge Altug-Gucenmez, Tuncay Kume, Balahan Makay, Omur Babayigit, Nur Arslan and **Erbil Unsal**, Dokuz Eylul University, Izmir, Turkey

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean Fever (FMF) is the most common auto-inflammatory disease with recurrent fever and serositis episodes. Abnormal pyrin protein due to MEFV gene mutations leads to clinical symptoms in FMF. Abdominal attacks happen due to the serosal inflammation in FMF. The sterile exudate which includes fibrin and polimorphonuclear cells occurs in the peritoneal space. Other gastrointestinal symptoms such as irritable bowel disease, colchicine related diarrhea and amyloidosis related malabsorption can be also detected. The rate of inflammatory bowel disease (IBD) is also shown to be increased in FMF. In recent years, some cases with FMF were reported with gastrointestinal involvement without amyloidosis, vasculitis and IBH. It is not yet known, whether the gastrointestinal involvement is a part of the disease or not. The aim of this study is to investigate the frequency of intestinal inflammation by using a noninvasive method, fecal calprotectin measurement, in pediatric FMF patients.

Methods: Sixty-five FMF patients, 30 healthy controls and 11 control patients with ulcerative colitis were included in the study. A standard survey which including gastrointestinal and other clinical symptoms and medications was used. MEFV mutations, whole blood count and CRP levels were recorded. Fecal calprotectin

was studied with the ELISA method from the feces samples of the all patients. The upper cutoff value was determined as 200 ug/g.

Results: The patients were similar in terms of age and gender among groups. None of the FMF patients had clinical signs of the IBD. Fecal calprotectin levels of the FMF patients were found significantly higher than the healthy controls (174.8 ± 150.8 vs 52.9 ± 36.5, p< 0.001). In contrast, fecal calprotectin levels of the ulcerative colitis patients were significantly higher than the FMF patients (523.5 ± 183 vs 174.8 ± 150.8, p< 0.001). Even though, there are no IBD signs, the fecal calprotectin levels were higher than the cutoff point in 19 of the FMF patients. There was a correlation between fecal calprotectin levels and neutrophil/lymphocyte ratio (r=0.324, p=0.009).

Conclusion: Our results supported the subclinical intestinal inflammation in pediatric FMF patients. Underlying chronic auto-inflammatory process or continuous colchicine usage could result this observation. Further studies are needed to clarify the reason of the intestinal inflammation in FMF patients.

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Deficiency of adenosine deaminase 2 (DADA2) is a recessive genetic condition in which children develop recurrent strokes, intermittent fevers, elevated acute-phase reactants, livedoid rash,

hepatosplenomegaly, and hypglobulinemia caused by mutations in the *CECR1* gene. Blood levels of ADA2 are very low or absent, compromising endothelial integrity while polarizing macrophage and monocyte subsets toward proinflammatory cells. In this abstract we aim to determine the safety of treating DADA2 patients with a history of stroke with anticoagulants and/or antiplatelet agents.

Methods: A single center study evaluated 22 patients who were positive for 2 mutations in *CECR1*. All patients underwent a clinical history and physical examination, neurologic evaluation, brain MRI/MRA, and testing for ESR/CRP, paying special attention to whether there was a history of stroke, the type of stroke (ischemic or hemorrhagic), and the history of the use of ASA either alone or in combination with anticoagulants and/or other antiplatelet agents. The primary outcome measure was to determine occurrence of hemorrhagic strokes while on anticoagulant and/or antiplatelet treatment.

Results: Out of 22 patients, 15 had strokes and 13 of those were subsequently started on anticoagulants and/or antiplatelet agents. Amongst the 13, 4 of the patients had a total of 6 hemorrhagic strokes. All 4 patients with hemorrhagic strokes were on ASA plus other anticoagulants and/or antiplatelet agents. Six of the patients with no hemorrhagic strokes were on ASA alone. Patients not on anticoagulants and/or antiplatelet agents did not have any hemorrhagic strokes. Nine out of the 13 patients who were put on anticoagulants and/or antiplatelet agents had an ischemic stroke only. Upon analyzing the statistical data, the probability of a hemorrhagic stroke following anticoagulants and/or antiplatelet agents was 4/13 while the probability of a hemorrhagic stroke following no anticoagulants and/or antiplatelet agents was 0/9. A Fisher's exact test was be used to examine whether these 2 probabilities truly differ and the p-value was 0.115 which is short of statistical significance. The proportions of patients with hemorrhagic strokes on no antiplatelet or anticoagulant treatment, ASA alone, and ASA plus other anticoagulants and/or antiplatelet agents were 0/9, 0/6 and 4/7, respectively (p = 0.007, Fischer's exact test).

Conclusion: In patients with DADA2, we oberseved an increased frequency of hemorrhagic strokes in those treated with ASA plus other anticoagulants and/or antiplatelet agents, although we observed no hemorrhagic strokes in patients treated with ASA alone. These observations suggest extreme caution in the use of ASA plus other anticoagulants and/or antiplatelet agents in DADA2.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The deficiency of adenosindeaminase 2 (DADA2) is a recently described autosomal recessive autoinflammatory disease, caused by mutations of CECR1 and characterized by early onset vasculopathy with livedoid skin associated to systemic inflammation. In some patients, the disease is mild and skin-limited, in others is severe, with multi-organ involvement including ischemic or hemorrhagic strokes. In some DADA2 patients a mild immunodeficiency was detected involving adaptive immunity. TNF inhibitors are very efficacious. Recently, an upregulation of type I interferon-stimulated gene transcripts, so called interferon signature, was described also in two DADA2 patients. We describe the clinical course of a 4 patients with CECR1 mutations and we assess the role of interferon type I signature as marker of disease's activity

Methods: Molecular analysis of CECR1 was performed using next generation sequencing and confirmed by sanger sequencing. Blood was collected into PAXgene tubes and expression levels of IFI-27 IFI-44L IFIT-1, ISG-15, RSAD-2 and SIGLEC- determined. The IFN score was derived as described (1). The mean interferon score of the controls plus two SD was calculated: 1.62 and scores higher than this value were considered positive

Results: Four Caucasian patients (2 brothers males and 2 unrelated females) were identified carrying CECR1 mutations (compound eterozygous Leu249Pro/Pro344Leu in the two brothers, compound heterozygosity T360A/R49Gfs*4 deletion in one and homozygous Y453C mutation in one). Mean age was 12.2 ± 2.0 years. Three of the described patients presented with clinical features consistent with the phenotype of DADA2 already reported including recurrent fever, livedo reticularis, persistent elevation of inflammatory markers, arthralgia/ arthritis. Unusual/undescribed manifestation included in 1 patient: early onset gastrointestinal involvement with a biopsy consistent with unspecific inflammation, posterior reversible encephalopathy with seizures, deafness and malignant hypertension. The latter is due to nephrogenic hypertension secondary to kidney infarction. His younger brother showed a very mild phenotype characterized by a single episode of prolonged fever with abdominal pain and arthralgia. He is the 1 patient showing hypogammaglobulinemia. All patients showed a complete normalization of clinical and laboratory findings with no recurrences after treatment with etanercept (follow-up ranging from 8 months to 20 months). The interferon score before treatment was elevated in 3 (ranging from 3.6 to 10.4) out of 4 patients (except for the younger brother), and rapidly normalized after treatment

Conclusion: Our data confirm the highly variability of DADA2 regarding age of onset, severity and organ involvement, even within families and, for unknown reasons, among patients with the same mutations. Furthermore, these data suggest that type I interferon score could be used in DADA2 patients as a useful biomarker of disease's activity. The relation between type I IFN hyperactivity, deficiency of ADA2 and response to TNF inhibition remain elusive References: (1) Rice GI et al. Lancet Neurol. 2013 Dec;12(12):1159-6

Validation of Diary Score for the Assessment of Disease Activity in

Candle (Chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature) and SAVI (STING associated vasculopathy with onset in Infancy) Patients

Megha Sawhney[1], Gina A. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: CANDLE and SAVI are two rare autoinflammatory interferonopathies without validated outcome measures to assess disease activity; however, daily diaries of prominent disease symptoms have become standard in assessing clinical disease load and reporting treatment related outcomes in patients with the autoinflammatory disease spectrum CAPS (Cryopyrin associated periodic syndrome) where diary scores were accepted by the FDA in the context of drug approval. For novel AIDs with distinct organ manifestations new disease specific diaries need to be generated and validated. In pediatrics inflammatory diseases the Childhood Health Assessment Questionnaire (CHAQ), which measures physical function and the patient and physician-derived outcome measures, patient global VAS (PATG) and physician global VAS (PHYG) respectively are used to assess disease severity and response to treatment and have been used to validate patient related outcomes in the past.

Methods: The daily diary developed for NOMID was modified to reflect disease symptoms of CANDLE and SAVI. For CANDLE these include: fever, rash, joint pain, headache and fatigue (possible range, 0 to 20) For SAVI these also include respiratory symptoms and ulcerative lesions. Each symptom is rated on a scale from 0 to 4 for increasing severity. We correlated the diary score in CANDLE and SAVI patients against 6 validated outcome measures: Childhood Health Assessment Questionnaire (CHAQ), which measures physical function; physical global VAS (PHYG); global pain assessment (PAINGL); parent global(PARG); the patent quality of life (PATQL) and parent QL (PARQL) by correlating each symptom and the summary score with PHYG, PAINGL, PARG, PATQL and PARQL respectively. We used Pearson correlation and 1-sample t- test to assess whether these values plausibly centered at 0. P – values were not corrected for multiple comparisons but p-values of <0.01 were considered significant.

Results: 11 CANDLE and 4 SAVI patients and 3 undifferentiated interfernopathy patients were included. Mean diary scores computed for all patients correlated well with CHAQ (r-0.36, $p<0.001$).Mean diary score computed during the evaluation for CANDLE patients correlated well with CHAQ(r-0.36, $p<0.001$), pain global (r- 0.48, $p<0.001$). Individual symptoms like fever, rash etc correlated well with these outcome measures in both CANDLE and SAVI. However, the SAVI specific parameters, respiratory symptoms and ulcerative lesions did not show any significant correlation.

Conclusion: Our study shows that diary scores exhibit validity across other outcome measures validated for unrelated pediatric inflammatory diseases, but outcome measures in SAVI need to be further refined.

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile scleroderma (JS) is a rarely seen chronic connective tissue disorder. According to organ involvement, the disease is divided into two main forms: systemic and localized scleroderma. Localized form is more frequent in childhood, characterized with benign clinical course and favorable prognosis. Although extremely rare, juvenile systemic scleroderma (JSS) has far worse prognosis with multi-organ involvement and possible life-threatening complications. Its main pathophysiological characteristics include microvascular abnormalities and excessive fibrosis of the skin, subcutaneous tissues and internal organs. Pentraxin 3 (PTX 3) is a multifunctional protein produced at the inflammation site by macrophages, dendritic cells, endothelial cells, smooth muscle cells and fibroblasts. Previously studies reported an increased level of PTX 3 among adult patients with scleroderma. Study among patients with JS has not been provided yet. We aimed to measure the level of PTX 3 in patients with juvenile scleroderma comparing to healthy children. Thereby, we have tried to give an answer on question whether the PTX 3 could be a marker of fibrosis in patients with juvenile scleroderma.

Methods: We assessed patients with JSS and those with juvenile localized scleroderma (JLS) and age- and sex-matched health controls. A complete medical history, physical examination, and laboratory evaluation were performed for each patient at the time of enrollment. The same physical examination and laboratory investigation was performed in healthy controls, in order to exclude the coincidental disease. Circulating PTX3 levels were measured by enzyme immunoassay. The lower limits of detection for PTX3 was 0.1 ng/ml.

Results: We assessed 24 patients with JSS, 20 patients with JLS and 41 health controls. The mean age of patients was 15.38 ±3.156, 12.44 ±3.63 and 14.33±3.48 for JSS, JLS and healthy controls, respectively. Mean disease duration was 2 years (range: 0.6 -15 years) for JSS and 1.5 years (range: 0.6 - 18 years) for JLS patients. Mean serum level of PTX 3 was 10.63 ± 8.61 ng/ml, 11.75 ± 9.11 ng/ml and 2.76 ± 1.338 ng/ml for JSS, JLS and healthy controls, respectively. In both of patients group PTX 3 level was significantly higher comparing to healthy children ($p<0.001$). We didn`t find statistically significant difference between JSS and JLS patients according to level of

PTX3. A mean modified Rodnan skin score of JSS patients was 19.95 ± 11.088. PTX3 level was found to be in positive correlation with modified Rodnan skin score, in patients with JSS (Rho=0.497, p=0.030).

Conclusion: The circulating PTX3 level is significantly higher in both JSS and JLS patients than in healthy control subjects. The possible explanation is that fibrosis and increased fibroblast activation represent main pathophysiological mechanism in both form of the disease. This result support relevance of PTX 3 measurement in order to determinate fibrosis activity. PTX 3 should be considered a relevant marker of fibrosis in patients with juvenile scleroderma.

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pamidronate (PAM) may be effective in diminishing pain and permanent bone deformities in chronic non-bacterial osteomyelitis (CNO). Whole body magnetic resonance imaging (WB MRI) can be used to assess anatomical site, extent and inflammatory activity of bone lesions. The aim of this study was to evaluate the clinical and radiological outcome of children with CNO after one year of PAM treatment.

Methods: A retrospective evaluation of children diagnosed with CNO according to the Bristol criteria ADDIN RW.CITE{{216 Roderick,M. 2014}}(1). Children were treated with i.v. PAM 1mg/kg (max 60 mg/day) for 3 consecutive days every 3 months. We included 17 children (8 girls and 9 boys) median age 11 years (range 5-13). Medical history, clinical assessments and inflammatory biochemistry were obtained. WB MRI (1,5 Tesla) short tau inversion recovery (STIR) and T1-weighted images were performed at baseline, median -1 month (range -6-0) and after one year PAM treatment, median 12 months (range 9-19). Number of bone lesions are listed per patient

(median, range).

Results: Comorbidities were JIA (n=3) and IBD (n=1); none of the children had psoriasis. All children had been treated with NSAID as first line treatment. Further medical history was antibiotics (n=1), methotrexate (n=7), steroids (n=7) and anti-TNFα treatment (n=3). Six children had elevated sedimentation rate at baseline, which normalized after one year. At baseline there were in total 52 clinical symptomatic lesions, median 3 (range 1-8) and 113 radiological active lesions, median 6 (range 2-14). The most common sites of bone lesions were femur (19%), tibia (19%) and spine (12%). Six children had spinal lesions, median 1 (range 1-4), and 5 children had non-erosive lesions in relation to the sacroiliac (SI)-joints. After one year 11 children were still radiological active based on MRI with total number of 68 lesions, median 4 (range 1-21) (Table 1). Only one active spinal and one SI-joint lesion persisted. Ten children had new or worsening of lesions, median 2 (range 1-15). Three children had deformation of 11 vertebral bones (10 thoracic, 1 cervical) without sign of active inflammation. After one year the clinical symptoms in the radiological active group were; five with total pain relief, 5 with partial pain relief and 2 without any pain relief. In 6 children lesions resolved completely as assessed by MRI, but pain was still reported in 4 of them.

Conclusion: PAM given for one year is a potent second-line treatment for CNO. Axial lesions and SI-joint lesions respond well to PAM. Persistent pain or pain progression may exist despite total resolution as assessed by WB MRI. ADDIN RW.BIB (1) Roderick M. Efficacy of pamidronate therapy in children with chronic non-bacterial osteitis: disease activity assessment by whole body magnetic resonance imaging. Rheumatology (Oxford) 2014; 53(11):1973-1976

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic Nonbacterial Osteomyelitis (CNO) is a rare condition of largely unknown etiology with variable clinical and radiological features. It is an aseptic auto-inflammatory bone disease. The aim is to describe a cohort of patients with pediatric CNO and their outcomes.

Methods: This is a retrospective descriptive study of 26 cases seen from March 2009 to September 2015. We collected demographic and clinical data.

Results: Ages ranged from 2 to 19 years (mean 13.1) and F:M sex ratio was 16:10. Of 26 patients, 17 had a bone biopsy, 16 had a whole body MRI of whom 4 also had a bone scan, and 5 had only a bone scan. Of those with MRI, 15 children had multifocal lesions and in 13, asymptomatic lesions were detected. From those with labs, 18 of 23 had elevated ESR and 12 of 20 had elevated CRP. Other associated conditions included palmar plantar pustulosis (N=1), psoriasis (N= 1) and acne (N=2). Family history of psoriatic arthritis (N=1), psoriasis (N=1) and CrohnÕs disease (N=1) were present. Treatment consisted of NSAID (N=25), prednisone (N=7) and other immunosuppressive therapy (N=21). Almost all patients were treated with NSAID: naproxen (N=18), meloxicam (N=11), indomethacin (N=9), celecoxib (N=3), ketorolac (N=2) and diclofenac (N=1). However, in half (N=13) the therapy had to be escalated: oral prednisone (N=7), methotrexate (N=9), pamidronate (N=4), adalimumab (N=3), sulfasalazine (N=2), leflunomide (N=1), azathioprine (N=1), infliximab (N=1). The most common complication was vertebral body compression fracture (N=6). Four children needed bisphosphonate infusions due to vertebral involvement. Outcomes in regards to resolution of clinical symptoms and bone detected lesions were overall excellent since all but one patient responded to therapy.

Conclusion: Whole body MRI is the imaging modality of choice in CNO and has emerged as the most sensitive way to document the number and extent of lesions. In our cohort of children with a whole body MRI, the majority had asymptomatic multifocal lesions. Fifty percent of the cohort did not respond to NSAID monotherapy requiring second line immunosuppressive therapy. The most common complication was vertebral body compression fracture. We suggest the use of bisphosphonates for vertebral involvement.

CHARACTERISTICS	Mean age (years)	F:M (ratio)	Diagnostics (N=total)	Labs (%)	Complication (%)	Treatment (N=total)
	13.1					
		16:10				
Whole Body MRI			N=16			
Bone Scan			N=9			
Bone Biopsy			N=17			
ESR				78.2%		
CRP				60%		
NSAIDS						25
Prednisone						7
Methotrexate						9
Pamidronate						4
Adalimumab						3
Sulfasalazine						2

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. Several adult publications looked at the differences between limited (ljSSc) and diffuse subtype (djSSc). There is few data regarding this topic in pediatric jSSc. The juvenile scleroderma inception cohort is a prospective standardized register for patients with jSSc.

Methods: Patients with jSSc were included worldwide to the jSSc cohort. Patients fulfilled the ACR criteria for

jSSc. We compared the demographics and clinical features of the ljSSc and djSSc patients.

Results: Up till now 80 patients were enrolled, 58 (72.5%) with djSSc and 22 (27.5%) with ljSSc. 10% in djSSc and 23% in ljSSc showed overlap features. Disease duration at time of inclusion in the cohort was 3.7 years in the djSSc and 3.0 years in ljSSc. 83% in the djSSc and 81% in the ljSSc group were female. The mean age at onset of Raynaud symptoms was 9.0 years in the jdSSc and 10.4 years in ljSSc group and the mean age at onset of the non-Raynaud symptoms was 9.4 in djSSc and 10.9 ljSSc. At the time of inclusion the mean of modified Rodnan Skin Score was 18.2 in the djSSc and 9.1 in ljSSc. Anti-Scl 70 positivity was found in 30.4% of djSSc and 33.3% in ljSSc. Only 2 patients in the djSSc group and 2 in the ljSSc group presented anticentromere positive. Capillary changes occurred in 62.1% in the djSSc and 54.5% in ljSSc . History of active ulceration was present in 56% in the djSSc and in18% in ljSSc. Active ulcerations were present in 21.1% in the djSSc and 4.5% in the ljSSc. The mean of 6 Minute walk test was 392 m in the djSSc group and 504 m in the ljSSc group. 15.5% of djSSc and 41% of ljSSc had cardiac involvement. Pulmonary hypertension occurred in 8% in djSSc and 13% in ljSSc. 56% in djSSc and 31% in ljSSc group had signs of interstitial lung disease on imaging. Renal involvement occurred in 7% in djSSc and 4.5 % in ljSSc. None had systemic hypertension. 38% of djSSc and 18% of ljSSc had gastrointestinal involvement. 57% in djSSc and 73% in ljSSc had musculoskeletal involvement. Patient global disease activity measured by VAS was 44.2 in the djSSc and 46.3 in ljSSc. Patient global disease damage was 42.6 in the djSSc and 33.8 in ljSSc. Physician global disease activity measured by VAS was 40.3 in the djSSc and 25 in the ljSSc and physician global disease damage measured by VAS was 35.4 in the djSSc and 15.0 in the ljSSc.Mean CHAQ score was 0.4 in both groups.

Conclusion: Patients with djSSc were younger at onset; have more often capillary changes, active ulcerations and gastrointestinal involvement, and less pulmonary hypertension and musculoskeletal involvement. They also present moresevere disease and more disease damage. Features of the pediatric subtypes of jSSc differ from adults with SSc, especially the high proportion of patients with diffuse subtype.

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile Localised Scleroderma (JLS) is an orphan disease which is complicated by difficulties in robust measurement of disease activity. Several outcome measures to assess disease activity have been described with some recent trials using the mLoSSI (modified localized scleroderma skin severity index which is a validated cutaneous assessment tool in JLS. Whilst such measures are a step forward in assessment of this disease, they do not capture all aspects of the disease that are taken into consideration by clinicians when judging the degree of disease activity and therefore making decisions regarding treatment. In particular extra-cutaneous manifestations are poorly captured. With potential innovative and more effective treatment options emerging, it has become extremely important to define a validated activity index that captures skin, extra-cutaneous disease activity and patient reported outcomes in order to monitor response to treatment.

Methods: Members of the PRES Scleroderma working group and other paediatric rheumatologists and dermatologists interested in JLS met to develop an activity index using the nominal group technique in a consensus meeting in Hamburg, Germany, in December 2015. Eithy percent agreement was chosen for the selected domains and items.

Results: Summarises the proposed domains and items to assess the activity of localised scleroderma. **Skin:** Change in skin thickening – *Modified Rodnan Skin Score (mRSS); Total Skin thickness score of mLoSSi; Research tool: A, durometer B, Ultrasound* Degree of change in white waxy appearence since last visit – *Marked worsening /some worsening and some improvemnet/no change/ significant improvement* Change in Erythema/violaceousness since last visit – *mLoSSI* Change in Subcutaneous induration since last visit – *Yes or no & elements of mLoSSi* Enlargement of the lesion since last visit – *Yes or no (captured within mLoSSi)* New lesion per anatomical region of mLoSSI – *mLoSSI* Worsening alopecia (eyelash, beard, body hair) – *marked worsening,/some worsening and some improvement/no change/ significant improvement/no hair in the lesion / decreased* Increase in face atrophy – only Parry Romberg patients – *3 D photography* **Optional item**: Change in blood flow in the lesion - *Ultrasound with doppler / laser doppler* **Extracutaneous involvement:** Change in Activity of anterior uveitis since last visit – *Yes or no* Change in active joint count – *Number of active joints* Worsening of lim discrepancy – *Yes or no* Active CNS involvement – *Yes or no* **Patient reported outcomes:** Change in subcutaneous induration since last visit – *marked worsening /some worsening and some improvemnet/ no change/ significant improvement* Uncomfortable feeling in the lesion (not including itch) – *VAS score 0-100* Itching in the lesion – *VAS score 0-100* Quality of life assessment – *PEDsQL, CHQ, CDLQII* Functional assessment of daily life – *CHAQ/HAQ*

Conclusion :

We propose extended domains to define an activity index for JLS which aim to capture the heterogeneity of disease activity. This may become an important instrument for evaluating treatment efficacy but requires prospective validation from the PRES and CARRA scleroderma working groups.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. Currently just retrospective data exist regarding evolvement of organ involvement. In the retrospective studies assessment of the organ involvement is not standardized. Our project is the first project, where prospectively and with a standardized assessment data of jSSc patients are collected. We present the data of the patients at the entry into the cohort.

Methods: Patients with jSSc, according the ACR criteria, were recruited worldwide and were prospectively assessed, using the proposed standardized patient assessment protocol.

Results: 26 centers from 17 countries applied to participate on the project. The assent and consent forms were translated into the local native languages. Up till now 80 patients were enrolled. Sixty-six (82.5%) of the 80 patients were female. The mean age of the onset of Raynaud symptomatic was 9.4 years (0.2 – 15.9). The mean age at the onset of the non-Raynaud symptomatic were 9,9 years (0.3 -15.9). 58 (72.5%) had diffuse subtype and 22 had limited subtype (27.5%). 11 (14%) of them have an overlap symptomatic, in 6 (10%) in the diffuse and 5 (23%) in limited subtype. At the time of the inclusion the mean modified Rodnan Skin Score was 15.7 (0-51). ANA positive were 60/77 (78%), 24/77 (31%) of them were anti-Scl 70 positive and 4/46 (9%) were anticentromere positive. 48/80 (60%) had already capillary changes and 36/78 (46%) inactive ulcerations, 13/78 (17%) had active ulceration at the time of the inclusion. 39/80 (49%) had cardiopulmonary involvement, 22/45 (49%) of had signs of interstitial lung disease on imaging, 16/36 (44%) had FVC <80% and 10/19 (52%) had DLCO < 80%. 6/44 (14%) patients had pulmonary hypertension. The mean 6 Minute Walk Test was 419.3 m (60-615). 5/80 (6%) had renal involvement, none of them had hypertension. 26/80 (32.5%) had gastrointestinal involvement, and 18/26 (69%) of them esophageal involvement. 48/79 (62%) had musculoskeletal involvement, mostly limited range of joint movement in 21/49 (43%). Isolated muscle weakness occurred in 3/46 (6.5%). 2/80 (2.5%) showed neurologic involvement. The mean CHAQ score (n=51) was 0.4 (0-2.5). Patient global disease activity (n=40) on VAS (0-100) was 44.4 and disease damage 41.6. Physician global of disease activity (n=44) on VAS (0-100) was 37.5 and physician global of disease damage (n=43) was 32.1.

Conclusion: We present the data on the first 80 patients with jSSc at the time of inclusion in our cohort. The current recruitment data confirms that pediatric patients are different from the adult patients; there is a significantly higher proportion of diffuse subset patients with 72.5%. 14% of the patients had an overlap features. The patients had significant disease burden assessed by patients and physician at the entry of the cohort.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Localized scleroderma (LS) can affect patients' physical function and psychosocial well-being, but, published studies of the impact of pediatric LS on health-related quality of life (HRQoL) show mixed results (Table 1). Present studies are limited by small sample sizes and cross-sectional study designs. Furthermore, there is no current consensus on which HRQoL domains are most relevant in LS, resulting in use of generic HRQOL instruments which may not capture all HRQOL areas of interest. The goal of this study was to examine the domains captured by existing tools and to qualitatively identify new, potentially important domains of HRQoL impact through focus groups with pediatric LS patients and their parents.

Methods: Domains of LS HRQoL impact were identified in two ways: (1) review of extant literature using generic and dermatology-specific HRQoL instruments and 2) focus groups with LS patients and their parents. Three patient and 3 parent focus groups were conducted with 3-5 patients in each patient group and 4-7 parents per group. Groups were divided by patient age range (8 to 10 yo, 11 to 13 yo, 14 years and older).

Results: Table 1 summarizes generic HRQoL instruments available in the literature used with LS patients and the domains they measure. Skin symptoms and joint/muscle pain are the most well studied symptoms in pediatric LS, while effects on body image and peer relationships are less well-characterized. Seven domains were ultimately identified as potentially important contributors to HRQoL in LS (Table 2). Physical functioning is often studied but focus groups revealed effects on fine motor activity not readily captured by existing instruments (Table 2). Side effects from treatment with systemic medications are also not currently well studied in LS, although patients and parents indicate they are bothersome (Table 2).

Conclusion: LS patients experience adverse HRQoL impact across multiple physical and psychosocial domains, as corroborated by LS patients themselves. Existing generic HRQoL instruments do not assess all of these domains fully and underexplore domains such as treatment effects. The literature review and focus groups yielded candidate domain for LS HRQoL measurement, but future research is needed to assess how these domains can be quantified effectively. Development of an LS-specific HRQoL tool may be indicated. **Table 1: Current domains captured by existing quality of life instruments used with pediatric LS patients.**

Survey	No. items	Type of Instrument	Domains
DLQI/CDLQI[1,2,3,4,7,8]	10	Dermatology specific	Symptoms/ feelings, leisure, school/ holidays, personal relationships, sleep, treatment
Visual Analogue Scales[4,9,10,11]	1	Varied by study	Symptoms, severity, or quality of life.
ISDL[9,10]	22	Dermatology specific	Work, hobbies, sleep, sexuality, relationships, stigmatization, and illness cognitions.
CHQ[1,6]	87	Generic	Physical functioning, bodily pain, role/social-physical, general health perceptions, role/social-emotional behavior, mental health, general behavior, self-esteem, parental emotional impact, parental time impact, family impact.
Skindex[3,5]	29	Dermatology specific	Symptoms, emotions, and functioning
CHAQ[1]	30	Generic	Disability, discomfort, pain
CQOL[1]	15	Generic	Activities, appearance, communication, continence, depression, discomfort, eating, family, friends, mobility, school, sight, self-care, sleep, worry
KINDL[8]	24	Generic	Physical well-being, emotional well-being, self-esteem, family, friends school

Domain	Examples from focus group transcripts
Uncomfortable skin sensations like itch, pain, and tightness.	"I keep [my skin] soft because if I don't I can feel it pull and it kind of hurts."
	"Mine doesn't usually hurt, but it sometimes itches."
	Parent: "[*Redacted*] doesn't have pain, but he does feel it."
Nuanced effects on fine motor functioning after prolonged repeated movements	"I've been taking standardized tests lately and my hand will cramp…I'm given 25 minutes to write an essay and…[I spend] 5 minutes just trying to wrestle my hand back to normal."
	Parent: "She had to wear braces on her fingers…she had to use putty. She had all these little mechanisms of things she had to squeeze."
Limitations or worry about elective activities	"They ask…'You've been dancing for so long why can't you do these basic things?' And [I] tell them that I'm physically unable to."
	"I love playing soccer…when I first noticed it, I would always be careful. I would always be watching everywhere just to make sure nothing would hit me."
	Parent: "She wanted to play volleyball, but I said, you'll hurt your fingers. You know, you hit with the palm of your hand [where your scleroderma is]"
Joint/muscle pain or cramping	"When I'm doing school work, [my hand] will just cramp up. Like what [*redacted*] said, you know, it's painful."
	"I play the viola in orchestra…and sometimes I have to position my hand a different way so my hand doesn't cramp up."
	Parent: "At one time her hand was hurting so bad they thought she was going to have to go to using a computer in school"
Body image/appearance	"You wake up and you just look in the mirror and you're just like what's wrong? Why is that here?"
	"The staring makes me feel different and I used to wear a bunch of long-sleeved shirts and never show my arms."
	Parent: "He wished his face would change and knowing he had to go to school that day and be seen by his friends and the girls in his classes."
Peer relationships	"The bad days are when people are commenting and… you just don't want to leave your room. You just want to stay inside because you are afraid of what people will say."
	Parent: "They laugh at her because [of] her skin condition and even her cousins are really mean. They laugh at her. They make fun of her and its terrible."
Systemic medication side effects	"In the middle of the week I'd get sick and start throwing up and… then I'd just throw up and then go to school and try to fight through it."
	"With the methotrexate it would just feel weird, it'd make me throw up, I'd feel dizzy."

	Parent: "She went from being a skinny little kid…to having big puffy cheeks and gaining weight from the steroids. She hated it…and I think that affected me horribly."

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA,

Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. Currently there is no data regarding use of medication in jSSc patients. Our project is the first project, where prospectively and with a standardized assessment data of jSSc patients are collected and the applied medication assessed. We present the data of the medication us at the time point of entry into the cohort.

Methods: Patients with jSSc, according the ACR criteria, were recruited worldwide and were prospectively assessed, using the proposed standardized patient assessment protocol.

Results: Up till now 80 patients were enrolled. Sixty-six (82.5%) of the 80 patients were female. 58 (72.5%) had diffuse subtype (djSSc) and 22 had limited subtype (27.5% (ljSSc). 88% of the patients in the djSSc and 86% in the ljSSc patients received medication. Table 1.

	Whole group	**Diffuse subtype**	**Limited subtype**	
Number of patients	**80**	**57 (71%)**	**23 (29%)**	
Sex female /male	66/14 => 4.7:1	47/10 => 4.7:1	20/4 => 5:1	0.924
Medication	62/71 (87%)	44/50 (88%)	18/21 (86%)	0.945
Corticosteroids	36/62 (58%)	27/44 (61%)	9/18 (50%)	0.667
Cyclophosphamide	5/62 (8%)	5/44 (11%)	0/18 (0%)	0.159
Chloroquine/Hydroxy-chlorqquine	10/62 (16%)	6/44 (14%)	4/18 (22%)	0.485
Methotrexate	35/62 (56%)	24/44 (54%)	11/18 (61%)	0.804
Mycophenolate	11/62 (18%)	8/44 (18%)	3/18 (17%)	0.905
Azathioprin	1/62 (2%)	1/44 (2%)	0/18 (0%)	0.524
Tocolizumab	1/62 (2%)	0/44 (0%)	1/18 (6%)	0.125
Rituximab	2/62 (3%)	1/44 (2%)	1/18 (6%)	0.523
Bosentan	11/62 (18%)	10/44 (23%)	1/18 (6%)	0.165
PDE5 inhibitors	4/62 (6%)	3/44 (7%)	1/18 (6%)	0.863
Prostanoids	1/62 (2%)	0/44 (0%)	1/18 (6%)	0.125

Conclusion: Interestingly the most frequently used DMARD was Methotrexate, followed by Mycophenolate. Only small number of patients received biologics. Interestingly higher number of patients in the diffuse group received Bosentan. Interestingly 9 patients did not received any DMARDS /biologics or medication again pulmonary hypertension.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pediatric localized sclerodermaÕs (LS) effects on patient/family well-being are underexplored. Contributions of HRQoL domains and family dynamics to LSÕs impact on patients has not yet been examined. This study evaluates correlates of LS patient/parent global assessments of disease impact (Pt-GA; Par-GA).

Methods: Cross-sectional data from the National Registry for Childhood Onset Scleroderma (NRCOS) spanning 2015-2016 were used. Pt-GA/Par-GA were scored on a 100mm visual analogue scale. Clinical data (i.e. modified Localized Scleroderma Skin Index [mLoSSI], Localized Scleroderma Damage Index [LoSDI], physician global assessment of disease activity/damage [PGA-A; PGA-D]) were examined. Patients completed PedsQL-Generic Core Scales and Rheumatology Module (PedsQL-GC/-RM). Parents completed PedsQL-Family Impact Module (PedsQL-Fam). ChildrenÕs Dermatology Life Quality Index (CDLQI) assessed skin-specific HRQoL. Descriptive statistics, HRQoL score distributions, and SpearmanÕs correlations ($p<0.05$) were evaluated for Pt-GA, Par-GA, activity/damage, PedsQL-GC/-RM/-Fam (and individual domains), and CDLQI.

Results: Table 1 summarizes clinical/HRQoL data. Pt-GA/Par-GA were correlated (0.67, $p<0.001$), with Par-GA greater than Pt-GA by paired samples Wilcoxon ($p=0.007$). Pt-GA/Par-GA did not correlate with mLoSSI, LoSDI, PGA-A, or PGA-D. Pt-GA/Par-GA correlated comparably with CDLQI (0.44, $p=0.001$). Pt-GA correlated with PedsQL-GC/-Fam (-0.35, $p=0.012$; -0.45, $p=0.001$). Par-GA correlated with PedsQL-Fam (-0.49, $p<0.001$), not PedsQL-GC. Pt-GA correlated with PedsQL-GC psychosocial health summary score (-0.37, $p=0.008$), and social/school domains(-0.41, $p=0.003$; -0.37, $p=0.007$). Pt-GA correlated with PedsQL-RM worry (-0.35; $p=0.011$) and treatment domains (-0.28, $p=0.047$). Par-GA correlated with PedsQL-GC social domain (-0.32, $p=0.023$) and weakly with PedsQL-RM worry domain (-0.28, $p=0.047$). Par-GA correlated with all PedsQL-Fam domains (-0.36 to -0.51, $p\leq0.009$), as did Pt-GA for all but the cognitive domain (-0.32 to -0.52, $p\leq0.023$). CDLQI items most often scored > 0 were about teasing (25%), embarrassment (23%), treatment burden (21%), and itch/pain (17%). Table 2 lists PedsQL items showing most frequent HRQoL impact.

Table 1: Patient Characteristics (n = 52)		
Demographics		
Female, n (%)	35	67
Caucasian, n (%)	46	89
Age at study visit, median, IQR	12.8	10.4-15.4
Age at onset, median, IQR	7.2	3.8-9.6
Time from onset to diagnosis, median, IQR	1.1	0.5-2.4
LS Subtype, n (%)		
Linear Trunk/Limb	14	27
Linear Face/Scalp	17	33
Generalized Morphea	6	11
Circumscribed Morphea, Superficial	4	8
Circumscribed Morphea, Deep	2	4
Eosinophilic Fasciitis	1	2
Pansclerotic Morphea	1	2
Mixed Subtype	7	13
On Systemic Immunosuppressive Therapy, n (%)	37	88
Clinical measures (median, IQR)		
Cutaneous Activity/Damage		
mLoSSI	0	0-1
LoSDI	6	3.3-18.5
Physician Global Assessments		
PGA-A	0	0-0
PGA-D	32.5	22.3-39.8
Patient/Parent-Reported Measures (median, IQR)		
Patient/Parent Global Assessments		
Pt-GA	4	0-12
Par-GA	10	0-23
PedsQL-GC Total Score	93.3	83.5-97.9
PedsQL-RM - Pain	100	81.3-100
PedsQL-RM - Daily Activities	100	100-100
PedsQL-RM - Treatment	89.3	70.2-100
PedsQL-RM - Worry	91.7	83.3-100

PedsQL-RM - Communication	100	83.3-100
PedsQL-Fam Total Score	90	71.4-96.2
CDLQI	1	0-2

Table 2: PedsQL-GC/-RM/-Fam Items Most Frequently Scored < 75 (i.e. Sometimes/Often/Almost Always)

Scale/Item	Domain	n	%
PedsQL-GC			
I have low energy	Physical Functioning	13	25
I miss work or school to go to the doctor or hospital	School Functioning	24	46
PedsQL-RM			
I ache or hurt in my joints and/or muscles	Pain and Hurt	14	27
My medicines make me feel sick	Treatment	13	25
It is hard to be responsible for my medicines or physical therapy	Treatment	15	29
I get scared when I have to have blood tests	Treatment	12	23
I worry about my illness	Worry	12	23
It is hard for me to explain my illness to other people	Communication	14	27
PedsQL-Fam			
I feel tired during the day	Physical Functioning	14	27
I feel tired when I wake up in the morning	Physical Functioning	15	29
I get headaches	Physical Functioning	11	21
I feel anxious	Emotional Functioning	24	46
I feel sad	Emotional Functioning	19	37
I feel frustrated	Emotional Functioning	18	35
It is hard for me to keep my attention on things	Cognitive Functioning	12	23
I feel that others do not understand my family's situation	Communication	13	25
I worry about whether or not my child's medical treatments are working	Worry	32	62
I worry about the side effects of my child's medications/medical treatments	Worry	38	73
I worry about how others will react to my child's condition	Worry	21	27
I worry about how my child's illness is affecting other family members	Worry	13	25
I worry about my child's future	Worry	32	62
Stress or tension between family members	Family Relationships	11	21

Conclusion: Pt-/Par-GA correlate with measures of HRQoL and family impact, but not physician-scored disease activity/damage. Psychosocial function, child/parent worries, treatment burden, and family impact should be routinely measured as they may more fully explain LSÕs impact than cutaneous manifestations.

The Performance of the Kobayashi and Egami Scores in Detecting IVIG Resistance in Kawasaki Disease in a Single Centre Canadian Cohort Treated with IVIG and Low Dose Aspirin

Dania Basodan and Rosie Scuccimarri, Division of Pediatric Rheumatology, Montreal Children's Hospital / McGill University Health Centre, Montreal, QC, Canada

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Kawasaki disease (KD) resistant to IVIG remain a challenge. IVIG resistance has been recognised as a risk factor for the development of coronary artery abnormalities (CAA). Prediction of IVIG resistance in Japanese patients has been successful with the Kobayashi and Egami scores. However, these scores lack sensitivity when applied to patients with KD outside of Japan. We aim to evaluate IVIG resistance, assess if it is a risk factor for CAA, and calculate the sensitivity and specificity of the Kobayashi and Egami scoring systems in predicting IVIG resistance in this single centre Canadian cohort treated with IVIG and low dose aspirin (ASA).

Methods: A retrospective chart review was performed for all patients diagnosed with KD and treated with at least one dose of IVIG (2 g/kg) and low dose ASA (< 10 mg/kg/day) between January 2004 and December 2014. Patients were excluded if they were transferred from another centre, if they had a significant structural cardiac defect not-related to KD, or if there was insufficient laboratory data to perform the Kobayashi and Egami scores. Demographic data, clinical criteria, coronary involvement, laboratory results, and doses of ASA and IVIG were recorded. IVIG resistance was defined as the requirement of a second dose of IVIG. Coronary arteries were considered abnormal if the dimension adjusted for body surface area and expressed in SD units had a z score > or equal to 2.5 at the 6 to 8 week echocardiogram. Sensitivity and specificity calculations were performed. P-values for categorical variables were calculated with the Chi-square test; Wilcoxon rank sum test for continuous variables.

Results: Of the 313 patients identified, 304 charts were reviewed and 262 patients met the inclusion criteria. There were 149 (56.8%) males; 113 (43.2%) females. The mean age was 3.3 years. Criteria for complete KD

were met by 198 (75.6%) patients and 64 (24.4%) had incomplete KD. IVIG resistance was seen in 29.8% (78/262) of the study cohort. In patients with complete KD, the sensitivity of the Kobayashi and Egami scores was low at 33.3% and 31.7% respectively but the specificity was high at 79.3% and 83%. In incomplete KD, the sensitivity of the Kobayashi and Egami scores was also low at 26.7% and 40% respectively but again the specificity was high at 87.8% and 79.6%. From the study cohort, 21 out of 262 patients (8%) had CAA. There was a statistically significant increase in CAA in those who were IVIG resistant with 15 patients (19.2%) developing CAA in the IVIG resistant group compared to 6 patients (3.3%) in those who responded to one dose of IVIG (p<0.0001). IVIG resistant patients did not differ statistically from IVIG responders in regards to age, gender or duration of fever at diagnosis.

Conclusion: To our knowledge, this is the largest non-Japanese cohort that assesses the performance of both the Kobayashi and Egami scores. In this Canadian cohort, both failed to predict IVIG resistance. Patients with IVIG resistance had a significantly higher incidence of CAA. These results further highlight the need for the development of a new risk assessment tool for the prediction of IVIG resistance in North American children with KD so that risk stratification could be considered in future treatment strategies.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a group of rare systemic vasculitidies with significant morbidity and mortality. There have been no comparative effectiveness studies of AAV in children. We aimed to determine if use of plasma exchange (PLEX), in addition to standard immunosuppression, was associated with a decreased need for dialysis among children hospitalized with AAV.

Methods: We used the Pediatric Health Information System (PHIS) database to conduct a retrospective cohort study of children hospitalized with AAV from 2004-2014. PHIS contains inpatient administrative and billing data from 47 hospitals in the United States. Patients with the ICD-9-CM code 446.4 as one of the discharge diagnoses

and ≥1 charge for glucocorticoids were included. Patients who underwent a renal transplant during their first hospitalization were excluded. We used multivariate mixed effects logistic regression models accounting for clustering by hospitalization to determine if initiation of dialysis within 6 months of the first admission was associated with use of PLEX within the first 7 days (primary exposure) or use of cyclophosphamide (CYC) or rituximab during the first admission. For regression modeling, patients initiating dialysis within the first 3 days of hospitalization were excluded (N= 36). We adjusted for intensive care unit (ICU) stay in the first 24 hours as a proxy for disease severity.

Results: During the study period there were 1284 admissions for 389 children with AAV, 78 (20%) of whom required dialysis at some point during the study period. Median age at first admission was 14.7 years (interquartile range (IQR) 12.2, 16.1) and 61% were female. Median time to initiation of dialysis was 3 days (IQR 1, 21); 68 (87%) patients started dialysis within 6 months of initial hospitalization. Twenty-five (6%) patients received a renal transplant at a median of 20.6 months (IQR 11.5, 26.4) after first admission. No patients received a renal transplant before initiation of dialysis. Of the 32 patients receiving dialysis included in the regression model, 60 % were female, with a median age of 13.7 years (IQR 10.8, 15.4), 14 (44%) had ICU admissions in the first 24 hours, and 25%, 65%, and 9% received PLEX, CYC , or rituximab, respectively, prior to dialysis. PLEX and ICU stay in the first 24 hours were significantly associated with increased odds of needing dialysis within 6 months in univariate, but not multivariate analysis (Table). CYC use was not associated with an increased or decreased likelihood of dialysis in univariate or multivariate analysis. Associations with rituximab could not be determined due the rarity of its use before dialysis.

Conclusion: Twenty percent of children hospitalized with AAV require dialysis with the vast majority initiating dialysis within 6 months of their first admission for AAV. Neither use of PLEX, nor use of CYC is associated with initiation of dialysis within 6 months in children with AAV.

Table: Treatments associated with initiation of dialysis within 6 months

Variable	Odds ratio	95% Confidence Interval	P-value
Univariate analysis			
Plasma exchange within 7 days*	2.58	1.10, 6.04	0.03
ICU stay within 1st 24 hours^	2.67	1.20, 5.94	0.02
Cyclophosphamide#	1.70	0.85, 3.40	0.14
Multivariate analysis			
Plasma exchange within 7 days*	1.55	0.58, 4.12	0.38
ICU stay within 1st 24 hours^	2.15	0.89, 5.20	0.09

Developing a Role for 18f-Flurodeoxyglucose PET/MRI in Pediatric Takayasu Arteritis

Miriah Gillispie[1], Patricia Rosillo[2], Marietta De Guzman[3], Victor Seghers[4], Prakash Masand[4] and Eyal Muscal[5], [1]Pediatric Rheumatology, Baylor College of Medicine/Texas Children's Hospital, Houston, TX, [2]Allergy, Immunology and Rheumatology, Baylor College of Medicine/Texas Children's Hospital, Houston, TX, [3]Pediatric Immunology, Allergy, and Rheumatology, Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [4]Radiology, Texas Children's Hospital, Houston, TX, [5]Immunology, allergy and Rheumatology, Baylor College of Medicine, Texas Children's Hospital, Houston, TX

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Assessing disease activity is often challenging in pediatric Takayasu Arteritis (TA). TA inflammation may be clinically silent and not always reflected on laboratory or clinical evaluation. The gold standard for vascular assessment, conventional angiography, cannot always be safely performed. Reliance on other modalities such as contrast-enhanced CT and MRI evaluate anatomy, but may not show the full extent of inflammation. PET/CT offers improved assessment of inflammation but at the expense of radiation exposure and poor anatomic resolution. Our facility is the first stand-alone pediatric hospital in North America with PET/MRI, which offers potential for superior functional and anatomic information with lower radiation exposure relative to stand-alone PET/CT with documentation of a 40% lower dose of radiation of whole body PET/MR relative to PET/CT. We describe cases where PET/MRI influenced pediatric TA patient care.

Methods: With IRB approval we reviewed ^{18}F-flurodeoxyglucose (FDG) PET/MRI on two pediatric patients with TA obtained as part of their clinical care. Anatomic whole body MRI sequences as well as FDG PET were acquired as part of the PET/MRI protocol.

Results: Two adolescents obtained PET/MRI during 2015. A 17-year old female had been in clinical remission (off medications) for two years had newly elevated inflammatory markers. Her contrast MRI was interpreted as showing improved disease activity as compared to prior scans. Corresponding FDG-PET indicated ongoing disease activity in the walls of the aortic arch, right innominate artery, and left common carotid artery. Analysis of lab and PET/MRI data led to re-initiation of infliximab, methotrexate, and corticosteroids. A 12-year old female diagnosed at an outside hospital 3 months earlier and on infliximab, methotrexate, and corticosteroids was transferred in acute heart failure. Her inflammatory markers were normal and clinical exam was unchanged from recent rheumatology evaluation. PET/MRI showed involvement of the right common and internal carotid arteries, the aortic root to the suprarenal abdominal aorta, the right pulmonary artery, as well as hypermetabolism within the pericardial fluid. The disease was more extensive than had recently been shown on conventional imaging and led to initiation of tocilizumab.

Conclusion: PET/MRI may delineate the extent of large vessel inflammation and persistence of disease activity in all stages of pediatric TA evaluation. PET vascular metabolic data may be obtained longitudinally with a reduced radiation burden and may allow for timely targeting of ongoing inflammation.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a dire need for pediatric rheumatologists in the US, as 11 states and several large cities are without these specialists. Likewise**,** 40% of pediatric residency programs lack pediatric rheumatology (PR). Thus pediatric residents insufficiently trained in PR may care for children with rheumatic disease. Telecommunication technology has helped close the geographic gap in delivery of health care, along with dissemination of distance learning. To address workforce shortage and bridge the knowledge gap in PR, we created a pilot PR tele-learning program sponsored by Baylor PR fellowship program for the pediatric residency at Texas Tech Univ. Health Sciences Center (TTUHSC) in El Paso, TX.

Methods: TTUHSC has 44 pediatric residents and the freestanding children’s hospital serves a catchment area of

2.5 mil. inhabitants (El Paso–Juárez–Las Cruces). We conducted a needs assessment by completing structured interviews with a focus group of residents and pediatric faculty. Using the needs assessment results, and the American Board of Pediatrics content outline, we designed a six lecture curriculum consisting of high priority PR conditions, presented by a senior PR fellow (B.S.). The first two lectures, including interactive musculoskeletal assessment training were conducted in person. Subsequent lectures were given live via TeamViewer®, a computer-based application that is free to use with with a personal license. TeamViewer® transmits live video and PowerPoint using widely available computer infrastructure. Residents interacted with the presenter by answering case questions and open responses via text messaging with Poll Everywhere®. Residents completed lecture evaluations after each didactic session. Members from the initial focus group provided midway feedback on program success.

Results: TeamViewer® was adequate in transmitting our tele-learning program and it was easy to use. Access to the lecture stream only required recipients to click an e-mail web link which connected the live feed automatically. Its limitation is primarily audio feed which was overcome by use of telephone connection. Mean response rate for evaluations was 74%. There was significant improvement in knowledge of all learning objectives compared to before the curriculum (Table 1). Residents indicated overall satisfaction with the PR tele-learning program (mean likert 4.8). Unintended outcomes included increase frequency of real patient consultations and greater resident interest in PR fellowship.

TABLE 1: Perceived level of knowledge based on lecture objectives (Likert scale 1-5)

Learning Objectives	Before (Mean)	After (Mean)	*p*	*n*
Diagnosis of jSLE	2.7	4	0.002	7
Laboratory testing for jSLE	2.7	4.1	0.002	7
General management of jSLE	2.6	4	0.004	7
When to use pGALS*	1.7	4.7	<0.001	26
How to perform pGALS*	1.6	4.7	<0.001	26
How to document pGALS*	1.6	4.5	<0.001	26
Clinical features of vasculitis	2.9	4.3	<0.001	23

Disease course and refractory KD	2.8	4.4	<0.001	23
Different types of JIA*	2.1	4.3	<0.001	24
Limited role of labs to diagnose JIA*	2.1	4.2	<0.001	24
Complications of JIA*	2.4	4.3	<0.001	24
Primary care role for patients with JIA*	2.1	4.3	<0.001	24
Diagnosis of JDM	2.1	4.4	<0.001	28
Clinical features and complications of JDM	2.3	4.5	<0.001	28
Disease course and prognosis of JDM	2.2	4.4	<0.001	28

*Lecture given in person

Conclusion: The small PR workforce is inadequate to educate future pediatricians in many parts of the country. To help overcome this problem, we created a tele-learning program that is cost effective, satisfying to learners, generalizable to many locations and is scalable. Our tele-learning program is a novel educational intervention that enables PR divisions to reach beyond their locale and to stimualte resident interest in PR.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite a historically robust vaccination program, hepatitis B infection remains a significant public health challenge, and particularly for patients on chronic immunosuppressive therapy. There is a considerable risk of hepatitis B reactivation while on these medications with reports of up to 25% mortality. A complete serologic screen should include hepatitis B surface antibodies (anti-HBsAb) to assess for immunity, in addition to hepatitis B core antibodies (anti-HBcAb) and hepatitis B surface antigen (HBsAg) to evaluate for acute or chronic infection. Our aim was to collect and examine hepatitis B serology screenings on patients receiving intravenous biologic medications within rheumatology and gastroenterology (GI) at Cincinnati Children's Hospital Medical Center (CCHMC).

Methods: We identified all rheumatology and GI patients receiving intravenous biologic medications between October 2015 and June 2016 and determined if a complete hepatitis B serology screening had previously been obtained. For patients without previous serology or with results older than 1 year, we ordered a complete panel at the time of a scheduled infusion.

Results: During the study period, we screened a total of 307 patients (109 rheumatology, 198 GI) with an age range from 2 to 27 years (mean 15.5, SD 4.3). A majority of patients (83%) were on infliximab, including all GI patients. In addition to infliximab, rheumatology patients were also on tocilizumab (12%), abatacept (3%), belimumab (1%), rituximab (1%), and golimumab (<1%). Of the total patients tested, 62% had either a negative or indeterminate result for anti-HBsAb, representing non-immune status. The most vulnerable age range for non-immune status (anti-HBsAb negative) was 11-20 years of age (see Figure 1). Interestingly, this trend was more pronounced in rheumatology patients on infliximab versus GI patients on infliximab. Surprisingly, there was 1 rheumatology patient on infliximab who had a positive anti-HBcAb, indicating chronic infection that presumably occurred via transplacental transmission. However, no patients had a positive HBsAg, or evidence of active infection.

Conclusion: Results from this study support the need for routine hepatitis B screening in immunocompromised patients. We determined that a majority of our patients on intravenous biologic medications were seronegative for hepatitis B and will require repeat vaccination. We also identified 1 patient with evidence of chronic infection who is now being closely monitored by hepatology. Our next steps include expanding hepatitis B screening to all patients identified as immunocompromised in rheumatology clinic; further investigating differences between

rheumatology and GI immunity; and collecting post-vaccination serology data on patients who require repeat vaccination.

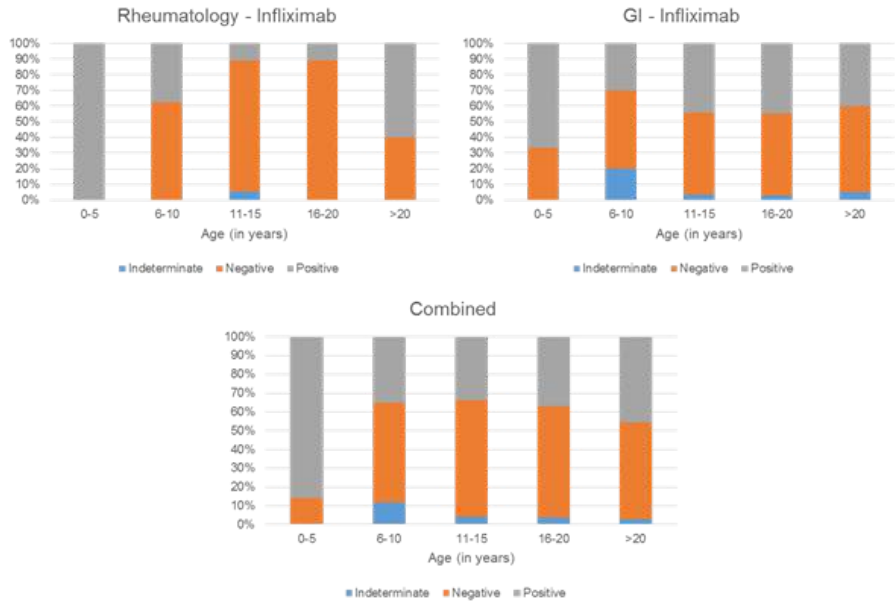

Figure 1. Hepatitis B surface antibody results by age.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Few factors have been consistently linked to antibiotic-refractory Lyme arthritis (ARLA) other than premature intra-articular glucocorticoid injections. We sought to identify clinical and treatment factors associated with ARLA in children.

Methods: We identified children age 18 years and younger with a diagnosis of Lyme disease seen in pediatric rheumatology clinics across three hospital systems who met clinical and Western blot laboratory criteria for Lyme arthritis. ARLA was defined as having persistent, documented arthritis at least 2 months after adequate antibiotic treatment (≥56 days of oral or ≥14 days of parenteral antibiotics) per IDSA/Red Book guidelines. We compared prespecified demographic, disease, and early treatment characteristics of primary interest between children with ARLA and children whose arthritis resolved within 3 months using descriptive statistics and multivariable logistic regression.

Results: There were 46 children with ARLA and 119 children whose arthritis resolved within 3 months. Multiple clinical factors were independently associated with ARLA in univariable analysis (Table 1). These factors included older age; presentation with unilateral knee synovitis or continuous synovitis ≥6 weeks; and marked clinical worsening (e.g., joint capsule rupture, joint recruitment) after antibiotic initiation. Presentations with severe joint pain or with non-knee joints were associated with rapid resolution. There were few instances of premature glucocorticoid joint injections, limiting statistical power to detect a difference between groups. In multivariable analysis, ARLA was associated with age ≥10, clinical presentations with prolonged arthritis, knee-only synovitis, lack of severe features (fever, severe pain, high inflammatory markers), and worsening arthritis while on treatment (Table 2). Results were consistent after adjustment for clinical center and when using an alternate definition of persistent arthritis ≥6 months after antibiotic initiation. In exploratory analyses of variables that were not of primary interest, antibiotic regimens below the recommended dose were associated with ARLA ($P = 0.03$), but low-frequency regimens (e.g., twice daily amoxicillin) were not ($P = 0.48$).

Conclusion: Pediatric antibiotic-refractory Lyme arthritis is associated with multiple clinical factors, including older age, prolonged knee synovitis at diagnosis, and clinical worsening on antibiotics. In contrast, younger children presenting with non-knee synovitis, severe pain, and a robust inflammatory response often respond quickly to antibiotics.

Table 1. Clinical and treatment characteristics of primary interest			
Characteristic	**Arthritis resolved within 3 months of antibiotic initiation (N = 114)**	**Antibiotic-refractory Lyme arthritis (N = 46)**	**P-value**
Demographics			
Age in years, median (IQR)	9.6 (7.0, 11.9)	12.0 (9.1, 14.7)	<0.01
Male sex, N (%)	82 (69)	28 (61)	0.33
Clinical presentation			
Duration of current joint symptoms in days, median (IQR)	5 (2, 14)	22 (7, 60)	<0.01
Prior self-resolving episodes of joint pain/swelling, N (%)	41 (34)	11 (24)	0.19
Acute migratory arthritis, N (%)	4 (3)	0	0.21
≥6 weeks of continuous joint symptoms, N (%)	3 (3)	9 (20)	<0.01
Fever within 2 weeks of diagnosis not from another cause, N (%)	38 (30)	8 (22)	0.34
Severe pain preventing mobility or requiring hospitalization, N (%)	28 (24)	0	<0.01
More than 1 joint involved,[1] N (%)	29 (24)	2 (4)	<0.01
Non-knee joint involved, N (%)	23 (19)	1 (2)	<0.01
Laboratory values			
Number of Western blot IgG bands (N), median (IQR)	10 (8, 10)	9 (9, 10)	0.21
Maximum erythrocyte sedimentation rate (mm/hr), median (IQR)	35 (19, 49)	17 (8, 34)	<0.01
Treatment and clinical course			
Glucocorticoid joint injection before first antibiotic course, N (%)	2 (2)	2 (4)	0.32
Marked worsening within 6 weeks of antibiotic initiation,[2] N (%)	6 (5)	10 (22)	<0.01
Characteristics of			

spondyloarthritis within 6 weeks of antibiotic initiation,[3] N (%)	2 (2)	1 (2)	0.83
Exam or imaging with chronic changes within 6 weeks of antibiotic initiation,[4] N (%)	18 (15)	4 (9)	0.28

IQR, interquartile range. [1]Two knees would count as two joints [2]New massive effusion, joint capsule rupture, or joint recruitment [3]Personal history of psoriasis, inflammatory bowel disease, acute anterior uveitis, or inflammatory back pain; presence of enthesitis, tendonitis, or dactylitis on exam [4] Flexion contracture, muscle atrophy, condylar hypertrophy, erosions on imaging

Table 2. Multivariable model of clinical factors associated with antibiotic-refractory Lyme arthritis or prolonged arthritis

	Antibiotic-refractory Lyme arthritis		**Arthritis lasting at least 6 months**	
Characteristic	**Adjusted odds ratio (95% CI)**	**P-value**	**Adjusted odds ratio (95% CI)**	**P-value**
Age ≥10 years	2.7 (1.1, 6.5)	0.03	2.2 (1.01, 4.9)	0.05
Continuous joint symptoms for ≥6 weeks at presentation	19.0 (3.6, 99.4)	<0.01	10.2 (2.3, 45.1)	<0.01
Presenting in knee(s) only	10.1 (1.9, 54.0)	<0.01	4.3 (1.3, 14.9)	0.02
Severity features present[1]	0.3 (0.1, 0.8)	0.02	0.5 (0.2, 1.1)	0.07
Worsening within 6 weeks of antibiotic initiation[2]	5.3 (1.5, 19.2)	0.01	3.5 (1.03, 12.1)	0.04

CI, confidence interval. [1]Recent, otherwise unexplained fever, severe pain limiting mobility, hospitalization for pain, or erythrocyte sedimentation rate ≥40 mm/hour [2] New massive effusion, joint capsule rupture, or joint recruitment within 6 weeks of antibiotic initiation

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Many patients with myelodysplastic syndromes with somatic trisomy 8 in the bone marrow and Behcet's-like ulcerations have been described. A handful of patients with constitutional trisomy 8 mosaicism with Behcet's-like disease have been reported but the spectrum of phenotypes has not been characterized in detail.

Methods: Patients with trisomy 8 mosaicism and chromosome 8 duplications who contacted the NIH Autoinflammatory Clinic were interviewed by phone regarding symptoms of recurrent fever, mucosal lesions, and rashes.

Results: A total of 52 patients were interviewed of whom 19 (37%) had trisomy 8 mosaicism and 33 (63%) had chromosome 8 duplications. The average age of patients was 13 years (range 13 months to 40 years). Thirty-eight percent reported a history of 4 or more fever episodes in one year. The average age of episode onset was 23 months; episodes on average lasted 3.7 days with 6 week intervals. During episodes, 65% reported pharyngitis or sore throat, 45% oral ulcers, 45% rash, 35% cervical lymphadenopathy, 35% headache, and 35% abdominal pain. Twenty-five (48%) reported a history of mucosal ulcers of which 84% were oral, 20% were esophageal, 8% were gastric, 8% were colonic, and 20% were genital. Eleven patients (21%) reported having large (>1cm), painful, oral ulcers that took over a week to resolve. Eleven patients (21%) reported recurrent, painful papular or ulcerative rashes. Two patients reported rapid resolution of fever flares with 1 dose of corticosteroid, while two others required longer steroid courses. One patient had episode remission while on colchicine while another had transient improvement on colchicine. Two patients underwent tonsillectomy with no effect. One patient with severe ulcers underwent bone marrow transplant with significant improvement in ulcerative disease.

Conclusion: Patients with trisomy 8 mosaicism and chromosome 8 duplications have a propensity for systemic inflammatory disease that is similar to Behcet's disease in some patients and similar to periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) syndrome in others. This could be due to duplication and subsequent overexpression of particular genes on chromosome 8 that regulate inflammatory responses. We are currently genotyping affected patients using high-density SNP arrays to identify a possible minimal duplicated region in common to these patients. We are collecting blood samples and biopsies from ulcers and rashes from these patients for future studies.

Predictive Value of the History and Labs in Distinguishing Inflammatory from Non-Inflammatory and Mechanical Joint Pain

Background/Purpose: Joint pain is one of the most common reasons for referral to pediatric rheumatology clinics throughout the world. Typically, these patients ultimately fall into one of 3 categories of diagnosis: (1) inflammatory, (2) non-inflammatory, or (3) mechanical, each requiring different management. Our objective was to determine what factors on clinical history best predict the final etiology of the joint pain in the 3 categories.

Methods: New patients between the ages of 2 and 22 seen by the pediatric rheumatology clinic at Hackensack University Medical Center between 1/1/2013 and 12/31/2014 with joint pain were included in our retrospective chart review. Data were collected regarding demographics, symptom history, and physician assessment. Final diagnosis was categorized as one of the 3 stated categories. Univariate statistics were performed for all covariates in the sample. Significant differences were tested using a Fisher's Exact test. A multivariate multinomial regression model was estimated to assess whether the characteristics associated with Mechanical or Non-inflammatory joint pain were significantly different than Inflammatory joint pain. A multinomial logistic regression was performed

as there was not an inherent ordering of severity of the groups of joint pain.

Results: 288 charts were included in the analysis. 31.6% were inflammatory, 25.35% non-inflammatory, and 28.47% mechanical (table 1). 42 patients, or 14.58% of the patients did not have a clear final diagnosis, with either resolution of their symptoms or failure to follow up. These patients were not included in the multivariate multinomial regression analysis. An abnormal CRP, presence of swelling, a lower pain score and the absence of a history of anxiety or depression increased the odds of inflammatory joint pain as compared to non-inflammatory. Compared to patients who have symptoms present for <6 weeks, patients who have symptoms for 3-12 months are 6.89 times more likely to have mechanical pain (OR= 6.893, p=0.0370) and 8.85 times more likely to have non-inflammatory pain than to have inflammatory pain (OR=8.854, p=0.0772) (table 2).

Conclusion: Our results indicate that while patients with non-inflammatory pain have higher pain scores, a longer duration of pain and perhaps more subjective pain, the objective data (swelling and increased CRP) are more consistent with inflammatory joint pain. This information is especially useful for the general pediatrician when triaging patients with joint pain and deciding upon referrals. Educating pediatricians could result in better management and therefore improved outcomes.

Table 1. Breakdown of diagnosis by category

Inflammatory		Non-Inflammatory	Mechanical
Dactylitis JDM	Rheumatic	Fibromyalgia	Chondrolysis
HSP JIA/RA	fever Serum	RSD Growing	Costochondritis
Lyme arthritis	sickness SLE	pains	Hypermobility
Reactive	Systemic		Overuse syndrome
arthritis PSRA	sclerosis		Patellofemoral
	UCTD		Pain Tendonitis
	Vasculitis KD		TMJ syndrome
			Trauma

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sleep disorders and fatigue are common in children with chronic pain syndromes, and contributes to psychosocial dysfunction, healthcare utilization, and school absences. We hypothesize that pediatric patients with chronic pain who are treated in an interdisciplinary pain rehabilitation program (IPRP) will have significant self-report of fatigue and sleep disturbance at baseline that will be corroborated by physiological evidence using actigraphy. We postulate that self-report measures and sleep physiology will improve after program completion.

Methods: This is a prospective longitudinal study of adolescents with chronic pain who completed an IPRP. This outpatient program provides daily intensive physical and occupational therapy, sleep education, self-regulation training, and behavioral health intervention. All pain and sleep medications are discontinued prior to program entry. 20 patients (16 female) age 12-18 with chronic musculoskeletal pain were evaluated at baseline, weekly during treatment, and again at 1-month after program completion by self-report PROMIS measures of fatigue and sleep disturbance (including items assessing sleep satisfaction and insomnia), and by actigraphy using Motionlogger watches. Paired samples *t*-tests were conducted with SPSS (V.23) and supplemented with hierarchical linear modeling (HLM7) for time-series analyses.

Results: Participants report difficulty falling asleep at baseline with insomnia score of 3.15 on a scale of 1 to 5. They are unsatisfied with sleep, with a score of 2.80. Both insomnia and sleep satisfaction significantly improve by program end ($P<0.001$), with continued improvement to 1.29 and 4.39 ($P<0.001$), respectively at 1-month follow-up. At baseline, patients report high daytime fatigue 24.30 on a scale of 0 to 40 and sleep disturbance 31.65 on a scale of 8 to 40. Both of these measures improved significantly, with fatigue changing from significantly impaired to normal (8.43, $P<0.001$) at 1-month follow-up. Actigraphy showed improvement in total minutes asleep after the first week ($P=.02$) and this was maintained at program end ($P=.03$), but not in the weeks after the program ($P=.21$). Sleep efficiency, sleep latency, and duration of first sleep episode did not show significant change during the program.

Conclusion: Children with chronic musculoskeletal pain report severe sleep impairments prior to starting an intensive pain rehabilitation program. Following the program they report significant improvements with insomnia, sleep satisfaction, daytime fatigue, and sleep disturbance. Despite

statistically significant change in all patient-reported outcomes, these findings are not mirrored by objective data using actigraphy. Long-term follow-up and a larger sample size is needed to determine whether these outcomes will eventually more closely match patient report, or whether subjective issues are the most important improvement.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic

JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The clinical course of type one diabetes (T1D) is frequently complicated by musculoskeletal manifestations such as Dupuytren's disease, trigger finger, shoulder adhesive capsulitis and in general tendinopathies (1). In a recent review Abate et Al. underline that an accepted hypothesis identified in the excess of advanced glycation end products (AGEs) the cause of tendon damages in T1D. There are several demonstrations that AGEs are able to form a covalent cross-link within collagen fibres causing a distortion of collagen layers that altered tendons structure and functionality (2). Previous ultrasonographic evaluations of diabetic patients tendons reported the presence of intratendinous areas with dishomogeneous ecostructure and an increase of normal tendon thickness. Up to now, at the best of our knowledge, no data about the ultrasonographic evaluation of T1DM patients enthesis has been published.

Methods: Twenty-three children and adolescents (12 M 11 F) affected by T1D, mean ages 13.9 years (range 9-18 yrs), mean disease duration 60 months (range 10-161 months), without any clinical sign or symptom of musculoskeletal involvement. A control group of 28 sex (12 M 16 F) and age-matched (14.2 years, range 8-18 yrs) was also evaluated. Both groups underwent an ultrasound examination with ESAOTE MyLAB 70 (Genova, Italy) equipped with 6-18 MHz linear array transducer. Brachial triceps, femoral quadriceps, Achilles, plantar fascia, and proximal and distal patellar entheses were all scored according with the 0-136 Madrid Sonographic Enthesis Index (MASEI).

Results: The percentage of enthesis with ultrasonographic revealed thickness (22.6% Vs 16.1% p= 0.04) and with dishomogeneous ecostructure (2.9% Vs 0% p=0.001) was statistically higher in T1D group. No difference has been observed in terms of percentage of bursitis presence (3.4% Vs 2.7% p= 0.76), percentage of enthesis with power Doppler score ≥2 (2.5% Vs 1.2% p= 0.21), erosions (0.4% Vs 0.3% p= 0.89) or calcification (4.7% Vs 3.3% p= 0.76). Hyperechoic spots can be observed at the level of the distal part of tendons in a percentage of T1D patients statistically higher than in controls (43.5% Vs 8.7%; p=0.0046).

Conclusion: In our study we observed that, even at the enthesis level, T1D patients present an higher percentage of thickness and dishomogeneity in echostructure when compared with an healthy control group. More investigations about the hyperechoic spots detected at the level of the distal parts of the tendons are needed. **References:** 1.Tom A Ranger et Al. Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Extra intestinal manifestations occur in 40-50% of patients with inflammatory bowel disease (IBD), with musculoskeletal involvement in 25%. Data regarding musculoskeletal manifestations in the pediatric population are scarce. The purpose of this study was to compare pediatric IBD patients initially presenting with arthritis, to patients presenting with arthritis of other etiologies, in order to identify clinical and laboratory red flags that may arouse suspicion of IBD.

Methods: This retrospective cohort study included patients followed up at "Schneider Children's Medical Center of Israel" between 1985-2016. We identified 23 children with IBD who presented with arthritis and matched them to a control group of 46 children. The latter included 21 patients with Juvenile Idiopathic Arthritis, 7 patients with Familial Mediterranean Fever and 18 patients with postinfectious arthritis. Clinical and laboratory data were collected and compared between the two groups. Fisher's exact test, χ^2 and analysis of variance were used for statistical processing.

Results: The most statistically significant clinical factor at presentation which predicted IBD was sacroiliitis (30.4% in IBD group vs. 2.2% in control group, P<0.001), and was more common in females (46.15% vs. 20% respectively). Additive arthritis was exclusive to the IBD group (21.7%). Twenty five percent of the IBD group reported a positive family history for IBD (mostly Crohn's Disease).The IBD group showed decreased hemoglobin and MCV levels as well as elevated RDW as compared to control (10.5, 69.1, 14.9 vs 12.0, 79.1, 13.2 respectively, P<0.001). Albumin mean

values were lower in the IBD group compared to control (3.5 vs. 4.3 respectively, P<0.001). Upon direct questioning of the IBD group at presentation, the following abdominal symptoms were reported: diarrhea (43.5%), abdominal pain (39.1%), weight loss (34.8%), fever (21.7%), aphthous ulcers (17.4%), bloody stools (13%) and vomiting (8.7%). Despite these signs and symptoms 8.7% of children were diagnosed with IBD at presentation, whilst 26% were diagnosed at a delay of >1 year. The overall mean time from arthritis presentation to IBD diagnosis was 1.17±1.89 years. Three patients (13.04%) from the IBD group developed residual joint damage.

Conclusion: Arthritis, specifically sacroiliitis, associated with microcytic anemia and/or hypoalbuminemia in children without specific signs of IBD should be considered red flags, and arouse suspicion for this disease, thus mandating thorough enquiry.

Mental Health Care for Adolescents with Rheumatologic Conditions: Perspectives from Pediatric Behavioral Health Providers in North America

Andrea Knight[1], Michelle Vickery[1], Natalie Stollon[1], Eyal Muscal[2], Alaina Davis[3], Julia Harris[4], Aimee Hersh[5], Martha Rodriguez[6], Karen Onel[6], Laura E. Schanberg[7], Tamar Rubinstein[8], Beth S. Gottlieb[9], Nina Washington[10], Elissa Weitzman[11], Emily von Scheven[12] and for the CARRA Investigators [1]Children's Hospital of Philadelphia, [2]Baylor College of Medicine, Texas Children's Hospital, [3]Vanderbilt University School of Medicine, Monroe Carell Junior Children's Hospital, [4]University of Missouri-Kansas City, ChildrenÕs Mercy Hospital, [5]University of Utah, [6]University of Chicago, [7]Duke University Medical Center, [8]Albert Einstein College of Medicine, Children's Hospital at Montefiore, [9]The Steven and Alexandra Cohen Children's Medical Center of New York, The Hofstra North Shore-LIJ School of Medicine, [10]University of Mississippi Medical Center, [11]Harvard University, Boston ChildrenÕs Hospital, [12]University of California San Francisco

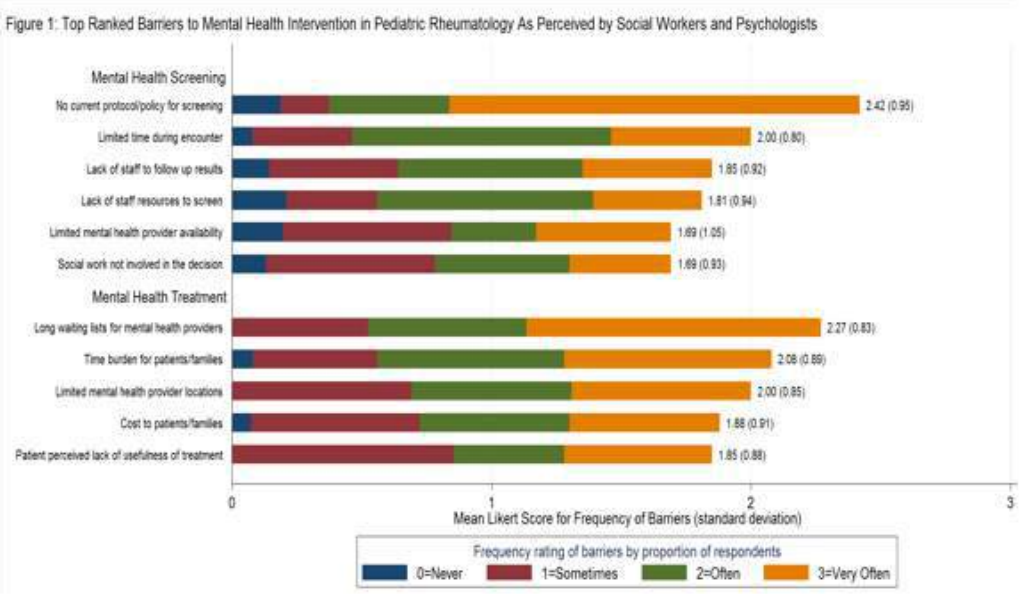
Background/Purpose: Mental health problems are common, but under-treated in adolescents with rheumatologic conditions. To identify gaps in mental health care, we examined perspectives from behavioral health providers working with adolescents in pediatric rheumatology clinics.

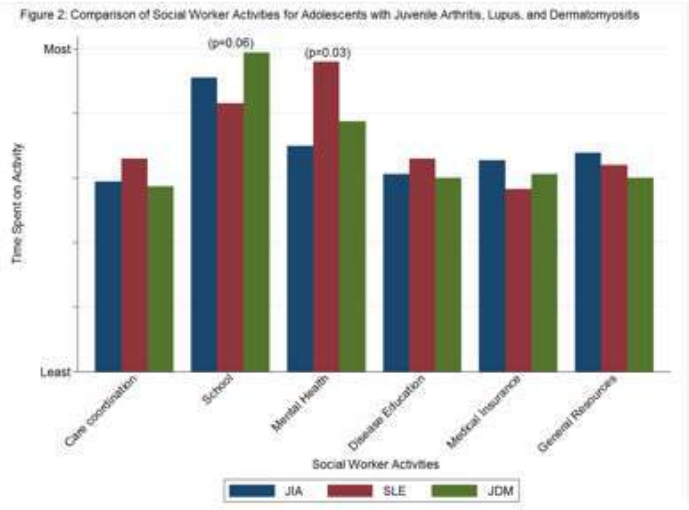
Methods: We surveyed social workers and psychologists at centers in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) with recent clinical experience (past 5 years) in pediatric rheumatology. The online survey assessed participant demographics, practices and beliefs for mental health care of adolescents with lupus (SLE), juvenile idiopathic arthritis (JIA), or juvenile dermatomyositis (JDM). Participants rated the frequency of 15 barriers to mental health screening and 18 barriers to treatment on a 4-point Likert scale. Social workers ranked their activities by current and desired amount of time spent (most to least) on: care coordination, school, mental health, disease education, general resources, and medical insurance. Case examples elicited comparative rankings of these activities for 3 exemplary adolescents with SLE, JIA or JDM; 2-way ANOVA was used to test for differences.

Results: Only 45% of CARRA centers had an eligible social worker or psychologist. Of 60 providers contacted, 31 (52%) responded. After exclusions (3 incomplete and 2 non-clinical), 26 responses from 21 social workers and 5 psychologists at mostly US university-based (88%) and urban (77%) centers were analyzed. All reported that screening for depression and anxiety should be routine for adolescents with JIA/SLE/JDM, but none reported it as current practice. Of 11 (42%)

reporting screening of selected patients, only 3 used a validated screening tool. Eleven (42%) reported that their practice lacked a follow-up plan after mental health referral. Figure 1 shows the most frequent barriers to mental health care. Social workers spent most of their time addressing mental health for adolescents with SLE (p=0.03), in contrast to school issues for those with JIA and JDM (p=0.06) (Figure 2). Overall, 8 (38%) social workers desired more time for mental health, and 6 (23%) for disease education, and 20 (76%) had high interest in providing mental health interventions.

Conclusion: Many pediatric rheumatology centers lack behavioral health providers despite known mental health burden in their patients. Implementation of policies for routine screening and follow-up on referrals, as well as utilization of social workers to provide mental health intervention may improve mental health care for adolescents with rheumatologic conditions.





Shown are rankings of social worker time spent on six activities compared between disease groups (JIA=juvenile idiopathic arthritis; SLE=systemic lupus erythematosus; JDM=juvenile dermatomyositis. Rankings are based on mean score (0=least time to 5=most time) and 2-way ANOVA was used to test for differences among these disease groups.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster III: Systemic JIA, Autoinflammatory Syndromes, Scleroderma, Vasculitis, Miscellaneous

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Acute Rheumatic Fever (ARF) and Post-streptococcal reactive arthritis (PSRA) are well known as post-streptococcal syndromes with arthritis in children. ARF have been declining in developed nations like Japan and it is generally thought to be a disease of the past. Despite decreasing incidence, focal outbreaks have been reported in developed nations. Despite its importance, ARF and PSRA epidemiology has not been reviewed recently. The aims of this study were to assess ARF and PSRA incidence between 2010 and 2015 in Japan.

Methods: This descriptive epidemiological study examined ARF and PSRA incidence in 2010-2015, using hospitalisation data included in a total of 528 hospitals.

Results: From a total of 323 hospitals (61% response rate), 44 cases of ARF and 21 cases of PSRA were reported. The mean age of ARF was 8.5 years (3-15 years), and female/male ratio was 16/28. Manifestations including; carditis, 27 (61.3%); arthritis, 36 (81.8%); Erythema marginatum in 7 (16%); Sydenham chorea, 3 (6.8%); Subcutaneous nodules, 1 (2.3%), respectively. And minor criteria were; fever, 39 (88.6%); first degree heart block, 9 (20.5%); elevated inflammatory markers (ESR, CRP), 43 (97.7%). ARF patients were treated with antimicrobial agent therapy.42 (95.5%); NSAIDs 29 (65.9%); and glucocorticoids therapy 24 (54.5%). During the follow up, four patients showed mild carditis and the other were improved. All ARF patients were prescribed with antimicrobial agent prophylaxis. On the other hand, the mean age of PSRA was 8.2 years (2-15 years), and female/male ratio was 12/9. Six (28.6%) patients had monoarthritis. And fever in 14

(66.7%) and Elevated inflammatory markers in 19 (90.5%). PSRA patients were treated with antimicrobial agent therapy.17 (81%); NSAIDs 16 (76.2%); and glucocorticoids therapy 1 (4.8%). During the follow up, there was no patient with carditis. Eleven (52.4%) patients with PSRA were prescribed with antimicrobial agent prophylaxis.

Conclusion: In this study, ARF is rare in the Japanese pediatric population, but ARF has not yet disappeared. We observed high incidence of arthritis, carditis and erythema marginatum. General pediatrician need to have updated information about ARF and PSRA even in industrialized countries.

Table

Acute Rheumatic Fever (ARF) and Post-streptococcal reactive arthritis (PSRA) cases

From January 1st, 2010 to December 31th, 2015

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Myeloid differentiation primary response 88 (MyD88) is a critical adaptor protein that connects Toll-like and IL-1 receptor signaling to activation of NF-κB. Germline loss-of-function mutations in MyD88 cause immunodeficiency, while somatic gain-of-function mutations have been linked to lymphoma. We investigated a child with a progressively destructive small-to-medium joint polyarticular JIA since the age of 2 with persistent neutrophil predominant synovial infiltrates.

Methods: We evaluated the patient and family members by whole exome sequencing (WES), peripheral blood immunophenotyping, and phosphorylated-STAT3 (p-STAT3) quantitation. Functional studies in monocytes and dermal fibroblasts included gene/protein expression, quantitation of neutrophil chemotaxis, and siRNA-mediated knockdown of MyD88 and NF-κ□B subunit p65 (p65). Wild type or S222R MyD88-GFP fusion proteins were re-expressed in MyD88-deficient THP-1 cells. NF-κ□B activity in THP-1 cells was measured via secreted embryonic alkaline phosphatase reporter assay.

Results: WES revealed a *de novo* heterozygous missense mutation in *MYD88*(c.666T>G, p.Ser222Arg), which was confirmed by Sanger sequencing in both peripheral leukocytes and dermal fibroblasts. Immunophenotyping showed an absence of CD16+ monocytes, an expansion of CD4+ Th17 T cells, and the presence of a previously uncharacterized CD123+CD11c+ dendritic cell population, as well as markedly increased basal and stimulated p-STAT3 in monocytes and T and B lymphocytes in the patient. Peripheral monocytes exhibited a baseline interferon gene expression signature and increased expression of neutrophil and monocyte chemokines. Fibroblasts exhibited significantly greater baseline expression of CXCL chemokines compared to controls, which abated upon MyD88 or p65 knockdown. Re-expression of wild type or S222R MyD88-GFP fusion protein in MyD88-knockout THP-1 cells demonstrated increased NF-κB activation at baseline and with stimulation in S222R-MyD88-expressing cells.

Conclusion: This is the first description of a *de novo* germline MyD88 mutation associated with severe polyarticular JIA. The gain-of-function effects demonstrated in the patient's hematopoietic and non-hematopoietic cells offer a plausible mechanism for arthritis and support a role for single gene defects contributing to extreme JIA phenotypes.

Genetic Insights into Juvenile Idiopathic Arthritis Derived from Deep Whole Genome Sequencing

James Jarvis[1], Lai Ping Wong[2] and Kaiyu Jiang[2], [1]Pediatrics, SUNY Buffalo School of Medicine, Buffalo, NY, [2]Pediatrics, University at Buffalo, Buffalo, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Deep whole genome sequencing (WGS) provides an unprecedented opportunity to comprehensively study genetic landscapes at finer resolution than can be achieved with chip-based methods. We studied juvenile idiopathic arthritis (JIA), a complex trait that represents one of the most common chronic disease conditions in children. While previous candidate gene approaches and genome-wide association studies (Hersh et al J Autoimmunity 2015) and genetic fine-mapping studies (Hinks et al Nature Genet 2013) have revealed some useful information about genetic risk in JIA, a finer mapping is needed to decipher genetic landscapes of children with this disease to gain insights into pathogenesis and treatment responses.

Methods: We conducted deep WGS on 48 children with JIA over 2 independent cohorts, comparing results with publically available WGS data from healthy individuals. Each cohort contained a replicate to ascertain the fidelity of the sequencing reactions, the first cohort (n= 29) was homogeneous, consisting of non-Hispanic Caucasian children. The second cohort (n=19) was a more heterogeneous group including Hispanic and Caucasian-Native American ancestry children.

Results: We achieved an average of 38.7X sequencing depth per sample, and 41 Giga passed quality control measures. Paired-end reads gave an average per sample mapping rate of 97.9%. We found 1,205,197 novel SNPs and 283,554 novel indels in JIA patients that are not reported in dbSNP141 public repository. We also identified 1,902 novel structural variants (SV) not present in Database of Genomic Variants. By tabulating SNP density in 1Mb windows across the entire genome, we identified 24 SNP hotspots when compared with the 1000 Genome Projects (1KGP). It is of interest to note that some of the genes located within 5kb upstream or downstream 5kb to those SNP hotspots show statistically significant enrichment in immunological processes (including T cell receptor signaling pathways and innate immune responses). Further analyses indicated that JIA SNPs have significantly more regulatory potential (e.g. transcription factor binding motifs, DNase1 hypersensitivity sites, eQTL) compared to 1KGP SNPs. It is also important to note that the JIA specific genetic variation (indels and SNPs) showed ~72% concordance between the 2 cohorts despite the ethnic heterogeneity between the 2 cohorts.

Conclusion: These studies demonstrate the utility of WGS, even on relatively small sample numbers, for elucidating underlying genetics of JIA and its response to therapy. For example, segregation of variants from WGS of JIA individuals in array-based SNP LD blocks overcomes the limitations of depth and coverage of arrays in identifying JIA risk variants. Distribution of JIA novel variants in regulatory elements serves as valuable resource from which to develop insights into epigenetic alterations underlying the effects of genetic variants.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: JIA is a heterogeneous group of conditions that are unified by the presence of chronic childhood arthritis without an identifiable cause. Systemic JIA (sJIA) is a rare form of JIA that is characterized by episodic systemic inflammation and chronic arthritis. Approximately half of children with sJIA go on to develop destructive, life-long arthritis that has phenotypic similarities with the oligoarticular / RF negative polyarticular (polygo) or RF positive polyarticular (RF+poly) forms of JIA. Therapies effective in treating other forms of JIA are much less effective in sJIA, particularly among patients with persistent arthritis. Investigating the genetic architecture of sJIA and comparing it with other forms of JIA may improve our understanding of these differences. However because of its rare nature, genomic studies of sJIA have been limited, providing few insights into its pathophysiology. Therefore we sought to identify genetic factors that influence sJIA pathogenesis and to compare the genetic architecture of sJIA with the other common forms of JIA.

Methods: We performed a genome-wide association study of 982 children with sJIA from 9 countries. Following stringent quality control procedures, over 6 million single nucleotide polymorphisms (SNPs) were tested for association with sJIA by logistic regression in 9 geographically-defined strata and association results were meta-analyzed. Weighted genetic risk scores (wGRS) based on established genetic risk factors for polygo or RF+poly JIA were calculated and wGRS were compared between sJIA cases and healthy controls using the Wilcoxon Rank Sum test. The correlation of wGRS with sJIA was tested by both logistic regression and by analysis of receiver operating characteristic (ROC) curves with calculation of the area under the curve. Quantile-quantile (QQ) plots were used to determine whether sJIA-associated SNPs were enriched within the set of polygo-associated SNPs from the Immunochip study by Hinks and colleagues.

Results: The HLA locus and a second locus on chromosome 1 both showed association with sJIA that exceeded the threshold for genome-wide significance ($p<5E-8$), and 23 additional loci had evidence suggestive of association with sJIA ($p<5E-6$). There was virtually no overlap between the sJIA susceptibility loci and the known risk loci for other forms of JIA. ROC curve analysis and

logistic regression of wGRS found no correlation between sJIA and either polygo or RF+poly JIA. QQ plots showed no evidence for enrichment of sJIA associations among polygo-associated SNPs. Collectively, we found no evidence of shared genetic architecture between sJIA and either polygo or RF+poly JIA.

Conclusion: sJIA has a distinct genetic architecture without evidence of shared genetic risk factors with other common JIA subtypes. This indicates that sJIA is unique in its pathophysiology, relative to the other JIA subtypes. As such, sJIA must be investigated separately from the other JIA subtypes to identify mechanisms and therapeutic targets specific to sJIA. Moreover, the management of children with sJIA should be directed by studies of sJIA, and not by trials or observations of other subtypes of JIA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Genome wide association studies (GWASs) and dense genotyping of immune-related disease regions have identified 17 loci associated with juvenile idiopathic arthritis (JIA) ($p<5\times10^{-8}$), 11 further loci with suggestive evidence for association ($p<1\times10^{-6}$), and 2 additional independent loci remaining after stepwise regression in the STAT1/STAT4 region. Given that the majority of these genome-wide associations are located in non-coding regions of the genome, we investigated if specific TFs might bind DNA at multiple JIA-associated genetic loci.

Methods: We defined a locus as those variants that had disequilibrium at $r^2>0.8$ with the most significant genotyped marker at the locus. We assembled a large collection of publically available datasets, including 1,613 chromatin immunoprecipitation with next generation sequencing (ChIP-Seq) datasets, and "Active Chromatin" maps generated from combinations of histone marks in 126 different cell and tissue types. We developed a simulation test to assess the statistical significance of the number of JIA loci that intersect with each ChIP-seq dataset. To generate a null distribution, 2,000 simulations were performed in which each JIA locus was randomly assigned to a genomic location, maintaining linkage disequilibrium and allele frequency structure, and the intersect with each dataset was calculated. Bonferroni corrected P-values (p_c) were estimated for each ChIP-seq dataset evaluated. We confined our attention to TF data sets that bound DNA in ≥3 JIA genetic loci and that had $p_c<0.01$. The Toppgene web portal was used to characterize functional annotations and protein interactions between TFs.

Results: Our procedure implicates several immune cell types in JIA pathogenesis, including multiple CD4+ cells (Th cells, Th17 cells, Tregs, and memory T cells), CD56+ NKT cells, and CD8+ T cells. 95 of the 1,613 ChIP-seq datasets had $p_c<0.01$. The top result involves STAT4 binding in IL-12 stimulated CD4+ Th1 cells ($p_c<10^{-12}$, 24-fold enrichment). Two Vitamin D receptor (VDR) ChIP-seq datasets are also highly significant (both $p_c<10^{-9}$), together comprising 7 of the 30 JIA loci. The 95 significant datasets collectively constitute 47 TFs (also including IRF3, STAT1, and RELA), which are significantly enriched for involvement in pathways that involve cytokine binding and activity ($p_c<10^{-4}$).

Conclusion: These data are consistent with common transcriptional control mechanisms operating across multiple JIA risk loci in a shared intracellular environment. Notably, most GWAS loci have small odds ratios (usually <1.2). If there are coordinated mechanisms across loci that alter disease risk with larger effect sizes, then shared gene regulatory mechanisms such as these are important in

generating disease risk.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Title: Human gut microbial species correlate with arthritis in the K/BxN mouse model

Background/Purpose: Studies have identified abnormalities in the microbiota of patients with arthritis. To evaluate the pathogenicity of human microbiota, we performed fecal microbial transplantation (FMT) from children with newly diagnosed enthesitis-related arthritis (ERA) and sex- and age-matched controls to germ-free KRN/B6xNOD (K/BxN) mice, a spontaneous arthritis model dependent upon an intact microbiota.

Methods: K/BxN mice were maintained under germ-free (GF) conditions and were gavaged with feces previously collected from children with ERA and healthy controls at 6 – 10 weeks of age, and maintained in isolators for 21 – 24 days following FMT. Additional controls included non-gavaged GF mice and mice transferred from the gnotobiotic to the conventional facility. Sequencing of the

fecal microbiota was performed on the Illumina MiSeq device, and analysis was performed with the Quantitative Insight into Microbial Ecology program.

Results: 24 mice were gavaged with human microbiota (12 each of ERA and controls). 23 non-gavaged mice were maintained in the gnotobiotic facility, and 11 additional non-gavaged mice were transferred into the conventional facility. Among transplanted mice, ankle swelling assessed 21 – 24 days post transfer was equivalent in those that received ERA (4.7 ± 0.5) vs control (4.4 ± 0.4) microbiota. Taken together, humanized mice had increased ankle swelling as compared to GF (3.5 ± 0.3, $p < 0.001$) and conventionally housed (4.0 ± 0.4, $p = 0.002$) mice. Principal coordinates analysis revealed incomplete uptake of the human microbiota, with clustering by species but not by donor-recipient dyad (Figure 1.) This was due to substantial over-representation of two genera (Bacteroides and Akkermansia) at the expense of the Firmicutes phylum among the transplanted mice. Taken together, the microbiota as a whole predicted the extent of ankle swelling ($R2 = 0.185$, $p = 0.018$, adonis test). At the level of the individual genera, the abundances of *Bacteroides* ($r = -0.510$, $p = 0.010$) inversely and *Akkermansia* ($r = 0.367$, $p = 0.078$) directly correlated with ankle swelling.

Conclusion: Perhaps due to incomplete humanization, there was no association between the diagnosis of the donor and extent of arthritis in the recipient mice. However, our study supports previous findings of a possible association between *Akkermansia muciniphila* and arthritis and opens up new avenues of research into the association between human microbiota and arthritis.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: MicroRNAs (miRNAs) modulate gene expression by inhibiting the translation of targeted mRNAs and causing mRNA degradation in a transcript-specific manner. Several miRNAs have been reported to play an important role in inflammation and autoimmune diseases. Our aim was to identify miRNA biomarkers in oligoarticular juvenile idiopathic arthritis (JIA).

Methods: Total RNA was isolated and microarray profiling on 84 inflammatory miRNAs was performed to identify differentially expressed miRNAs on pooled (n=5) healthy plasma, JIA plasma and synovial fluid (SF) by digital droplet PCR (DDPCR) that enables absolute quantification of nucleic acids. Levels of four candidate miRNAs; miR-125b, miR-146b, miR-155 and miRNA-192-5p in plasma and SF were quantified by DDPCR individually in additional 10 healthy controls and 10 age and gender matched oligoarticular JIA patients. All patients satisfied the ILAR classification criteria, were all ANA positive and non- or only NSAID treated at the time of joint injection when also the blood was collected.

Results: We identified 11 and 13 miRNAs on the microarray analysis that were at least 2-fold increased or decreased in JIA plasma compared to normal plasma, and in JIA SF compared to JIA plasma, respectively. The differential expression of miR-146b, miR-155 and miR-192-5p were confirmed on individual samples. Levels of miR-146b and miR-155 was increased in plasma ($p=0.03$ and $p=0.01$ respectively) of JIA patients and miR-146b was enriched even more at the site of the inflamed joints ($p=0.02$). MiRNA-192-5p expression was reduced in arthritic joints ($p=0.003$). MiRNA-125b expression did not show any significant difference.

Conclusion: This is the first study to investigate miRNAs by DDPCR in JIA and especially in SF. Similar to what is known in rheumatoid arthritis, miRNA-146b and miRNA-155 may promote an inflammatory process in oligoarticular JIA. Our novel finding is that miRNA192-5p is down-regulated in JIA in the inflamed joint. This may be involved in suppressing proinflammatory signals.

Investigation of miRNAs and exploring their potential biological functions could help to understand the pathogenesis of JIA. The inflammation regulating miRNAs may have the potential to serve as biomarkers of disease or novel therapeutic targets.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: CD163 is a hemoglobin scavenger receptor and innate pattern recognition receptor, and a marker of activated monocytes and macrophages. It is also expressed on monocytes from children with active systemic juvenile idiopathic arthritis, and associated with emergence of macrophage activation syndrome. However, the regulation of CD163 expression during monocyte and macrophage polarization is poorly understood. MicroRNA post-transcriptionally regulate gene expression, often serving as feedback loops to “fine tune” gene expression programs. We hypothesize that **microRNA dysregulated in active SJIA modulate expression of CD163 in polarized macrophage populations**

Methods: Human THP-1 monocytic cells and primary monocytes and monocyte-derived macrophages from healthy donors were polarized in vitro. CD163 expression was determined by quantitative RT-PCR or on a single-cell level by RNA flow cytometry using the PrimeFlow kit.

Cells were also transfected with specific microRNA mimics or antagomirs to miR-125a-5p, miR-181a or miR-181c. Direct binding of miR-181 family members to the CD163 3' untranslated region (UTR) was determined using a luciferase reporter system and through RNA immunoprecipitation (RIP). RNA-sequencing was used to identify differentially regulated genes in macrophages overexpressing miR-125a-5p or control mimics.

Results: Significantly increased CD163 mRNA levels were detected only in monocytes and macrophages polarized towards M2c conditions by IL-10. Similarly, single-cell analysis showed markedly increased CD163 surface protein and mRNA levels only with IL-10 treatment. Several candidate microRNA which are overexpressed in monocytes from children with active systemic JIA may regulate CD163. Here, we find that overexpression of miR-125a-5p and miR-181c significantly reduced CD163 mRNA expression in IL-10 polarized macrophages. *In vitro*, both miR-125a and miR-181 family members were elevated in polarizing conditions that restrict CD163 expression, and inhibition of these with antagomirs increased CD163 mRNA levels. Interestingly, these microRNAs regulated CD163 expression through distinct mechanisms. Computationally, miR-181 is predicted to bind directly to the 3' UTR of CD163 mRNA. Using both a luciferase reporter system and RIP assay we found direct interaction between miR-181 family members and the CD163 mRNA. In contrast, CD163 does not have a predicted miR-125a binding site. RNA-seq based genome wide target analysis identified "Cytokine-cytokine receptor interactions" as the most significantly repressed gene pathway upon miR-125a overexpression, and specifically decreased levels of *IL10RA* and *TGFbR2*. This finding suggests that miR-125a exerts global effects on macrophages to modulate polarization.

Conclusion: Taken together, these data show that microRNAs regulate the IL-10-induced expression of CD163 in human macrophages through distinct mechanisms, directly targeting of CD163 mRNA and indirectly inhibiting cytokine receptor expression. These findings highlight the diverse ways microRNA regulatory networks affect macrophage polarization and phenotype in active SJIA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophage activation syndrome (MAS) is a severe complication of rheumatic disease, particularly of systemic JIA (sJIA). It is currently classified among the secondary forms of HLH (secHLH). Primary HLH (pHLH) is caused by mutation of genes that code for proteins that are involved in cytotoxic functions. Mice carrying heterozygous mutations in more than one pHLH gene carry a higher risk to develop HLH following viral infection, suggesting that accumulation of partial genetic defects may be relevant in HLH (1).

Methods: Genes involved in pHLH were analysed with next generation sequencing (NGS) in patients with MAS in the context of different rheumatic diseases and in secHLH. We performed targeted resequencing on all patients using a panel including the 7 principal HLH-related genes (*PRF1, UNC13d, STX11, STXBP2, Rab27a, XIAP, SH2D1A*). Sequencing analysis were performed on the MiSeq® platform (Illumina, San Diego, CA); all variants identified were confirmed by Sanger. The possible functional impact of variants was studied by *in silico* analysis using SIFT and PolyPhen softwares. We took into account only variants with an allelic frequency in the global population <1%, in the dbSNP and Ensembl databases.

Results: We studied 25 patients, 20 MAS, 16 of whom developed this complication in the context of sJIA, and 4, in the context of other rheumatic diseases (vasculitis, Crohn's disease, systemic lupus erithematosus and Kawasaki disease, respectively) and 5 patients with secHLH. We identified at least 1 heterozygous variant in one of the pHLH associated genes in 14 (56%) patients: 10/20 MAS (50%), 4/5 secHLH (80%), with a detection rate of 56%. Nine patients showed variants in one gene, while variants in two or more genes were found in 5 patients. Five patients with MAS showed an heterozygous mutation in *PRF1* gene, the A91V variant was the most frequent (4), and 5 patients showed an heterozygous mutation in *UNC13d* gene. Three of the 20 MAS patients had mutations in two different genes, two of them had recurrent episodes of MAS with one presenting a severe disease with a prolonged ICU admission. Three (60%) patients with secHLH showed an heterozygous mutation of *Rab27a*, 2 of *UNC13d* gene and 1 of *PRF1*. Two of those patients had mutations in two different genes, one of them presented three episodes of HLH reactivation and the other one presented a severe disease and died. Overall patients carrying mutations in 2 genes showed higher frequency of recurrences (4/5, 80%) compared to patients carrying one mutations or no mutation (6/20, 30%) and higher frequency of severe disease (i.e. needed admission to intensive care unit or died) (4/5, 80% versus 7/20, 35%).

Conclusion: Mutations of *PRF1* and *UNC13d* genes are frequently observed in patients with MAS or secHLH; Rab27a variants may be more frequent in patients with secHLH. Re-occurrence and severe disease tend to be more frequent and more severe in patients who carry mutations in two genes. These data are consistent with a polygenic model of secHLH and MAS. **Reference.** 1. Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid factor (RF) positive polyarticular JIA (RF+ve pJIA) frequently progresses into adulthood with a clinical phenotype that ressembles rheumatoid arthritis (RA). Antibodies to cyclic citrullinated peptides (anti-CCP) have also been detected in a high proportion of sera from patients with RF+ve pJIA. We have previously described the use of an inherently autoreactive VH (variable heavy immunoglobulin chain) by anti-CCP in patients with early and also established adult RA [1]. Immunoglobulins derived from this gene (VH4-34) can be tracked using the rat monoclonal antibody, 9G4. This study profiles RF, anti-CCP and 9G4-CCP serology of a large adolescent JIA cohort compared with that of adult patients with RA.

Methods: Serum from 88 poly-JIA, enthesitis-related arthritis (ERA;n=29), extended oligoarthritis (EOA;n= 38), 31 gender/age matched controls, 35 adult RA and 30 age-matched healthy controls (HC). IgG, IgA and IgM isotypes of anti-CCP was tested. Cut-offs for positivity were defined by manufacturer's instructions or determined with reference to known positive standards and expressed as arbitrary units (AU). RF status was determined by in-house ELISA. 9G4 expression on antibodies binding to CCP-coated ELISA plates was as previously described. A capture ELISA was used to measure serum total 9G4-IgM. Mann-Whitney U was used to compare groups and linear regression for relationships between variables.

Results: Of 88 patients with polyJIA, 65 were RF-ve with 4 (6%) positive for IgG-CCP. In RF+ve pJIA and RF+ve adult RA groups, 20/23 (87%) and 30/35 (86%) sera contained IgG-CCP respectively. 1 patient (with EOA) in adolescent patient group had IgG-CCP. Levels of IgG-CCP were similar between RF+ve pJIA and RF+ve RA but both IgA- and IgM-CCP levels were significantly lower in the adolescent group ($p<0.01$ for both). Binding of 9G4 to anti-CCP antibodies was significantly higher in the RF+ve pJIA vs RhF-ve pJIA (Median 9.8 vs 1.2; $p<0.0001$). Similar median levels of 9G4-CCP were present in RF+ve pJIA and adult RF+ve RA ($p=0.13$). 9G4 expression on serum total IgM was significantly higher in RF+ve pJIA patients compared with adult healthy control and JIA disease control groups (EOA, ERA and RF-ve pJIA all $p<0.01$), but similar to that of adult RF+ve RA.

Conclusion: This study is the first to describe the inherently autoreactive idiotope recognised by 9G4 being detected on anti-CCP antibodies in RF+ve pJIA. Restriction in VH gene usage in both JIA and RA patient immune systems may bias their immunoglobulin repertoire and be instrumental in the elicitation of anti-CCP antibodies. IgG-anti-CCP response of RF+ve pJIA and adult RA patients were similar. However, significantly higher levels of IgA- and IgM-anti-CCPs were present in adult RA patients. Interestingly, we previously showed that in adult RA with onset of <1 year, percentage of samples positive for IgM- and IgA-CCP followed, rather than preceded positivity for IgG-anti-CCP. This suggests that the emergence of IgG-antibodies to a citrullinated proteins may arise early in the underlying pathogenic process with a sequence of events not shared with conventional antibody responses to pathogens. 1.Cambridge G et al: *PloS one* 2014, 9(9):e107513.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical management of polyarticular JIA with anti-TNF-alpha has been met with moderate success, with up to 50% of patients demonstrating clinically meaningful efficacy. Concerns with medium/long term drug toxicities has driven the clinical need to find predictors for successful drug discontinuation. Based on a solid foundation of preliminary and published data, our hypothesis is that adaptive T cell immunity plays a pivotal role in the pathogenic mechanisms which determine clinical fate in JIA. To distill this pathogenic signal located within the T cell immunome, a high dimensional single cell resolution platform, CyToF, was deployed to phenotype activated antigen experienced T cells. Patients treated with anti-TNF-alpha were recruited in the Understanding TNF-alpha trial and segregated into flare, active and inactive arms after discontinuation of therapy. The central aim of the project is to identify pathogenic immune mechanisms of clinical relapse and signatures capable of distinguishing clinical fates.

Methods: Patients treated with anti-TNF-alpha biologics were recruited into the study (Improved Understanding of the Biology and Use of TNF inhibition in Children with JIA Trial) with clinically inactive disease on treatment (Wallace criteria) and initiated with therapy discontinuation. The patients are followed up and evaluated as flare, inactive and active based on 6 JIA core set parameters; number of joints with active arthritis and/or loss of motion, MD global assessment of current disease activity, patient/parent global assessment of overall disease severity in prior week, a validated measure of physical function and ESR.

Results: PBMCs from n=17 JIA patients (n= 6 flare, 5 active and 6 inactive) were stained with a 37 markers CyToF panel designed to interrogate the T cell compartment. Cluster analysis was achieved through dimensional reduction of 37 markers onto a bivariate X-Y plane via T-SNE algorithm (ACCENSE). Binary comparison of clinical fates with the clustered dimensions revealed that patients experiencing flare within 6 months of drug discontinuation, were enriched with these striking characteristics: pro-inflammatory, recently antigen stimulated, and, most importantly, pre-existing withdrawal of therapy. The phenotype comprised of $CD3^+$ $CD4^+$ memory ($CD45RA^-$) antigen experienced ($CD40L^+$, $CD69^+$) T cells, expressing co-stimulatory markers ($CD28^+$,

ICOS$^+$), immune checkpoints (CTLA4$^+$) capable of secreting high levels of TNF-alpha ($p < 0.0\ 5$). Intriguingly within the Treg compartment, CD3$^+$CD4$^+$CD25^{hi} Foxp3^{hi} CD45RA$^-$CTLA4^{hi}CD28$^+$ICOS$^+$were found to be significantly ($p < 0.05$) up-regulated in flare patients.

Conclusion: These results are striking, in our opinion, as they define some important concepts: i) Teff mechanisms which lead to clinical relapse are pre-existing withdrawal from therapy; ii) Tregs cells, are significantly elevated in patients who flare, representing probably a mechanism of overcompensation, probably ineffective due to resistance to suppression by Teff; iii) that the clinical fate is immunologically predetermined; iv) patients who achieve different clinical fates can be stratified immunologically.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While the field of pediatric rheumatology has made enviable strides in improving the lives of children with juvenile idiopathic arthritis (JIA), there is still a great deal we do not understanding about the biology of treatment response and the achievement of remission. To gain a better understanding of how the adaptive immune system is altered during successful therapy for polyarticular JIA, we performed RNA sequencing (RNAseq) on purified CD4+ T cells during active disease and remission in a group of children with this disease.

Methods: We isolated RNA from CD4+ T cells of children with 3 distinct phenotypes: children with active, treated polyarticular JIA (ADt, n=12), children on medication who fit criteria for clinical remission by the Wallace criteria (CRM, n=10), and 10 healthy children, a control group. All JIA patients were on dual therapy with methotrexate and etanercept, and non were taking glucocorticoids. RNA sequencing was performed using the Illumina HiSeq 2500. Differentially expressed genes (DEGs) were considered with a cut-off of fold change >2.0 and false discovery rate <0.05.

Results: A comparison of ADt *vs* CRM transcripts revealed 143 differentially expressed genes, included 140 genes upregulated and 3 down regulated in the ADt group. The comparison of CRM vs. HC transcripts revealed 145 differentially expressed genes (3 up-regulated and 142 down regulated). The latter findings corroborate previous results from mixed populations of peripheral blood cells demonstrating that the CRM state is not associated with normalization of leukocyte transcriptomes. The top canonical pathways from IPA based on these DE genes (ADt vs CRM) include oxidative phosphorylation, mitochondrial dysfunction, EIF2 signaling and antigen presentation pathways. DE genes identified in the CRM vs HC comparison also included antigen presentation pathways, allograft rejection signaling, and NFAT regulation. Principle component analysis (PCA) of the expression genes in CD4+ T cells showed that ADt clearly separated with CRM. It was interesting to note, that CRM and HC subjects clustered closer together than ADt and CRM samples.

Conclusion: Our studies show that treatment response in JIA is associated with transcriptional alterations in peripheral blood CD4+ T cells. These responses involve gene regulatory networks associated with T cell activation (e.g., oxidative phosphorylation, antigen presentation). However, children who fit criteria for CRM, while phenotypically normal, have ongoing, underlying immune abnormalities.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: CD163 is involved in the regulation and resolution of innate inflammation and the removal of free hemoglobin from the blood via internalization of the hemoglobin-haptoglobin complex. It is also a cell surface marker of alternatively activated macrophages overexpressed in inflammatory disorders such as systemic juvenile idiopathic arthritis. To better understand the activation of myeloid cells in rheumatic disorders, a flow cytometry panel has been developed to define polarized monocyte and macrophage phenotypes. Along with detecting surface protein markers, the novel technique called PrimeFlow™ allows specific mRNA sequences to be detected at single cell resolution. This panel was utilized to define the expression of CD163 in polarized monocyte and macrophage populations.

Methods: A human monocytic cell line, THP-1, was cultured and stimulated in vitro with LPS and IFN-gamma, IL-4, LPS and IgG, TGFβ, or IL-10 toward M1, M2a, M2b, and M2c phenotypes, respectively. The cells were stained using the fluorochrome conjugated antibodies CD14-Pacific Blue, CD16-BV711, CD80-BV786, CD64-AF700, CD209-FITC and CD163-PE. Each condition also was stained for CD163 mRNA using the PrimeFlow™ kit's branching technology. Cells were acquired using an analytical cytometer, and data were analyzed by FACSDiva software.

Results: PrimeFlow™ staining of CD163 mRNA could reliably detect increased CD163 expression in THP-1 monocytic cells, primary CD14+ blood monocytes, and monocyte-derived macrophages. The PrimeFlow™ CD163 mRNA probe was also used simultaneously to detect protein surface markers, and this flow cytometry panel provided the same degree of positively stained cells as the results of staining for individual cell surface markers without mRNA labeling. This combined panel demonstrated that some alternatively activated populations, such as M2a (IL-4 conditions), show an increase in CD163 surface protein expression with no change in CD163 mRNA levels. In marked contrast and in agreement with qPCR data, increase in both CD163 mRNA and protein levels is limited to the IL-10 stimulated M2c conditions. The PrimeFlow™ technique was determined to be highly sensitive for increased mRNA expression, with a strong signal over a broad range of IL-10 concentrations in contrast to qPCR data and surface protein detection. The kinetics of CD163 induction with IL-10 stimulation were shown to be similar for both mRNA and protein. There is minimal increase in both mRNA and protein expression after 5 hours of stimulation, but significant increase after 24 hours.

Conclusion: PrimeFlow™ is a robust and sensitive system for RNA flow cytometry, and useful for studying CD163 expression in myeloid cells. CD163 shows distinct patterns of expression in different polarized populations. At single cell resolution, CD163 protein and mRNA levels increased in IL-10 stimulated M2c cells. This flow cytometry panel consisting of CD14, CD16, CD64, CD80, CD163, and CD209 cell surface markers can be used to identify different populations

of activated monocytes and macrophages in a broad range of inflammatory disorders.

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Genetics plays an important role in the pathogenesis of systemic lupus erythematosus (SLE). Up to 20% of those affected with SLE are diagnosed in childhood or adolescence. There is evidence for a higher burden of SLE susceptibility loci in those diagnosed in childhood compared to adulthood. This higher genetic burden in children may in part be attributable to consanguinity in prior generations. We hypothesized that higher coefficients of inbreeding are associated with younger age of SLE diagnosis and family history of SLE.

Methods: We included children diagnosed and followed for cSLE at The Hospital for Sick Children Lupus Clinic, Toronto (≥ 4/11 ACR classification criteria and/or ≥ 4/17 SLICC classification criteria) between1982-2014. Participants were genotyped on the Illumina Immunochip. Standard quality control methods were performed including sex inconsistency and filtering low call rates (<95%). We completed principal components (PC) analyses seeding our population with the 1000 genomes project data, to generate PCs, remove outliers and to define ancestral groups (European, African, East Asian, South Asian). Inbreeding coefficients were

calculated for each child (FSuite), stratified by ancestral group. We tested the association between inbreeding coefficients and age of SLE diagnosis using linear regression models, and with family history of SLE using logistic models.

Results: Of the 389 subjects, 8 failed QC, and 23 outliers were removed from PC analyses. A total of 358 cSLE contributed to analyses. The median age of diagnosis was 13.4 (IQR10.9 – 15.1) years and the mean inbreeding coefficient was 0.05% (IQR 0.01% – 15.4%). One percent of cohort had an inbreeding coefficient comparable to the expected proportion for 1st cousins (12.5%). We did not observe a statistically significant association between the inbreeding coefficient and age of diagnosis, adjusting for ancestry (beta = 0.15, SE 0.1 years, p-value = 0.12) nor with family history of SLE (OR = 0.93, 95% CI 0.77, 1.12).

Conclusion: We did not observe a significant association between inbreeding coefficients and age of SLE diagnosis nor with family history of SLE. Our inbreeding coefficients were low in our cohort, limiting our power to detect an association with age or family history. Replication and meta-analyses in independent cohorts are planned next steps for validating our findings.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Elevated levels of cell-bound complement activation products (C4d deposition on erythrocytes [EC4d] and B lymphocytes [BC4d], CB-CAPs) have been demonstrated to be sensitive and specific for the diagnosis of systemic lupus erythematosus (SLE) and C4d deposition on platelets (PC4d) to be specific for the diagnosis of SLE. We sought to evaluate the usefulness of CB-CAPs as a biomarker for disease activity in childhood-onset SLE (cSLE).

Methods: This is a longitudinal study of 28 patients with cSLE (diagnosed prior to their 19th birthdays) who fulfilled ACR-SLE classification criteria, with a mean follow-up of 6 months. Clinical and demographic data were recorded. Venous blood was collected every 3 months and shipped overnight to the reference clinical laboratory for the multi-analyte assay. The assay evaluates a full panel of autoantibodies, including anti-dsDNA, aPLs (beta-2 glycoprotein antibodies, aCL, and/or aPS-PT) and conventional serum complement levels (C3 and C4), as well as CB-CAPs; CB-CAPs results are reported as net mean fluorescence intensity (MFI). SpearmanÕs correlation was used to evaluate the correlation between CB-CAPs and disease activity scores; t-tests to evaluate the presence of CB-CAPs in APL patients.

Results: Clinical and demographic variables are presented in the Table. Mean SLEDAI was 4.3±3.8 (range 0-16). Elevated CB-CAPs correlated with SLEDAI scores in cSLE patients (r^2 range 0.23-0.38, $p<0.05$ for EC4d, BC4d, and PC4d, respectively) at baseline, 3 and 6 months. Higher levels of EC4d (>75 net MFI) were found to have better correlation with disease activity scores at all time-points ($p<0.05$). Additionally, in 11 cSLE patients with positive aPLs CB-CAPs were significantly elevated with $p<0.05$ for EC4d, but $p=0.06$ for BC4d and $p=0.15$ for PC4d; of note, C3 and C4 did not correlate with the presence of aPL in these patients (p=NS). Interestingly, several patients had normal levels of C3 and C4, but elevated CB-CAPs, possibly indicating fluctuating complement activation that was not captured by C3 and C4 measurements.

Conclusion: These pilot findings suggest that CB-CAPs could provide a useful biomarker for disease activity in cSLE, and may be particularly important in the monitoring of SLE patients with anti-phospholipid antibodies. Further longitudinal data is needed to establish CB-CAPs as a biomarker in cSLE and APS. Table: Patient demographics and results of CB-CAPs assays

	SLE (n=28)

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Maternal autoantibodies (Ab) reactive with the Ro/La ribonucleoprotein complex are associated with the development of cardiac injury in a fetus passively exposed to these Ab. This study evaluated the irreversible scarring phenotype characteristic of heart block involving the mitogen activated protein kinase (MAPK) pathway and its regulation by cAMP.

Methods: The aorta from a healthy 2nd trimester fetal heart was cannulated using a Langendorff preparation with the addition of proteolytic enzymes to yield a single cell suspension of primary human fetal cardiac fibroblasts. Cultured cells were treated with secreted products generated from activated macrophages with or without BIX 02189 (10uM, a specific MEK5/ERK5 inhibitor) and forskolin (10uM to raise cAMP). After RNA isolation and cDNA library preparation, RNA-Seq, transcriptome analysis (Data as log2 transcripts per million) and qPCR were performed.

Results: Incubation of fibroblasts with supernatants from macrophages transfected with hY3 (ssRNA associated with Ro60), shown to induce a pro-fibrotic phenotype, resulted in the increased expression of 3836 genes. Based on DAVID functional annotation, the top clusters represented were Actin Binding, Cytoskeletal Protein Binding, Cell Adhesion, Signal Peptide, and Contractile Fiber, all processes considered typical of the myofibroblast phenotype. In addition, RAPGEF3, an endogenous ERK5 inhibitor, and Adrenomedullin, which increases cAMP, were downregulated while PDE4D, an inhibitor of cAMP generation, was upregulated (Table 1). These data are consistent with previous literature supporting the association of lowered intracellular cAMP and upregulation of pro-fibrotic genes. Given that cAMP attenuates the activity of ERK5, BIX 02189 was used to evaluate the transcriptome. Of the 3836 genes upregulated by hY3 macrophage supernatants, 617 were reversed by the subsequent addition of BIX. Among the upregulated genes were pro-fibrosing genes such as EDN1 and TGFβ2 and among those downregulated were genes that resist fibrosis including CLU, RAPGEF3, and ADM. The latter two are associated with a cAMP dependent inhibition of ERK5 and increased cAMP, respectively. The pro-fibrosing EDN1 result was confirmed by qPCR and as expected was attenuated by forskolin.

Conclusion: These data support that the link of anti-Ro immune complex activated macrophages and the pathogenic fibroblast phenotype may relate to a decrease in cAMP levels. These results highlight potential novel targets for therapy and solidify the role of ERK5 in the transdifferentiation of fetal fibroblasts in the context of congenital heart block.

Table 1

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: JDM is a complex autoimmune disease with an interferon (IFN) signature, with a reported correlation with disease activity. Clinical features vary among myositis-specific autoantibody (MSA) groups, but partially overlap with 2 genetically defined autoinflammatory syndromes, Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated temperature (CANDLE) caused by mutations in proteasome genes and Sting-Associated Vasculopathy with onset during Infancy (SAVI) caused by mutations in *TMEM173/* STING. The comparison of an IFN score in JDM versus CANDLE and SAVI may help elucidate the role of IFN in JDM. Evaluation of IFN scores by MSA group and disease activity in JDM may pilot their potential as biomarkers.

Methods: A standardized 25 gene IFN score (IFN_s) previously developed in CANDLE patients (H. Kim, A&R 2014) was assessed in JDM patient RNA extracted from whole blood using the Nanostring nCounter gene expression system (Seattle, WA). JDM sera were characterized for MSAs by validated immunoprecipitation and immunoblotting methods; physician global disease activity (PGA) was clinically assessed on a visual analog scale. CANDLE and SAVI samples were positive IFN-mediated disease controls. Non-IFN controls were NOMID (IL-1 mediated autoinflammatory monogenic disease) and healthy controls (HCs). Nonparametric tests were used for non-normally distributed data; MSA group analysis was done if n>5. IFN score comparisons among disease groups and MSAs were performed by Mann-Whitney test. Spearman correlation was performed between PGA versus IFN_s for JDM, and by MSA group.

Results:

IFN Score

A. Diagnosis	n	median	25th %ile	75th %ile
JDM	57	34.4	1.3	225.8
HC	18	-6.2	-11.0	0.7
NOMID	19	-12.2	-14.6	-1.7
CANDLE	11	476.7	311.1	812.2
SAVI	7	497.0	345.7	701.1
B. MSA group	**n**	**median**	**25th %ile**	**75th %ile**
TIF1	20	36.6	-4.6	158.8
MDA5	9	131.7	29.5	382.2
MJ	9	29.7	-0.2	368.4
MSA-neg	9	169.8	7.1	340.2

Table 1: 25 gene IFN Score by (A) diagnosis and (B) JDM mysotis-specific antibody (MSA) groups with n>5.

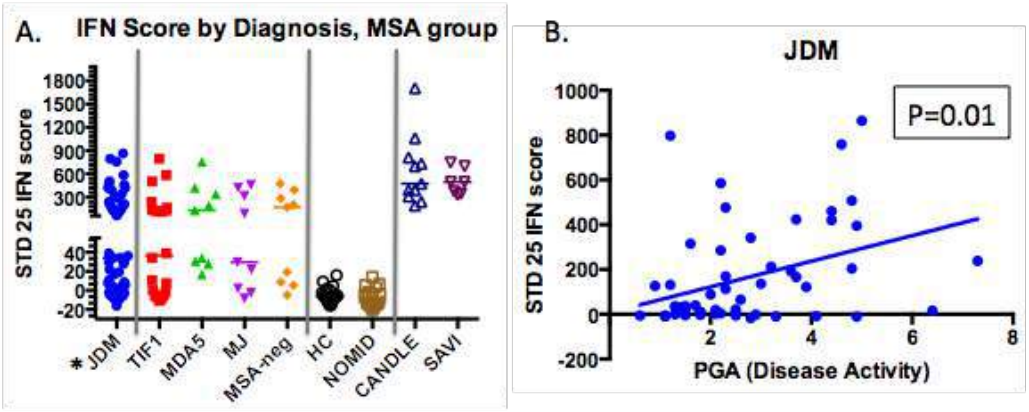

Figure 1. A. Standardized 25 gene IFN score (IFN_s) is plotted for JDM, then subtyped by 4 myositis-specific antibody (MSA) groups with n>5, non-IFN controls (Healthy controls and NOMID), and then Mendelian IFN positive controls (CANDLE and SAVI). Horizontal lines indicate medians. * P value is less than 0.001 for JDM versus each other diagnosis group (HC, NOMID, CANDLE, SAVI).
B. Interferon score is plotted versus physician global disease activity (PGA) on a visual analog scale of 0-10. Spearman r coefficient is 0.34 with a 95% confidence interval of 0.08-0.55.

JDM IFN_s was significantly lower than CANDLE and SAVI and significantly higher than HCs and NOMID (Table 1, Figure 1A). IFN_s was higher in MDA5 and MSA-neg groups (compared to anti-TIF1, MJ), but was not statistically significant. The 4 MSA groups remained significantly higher than HC and NOMID and significantly lower than CANDLE and SAVI. PGA (median 2.3, IQR 1.5-3.7) correlated significantly with IFN_s in JDM overall (Figure 1B), though correlation of IFN_s with PGA was not significant within the MSA groups analyzed.

Conclusion: Though JDM IFN_s is significantly higher than HCs and NOMID, it is significantly lower than CANDLE and SAVI, indicating IFN may not be the sole driver of pathogenesis in JDM. PGA does correlate with IFN score as a potential biomarker. No significant differences were found among MSA groups but further study is needed to identify what factors affect the IFN_s in JDM.
This research was supported by the Intramural Research Program of the NIH, NIEHS, NIAID, NIAMS and the CC.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM), a systemic autoimmune vasculopathy, and juvenile idiopathic arthritis (JIA) are representative rheumatic diseases in children. However the pathogenesis of these diseases are still poorly defined. More research in this area is required on identification of disease-specific biomarkers for clinical assessment. Anti-endothelial cell antibodies (AECA) have been detected in rheumatic diseases such as vasculitis. We aimed to detect target antigens for AECA in patients with pediatric rheumatic diseases comprehensively by proteomics and to investigate their clinical significance.

Methods: To comprehensively detect target antigens for AECA, we separated proteins extracted from human aortic endothelial cells by two-dimensional electrophoresis and then transferred them onto membranes. Autoantigens that were positive only in pediatric rheumatic disease sera from three patients with JDM and two patients with JIA but not in healthy children sera were detected by western blotting. The detected proteins were identified by peptide mass finger-printing. Bound IgG antibodies to antigens were detected using standard methods.

Results: We successfully identified 738 proteins out of eighteen protein spots that were candidate targets of AECA in pediatric rheumatic diseases. Antibodies appeared to target proteins with specific functions, e.g., ATP-related proteins (37%), muscle-related proteins (19%), calcium regulated protein and/or calcium binding proteins (13%) and redox related proteins (10%). Among the 140 muscle-related proteins were myosin light polypeptide 6 (MYL6) and myosin-9 (MYH9). IgG autoantibodies to MYL6 were detected in 20% of the patients with JDM (n=61) using ELISA assays. However, 50% of the untreated JDM patients with active disease (n=10) had anti-MYL6 antibodies, in contrast to 12% ($p<0.05$) of the patients with JIA (n=17) and in 16% ($p=0.05$) of control children (n=25). IgG autoantibodies to MYH9 were detected in 31% of the active patients with JDM (n=35), (50% of the untreated JDM patients with active disease), in comparison to 27% of the patients with JIA (n=15) and 12% ($p<0.05$) of control children. Among the 74 redox related proteins were peroxiredoxins (Prxs). IgG autoantibodies to Prx2 were detected in 24% of the active patients with JDM (n=25), (30% of the untreated JDM patients with active disease) and in 20% of the active patients with JIA (n=10), (40% of the untreated JIA patients with active disease) in contrast to 0% ($p<0.05$) of control children (n=20). Furthermore one of the identified 738 proteins was Von Willebrand Factor (vWF). IgG autoantibodies to vWF were detected in 20% of the active patients with JIA (40% of the untreated JIA patients with active disease), in comparison to 4% of the active patients with JDM and 0% of control children.

Conclusion: IgG antibodies to MYL6, MYH9, Prx2 and vWF were detected in the sera from

patients with pediatric rheumatic diseases, respectively. These antibodies were directed against autoantigens correlated with skeletal muscle function, redox functions and the coagulation/fibrinolytic systems and may be useful markers for pediatric rheumatic diseases.

The Vasculopathy of Juvenile Dermatomyositis (JDM); Evidence of Persistent Endothelial Injury, Hypercoagulability, Subclinical Inflammation and Increased Arterial Stiffness

Charalampia Papadopoulou[1,2], Ying Hong[1], Petra Krol[1,2], Yiannis Ioannou[3], Clarissa Pilkington[2,4,5], Hema Chaplin[6], Stephanie Simou[1], Marietta Charakida[7], Lucy R Wedderburn[5,8,9], Paul Brogan[10] and Despina Eleftheriou[1,8,11], [1]Infection, Inflammation and Rheumatology, UCL Institute of Child Health, London, United Kingdom, [2]Paediatric Rheumatology, Great Ormond Street Hospital NHS Trust, London, United Kingdom, [3]Rayne Institute, Arthritis Research UK Centre for Adolescent Rheumatology, UCL Division of Medicine, London, United Kingdom, [4]Paediatric Rheumatology, Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom, [5]Infection, Inflammation and Rheumatology Section, UCL Institute of Child Health, London, United Kingdom, [6]Centre for Adolescent Rheumatology, Arthritis Research UK, London, United Kingdom, [7]Vascular Physiology Unit, Institute of Cardiovascular Science , University College London, London, United Kingdom, [8]Paediatric Rheumatology Department, Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom, [9]Rheumatology Unit, Arthritis Research UK Centre for Adolescent Rheumatology, University College London, London, United Kingdom, [10]Department of Paediatric Rheumatology, UCL Institute of Child Health and Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom, [11]Arthritis Research UK Centre for Adolescent Rheumatology, University College London, London, United Kingdom

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Vasculopathy is considered central to the pathogenesis of Juvenile Dermatomyositis (JDM). The interplay between persistent JDM-vasculopathy, traditional cardiovascular risk factors, exposure to corticosteroids, and chronic inflammation could create a perfect storm for early atherogenesis. A major hurdle to the study of vasculopathy of JDM, monitoring of its trajectory over time and contribution to cardiovascular disease has been a lack of non-invasive biomarkers. Recently, we described 2 methods for detecting endothelial cell components in blood: circulating endothelial cells (CEC), and endothelial microparticles (EMP). We aim therefore to explore the vasculopathy of JDM by assessing: (i) biomarkers of endothelial injury (CEC and EMP), subclinical inflammation (cytokines) and hypercoagulability (MP-mediated thrombin generation); and (ii) structural arterial changes (indicative of premature atherosclerosis), and their relation to disease activity and treatment in children with JDM.

Methods: 64 patients recruited to the UK JDM Cohort & Biomarker Study were included; median age 10.5 (range 6.9 – 13.7) years with median disease duration of 1.5 (0.3-4.7) years. 40 (62.5%) were females. Inactive disease was defined as per modified PRINTO criteria: no skin rashes, CK≤150, CMAS≥ 48, MMT8≥78, Physician ‘s global assessment ≤0.2 on a visual analogue scale. CECs and MPs were identified with immunomagnetic bead extraction and flow cytometry, respectively. MP-mediated thrombin generation was determined using a fluorogenic assay. Cytokines and chemokines were measured by electrochemiluminiscence. Arterial stiffness was assessed using pulse wave velocity (PWV).

Results are expressed as median and range. Results:CECs were higher in JDM patients at 68 (32-128) cell/ml compared to 12 (8-21) cells/ml in 66 age-sex matched healthy controls, $p<0.0001$. Patients with active JDM had higher CEC than those with inactive JDM, $p=0.02$. CEC counts significantly correlated with levels of inflammatory cytokines/chemokines implicated previously in JDM disease pathogenesis: interferon regulated Monocyte Chemoattractant Protein-1 (MCP-1; $r=0.63$, $p=0.02$) and interleukin-8 (IL-8; $r=0.65$ and $p=0.01$). Total circulating MP counts were also significantly higher in active JDM, 1781 (981-2616) $x10^3$/ml compared to inactive JDM, 1116 (263-1393) $x10^3$/ml, $p=0.02$; and healthy controls 89 (25-236) $x10^3$/ml, $p=0.0001$. These circulating MPs were predominantly of platelet and endothelial origin. Enhanced MP mediated thrombin generation was demonstrated in active compared to inactive JDM ($p=0.03$) and controls ($p=0.001$). Lastly, children with JDM had increased carotid-radial PWV adjusted for age compared to healthy controls ($p=0.005$).

Conclusion: Our data demonstrate: 1. Increased endothelial damage in children with active JDM, possibly driven by pro-inflammatory cytokines; 2. High levels of circulating MP with propensity to drive thrombin generation and hence occlusive vasculopathy; and 3. Increased arterial stiffness, suggestive of accelerated atherosclerosis in patients with JDM. Validation of these biomarkers in multicentre prospective studies will provide data regarding their prognostic relevance.

Session Time: 9:00AM-11:00AM

Background/Purpose: Although proximal muscle weakness and skin rash are the typical features of juvenile dermatomyositis (JDM), little is known about disease pathogenesis, why other features develop, or why patients have differential responses to therapy. In complex diseases like JDM, large scale genomics and systems biology approaches may enable insight into dysregulated pathways involved in pathogenesis, and could lead to a more rational therapeutic approach.

Methods: Peripheral blood samples were obtained from patients enrolled in the Juvenile Dermatomyositis Cohort and Biomarker Study (JDCBS) at pre-treatment (n=13) and 11.8 [11.3-13.2] months post-treatment (n=13), including n=10 matched samples. CD4, CD8, CD14 and CD19 cells were sorted from PBMC by flow cytometry and RNA prepared for RNA-seq. Samples were

sequenced with 17.0 [14.5-18.5] million reads. Raw sequence reads were aligned to hg38 with TopHat and aligned reads processed using Picard tools and summarized by featureCounts. Differential expression analysis was performed using the edgeR package in R. Gene set enrichment analysis was performed using GSEA and the hallmark collection of gene sets. Over-represented gene sets are reported with the absolute value of the normalized enrichment score and Benjamini-Hochberg-adjusted q-value.

Results: Across all subsets, when pre-treatment samples were compared to post-treatment samples, GSEA uncovered over-representation of gene sets involved in "INTERFERON_ALPHA_RESPONSE" (2.8, $p<0.001$ for CD4; 2.8, $p<0.001$ for CD8; 3.2, $p<0.001$ for CD19; 3.3, $p<0.001$ for CD14) and "INTERFERON_GAMMA_RESPONSE" (2.6, $p<0.001$ for CD4; 2.7, $p<0.001$ for CD8; 2.6, $p<0.001$ for CD19; 3.1, $p<0.001$ for CD14). When post-treatment samples were compared to pre-treatment samples, gene sets over-represented across all subsets included "TNFA_SIGNALING_VIA_NFKB" (2.4, $p<0.001$ for CD4; 2.2, $p<0.001$ for CD8; 3.0, $p<0.001$ for CD19; 2.3, $p<0.001$ for CD14), and "HYPOXIA" (2.0, $p=0.004$ for CD4; 1.95, $p=0.002$ for CD8; 2.3, $p<0.001$ for CD19; 1.7, $p=0.016$ for CD14). Additionally, some pathways differed between cell types in over-representation either pre- or post-treatment. "IL6_JAK_STAT3_SIGNALING" was over-represented at pre-treatment in CD4 (2.1, $p<0.001$) and CD8 cells (2.1, $p<0.001$), but over-represented at post-treatment in CD19 cells. Similarly, the "COMPLEMENT" and "INFLAMMATORY RESPONSE" gene sets were over-represented pre-treatment in CD4 (1.7, $p=0.005$; and 2.0, $p=0.005$, respectively), CD8 (1.8, $p=0.005$; and 1.8, $p=0.005$, respectively) and CD14 cells (1.3, $p=0.03$; and 1.4, $p=0.02$, respectively), but over-represented at post-treatment in CD19 cells (1.4, $p=0.03$; and 1.9, $p<0.001$, respectively).

Conclusion: This study has identified several pathways that are altered during the first year of treatment of JDM. In addition to confirming involvement of the type 1 interferon pathway in active JDM disease, the purified subset approach enables identification of pathways that differ between immune subsets. Ongoing analyses are comparing pre- and post-treatment samples to age- and sex-matched healthy controls and investigating pathways associated with different clinical courses.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Children with juvenile idiopathic arthritis (JIA) are at risk for anterior uveitis which can lead to ocular complications and vision loss. The ANA is the only biomarker that guides the schedule of uveitis screening, but it is not definitive. Potential biomarkers have been identified in the serum and aqueous humor of children with JIA-associated uveitis (JIAU) and idiopathic uveitis. However, few studies have examined protein levels in the tears of children with chronic anterior idiopathic uveitis (CAU) and JIA-associated uveitis (JIAU). Tear collection is non-invasive, easily accessible and better tolerated by children. Our aim is determine if we can identify biomarkers using tear proteomics in children with anterior uveitis.

Methods: We collected tear samples from 2 pediatric female controls, 2 JIAU (oligoarticular) and 2 CAU. Children with uveitis were ≥10 years old, non-Hispanic, female, and had anterior involvement. We placed a Schirmer strip 6mm from the lateral canthus of the anesthetized eye for 2-5 minutes. Then, 50 ug of proteins were extracted for TMT labeling. The TMT pool was loaded onto an offline electrostatic repulsion interaction chromatography (ERLIC) fractionation HPLC system and 20 fractions were collected. LC-MS/MS analysis was then performed on all 20 fractions. Proteome Discoverer 2.1 (ThermoFisher Scientific, San Jose, CA) was used to search all the MS/MS spectra against a Uniprot human reference protein database (retrieved April 20, 2015; 90,411 target sequences) and TMT reporter quantitation was performed. We compared JIAU and IU to controls, and JIAU to IU using ANOVA statistics.

Results: In all, we were able to quantify 1224 unique protein groups and found 120 proteins that showed significant statistical changes. Of those differentially expressed proteins, 19 were significant across JIAU versus control and IU versus control, but not between JIAU and IU. The most significant included RAB7A ($p = 1.23E-03$), NPC2 ($p = 1.23E-02$), VPS4B ($p = 3.05E-03$), CTSS ($p = 2.02E-02$), and ASAH1 ($p = 1.19E-02$). The gene ontology showed cellular component enrichment for lytic vacuole and biological pathway enrichment for sterol transport and transmembrane receptor signaling.

Conclusion: In our pilot study, we identified proteins that may be specific to pediatric chronic anterior uveitis. Our next step is to validate in larger cohorts of children with anterior uveitis, and to compare the tear proteomic profile of children with JIA alone. Tear proteomic analysis is a promising area since tear collection is non-invasive and can be used to examine children with JIA who do not have uveitis. Discovery of biomarkers for screening and early detection of uveitis in

children with JIA will help us identify those at highest risk for ocular disease.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibodies directed against N-methyl-D-aspartate type glutamate receptor (NMDAR), voltage-gated potassium channel (VGKC) or glutamic acid decarboxylase (GAD65) are frequently associated with autoimmune encephalitis (AE) in pediatric patients. Yet, the full repertoire of the autoantibody diversity in children remains poorly defined.

Methods: Eighty-eight consecutive patient samples (59 sera and 29 CSF) received at ARUP Laboratories from Intermountain Healthcare's Primary Children's Medical Center, Salt Lake City, Utah and Texas Children's Hospital, Houston, Texas for evaluation for NMDAR (cell based assays, CBA), VGKC (radioimmunoprecipitation), or GAD65 (enzyme immunoassay) antibodies were identified over a period of 12 months. Residual volume of patient samples were evaluated on a research basis by indirect immunofluorescence technique (IIFT) using cerebellum (monkey and rat), intestine (monkey), peripheral nerve and pancreas tissue sections for neuronal nuclear, Purkinje cell cytoplasmic, myelin, non-medullated and astrocyte autoantibodies (PNS Mosaic IFFT), and an CBA for Delta notch-like epidermal growth factor-related receptor (DNER). In addition, the AE mosaic

IIFT with hippocampus (rat) tissue and CBA to detect antibodies to NMDAR, alpha-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPAR), gamma amino butyric acid type B receptor ($GABA_bR$), leucine-rich glioma inactivated 1 (LGI1), contactin associated protein-2 (CASPR-2), dipeptidyl-peptidase-like protein-6 (DPPX-6), and glycine receptor (GlyR) was utilized. This study was conducted in accordance with a University of Utah Institutional Review Board approved protocol and in compliance with ARUP policies.

Results: Samples were received from 60 unique patients including 32 females (median age 11.8; range 0-19 years) and 28 males (median age 9.0; range 0-18 years). Antibodies were detected in 30/60 patients (50%); 23 with single antibodies and 7 subjects with 2 or more antibodies. NMDAR antibody was the most prevalent (n=15) followed by GAD65 (n=7), VGKC (n=6), non-medullated (n=4), Purkinje cell (n=3), myelin (n=3), and astrocyte (n=1) antibodies. Of the 28 patients with paired serum and CSF, 16 possessed autoantibodies; 8 NMDAR-positive (7 seropositive, 8 CSF positive), and 5 GAD65- and 4 VGKC-seropositive only. Eighty percent (24/30) of the antibody-positive patients in our cohort had NMDAR, GAD65 and/or VGKC antibodies; however, a sizable number of patients possessed autoantibodies not typically associated with pediatric AE.

Conclusion: Overall, NMDAR, GAD and VGKC autoantibodies were the most prevalent antibodies detected in this two center pediatric cohort of samples analyzed at a large referral lab. Prevalence of these antibodies approximates previous reports in the pediatric literature. Additional autoantibodies targeting diverse proteins and associated neurologic functions were also detected demonstrating a need for the validation of additional markers for pediatric AE such as the Purkinje cell and nerve (i.e. non-medullated nerve and myelin) autoantibodies detected in this cohort of patients.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: STING-Associated Vasculopathy with Onset in Infancy (SAVI) is a monogenic autoinflammatory interferonopathy caused by gain-of-function mutations in *TMEM173/STING*, a nucleic acid sensor adaptor linked to IFNβ transcription. Patients (Pts.) develop acral vasculitis and variable severity of interstitial lung disease (ILD)(Liu Y, NEJM, 2014). We hypothesized that a common STING variant modulates lung disease severity, and investigated a mechanistic role of STING in ILD.

Methods: We assessed chest computed tomography (CT) and pulmonary function tests (PFTs) in 12 SAVI pts. (*N154S, V155M, V147L, V147M*); lung biopsies were available for 7 pts. DNA samples were typed for the *STING* SNP R232H, rs1131769 (Yi G, PLoSOne 2013). Transfection studies in HEK293T cells with wildtype or "SAVI mutations" constructs on the R232 and H232 haplotypes, and stimulations of pt. fibroblast and endothelial cell lines (HUVECs) were performed. *IFNB1*luciferase reporter activity was assessed upon stimulation with the endogenous: 2'3'cGAMP, or the microbial: 3'3'cGAMP, c-di-AMP and c-di-GMP, STING activators. Gene expression (q-

RT-PCR, RNA-seq), cytokine production, and endothelial-mesenchymal transition (endo-MT, by cell morphology and gene expression studies), were assessed.

Results: The presence of R232 in *cis* with the disease-causing STING mutations is associated with severe lung disease. Of 9 pts. with severe ILD, 4 pts. succumbed to pulmonary complications; all but one were homozygous for R232/R232. The pt. with no ILD was homozygous for the H232 allele (H232/H232); 2 pts. with mild ILD were heterozygous (R232/H232) for the SNP. Transfection of HEK293T cells with mutant STING on the R232 and H232 haplotypes showed increased *IFNB1* expression upon stimulation with microbial stimulants but not endogenous cGAMP; which was only significant when the SAVI mutations were on the R232 but not on the H232 haplotype. Similarly, *IFNB1*transcription in response to exogenous stimuli in fibroblasts from 4 pts. were higher in cells with R232/R232 than in cells with H232/H232 haplotype. RNA-seq of stimulated pt. and control fibroblasts showed no expression of myofibroblast and extracellular matrix (ECM) markers ruling out that STING pathway activation would induce myofibroblast-differentiation as a mechanism for pulmonary fibrosis. Trichrome stains of SAVI lung tissues (n=2) revealed localized fibrosis around the pulmonary vessels, suggesting that STING pathway activation may induce endo-MT. Endogenous cGAMP stimulation on endothelial cells induced morphologic transition to fibroblasts with increased expression of the mesenchymal marker αSMA and the pro-fibrotic markers SLUG and TWIST. EndoMT was TGFβ independent and not induced by microbial STING stimuli. However, IFNβ significantly increased the endo-MT process over 2'3'cGAMP stimulation alone.

Conclusion: The minor allele H232 of a STING SNP confers a protective role by mitigating IFNβ responses in the context of STING activating infections while the R232 haplotype accelerates endo-MT amplified by IFNβ. Our findings suggest a novel mechanism for inducing endo-MT as a cause for the development of lung fibrosis in SAVI through endogenous STING activation.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Tyrosine-protein kinase Lyn is a Src-family tyrosine kinase expressed by hematopoietic and non-hematopoietic cell types. Phosphorylation of a tyrosine residue at position 508 renders the molecule inactive. In a mouse model, amino acid modification Y508F causes severe anemia, autoimmune glomerulonephritis and positive ANA ($Lyn^{up/up}$ mice) but the human phenotype and its role in human disease remain unkonwn. We characterize the clinical phenotype and cellular function of mutant Lyn kinase in two patients with systemic inflammation and vasculitis both presenting with a *de novo* germline mutation at the regulatory tyrosine residue 508 in *LYN*.

Methods: Patients were clinically evaluated, records were reviewed, WES (Illumina HiSeq2000 platform) of the *de novo*mutations were confirmed by Sanger sequening. B and T lymphocyte and monocyte immunophenotyping were performed through flow cytometry.

Results: The *de novo* mutations in *LYN* leads to a premature stop-codon at p.Y508* which removes 5 terminal amino acid residues (pt.1) 1 and revealed the missense p.Y508F that was studied in the lyn up/up mice (pt.2). The clinical features of both patients included perinatal-onset of systemic inflammation. Patient 1 presented with hydrops fetalis, requiring an intra-utero blood transfusion and post partum, purpuric skin rash, hepatosplenomegaly, periorbital erythema and testicular pain and swelling with increased CRP. Cytopenias including anemia, and thrombocytopenia required a

splenectomy at the age of 9mo. Post-splenectomy development of chronic leukocytosis and thrombocytosis with persistent anemia and Increased liver enzymes led to a liver biopsy at age 23 mo showing a periportal lymphocytic infiltrate, vanishing bile duct disease and evidence of periportal bridging fibrosis. A skin biopsy confirmed neutrophilic small vessel vasculitis and low titer circulating autoantibodies (positive ANA, anti-Sm, anti-SSA, anti-phospholipids and anti-mitochondrial antibodies). Initiation of prednisone and IVIG infusions led to some improvement but prednisone could not be weaned. Pt. B lymphocytes showed constitutive phosphorylation of Lyn and a significantly diminished frequency of immature B cell populations in peripheral blood and in bone marrow. Reduced B cell activation in response to IgM stimulation compared to healthy controls was observed. The tyrosine kinase inhibitor dasatinib normalized lyn phosphorylation in pt B cells and was initiated with significant clinical and laboratory response. Patient 2 presented with a generalized purpuric skin rash and recurrent episodes of fevers since his first hours of life. Other symptoms included abdominal and testicular pain, headaches, conjunctival erythema, arthralgias, oral ulcers and fatigue. The recurrent symptoms have responded to short courses of oral steroids. He had a partial response to colchicine, no response to anakinra and tocilizumab and was recently started on etanercept.

Conclusion: We identified activating mutations in Lyn kinase gene (*LYN*) as cause for a novel immunedysregulatory syndrome presenting with neonatal-onset of fever, small vessel neutrophilic vasculitis and systemic inflammation.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: We recently described two rare autoinflammatory interferonopathies, STING Associated Vasculopathy with Onset in Infancy (SAVI) and Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated temperature (CANDLE), caused by mutations in *TMEM173/STING* and in proteasome components, respectively which present with systemic inflammation and a strong IFN response gene signature. However the cellular source for Type I IFN remains unknown.

Methods: The cellular origin of Type I IFN was assessed in FACS sorted PBMCs (T, B, NK and monocytes) from SAVI (n=5) and CANDLE (n=6) patients compared to healthy controls (HC), and from lesional skin biopsies, n=3 for SAVI and for CANDLE. Type I IFN transcription and production and cell activation status were evaluated. Most CANDLE and SAVI pts were on JAK inhibitor treatment.

Results: Serum IFNa levels were increased in SAVI and CANDLE compared to HCs, IFNb is not reliably measured. SAVI pts' monocytes had 481-fold [IQR 56-38,242] increased *IFNB1* expression compared to HCs and CANDLE pts. However, during a CANDLE disease flare, monocyte *IFNB1* transcription increased 4 and 51 fold. *IFNA7/IFNA17* is constitutively 60 fold increased [IQR3-116] in SAVI but not in CANDLE. Monocyte depletion reduced the IFN message by 90% in the monocyte of PBMC/neutrophil fractions in SAVI pts., pointing to the presence of monocytes in the neutrophil fraction. Intracellular IFNa staining of monocytes confirmed that monocytes and not dendritic cells are the main source of IFNs for SAVI. The mean ratio of *IFNB1* to *IFNA7/17* was 1200:1 in SAVI and 1:1 in CANDLE monocytes. STING pathway activation with cGAMP in the presence of a blocker of translational elongation, cycloheximide (CHX), did not block *IFNB1* transcription but blocked *IFNA1,2,7,17,21* thus confirming constitutive *IFNB1* transcription. A left-shift with a 2.3 and 1.5-fold increase of immature CD13lo CD16+ neutrophils in CANDLE and SAVI compared to HC was seen. Activation markers CD36+, CD64, were 87%, 65% on monocytes, and 26.1%, 60.3% on granulocytes in SAVI and CANDLE respectively, (HC 0.22%-5.32%). Morphologically, CANDLE monocytes had the highest content of cytoplasmic vacuoles with 6.4+/-2.1SD vacuoles/cell (V/C) compared to SAVI 3.5+/-2.5SD V/C ($p>0.05$) and HC 2.2+/-1.2SD V/C ($p<0.004$). CXCL10/IP-10 serum levels are equally high in CANDLE and SAVI patients and nanostring IP-10 counts were similar in CANDLE and SAVI (314+/-63SEM and 357+/-66SEM p=0.0007), (HC 91+/-14SEM, $p<0.05$); in skin IP-10 levels were 30-400 fold

increased in CANDLE (81,803+/-28,605SEM) than SAVI (28,443+/-20,439SEM, compared to HC (28+/-20SEM, p>0.05).

Conclusion: In conclusion, the source for production of Type I IFNs varies in CANDLE and SAVI with constitutive transcription of *IFNB1* in predominantly monocytes in the blood in SAVI pts. In CANDLE and SAVI lesional skin showed similar elevated transcription in *IFNAs*, and higher levels for *IFNB1* in SAVI. IP-10 levels were highest in CANDLE skin samples. Understanding differences in intracellular signaling pathways activating IFN production and the IFN loop is needed to design targeted treatment approaches for the different interferonopathies.

Session Title: Pediatric Rheumatology – Pathogenesis and Genetics - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Animal and human data suggest that IFNγ plays a pathogenic role in HLH. A phase 2 trial with the anti-IFNγ monoclonal antibody NI-0501 in primary HLH provides encouraging preliminary data. Gain-of-function mutations in *NLRC4* are associated with a distinct autoinflammatory syndrome, with recurrent HLH, fever episodes and enterocolitis.

Methods: We reported a patient with severe early onset progressive HLH carrying a *de novo* missense mutation in *NLRC4*(T337N), the immune abnormalities leading to abnormal production of IFNγ and the response to treatment with NI-0501. We evaluated cytokine levels by multiplex assay and by specific ELISAs and expression of IFNγ in freshly isolated PBMCs by cytometry.

Results: LR, caucasian male, presented, at 20 days of age, fever and rash and progressively developed clinical and laboratory features of HLH leading rapidly to liver failure and subsequent multiorgan failure. Genes causing primary-HLH and functional tests were negative. High-dose glucocorticoids and cyclosporine-A led to partial improvement. Development of sepsis triggered HLH reactivation. Measurable IFNγ levels (6pg/ml) and high levels of the IFNγ inducible chemokines CXCL9 (5670pg/ml) and CXCL10 (4400pg/ml) were found, the latter demonstrating activation of the IFNγ pathway. NI-0501 was started (compassionate use) on background of dexamethasone (13.6mg/m2) and cyclosporine-A. After 3 months, the child was discharged in excellent conditions (prednisone 0.3 mg/kg). Markedly elevated production of IFNγ was revealed by the administration of NI-0501 through measurement of total IFNγ bound to circulating NI-0501. This IFNγ was fully neutralized, as shown by rapidly undetectable levels of CXCL9 and CXCL10. The percentage of CD4+, CD8+ and CD56+ cells expressing IFNγ was significantly increased in the NLRC4 patient without (0.95%, 0.88%, 0.80%, respectively) and with stimulation with PMA/ionomycin (6.44%, 10.20%, 25,00%). Serum levels of IL-18 were markedly higher (as expected in NLRC4-mediated disease) at >300 ng/ml before treatment and remained elevated throughout treatment (ranging between 25 and 35 ng/ml), with the patient showing no symptoms. Incubation of PBMCs from healthy controls with NLRC4 patient's sera in the presence of IL-12 (known costimulus for IFNγ synthesis) led to a marked hyperproduction of IFNγ (>20ng/ml), compared to sera from patients with other autoinflammatory diseases (0.59±0.47 ng/ml). This increase in IFNγ production was neutralized by incubation with an anti-IL18 receptor antibody. After 7 months of NI-0501 treatment, all therapies, including NI-0501, were discontinued, without any clinical or laboratory sign of HLH reactivation, even in the presence of occasional increases in IL-18 levels.

Conclusion: Our data suggest that in NLRC4-related disease overproduction of IL-18, induced by an hyperfunctional NLRC4 inflammasome, may be one of the contributors to the up-regulation of IFNγ production that appears to be driving HLH. In this patient, neutralization of IFNγ allowed control of all disease features, enabling withdrawal of all treatments, including glucocorticoid and cyclosporyn-A. No safety concern emerged. C.B. and G.P. contributed equally to this study

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Data suggest that hydroxychloroquine (HCQ) use during systemic lupus erythematosus (SLE) pregnancies improves outcomes. In the past decade, single-center studies report that a high percentage of patients receive HCQ during pregnancy, yet HCQ use at a population level has not been studied. Therefore, we sought to describe time-trends in the use of HCQ in a large population-based cohort of pregnant women with SLE.

Methods : A cohort of pregnant women with SLE enrolled continuously in public (Medicaid, 2001-2010) or private (United Healthcare, 2004-2012) health insurance between three months prior to conception and one month after delivery was identified. Included patients were stratified based on their use of HCQ in the 3-month period immediately prior to pregnancy. Among women with SLE not using HCQ prior to pregnancy, we assessed the proportion initiating HCQ during pregnancy each calendar year. For women using HCQ prior to pregnancy, we calculated the proportion of women continuing HCQ during pregnancy each calendar year. Further, we described time-trends in the cumulative day-supply of HCQ prescriptions dispensed during pregnancy as a measure of the duration of HCQ use. Linear trend tests were conducted for proportions and total day-supply over the study years for both groups.

Results : A total of 4,904 women with diagnosis of SLE who became pregnant were included. Of those, 739 (15.1%) were on HCQ treatment in the 3-month period immediately prior to their pregnancy. The proportion of women initiating HCQ during pregnancy increased from 2.7% in 2001 to 11.3% in 2012 ($p<0.0001$, **Figure 1**) and the proportion of women continuing HCQ increased from 63.7% in 2001 to 83.8% in 2012 ($p=0.06$, **Figure 2**). Among women initiating HCQ, the

average cumulative day-supply of HCQ prescriptions during pregnancy increased from 37 days in 2001 to 117 days in 2012 ($p<0.01$). Similarly, among women continuing HCQ treatment, the average cumulative day-supply of HCQ prescriptions during pregnancy increased from 79 days in 2001 to 172 days in 2012 ($p<0.0001$).

Conclusion: The proportion of women with SLE initiating or continuing HCQ during pregnancy increased from 2001 to 2012. Similarly, average cumulative day-supply of HCQ prescription increased during the same time frame. While these findings are encouraging, overall HCQ use during pregnancy remains low and is a potential area for clinical intervention.

COUNSELING ON FAMILY PLANNING AND CONTRACEPTION, AND PREGNANCY OUTCOME IN WOMEN WITH RHEUMATIC DISEASES: ANALYSIS OF 398 PATIENT-REPORTED QUESTIONNAIRES FROM A MULTICENTER ITALIAN STUDY

Background/Purpose: Rheumatic diseases (RD) predominantly affect young women during reproductive age. Pregnancy, contraception and family planning are crucial for the quality of life of these patients. We aimed at investigating 'women's health' issues through a self-reported questionnaire. Answers from patients with connective tissue diseases (CTD) vs. chronic arthritis (CA) were compared.

Methods: 24 Italian participating centers distributed a self-reported questionnaire (65 multiple-choice and 12 open-answer questions) to women with RD (> 18years).

Results: Answers were collected from 279 CTD and 163 CA; the mean age at diagnosis was 31.6 and 30.6 years respectively. Subsequent analysis was performed on 249 CTD vs. 149 CA. Patients who developed a RD after 45 years old were excluded from this analysis.

Nearly 40% of all patients declared that RD influenced their desire to have children: about 55% of them reduced the number of children they wanted (Table 1). In particular 39% CA vs.29%CTD declared to be afraid of being mother because of their disability.

24% CTD vs. 18% CA had at least one miscarriage; 21% CTD vs. 2% CA had more than one miscarriage.

31% CTD and 34% CA were never asked by their rheumatologist about the desire to have children. 61% CTD vs.70% CA received counseling about contraception, given by a gynecologist (58% vs. 64%), rheumatologist (22% vs. 14%), or both (7% vs. 9%).

About 60% in both groups received a counseling before pregnancy: 34% vs. 39% of them from both rheumatologist and gynecologists, 14% vs. 22% only by rheumatologist. The counseling positively changed the family planning in 64% and 59% respectively.

About 50% of all patients had no knowledge about the use of immunosuppressive drugs during pregnancy. About 40% of patients who were in menopause declared that it started before 45 years of age.

Conclusion: This survey suggested that CTD have a major impact on reproductive planning and restriction of family size, possibly mediated by the reported increased rate of miscarriages as compared to CA. The concerns about reproductive issues could be positively overcome by adequate counseling.

Rheumatologists should implement the discussion about family planning and the compatibility of drugs with pregnancy in the management of young women with RD. This is particulary relevant in CTD patients in whom contraception and pregnancy have particular implications.

Early menopause appears to be a relevant issue in women with RD.

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE mothers are known to have higher rates of pre-term birth and low birth weight compared to women in the general population. We evaluated birth outcomes in women with systemic lupus erythematosus (SLE) before and after developing disease on a population level.

Methods: The Georgia Lupus Registry (GLR) is a population-based registry of SLE patients living in Atlanta, GA from 2002-04. Patients were validated by meeting ³4 ACR criteria or 3 ACR criteria with a final diagnosis of SLE by a board certified rheumatologist and were matched to the Georgia Birth Records database (1994-2013), which provided various information on the births. Births were dichotomized into 2 periods, one before lupus activity began (ÒPreLupusÓ) and the other after (ÒPostLupusÓ), and compared. In order to take into account subclinical and/or significant immunologic activity just prior to being diagnosed with SLE, the time point separating the periods was made to be 1 year prior to the physician diagnosis date.

Results: 345 total patients were incident in 2002-04. 87% were women and 73% were black. A total of 77 births in the PreLupus period and 247 in the PostLupus period were observed. Among incident SLE mothers, there were significant increases in pre-term births from 18.7% in the PreLupus period to 44.8% in the PostLupus period, number of low birth weight births from 20.8% to 55.2%, and number of births with low APGAR scores from 6.2% to 41.4%. There was a trend to increasing number of previous terminations from 25% to 33.3%. 1,446 patients were prevalent in 2002. 89.9% were women and 75.7% were black. Only low birth weight changed significantly from 14.7% in the PreLupus period to 30.1% in the PostLupus Period. There was generally good reported prenatal care and frequency of care and little, if any, reported alcohol or tobacco use during pregnancy on the birth certificates.

Conclusion: This is the first population-based description of birth outcomes in SLE in the US. The ratio of births to mothers in the PreLupus compared to the PostLupus periods predictably goes down but not dramatically, demonstrating reproductive capacity and resolve in these patients. Our study supports previous observations of more frequent rates of adverse birth outcomes in those with SLE. Pre-term birth, low birth weight, and low APGAR scores are significantly more frequent, particularly in incident SLE patients. More study is needed to better understand the impact of SLE on birth outcomes in order to guide patients interested in reproduction.

Birth Outcomes By Incident and Prevalent (prevalence in 2004, incidence in 2002-04)

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Women with SLE and RA have an increased risk of delivering a preterm infant. However, the causes of these preterm births remain unknown. Some theories suggest that maternal inflammation induces preterm labor and/or rupture of membranes. We sought to identify what prompted each preterm delivery, as well as the mode of delivery among a cohort of patients with SLE and RA.

Methods: SLE patients meeting ACR and/or SLICC criteria and RA patients meeting ACR criteria were prospectively followed in a pregnancy registry. Pregnancy outcomes were collected from the patient and medical records. Preterm birth was defined as a birth <37 weeks gestation. Only

singleton live births with a visit prior to 25 weeks gestation and data available on mode of delivery were included. At our institution, pregnancies in women with rheumatic diseases are routinely induced at 39 weeks for delivery, regardless of maternal complications. Differences between term and preterm births were determined by Fisher's exact test.

Results: Among 82 SLE live births, 46% of mothers were white and 46% were black, with a median maternal age of 30 years. Among 45 RA live births, 78% of mothers were white, with a median maternal age of 35 years. There were 20 preterm births (24%) among SLE pregnancies and 7 preterm births (16%) among RA pregnancies. While only 30% of preterm SLE births were spontaneous, 71% of preterm RA births were spontaneous. The frequency of C-section was greater in patients who had induced compared to spontaneous labor (65% vs. 24%, respectively, for SLE and 52% vs. 8%, respectively, for RA). Among SLE patients, preeclampsia and concern over the health of the mother were the primary drivers behind induced preterm labor and preterm C-sections (Table 1). Preeclampsia was diagnosed in 35% of preterm deliveries compared to 8% of term deliveries ($p=0.002$). Labor was induced in 70% of preterm births and 55% of term births. The reason for induction differed, however, with 64% of preterm births induced for maternal preeclampsia/hypertension compared to 15% of induced term births ($p=0.001$). In contrast, among women with RA, C-sections and preterm birth were both less frequent than in SLE, and labor was more often spontaneous. Half of term deliveries were induced, primarily for gestational age, although 21% of term births were induced due to maternal preeclampsia/hypertension and 16% were induced because the infant was not well.

Conclusion: Spontaneous preterm labor does not appear to be driving the high preterm birth rate among women with lupus. Instead, physician-directed labor induction to manage the risks of preeclampsia, placental insufficiency, and lupus activity prompts the majority of preterm births. These results suggest future research attention should focus on placental dysfunction and away from causes of spontaneous preterm labor.

Increased Risk of Postpartum Depression in SLE Pregnancies

Evelyne Vinet[1], Susan Scott[2], Debbie Ehrmann Feldman[3], Christian A. Pineau[4] and Sasha Bernatsky[2], [1]Divisions of Rheumatology and Clinical Epidemiology, McGill University Health Centre, Montreal, QC, Canada, [2]Clinical Epidemiology, Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [3]School of Rehabilitation, Université de Montréal, Montreal, QC, Canada, [4]McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic diseases have been shown to be a strong risk factor for postpartum depression. Although there is a 2-fold increased risk of major depression in SLE, the risk of postpartum depression in mothers with SLE is unknown. Within a large population-based cohort, we evaluated the risk of postpartum depression in women with SLE compared to unaffected women and explored potential mediators of postpartum depression in SLE pregnancies.

Methods: The "Offspring of SLE mothers Registry (OSLER)" includes all women who had ≥1 hospitalization for delivery after SLE diagnosis, identified through Quebec's universal healthcare databases (1989-2009). OSLER also includes a randomly selected control group of women, matched at least 4:1 for age and year of delivery, without an SLE diagnosis prior up to the time of delivery. We ascertained postpartum depression based on ≥1 hospitalization or physician visit with relevant diagnostic codes, within the first 12 months after delivery. We performed multivariate analyses to adjust for maternal education, race/ethnicity, and pre-existing mood disorders in the 2 years prior to delivery. In secondary analyses, we further adjusted for pregnancy complications, including preterm birth, gestational diabetes, and stillbirth, to explore potential mediators of postpartum depression in SLE pregnancies.

Results: 509 women with SLE had 729 births, while 5824 matched controls had 8541 births. We identified postpartum depression in 11.0% (95% CI 8.8, 13.5) of SLE pregnancies versus 8.3% (95% CI 7.7, 8.9) of unexposed pregnancies. More SLE pregnancies were preceded by a mood disorder in the 2 years prior to delivery as opposed to unexposed pregnancies [15.4% (95% CI 12.9, 18.2) vs 11.0% (95% CI 10.2, 11.5)]. In primary multivariate analysis, accounting notably for pre-existing mood disorders, SLE pregnancies were at increased risk of postpartum depression versus unexposed pregnancies [OR 1.32 (95% CI 1.01, 1.73)]. The effect estimate for SLE was attenuated when we further adjusted for pregnancy complications [OR 1.20 (95% CI 0.92, 1.58)]. Preterm birth [OR 1.55 (95% CI 1.20, 2.00)] and stillbirth [OR 6.49 (95% CI 3.32, 12.67)] were independent predictors of postpartum depression. Pre-existing mood disorders in the 2 years prior to delivery also was an independent predictor of postpartum depression in both primary and secondary multivariate analyses [OR for primary analysis 4.44 (95% CI 3.73, 5.29)].

Conclusion: Compared to women from the general population, women with SLE have an increased risk of postpartum depression. Mediators of postpartum depression in SLE potentially include pregnancy complications, such as preterm birth and stillbirth. Further research is needed to evaluate the role of disease activity and/or flare during pregnancy, as well as medication exposures on the risk of postpartum depression in SLE.

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pregnancies in women with systemic lupus erythematosus (SLE) are associated with increased frequencies of adverse pregnancy outcomes (APOs). Preconception counseling including risk stratification and adjustment of medication is strongly recommended by EULAR[1]. However, a considerable number of women with SLE do not seek such advice before conception. Our aim was to assess the impact of pregnancy counseling prior to conception on the outcome of pregnancies in women with SLE referred to our lupus pregnancy clinic (2000-2015).

Methods: All pregnancies in women with SLE who received an individual pregnancy counseling prior to conception were prospectively followed during pregnancy and postpartum period according to a standard protocol (group A). Outcome of these pregnancies was compared to pregnancies in women with SLE who were already pregnant by the time of their first appointment in our clinic (group B). APOs were defined as fetal loss (spontaneous abortion or stillbirth), severe pregnancy disorders (preeclampsia, HELLP-syndrome), birth before 36 weeks (due to placental insufficiency, hypertension, or preeclampsia) and low birth weight (< 2500 g). Systemic Lupus Erythematosus Pregnancy Disease Activity Index (SLEPDAI) was used to gauge disease activity during pregnancy.

Results: A total of 188 pregnancies in 151 women with SLE (median age 31 years) were included (group A = 137; group B = 51). 67 % of all women had been pregnant before, 33 % had experienced at least one fetal loss and 9 % severe pregnancy disorders. With respect to all pregnancies, a live birth was documented in 172 (91.5 %) [group A 94.2% vs group B 86.3 %)]. A fetal loss occurred in 16 (8.5 %) pregnancies [group A 5.8 % vs. group B 15.7 %). Twenty-three (12.2%) of all pregnancies were complicated by severe pregnancy disorders (group A 5.8 % vs group B 29.4 %)

and 28 (14.9 %) by preterm birth (group A 7.3 %; group B 35.3 %). One newborn (group B) died shortly after extreme preterm birth. After adjusting for maternal age and for higher disease activity in the first trimester (SLEPDAI ≥ 4) we observed significantly higher rates of fetal losses (RR = 3.4; 95%CI 1.4-8.6), severe pregnancy disorders (RR = 5.5; 95%CI 2.5 – 12.1), preterm birth (RR = 5.6; 95%CI 2.8 – 11.2) and low birth weight (RR = 3.2; 95%CI 1.9 – 5.4) in group B compared to group A.

Conclusion: The main prognostic risk factor for adverse outcomes in our observational cohort of 188 SLE-pregnancies was the lack of preconception counseling. These patients had significant higher risks of fetal loss, preterm birth, low birth weight and severe pregnancy disorders. Though our observed live birth rate was considerable high in both groups, probably due to an adapted multidisciplinary management during the course of pregnancy, consultation before conception was still associated with higher live birth rates (94,2 vs. 86,3%). Women with SLE and pregnancy wish should be informed about the obvious beneficial effect of preconception counseling. [1]Andreoli L. "EULAR recommendations for women's health and the management of family planning, assisted reproduction, pregnancy, and menopause in patients with Systemic Lupus Erythematosus and/or the Antiphospholipid Syndrome." Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: There is limited evidence on the safety of treatment during pregnancy and lactation. With the increasing number of new therapeutic options for inflammatory rheumatic diseases, there is a growing need for real-life data. Prospective randomized studies are not conducted in women who are pregnant or wish to conceive. The purpose of our register is to determine the safety of various drug treatments during pregnancy and the influence of the underlying rheumatic disease on pregnancy outcome and child development.

Methods: The Rhekiss register is designed as a web-based nationwide cohort study. Pregnant patients with confirmed diagnosis of inflammatory rheumatic disease are enrolled until the 20th week of pregnancy regardless of treatment. Rheumatologists and patients report each trimester during pregnancy and semi-annually after birth until the child's 2nd birthday. Information on all given drug treatments, the course of the maternal disease, maternal or fetal complications during pregnancy, pregnancy outcomes and child development are collected. At first visit sociodemographic parameters, prior pregnancies, and comorbidities are reported. Only pseudonymized data are used, data security issues conform with regulatory authorities have been implemented.

Results: The register started on 15th of September 2015. Until end of May 2016, 84 rheumatologists recruited 200 pregnant women. We report first data of 182 patients. Of these, 28% had rheumatoid arthritis (RA), 23% systemic lupus erythematosus, 19% other connective tissue diseases, 18% spondyloarthritis or psoriatic arthritis, 6% juvenile idiopathic arthritis (JIA), 4% autoinflammatory diseases and 2% systemic vasculitis. Mean age of all patients was 32.5 (± 4.6) years, mean disease duration 8.3 (± 7.5) years. Mean disease activity over all diagnoses assessed by the rheumatologist on a numeric rating scale from 0-10, was 2.3 (± 2.1). On a disease severity scale ranging from 1 to 5 (highest grade), two thirds of all patients were reported grade 2 or 3. With respect to the different underlying diseases up to 60 % received treatment with biological DMARDs within 12 months before first visit, mainly patients with RA or JIA. One quarter of these patients continued biological DMARDs at least until conception.

Conclusion: The German pregnancy register Rhekiss was initiated to fill the knowledge gap on the course and outcomes of pregnancies in patients with rheumatic diseases as well as on the current use and safety of treatments during pregnancy and lactation. The fast uptake of patients shows that there is a substantial need for and a high interest in real-life data to guide treatment decisions

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

<>

Background/Purpose: Rheumatoid arthritis (RA) has been reported to improve during 50-60% of pregnancies. In this study, we evaluated RA disease activity during pregnancy and pregnancy outcomes in a longitudinal registry. <> <>

Methods: We identified women enrolled in a single-center, prospective RA registry at a large academic medical center, 2003-2015, who reported being pregnant on a semi-annual registry questionnaire. We performed a detailed electronic medical record review to identify occurrence of RA flares during each of three trimesters and up to three months post-partum, based on clinical documentation by the treating rheumatologist. Medication use was recorded during each trimester, and medication changes at the time of flare were recorded. The medical record was also reviewed for use of assistive reproductive technology (ART, including *in vitro* fertilization and ovulation stimulation), pregnancy outcomes, infant outcomes, and maternal complications. Pregnancy outcomes were categorized as live birth, elective termination, miscarriage (<12 weeks or 12-20 weeks gestation), or stillbirth (≥20 weeks gestation). <> <>

Results: 45 pregnancies occurred among 34 women with mean age 33.6 (SD 4.7) and mean RA disease duration 7.3 (SD 4.9) years at conception. 88.9% were White and 69.9% were seropositive (RF and/or anti-CCP). 39 (86.7%) pregnancies resulted in a live birth. Flares occurred in 26.7% of pregnancies; these were equally distributed among trimesters (Figure). Post-partum flare was documented after 56.4% of pregnancies that resulted in a live birth. Six (13.3%) pregnancies were the result of ART. There was one tubal pregnancy requiring elective termination. Five (11.1%) pregnancies resulted in miscarriage, all of which occurred at <12 weeks gestation; no stillbirths were documented. Among live births, one pair of twins required intensive care; no other adverse outcomes were documented. Maternal complications included gestational diabetes in two women, pre-eclampsia in one woman, and hemolysis with low platelets and elevated liver enzymes in one woman. <> <>

Conclusion: The majority of patients did not flare during pregnancy, but most flared within three

months post-partum. The majority of pregnancy outcomes were favorable in this prospective RA registry at an academic medical center.

Use of Nonsteroidal Anti-inflammatory Drugs in Pregnant Women with Inflammatory Arthritis

Background/Purpose: Nonsteroidal anti-inflammatory drugs (NSAIDs) are generally contraindicated in the third trimester of pregnancy due to concerns for potential maternal or fetal complications. However, data are limited on NSAID use in pregnant women with inflammatory arthritis. The objective of our study was to describe the prevalence of NSAID use in pregnant women in this population and to explore associations between NSAIDs and selected adverse fetal or pregnancy outcomes

Methods: The sample was selected from the Organization of Teratology Information Specialists (OTIS) Autoimmune Diseases in Pregnancy project, a North American prospective cohort study of pregnant women. Women with singleton, live births (enrolled 2005-2015) who had rheumatoid arthritis, psoriatic arthritis, or ankylosing spondylitis were selected. NSAID exposure was captured through interviews; outcomes were obtained from interviews and medical records. ÒExposedÓ women were defined as those with any NSAID use in pregnancy. Women who reported no NSAID use were classified as ÒunexposedÓ. The primary outcome was prevalence of NSAID use in pregnancy. We also examined the incidence of premature closure of ductus arteriosus, patent ductus arteriosus, persistent pulmonary hypertension, intracranial hemorrhage, small for gestational age infants, preterm birth and postpartum hemorrhage in the exposed compared to the unexposed.

Results: A total of 855 pregnant women with inflammatory arthritis were included, of which 294 (34%) reported NSAID use at some time during pregnancy. The most commonly utilized NSAIDs were ibuprofen (39%), aspirin (30%), naproxen (17%), and celecoxib (14%). The prevalence of use was highest in the first trimester (88%), and decreased thereafter (46% second trimester, 31% third trimester). Among those who reported NSAID use in the third trimester (n=92), the mean cumulative days of use was 53.89±30.90 days, with average gestational age at cessation of use being 38.09±1.95 weeks. There was no evidence of an increased risk for any of the outcomes

studied except for maternal hypertension associated with 3rd trimester NSAID use (aRR 2.13, 95% CI 1.18,3.59) (Tables 1 and 2).

Conclusion: NSAID use in this cohort was common with almost one third of the women using this class of medication in the third trimester. Although the sample size was limited, we did not find evidence of increased risk for most of the evaluated outcomes. Additional studies are needed to determine whether NSAID use in the third trimester is associated with increased risk of gestational hypertension/pre-eclampsia.

Table 1. Fetal and Maternal Outcomes among NSAID Exposed and Unexposed

		Anytime during Pregnancy		**3rd Trimester Use**	
	NSAID Unexposed (n=561)	NSAID Exposed (n = 294)	RR	NSAID Exposed (n=94)	RR
Patent ductus arteriosus	5	3	1.14 (0.24,4.63)	2	2.44 (0.35,11.14)
Intracranial hemorrhage	1	3	5.72 (0.74,1.15)	1	6.10 (0.24,155.33)
Postpartum hemorrhage	31	14	0.85 (0.44,1.53)	6	1.15 (0.44,2.48)

Pregnancy Comorbidities and Outcomes in Psoriasis and Psoriatic Arthritis: A Prospective Cohort Study

Background/Purpose: While there is some evidence that women with psoriasis (Pso) and psoriatic arthritis (PsA) are at increased risk of various comorbidities, this has not been well described in pregnancy. In addition, there are limited data on the risks of adverse pregnancy outcomes in women with these conditions.

Methods: Individuals were selected (enrolled 2005-2015) from the Organization of Teratology Information Specialists (OTIS) Autoimmune Diseases in Pregnancy project, a North American prospective cohort study of pregnancy outcome. The ÒexposedÓ were defined as women with singleton live births and PsA (with or without Pso) or psoriasis (Pso) alone. ÒUnexposedÓ were non-diseased pregnant women without exposure to known human teratogens or underlying chronic conditions. The outcomes of interest were baseline differences among the three groups (PsA, Pso, unexposed) and maternal comorbidities. As a secondary objective, we compared selected adverse birth outcomes in the exposed (PsA/Pso) and unexposed groups.

Results: A total of 180 exposed women were identified (91 with PsA and 89 with Pso alone). These were compared to 379 non-diseased unexposed women. Except for greater use of biologics in women with PsA, there were no baseline differences between women with PsA and Pso. However, compared to the unexposed group, the PsA/Pso women had a higher prevalence of unplanned pregnancies, pre-pregnancy overweight or obesity, smoking, and illicit drug use. Moreover, compared to the unexposed, Pso/PsA women had higher rates of pre-existing depression (19.4% vs. 9.4%) and hypertension (6.7% vs. 2.1%) (Table 1). In terms of pregnancy outcomes, there were no differences comparing women with PsA to those with Pso. However, pregnant women with either PsA or Pso were at increased risk for cesarean section (RR 1.42 (95% CI 1.10,1.83)) and preterm birth (RR 1.81 (95% CI 1.02,3.23)) compared to the unexposed (Table 2). There was no increased risk for preeclampsia/pregnancy-induced hypertension or small for gestational age infants in exposed.

Conclusion: In this prospective study, pregnant women with PsA (with or without Pso) and Pso alone were similar in their baseline demographics, comorbidities and frequency of adverse pregnancy outcomes. However, compared to healthy controls, PsA/Pso women had more risk factors for adverse pregnancy outcomes (tobacco use, increased pre-pregnancy BMI, and pre-existing depression and hypertension). After adjusting for covariates, PsA/Pso women had increased risks for cesarean section delivery and preterm birth compared to healthy controls.

Table 1. Baseline characteristics in PsA/Pso exposed compared to unexposed pregnant women			
Characteristic – mean (SD) or n (%)	Exposed (N=180)	Unexposed (N=379)	P value
Maternal Age, years	32.29 (4.52)	31.80 (4.86)	0.26

Effects of Disease Activity and Drug Exposure on Pregnancy Outcomes with Inflammatory Arthritis

Emily Fishman[1], Kathryn H. Dao[2] and John J. Cush[3], [1]Texas A&M HSC College of Medicine, Dallas, TX, [2]Texas Health, Dallas, TX, [3]Baylor Research Institute, Dallas, TX
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Reproductive Issues in Rheumatic Disorders - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Pregnancy is often encountered in women who have inflammatory arthritis (IA), such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), juvenile arthritis (JIA) or ankylosing spondylitis (AS). While patients often forego medications during pregnancy due to safety concerns, rheumatologists often are reluctant to start antirheumatic therapy or maintain tight control of disease activity during pregnancy. Uncertainty exists as to the best practice to achieve optimal pregnancy outcomes. Our goals were to evaluate the effects of disease activity and medication exposure on pregnant patients with IA.

Methods: A retrospective, observational cohort study was carried out at one center, enrolling females aged 18-45 years, diagnosed with RA, JIA, AS or PsA who had: 1) >12 months follow-up and a documented pregnancy in this period; and 2) clinic visits that qualified as being preconception (PRE), pregnancy (1^{st}, 2^{nd} or 3^{rd} trimester) and post-partum. Drug exposure was classified as occurring PRE (>1 month before conception), at risk (RISK- 1^{st} trimester plus 1 month preconception) or during 1^{st}, 2^{nd} and 3^{rd}trimesters of pregnancy (PREG). Data collected included therapies (DMARDS, biologics, steroids, NSAIDS), modified health assessment questionnaire (mHAQ), tender joint count (TJC), swollen joint count (SJC), pain score, and global arthritis score (GAS). GAS was the sum of TJC (0-28) + pt. pain (0-10) + mHAQ (0-24); and remission (REM) <3; low activity 3-7; moderate activity 8-19; high activity >20 Maternal disease activity was further classified as flared or improved (defined: 20% change in TJC+SJC or >3 increase in joint count if PRE count <2). Fetal outcomes were classified as live births or adverse fetal outcomes (AFO: defined as preterm labor, miscarriages, preeclampsia, fetal growth restrictions, or malformations). A $\chi 2$ test of homogeneity was calculated to determine if AFOs were more likely a result of drug exposure or maternal disease activity during pregnancy.

Results: 28 pregnancies (9 RA, 7 PsA, 4 AS, 8 JIA) were observed in 22 patients (8 RA, 6 PsA, 3 AS, 5 JIA). Mean age at delivery was 32 years and disease duration was 10.4 yrs. During PRE the most common drugs used were TNFi (61%), methotrexate (18%), other DMARDS (11%), other

Biologics (11%), Prednisone (21%), and NSAIDs (79%). Drug use during PREG: TNFi (57% same), DMARDS (14% same), Prednisone (21% same), NSAIDs (32% less) and no drugs (14% more). Of the 11 PRE patients in REM, 7/11 stayed in REM or LDAS during PREG; 4/11 were in MDAS or HDAS during PREG. Of the 17 PRE patients with GAS >4, only 4/17 improved to REM or stayed in LDAS during PREG; 13/17 were in MDAS or HDAS during PREG. There were 4 AFOs (2 preterm, 2 miscarriage), but no malformations. The 4 AFOs occurred in women with moderate/high disease activity during pregnancy, and none of the women in remission or low disease activity states had an AFO. There was no significant correlation between the different drug therapies and AFOs (p=0.95).

Conclusion: These observational data showed that adverse fetal outcomes were best avoided by being in REM or LDAS and that AFOs are more likely to be related to disease activity and not drug exposure.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Reproductive Issues in Rheumatic Disorders - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

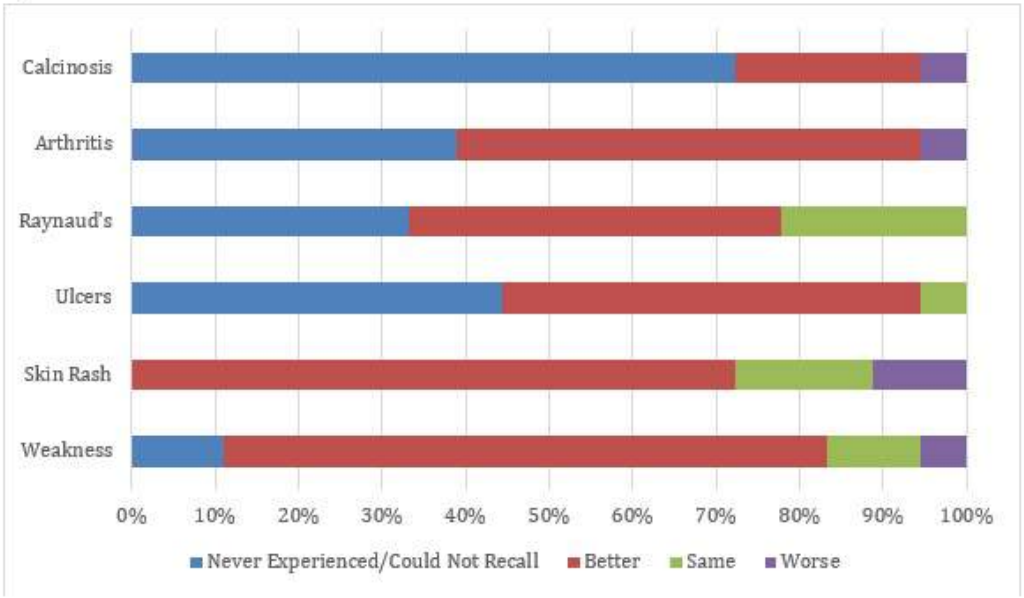
Background/Purpose: The effect of pregnancy on Dermatomyositis (DM) disease activity and on

maternal and fetal outcomes in patients with DM is unclear**.** Study objective is to evaluate disease activity and pregnancy outcomes complicated by maternal dermatomyositis.

Methods: A total of 10 patients with 21 pregnancies from a cohort of 438 DM patients of child-bearing potential, diagnosed between 2006 and 2015 from two centers, were eligible for interview with a specific questionnaire regarding pregnancy and fetal outcomes.

Results: Weakness, rash and arthritis were the most common clinical symptoms that improved during pregnancy in affected patients (Figure 1). In 16 out of 18 pregnancies, patients experienced weakness. Weakness improved during 13 pregnancies (81.3%), stayed the same during 2 pregnancies (12.5%), and worsened during one (6.3%). All 10 patients experienced cutaneous rash during all 18 pregnancies carried to live birth. Cutaneous rash improved during 13 pregnancies (72.2%), remain unchanged during 3 (16.7%), and worsened during 2 (11.1%). Five patients experienced arthralgias or arthritis in a total of 11 pregnancies. Symptoms improved during 10 of these pregnancies (91%) and worsened during one (9%).There were no cases of interstitial lung disease, cancer or antiphospholipid antibody syndrome among the 10 patients studied. One patient suffered from pre-eclampsia while diagnosed with DM. 3 total pregnancy losses: two early miscarriages (< 10 weeks gestation) one therapeutic abortion for an ectopic pregnancy. 3 neonates out of 18 live births went to the NICU after delivery – reasons for transfer: meconium aspiration; apnea and pre- term birth.

Figure 1.



Conclusion: Pregnancy does not appear to carry a worse prognosis for DM patients and all but one of our patients experienced improvement in clinical symptoms during pregnancy.

Infantile Hemangiomas in Infants Born to Women with Autoimmune Diseases

Chelsey Forbess Smith[1], Kenneth L Jones[2], Diana L Johnson[2] and Christina D Chambers[2], [1]University of California San Diego Department of Rheumatology, La Jolla, CA, [2]University of California San Diego Department of Pediatrics, La Jolla, CA

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Infantile Hemangiomas (IH) are the most common benign vascular tumor in infants, estimated to occur in 4-5% of the general population. Many of the known risk factors for IH (low birth weight, female infant, white race, preterm birth, multiple gestations) are also seen with increased frequency in pregnancies with autoimmune disease. The purpose of this study was to compare the incidence of IH in infants born to women with autoimmune diseases to the incidence in infants born to healthy comparison women, to determine if specific diseases/treatments were associated with risk for IH, and to describe characteristics of infants with more severe IH.

Methods: Data were obtained from the Organization of Teratology Information Specialists (OTIS) Autoimmune Disease in Pregnancy Project, a prospective cohort study of pregnancy outcomes among women in the U.S. and Canada. Pregnant women who were recruited into the study from 2004 to 2013, enrolled before 19 weeks gestation, and delivered at least one live born infant were eligible for analysis. To increase the reliability and validity of the diagnosis of IH, the sample was further restricted to infants that had received a blinded dysmorphological examination for major and minor defects.

Results: 1233 infants born to 1191 women met criteria for inclusion. The overall incidence of IH was 60/1233 or 4.9%. Of these, 52/993 (5.2%) infants with IH were born to mothers with an autoimmune disease, and 8/240 (3.3%) infants with IH were born to mothers without autoimmune disease ($p = 0.219$). There was a significant association between the presence of ulcerative colitis in the mother and IH in the child ($p = 0.014$) compared with other autoimmune diseases [See Table 1]. In multivariate analysis, this association remained. Of the 60 infants with IH, 5 were classified as at least 3x3cm; all 5 of these infants were born to mothers in the autoimmune disease group who were taking a biologic medication during pregnancy.

Table 1. Outcomes among women in OTIS cohort 2004-2013 with autoimmune disease (n = 993) categorized by presence of Infantile Hemangioma (IH)

Outcome	No IH (n = 941)	IH (n = 52)	p value
	n (%)	n (%)	
Presence of autoimmune disease (n = 993)	941 (80.2)	52 (86.7)	p = 0.219
Ankylosing spondylitis (n = 83)	79 (95.2)	4 (4.8)	p = 0.858
Crohn's Disease (n = 220)	208 (94.5)	12 (5.5)	p = 0.869
Lupus (n = 13)	13 (100)	0 (0)	p = 0.394
Psoriasis (n = 197)	190 (96.4)	7 (3.6)	p = 0.236
Psoriatic arthritis (n = 101)	96 (95)	5 (5.0)	p = 0.892
Raynauds Phenomenon (n = 20)	19 (95)	1 (5.0)	p = 0.962
Rheumatoid arthritis (n = 520)	492 (94.6)	28 (5.4)	p = 0.826
Sjogren's Syndrome (n = 14)	14 (100)	0 (0)	p = 0.376
Ulcerative Colitis (n = 35)	30 (85.7)	5 (14.3)	*p = 0.014*
Other autoimmune disease (n = 55)	52 (94.5)	3 (5.5)	p = 0.941
Medication Use			
NSAIDs (n = 300)	288 (96)	12 (4.0)	p = 0.250
Steroids (n = 409)	389 (95.1)	20 (4.9)	p = 0.682
Biologics (n = 773)	728 (94.2)	45 (5.8)	p = 0.121
DMARDs (n = 226)	220 (97.3)	6 (2.7)	*p = 0.047**

*negative association

Conclusion: The incidence of IH in this cohort was similar to the estimated incidence in the general population. While there was no significant difference between the overall incidence of IH in children born to women with autoimmune disease compared to healthy controls, the fact that all 5 of the largest and thus more clinically significant cases of IH occurred entirely within the autoimmune disease cohort may have important implications. These results add to the limited knowledge available regarding fetal outcomes and presence of malformations in this population.

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cervical neoplasia is increased in women with SLE. HPV types 16 & 18 account for 70% of cervical cancer. Natural HPV cervical infection generates type specific anti HPV antibodies (HPV-Ab) which are usually cross protective and low titer. For this study, HPV-Ab to types 6, 11, 16 and 18 were obtained pre and post vaccine (Phase I trial for Gardasil® in SLE) and analyzed to determine if antibody (Ab) vaccine response (AVR) related to abnormal pap smear/cervical neoplasia (AP/CM) or history (h/o) of preceding HPV infection (HPV-I). AVR in SLE could be suppressed in those with AB/CN, due to inability to clear persistent infection; alternatively, previous exposure could lead to a more vigorous anamnestic response.

Methods: In this trial**,** approved by the Human Investigation Committee at Wayne State University & the U.S. Food and Drug Administration, 34 women ages 19-50 years (yrs.) with a h/o of mild to moderate SLE by ACR criteria & minimally active or inactive SLE received qHPV vaccine (Gardasil®) at the standard dosing schedule (0, 2 months, 6 months). Patients excluded if they had active disease (SELENA-SLEDAI >2), h/o of severe disease, deep venous thrombosis, on >400 mg/day of hydroxychloroquine, on >15 mg/day of prednisone, or had active infections. Ab titers to HPV 6, 11, 16 &18 and h/o of AB/CN were evaluated pre-vaccine. Ab titers were measured by HPV competitive Luminex Immunoassay. Pearson Chi Square & logistic regression controlling for patient demographics (PD) were used to evaluate pre-vaccine HPV-Ab titers in relation to h/o of AB/CN. Linear regression controlling for PD & t-test were used to evaluate the magnitude of rise of Geometric Mean Titers (GMTs) in relation to h/o of AB/CN or preceding HPV-I.

Results: Women in the study (n=34) were predominantly African-American (79%), mean age 38.1 yrs., mean age at diagnosis of SLE at 28.6 yrs., 32.4% had h/o of smoking, 91% had ≥4 sexual partners, 50% had a h/o of sexually transmitted diseases, & 27.3% used condoms on a regular basis. History of AB/CN occurred in 52.9% {ASCUS (atypical glandular cells of undetermined significance) to CIN 3 (cervical intraepithelial neoplasia grade 3)}. Seven women were negative at baseline for all 4 Ab types in the vaccine; positive HPV Ab titers at baseline were seen in 79 % (n=27) for ≥1 of the HPV types in the vaccine, indicating previous HPV-I in most patients (15=exposed to only one HPV type, 12=exposed to ≥1 of the 4 types). Statistical analysis showed: those with a h/o of AP/CN were likely to have a positive HPV Ab result pre-vaccine to ≥ 1 of the 4 types contained in the vaccine, p=0.035. However, there was no difference in the magnitude of rise of HPV-Ab GMTs between those with a history of AB/CN vs. those that had no h/o of AB/CN or between those with preceding HPV-I vs. those who were Ab negative at baseline.

Conclusion: Our study shows that in women with SLE, the presence of HPV-Ab for 6, 11, 16, and 18 prior to receiving q HPV vaccine clearly correlates with h/o of AB/CN. However, neither AB/CN nor preceding HPV-I had an impact on humoral response to vaccination, showing no anamnestic response to previous natural infection. This supports not checking HPV antibody status before vaccinating women with SLE.

Contraceptive Methods in Women with Rheumatoid Arthritis

Megan E. B. Clowse, Gary McDaniel and Amanda M. Eudy, Rheumatology, Duke University Medical Center, Durham, NC

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Women with rheumatoid arthritis (RA) often take medications to control disease activity that, should a woman become pregnant, may increase the risk of poor pregnancy outcomes, such as miscarriage and birth defects. The objective of this study was to determine if women with RA are using highly effective contraceptives, and if contraception differs by current medication use.

Methods: Women with RA (2010 ACR/EULAR criteria) aged 20-40 seen in a university clinic without a history of ovarian surgery or prior exposure to possible ovary-toxic medications were invited to participate in a cross-sectional survey. The survey included questions on current medications taken for RA and contraceptive methods used in the previous three months. Contraceptive methods were categorized as highly effective (tubal ligation or vasectomy, IUD, Implanon/Nexplanon), effective (progesterone-only pill, estrogen-containing pill, Depo-Provera injections), and ineffective (abstinence, patient didn't think she could get pregnant, withdrawal, condoms, diaphragm, and none). Additionally, patients were asked if they had discussed contraceptives with their rheumatologist. Contraceptive methods were reported as counts and frequencies overall and in each medication class, and Fisher's exact test analyzed differences across medication classes.

Results: There were 52 RA patients; 79% white with a mean age of 32 and mean RA duration of 9 years. Education beyond high school was completed by 98% of patients, 61% of patients were

married, and 56% of patients worked full time. Discussing contraception with their rheumatologist was recalled by 71% of patients. Current medications included TNF-inhibitor (50%), methotrexate (48%), hydroxychloroquine (38%), NSAIDs (31%), corticosteroids (29%), sulfasalazine (15%), other biologics (13%), and other DMARDs (8%). In the 47 patients of reproductive age who were not trying to conceive, 38% were using ineffective, 34% were using effective, and 28% were using highly effective contraceptive methods (Table 1). Among 25 methotrexate users, 44% were using highly effective contraceptives, compared to 9% of patients not taking methotrexate (p=0.02). However, 24% of methotrexate users were using ineffective contraceptives. Among patients taking other DMARDs or biologics, drugs with very limited pregnancy safety information, 18% were using highly effective, 45% were using effective, and 36% were using ineffective contraceptive methods.

Conclusion: In this highly educated group of RA patients, most women were using effective or highly effective methods of contraception. It appears that rheumatologists are targeting highly effective contraceptives to women who are taking methotrexate, a highly teratogenic drug. However, there is room for improvement for women taking newer DMARDs and biologics, for which we have inadequate safety data in pregnancy.

Table 1. Contraceptive methods in RA patients stratified by current medication use (n=47).

		Highly Effective	Effective	Ineffective
Overall (n=47)	n (%)	13 (27.7%)	16 (34.0%)	18 (38.3%)
Methotrexate (n=25)	n (%)	11 (44.0%)	8 (32.0%)	6 (24.0%)
TNF-inhibitor (n=22)	n (%)	4 (18.2%)	10 (45.5%)	8 (36.4%)
Hydroxychloroquine (n=18)	n (%)	4 (22.2%)	7 (38.9%)	7 (38.9%)
NSAIDs (n=14)	n (%)	4 (28.6%)	5 (35.7%)	5 (35.7%)
Steroids (n=13)	n (%)	6 (46.2%)	3 (23.1%)	4 (30.8%)
Other Biologics* (n=7)	n (%)	2 (28.6%)	2 (28.6%)	3 (42.9%)
Sulfasalazine (n=5)	n (%)	1 (20.0%)	0 (0.0%)	4 (80.0%)
Other DMARDs* (n=4)	n (%)	0 (0.0%)	3 (75.0%)	1 (25.0%)

*Other biologics included abatacept, rituximab, and tocilizumab. Other DMARDs included leflunomide and tofacitinib.

Infertility in Women with Rheumatoid Arthritis

Megan E. B. Clowse, Gary McDaniel and Amanda M. Eudy, Rheumatology, Duke University Medical Center, Durham, NC

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a rheumatic disease that can affect women of reproductive age, and data suggest infertility is increased in RA. The objective of this analysis was to determine the frequency of infertility among RA patients, as well as reasons for infertility.

Methods: Women with RA aged 20-40 seen in a university clinic without a history of ovarian surgery or prior exposure to possible ovary-toxic medications were invited to participate in a cross-sectional survey. The survey included questions on infertility, reasons for infertility, physician-assisted reproductive methods, and how RA affected the desired number of children. Infertility was defined as a patient reporting being unable to get pregnant after 12 months of trying or a patient reporting physician-diagnosed infertility. Ovarian reserve was assessed by measuring anti-Müllerian hormone (AMH). Decreased ovarian reserve was defined as AMH <1 ng/ml. Multivariate linear models estimated the effect of age, hormonal contraceptives, and cumulative methotrexate (MTX) dose on AMH levels.

Results: There were 52 RA patients; 79% white with a mean age of 31. Infertility was reported in 23% of 26 patients who had previously tried to conceive. Reasons for infertility included problems with ovulation (17%), unexplained infertility (50%), or unknown (17%). Physician-assisted reproductive methods had been used by 19% of patients who had previously tried to conceive, including taking oral medications (100%), injections (60%), insemination with partner's sperm (20%), and in vitro fertilization with patient's eggs (20%). Half of the 50 patients who had not completed childbearing prior to RA diagnosis responded that being diagnosed with RA led to wanting fewer children. The main reasons for wanting fewer children included concerns of being able to care for children, RA medications harming the baby, and a postpartum flare. Health was the most frequently reported factor patients took into consideration when making the decision to have children (73%), followed by financial concerns (56%), fatigue (50%), and pain (39%). Mean AMH was 3.2 ng/ml (SD: 2.6), with 21% of patients having decreased ovarian reserve. Decreased ovarian reserve was found in 23% of patients with prior MTX use and 11% of patients without prior MTX use (p=0.7). In a multivariate linear model, AMH decreased with age (-0.23 ng/ml per 1-year increase in age) and current hormonal contraceptive use (-1.43 ng/ml compared to patients not taking hormonal contraceptives), but cumulative MTX dose had no observed effect on AMH levels. There were no observed differences in AMH levels in women who reported infertility compared to fertile patients.

Conclusion: The prevalence of infertility among RA patients who had tried to conceive was greater than the prevalence in the general population (23% compared to ~10%). There was not obvious cause for infertility among these women with RA. Age and hormonal contraceptives appeared to be associated with decreased AMH levels. However, there was no evidence of decreased AMH levels with increasing cumulative MTX, and AMH levels did not differ in patients reporting infertility.

Do Patients with Systemic Lupus Erythematosus and Rheumatoid Arthritis Have Reduced Fertility and Parity? a Systematic Review

Claire-Louise Murphy[1], Harriet Sharp[2], Hanh Nguyen[3], Anisur Rahman[1] and Ian Giles[4], [1]Rayne Institute, Centre for Rheumatology Research, UCL Division of Medicine, London, United Kingdom, [2]Rheumatology, University College London, London, United Kingdom, [3]Rheumatology, University College London Hospital, London, United Kingdom, [4]Department of Rheumatology, University College London Hospital NHS Foundation Trust, London, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) and Rheumatoid Arthritis (RA) often affect women of reproductive age. It remains unclear as to whether these inflammatory rheumatic conditions have an impact on fertility and parity. The aim of our study was to perform a systematic review of the literature to determine if fertility and parity are affected in patients with SLE and RA.

Methods: MEDLINE and EMBASE databases were searched for relevant publications from their inception through to October 2015, using terms including SLE and RA combined with fertility and parity. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines were followed. MeSH terms such as fertility (fertil*) and pregnancy (pregn*) were included. Two authors screened abstracts to identify eligible articles.

Results: 2,444 articles were identified which consisted of 1,724 and 720 articles from EMBASE and MEDLINE databases respectively. 1,840 duplicated articles were excluded. After exclusion of non-rheumatological conditions, 334 articles remained. 38 papers related to SLE and RA were identified of which 4 papers had both SLE and RA data totalling RA=22 and SLE n=20. A total of 7293 patients, 4406 with RA and 2287 with SLE were included. Articles captured retrospective and prospective case control, cohort and cross-sectional studies ranging from years 1956 to 2015. There

was variation in SLE and RA diagnostic criteria used. Exclusion criteria such as other rheumatic diseases such as antiphospholipid syndrome, effects of fertility on disease, assisted reproduction, conference abstracts and non-English papers were applied. In the RA cohort, 5 studies reported no difference in fertility and/or parity. 8 RA studies reported reduced fertility/early menopause and 9 reduced parity/increased pregnancy loss. In the SLE cohort, 5 studies reported no difference in fertility and/or parity. 11 reported reduced fertility/ovarian reserve or menstrual dysfunction affecting fertility and 6 reported reduced parity/pregnancy loss.

Conclusion: This comprehensive review captured fertility and parity information on 7,293 patients. Limitations of our analysis included heterogeneity of outcome measures, which included ovarian reserve, anti-mullerian hormone (AMH) levels, TTP (time to pregnancy), nulliparity, premature menopause and pregnancy rates. Additionally, potential confounding factors included the effect of disease activity and differences between older and more recent studies. Despite the limitations, the majority of studies showed reduction in fertility and/or parity. Data from multicentre cohorts would be valuable.

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The onset of childhood systemic lupus erythematosus (cSLE) most frequently occurs after age 12. Studies in adolescents with cSLE suggest that ovarian dysfunction may be common, however little is known about mechanisms of ovarian dysfunction in these patients, the potential for permanent ovarian damage and the impact on future fertility. Anti-müllerian

hormone (AMH) has been found to be useful in assessing ovarian reserve. Human oocytes peak in number during fetal life and decrease with age. Accordingly,, AMH levels decrease very slowly from puberty until menopause. AMH is has been demonstrated as a highly sensitive marker of diminished ovarian reserve in patients with cancer after chemotherapy. Only one study of ovarian reserve in adult women with SLE suggests lower levels of AMH compared to healthy controls. To our knowledge, examination of ovarian reserve and its clinical implications has not been studied in adolescent females with SLE.

Methods: Data is being collected prospectively on an ongoing basis since October 2014. Female adolescents, 14 to 19 years old, with diagnosis of SLE by ACR criteria, oligoarticular and polyarticular JIA by ILAR criteria and healthy controls with gynecological age (chronological age minus age at menarche) ≥ 2 years, are eligible to participate. Pregnant patients, patients on any form of hormonal contraception and with a diagnosis of polycystic ovarian syndrome were excluded. The primary outcome is ovarian reserve, measured by AMH levels (AMH AssessR), for which normative data is available. Demographic and clinical data is collected, including: age, race, age of menarche, characteristics of menses, birth control behaviors, weight and BMI for all patients. Additionally,age of disease onset, disease activity measured by SLEDAI, disease damage measured by SLICC, current medications and prior exposure to cyclophosphamide is being collected for SLE patients.

Results: To date, 16 subjects with SLE, 26 healthy controls and 6 subjects with diagnosis of JIA have been enrolled. Median age at enrollment was 17.4 years (IQR: 16.5, 19.4). Race and ethnicity were similar in the two groups; 22.5% of subjects were black, 57,1% Hispanic, 18.4% other/ mixed race, 2% white. Median age at menarche was 12 years. AMH levels were obtained in all participants. Median AMH was significantly lower in SLE (2.87 ng/ml, IQR: 2.12-3.70) vs health controls (4.80 ng/ml, IQR: 3.26-5.78), (p value = 0.04). Three out of 16 (19%) SLE subjects had AMH levels below normative values for healthy adolescents. Out of these 3 patients one had previously received cyclophosphamide and one had been pregnant 3 years prior to enrollment with a normal pregnancy and delivery.

Conclusion: Ovarian reserve, measured by AMH levels, appears to be affected in a small proportion of pediatric SLE patient compared to healthy controls. This information is important to keep in mind when educating and counseling patients on expectations regarding fertility.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Reproductive Issues in Rheumatic Disorders - Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) occurs during reproductive age and therefore ovarian reserve and future fertility are a relevant issue for this population. There is, however, no study performing a complete assessment of ovarian function in this chronic inflammatory disease.

Methods: One hundred and seven adolescent and young adult female patients with JIA (ILAR criteria) were selected for this study. Eight-four patients were excluded due to: hypothyroidism (n=6), current amenorrhea (n=4), current pregnancy/lactation (n=3), polycystic ovarian syndrome (n=2) and unwillingness to stop hormonal contraceptive or not agreeing to participate in this study (n=69). Therefore, 23 JIA patients and 23 healthy controls were studied. Complete ovarian function was assessed during the early follicular phase of the menstrual cycle (between the first and fifth day of menses) with estradiol, luteinizing hormone (LH), follicle stimulating hormone (FSH) - all three by radioimmunoassay, anti-Müllerian hormone (AMH) - by automated Access AMH immunoassay, Beckman Coulter, and antral follicle count (AFC) - by transvaginal or abdominal ultrasound. Demographic data, menstrual abnormalities, patient and physician visual analogue scales (VAS), number of active and limited joints, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and treatment were also evaluated.

Results: The median current age (22 vs. 23 years, p=0.834), menstrual flow duration (5 vs. 5 days, p=0.478) and cycle length (28 vs. 29 days, p=0.750) were similar in JIA patients and healthy controls. The median of AMH levels [2.66 (0.47-6.47) vs. 5.43 (0.98-17.24) ng/mL, p=0.010] were significantly reduced in JIA patients *versus*controls, whereas FSH [6.3 (4.7-12.2) vs. 5.7(2.6-9.8) IU/L, p=0.029], LH [7.7(2.4-13.2) vs. 4.9(1.1-14.4) IU/L, p=0.027] and estradiol levels [47.4 (25-8-160.2) vs. 35.1 (26.2-71.0) pg/mL, p=0.02] were significantly elevated in the latter group. AFC was comparable in JIA and controls (p>0.05). Further analysis of JIA patients revealed that current age, disease duration, number of active and limited joints, ESR, CRP, patient and physician VAS,

cumulative glucocorticoid and cumulative methotrexate dose were not correlated with AMH, FSH, estradiol levels or AFC ($p>0.05$).

Conclusion: The present study was the first to identify a subclinical ovarian dysfunction in JIA patients during reproductive age, not correlated with disease activity or treatment factors. Future studies are necessary to determine the possible role of ovarian autoantibodies for this condition.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There are presently no official guidelines about the prevention, screening, and treatment of congenital heart block (CHB) due to maternal Ro antibodies. The objective of this study was to survey an international sample of providers to determine their current practices.

Methods: A survey was designed by the organizing committee of the 9thInternational Conference or Reproduction, Pregnancy and Rheumatic Diseases. The survey was sent to 330 people who had attended prior conferences or were registered for this conference, were authors of recent publications on rheumatic diseases and pregnancy, or were authors of abstracts on rheumatic

diseases and pregnancy from the ACR meetings in 2012, 2013, and 2014. Respondents who did not provide demographic information were excluded from the final analysis (n=11).

Results: There were 48 respondents. Most (55%) follow >15 pregnancies in rheumatic patients per year, and 33% were practicing rheumatologists for >15 years. Most were university-based physicians (88%) and from North America (42%) or Europe (42%). Screening: For anti-Ro/SSA positive women, 80% recommended serial fetal ECHOs, with most starting at gestational week 16 (59%) and stopping at week 28 (25%), although the time to stop varied widely between weeks 22 and 34. For women without a prior infant with neonatal lupus, respondents recommend every other week (44%) or weekly (28%) fetal ECHOs, and 5% of respondents preferred a plan of two fetal echoes. For women with a prior infant with neonatal lupus, 80% recommend weekly fetal ECHOs. Prevention: Hydroxychloroquine was recommended by 67% of respondents to prevent CHB and most would recommend starting the drug prior to pregnancy (62%). Treatment: Respondents were asked about medications for varying degrees of CHB in a 20-week pregnant, anti-Ro and La positive SLE patient.Respondents recommended dexamethasone (53%) or HCQ (43%) for 1st degree HB; dexamethasone (88%) for 2nd degree HB; and dexamethasone (55%), IVIg (33%), or no therapy (27%) for complete HB. When dexamethasone was started for 2nd degree CHB, 58% would stop dexamethasone if it progressed to complete heart block, 47% would stop if heart block disappeared, and 24% would stop if the 2nd degree CHB remained.

Conclusion: Despite the absence of official guidelines, many physicians with a focus on pregnancy and rheumatic disease have developed similar patterns in the screening, prevention, and treatment of CHB. These include serial fetal ECHOs, preventive HCQ, and treatment of early heart block with dexamethasone. These practices are not uniform, however, and have not been formally tested in prospective trials. The next step in this field must include testing of these approaches to identify the most cost effective and efficacious plan for these pregnancies.

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Third degree atrioventricular block(AVB), a rare congenital complication, duplicate-triplicate frequency up to 2% when Ro/La maternal antibodies are present. Incidence rises to 17-20% in mothers with a previous child with AVB. Maternal consumption of hydroxychloroquine seems to reduce this risk. The purpose was to evaluate the incidence of fetal AVB and its relationship with the consumption of hydroxychloroquine in women with Ro/La antibodies whose pregnancies have been followed at our hospital.

Methods: We reviewed the electronic medical records from years 2000 to 2014 of a) all pregnant women with known Ro/La antibodies, b) all pregnant women with hydroxychloroquine consumption in the pharmacy registry and c) all mothers of children younger than 2 years old with AVB and/or pacemaker placement.

Results: 62 pregnancies in 47 mothers with Ro/La antibodies were identified. Pregnant women who had consumed hydroxychloroquine during all the pregnancy (n=14) were compared with those who had not(n=48). Demographic characteristics are shown in table 1. One newborn (7.1%) suffered a AVB in the hydroxychloroquine group versus 7 newborn in the group without hydroxychloroquine (14.6%)(p=0.5). None of the mothers had more than one pregnancy with AVB. AVB was detected at a median gestational age of 20 weeks and they were all intrauterine (table 2). Between 2000 and 2014, 23 AVB were diagnosed on children younger than 2 years old, 10 of them were associated with the presence of antibodies and/or a maternal rheumatologic disease. 3 of these children (30%) required the collocation of a pacemaker before 2 years of age and 2 children (20%) died before a pacemaker could be implanted. The other 13 (10 followed up for more than 2 years) congenital AVB were associated to congenital structural heart disease and 100% required a pacemaker implantation ($p<0.001$ versus AVB without structural heart disease)(table 2).

Conclusion: A high incidence of AVB in patients with Ro/La antibodies in our hospital was observed (12.9 %), perhaps due to derivation bias. Although AVB was more frequent in mothers without hydroxychloroquine (14.6% versus 7.1%), the difference was not statistically significant. All congenital AVB diagnosed at our hospital without structural heart disease were associated with a rheumatic disease or presence of maternal antibodies. Table 1: Pregnancy characteristics of women with Ro/La antibodies

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Histologic correlates of anti-Ro associated congenital heart block (CHB) are apoptosis and calcification of cardiomyocytes with fibrosis of the AV node surrounded by infiltrating macrophages and giant cells. This study leveraged an unprecedented opportunity to interrogate the transcriptome of different cell types in a fetal heart dying with CHB.

Methods: Aortas from a 19 wk CHB fetal heart and a healthy 22 wk heart were cannulated using a Langendorff preparation with proteolytic enzymes to yield a single cell suspension. DAPI negative cells were isolated by flow using antibodies to CD14/CD45, CD31, and podoplanin, to yield leukocytes, endothelial cells, and fibroblasts, respectively. After RNA isolation and cDNA library preparation, RNA-Seq and transcriptome analysis were performed. Expression of lineage markers was consistent with the isolates based on flow markers. Data are expressed as log2 transcripts per million.

Results: Transcriptomes of the two hearts for each isolated fraction were compared. For leukocytes, in CHB vs healthy there were 5000 genes greater than a threshold ratio of 0.78 (expressed as log2 difference). Based on the DAVID annotation, data were organized into clusters of closely related genes. Within the term inflammatory response (p=1.66E-4) for the ratio of CHB/healthy, the genes were IL8 (4.13), IL6 (6.72), TNFa (0.78), and EDN1 (5.17). In addition, leukocyte gene expression of FCGR3A, TLR7 and IRF5 was higher in CHB vs control (2.6,1.37 and 0.91, respectively), a result supporting that the requisite machinery is upregulated to effect anti-Ro-hYRNA ligation and activate macrophages via TLR signaling. For endothelial cells, 7000 genes exceeded a ratio of 0.78 for CHB/healthy. Within the term inflammatory response (p=1E-5), FOS, FOSB, NFKB1A, and NFKBIZ were expressed with ratios of 1.47, 2.46, 1.03, and 2.75. Within the categories IMMUNE (p=4E-2) and cell adhesion (p=1.42E-06) higher expressed genes included CTGF (2.06), PTGS2 (2.53), SOCS3 (1.56), and OAS3 (2.52) along with ICAM1 (2.12), CCL2 (2.75), IL32 (2.81), VCAM1 (3.85), and SELE (2.4). Likewise within the death category (2.62E-08), PPP1R15A (1.39), XAF1 (3.77), GADD45B (1.94), and TNFAIP3 (3.06) were increased in CHB. These data support endothelial cells in leukocyte recruitment. For the fibroblasts, 4500 genes were above the CHB/healthy threshold (Table 1). CHB fibroblasts showed increased expression of

pro-fibrotic genes while attenuating anti-fibrotic genes. The cardiomyopathy marker, XIRP2 (3.15), as well as genes resisting and promoting vascular stiffness (ELN [-2.23] and TTN [2.12], respectively) were also identified.

Conclusion: These data support that autoimmune CHB is a complex disease with contributions from death pathways, inflammation and fibrosis. Scarring likely results from a multi pronged pro-fibrotic environment whereby fibrosis promoting genes undermine genes that forestall fibrosis.

Table 1 - Fibroblasts

Genes that promote fibrosis		
Candidate	CHB	Control
SCN5A	11.25*	9.96
CPEB4	11.23	9.76
EDN1	8.4	7.01
Genes that resist fibrosis		
CLU	11.77	13.52
DUSP1	12.37	13.54

Risk Factors for Adverse Pregnancy Outcome in Antiphospholipid Antibodies Carriers:

Results From a Multicenter Italian Cohort Over 20 Years Of Experience

Background/Purpose: Antiphospholipid antibodies (aPL) are risk factors for Adverse Pregnancy Outcome (APO). In particular, for aPL carriers (patients with aPL positivity with no thrombotic or obstetric history) pregnancy outcome and treatment are still not defined. Here we critically reviewed pregnancy outcome in a large multicenter cohort of aPL carriers patients, according to different serological profile and treatment protocols.

Methods: We reviewed 70 pregnancies in 62 patients, that were prospectively followed in 3 Italian centers over 20 years (1994-2015). Patients with previous clinical events (thrombosis, any APO in previous pregnancies and also preterm birth <37 w for any reasons) or concomitant autoimmune diseases were excluded. Patients with aPL positivity and non-criteria manifestations were included. aPL profile was defined as the combination of the 3 criteria tests for aPL (Lupus Anticoagulant, anti-cardiolipin, anti-Beta2 Glycoprotein I). APO was defined as at least one of the followings: miscarriage (<10^{th} week), fetal death (≥10^{th} week), severe preterm delivery (≤34^{th} week) with or without preeclampsia (PE), HELLP syndrome or perinatal death.

Results: Mean age at discovery of aPL was 31 years and mean age at pregnancy was 32 years. Regarding aPL profile: 44 (63%) were single positive, 17 (24%) were double and 9 (13%) were triple. aPL non criteria manifestations were present in 6 (8%) and lupus-like manifestations in 5 (7%). Nine pregnancies had a combination treatment with prophylactic low molecular weight heparin (LMWH) plus low dose aspirin (LDA), 37 had LDA alone and 24 had no treatment. We observed 2 thrombotic events (3%), 1 deep venous thrombosis (6th week, in a single positive low titer, before the start of treatment) and 1 ischemic stroke (37th week, in a triple positive, already in treatment with combination therapy). We recorded 6 APO, all in spontaneous pregnancies: 3 fetal deaths and 3 pre-term birth ≤34^{th} week with PE. We then performed a univariate analysis comparing

8 complicated pregnancies (6 APO plus 2 thrombosis) with 62 non-complicated pregnancies (Table 1). Acquired risk factors (p:0.007), non-criteria aPL (p:0.017) and lupus-like manifestation (p:0.009), triple positive aPL profile (p:0.0005) were associated with APO. The combination treatment was also more frequent in APO pregnancies (p:0.007).

Conclusion: Acquired risk factors, aPL profile (triple positivity), lupus-like and non-criteria aPL manifestations could represent risk factors for pregnancy complications and could determine failure even to conventional treatment with LDA plus prophylactic LMWH. These patients may deserve additional treatment, for example LMWH at higher/anti-coagulant dose or an immunomodulatory treatment to increase the probability of success during pregnancy, such as hydroxychloroquine, also considering its anti-platelet/anti-thrombotic effects.

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Heparins and/or low-dose aspirin represent the treatment of choice for the management of pregnant women with antiphospholipid antibodies (aPL). However, despite these treatments, maternal, fetal, and neonatal adverse outcomes related to the presence of aPL may still occur. In this study we aimed to assess the pregnancy outcome in women with aPL without other underlying connective tissue disease (CTD) who were treated with hydroxychloroquine (HCQ) in addition to conventional treatment during pregnancy.

Methods: Eighty-nine pregnancies in 48 women with persistent aPL were included in this observational, retrospective, cohort study: -Group 1: 17 pregnancies that occurred in 13 women were treated with HCQ for at least 6 months before pregnancy, and the therapy continued throughout gestation; -Group 2: 72 pregnancies that occurred in 35 women with aPL that were not treated with HCQ were included as controls. All the patients were tested positive for aPL in the absence of conclusive clinical signs/symptoms of CTD.

Results: HCQ-treatment was associated with a higher rate of live births (82% group A vs 58% group B; p = .05). Placenta-mediated complications (pre-eclampsia and abruption placentae) were

not observed in group 1 but occurred in 5 cases of group 2. Pregnancy duration was longer in group 1 than group 2 (36.4 [6-40] vs 33.5 [6-40] weeks; p = .04).

Conclusion: Despite the limit of the small sample size, our observations support that HCQ may improve pregnancy outcome in women with aPL. A prospective randomised controlled trial of HYdroxychoroquine versus placebo during Pregnancy in women with AnTIphospholipid Antibodies (HYPATIA) also including women witn aPL without other underlying CTD is about to start recruiting.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Given the obvious female predominance of rheumatic diseases, significant attention has already been drawn to the impact of these conditions on female sexual function. Nevertheless, rheumatic diseases can also present with challenges that are unique to male sexual function and thus, we aimed to systematically review the prevalence of erectile dysfunction in rheumatic diseases.

Methods: Using Medline, EMBASE, and Web of Science electronic databases, we performed a systematic review to identify original articles evaluating the prevalence of erectile dysfunction, assessed using the validated international index of erectile function (IIEF-5) questionnaire, in men

with rheumatic diseases, including systemic sclerosis (SSc), systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and ankylosing spondylitis (AS). The search was restricted to English articles and performed in May 2016. We hand-searched reference lists, review articles, and grey literature for relevant articles not captured by the electronic searches.

Results: Our literature search identified 54 studies of which 34 were selected for full-text review. Of the potentially relevant studies retrieved, 12 studies were included in the final analysis. Five studies (n=219) focused on patients with SSc and reported ED prevalence ranging from 81-88%. In these studies, ED was found to correlate with disease severity and was associated with ultrasonographic evidence of penile vascular impairment. Comparatively, in RA (3 studies, n=138) and AS subjects (4 studies, n=272), ED prevalence ranged respectively from 46-54% and 12-42%. In AS, increased Bath Ankylosing Spondylitis Disease Activity Index scores, duration of morning stiffness, and disease duration were associated with ED. In the aforementioned studies, the age-matched healthy control population had ED rates ranging from 11-27%. Of note, only 2 studies (n=35) examined SLE and/or antiphospholipid-antibodies-positive subjects but standardized questionnaires were not used to evaluate ED and thus, these studies were excluded.

Conclusion: Men with SSc, RA, and AS have a substantially higher prevalence of ED compared to age-matched healthy controls. Given the importance of normal erectile function in sexual health and quality of life, clinicians should be aware of the increased prevalence of ED in men with rheumatic diseases and offer preventative, as well as therapeutic strategies to minimize its impact.

Session Title: Reproductive Issues in Rheumatic Disorders - Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although systemic lupus erythematosus (SLE) has a higher prevalence in women, the disease usually has a more aggressive course in men. Information regarding erectile function in men with SLE is quite scant. Therefore, the aim of this study was to describe the prevalence of erectile dysfunction (ED) as well as associated demographic and clinical features in men with SLE, by means of a systematic, standardized evaluation.

Methods: We performed a transversal study in five tertiary care centers in Latin America (3 in Mexico, one in El Salvador and one in Nicaragua). We included male patients older than 16 years who fulfilled ≥4 ACR criteria for SLE, and who had reported regular sexual activity in the previous 6 months. Patients with other rheumatic diseases (except for APS), chronic viral infections, concomitant diagnosis of benign prostate hyperplasia, and late-onset SLE (≥50 years of age) were excluded. All patients answered the self-administered International Index of Erectile Function-5 Questionnaire (IIEF-5), which has been validated in Spanish. Other relevant demographic, clinical and serological characteristics were documented from the clinical records.

Results: We included 118 subjects. The prevalence of ED in our study population was 67.7% (80/118), the majority were classified as mild to moderate (17.5±3.8 points; normal score: 22-25 points). The mean age of patients with ED was 35.6±11, while in patients without ED it was 32.3±9 (p=0.11). There were no significant differences in most of the demographic and clinical variables between both groups, either (Table 1). There was a trend regarding current prednisone intake in patients with ED (67 vs 48%, p=0.066). Furthermore, patients with ED had a higher MMF dose (1461±989 vs 860±1011 mg p=0.036) and a lower lymphocyte count (1398±634 vs 1717±814 cells/µl, p=0.022) than controls. Complement levels, anti-dsDNA antibodies and serum creatinine did not differ between groups. Also, both SLEDAI (p=0.16) and SLICC (p=0.13) scores were similar between groups.

Conclusion: Regardless of acute disease activity, accrual damage, type of previous SLE activity and comorbidities, men with SLE have a high prevalence of ED, considering most are young patients. Interestingly, prednisone dose was not associated with this condition, and the only difference in immunosuppressive drugs between groups was a higher dose of MMF in the patients with ED. Besides, lymphopenia could play a physiopathogenic role, associated with microvascular damage. The high prevalence of ED could potentially be associated to diminished quality of life, which must be addressed by prospective studies. *Table 1. Demographic features and comorbidities of patient with and without ED and SLE*

Predictive Factors of Good Response to Conventional Dmards

in Patients with Early Seronegative Rheumatoid Arthritis: Data from the Espoir Cohort

JULIA MARY[1], B Combe[2], Cédric Lukas[3] and Michel De Bandt[4], [1]RHEUMATOLOGY, CHU Fort de France, 97261, Martinique, [2]Immuno-Rhumatologie, CHU Lapeyronie, University of Montpellier, France, [3]Rheumatology, CHU Lapeyronie and EA2415, Montpellier University, University of Montpellier, France, [4]Rheumatology department, CHU Fort de France, Fort de France, France

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Early seronegative rheumatoid arthritis (RA) is a separate entity. Less is known about its initial clinical presentation and outcome due to the difficulty in identification among patients with undifferentiated arthritis. The objective of this study was to determine predictors of good response to conventional DMARDs in seronegative RA patients in the ESPOIR cohort.

Methods: Patients from the ESPOIR cohort with an early seronegative RA fulfilling the ACR-EULAR 2010 criteria were included. Primary endpoint was a good or moderate EULAR response evaluated at one year, after at least three months of treatment with conventional synthetic DMARDs (csDMARDs). Secondary objectives were to compare the early therapeutic response to methotrexate (MTX) and leflunomide (LEF) versus other csDMARDs (hydroxychloroquine, sulfasalazine), and to identify factors associated with functional disability (HAQ-DI > 0.5 at one year) and structural progression (modified total Sharp score > 1 and >5 points at one year). A Fisher exact test was used to compare categorical variables, and the Student or Mann Whitney tests for quantitative variables. Logistic regression analysis was used to determine independent predictors of outcome in multivariate analysis.

Results: 172 patients were analyzed: 81% women, mean age of 49.5+12.8 years. Mean DAS28 was 5.5+1.1 at baseline. 57% of patients were then treated with MTX. csDMARDs instituted early, i.e. within three months following the first joint swelling was significantly associated with EULAR good or moderate response at one year (OR = 2.41 95% CI [1.07- 5.42] p = 0.03) on univariate and multivariate logistic regression. Observed response rates were neither influenced by the type of first line csDMARDs (MTX vs other DMARDs), nor by other classical prognostic factors. Presence of erosions at baseline was significantly associated with progression of the Sharp score > 1 point (p = 0.03) and > 5 points (p = 0.03) at one year. HAQ ≥1 at inclusion and active smoking were significantly associated with an HAQ > 0.5 at one year.

Conclusion: Our results suggest that more than baseline clinical, biological or imaging features, it is the delay in initiation of csDMARD that greatly affects the outcome in patients with early seronegative RA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The flare-assessment in RA (FLARE) questionnaire was developed for the detection of disease activity flares in patients with rheumatoid arthritis (RA) based on the joint symptoms and systemic impact of RA disease. As of now, there is no clear FLARE score cut-off for identifying a flare in RA. We aimed to establish a threshold for RA flare using the FLARE questionnaire in patients with RA.

Methods: Patients with RA (age≥18 yrs; 2010 ACR criteria) participating in an ongoing prospective study completed the FLARE questionnaire on a monthly basis. The Health Assessment Questionnaire-II (HAQ-II), visual analogue scales (0-100 mm) for pain (VAS pain) and patient and provider global assessments of RA disease activity; assessment of tender (TJC28) and swollen joint counts of 28 joints (SJC28), and C-reactive protein (CRP) measurement were completed during the baseline visit. Generalized estimating equations were used to model the relationship between the FLARE questionnaire and patient report of flare incorporating random patient and visit effects to account for within patient variability.

Results: The study included 66 patients with RA (mean age 59.7 years; 64% female). The mean (standard deviation, SD) for TJC28 joints was 2.3 (4.8), SJC28 was 1.1 (2.9), HAQ-II score 0.6 (0.5), VAS pain 33.3 (26.1), provider global assessment 17.2 (22.3), patient global assessment 33 (26.2) and CRP 7.7 (12) mg/L. A total of 307 monthly questionnaires were completed. As expected, the FLARE score overall, as well as systemic and joint subscale measures were significantly higher in months when patients reported flare vs no flare (Table). Several measures of RA activity including TJC28, HAQ-II, VAS pain, patient and provider global assessment were also significantly higher in patients reporting a RA flare vs those not reporting a flare (see the Table). Based on the ROC analysis, the optimal cutpoint (using the DeLong-Delong method) for the FLARE questionnaire was identified at 2.5. The sensitivity is 77.1% and the specificity is 78.9% using this cutpoint (Figure). The positive predictive value is 51.9% and the negative predictive value is 92.1%. The area under the curve was 89% for FLARE overall and 88% for both the joint and systemic subscales of the FLARE questionnaire.

Conclusion: We suggest a threshold of 2.5 for the FLARE questionnaire score to aid in the accurate identification of flare status in patients with RA. This threshold may be particularly useful in helping to rule out flare in RA patients where the diagnosis of flare is questionable, if their FLARE score is <2.5. Further studies are needed to validate this threshold in other populations of patients with RA. Future identification of an individualized threshold for RA flare using the FLARE questionnaire may aid in disease management.

Table. FLARE scores and RA activity measures in patients reported to be in RA flare vs not in a flare

Variable	RA flare per patient report	Not in a flare per patient report	p-value
Overall FLARE score	5.0 (2.4)	1.5 (1.9)	<0.001
FLARE systemic subscale	4.6 (2.8)	1.3 (1.9)	<0.001
FLARE joint subscale	5.6 (2.3)	1.9 (2.2)	<0.001
TJC28	5.9 (6.5)	1.7 (3.6)	0.019
SJC28	2.8 (3.2)	1.2 (3.6)	0.20
HAQ-II	0.9 (0.5)	0.5 (0.6)	0.040
VAS pain	55.3 (21.5)	28.4 (26.4)	0.005
Patient global assessment	54.9 (21.6)	27.9 (24.7)	0.004
Provider global assessment	35.7 (19.6)	16.5 (25.2)	0.049
CRP, mg/L	6.4 (5.5)	7.7 (12.2)	0.73

*All measures are shown as mean (standard deviation)

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The swollen and tender joint count is included in composite scores (DAS28, CDAI, SDAI, ACR/EULAR Boolean remission). Low swollen/tender joint ratio (STR) has been found to be associated with reduced clinical response[1]. Ultrasound (US), including grey scale (GS) synovitis and power Doppler (PD) assessment of vascularity is sensitive for detecting inflammatory activity. Presently we explored associations between STR and pain catastrophizing, PROs, composite scores, clinical evaluation and US assessments, and more importantly, with composite score remission, in a follow-up study of established RA patients initiating bDMARDs.

Methods: 209 patients with RA (mean (SD) age 53 (13) years, disease duration 10 (9) years, 81% women, 79% anti-CCP positive) were included when initiating bDMARDs and assessed at baseline and after 1, 2, 3, 6 and 12 months with PROs (joint pain VAS, patient's global VAS, RAID score and MHAQ), clinical examinations (assessor's disease activity VAS, tender and swollen joint counts (of 28)) and laboratory variables (ESR and CRP). STRs were calculated with insertion of 1 if 0 in the denominator. Pain catastrophizing was assessed by two questions from the Coping Strategies Questionnaire. All US examinations (semi-quantitative scoring (0-3)) of GS and PD (PIP 2-3, MCP 1-5, wrist (RC, IC, RU), elbow, knee, tibiotalar, MTP 1-5 and ext.carpi ulnaris/tib.post.tendons bilaterally) were performed by one rheumatologist (HBH) (Siemens Acuson

Antares, excellence version, 5-13 MHz probe). Statistical calculations included Pearson's correlations, independent samples T-test and cross-tabs for assessing risk levels.

Results: There was a wide distribution of STR levels (median 1.0 (IQR 0.6-2.5), mean (SD) 2.4 (3.8)). During follow-up there were no/low cross-sectional correlations between STR and all the PROs and laboratory markers (r= -0.03-0.24), but moderate to high correlations with assessor's global (r= 0.27-0.42, p<0.001) and the US examinations (GS; r=0.48-0.63/PD; r=0.38-0.67, p<0.001). Patients were divided into groups with STR ≥ 1.0 or <1.0. The table (including mean values) shows that patients with STR<1.0 during follow-up had significantly higher levels of PROs and composite scores but lower US scores. Patients with STR < 1.0 achieved less often remission according to the composite scores (STR<1.0/STR≥1; DAS28 4.3%/36.4% and 3.3%/35.5%, CDAI 2.7%/17.9% and 1.3%/23.7%, SDAI 3.3%/20.1% and 3.3%/24.3%/, Boolean 2.7%/18.5% and 1.3%/21.7% at 6 and 12 months, respectively).

Conclusion: Established RA patients with higher number of tender than swollen joint count had higher levels of PROs and composite scores, but lower US pathology, and more importantly, lower achievement of clinical remission. Thus, these patients may have a trait including higher subjective scores, which is relevant within the treat-to-target strategy. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: High sodium intake has been reported to be associated with increased ACPA positivity in smoker RA patients. However, apart from this, the associations with high sodium intake in the general population, elevation in blood pressure, endothelial dysfunction, albuminuria and cardiovascular (CV) morbidity and mortality, have not been examined in RA patients before. In this study, we assessed the association between sodium intake and subclinical atherosclerosis identified by the carotid ultrasound (US), in RA patients.

Methods: RA patients without any CV disease, diabetes, chronic kidney disease, or who were not on diuretic treatment were included. To estimate dietary sodium intake, sodium excretion in 24h urine samples were determined. High sodium intake was defined as >200mmol/day (>12g/day) sodium in 24h urine. Carotid US findings of carotid intima-media thickness (cIMT) > 0.90 mm and/or carotid plaques were regarded as subclinical atherosclerosis. Along with disease characteristics, traditional CV risk factors, DAS28 scores, ESR and CRP values of each visit during the entire followup were recorded. Average DAS28, ESR, and CRP were calculated. Multivariable logistic regression was used to adjust for RA severity measures and other CV risk factors influencing atherosclerosis.

Results: Of the 110 RA patients (F/M=89/21, age 54±11 years, disease duration 14±7 years, hypertension 27.3%) 24 (21.8%) had subclinical atherosclerosis (cIMT>0.90 mm: 14 patients, plaques: 20 patients). The mean daily sodium excretion was 189.2±72.9 mmol/day, equal to a sodium intake of 11.1±4.3g/day. Overall, 48 (44%) patients had high sodium intake (mean 15.1±2.8g/day). Sodium intake 14.8±4.5g/day *vs* 10.1±3.7g/day (P<0.001), and % of high sodium consumers 66.7% *vs* 37.2 % (P=0.010) were significantly higher in patients with subclinical atherosclerosis. Daily sodium intake was positively correlated with cIMT (r=0.32, P=0.001), average ESR (r=0.22, P=0.024) and CRP (r=0.29, P=0.003), and serum uric acid levels (r=0.27, P=0.005). There was a nonsignificant positive correlation between systolic and diastolic blood pressures and sodium intake. Sodium intake in NSAID or glucocorticoid using RA patients was similar to non-users. Similarly, hypertensive, obese, smoker or seropositive patients' sodium intake was not higher. When disease characteristics, cumulative disease activity, and traditional CV risk

factors were adjusted by using multivariable logistic regression analysis, sodium intake was found to be associated with subclinical atherosclerosis in RA patients (OR=1.46, 95% CI, 1.11-1.90, *P*=0.006).

Conclusion: Higher sodium intake is associated with subclinical atherosclerosis in RA patients. These preliminary results should be confirmed in a larger sample. Considering the high CVD risk in RA patients, further investigation is needed to determine whether high sodium intake is associated with inflammation, CV morbidity and mortality, and other comorbid conditions such as hypertension in RA. As recommended for the hypertensive adult population, sodium intake reduction may be considered in RA patients, particularly in hypertensive and high CV risk patients.

Comparison of Disease Activity Score (DAS) 28-CRP to DAS28-ESR in Patients with Active Rheumatoid Arthritis

In Ah Choi, Division of Rheumatology, Department of Internal Medicine, Division of Rheumatology, Department of Internal Medicine, Chungbuk National University Hospital, Cheongju, Korea, The Republic of

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Assessment of disease activity is a key part of clinical decision in rheumatology care. High disease activity presented by disease activity score 28 ((DAS28) > 5.1 is used as a cutoff for biologic use in many countries include Korea. This study is to find confounding factors affecting erythrocyte sedimentation ratio (ESR) and C-reactive protein (CRP) to patients with rheumatoid arthritis to find the best tool to access rheumatoid arthritis (RA) disease activity, and to compare DAS28-ESR and DAS28-CRP to see whether we can use these indices interchangeably.

Methods: A cross-sectional study was conducted in 1117 patients with RA, using initial

registration data from Korean Biologics Registry (KOBIO).

Results: ESR levels were increased with age ($r = 0.120$, $p < 0.001$) and serum rheumatoid factor ($r = 0.111$, $p = 0.001$) but did not correlate with BMI, disease duration, and anti-CCP antibody titer. There were no differences in ESR levels according to the gender, smoking status, presence of diabetes mellitus, obesity (BMI ≥ 30) or low body weight (BMI < 20). CRP levels did not correlate with age, BMI, disease duration, RF and anti-CCP antibody. They were higher in female compared to male ($p < 0.001$) and higher in never-smoker compared to ever-smoker ($p = 0.003$). However, those differences of CRP levels were not significant when stratified by smoking status and gender, respectively. There were no differences in CRP levels according to the presence of diabetes mellitus, obesity (BMI ≥ 30) or low body weight (BMI < 18.5). In comparison of composite indices, DAS28CRP showed excellent correlation with DAS28ESR ($r = 0.943$, $p < 0.001$). However, in defining high disease activity, DAS28CRP showed only a fair agreement with DAS28ESR (kappa 0.381). To make best agreement with DAS28ESR in defining high disease activity, DAS28CRP need to be lowered to 4.5 (kappa 0.679, sensitivity 85.8%, specificity 88.0%, AUC 0.936).

Conclusion: DAS28CRP is a useful marker for inter-patient-comparison of RA disease activity when comparing patients with different age or rheumatoid factor status. DAS28CRP correlates well with DAS28ESR but the cutoff for high disease activity needs to be lowered to 4.5 to be used interchangeably with DAS28ESR in defining high disease activity.

Discordance Between Tender and Swollen Joint Count and Patient's and Evaluator's Global Assessment May Reduce Likelihood of Remission in Rheumatoid Arthritis

Brigitte Michelsen[1,2], Karen M Fagerli[1], Elisabeth Lie[1], Hilde B Hammer[3], Eirik K Kristianslund[1], Glenn Haugeberg[4,5] and Tore K Kvien[1], [1]Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, [2]Dept. of Rheumatology, Hospital of Southern Norway Trust, Kristiansand, Norway, [3]Dept of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, [4]Dept. of Rheumatology, Martina Hansens Hospital, Bærum, Norway, [5]Dept. of Rheumatology, The Norwegian University of Science and Technology, Trondheim, Norway

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

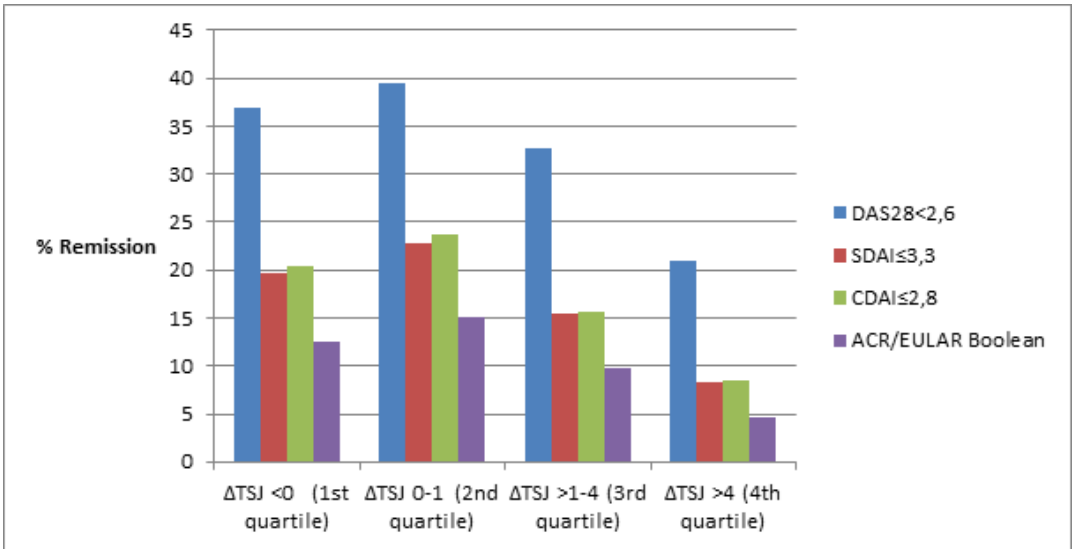
Session Type: ACR Poster Session C

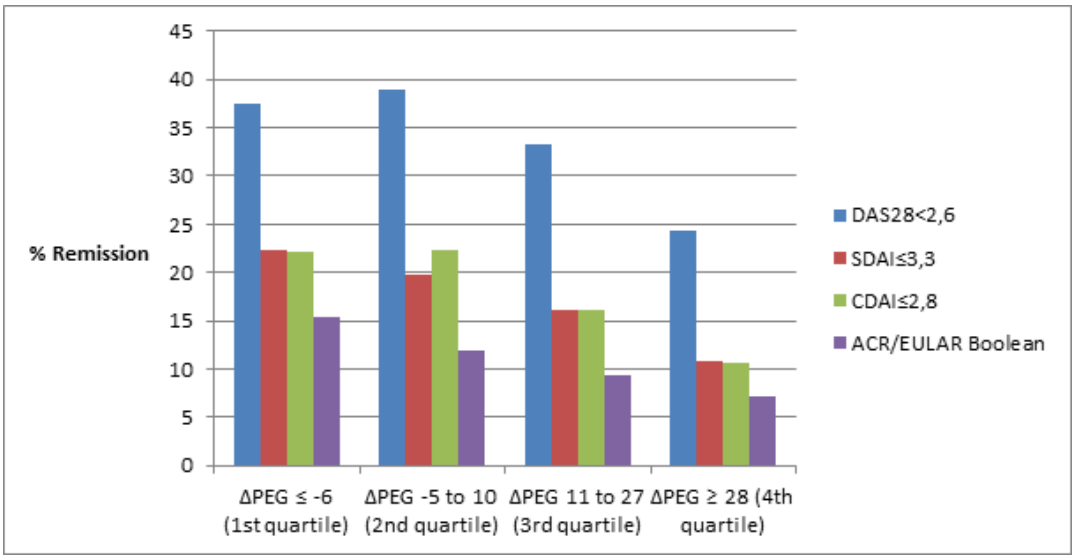
Session Time: 9:00AM-11:00AM

Background/Purpose: Chronification of pain and development of central sensitization and conditioned pain modulation can lead to disconnection between tender and swollen joint count, which may be challenging for disease evaluation and treatment. Studies exploring the relationship between tender and swollen joints discordance as predictor of remission in inflammatory arthritides are lacking in the current literature. In this study we aimed to investigate the predictive value of numeric differences between 28 tender and swollen joint count (deltaTSJ) and patient's and evaluator's global assessment (deltaPEG) on remission in rheumatoid arthritis (RA).

Methods: From the prospective, multicenter NOR-DMARD study we included RA patients starting first-time tumor necrosis factor inhibitors (TNFi) and DMARD naïve patients starting methotrexate between 2000 and 2012. The predictive value of deltaTSJ and deltaPEG on remission was explored in prespecified logistic regression models adjusted for age, sex, disease duration and smoking.

Results: A total of 2735 RA patients were included (mean (SD) age 55.0 (13.5) years, disease duration 4.5 (8.2) years, 69.7% females, 31.7% current smokers, baseline median (IQR) 28 tender joints 6 (9), 28 swollen joints 6 (7), deltaTSJ 1 (5), baseline mean (SD) evaluator's global assessment 40.3 (19.4), patient's global assessment 49.7 (24.8), deltaPEG 9.4 (25.0), DAS28ESR 5.0 (1.4), baseline median (IQR) SDAI 24.5 (19.6), CDAI 10.4 (13.3). Bar charts of percentages of patients in remission at 6 months according to categorization of deltaPEG and deltaTSJ into quartiles showed reduced probability of remission with increasing deltaPEG and deltaTSJ (unadjusted values; figures).





Baseline deltaTSJ and deltaPEG were negative predictors of achieving DAS28<2.6, SDAI≤3.3, CDAI≤2.8 and ACR/EULAR Boolean remission after 3 and 6 months (table).

	Months	DAS28ESR < 2.6	SDAI ≤ 3.3	CDA I ≤ 2.8	ACR/EULAR Boolean
deltaTSJ	3	0.97 [0.95, 0.99] p<0.001	0.96 [0.94, 0.98] p<0.001	0.95 [0.93, 0.98] p<0.001	0.96 [0.94, 0.99] p=0.003
	6	0.96 [0.95, 0.98] p<0.001	0.96 [0.94, 0.98] p<0.001	0.96 [0.94, 0.98] p<0.001	0.96 [0.94, 0.98] p=0.001
deltaPEG	3	0.96 [0.94, 0.99] p=0.009	0.99 [0.99, 0.998] p=0.01	0.99 [0.99, 0.997] p=0.004	0.99 [0.98, 0.996] p=0.001
	6	0.99 [0.99, 0.997] p=0.002	0.99 [0.98, 0.99] p<0.001	0.99 [0.98, 0.99] p<0.001	0.99 [0.98, 0.995] p=0.001

Data are presented as OR [95% CI]

Conclusion: Discordance between patient's and physician's evaluation of disease activity reflected through deltaTSJ and deltaPEG may reduce likelihood of remission in RA. The findings are relevant for use of the treat-to-target strategy.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Remission rates in patients with rheumatoid arthritis (RA) according to RAPID3 (routine assessment of patient index data) are reported at 25% in France[1] and 21% in Norway[2]. Remission according to RAPID3 or DAS28 (disease activity score) criteria are similar and less stringent compared to the American College of Rheumatology (ACR)/European League against Rheumatism (EULAR) criteria. Addition of whether only one or no joint is swollen renders RAPID 3-based remission criteria similar to ACR/EULAR Criteria[1]. However, RAPID3 is more feasible for routine care. We examined the prevalence of remission according to RAPID3 in RA patients at three USA sites.

Methods: All patients with all diagnoses seen at 3 academic rheumatology centers complete a multidimensional health assessment questionnaire (MDHAQ), which includes RAPID3, at all visits in the waiting area, before seeing the rheumatologist in routine care. The MDHAQ includes 0-10 scores for physical function (FN), a pain (PN) visual analog scale (VAS), patient global estimate (PATGL) VAS, compiled into a 0-30 RAPID3, as well as a 0-10 fatigue VAS, RADAI self-report of painful joints of 16 joint groups bilaterally scored 0-3, and demographic data. RAPID3 categories for severity are high =≥12, moderate=6.1-12, low=3.1-6, and near-remission=≤3. Physicians complete a Rheumetric checklist, which includes 4 physician 0-10 VAS estimates for overall global status and 3 subscales for inflammation, damage and distress. A random visit for each RA patient from each site with complete data to calculate RAPID3 was analyzed for the percentage of patients in each category, compared using a chi-square test.

Results: 420 patients with RA from three different sites were analyzed. Demographic characteristics were similar at the 3 sites. RAPID3 remission rates ranged from 23% to 26%, comparable to reported rates from France[1] and Norway[2]. Other categories were virtually identical

at sites 1 and 2, but patients at site 3, a private practice, appeared to have better status; low severity ranged from 7-24%, moderate from 23-29% and high disease severity from 21-46%. Patients in remission had lower scores for fatigue and RADAI self-report painful joint than patients in other categories at all 3 sites, as well as lower physician global estimates for overall status, inflammation, damage and distress (data not shown).

Conclusion: RAPID3 remission rates at 3 US sites were 23%-26%, similar to 25% in France and 21% in Norway. RAPID3 provides a feasible approach to identify remission in busy clinical settings, as the patients do almost all the work, although addition of whether only one or no joint is swollen adds to stringency so that RAPID 3-based criteria are comparable to ACR/EULAR remission criteria. **References: 1)** Castrejon I, Dougados M, et al. *J Rheumatol* 2013, 40(4):386 - 393. 2) Uhlig T, Lie E, et al. *J Rheumatol* 2016, **43**(4):716-723.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Rheumatoid Arthritis (RA) commonly suffer disease flares. The FLARE questionnaire was developed in order to detect the presence of a flare within the 3 months previous to the medical visit. The objective of our study was to validate the FLARE questionnaire into the Spanish language and to estimate the cut-off value for defining a disease flare.

Methods: Patients with RA according to ACR/EULAR 2010 criteria, ≥ 18 years of age were included. Sociodemographic and disease characteristics were recorded. Patients attended a baseline visit and thereafter every 3 months. Disease activity (28 joints count, ESR, CRP, DAS28) and functional status (HAQ) were assessed at each visit. Baseline treatment was recorded and at each follow-up visit a treatment change was analysed. FLARE was translated into Spanish and cultural adapted. Patients completed the FLARE questionnaire, consisting of 13 statements that are answered on a 6/Likert scale. The final scores results of the addition of the 13 questions, with a final results range between 13 and 78; 13 representing the highest probability of having suffered a disease flare. Both patients and physicians had to answer if they considered having suffered a disease flare. Between each visit, patients completed a RAPID-3 questionnaire weekly. A disease flare was defined as an increase in DAS28 ≥ 1.2 or ≥ 0.6 if the previous DA28 was ≥3.2, a difference in RAPID-3 > 3.6 between each visit or a significant treatment change.

Results: 105 patients were included, 84.8% were women, with a median age of 44 years (IQR 34 to 54.7), median disease duration of 20.5 months (IQR 6 to 45.7 months). Patients were evaluated over 6 consecutive visits, however due to a lost to follow-up of more than 50%, only the first 3 visits were analyzed. The treatment change frequency at each visit was: N°1= 54/101 (53.5%), N °2= 31/57 (54.4%) and N°3= 16/33 (48.5%). And the types of treatment change frequency were: Steroid increase (43.8%), DMARDs increase (26.6%), DMARDs combination (8.3%), biologic therapy addition (16.3%), intraarticular steroid injection 41%. Association between mean FLARE values and changes in disease activity is shown in Table 1. In the ROC curve analysis a FLARE cut-off value of 50.5 showed a sensitivity and specificity greater than 60.

Conclusion: The FLARE questionnaire is a valid and simple to use instrument for detecting a disease flare in RA patients. A cut-off value ≤ a 50.5 determines the presence of a disease flare within the 3 months previous to the medical visit. **Table 1. Comparison between the FLARE questionnaire and other definitions of disease flare**

Flare according to RAPID (increase > 3.6 between 2 visits)			
	YES	NO	p
FLARE X (SD)	44 (±27.5)	51.3 (±22.1)	0.61
Flare according to DAS28 increase between visit 1 and 2			
	YES	NO	p
FLARE X (SD)	43.7 (±23.1)	54.7 (±18.7)	0.17
Flare according to physician´s opinion			
	YES	NO	p
FLARE X (SD)	43.6 (±15.9)	51.1 (±18.1)	0.24
Flare according to patient´s opinion			
	YES	NO	p
FLARE X (SD)	34.1 (±10.4)	57.2 (±15.4)	0.0001
Flare according to treatment change between visits			
	YES	NO	p
FLARE 1 X (SD)	46.1 (±16.4)	54.8 (±17.9)	0.012
FLARE 2 X (SD)	44.1 (±20.2)	61.1 (±14.9)	0.002
FLARE 3 X (SD)	36 (±16.4)	59.1 (±18.8)	0.003

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Due to the lack of consensus of the definition of a rheumatoid arthritis (RA) flare, the French "FLARE" (**FL**are **A**ssessment in **RA**) instrument was developed and validated to assess worsening of disease activity between visits for the purposes of clinical trials. Prior work by our group ensured a robust validation process of translation and back-translation from French to American English (1). The objective of this study was to assess the performance of the American-English version of the FLARE questionnaire and to assure its validity in an American Native English-speaking RA cohort.

Methods: Fifty consecutive RA patients were recruited from the UCLA multi-physician rheumatology clinics who met the 1987 American College of Rheumatology (ACR) RA criteria. Patients completed a questionnaire with the following information: demographics, Routine Assessment of Patient Index Data 3 (RAPID3), patient global visual analogue scale (VAS), self-reported flare (Y/N), and American-English FLARE. The FLARE questionnaire was subcategorized into: physical component and emotional component. Other items obtained included: MD global VAS, MD reported flare, seropositivity, disease duration, swollen joint count (SJC), and tender joint count (TJC). The clinical disease activity index was calculated (CDAI). Analyses included Wilcoxon rank sum test and Spearman correlations.

Results: Subjects were separated in to two groups based on their report of RA flare (Y/N). RAPID3, CDAI, and FLARE totals were all significantly different between the groups (Table, $p<0.05$). In addition, there was a strong correlation between FLARE total and RAPID3 (corr=0.66, $p<0.05$) and a correlation between FLARE total and CDAI (corr=0.52, $p<0.05$). In addition, the correlation between CDAI and RAPID3 was 0.76 ($p<0.5$).

Conclusion: The French/Danish and the American-English translation of the FLARE questionnaire correlate similarly with CDAI and RAPID3 (2, 3), and validates the suitable translation of the FLARE to American-English. There may be merit in using this instrument to assess flare in RA patients. However, further validation of the American-English FLARE questionnaire will be required to evaluate it prospectively in a randomized controlled trial. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Over the last two decades, survey and observational studies of drug-related consultations have consistently shown a lack of adequate medication related discussions between patients and providers. The purpose of this study is to describe medication-related discussions between patients and rheumatologists concerning prescription of a new DMARD. We specifically address whether patient-provider discussions cover clinical guideline recommendations for DMARD communication, including discussion of medication side effects, treatment options, etc.

Methods: This observational study includes data from clinic visits of 38 RA patients (3 rheumatologists) that occurred in a southeastern state from May 2014 to December 2015. Patients were eligible if they were prescribed a new or different DMARD (never prescribed before) at their rheumatology appointment. Clinic visits were audio recorded and medication-related segments transcribed verbatim. Transcripts were coded to measure aspects of the following 15 DMARD topics concerning the DMARD prescribed during the clinic visit: dosage, how to take (e.g., with food), frequency, timing, duration, types of negative side effects, side effect severity, contraindications, long-term effectiveness, drug interactions, mechanism of action, cost, length of time until medication works, medication benefits, and strategies to reduce or monitor risk. Descriptive statistics were calculated using SPSS.

Results: Approximately one third of patients (32%; n=12) had never taken a DMARD. The number of DMARDs rheumatologists discussed with patients ranged from one to seven (M=1.82, SD=1.40). The number of prescribed DMARD-related topics ranged from 7 to 14 (M=11.03, SD=1.73). No

clinic visit addressed all 15 topics and rheumatologists initiated 88% of the topics. Patients initiated the most discussions related to the following topics: drug interactions (62%), long-term effectiveness (43%), and length of time until medication works (19%). Topics that were covered most often included types of negative side effects (100%) and strategies to reduce or monitor risk (97%). Cost was not covered in about one third (34%) of clinic visits – yet, cost was one of the top three topics for which patients (40%) asked the most question, the other two being drug interactions (67%) and types of negative side effects (42%). Rheumatologists discussed an average of 4.6 negative side effects (SD = 2.7, range 1-16). The majority of patients 84% (n=32) did not express concern about any side-effects.

Conclusion: Our findings counter other studies showing patient-provider medication-related discussions lack breadth and results show that DMARD topics covered during RA patient-rheumatologist encounters address many guideline recommended topics. Findings highlight areas of strength as well as areas for improvement regarding patient-provider medication-related discussion.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treat to target (T2T) strategy has been widely recognized as effective and leading to better outcomes. There have been no questions regarding its theoretical bases however its applicability in clinical practice is challenged, particularly when audit researches on patient files are reported. Composite indices of disease activity, cornerstones of T2T strategy, should be regularly applied in therapeutic decision making and readily available. Therefore were included as desirable but not as a mandatory item in association with a questionnaire dealing with patients perspectives and barriers to T2T implementation while information about social-economical and educational patient´s backgrounds were totally compulsory. The aim of this study was to analyze the availability of composite indices of disease activity and its optional inclusion in a data base with a different focus.

Methods: the data collected by 11 investigators committed to T2T strategy in different areas of the country, in rural and urban settings, in public academic centers and in private practice were reviewed regarding the noncompulsory inclusion of the composite measures of disease activity: DAS28, CDAI e SDAI.

Results: 485 RA patients were included in the database, 86% had DAS28 (mean=3.6±2,33) ; 53.4% SDAI(19.3±22.5) and 59% had CDAI(14.913.5). The percentages of patients with composite indices collected in each center are depicted below as well the percentage of patients in private practice(last column):

Investigator	DAS28 %	DAS28 mean(SD)	SDAI %	CDAI%	missing public	missing private	Private practice
1 -south/urban	98	3.5(1.6)	80	0.8	0	4	66
2 -south/urban	100	3.8(1.5)	100	100	0	0	68
3 -south/urban	90	3.4(1.3)	0	10	10	0	0
4 -west/urban	96	3.2(1.0)	26	13	4	0	30
5 - southeast/urban	92	3.7(1.4)	86	100	8	0	10
6 - southeast/urban	0	---------- -	0	0	90	10	10
7 -southeast/rural	85	3.5(1.7)	48	50	6	2	4
8 - southeast/urban	98	3.5(1.3)	66	68	2	4	10
9 - southeast/urban	100	3.8(1.7)	100	100	0	0	36
10- north/urban	100	3.8(1.3)	0	0	0	0	38
11- north/urban	100	3.6(0,9)	0	0	0	0	100

Conclusion: DAS28 was easily obtained in the vast majorities of cases; PCR dosage was the great

obstacle to SDAI application. In the absence of laboratory tests CDAI was applied by some investigators. Academic or private settings were not a factor.

What Are the Reasons of Discrepancies Between Patients and Physicians in Their Perceptions of Rheumatoid Arthritis Disease Activity and What Is the Impact of This Discordance on Remission, Function and Structure at 1 Year?

Cécile Gaujoux-Viala[1], Nathalie Rincheval[2], Laure Gossec[3], Francis Guillemin[4], Maxime Dougados[5], Jean-Pierre Daures[6] and Bernard Combe[7], [1]Rheumatology Department, University Hospital of Nîmes and EA2415, Montpellier University, Nîmes, France, [2]Biostatistic, EA 2415, Epidemiology unit, Montpellier, France, [3]Paris 06 University and AP-HP, Hôpital Pitié Salpêtrière, Paris, France, [4]University of Lorraine, Nancy, France, [5]Paris Descartes University, Paris, France, [6]EA2415, Nîmes, France, [7]Département Rhumatologie, Hôpital Lapeyronie, Montpellier, France

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients and physicians often differ in their perceptions of rheumatoid arthritis (RA) disease activity, as quantified by the patient's global assessment (PGA) and by the evaluator's global assessment (EGA). The quest for understanding the reasons for discrepancies in evaluations of disease activity becomes particularly important in the context of recent recommendations that define Boolean-based ACR EULAR remission as the treatment target. The objectives of this study were 1) to explore the extent and reasons for this discordance 2) to determine if this discordance at baseline is associated with RA outcomes at 1 year (remission, function and structure) in early arthritis (EA) in daily clinical practice.

Methods: -Patients: from the French cohort of EA ESPOIR (at least 2 swollen joints for less than 6 months, DMARD naïve), fulfilling the ACR-EULAR criteria for RA at baseline -Analyses: At baseline, agreement between PGA and EGA (Bland-Altman plot) was assessed. Multivariate linear regression was used to determine the patient and EA features independently associated with discordance (calculated as PGA - EGA). Logistic regression was used to analyze discordance as $|PGA - EGA| \geq 20$. Multivariate logistic models were used to determine if discordance at baseline is associated with remissions (Boolean, SDAI and DAS28), functional stability (HAQ≤0.5 and deltaHAQ≤0.25) and absence of radiographic progression (delta Sharp score<1) after 1 year of follow-up.

Results: In 645 patients with ERA (mean age=48.8±12.2 years, 77% female, 48.7% ACPA +) agreement was better at both ends of the spectrum, especially for patients with high disease activity. The direction of the discrepancy usually points toward a higher rating by the patients than by physicians themselves. Evaluation of disease activity yielded discordant scores between the patients and their physicians in 30% of our cohort: 153 patients (24%) had higher PGA scores, 41 patients (6%) had higher EGA scores, and 451 patients (70%) had concordant PGA and EGA scores ($|PGA - EGA| < 20$). In multivariate linear regression center-adjusted, higher PGA has been found to be associated with absence of fulfilling ACR 1987 revised criteria for RA (p=0.0005), higher levels of fatigue (p<0.0001) and lower number of swollen joint counts (SJC) (p=0.0022). With logistic regression center-adjusted, low number of SJC (OR 95%CI=1.92 [1.26-2.91]), low mental component of the SF-36 (OR 95%CI=1.82 [1.23-2.69]) and living alone (OR95%CI=1.68 [1.09-2.58]) were associated with discordance between PGA and EGA. In multivariate analyses, discordance at baseline was not associated with remission, function and structural progression at 1 year.

Conclusion: In early RA, the discordance between PGA and EGA is multifactorial with objective measures like low SJC and absence of ACR 1987 revised criteria for RA, but also patient reported outcomes like high level of fatigue and low mental status, and environmental factor: living alone. Discordance between PGA and EGA at baseline was not associated with RA outcomes at 1 year. Understanding the reasons for a discordant view of disease activity will help to facilitate the sharing of decision-making in the management of RA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Predictors of rheumatoid arthritis (RA) response to anti-TNF agents have been described. Except for certolizumab, the value of interim analysis before 24 weeks of treatment is not clear to predict response. The purpose of this observational study was to evaluate predictors of response of anti-TNF agents in RA patients in a real-life situation tertiary center.

Methods: An inception cohort of all RA patients (ACR 1987) who received the first anti-TNF dose in the rheumatology outpatient infusion center between July, 2007 and July, 2012 was analyzed. Demographic, clinical and laboratorial data, including disease activity score (DAS28) were recorded at baseline and each 6-8 weeks and at each therapeutic change or interruption. Drug response at 24 weeks was evaluated. Remission was defined as DAS28 was ≤ 2.6 at 24 weeks. Drug survival was also analyzed. Baseline data, early (6-8 weeks) and late (14-16 weeks) significant (≥ 0.6) and very significant (≥ 1.2) changes in DAS28 were evaluated in order to predict remission at 24 weeks. Any cycle of anti-TNF was included.

Results: One hundred sixty-six RA patients were included, corresponding to 215 cycles of anti-TNF treatments. Patients were predominantly female (n= 91%;n=151); and had a positive rheumatoid factor (RF) (80%; n=133). Mean age and mean disease duration: 49.2 ± 12.2 and 12.5 ± 8.8 years, respectively. The cycles analyzed corresponded to the first one in 54% (n=116), the second in 40% (n=85) and the third in 6% (n=14). Infliximab corresponded to the main used drug (41%; n=89 cycles), followed by adalimumab (32%; n=69) and etanercept (27%; n=57). The analysis per cycle showed that, after 24 weeks, only 35 (16%) patients achieved remission. Patients who achieved remission and those who did not were similar according to age, gender, RF positivity, disease duration, number of cycles of anti-TNF, drug used, or association with methotrexate,

leflumomide or any traditional disease-modifying antirheumatic drug (p>0.05). Patients who achieved response had lower disease severity at baseline according to DAS28 (4.7 ± 1.1 *vs*. 5.7 ± 1.2; p<0.001)**,** number of painful joints (10 ± 9 *vs*. 19 ± 14; p<0.001), pain visual analogue scale (VAS) (5 ± 2.6 *vs*. 6.4 ± 2.2; p=0.01), patient global VAS (4.9 ± 2.4 *vs*. 6.5 ± 3; p<0.001), physician VAS (4.9 ± 2.1 *vs*. 6.4 ± 2.7; p<0.001), ESR (20 ± 14 *vs*. 32 ± 24; p=0.006), and HAQ (1.2 ± 0.7 vs. 1.5 ± 0.7; p=0.012). Patients who achieved remission at 24 weeks also had deeper falls in DAS28 at 6-8 weeks (1.77 ± 1.27 *vs*. 1.06 ± 1.38; p=0.009). Moreover, significant (≥ 0.6) early (weeks 6-8) falls in DAS28 [26 (84%) *vs*. 102 (64%); p=0.032) and very significant (≥1.2) late falls (weeks 14-16) were also related to remission [22 (71%) *vs*. 76 (48%); p=0.018). Significant rises (≥0.6) in DAS28 in any interim analysis were less frequent among patients who achieved remission than in patients who did not [5 (17%) vs. 47(36%), p=0.047]. Mean drug survival was 57.1 ± 50.1 weeks, without differences among the anti-TNF drugs (p>0.05). At 52 weeks, remission rate was stable (14%), but has fallen continuously every 6 months: 7% to 5% (18 to 24 months), 3% to 1% (30 to 48 months), up to 0 in 54 months.

Conclusion: The low and not sustained remission rate, regardless of the anti-TNF treatment, with short drug survival, shows the actual difficulties in treating RA in a real-life setting. Interim positive and negative significant variations in disease activity before 24 weeks of treatment can help to avoid prolonged and unnecessary exposition to such drugs.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The use of swollen (SJC) and tender joint counts (TJC) for rheumatoid arthritis (RA) disease activity and treatment effectiveness is well established. Patient reported outcomes (PRO) are important. However, it is unknown if patient scoring is as reliable as trained professionals.

Methods: PRO including SJC and TJC were assessed at baseline, 6 and 12 weeks by patients and clinicians. Data was collected using ePRO (electronic) and pPRO (paper) The Least Squares Method (LSM), Pearson correlation (Rs.) and weighted Kappa scores were used to assess inter-rater reliability and agreement of responses between the patient, nurse and physician for changes in TJC and SJC from 0 to 12 weeks treatment.

Results: Total 341 evaluable individual assessment episodes comprising 157 Nurse, 106 Patient and 78 Physician joint count episodes in 52 patients with RA of mean duration 11.7 (SD 10.97) years and mean age 55 (SD 14.3, 77% female) enrolled in the study. At baseline, matched joint count episodes were available for 104 Patient - Nurse, 72 Physician - Nurse and 21 Patient - Physician pairs. Correlation of TJC scores per assessor pairs were Rs. 0.83; $p<0.001$(Patient-Nurse), Rs 0.85; $p<0.001$(Physician-Nurse) & Rs. 0.59; $p=0.005$(Physician-Patient) (Table 1). The inter-rater reliability (agreement) of the Patient-Nurse pairs had a weighted Kappa of 0.59 (0.53, 0.68) (Figure 1). Correlation of SJC scores per assessor pairs were Rs. 0.69; $p<0.001$(Patient-Nurse), Rs 0.66; $p<0.001$(Physician-Nurse) & Rs. 0.42; $p=0.058$(Physician-Patient) (Table 1). The inter-rater reliability (agreement) of the Patient-Nurse pairs had a weighted Kappa of 0.48 (0.41, 0.55). The comparison suggests that the biggest discrepancy is from Physician assessments of improvement (interaction between assessor and time).

Conclusion: There is a moderate to high level of agreement between clinicians and patient TJC and SJC assessments that suggest it may be a useful option in assessing joints and response in RA. Further evaluation of activity tools ie DAS28, CDAI or SDAI utilising patient assessments may be worth exploring. Acknowledgements 1. UCB Australia for access to database, assistance with analysis and financial support. 2. Australian Rheumatologists contributing patients to the study.

Table 1: PRO Spearman Correlation coefficients scores (p values) for Swollen Joint Count(SJC) and Tender Joint Count(TJC) between Nurse, Physician and Patient

Joint Assess	Assessor	Nurse	Patient	Physician
PRO- TJC	Nurse	1.00	0.83(<.0001)	0.85(<.0001)
	Patient	0.83(<.0001)	1.00	0.59(0.005)
	Physician	0.85(<.0001)	0.59(0.005)	1.00
PRO- SJC	Nurse	1.00	0.69(<.0001)	0.66(<.0001)
	Patient	0.69(<.0001)	1.00	0.42(0.058)
	Physician	0.66(<.0001)	0.42(0.058)	1.00

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment of patients with rheumatoid arthritis (RA) is guided by monitoring changes in disease severity. At present, patients do not routinely record disease severity between clinic visits, despite the availability of a range of validated patient reported outcome measures (PROMs). In response this, the REMORA study (**RE**mote **MO**nitoring of **R**heumatoid **A**rthritis) is developing and evaluating a Smarthphone app which patients can use to record key ePROS (electronic patient reported outcomes) between clinic visits, and link these to the electronic patient record (EPR). The aim of this analysis is to examine patients' views of using the beta version of the app and explore its impact on their post-app clinical consultation. In particular we were interested in seeing if the app could overcome some of the limitations of the current consultation process, i.e. reliance on patient recall, eloquence and stoicism regarding their symptoms between clinic visits.

Methods: The 'beta app' was tested by eight patients for one month during which they completed routine question sets at home, with the data integrated into the hospital EPR. Question sets included seven visual analogue scales for daily symptoms including pain and fatigue; weekly self-reported count of tender and swollen joints, flares, and impact on work; and monthly completion of the health assessment questionnaire (HAQ). A free text diary function was provided for ad hoc recording of information, although this wasn't exported into the record. Patients were invited to a clinical consultation 'pre' and 'post' app use. These were used to determine the value of having access to routinely recorded ePROS at the consultation. Individual interviews were held with participants to discuss their experience of using the app and the use of the data as part of the clinical consultation. Feedback was also obtained from the consulting clinician.

Results: Patients' felt that the app was "a great idea" and made care "more personal to you". Data recording improved the consultation as it aided recall and made it easier for patients to have a "shared conversation" with the clinician at the consultation as "with a graph…you can see what's going on." "I found it made a difference, because it wasn't all me telling him and trying to remember. The information was there so you've got solid proof straightaway" These views were echoed by the consulting clinician as the ePROS made it possible to quantify responses to treatment across physical and mental health. The graphs highlighted flares that patients hadn't mentioned, and

demonstrated gradual improvements in symptoms in response to treatment that may otherwise have been missed, therefore supporting decision making regarding the continuation of treatment. Routine completion of data was relatively straightforward - "it's a doddle" - and not too onerous. A number of minor refinements to the app design and question sets were suggested by patients and will be incorporated into the app.

Conclusion: The app was well received by patients and feedback suggests that the data recorded will have a number of benefits for both patients and clinicians.

Identifying Key Variables for Inclusion in a Smartphone App to Support Clinical Care and Research in Patients with Rheumatoid Arthritis

William G Dixon[1], Caroline Sanders[2] and **Lynn Austin**[3], [1]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, Great Britain, [2]Institute of Population Health, Centre for Primary Care, The University of Manchester, Manchester, United Kingdom, [3]Centre for Primary Care, University of Manchester (UK), Manchester M21 9JD, United Kingdom

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment for patients with rheumatoid arthritis (RA) is shaped by monitoring changes in disease severity over time. At present, clinicians managing RA have few (or no) objective measurements of disease activity between clinic visits, even though a number of patient related outcomes measures (PROMs) exist. Smartphones provide a possible solution to allow regular monitoring of disease severity between clinic visits with integration into electronic medical records. Benefits could include better information for consultations, triaging of outpatient appointments and aiding patient self-management. Such data can also support novel research by

providing temporally-rich data. REMORA (**RE**mote **MO**nitoring of **R**heumatoid **A**rthritis) is a study which is designing, implementing and evaluating a system of remote data collection for people with RA for health and research purposes. The project asks whether electronic collection of patient reported outcomes (ePROS) directly from patients between clinic visits can enhance clinical care and provide a sustainable source of data for research. The aim of this paper is to describe the process of determining the ePROS for inclusion in the app, in preparation for piloting the app in clinical practice, and to present the final dataset.

Methods: This study obtained stakeholders' views on the potential value of recording a range of ePROS. Interviews were conducted with 10 RA practitioners (clinicians, nurses and physiotherapists), 12 RA researchers and 21 patients. Interviews determined provisional ePROSs for inclusion, recording frequency, and value of a free text diary. Table 1 summarises the approach to gaining consensus on app components.

Results: All stakeholder groups wanted to capture information on changes in disease activity and the impact of the disease (physically and emotionally). Practitioners and researchers wanted routine data that had been recorded consistently using existing validated tools (such as the DAS 28 and the HAQ), but saw the value of a diary for recording triggers and alleviators of disease activity. Patients favoured recording notable events (such as flares) as they occurred, however, they could see the benefits of recording data routinely to see patterns in disease activity. The final data set therefore comprised a combination of routine data and a diary (table 2).

Conclusion: Consensus on the key components of the Smartphone app was achieved using the process outlined in table 1. The components shown in table 2 have now been incorporated into the 'beta app' in readiness for piloting within clinical practice.

Table 1: Consensus process

- Qualitative interviews were conducted with researchers and practitioners to determine their preferences regarding the components of the app and the rationale for their choices

- A table summarising the key components suggested by practitioners and researchers was generated in preparation for discussion and feedback from the PPI (patient and public involvement) group working alongside the research team

- The content and wording of the tabulated information was refined in response to suggestions made by the patient group in preparation for patient interviews

- Qualitative interviews were conducted with patients with RA to determine their preferences regarding the components of the app. Following this open discussion, patients were shown the tabulated information, derived from practitioner and researcher interviews, and patient feedback sought on the suitability of components suggested

- The components which had widespread consensus across the stakeholder groups were incorporated into the app

- Suggested components that did not have consensus across all groups, or were beyond the scope of the study, were documented with a view to being incorporated into future developments. Components suggested included the facility for taking photographs, and linking the app to a device, such as a pedometer, for measuring exercise

- PPI group members reviewed and commented on the final components prior to their incorporation into the beta app

Table 2: Final data set – frequency, components and mode of data capture		
Daily question set	Pain Difficulty with physical activities Fatigue Sleep difficulties Physical wellbeing Emotional wellbeing Coping	10 point visual analogue scale
	Morning stiffness	Fixed 7 point scale (radio button)
Weekly question set	Number of tender joints Number of swollen joints	Numeric value
	Global assessment of wellbeing	10 point visual analogue scale
	Employment status	Yes/No response (radio button)
	Impact on hours worked	Numeric value
	Experienced a flare	Yes/No response (radio button)
	Description of flare	Free text box
Monthly question set	Health Assessment Questionnaire (HAQ) impact of disease on daily activities including function, mobility and grooming	Fixed point scales (radio button) plus free text entry box

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : To compare the performance of DAS-28 CRP, CDAI and SDAI composite measures to assess status of patients with Rheumatoid Arthritis on Methotrexate, versus DAS-28 CRP as the gold standard.

Methods : 135 patients with RA as per the 2010 ACR/EULAR criteria were included in the prospective study. The disease activity was assessed at baseline and at every 6 weeks for 24 weeks, by DAS-28 CRP, CDAI and SDAI. Patients were divided into groups of remission, low, moderate and high activity on the basis of predefined cut-offs for DAS-28 CRP, CDAI, and SDAI. A Spearman correlation between composite measures and inter-group comparison of the measures were performed.

Results : There was an excellent positive correlation between DAS-28 CRP and CDAI (linear weighted k baseline – 0.545), DAS-28 CRP and SDAI (linear weighted k – 0.689) at baseline. There was moderate agreement between DAS-28 CRP and CDAI (linear weighted k final visit – 0.458) at final visit. There was moderate correlation between SDAI and DAS 28 CRP at final visit (linear weighted k– 0.470). (Fig shows excellent correlation between CDAI vs DAS 28 CRP and SDAI vs DAS28 CRP at base line but not at final visit. However, correlation between CDAI vs SDAI remained excellent). Patients in remission as per DAS-28 CRP had significantly more residual disease activity compared to SDAI and CDAI remission criteria.

Conclusion: The study shows an excellent strong positive correlation between DAS-28 CRP, CDAI and SDAI at initial evaluation but not at final visit. SDAI and CDAI based remission criteria seems to be better than DAS28-CRP based remission criteria.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Aiming at rapid decrease of disease activity, there has been a trend to start with higher doses of methotrexate (MTX) for newly diagnosed rheumatoid arthritis (RA) patients, not only for MTX monotherapy, but also in combination with other antirheumatic drugs (DMARDs). We hypothesized that in combination with other very effective medication, there might be no additional benefit of high over low doses of MTX. We studied the relationship with early clinical response of high versus low doses of MTX in mono- and combination therapy in DMARD naive early RA patients.

Methods: RA patients included in the observational international METEOR cohort with symptom duration ≤5 years, time between diagnosis and first visit ≤2 months, MTX prescribed at first visit, no medication change within 3 to 6 months and available disease activity information were selected. Patients were divided into 4 medication groups: MTX monotherapy, MTX + synthetic (cs)DMARDs, MTX + oral glucocorticoid (+ possibly csDMARDs) or MTX + biologic (b)DMARDs (+ possibly csDMARDs). Missing data were imputed using multivariate normal imputation. MTX dose was dichotomized: low dose ≤10 mg/week & high dose ≥15 mg/week. A propensity score (PS) was calculated to adjust the relationship between MTX doses and outcome for potential confounding by indication. Linear mixed model analyses for DAS, DAS28, and HAQ were performed for each medication group, with 'MTX-dose' & 'days between visit and baseline assessment (time)' as co-variates. Associations were adjusted for the PS. Random intercept and slope were used to account for irregular time intervals between visits. Each model was tested for the presence of an interaction between 'MTX dose' and 'time'.

Results: Patients on MTX monotherapy had lower baseline disease activity and fewer were erosive and autoantibody positive; other baseline characteristics were comparable between medication groups. The number of patients on combination therapy with bDMARDs was too small to perform analyses (n visits=26, n patients=11). For patients on MTX monotherapy, no differences in efficacy

between high and low MTX dose were seen for DAS28 and HAQ. Only DAS decreased slightly *less* in the high dose initial MTX compared to the low dose group (β=0.0021, 95% CI=0.00012; 0.0041) for interaction between MTX dose and time). No differences in clinical response between high or low dose MTX were seen in patients on combination therapy with csDMARDs or glucocorticoids (table 1).

Conclusion: In DMARD naive early RA patients, there seems to be no early clinical benefit of high over low initial MTX doses, neither for MTX monotherapy nor for combination therapy with MTX/csDMARDs or glucocorticoids. Contrary to expectations, DAS (but not DAS28 or HAQ) even appeared to decrease slightly less after higher doses of MTX monotherapy. However, this effect was very small and may be explained by unmeasured baseline differences between high and low MTX dose groups not captured by the PS.

Table 1. Results of the linear mixed model analyses to investigate the effectiveness of high versus low methotrexate doses on disease activity and physical functioning, stratified per medication group.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Poor prognostic factors can determine the extent of disease progression, disability and treatment outcomes in patients (pts) with RA. It is currently unknown whether the presence of poor prognostic factors influences treatment decisions in pts with RA. The purpose of this study was to report patterns of medication use and the change in CDAI score between baseline and 12 months by prognostic factors.

Methods: Using the Corrona RA registry, we identified pts with RA who were biologic naïve at enrollment and had a follow-up visit at 12 months (± 3 months). Pts were characterized at enrollment in terms of RA prognosis based on the 2008 ACR treatment recommendations,[1] including functional limitation (based on modified Health Assessment Questionnaire), extra-articular disease (Sjögren's syndrome, RA lung disease and/or nodules), seropositivity (RF and/or anti-cyclic citrullinated peptide antibodies) and erosions. Pts were categorized as having 0–1, 2 or 3+ poor prognostic factors. Outcomes investigated included the use of a biologic/targeted synthetic DMARD

(b/tsDMARD) over the 12-month follow-up period and examination of initiation of any DMARD (e.g. conventional or b/tsDMARD). Logistic regression models (unadjusted and adjusted for sex, age and baseline CDAI) examined the relationship between prognosis and outcomes. In the subset of pts with CDAI score at baseline and 12 months (n=3510), the reduction of disease activity was examined in adjusted models in the three poor prognosis groupings.

Results: There were 3621 pts enrolled on/after January 2005 who met the selection criteria: 1554 (42.9%), 1263 (34.9%) and 804 (22.2%) pts with 0–1, 2 or 3+ poor prognostic factors, respectively. An increased number of poor prognostic factors was associated with older age (median age: 58, 60 and 62 years, $p<0.001$), greater disease duration (median: 1, 2 and 4 years, $p<0.001$) and increasing disease activity (median CDAI score: 7, 9.6 and 14, $p<0.001$, for the 0–1, 2 or 3+ prognosis groupings, respectively). The proportion of pts initiating a b/tsDMARD was greatest in those with 3+ vs 0–1 poor prognostic factors ($p=0.024$). However, when adjusting for differences in baseline characteristics (including CDAI score), there was no significant relationship between poor prognosis and b/tsDMARD use (Table). There was no significant relationship between poor prognosis category and any DMARD initiation in the unadjusted and adjusted analyses (Table). After adjusting for CDAI score at enrollment, mean reduction in CDAI score over 12 months was significantly less for those with 3+ vs 0–1 poor prognostic factors (Table; $p<0.001$).

Conclusion: These findings suggest that the presence of poor prognostic factors does not influence treatment decisions. This may warrant reconsideration as there was a diminished reduction in disease activity in those with a greater number of poor prognosis factors. 1. Saag K, et al. *Arthritis Rheum* 2008;**59**:762–84.

Table. Logistic regression analysis to predict biologic use by the 12-month visit, change in overall treatment approach and change in CDAI from enrollment to 12 months according to poor prognosis category				
	Poor prognosis indicators			
	0–1	2	3+	p value**
Biologic use by the 12-month visit				
Unadjusted OR (95% CI)	Reference	1.16 (0.97, 1.39)	1.39 (1.14, 1.70)	0.005
Adjusted OR* (95% CI)	Reference	1.00 (0.82, 1.23)	1.10 (0.87, 1.40)	0.49
Change in overall b/tsDMARD treatment from enrollment to 12 months†				
Unadjusted OR (95% CI)		1.11 (0.95, 1.29)	1.19 (1.00, 1.41)	0.13
Adjusted OR* (95% CI)		1.00 (0.84, 1.18)	1.00 (0.81, 1.23)	>0.99
Change in CDAI from enrollment to 12 month				
Unadjusted, mean (SE)	–3.05 (0.32)	–4.96 (0.36)	–5.44 (0.45)	<0.001
Adjusted,‡ mean (SE)	–4.92 (0.24)	–4.50 (0.26)	–2.50 (0.34)	<0.001
*Adjusting for sex, age, duration of RA and baseline CDAI **p value is calculated based on an overall likelihood ratio test of the impact of poor prognosis †Change in overall treatment from enrollment to the 12-month visit reports the treatments a patient initiated over the 12-month period (e.g. conventional or b/tsDMARD) ‡Adjusted by CDAI at enrollment OR=odds ratio

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a known cause of work productivity loss. Participation in work-related activities is defined as part of the primary goal of RA treatment in the 2015 Treat-to-Target recommendations (1). The objective of the current study was to compare sick leave rates in early RA patients in a tight control Treat-to-Target study to early RA patients followed in an observation study without treatment algorithms.

Methods: We used data from two studies, ARCTIC (inclusion Oct 2010 – April 2013, fulfillment of 2010 classification criteria, symptom duration<2 years, DMARD-naive with indication for DMARD) and the NOR-VEAC study (inclusion Oct 2004 – Aug 2010, patients included in the analyses fulfilled 2010 criteria for RA, symptom duration <16 weeks, DMARD-naive). Patients in ARCTIC were treated according to a predefined algorithm with treatment target of DAS<1.6 and SJC44=0. In half the patients, an additional target was no ultrasound power Doppler signal. NOR-VEAC patients were treated according to the physicianÕs preference. Data collection included identical questions on work participation, and in the ARCTIC study additionally the Work Productivity and Activity Impairment Questionnaire. We compared the proportion of patients reporting sick leave among patients not reporting retirement or disability pension across studies at baseline, 8 and 16 months, the time points with most data available in both cohorts, by chi-square test.

Results: The mean (SD) age for the 229 patients in ARCTIC was 51.4 (13.7) years, disease duration 7.1 (5.4) months, DAS28 4.4 (1.2), 61% were female and 86% seropositive. The 259 NOR-VEAC patients had shorter mean (SD) disease duration (2.0 (1.0) months, p-value <0.001), higher DAS28 (5.3 (1.3), p-value<0.001) and lower seropositivity rate (74%, p-value <0.001). NOR-VEAC patients had comparable age (52.7 (14.1) years) and gender distribution (64% females) to ARCTIC. In ARCTIC, levels of presenteeism and absenteeism at two years were overall very

low, with substantial improvement from baseline (figure 1). While 30.9% of employed ARCTIC patients reported 100% absenteeism at baseline, the corresponding number at 24 months was 3.7%. When comparing the cohorts after 16 months 14.5% of patients in ARCTIC and 26.1% of patients in NOR-VEAC reported any sick leave (p-value 0.01). No difference in sick leave was found between ARCTIC and NOR-VEAC at baseline but a trend was observed at 8 months (figure 2).

Figure 1: Follow-up data from patients treated according to a tight control treat-to-target regimen (ARCTIC) **A)** Absenteeism (in employed patients) **B)** Presenteeism (patients with work attendance)

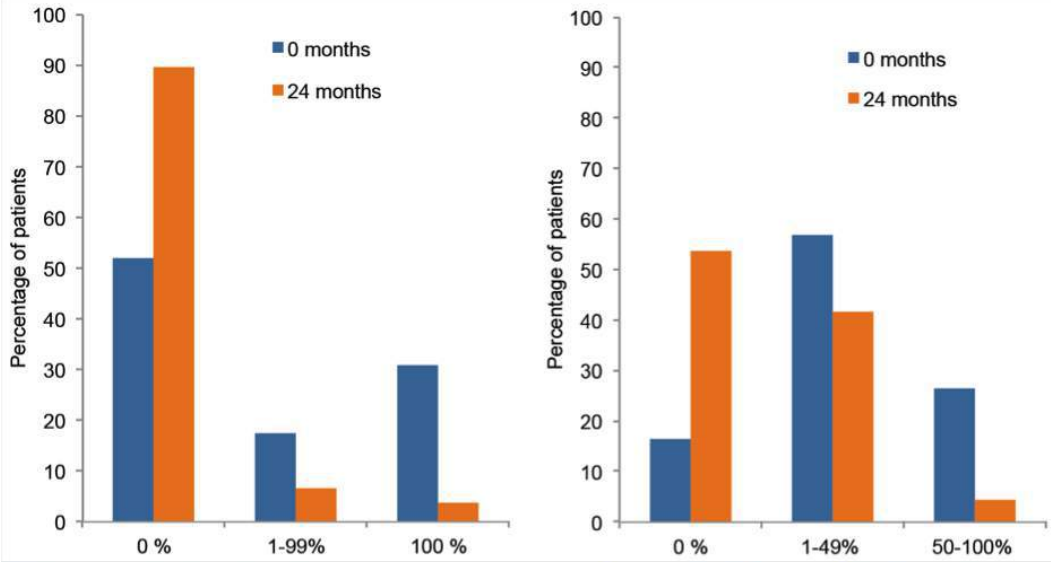

Figure 2: Sick-leave rates in patients followed with treat-to-target tight control (ARCTIC) and without (NOR-VEAC)

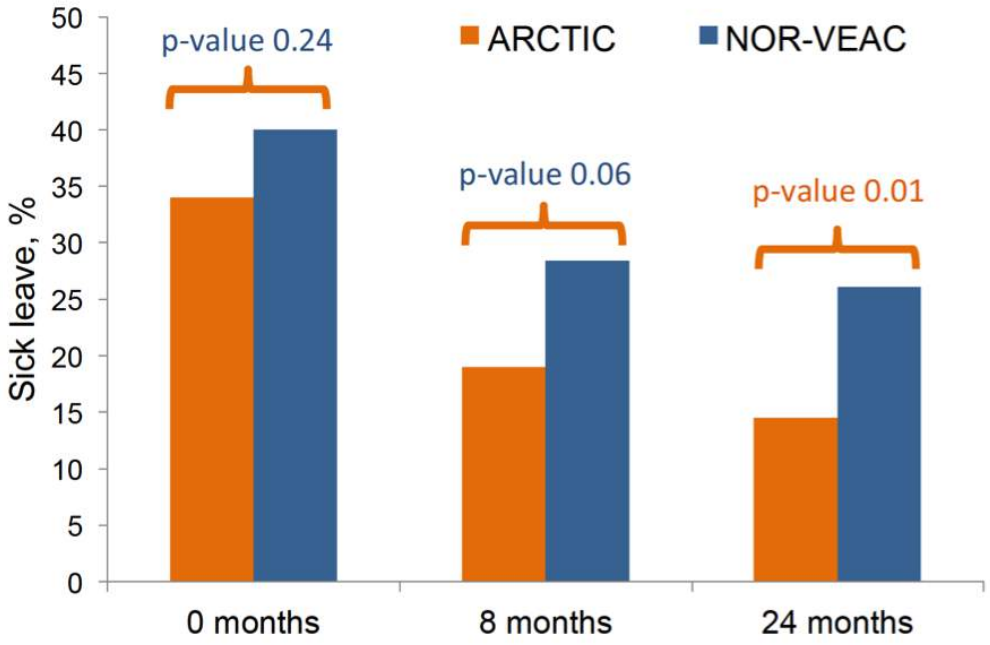

Conclusion: Patients with early RA in a tight control treat-to-target study reported very little work productivity loss after two years. Sick-leave rates were significantly lower than in a previous cohort of early RA patients followed without implementation of such principles. The results support that patient care based on modern treatment strategies improves participation in work-related activities, a defined goal for RA treatment. **References:** (1) Smolen et al. Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, there has been a trend to start methotrexate (MTX) in higher doses, either as monotherapy or in combination with other drugs in rheumatoid arthritis (RA) trials –and likely also in daily practice. It is unclear whether higher initial doses are associated with better short term clinical responses, especially in combination therapy with other effective disease modifying anti-rheumatic drugs (DMARDs). We investigated the short term relationship with early clinical response of various doses of MTX in monotherapy and combination therapy in DMARD naive early RA patients.

Methods: A systematic literature search was performed, including early, DMARD naive RA patients, treated with MTX, showing disease activity results within 3 to 6 months follow-up.

Cohen's effect sizes (ratio of mean change in score and baseline SD, with negative scores indicating improvement) were calculated for the health assessment questionnaire (HAQ), erythrocyte sedimentation rate/c-reactive protein (ESR/CRP) and/or DAS/DAS28 in 4 treatment groups: MTX monotherapy, and MTX in combination with synthetic (cs)DMARDs, or with biologic (b)DMARDs or with oral glucocorticoids. Multivariate random-effects meta-regression analyses were performed for each outcome, with treatment group as predictor corrected for standardized baseline disease activity and month of assessment.

Results: Out of 2567 articles and 417 meeting abstracts, 31 studies including 5589 patients were extracted. The meta-regression (table 1) did not show any indication for higher effectiveness of increasing MTX doses in monotherapy. In combination with glucorticoids a higher MTX dose was statistically significantly associated with higher HAQ (β=0.012, 95% CI 0.00070;0.023), but not with DAS/DAS28 or ESR/CRP. In combination with bDMARDs a higher MTX dose was statistically significantly associated with higher HAQ (β=0.042, 95% CI 0.012;0.073) and DAS/DAS28 (β=0.033, 95% CI 0.0070;0.059). These effect sizes were too small to indicate clinical relevant effects on disease activity/functional ability. There were too few treatment groups using MTX in combination with csDMARDs to evaluate in the meta-regression.

Conclusion: In DMARD naive early RA patients, a higher initial dose of MTX either as monotherapy or in combination with a bDMARD or glucocorticoid was not associated with better clinical responses within 3 to 6 months of treatment start. Initial combination therapies with a bDMARD or glucocorticoid show higher effect sizes than initial monotherapy. The results suggest that such initial combination therapies give better short term clinical outcomes, but that the benefits to be expected from higher in stead of lower doses of MTX is negligible.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The anti-TNF monoclonal antibody Infliximab (Ifx), has proven effective in treating rheumatoid arthritis (RA), although in 40% of cases may fail, mainly due to immunogenicity. A good clinical response is usually associated with high serum drug levels; however, it is not clear why some patients have a faster drug clearance since the beginning of the therapy. Formation of immunocomplexes between antibodies to Ifx (ATI) and Ifx can increase drug clearance, leading to treatment failure.The aim was to analyze whether serum Infliximab trough levels (ITL) at the induction phase were related to Ifx disappearance and clinical outcomes at week (w) 54. The early development of immunogenicity as a related factor with low ITL was also investigated.

Methods: In this observational retrospective study ITL were measured from 66 RA patients from the prospective biological cohort of La Paz Hospital. Serum samples were taken at w2, w6, w14 and w22. Serum-dependent receiver operating characteristics (ROC) curves were used to establish the ITL value that better predicts the absence of Ifx atw54. ATI were measured by bridging ELISA and by an acid-dissociation method without drug interference IDK (Immundiagnostik®, Germany). Patients were grouped as ITLpos if they had detectable Ifx at w54 and ITLneg otherwise.

Results: ITLneg patients (n=25) had significantly lower levels at all time points than ITLpos (n=41). Based on ROC values ITL at w6 (4.44 μg/ml) had the best predictive value for disappearence of Ifx at w54 with a 70% sensitivity (95%CI 45.7-88.1), 95% specificity (95%CI 83.1-99.4) and positive likehood ratio of 14. Most patients in low disease activity or remission at w54 had at w6 ITL upper the predictive cut-off [20/44(45%) upper cut-off vs 3/20(15%) under cut-off p=0.02] and most EULAR responder at w54 had ITL upper the predictive cut-off at w6 [33/43(77%) vs 10/21(48%);p=0.08]. Treatment survival of patients with ITL upper 6w cut-off was longer: 5 years (1.6-5.0) vs 1.7 years (0.2-0.6); p=0.012.In the multiple logistic regression analysis, after adjusting for confounders (age, sex, body mass index, baseline DAS28, PCR, TNF and IL6) with ITL at w2 and at w6, the absence of Ifx levels at w54 was significantly associated with ITL under the cut-off at w2 (OR: 15.85; 95%IC 2.95-85.03; p=0.01), at w6 (OR: 86.64; 95%IC 6.58-1139.99; p=0.001) and no MTX use (OR: 12.26; 95%IC 1.83-82.22; p=0.001 for w2; OR: 6.9; 95%IC 1.04-45.84; p=0.04 for w6). Most patients with ITL under the cut-off at w6 were positive for ATI along the first year [15/20(75%) under cut-off vs 5/44(11%) upper cut-off, p<0.0001]. Most ATI were detected earlier by the IDK than with bridging.

Conclusion: Low ITL at early stages (w2 and w6) are associated with the Ifx absence, the early drop-out of the treatment and the clinical outcome at w54, being the presence of ATI the main reason for the low early circulating drug levels. We also conclude that the cut-off value at w6 (4.44 μg/ml)

provides the clinicians with a useful prognostic tool of treatment efficacy.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor alpha (TNF-α) inhibitors are effective, safe and widely used treatment for rheumatoid arthritis (RA). The therapy is often started in combination with methotrexate (MTX). However, less is known about the effectiveness of the combination with (or without) MTX on long term TNF-α inhibitor use. The aim of this study was to assess the nine year drug survival of patients started on etanercept or adalimumab treatment with or without concomitant MTX.

Methods: A total of 1230 consecutive patients were included in the etanercept (EtRA, n=643, 52%) and adalimumab (AdRA, n=587, 48%) cohort at the Jan van Breemen research centre in Amsterdam,

The Netherlands, from Feb 6th 2004 to March 12th 2014. The choice of biological was determined by the treating rheumatologist. If patients switched between both biologicals, only the first biological was used in this study. All patients fulfilled the American College of Rheumatology classification criteria for RA. Drug survival was assessed with Cox Regression.

Results: For etanercept, 186 (28%) used MTX at baseline and 371 (58%) dropped out. Median survival was 1.6 (0.4-4.0) and maximum survival was 9.2 years. In the adalimumab treated group, 373 (64%) used MTX at baseline and 350 (60%) dropped out. Median survival was 1.3 (0.4-4.4)and maximum survival was 9.3 years. Adalimumab patients without MTX were 2.61 (2.11-3.24) times more likely to drop-out than adalimumab patients with concomitant MTX (Figure 1). For etanercept treated patients this was 1.23 (0.98-1.54) for those with versus without MTX.

Conclusion: Although the drug survival of etanercept patients with and without MTX differed slightly, there was a much greater difference in the drug survival of adalimumab patients with MTX versus without MTX. This is probably due to the inhibition of anti-adalimumab antibody formation by MTX, whereas no clinically relevant antibodies for etanercept have been found. Whether or not the choice for adalimumab or etanercept should be guided by tolerance for MTX remains to be established.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Discordance in the assessment of rheumatoid arthritis (RA) disease activity has been reported in 30% of patient-clinician dyads, with discordance higher for those with depressed mood. Our objective was to pilot-test a tablet-based, patient-reported symptom tool to improve communication around preference-sensitive symptoms among diverse RA patients.

Methods: We conducted a pilot study to test the acceptability, feasibility and efficacy of CHOICE RA, a tablet-based, preference-sensitive symptom reporting tool. 58 symptoms derived from the literature and patient and rheumatologist focus groups populate the tool across 4 categories: 1) Physical symptoms, 2) Function; 3) Feelings and relationships, 4) Joint pain and swelling. Patients select and prioritize symptoms based on their perceived need for care. Eligibility was: age ≥18, Spanish or English speaking, and diagnosis of RA. Participants from two university-affiliated rheumatology clinics were enrolled into one of two study arms. All patients completed CHOICE RA before their appointment, and later a post-visit survey. In Arm 2, clinicians received a summary of patients' choices but not in Arm 1. The primary outcome was congruence between mean total patient-reported symptoms and those discussed in the visit. Congruence for high priority symptoms stratified by language was investigated. Acceptability and satisfaction were measured in clinicians and patients. We compared means using t-tests and proportion of high priority symptoms discussed using Fischer's exact tests.

Results: 45 patients enrolled (Arm 1: 24, Arm 2: 21), 91% were female; mean age 53±13, 56% Spanish-speaking, 42% had limited health literacy. There were no statistically significant differences in congruence scores by study arm. However, in subgroup analyses, a significantly

greater number of high-priority mood symptoms were discussed in arm 2 (55%) compared to Arm 1 (0%) among Spanish-speakers (p=0.04). Majority (≥ 90%) found the tool acceptable based on ease of use and usefulness. 98% reported the tool facilitated communication with their doctor.

Conclusion: CHOICE RA was highly acceptable to Spanish and English-speaking RA patients and clinicians, and helped patients communicate high priority symptoms to their clinician. While it did not increase congruity in total symptoms listed vs. discussed overall, it increased discussion of mood symptoms highly prevalent in this vulnerable group with communication barriers. Results from this promising pilot study should lead to a larger, multi-site trial to evaluate its impact on a broader population.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Treat to Target (TTT) model is well established in the treatment of rheumatic disease. Achieving DAS remission is one of the primary goals of clinicians managing RA.

It has become increasingly apparent that the Treat to Target approach is not feasible in all patient subgroups. Rather, patients often enter a low disease activity state but even with modern therapy, cannot achieve TTT remission. The important question is whether low disease activity state is sufficient to prevent joint damage progression. To assess the impact of TTT DAS low disease activity and remission states on MRI and x-ray progression in Rheumatoid Arthritis (RA) in patients treated with Adalimumab and synthetic DMARD's.

Methods: Single blind, observational radiological outcome study; four sites. Inclusion criteria: RF/CCP positive RA with stable therapy over 6 months. Cohort A: Disease Activity Score (DAS) of < 2.6 on conventional DMARD therapy; Cohort B: DAS score of > 3.2 on Adalimumab therapy; Cohort C: DAS score of < 2.6 on Adalimumab therapy. Participants reviewed every 3-months for 18 months. MRI (T1 GRE and T2 STIR) of the dominant MCP 2-5 / wrist and plain radiographs hands/feet undertaken at baseline and at 18 months. MRI and radiographs were be assessed by one blinded central reader using the RAMRIS score and van der Heijde modification of the Sharp score. Statistical analysis: Differences between Cohorts at baseline were assessed using the Wilcoxon Rank Sum Test. Logistic regression was used to examine associations between radiological progression and cohort, baseline MRI features of synovial thickening, erosion and osteitis.

Results: 110 patients completed the study: 54 in cohort A, 33 in cohort B and 23 in Cohort C. Baseline demographics were similar across all three groups. Cohort A mean age 61, B 58, C 59 years. Disease duration A mean 10 years, B 11 years, C 14 years. The cohorts demonstrated statistically significant differences at baseline for measures of pain, global status, RAPID 3 scores, and Patient Global Assessment (PGA) with no statistically significant differences between XRay and MRI scores at baseline. DAS28 CRP changed in all cohorts, increasing in Cohort A but decreasing in Cohorts B and C. There was no statistically significant difference in Xray progression or MRI measures of progression between the cohorts.

Conclusion: Despite differences in remission status at baseline and taking into account changes in DAS CRP over time, there were no statistically significant differences in radiograph or MRI progression between the three cohorts. This study underscores the need to continue to re-evaluate the Treat to Target approach. Smolen JS,Breedveld FC, Burmester GR,et al. Ann Rheum Dis 2015 annrheumdis-2015-207524

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Flares are a common experience in RA, often associated with worse clinical outcomes such as cardiovascular disease, lower functional status, and radiographic progression. Many flares develop between rheumatology visits, thus little is known about management strategies. This study aims to examine which strategies contribute to a successful post flare outcome.

Methods: Data from 317 patients enrolled in a prospective RA registry were collected, including clinical and patient reported outcomes. Patients completed a flare survey asking about frequency, outcomes, and management; including a Likert scale assessing if post flare symptoms were better, unchanged, or worse (Figure 1). Ordinal logistic regression analysis adjusting for age, sex, number of flares in past 6 months, severity of most recent flare (0-10), home management, clinical treatment, and medication change was performed with symptoms post flare as the outcome.

Results: 114 patients had a flare that had ended (87.7% female, mean age 59 (±14.2) years, median disease duration 14 (IQR 9, 24) years). Median flare severity was 7 (5, 8). Compared with RA symptoms before the flare, 16 (14%) patients reported worsened RA symptoms post flare, 71(63%) were unchanged, and 26 (23%) were improved. To manage flares, 90 (79%) patients used home management (e.g. ice/heat (53%) and rest (61%)), and 58 (51%) reported making a medication change (50% NSAIDs, 32% corticosteroids, 26% DMARDs). Only 30 (26%) patients sought clinical advice (e.g. rheumatologist (87%) and PCP (7%)). Of note, 59% of patients who made a medication change did so without seeking clinical advice. The logistic model (Figure 2) revealed that patients who made a medication change, of any kind, to treat their flare were more likely to have improved RA symptoms post flare than patients who made no medication change (OR=3.715, p=0.004). No other covariates were significant, including flare frequency and severity. In a sub analysis, individual medication category did not influence post flare outcome.

Conclusion: Independent of home based or clinically guided care, making a medication change is strongly associated with improved post flare outcomes. This improvement was not attributable to any one category of medication and the decision to make a medication change was frequently made without seeking clinical advice. This has implications for understanding how best to intervene when patients flare. Future directions could examine if specific medication changes in combination with home or clinical management strategies facilitate better post flare outcomes. **Figure 1: RA Symptoms Post Flare**

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by inflammation, joint pain, destruction of the synovial membranes and metabolic alterations due mainly by the liberation of tumor necrosis factor alpha and interleukin-1 beta, leading to rheumatoid cachexia. Dynamic exercise has demonstrated to improve muscular function and strength, as well as joint mobility without negative effects on RA. Also, a diet focused on the consumption of certain

fatty acids like the Mediterranean is recommended to reduce inflammation. Thus, the aim of this study was to assess the effect of a dynamic exercise program in combination with a Mediterranean diet (MD) in strength, joint mobility and disease activity in women with RA.

Methods: We undertook a randomized controlled trial including 95 women with diagnosis of RA (2010 ACR/EULAR classification criteria). Handgrip strength, goniometry and DAS28 score were evaluated at baseline and 6 months follow-up. Patients were classified into four groups: G1 (n=28) with dynamic exercise and MD; G2 (n=21) with dynamic exercise only; G3 (n=26) with MD only, and G4 (n=20) controls. G2 and G4 were given general dietary recommendations as well as G3 and G4 were given general physical recommendations. All patients received standard medical treatment for RA prescribed by a rheumatologist. Percentage change was calculated to assess the magnitude of effect and ANOVA test was used for comparison between groups. The results were adjusted according to functional class following the ACR guidelines.

Results: Ninety-five women were included, with a median age of 49.5 (40-60) years, median disease duration of 14 (6-20) years, and a median DAS28 score of 2.5 (1.6-3.2). Significant differences between groups were found in DAS28 score (G1= -13.1, G2= 6.1, G3= 6.4, G4= 20.8 % of change, p=0.02); handgrip strength (G1= 4.1, G2= 18.5, G3= -7.1, G4= 7.1% of change, p=0.005); joint mobility in ankle plantar flexion in the right side (RS) (G1= 17.6, G2= 10.7, G3= 10.7, G4= -30.4 % of change, p<0.001) and left side (LS) (G1= 30.5, G2= 23, G3= 5, G4= -11, p=0.002); in knee flexion in the RS (G1= 14.3, G2= 12, G3= 16.6, G4= 5.1, p=0.01) and LS (G1= 6.9, G2= 8.6, G3= 18.6, G4= 4.6, p=0.05) and hip internal rotation in the RS (G1= 3.3, G2= -16.4, G3= -15.5, G4= -3.4, p=0.09) and LS (G1= 16.6, G2= 7.5, G3= -0.3, G4= -10.4, p=0.05).

Conclusion: Dynamic exercise in combination with MD improves physical capacity, muscular strength and joint mobility as well as disease activity when compared with either therapy individually or controls.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Ultrasound (US) detected synovitis predicts flare in patients with rheumatoid arthritis (RA), while the role of tenosynovitis has yet to be established. The aim of this study was to investigate the predictive role of US tenosynovitis and synovitis over disease flare in patients with RA in clinical remission in which treatment is tapered.

Methods:

STARTER is a multicentre cohort study of the US Study Group of the Italian Society for Rheumatology, involving rheumatologists selected by a reliability exercise and the availability of high-end equipment and high frequencies probes. At the beginning of the study, patients with RA in clinical remission were clinically evaluated. US synovitis (S) and tenosynovitis (T) were assessed categorically for Grey Scale (GS) and power Doppler (PD) at 11 joints, extensor and flexor tendons in both hands. Patients were seen at 6 and 12 months. Treatment tapering was defined as dose reduction or discontinuation of any DMARD or corticosteroids. Flare within 12 months was defined as increase in DAS28 $\geq$1.2 or $\geq$0.6 if final DAS28>3.2. The relationship between the presence of GS-T/-S, PD-T/-S and flare was tested by logistic regression models, presented as odds ratios (OR) and 95% confidence interval (CI), adjusted for pre-specified confounders (age, sex, disease duration, comorbidities, rheumatoid factor, synthetic or biologic DMARDs, corticosteroids or NSAIDs). The models were applied to the whole population and separately in subgroups of patients in which treatment was or was not reduced.

Results:

361 patients were included, in 161 treatment was tapered [72. % F, mean age (sd) 56.1 (13.3) years, mean disease duration (sd) 9.75 (8.07) years]. 98/361 patients had a flare within 12 months, 48/154

among those tapering treatment. Considering US variables separately, only PD-S significantly predicted flare both in the whole population and in patients tapering treatment, but not in patients on stable treatment. When the model included both T and S, only the concurrent presence of T and S predicted flare [PD-T+-S: OR 2.06(1.04, 4.07)] in the overall population, while isolated S and T did not. The predictive value of PD-T+-S was not confirmed in patients in stable treatment, while it was enhanced in patients tapering treatment [OR 3.16(1.18,8.45)]. In the whole population GS-T+GS-S led to an increased risk of flare [OR 2.27, (1.01,5.10)], but this was not confirmed in the subgroups (Table 1).

Conclusion:

In patients with RA in clinical remission PD-T and PD-S predict subsequent disease flare, especially if treatment is tapered down. In addition to clinical evaluation, US could provide helpful information to drive treatment strategies in patients in clinical remission.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is associated with increased cardiovascular (CV) risk. The mechanisms of CV disease in RA remain poorly understood. Observational data suggest that earlier treatment of RA produces better responses. This RCT (ACTRN12611000972921) evaluated whether adalimumab (ADA) improves CV risk biomarkers in patients ACPA-positive RA and to explore the contribution of known risk factors.

Methods: 60 (30 early, 30 established) patients with moderate-highly active ACPA-positive RA were enrolled in a RCT of humira versus placebo (1:1). Patients underwent assessments of Reactive Hyperaemic Index (RHI), carotid-femoral pulse wave velocity (PWV) and disease activity twice before receiving treatment and then at weeks 1,4,12 and 24. Intention-to-treat analysis compared changes in each treatment arm by t test. Secondary analysis by random effects GLS regression modelling evaluated effects upon RHI and PWV adjusting for clustering within individuals.

Results: There were no significant differences between in treatment arms for RHI. While preliminary analysis suggested that positive shared epitope (SE) status was associated with poorer endothelial function (p 0.02) rather than for inflammation (CRP p0.379) or treatment (p 0.487) this was not significant after adjustment for clustering. A large 0.65m/sec reduction in PWV was seen prior to treatment in both groups. At weeks 4 and 12 PWV was significantly lower in the ADA arm.

This trend was seen more consistently in patients with recent onset (<12 months) disease. Secondary analysis found that the most significant effects upon PWV were age (p 0.000), mean arterial pressure (p0.000) and CRP (p0.004).

Conclusion: Treatment with ADA may improve aortic stiffness and treatment may be more effective in early disease. However the greater effects are from blood pressure and ageing. While PWV is clearly influenced by CRP RHI may be influenced more by SE status. Further work is needed evaluating ACPA-negative and SE-negative subjective and pre-clinical RA.

Table:

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A physician estimate of global status (DOCGL) on a 0-10 visual analog scale (VAS) was developed initially to assess inflammation in patients with rheumatoid arthritis (RA), particularly to assess change in clinical trials, in which DOCGL has greater relative efficiency than the other 6 RA Core Data set measures to distinguish active from control treatments. Some rheumatologists interpret DOCGL as based entirely on inflammation, while others also may consider joint damage and/or psychological distress as in fibromyalgia, in addition to inflammation, in formulating a 0-10 DOCGL VAS estimate. One approach to clarifying this matter is for physicians to estimate 3 additional 0-10 VAS for inflammation, damage, and distress. We analyzed scores at 2 academic rheumatology sites for 4 VAS estimated by rheumatologists, for overall DOCGL, inflammation, damage, and distress, compared to high, moderate, low, and near-remission according to RAPID3 on an MDHAQ in patients in RA seen in routine care.

Methods: All patients seen at 2 academic sites complete an MDHAQ/RAPID3 at each visit. Rheumatologists complete 4 0-10 VAS for DOCGL, inflammation or reversible disease, damage or irreversible disease, and distress explained by neither inflammation nor damage. Mean estimates for overall status, inflammation, damage, and distress or fibromyalgia, were analyzed in patients according to RAPID3 categories for high (=≥12), moderate (=6.1-12), low (=3.1-6), and near-remission (=≤3), with statistical significance computed by analysis of variance (ANOVA). Differences between damage and inflammation estimates also were calculated.

Results: Site A included 71 RA patients, mean age 59 years, formal education 11 years, and 76% female; site B included 137 RA patients, mean age 57 years, formal education 14 years, 88% female. The mean DOCGL at both sites A and B was 3.8. DOCGL was 1.5 and 1.6 for patients in remission, at Sites A and B respectively, 1.4 and 3.7 for those in low severity, 3.4 and 3.1 for patients in moderate severity, and 5.3 and 5.4 in patients with high severity (all $p \leq 0.01$) (Table). Scores for damage were higher than scores for inflammation at both sites, 3.5 versus 2.3 at site A, and 2.7 versus 2.2 at site B for all patients, as well as in all 4 RAPID3 severity groups at both sites (Table); damage scores were 0.2-1.2/10 units higher than inflammation scores (Table). Scores for distress were somewhat higher for all patients than for inflammation but lesser than for damage at site A and lower than both inflammation and damage at site B for all patients.

Conclusion: Joint damage appears to be a more significant clinical problem than inflammation in RA patients at 2 sites. These findings may explain in part why most RA patients are not in remission despite a “treat to target” of remission with powerful biologic agents. Joint damage may be a more severe problem than inflammation in the management of RA at this time.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic arthritis that mainly affects small and medium joints. It is the most common form of inflammatory arthritis, capable of producing significant joint damage, deformity and functional disability. An association between increased body mass index (BMI) and some inflammatory and autoimmune conditions have been suggested in observational studies. Adipose tissue is considered as an active participant in physiological and pathological processes associated with inflammation and immunity. Evidence suggests that the effect of obesity on joint structure goes beyond overload, which is based on multiple complex factors such as cytokines, hormones, growth factors and intracellular regulators that can modify the course of disease and clinical response; so we set as main objective to assess activity indices in patients with rheumatoid arthritis and its relationship with BMI.

Methods: Descriptive cross-sectional study, in which 3,858 patient records were analyzed in the period from January 2012 to January 2016; 1,235 met RA criteria by the American College of Rheumatology (ACR) 2010, 131 patients met criteria for inclusion, it was assessed patient's age, sex, BMI, index of disease activity in 28 joints (DAS28), erythrocyte sedimentation rate, disease-modifying drugs (DMARDs) and glucocorticoids, data was obtained in the second visit. SPSS V.22 was employed for Windows 8, developing a database with the aforementioned variables, descriptive statistical analysis was performed with frequencies and percentages, crossed tables were made to establish association between different variables and finally to analyze age, mean and standard deviation (SD) were used.

Results: Females accounted for 96.2%, the average age was 56.48 ± 12 years, 33.5% of patients were overweight, 11.5% obesity class I, class II obesity for a 5.3%, 0.8% class III obesity; 51.1% had a BMI above normal levels; 48.9% were in normal range, 6% achieved remission in normal weight and 1.5% in the scale of overweight; in terms of low activity in normal weight was 6.6% versus 6% with high BMI; 29% was found in moderate activity in normal weight and 22.9% in the high BMI, 10% in normal weight had high activity, compared with 18% of increased BMI patients, the DMARD most used was methotrexate, the most common glucocorticoid used was prednisone.

Conclusion: In our population, we found that higher BMI limits the possibility of achieving low activity or remission and increased BMI was associated with higher doses of DMARDs and glucocorticoids. Prospective studies with more patients, longer follow-up are necessary and remind patients the importance of maintaining an adequate body mass index for better control of their disease.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: All biologic agents (bDMARDs) currently used in rheumatology can induce anti-drug antibodies (ADAB), which will influence the drug levels and the drug effectiveness. Why only certain patients develop these antibodies is not yet clear, although there is already some literature dealing with anti-drug antibodies and trough drug level in rheumatic diseases.The aim of this study was to look for predictive factors of occurrence of such antibodies.

Methods: Since March 2013, we measure ADABs and trough levels for all anti TNF agent and also for rituximab and tocilizumab. Half of all our patients under biologic treatments have been tested. The method used is a sandwich ELIS A. ADABs, trough and TNF levels can be measured simultaneously. The reproducibility and the cut-offs have been tested among patients exposed and non-exposed to the medication. Clinical predictors of ADABs development were analyzed using multi and monovaraite regression analysis :.They comprised : gender, age, duration of the disease type of disease, duration of treatment, type of treatment, co-medication, previous biologic agent. Biologic predictors were: though level, TNF level, CRP and ESR

Results: 297 patients had at least one measurement of ADAB and drug through level up to January 2016. 124 patients tested were treated with a biologic agent for rheumatoid arthritis, 116 for spondylarthritis, 30 for psoriatic arthritis, 27 for other diagnoses. In 63 out of 297 (21%) ADABs against at least one of the bDMARD agents were detected. All the patients with ADABs were exposed to the medication, except for 3 patients (specificity: 98%). In patients exposed to bDMARDs, ADABs were found respectively for infliximab in 46/106 (44%) pts, adalimumab:

10/60 (16%) pts, certolizumab: 2/4 (50%) pts, etanercept: 1/20 (5%) pts, golimumab: 4/34 (12%) pts, tocilizumab: 1/75(1%) pts, rituximab: 4/46 (8%) pts. When ADABS against several bDMARDs were tested the % of patients developing ADABs against the second bDMARD: 33% tended to be higher than against a for the previous one : 21%, but not significantly p= 0.08).

	Monovariate analysis		**p**	**multivariate**	**p**
	ADBA+	**ADAB-**		**ADBA+ OR (CI)***	
Clinical predictors					
Age: mean (SD): years	50(13)	53(014)	0.11

Type of disease (AS/apso/RA/ others)"	26/9/18/3	87/21/105/27	0.09+		
Duration of disease : mean (SD):years	8.(6)	11(10)	0.018		
Duration of treatments: mean (SD)/months)	41(33)	28(37)	0.015		
Type of treatments (mab ;antiTNF/others) n (%)	60/5 (94/6%))	137/60 (69/31%)	<0-0001	26(2.6-264)	0.005
Co-medication(Y/N/ n (%)	22/40 (35%)	78/122(38%)	0.6		
Previous biologic agent(Y/N/ (%))	51/13 (79%)	149/81 (65%)	0.027	5.9(1.14-30)	0.03
Biological predictors					
CRP: >5, (Y/N/ n (%)	26/44(37%)	31/152(16%)	0.0005		
ESR : >20 (Y/N/ n (%),	33/54(37%)	25/162(13%)	0.0001		
Trough level undetectable(Y/N (%))	41/15 (81%)	36/162/ (18%)	<0.00001	34(7.21-160.8)	0.0001
TNF level elevated (Y/N/ (%)	30/28(52%)	51/149 (26%)	0.00006	4.2(1.1-15)	0.025

On univariate analysis, several clinical and biological factors were significantly predictive of ADABS. After multivariate analysis only two clinical factors and two laboratory parameters remained independently associated: MAB anti-TNF treatments (OR: 26), previous bDMARD (OR: 5.9), undetectable through level (OR: 34) and High TNF trough level (OR:4.2).

Conclusion: In this large real world cohort of patients with rheumatological conditions requiring bDMARD therapy, either by anti TNF or other biological agents and tested for ADAbs at different time point of their treatments, the best predictors of the presence of ABABs were:treatment by an MAB anti TNF agent, previous exposure to another biologic agent, undetectable through level of the medication and elevated TNF levels

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The high prevalence and significant burden of RA has led to the development of a wide variety of treatments; specifically, conventional synthetic DMARDs, and biologic DMARDs (bDMARDs). Mode of administration and dosing frequency can impact on patient treatment satisfaction and adherence. This study qualitatively explored patients' and clinicians' views of the 'ideal' treatment, and the preferred mode of administration, in patients with moderate to severe disease activity and on active treatment.

Methods: Semi-structured interviews were conducted with 46 patients with RA from Germany (n=15), France (n=15), UK (n=10), and Spain (n=5). Eligible patients had been diagnosed for 2-5 years and had a current disease activity score in 28 joints (DAS28) >3.2. Initial questions were open-ended followed by more probing questions. Patients reflected on their treatment experiences, in relation to mode of administration (oral and subcutaneous injection), dosing frequency, and advantages/disadvantages of each mode of administration. Patients completed an 'ideal treatment task' and answered the following question: "*How would the treatment be administered?"* Qualitative interviews were conducted with 10 rheumatologists from Germany (n=2), France (n=2), UK (n=4), and Spain (n=2), to explore their perspectives on modes of treatment administration.

Results: Patients had a DAS28 mean score of 4.23 (SD=1.0) and either, were eligible for but had not yet received bDMARDs (23/46; 50.0%), were receiving bDMARDs (12/46; 26.1%), had received >1 anti-TNF treatment previously and were now receiving a treatment with a different mode of action (3/46; 6.5%), or were receiving another treatment regimen (8/46; 17.4%). Of the 41 patients who took part in the 'ideal treatment task', 22/41 (53.7%) would prefer an oral treatment, 14/41 (34.1%) an injectable treatment, and 5/41 (12.2%) had no preference. Patients reported an oral treatment to be: easy to manage (2/41), convenient (especially when travelling) (1/41), and preferable to an injection (9/41); however, patients acknowledged that an oral treatment can be difficult to remember to take (4/41), can be harsh on the stomach (1/41), and can have a strange taste (1/41). Patients reported the advantages of an injectable treatment to be: independence associated with self-injecting (3/41), and less harsh on the stomach than an oral treatment (1/41); however, their disadvantages included: a dislike of needles (5/41), problems at injection site (1/41), and difficulty in gripping an injection device (1/41). The majority of clinicians (6/10; 60.0%) perceived patients to prefer an oral treatment, compared with 2/10 (20%) who perceived patients to prefer an injectable treatment (2/10 [20%] did not report a perceived preference). Of the 10 patients who discussed frequency of oral treatment, 8/10 (80%) would find a daily tablet acceptable.

Conclusion: Patients and physicians in this survey identified a range of perceived advantages and disadvantages associated with different modes of drug administration. These findings help inform the dialogue between patient and physician when considering the most appropriate treatment choice for an individual.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Infliximab (IFX) and golimumab (GLM-IV) for intravenous use are anti-TNF agents indicated for rheumatoid arthritis (RA) and differ in weight-based dose, induction schedule, and infusion time. Few real-world GLM-IV utilization studies exist, and none compare GLM-IV to IFX utilization in the same patient (pt) population. To describe pt characteristics and utilization patterns in IFX-treated RA pts later treated with GLM-IV.

Methods: A large US health claims database was used for a retrospective analysis. Pts had ≥ 1 RA diagnosis (ICD-9 CM;714.0), ≥ 6 months continuous enrollment before IFX initiation and ≥ 1 GLM-IV claim after IFX discontinuation. Pts < age 18 years or with pregnancy were excluded. The IFX index date was defined as the 1st IFX infusion of the most recent IFX episode before GLM-IV initiation. GLM index was the date of first GLM-IV claim between 1/1/2014 and 6/30/2015. Patient characteristics, Claims-based Index for Rheumatoid Arthritis Severity (CIRAS), average vials per infusion (VPI), infusion interval and billed infusion time were studied over a variable length follow up. IFX or GLM VPI were estimated by dividing paid cost by drug wholesale acquisition cost. Infusion time was estimated by the proportion of claims with 2nd hour infusion codes (CPT- 96415 or 96366). Where appropriate, claims associated with $0 cost were removed from the analysis.

Results: A total of 188 IFX patients who transitioned to GLM-IV were identified**.** At the IFX index date**,** the population was 78% female; mean age was 56 years; 79% were commercially insured. The average time between end of IFX and GLM-IV index was 419 days (d); 86% of pts received GLM-IV as their next anti-TNF after IFX. Mean CIRAS was 5.4 at IFX and GLM-IV index dates. Concomitant methotrexate was used in 30% of IFX and 25% of GLM-IV pts. The mean (SD) duration of IFX was 512 (554) d. During IFX treatment, 2,176 IFX infusions were administered. Mean (median) number of infusions per pt were 12 (8) and median VPI was 5. The majority of IFX infusions (97%) had at least one 2nd hour infusion code. The average time between maintenance infusions was 51 d; 40% were 7 to 9 weeks apart. The mean (SD) observation period for GLM-IV treatment was 151 (142) d; the majority (66%) appeared to remain on therapy (censored) at end of data availability. During the observation period, 734 GLM-IV infusions were administered. Pts received a mean of 4 GLM-IV infusions during observation; 36% of pts received 5 or more infusions. Few (2%) GLM-IV infusions had a 2nd hour infusion code. Median GLM-IV VPI was 4. The average time between GLM-IV maintenance infusions was 57 days; 82% were 7 to 9 weeks apart.

Conclusion: This retrospective analysis describes pt characteristics and medication utilization for

IFX-treated RA pts who later used GLM-IV. On average, GLM-IV was associated with lower VPI, greater consistency in dosing patterns (proportion of maintenance infusion intervals every 7 to 9 weeks) and better administration time efficiency as evidenced by a lower proportion of claims for a second hour infusion billing code. These findings may be relevant for healthcare decision-makers interested in understanding potential variation in healthcare delivery.

The Effect of Body Mass on DAS28 Response in Patients with Rheumatoid Arthritis Treated with Abatacept

J Fransen[1], L Tweehuysen[2], A den Broeder[3], R Postema[4], E Alemao[5] and F van den Hoogen[6], [1]Department of Rheumatolgy, Radboud UMC, Nijmegen, Netherlands, [2]Sint Maartenskliniek Nijmegen, Nijmegen, Netherlands, [3]Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [4]Bristol-Myers Squibb, Uxbridge, United Kingdom, [5]Bristol-Myers Squibb, Princeton, NJ, [6]Rheumatology, Radboud UMC, Nijmegen, Netherlands

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept is an effective biologic agent indicated for the treatment of RA.[1] Recent studies have indicated that obesity and being overweight could reduce the effect of conventional DMARDs and of anti-TNF treatment in patients with RA. However, there are limited data on the effect of weight on the treatment response for abatacept.[2,3] The aim of this study was to evaluate whether BMI is a modifier for the effect of abatacept measured by DAS28 (CRP) over the first 6 months of treatment in patients with RA.

Methods: Patients with RA from Radboud UMC and the Maartenskliniek were consecutively included if they were treated for ≥5 months with abatacept. Length and weight to calculate BMI had been assessed before treatment start. DAS28 (CRP) was prospectively assessed at baseline and 6 months. Concomitant treatment and treatment history were assessed at treatment start, and closest values for RF and anti-cyclic citrullinated peptide (anti-CCP) positivity obtained before baseline were used. BMI was classified as normal (BMI ≤25 kg/m^2) or overweight (BMI >25 kg/m^2). The relationship between BMI and response according to DAS28 (CRP) was analyzed using multivariate linear regression to control for confounding baseline covariates.

Results: A total of 113 patients were included in this analysis: 81% were female, mean (SD) age was 59 (13) years and median (P25–P75) disease duration was 13 (9–20) years. All patients had previously used other biologics, including anti-TNF. Conventional DMARDs were used as concomitant therapy in 58% of patients, most often MTX (32%); 69% of patients used IV abatacept. There were some baseline differences (p<0.10) between normal weight (39%) and overweight (61%) patients. Overweight patients were on average older (mean [SD] 60 [13] vs 56 [14] years), the proportion of males was higher (26 vs 7%), RF (75 vs 57%) and anti-CCP (77 vs 61%) positivity occurred more often, and SC abatacept was more frequently used (38 vs 21%), while they used more (median [P25–P75]) previous biologics (4 [3–4] vs 3 [2–4]). The mean (SD) baseline DAS28 (CRP) was 4.2 (1.0) in normal weight and 4.2 (1.2) in overweight patients (p=0.81). The mean (SD) change from baseline in DAS28 (CRP) over 6 months was –0.51 (1.4) in normal weight and –0.70 (1.8) in overweight patients (p=0.55). The difference of –0.19 in change of DAS28 (CRP) was reduced to –0.10 (p=0.71) after correcting for age, sex and baseline DAS28 (CRP), and further attenuated to –0.026 (p=0.92) if also corrected for anti-CCP positivity and number of previous biologic agents. Remission percentages (DAS28 <2.6) at 6 months were 23% in normal weight patients and 26% in overweight patients with an odds ratio (95% CI) of 1.2 (0.5, 2.9), which became 1.1 (0.4, 2.8) after correction for the same confounders.

Conclusion: In patients with RA, BMI was not a modifier of the effect of abatacept on DAS28 (CRP) at 6 months after treatment start. After controlling for confounders, the reduction in DAS28 (CRP) was the same for normal weight (BMI ≤25 kg/m^2) and overweight (BMI >25 kg/m^2) patients.

The Prevalence of Loss of Response to Treatment with a Tumor Necrosis Factor Inhibitor and/or Methotrexate in Patients with Rheumatoid Arthritis

Josef Smolen[1], Yihan Li[2], Iain Sainsbury[2], Stefan Florentinus[2], Kershnie Rambalee[2] and GR Burmester[3], [1]Internal Medicine III, Div. of Rheumatology, Medical University of Vienna, Vienna, Austria, [2]AbbVie Inc., North Chicago, IL, [3]Charité – University Medicine Berlin, Berlin, Germany
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients (pts) with rheumatoid arthritis (RA) who achieve disease control in response to treatment with a tumor necrosis factor inhibitor (TNFi) may lose that response permanently under continuous treatment (1). We examined whether pts with early RA, in sustained clinical remission (REM) or low disease activity (LDA) lose their state of clinical response during continuous treatment with originator adalimumab (ADA) and/or methotrexate (MTX).

Methods: This post hoc analysis used data from PREMIER, a 2-year trial in early RA pts who were TNFi- and MTX-naïve. Pts received ADA, MTX, or ADA+MTX. Responders were defined as pts who sustained one of the following states at both Weeks (Wk) 20 and 24: 28-joint disease activity state based on C-reactive protein (DAS28-CRP) <2.6 or <3.2 (LDA); simplified disease activity index (SDAI) SDAI ≤3.3 (SDAI REM) or ≤11 (SDAI LDA), clinical disease activity index (CDAI) ≤ 2.8 (CDAI REM) or ≤10 (CDAI LDA) or ACR-EULAR Boolean REM. A loss of response was defined as loss of DAS28-CRP LDA for all remaining visits (up to Wk 104 or premature discontinuation) starting after Wk 24 (with ≥2 consecutive visits of LDA loss). The percentage of pts who lost DAS28-CRP LDA response in each treatment arm, and mean CDAI values, were calculated at each visit.

Results: Overall, for each response category, few pts permanently lost their DAS28-CRP LDA state after Wk 24 through Wk 104 (Table 1). Pts on ADA+MTX lost DAS28-CRP LDA less often, although the number of pts was small to begin with in some response categories in the monotherapy groups. For pts in DAS28-CRP LDA through Wk 104, the mean CDAI scores (shown at Wks 24, 26 and 104 in Table 1) ranged from 0.8-5, and these pts also remained in CDAI LDA at those time points. Pts in stringent REM (SDAI, CDAI or Boolean) at Wk 20 and 24 had lower mean CDAI scores than pts with DAS28-CRP <2.6 or LDA. Further, they maintained that response and a low CDAI value throughout the subsequent period, while pts with DAS28-CRP<2.6 experienced an increase of DAS28-CRP above that threshold on the group level. The CDAI score of pts who lost

their DAS28-CRP LDA state rose at the visit at which the first loss was recorded (Fig 1).

Conclusion: A majority of TNFi- and MTX-naïve pts with early RA in sustained REM or LDA after 20-24 wks of treatment maintained a low disease state through the period assessed. The loss of response was an infrequent phenomenon. **References:**

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) can be divided into two major subsets based on the presence or absence of antibodies to citrullinated peptide antigens (ACPA). Some studies have indicated that RA patients who are positive for ACPA have a worse prognosis than ACPA negative patients and may require a more aggressive therapeutic approach to control disease. The purpose of this review was to determine if the presence or absence of ACPA antibodies is associated with a more active disease and if patients were more likely to be placed on biologics based on their ACPA

status.

Methods: The de-identified data of RA patients were reviewed. Patients were seen in one academic center between 2008 and 2016. ACPA+ status was determined by at least one anti-CCP titer >20 units, using the QUANTA Lite CCP3.1 IgG/IgA ELISA testing. RF positive status was determined by a titer >14 units using turbidometry. RF data was available in 97% of ACPA positive patients and 96% of ACPA negative patients. RA patients with interstitial lung disease (N=130) were excluded. Self-reported disease activity was available for 43% ACPA+ and 35% of ACPA- patients using the Multidimensional Health Activity Questionnaire (MDHAQ) and RAPID 3 instruments on at least one visit. Fisher's Exact Test was used to determine differences in drug utilization between ACPA positive and negative RA patients. A Bonferroni-adjusted P <0.05 was considered statistically significant.

Results: The demographics of the study group (N=1070) are listed in Table 1. The characteristics of the patients in the two groups were quite similar. Disease severity was similar between the two groups as measured by RAPID 3 (11.2 and 11.9) or by MDHAQ (0.72 and 0.71). As expected, ACPA+ patients were also more likely to be RF+ (84%) than ACPA- patients (64%). The medications used to treat these patients are depicted in figure 1 showing that a higher percentage of ACPA+ patients used MTX and prednisone. Except for a slightly higher number of ACPA+ patients receiving abatacept, ACPA- and ACPA+ patients had similar use of biologics.

Conclusion: This retrospective study shows that ACPA+ and ACPA- RA patients had similar demographic characteristics and similar level of disease severity in our institution. The use of MTX and prednisone was higher among ACPA+ patients; however ACPA- patients had similar use of biologics, except for a slightly lower use of abatacept.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

We hypothesized that increased dietary intake of vitamin D and omega-3 fatty acids (FA) prior to disease modifying anti-rheumatic drug (DMARD) initiation may associate with superior response to anti-rheumatic treatments. On the other hand, high dietary folate intake may be associated with worse response to methotrexate (MTX). The aim of this study was to investigate the association between dietary intakes of vitamin D, omega-3 FA, and folate and treatment results of DMARDs in patients with early RA.

Methods:

This study included 727 early RA patients from Epidemiological Investigation of Rheumatoid Arthritis (EIRA) study linked with the Swedish Rheumatology Quality register (SRQ). Data on dietary vitamin D, omega-3 FA and folate intake based on food frequency questionnaires were linked with data on response to DMARDs using European League Against Rheumatism (EULAR) response criteria at 3-month follow-up. Associations between dietary intakes of vitamin D, omega-3 FA, and folate and EULAR response, respectively, were analyzed with binary logistic regression adjusting for potential confounders.

Results:

The majority of the patients were initially treated with monotherapy of MTX (n=653 [89.9%]) and more than half of the patients had combined DMARD(s) with glucocorticoids (n=414 [56.9%]). Higher intakes of vitamin D and omega-3 FA were associated with good EULAR response. Folate intake around the recommended dose (300 µg/day), but not higher, was associated with EULAR response (Table). Similar associations were observed in the subgroup of patients who were initially treated with MTX monotherapy at baseline.

Nutrient intake	N	OR_{crude} (95 % CI)	$OR_{adjusted}$ (95 % CI)
Vitamin D	**727**		
1st quartile: ≤4.25 µg/day	182	1.00	1.00
2nd quartile: 4.26-5.42 µg/day	170	1.07 (0.70-1.64)	1.07 (0.69-1.65)
3rd quartile: 5.43-6.96 µg/day	184	1.15 (0.75-1.77)	1.25 (0.81-1.94)
4th quartile: >6.97 µg/day	191	1.75 (1.13-2.71)	1.71 (1.09-2.67)
p value		0.012	0.019
Omega-3 FA	**727**		
1st quartile: ≤0.45 g/day	180	1.00	1.00
2nd quartile: 0.46-0.62 g/day	192	1.25 (0.82-1.89)	1.27 (0.83-1.94)
3rd quartile: 0.63-0.83 g/day	183	1.35 (0.89-2.07)	1.37 (0.89-2.12)
4th quartile: >0.84 g/day	172	1.64 (1.07-2.53)	1.60 (1.03-2.48)
p value		0.024	0.038
Folate	**727**		
1st quartile: ≤244.88 µg/day	201	1.00	1.00
2nd quartile: 244.89-296.86 µg/day	182	1.32 (0.88-1.99)	1.36 (0.89-2.06)
3rd quartile: 296.87-365.70 µg/day	193	1.59 (1.07-2.38)	1.54 (1.02-2.33)
4th quartile: >365.71 µg/day	151	1.14 (0.74-1.75)	1.09 (0.70-1.70)
p value		0.557	0.712

OR_{crude}: Adjustment for age and sex.

$OR_{adjusted}$: Adjustment for age, sex, smoking, total energy intake and supplementation (vitamin D, omega-3 FA/fish oil, or folic acid).

p value: Comparison between 4th and 1st quartiles.

Conclusion:

Increased intake of dietary vitamin D and omega-3 FA during the year preceding DMARD initiation may associate to better treatment results in early RA patients. Moderate dietary folate intake, but not lower or higher, was associated with better response to treatment. Our results suggest that several specific nutrients may associate with enhanced treatment results in early RA.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) care has moved towards early diagnosis and treatment to improve long-term patient outcomes. Our objective was to assess prognostic factors for sustained remission and absence of clinical inflammation in an early RA population treated according to a strict tight-control algorithm with semi-personalized treatment adjustments.

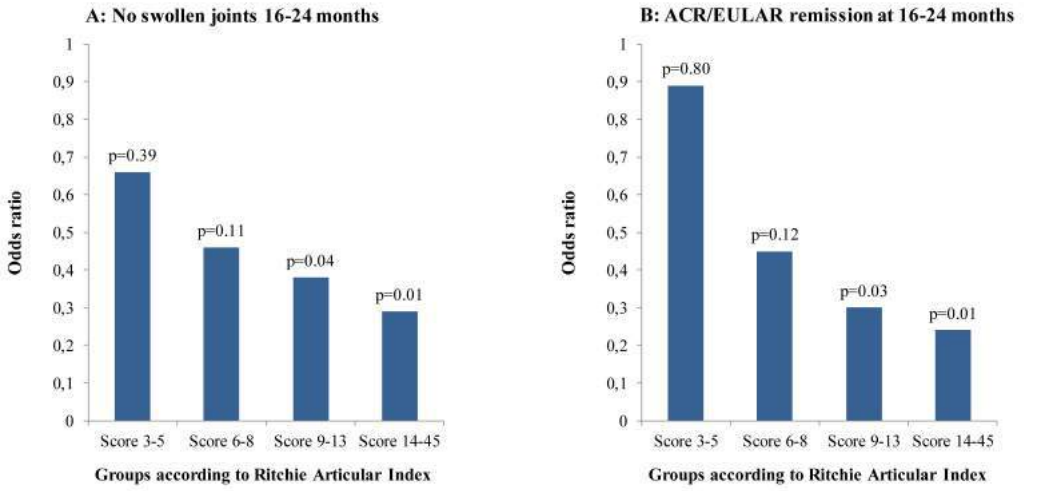
Methods: RA patients who fulfilled the ACR/EULAR 2010 classification criteria, with <2 years from first swollen joint and who were DMARD naive with indication for DMARD treatment were included in the ARCTIC trial. Patients were followed by a tight control regimen with defined treatment target (DAS <1.6, SJC44=0 + no power Doppler signal in half the patients) and response evaluation. Rapid escalation of medication was allowed if negative prognostic factors for joint destruction were present (seropositivity with baseline radiographic erosions or MRI bone marrow edema). Data collections included clinical examination, laboratory tests, patient reported outcomes, ultrasound examination and radiographs. Multivariate logistic regression was used to assess the associations between baseline variables and different definitions of sustained remission between 16 and 24 months.

Results: Mean [SD] disease duration of the 222 patients was 7.2 [5.4] months, mean original DAS 3.5 [1.2], 72% were RF and 82% ACPA positive, and 16% escalated treatment more rapidly to biologic therapy. Sustained (16 to 24 months) SDAI and ACR/EULAR remission were reached by 33% and 24% respectively. Tender joints assessed by Ritchie Articular Index was a consistent independent negative predictor of reaching sustained SDAI remission, ACR/EULAR remission, no swollen joints in any of the 44 joints evaluated, and a composite outcome of no swollen joints + radiographic progression≤0.5 per year + DAS remission between 16-24 months (table). Patients with high scores on the Ritchie Articular Index had low odds ratios for sustained remission and sustained absence of swollen joints when adjusting for baseline swollen joint count (figure).

Table: Baseline predictors for being in sustained remission between 16 and 24 months. The final multivariate models shown (corrected for age and gender).

Baseline variables	**Sustained SDAI remission** **N=73/222**	**Sustained ACR/EULAR remission** **N=53/222**	**Sustained no swollen joints** **N=121/222**	**Sustained no swollen joints, DAS remission, and radiographic progression ≤0.5** **N=71/222**
	OR **[25, 75 percentile]**	**OR** **[25, 75 percentile]**	**OR** **[25, 75 percentile]**	**OR** **[25, 75 percentile]**
Tender joints assessed by Ritchie Articular Index	0.94 [0.90, 1.00]	0.93 [0.88, 0.99]	0.94 [0.91, 0.98]	0.92 [0.87, 0.97]
Patient global (VAS 0-100)	0.98 [0.97, 1.00]	0.98 [0.97, 1.00]		
van der Heijde-modified Sharp erosion score	1.12 [1.01, 1.25]			
DMARD initation < 3 months	2.68 [1.35, 5.32]	2.15 [1.04, 4.45]		
Ultrasound power Doppler score (range 0-96)		1.04 [1.01, 1.08]		1.07 [1.01, 1.13]
Ultrasound grey scale score (range 0-96)				0.93 [0.89, 0.97]

Figure: Odds ratio for reaching sustained absence of swollen joints (**A**) and ACR/EULAR remission (**B**) according to quintiles of Ritchie Articular index at baseline, with the lowest quintile as reference category (score 0-2). Analyses adjusted for 44 swollen joint count.



Conclusion: In this early RA treat-to-target study, tender joints assessed by Ritchie Articular Index at baseline is a consistent negative predictor of reaching sustained remission. Our findings support that semi-personalized targeted treatment might modify the impact of known predictors.

Tocilizumab achieves rapid reduction of disease activity and has beneficial effects on bone mineral density in patients with rheumatoid arthritis

Maria Höhle, MD[1]

[1]*Orthopedic, Medical, Rheumatologic Center, Hamburg, Germany*

Background/Purpose: Tocilizumab (TCZ) leads to a rapid improvement of the clinical course in patients with highly active rheumatoid arthritis (RA). However, a residual rheumatic activity can still be detected.[1] RA is a known risk factor for osteoporosis related bone fractures.[2] It is well established that TCZ has beneficial effects on bone remodeling.[3]

The aim of this analysis was to investigate the effects of TCZ on bone mineral density in a real world patient population.

Methods: 50 rheumatoid factor positive patients with RA (17 male, age 20-72 years) who received TCZ as monotherapy since 2008 were prospectively investigated. At baseline and the following 4-6 clinical visits, DAS28 was determined and ultrasound performed. At baseline and every 6 months thereafter, biochemical parameters for bone metabolism and protein diagnostics were recorded. Once a year, the subjects underwent MRI, CT and DXA scan.

Results: In all 50 patients the DAS28 normalized at the latest by the 3rd infusion cycle of TCZ. The initial RAMRIS score of >5 was reduced to <2 after 6-18 months. Ultrasound revealed a decline of synovialitis and tenodynovialitis after 8 weeks and 12 months, respectively. At baseline in 22 women with early RA, axial QCT/DXA values and lateral DXA values were within reference. 3 patients with early RA had osteopenia, 2 had osteoporosis. Patients with manifest RA had a BMD in the reference range, 3 had osteopenia and 2 were diagnosed with osteoporosis. In 6 male patients, BMD values were within the reference range. 2 men with early RA had osteopenia and 2 had manifest osteoporosis. In 1 male patient with manifest RA, normal BMD values were documented. 2 men with manifest RA hat osteopenia and 4 had osteoporosis. 10 patients had vitamin D3 deficiency and were treated with vitamin D3. 2 patients with osteoporosis were treated with antiresorptive medication. In all patients, BMD values were within the reference range after 1 year of treatment with TCZ, despite 18% of patients presenting with a DAS score > 2.7. 2 patients presented with pustular dermatosis in the palms. No allergic reactions were observed.

Conclusion: Treatment with TCZ leads to a rapid decline of inflammatory activity of the affected

joints in patients with RA and minimizes cartilage destruction. TCZ showed a positive effect on bone remodeling and therefore BMD. Thus, the risk for the development of osteoporosis and its related fractures can be minimized by TCZ treatment. Furthermore, TCZ has a positive effect on BMD in manifest RA thus preventing sarcopenia. Temporary elevations of DAS28 during TCZ therapy do not negatively affect BMD.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Swedish Society for Rheumatology guidelines recommend remission as treatment goal for patients with rheumatoid arthritis (RA). The Swedish quality registry (SRQ) is a nationwide registry for rheumatic diseases in which all 64 rheumatology units in the country participate. The aim of this study was to examine how many patients reach sustained remission (SR) (DAS28<2.6 or SDAI<3.3 or CDAI 2.8 or ACR remission on at least 2 consecutive occasions and for at least 6 months) during follow up and to compare patients with early RA (first visit within 6 months symptom duration) with patients with established RA.

Methods: All adult patients with RA (n=29084) included in SRQ between 1992 and 2013, with at least 3 registered visits were eligible for the present study. 72% were female. Mean age was 58.8 years. 6691(20.5%) fulfilled the criteria for early RA described above. ACR 1987 criteria were satisfied by 95% of patients and 73.2% were ACPA positive. Duration of remission was defined as time between first visit fulfilling the remission criteria and subsequent first visit with higher disease activity.

Results: 12193 (41.9%) patients reached DAS28 SR, and 22.2%, 21.3% and 17.5% of patients reached sustained CDAI, SDAI and ACR remission, respectively, at some time point during follow up. The point prevalence of DAS28 SR 12 months after symptom onset was 16.4%, and 6.5%, 6.0% and 4.6% for CDAI, SDAI and ACR SR, respectively, and peaked after 5 years (figure1). The prevalence of DAS28 SR one year from symptom onset was 21.3% and 9.8% for early RA and established RA, respectively, and the difference remained for at least 10 years ($p<0.001$). Figure1 shows the percentage of patients being in SR in relation to symptom duration in years according to different remission criteria and stratified into early and established RA. The median time from symptom onset to DAS28 SR was 3.9 years, of those that reach SR, 75% have done so within 12 years (Range 0-74 years). Median time in DAS28 remission was 2.8 years (range 0.5-18.3), and 2.2 (0.5-17.1), 2.2 (0.5-17.1) and 2.1 (0.5-17.0) for CDAI, SDAI and ACR remission, respectively.

Conclusion: About 42% of patients with RA in Sweden reached DAS28 SR during the course of the disease, twice as many as those that reached SDAI, CDAI or ACR SR. The prevalence of SR is higher among early RA patients. Median time in DAS28 SR was just under three years and lower in SDAI, CDAI and ACR remission. The findings underline the need for early intervention but also shows that there is room for further improvement of the treatment strategy. Figure1. The percentage of patients being in SR in relation to symptom duration in years according to different remission criteria and stratified into early and established RA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory disease leading to joint destructions, if untreated. Treatment with biologic DMARDs has shown to favourably influence disease activity, joint destruction, and patient related outcomes (PROs). However, to our knowledge, no studies in larger patient cohorts have investigated the correlation between disease duration with radiographic outcome, disease activity, and disability in the new era of biologic treatment. To analyse cross-sectionally patients with RA for radiographic damage, PROs, and disease activity dependent on disease duration.

Methods: All RA patients from the Swiss national cohort (SCQM) with information on disease duration as documented in the database (time point of diagnosis) were included in the analysis. The primary endpoint was the association between disease duration and the status of radiographic joint destruction, assessed by Ratingen scores (range from 0 to 190, analysed by two independent and

blinded assessors) at the last clinical visit in the database. This endpoint was analysed by a multiple negative binomial regression model corrected for confounding factors (gender, age, rheumatoid factor (RF), antibodies to citrullinated protein antigens (ACPA), pre-exposition of anti-TNF drugs or methotrexate). Disease activity (DAS-28) and disability (HAQ DI) were analysed as secondary outcomes.

Results: The original 52'753 records on 8'678 patients resulted in 6'525 evaluable observations with documented Ratingen scores and disease durations. Disease duration ranged between less than 1 and more than 65 years (median 8.3). Anti-TNF drugs were used in 58.4% of patients. We found a significant association between disease duration and the status of radiographic joint destruction with an average increase of Ratingen scores by 8.3% per year of disease duration. RF was the highest predictor for radiographic destruction (estimate 1.41), whereas ACPA positivity was a negative predictor (estimate 0.812). In patients with a disease duration of less than 5 years, clinical disease activity and disability decreased depending on the time since diagnosis. While DAS-28-scores remained on a stable level thereafter (median DAS-28: 2.8, i.e. low disease activity), HAQ-DI scores increased continuously by 0.018 per year of disease duration. DAS-28 and HAQ-DI at the end of follow up correlated moderately (Kendall´s Rank-correlations 0.307) whereas no correlation was found between Ratingen scores and HAQ-DI (-0.009).

Conclusion: In this RA cohort, patients showed cross-sectionally a continuous increase of joint destruction and disability depending on disease duration, despite treatment with biologics and satisfactory control of disease activity, in the majority of patients. Even though, in the era of biologic treatment, a satisfactory control of disease activity can be achieved in most patients, RA remains a progressive disease leading to joint destruction.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Individuals with rheumatoid arthritis (RA) have a two-fold higher risk of sudden death than the healthy age- and sex-matched general population. Although the underlying mechanisms have not been clarified, evidence suggests the effects of systemic inflammation on ventricular repolarization. Consequently, prolongation of the corrected QT (QTc) interval in patients with RA is more frequent than in individuals without RA. We prospectively evaluated the impact of tocilizumab (TCZ) treatment on the QTc interval in patients with RA without cardiac symptoms and investigated the associations of QTc interval with RA disease activity and severity measures.

Methods: This was a prospective interventional study from March 2012 to December 2015 in Itabashi Chuo Medical Center. The RA study inclusion criteria were fulfillment of American College of Rheumatology (ACR) for the classification of RA or 2010 ACR/EULAR RA criteria. Exclusion criteria were diabetes, previous cardiovascular events, hypertension, dyslipidemia, cardiomyopathy, renal disease, and current atrial fibrillation. Healthy age- and sex-matched individuals without cardiac symptoms were selected as controls. TCZ (8 mg/kg IV every 4 weeks or 162 mg SC biweekly) was prescribed for patients with active RA with an inadequate clinical response to methotrexate. Electrocardiography and clinical and biological monitoring were performed at baseline and 24 weeks after TCZ treatment in patients with RA. A QTc interval of 440 ms was considered prolonged in this study.

Results: We enrolled 94 patients with RA (mean age, 56.4±10.4 years; 85% female) and 40 healthy age- and sex-matched controls (mean age, 55.6±9.4 years; 86% female). 20% and 14% of RA patients received anti-hypertensive and anti-hyperlipidemia therapy respectively. The 24-week disease activity scores (DAS28-ESR) were significantly lower than those at baseline. We identified 8 (8.5%) patients with a prolonged QTc interval. However, the QTc interval at baseline was higher in the control group (422.3±25.8 ms vs 402.3±31.2 ms; $p = 0.04$). The QTc interval decreased 20 ms from baseline to 24 weeks ($p = 0.001$) following TCZ treatment. The percentage change in the QTc interval significantly correlated with C-reactive protein (CRP), anti-cyclic citrullinated peptide antibody (ACPA), and DAS28 at baseline ($\rho = -0.43$, $p < 0.0001$; $\rho = -0.23$, $p = 0.024$; $\rho = -0.21$, $p = 0.04$, respectively). The percentage change in the QTc interval strongly correlated with that in matrix metalloproteinase-3 (MMP3) after TCZ therapy ($\rho = 0.38$, $p = 0.001$). After adjusting for confounding variables, such as age, RA duration, ACPA, and CRP, the association of percentage change in the QTc interval with ACPA remained significant ($p = 0.004$, $R^2 = 0.29$).

Conclusion: The data suggest that the anti-arrhythmic potential for TCZ therapy may have a beneficial impact on patients with RA. The data may provide further evidence of the degree of association between ACPA and QTc interval. Furthermore, MMP3, which may affect ventricular remodeling, might contribute to the QTc interval.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Little is known on what subjective or objective data that rheumatologists

consider most important for them to inform their treatment decisions for patients with rheumatoid arthritis (RA). **Objective:** To understand what data is most relevant for rheumatologists to inform treatment recommendations for their RA patients.

Methods: Participants were recruited nationally by email invitation to participate in one of 3 nominal groups held in March and April of 2016. Each of the 3 groups generated a list of elements from their patients' history, signs, and symptoms ('items'), that they deemed helpful in making treatment decisions. The results of each group were combined into a single data set, categorized by a sorting procedure, in which items were independently reviewed and then aggregated into common topic groups, redundant or duplicate items were removed, and the topic groups were then identified according to the major theme emerging from each group. These themes were then evaluated through calculation of a rank-order coefficients based number of items in each theme, number of items in each theme ranked in the top 3 in terms of importance, and the average score for each item within a theme.

Results: A total of 21 rheumatologists participated. Twelve themes emerged and 10 of these received ranking votes (Figure). Subjective information such as patient symptoms was the theme with the highest amount of votes (43%) while more objective data such as signs and tests captured only 21% of the ranking votes. These physicians did not rank assessment of medication adherence very highly. Among the unranked themes, "social relationships" had the fourth highest number of items (7 items emerged but no votes to any for any of these items), consistent with the concept that rheumatologists are aware of patients' social context for their health, but most do not yet recognize it as an important component in patients' care.

Conclusion: Most rheumatologists highly valued patients' symptoms to inform their treatment decisions. Collection of subjective data from patients between physician appointments (e.g. via Smartphone technology), even for domains not directly related to RA (e.g. sleep symptoms), appears valuable to rheumatologists to have a more complete representation of RA patient's health.
Figure: Themes that emerged during physician nominal groups regarding the elements of RA patient's history, signs and symptoms they value the most and their respective percentage of votes

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic inflammation in rheumatoid arthritis (RA) is associated with an increased cardiovascular risk, possibly due to disrupted vascular vasodilation. Within 12 weeks adalimumab and etanercept normalize vascular dysfunction. We here analyze whether stopping adalimumab or etanercept is associated with worsening of vasodilator function using the forearm vascular model using intraarterial AcetylCholine (ACh) and Sodium NitroPrusside (SNP) measuring forearm vasodilator function with plethysmography.

Methods: 35 patients participating in the nationwide tumor necrosis factor inhibitor stop study were assessed for eligibility and provided informed consent for this add-on study (exclusion criteria: uncontrolled hypertension); 8 were randomly allocated to the continuation arm of adalimumab/etanercept, 27 to the intervention arm of stopping the adalimumab or etanercept. Lost in follow up were 2 and 5 patients respectively. In the stopped group 8 flared and 14 did not flare. Forearm Vasodilation was assessed twice: before cessation of the intervention (visit 1) and 6 months afterwards (visit 2) or earlier when flaring occurred; flare defined as DAS28>3.2 plus increase exceeding 0.6 compared with baseline.

Results: In patients who stopped but did not flare (group B) vasodilator response to SNP and ACh did not differ between visit 1 and 2. In patients who flared after stopped adalimumab or etanercept (group C) vasodilator responses to ACh and SNP were significantly reduced during visit 2 when compared with visit 1, see table. In patients from group A who continued adalimumab/etancercept no flares were observed and vasodilator responses did not significantly differ between both visits. Table: percentage change in forearm blood flow (FBF) in infused versus non-infused arm in group C (n=8) vs group B (n=14); means (SE)

	ACh0.5	ACh2	ACh8	SNP0.06	SNP0.2	SNP0.6
A visit 1	124(34)	594(167)	1246(575)	52(21)	299(128)	651(223)
A visit 2	244(113)	477(228)	503(136)	222(45)	465(133)	821(256)
B visit 1	210(45)	582(156)	726(143)	93(16)	223(42)	358(54)
B visit 2	241(49)	418(74)	739(95)	99(14)	219(33)	486(94)
C visit 1	274(74)	608(185)*	1367(330)	121(30)	287(63)*	614(185)
C visit 2	142(33)	267(54)*	724(195)	105(24)	162(31)*	340(87)

* $P<0.05$ for comparison visit 1 to visit 2 (repeated measures ANOVA with vasodilator dose and visit as within subject factors)

Conclusion: Forearm vasodilator function is reduced after interruption of adalimumab or etanercept but only when rheumatoid arthritis reactivates. This indicates that without close rheumatological monitoring after interrupted biological treatment, ie stopped TNF inhibitor therapy, microvascular functional impairment will occur in those who flare, with potentially devastating implications for cardiovascular health. Funding for this study was gratefully acknowledged from Abbvie (unrestricted grant)

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Given the increasing number of available treatments for RA with varying efficacy and safety profiles, it is critical to understand the level of trade-offs that patients are willing to make between benefits and risks. This study quantified the thresholds of benefit-risk trade-offs that patients are willing to accept in the treatment of RA.

Methods: Adult patients with moderate to severe RA were invited to participate in a discrete choice experiment that solicited their preferences for hypothetical RA treatments. These hypothetical RA treatments consisted of 9 attributes, including 3 efficacy measures (reduction in number of swollen joints, reduction of RA-related pain, and improvement of physical function), 3 adverse events (AEs; abnormal laboratory results [including abnormal liver function tests, blood count, and lipid profile], cancer, and serious infection), and 3 process-related features (route of administration, dose frequency, and out of pocket cost). Each participant completed 14 choice cards, and on each card was asked about their preference between two hypothetical RA treatments with varying levels of the 9 attributes. A multivariable logistic regression model was estimated to assess the association between the attributes and patient preference. Using the model, benefit-risk thresholds were calculated for the efficacy measures and AEs.

Results: 510 eligible patients with moderate to severe RA completed the experiment. The average age of the participants was 56.4 years, 64.7% were female, 38.4% were employed, 43.1% had RA for more than 10 years, and 45.1% received biologic agents. To achieve a 50% improvement in physical function, patients were willing to accept risk-increases of 91.1%, 4.7%, and 18.4% for abnormal laboratory results, cancer, and serious infection, respectively. Similarly, to achieve a 50% reduction in RA-related pain, patients were willing to accept risk increases of 70.6%, 3.7%, and 14.2% for each AE. Moreover, patients were willing to trade risk-increases of 42.0%, 2.2%, and 8.5% for each AE to obtain a 50% reduction in the number of swollen joints. Physical function affects patients' preference for the treatment the most (odds ratio [OR]=4.03 for a 50% improvement), followed by RA-related pain (OR=2.95 for a 50% reduction) and number of swollen joints (OR=1.90 for a 50% reduction). Increased risk of cancer affects patients' avoidance of the treatment the most (OR=0.74 for a 1% increase), followed by serious infections (OR=0.93 for a 1% increase) and abnormal laboratory results (OR=0.98 for a 1% increase). In addition, patients preferred oral and subcutaneous treatments (OR=2.30 for oral vs. intravenous and OR=1.69 for subcutaneous vs. intravenous), treatments with less frequent dosing (OR=1.69 for monthly vs. daily dosing), and lower out of pocket costs (OR=0.48 per $100 increase).

Conclusion: Patients with moderate-to-severe RA are willing to accept increased treatment risks to achieve improved physical function and disease control.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There are limited data regarding the role of and response to treatment, of bone biomarkers in early rheumatoid arthritis (RA) treated with conventional DMARDs. We sought to determine whether levels of bone biomarkers associated with osteoclast activation [RANKL and Dickkopf-1 (Dkk-1)] or inhibition [osteoprotegerin (OPG)] correlated with response to treatment in an inception cohort of RA patients receiving treat-to-target combination DMARD therapy.

Methods: Patients with early RA (< 1 year; fulfilling 2010 classification criteria, n=112) received triple therapy (methotrexate, sulfasalazine and hydroxychloroquine) escalated to achieve DAS28 remission, without oral corticosteroids. RANKL, OPG and Dkk-1 were analysed by Luminex kits at 0, 6 and 12 month and in healthy controls (n=33). OPG levels were log-transformed prior to analysis; as a significant proportion of RANKL levels were below detection, results were dichotomised (positive/negative). Correlations between biomarkers and changes following treatment were analysed using Spearman's rank coefficient and mixed-model longitudinal regression respectively.

Results: At baseline, 69% were positive ('seropositive') for rheumatoid factor (RF) and/or anti-CCP (cyclic-citrullinated peptide), mean (±SD) age was 58(13) years, 72% were females, 60% current/past smokers, mean symptom duration prior to diagnosis of 18 (±11) weeks and mean DAS28 was 5.52 (1.30). Median (IQR) total SvH score was 3 (8); 20% had erosive disease. At baseline, compared to controls, OPG levels were elevated in both seronegative ($p < 0.001$) and seropositive ($p < 0.001$) patients. In seropositive patients, RANKL was more frequently detectable ($p < 0.001$) and negatively correlated with Dkk-1 ($p < 0.05$). In contrast, seronegative patients had higher Dkk-1 ($p < 0.001$) which strongly correlated with OPG ($p < 0.001$) and RANKL was not significantly different from controls ($p = 0.36$). Following treatment, mean DAS28 at 6 and 12 months was 3.55 (1.55) and 3.28 (1.60) respectively. In seropositive patients, there was a significant reduction in proportion of patients with detectable RANKL ($p = 0.002$) and an increase in OPG levels ($p < 0.01$) but no significant change in Dkk-1 levels. Seronegative patients, in contrast, had no change in proportion of patients with detectable RANKL ($p = 0.76$) or OPG levels ($p = 0.5$), but had a significant reduction in Dkk-1 ($p < 0.001$).

Conclusion: Individual bone biomarkers show significant differences at baseline and following conventional DMARD treatment, between seropositive and seronegative patients. Reduction in Dkk-1 and reduction in RANKL and increase in OPG may be useful biomarkers of treatment response in seronegative and seropositive patients respectively. The differential response of biomarkers, depending on seropositivity, may help direct therapeutic decisions in order to optimise prevention of joint damage. Further analysis of these biomarkers in relation to disease activity and erosive disease is warranted.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) has been recommended for the first line therapy of rheumatoid arthritis (RA), either alone or in combination with other DMARDs such as leflunomide. Although MTX is thought to have long term safety, there is still controversy whether long term use of MTX and its cumulative dose causes liver fibrosis in RA patients**.** This study was performed to assess the degree of liver fibrosis among the RA patients treated with MTX by transient elastography (TE), and to identify associated factors with liver fibrosis in those patients.

Methods: We restrospectively reviewed the medical records of 160 patients with RA taking MTX over 3 years, and who had liver fibrosis examination using TE. Liver fibrosis was defined as liver stiffness value over 5.3 kPa according to the reference of healthy Korean organ donor. The duration, cumulative doses of medications including MTX and leflunomide, and serologic markers related to liver fibrosis were analyzed by comparing 2 groups with and without liver fibrosis. E), and to identify associated factors with liver fibrosis in those patients.

Results: The mean disease duration of patients was 10.7 ± 5.1 years, and the median liver stiffness value was 4.5 ± 2.7 kPa. Twenty one (13.1%) patients showed liver fibrosis while only 1 (0.01%) patient progressed to liver cirrhosis. The cumulative dose of MTX and leflunomide showed no significant difference between 2 groups. A history of taking LFNM and concomitant medications did not affect to the development of liver fibrosis. Patients with liver fibrosis had higher glucose, aspirate aminotransferase (AST), and alkaline phosphate (ALP) level with a tendency of lower level of hemoglobin, platelet and longer treatment duration with MTX. The history of glucose

abnormality including pre-diabetes and diabetes mellitus (odds ratio [OR] 5.154, $P = 0.011$), serum hemoglobin (OR 0.608, $P = 0.023$), platelet (OR 0.989, $P = 0.025$), AST (OR 1.052, $P = 0.014$), and ALP level (OR 1.034, $P = 0.022$) were related with liver fibrosis in multivariate analysis.

Conclusion: Long term use of low dose MTX and combination of leflunomide in patients with RA were relatively safe in terms of severe liver fibrosis measured by TE. RA patients with risk factors such as impaired glucose tolerance should be more carefully monitored for development of liver fibrosis in long term use of MTX.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There are more than 5 million rheumatoid arthritis (RA) patients in China, but only 5,000 rheumatologists. Treat-to-Target (T2T) strategy are critical for the treatment of RA, but the Chinese rheumatologists can hardly provide patients with a complete assessment in the clinic due to limited time. The purpose of this study is to explore the effectiveness of applying SSDM in improvement of disease activity after repeated self-assessment in Chinese RA patients.

Methods: The SSDM includes interfaces of both physicians' and patients' application. After entering the data of lab test records, treatment regiments, and executing DAS28 assessment by patients, all data can be synchronized automatically to the authorized physicians' mobile tool. The rheumatologist can adjust treatment regiments base on patients' profile. From August 2014 to June 2016, 126 rheumatologists from 83 hospitals in China participated in the study. Patients were educated to assess DAS28 with SSDM and asked to repeat the self-assessment once a month. Descriptive statistics were performed for patient and disease characteristics. According to DAS28 scores, disease activity was divided into four groups: remission (Rem), low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA).

Results: 1,058 RA patients with repeated self-assessment of DAS 28 were recruited, 819 (77.4%) women and 239 (22.6%) men respectively. Mean age was 48.3 ± 13.1 (11 to 83) years. Mean interval of repeat self-assessment was 38.2±38.1 days. Mean self-assessment frequency were 3.39±2.84 (2 to 31) times. Mean DAS28 score was 3.78 ± 1.45 (0.56 to 8.66) at baseline and 3.31 ± 1.35 (0.08 to 9.07) at the last assessment. Proportion of patients in Rem, LDA, MDA and HDA was 22.12%, 16.26%, 43.29% and 18.34% respectively at baseline, and changed into 32.61%, 18.81%, 39.22% and 9.36% at the last assessment. The rate of T2T (DAS28≤3.2) at the last assessment was higher than that of baseline significantly ($P<0.01$). The rate of HDA patients for last assessment was significantly lower than baseline ($P<0.01$). To further explore weather tight control of disease activity with SSDM could influence RA patients' outcome, we stratified the patients who did not achieve clinical remission (DAS>2.6) at baseline into twice assessments group and multiple assessments group with 6 months follow-up. The result showed that 149 patients made only twice assessments of DAS28 within 160.8±94.9 (60-578) days. Their mean DAS28 score was 4.27±1.15 (2.61 to 7.86) at baseline and improvement of DAS28 score was 0.55±1.51 (-4.49 to 4.18) at their last assessment. While another 170 patients made 4 to 10 times of self-assessment during 178.9±139.3 (28 to 648) days follow-up. Their mean DAS28 score was 4.24±1.10 (2.61 to 7.77) at baseline and average improvement of DAS28 score was 1.09±1.37 (-1.86 to 5) at the last assessment, which was significantly better than patients who had only two self-assessments ($T=3.331$, $P=0.001$).

Conclusion: Under repeat self-assessment of DAS28 using SSDM, RA patients can achieve better T2T result. SSDM can assist rheumatologist to rationally adjust treatment for RA patients.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the implementation of the treat to target (T2T) concept in rheumatoid arthritis (RA) patients.

Methods: Academic rheumatology units were invited to participate in a retrospective study evaluating the implementation of the T2T concept in RA patients. The charts of consecutive RA patients attending the centers during June 2015, with 3 or more previous visits, were evaluated using a common questionnaire. Data collected included demographic parameters, alcohol consumption, smoking, concomitant diseases, age at RA onset, and the presence of rheumatoid factor (RF) and erosions. Validated disease activity scores [Disease Activity *Score* (DAS-28), Clinical Disease Activity Index (CDAI), Simple Disease Activity Index (SDAI), Routine Assessment of Patient Index

Data (RAPID3)], RA treatment including conventional or biological DMARDS, drug dosages, side effects, and patients' preferences were recorded. Two independent rheumatologists evaluated the data to assess the implementation of T2T concept. Statistical analysis: The associations between T2T concept implementation and categorical and continuous variables were assessed by Chi square test, t-test or Mann-Whitney test as appropriate. ANOVA or Kruskal-Wallis test was used to compare continuous variables between centers as appropriate.

Results: The seven participating centers reported 724 patients; age 62.6±13.97 years, 575 (80.4%) of them women. According to the reported data, 353 (65.4%) never smoked, 474 (73.3%) were married, 592 (86.8%) lived in cities, 191 (45.7%) had above high school education, 524 (72.4%) had comorbidities, 399 (66.4%) were RF positive and 125 (59.8%) had erosions. Four centers used more than one scoring method, DAS-28 and CDAI being the most popular. Only 276 (38.1%) of the patients had disease score results in ≥3 visits. The T2T approach was implemented in 245 (33.8%) of the 724 patients. The rate of implementation varied between centers (11.1%-87% $p<0.0001$), and was higher in younger patients ($p=0.028$), non-Jews ($p=0.048$), alcohol consuming ($p=0.009$) and RF positive patients ($p=0.011$). There was no correlation between the T2T implementation and gender, place of residence, education, smoking, treatment regimens, and the presence of erosions or comorbidities.

Conclusion: In our sample, the implementation of the T2T concept was limited. Further studies are needed to determine the reasons for this deviation from this desirable standard as well as its consequences.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To develop recommendations for the management of parenteral MTX in rheumatic diseases based on best evidence and experience.

Methods: A group of 21 experts on parenteral MTX use was selected. The coordinator formulated 13 questions about parenteral MTX (indications, efficacy, safety and cost-effectiveness). A systematic review were performed in order to answer the questions. Using this information, inclusion and exclusion criteria were stablishes as well as the search strategies (Medline, Embase and the Cochrane Library were searched). Three different reviewers selected the articles. Evidence tables were produced. At the same time, EULAR and ACR abstracts were evaluates. With this evidence the coordinator proposed preliminary recommendations that the experts discussed and voted in a nominal group meeting. The level of evidence and grade of recommendation was established using the Oxford Center for Evidence Based Medicine and the level of agreement with the *Delphi* technique (2 rounds). Agreement was established if at least 80% of the experts voted yes (yes/no).

Results: A total of 13 preliminary recommendations on the use of parenteral MTX were proposed of which 11 were accepted (see table). Two were not voted and were explained in the main text of the document.

Conclusion: This document pretends to help solve usual clinical questions and facilitate decision making when treating rheumatic patients with parenteral MTX. **Table**. Recommendations and their level of evidence (LE), grade of recommendation (GR) and grade of agreement (GA).

#	RECOMMENDATION	LE; GR; GA
1	Parenteral MTX biodisponibility compared with oral MTX is superior, mainly if the dose is ≥15 mg/w	NE 2b; GR B-C; GA 100%
2	In MTX-*naïve* patients, parenteral MTX efficacy compared with oral MTX is superior (doses of 15 mg/w)	NE 1b; GR A; GA 94%
3	In patients refractory to oral MTX (15 mg/w) the efficacy of dose escalation is higher with parenteral MTX	NE 2a; GR B; GA 94%
4	Safety profile and tolerability of parenteral MTX is similar to oral MTX	NE 1b; GR B; GA 100%
5	It is recommended to use parenteral MTX in patients with high disease activity, in those with low adherence to oral MTX, polypharmacy, obese patients, in order to avoid dosing errors, and always taking into account patients preferences	NE 4; GR D; GA 100%
6	It is recommended to initiate, increase and decrease parenteral MTX the same way as with oral MTX	NE 5; GR D; GA 81%
7	It is recommended to increase parenteral MTX dose up to 25-30 mg/w	NE 5; GR D; GA 88%
8	According to available pharmacokinetic data, the dose conversion between oral and parenteral dose would be: up to 15 mg/w the same dose, 20 mg of oral MTX would be 15 mg of parenteral MTX and for 25 mg of oral MTX, 20 mg of parenteral MTX	NE 2b; GR B; GA 100%
9	Subcutaneous MTX could be cost-effective in early RA naive to MTX	NE 2a; GR B; GA 94%
10	Parenteral MTX might increase patients adherence to MTX	NE 2b; GR B; GA 94%
11	Self-administration education provides a high adherence to treatment, satisfaction, patients autonomy and improves and adequate administration	NE 2b; GR B; GA 100%

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Methotrexate-associated lymphoproliferative disorder(MTX-LPD) is rare but one of important complications in treatment of rheumatoid arthritis (RA). There are few reports about disease activity and optimal therapy of RA with MTX-LPD.

Methods:

We retrospectively analyzed background of patients, histology of LPD, treatment and disease activity of RA in 15 patients with MTX-LPD in our hospital between 2008 and 2014.

Results:

Our cases included 4 males and 11 females, and the median age of MTX-LPD onset was 70 years old (52-81). Average dose and period of MTX administration were 8.8 mg /week (4-16), 8.7 years (2.2-19.8), and 3681 mg in total (1372 -9485). Mean DAS28 (CRP) at MTX-LPD diagnosis was 2.00 (1.17-3.18). Extranodal lesions were observed in 8 cases. Three of 15 patients were diagnosed as Hodgikin lymphoma (HL), 2 as diffuse large B-cell lymphoma (DLBCL), 1 as Follicular lymphoma (FL), 1 as peripheral T-cell lymphoma (PTCL), 1 as Angioimmunoblastic T-cell lymphoma (AILT).

Lymphoproliferative lesions were improved spontaneously by discontinuation of MTX in 8 cases. Six of them showed relapse of RA in 3 to 65 months after MTX cessation, and Abatacept (ABT), administered in four cases, was effective without recurrence of LPD. Chemotherapy (CTx) was required in seven patients. Flare of arthritis, seen less common in CTx group, occurred in two cases in 18 and 36 months after CTx was finished. The propotion of patients associated with Sjögren's syndrome (SS) was significantly larger in CTx group (57 % v.s. 0 %, p=0.026).

Conclusion:

It is suggested that RA flare is common after MTX-LPD and ABT can be safe and effective treatment in RA relapse. Absense of SS was associated with spontaneous remission of MTX-LPD.

Patients With Spontaneous Remission

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Remission has become a treatment goal in rheumatoid arthritis (RA) especially after the introduction of biologic treatment in 1999. The Swedish quality registry (SRQ) is a nationwide registry for rheumatic diseases in which all 64 rheumatology units in the country participate. The aim of the present study was to investigate the impact of changing treatment goals in the national guidelines on secular trends in achieving sustained remission (SR) i.e. DAS28<2.6 on at least 2 consecutive occasions lasting at least 6 months in a national Swedish RA cohort.

Methods: All adult patients with RA included in the registry 1992-2013, with follow up through 2014 with at least 3 registered visits were eligible, a total of 29084 patients. Their median age was 59.6 years and 72% were female. Symptom onset ranged from 1934 to December 2012, but for parts of the comparisons only patients with symptom onset between 1999 and 2009 were studied. The median time from symptom onset to inclusion was 2.6 years (range 0-78 years). Last follow up visit was median 10.5 years after symptom onset. In total, 95% of patients fulfilled the ACR 1987 classification criteria for RA and 73.2% were ACPA positive. Registrations were made with a median interval of 6 months (range 1 to 215). Duration of remission was defined as the time between first visit fulfilling the remission criteria and subsequent first visit with higher disease activity, after median 2.8 years. Estimated time to SR for each year was calculated with life table analysis and compared using log-rank test.

Results: 12193 (41.9%) patients reached DAS28 sustained remission at some time point during follow up. Figure 1 shows the fraction of patients with symptom onset in a certain calendar year reaching DAS28 remission occasionally or SR. Of patients with symptom onset between 1981-1990, 1991-2000 and 2001-2010, 35.0%, 43.0% and 45.6% reached SR respectively ($p<0.001$ for each increment). Figure 2 shows the estimated fraction of patients in SR during the first 5 years after symptom onset. The time period from symptom onset to SR decreased every other year with only

two exceptions ($p<0.001$; log-rank test). The estimated mean time to SR was 11.7 years in 1999 compared to 4.2 in 2009.

Conclusion: The prevalence of sustained remission was higher 2001-2010 compared to the previous two decades. Time from onset of RA symptoms to sustained remission decreased gradually between 1999 and 2009. The treatment strategy the last decade has improved outcome of RA but further improvement concerning time to diagnosis and early effective treatment is required to reach the treatment goal of sustained remission in the majority of patients.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Remission constitutes the best achievable state in patients with rheumatoid arthritis (RA). And if remission is a goal, it need to be maintained. The objective of this study was to evaluate stable remission in (RA) over 7 years follow-up in "real life" conditions and its predicitive factors.

Methods: The records (clinical, biological, immunogenetic, and radiographical data) of 364 patients with active RA, fulfilling the American College of Rheumatology (ACR) criteria, seen between January 2008 and December 2008 in a University Hospital Rheumatology were analyzed. Mean age was 62,9 years. 188 were treated with cDMARDs (monotherapy or association), 86 were treated with bioDMARDs (monotherapy or combined with methotrexate), 36 had only corticosteroids. The ACR-EULAR remission, defined as DAS28 <2.6 was achieved by 97 patients after 1 year (39 patients had only cDMARDs, 49 had bioDMARDs (43 anti-TNF and 6 others), 9 had no long-term treatment. Patients were seen at least once a year In out patient clinic. All data were collected until end of 2015.

Results: Data from 233 patients (75%) followed up to 7 years were avalaible. Remission was obtained for 133 patients (57%).102 were treated with cDMARDs (monotherapy with methotrexate, arava, plaquenil or tritherapy),130 were treated with bioDMARDs (30 had monotherapy and 100 had combined treatment with cDMARDs), 1 had only corticosteroids. Mean activity in DAS28 was 3,44 after 1 year and dicreases to 2,67 after 7 years follow up. Corticosteroids have been stopped for 38% of our patients. Among the 97 patients getting strict remission after 1 year, 82 patients (84%) kept long term remission and 51 others entered in remission during follow up. Remission rate was 31% after 1 year, remained stable for 84% of our patients and long term remission rates (DAS28<2.6) was obtain for 57% of our patients, and 38 patients (16%) kept a low disease activity (DAS28 <3,2). Long term remission was more frequent when cDMARDs was associated with bioDMARDs, especially anti-TNF.

Conclusion: In our study 84% of patients who had remission after 1 year of treatment kept long term remission. In RA patients, targeted treatment with a combination of conventional DMARDs and biologic induces a higher rate of long term remission.

Does Combination of Conventional Synthetic Disease Modifying Antirheumatic Drug with Anti-TNF Influence the

Long Term Retention Compared to Anti-TNF Monotherapy in Psoriatic Arthritis? an Analysis from Rhumadata® over 12 Years

Isabelle Ferdinand[1], Louis Bessette[2], Josiane Bourré-Tessier[3], Boulos Haraoui[4], Jacques Brown[5], Frédéric Massicotte[3], Jean-Pierre Pelletier[3], Jean-Pierre Raynauld[4], Marie-Anaïs Rémillard[6], Diane Sauvageau[3], Angèle Turcotte[5], Édith Villeneuve[3] and Louis Coupal[3], [1]University of Montreal, Montreal, QC, Canada, [2]Rhumatology, Centre d'Ostéoporose et de Rhumatologie de Québec (CORQ), Québec, QC, Canada, [3]Rheumatology, Institut de Recherche en Rhumatologie de Montréal (IRRM), Montréal, QC, Canada, [4]1551, Ontario Street East, Institut de Recherche en Rhumatologie de Montréal (IRRM), Montreal, QC, Canada, [5]Rheumatology, Centre d'Ostéoporose et de Rhumatologie de Québec (CORQ), Québec, QC, Canada, [6]Rhumatology, Institut de Recherche en Rhumatologie de Montréal (IRRM), Montréal, QC, Canada

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis, it has been shown that anti-TNF therapy (TNFi) in combination with a conventional synthetic disease-modifying antirheumatic drug (csDMARD), often methotrexate (MTX), is more effective than anti-TNF monotherapy to improve clinical outcomes and TNFi retention. A recent article on psoriatic arthritis (PsA) has observed a trend towards better retention of TNFi in combination with MTX vs monotherapy. We assessed the long-term retention of TNFi with and without csDMARDs in the first-line treatment of PsA in the real world Rhumadata® clinical database.

Methods: The data of all PsA patients treated with a first biological agent was extracted from Rhumadata®. The data included age, gender, clinical variables, patient and physician specific assessments, and laboratory measures. Composite assessment of disease activity including the DAS28-CRP and the simplified and clinical disease activity indices (SDAI and CDAI) were calculated using readily available formulas. Concomitant use of csDMARDs (MTX, hydroxychloroquine, leflunomide, and sulfasalazine) was collected. Patients were classified into four groups: TNFi alone, TNFi+MTX alone, TNFi+non-MTX csDNMARDs and TNFi+MTX+other csDMARDs. Kaplan-Meier methods were used to compute the cumulative incidence of biologic agent discontinuation in those groups and differences in discontinuation rates were tested using the log-rank tests. Potential predictors of biologic retention were entered in univariate and multivariate proportional hazard regression models. Statistical analysis was performed using SAS version 9.4.

Results: Our cohort included 398 patients, 102 receiving anti-TNF monotherapy, 165 concomitant MTX only, 90 MTX + other csDMARDs and 41 concomitant non-MTX csDMARDs . Men represent 55% of our cohort with a mean disease duration of 6 years (SD=8). Mean baseline disease activity measured using DAS28-ESR or CRP are respectively, 4.1 and 4.0. Drugs survival analysis showed no significant difference between groups: Anti-TNF monotherapy versus combination with MTX only, or with MTX + other csDMARDs or with a non-MTX csDMARDs (p=0.09). Drugs survival analysis for each of the anti-TNF (adalimumab, etanercept or golimumab) did not demonstrate a significant difference when adding MTX +/- other csDMARDs. As for infliximab (IFX) used in combination with MTX +/- other csDMARDs showed a trend towards better retention (p=0.07). Multivariate analysis showed that anti-TNF in combination with MTX and at least one other csDMARDs was a predictor of improved retention (HR 0.49, 95% CI 0.31-0.78, p=0.003). Smoking, female gender and higher DAS28 (CRP) were associated with increased drug discontinuation. Main reason for treatment discontinuation in all groups was lack of efficacy.

Conclusion: In this real world analysis, anti-TNF therapy in combination with csDMARDs vs monotherapy, did not significantly influence the biologic long-term retention, except for IFX, where a tendency was observed. Combination therapy with MTX and at least another csDMARDs is a predictor of better retention whereas smokers, women and patients with higher DAS28 (CRP) were more likely to discontinue therapy.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-reported outcomes (PROs) are important measures when determining response to therapy in patients with RA. Previous RCTs have shown that TCZ monotherapy is superior to both MTX alone and ADA monotherapy for improving RA disease activity.[1,2] These post hoc analyses compared the efficacy of TCZ monotherapy with MTX or ADA monotherapy for improvement of PROs in 2 RCT populations, providing change in Clinical Disease Activity Index (CDAI) as a reference.

Methods: AMBITION and ADACTA were independent RCTs evaluating the efficacy and safety of TCZ compared with MTX or ADA, respectively, in patients with active RA. In AMBITION, patients who were MTX-naive or had discontinued MTX ≥ 6 months prior to baseline without previous inadequate responses to MTX or tumor necrosis factor inhibitors received TCZ 8 mg/kg IV every 4 weeks or MTX. In ADACTA, biologic-naive patients intolerant to or inappropriate for MTX received TCZ 8 mg/kg IV every 4 weeks or ADA 40 mg SC every 2 weeks. PROs, assessed at 24 weeks, included patient global assessment (PtGA; visual analog score [VAS], 0-100 mm), pain (VAS), Health Assessment Questionnaire Disability Index (HAQ-DI, 0-3), Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue (0-52) and Short Form (SF)-36 (0-100). The proportions of patients reporting PRO scores ≥ minimum clinically important differences (MCID) as well as ≥ age/sex-matched normative values were assessed for each treatment group.

Results: In both RCTs, patients receiving TCZ reported greater improvements across all PROs at week 24 compared with MTX or ADA. In AMBITION, 45.0-84.0% of patients who received TCZ reported scores ≥ MCID in PtGA, pain, HAQ, FACIT, SF-36 PCS/MCS and all domains at week 24 compared with 39.4-81.8% with MTX (**Table 1**); 24.3-52.1% who received TCZ reported scores ≥ normative values in HAQ (< 0.5), FACIT (≤ 40), SF-36 PCS/MCS (≥ 50) and all domains compared with 14.5-45.0% with MTX (**Table 2**). In ADACTA, 57.7-83.3% of patients who received TCZ reported scores ≥ MCID in PtGA, pain, HAQ, FACIT, SF-36 PCS/MCS and all domains at week 24 compared with 50.8-75.6% with ADA (**Table 1**); 22.1-49.3% who received TCZ reported scores ≥ normative values in HAQ, FACIT, SF-36 PCS/MCS and all domains compared with 13.6-37.8% with ADA (**Table 2**).

Conclusion: Consistent with the CDAI responses from these RCTs, TCZ monotherapy resulted in

more patients achieving MCID and normative values, indicative of clinically meaningful improvements, in PROs compared with either MTX or ADA monotherapy in AMBITION and ADACTA. **References:**

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown differences in the effectiveness and survival of subcutaneous vs. oral methotrexate. Furthermore, concurrent methotrexate therapy has been shown to enhance the efficacy of anti-TNFs. The purpose of this study was to describe the pattern of methotrexate utilization in RA patients initiating biologic treatment in a large observational cohort and to compare the impact of methotrexate route of administration and dose on biologic durability in real-life.

Methods: Patients enrolled in the Ontario Best Practice Research Initiative (OBRI) initiating combination therapy with a biologic and methotrexate were included. Analysis was primarily descriptive. Cox regression was used to examine the impact of methotrexate route of administration and dose at baseline on biologic durability. Methotrexate dose was classified as low (≤15 mg/week), moderate (15-20 mg/week), and high (>20 mg/week).

Results: Among 2,585 RA patients enrolled in OBRI, 885 initiated biologic therapy. Of the latter, 517 (58.4%) were treated concomitantly with methotrexate and were included in the analysis. Mean (SD) age and disease duration were 55.8 (13.1) years and 9.2 (9.8) years, respectively, while the majority were females (78.9%) and treated with an anti-TNF agent (83.0%). Overall, 271 (52.4%) were treated with oral methotrexate and 236 (45.6%) with subcutaneous without any significant differences between biologic types. The predominant dose was 15-20 mg/week for oral methotrexate (43.2% of patients) and >20 mg/week for subcutaneous use (47.0%). Mean (SD) disease parameters at baseline were: DAS28 = 4.6 (1.4); swollen joint account = 6.3 (4.9); tender joint count = 6.9 (6.4); physician global = 5.1 (2.4); patient global = 5.3 (2.7). Over a mean (SD)

follow-up of 1.8 (1.5) years biologic discontinuation was reported for 39.5% of patients. Neither route of administration [$HR_{SC\text{-}Oral}$ (95%CI) = 1.2 (0.9-1.6)] nor dose [$HR_{Moderate\text{-}Low}$ (95%CI) = 1.05 (0.74-1.49); $HR_{High\ vs.\ Low}$ (95%CI) = 1.08 (0.76-1.53)] of methotrexate at baseline were significantly associated with biologic discontinuation. Similar results were observed upon adjusting for gender, baseline age, disease duration, and DAS28.

Conclusion: This analysis has shown that subcutaneous methotrexate is used in Canadian routine care in a significant proportion of patients which is higher than that in other international registries. Neither route of administration nor dose of methotrexate were significant predictors of biologic durability despite the fact that previous studies have shown differences in efficacy when methotrexate is used without a biologic. Additional analyses considering changes over time in the mode of methotrexate administration are required to further validate these findings.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adherence to disease modifying anti-rheumatic drug (DMARD) therapy is suboptimal in patients with rheumatoid arthritis (RA). Efficient, low-cost measures are required for optimal monitoring of medication adherence in the rheumatology clinic. Self-report tools are the most efficient and cost-effective measures available. Recently, a 5-item version of the Compliance Questionnaire Rheumatology (CQR5) was developed from the original 19-item version and was validated in a group of RA patients[1]. We also recently demonstrated that the CQR5 exhibits excellent test-retest reliability and significant correlation with medication beliefs in people with RA in the short-term[2], however long-term stability of the questionnaire remains unknown. Therefore, in the same group of patients, we investigated 1) test-retest reliability of the CQR5 and 2) correlation of the CQR5 with medication beliefs in the long term.

Methods: RA patients (disease duration ≥ 1 yr) taking at least one DMARD prescription were randomly selected from a rheumatology outpatient clinic database. Patients were assessed at baseline and three months. At each visit, medication adherence was assessed with the CQR5. Each item on the CQR5 was scored on a four point Likert scale (1 = strongly disagree, 4 = strongly agree). Scores for each item were then summed into a total score which varied between 0 and 20. Higher scores indicated greater adherence. Medication Beliefs were evaluated using the Beliefs about Medicines Questionnaire (BMQ)[3], which examines beliefs around concern, necessity, harm and overuse of taking medications (high scores reflect strong beliefs). Intraclass correlation coefficients (ICC) were used to evaluate test-retest reliability, and bivariate correlations (Pearson's r) were performed to determine relationships between medication adherence measured by CQR5 and medication beliefs measured with the BMQ.

Results: 100 RA patients, [age, mean (SD) = 60.75(12.67) yrs], were recruited and 10 dropped out of the study by three months. In this sample (n=90), the CQR5 demonstrated good test-retest reliability (ICC=0.73, 95% confidence interval = 0.61-0.81; Cronbach's $\alpha = 0.84$). At 3 months, adherence measured by CQR5 also had a significant positive correlation with BMQ necessity scores ($r = 0.67$, $p<0.01$) and significant negative correlations with BMQ concerns ($r = -0.24$, $p<0.05$), harm ($r = -0.39$, $p<0.01$), and overuse ($r = -0.44$, $p<0.01$) scores.

Conclusion: The CQR5 demonstrates long-term stability by maintaining its reliability and ability to predict medication beliefs over time. A more in-depth investigation of the predictive validity of the CQR5 using multiple chain imputation and multivariate analysis is currently underway.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There has been increasing emphasis on intensive treatment of RA but little direct evidence of the impact of such strategies on long term outcome. We evaluated disease activity and outcomes in a prospective observational cohort study over 10 years at a single unit aiming to treat to a target DAS28<2.6.

Methods: We included 1,693 patients seen on 10,773 occasions between 2005 and 2015. At first visit, mean age was 55 years with mean disease duration 10 years. Treatments comprised DMARDs often in combination, and a range of biologics. DAS28, HAQ and quality of life (EQ5D) were recorded at each visit. Temporal changes were assessed by descriptive statistics and maximum likelihood regression models. To further understand outcome in different mean DAS28 categories, we also assessed a subgroup of 714 patients with ³5 follow-up visits between 2010 and 2015 (6728 visits). Mean HAQ, EQ5D and treatment were assessed for each group.

Results: 10 year follow up Mean DAS28 scores fell from 4.1 to 3.7 between 2005 and 2015. Mean HAQ fell from 1.26 to 1.15 and mean EQ5D scores improved from 0.47 to 0.56. Regression models showed annual changes for DAS28 scores were -0.03 (95% confidence intervals -0.04, -0.02), HAQ -0.019 (95% CI -0.025,-0.013) and EQ5D 0.006 (95% CI 0.003, 0.008). The number of patients with high disease activity (DAS28>5.1) decreased from 25% to 16% while DAS28 remission increased from 18% to 27%. The four components of DAS28 showed divergent patterns of change. Mean swollen joint count fell from 3.1 to 2.1 (33%), mean ESR fell from 25 to 18 (26%), and mean tender joint count fell from 5.0 to 4.5 (12%). Mean patient global responses increased by 9% (43.2 to 47.1). Impact of DAS28 category 154/714 (22%) had persistent high disease activity. Compared to patients in remission, HAQ was increased by 1.06, and EQ5D reduced by 0.27. All

groups had similar DMARD use, including combination DMARDs. Only 64 (9%) patients with persistent high disease activity were receiving biologics, compared to 18-20% of other groups (P=0.034). This variation results from failure to respond to biologics, an unwillingness to take them, or contraindications to their use.

Conclusion: Intensive management regimens are associated with progressive improvement in disease activity, function and quality of life. Improvements are seen across all strata of disease activity levels with less active disease and more remissions. However, patient global scores do not improve which requires further investigation. A minority of patients have continued high disease activity with substantial disability and reduced quality of life. This group of patients are less likely to receive biologics. Individualised strategies may be required for this group including novel therapies or psychological interventions.

Session Time: 9:00AM-11:00AM

Title: Predictors of flare in rheumatoid arthritis patients treated preventively with rituximab: a prospective study using ultrasound and patient reported outcomes

Background/Purpose: Rituximab (RTX) is an effective and relatively safe treatment for rheumatoid arthritis (RA). Following treatment, controversy remains on how best to optimise further retreatment while limiting risks of cumulative immunosuppression and cost. At UCLH/UCL RA patients are offered individualized preventive retreatment with RTX based on the duration of their response to initial treatment. This strategy, while allowing continued control of disease activity in many patients with flare prevention may lead to patient overtreatment. The aim of this study was to identify predictors of flare in patients with RA 1 month prior to RTX retreatment.

Methods: A prospective study of 18 RA patients retreated with RTX preventively, were assessed 4 weeks prior to scheduled RTX retreatment where clinical and laboratory assessment, US of wrists and small joints of the hands were performed. Patient reported outcomes (PROs) (HAQ (health assessment questionnaire), Facit-F (functional assessment of chronic illness therapy), SF-36 (short form health survey), EuroQol 5D 3L) were completed weekly until RTX retreatment 4 weeks later. At this time point clinical assessment and US scan were repeated. The study is ongoing.

Results: We have so far studied 11 females and 7 males, with a mean age of 64 years. The patients were assessed at mean 7.2 months after their previous RTX treatment. At initial assessment (week 0) 66.7% (12/18) of patients remained depleted (CD19 count <0.005) while 33.3% (6/18) had already started repopulating. ESR and CRP increased, decreased or remained stable as shown in Figure 1. The number of joints with synovial hypertrophy (SH) on US increased in 61.1%, and decreased in 27.8%. The number of joints showing power Doppler (PD) increased in 27.8%, and reduced in 33.3%. All patients with PD (9/18) on US, reported worsening of their joint pain and/or early morning stiffness. Surprisingly, the general VAS and DAS28 scores decreased by13.3% and 34.9% respectively in the majority of patients, (44.4% and 77.8% respectively) from week 0 to week 4. The weekly PROs were completed by 9/18 patients. HAQ, Facit-F and physical component summary (PCS) of SF-36 scores showed similar changes. The mental component summary (MCS) of SF-36 increased in 33.3% with no change in 44.4%. EuroQol 5D 3L scores increased in 22.2%.

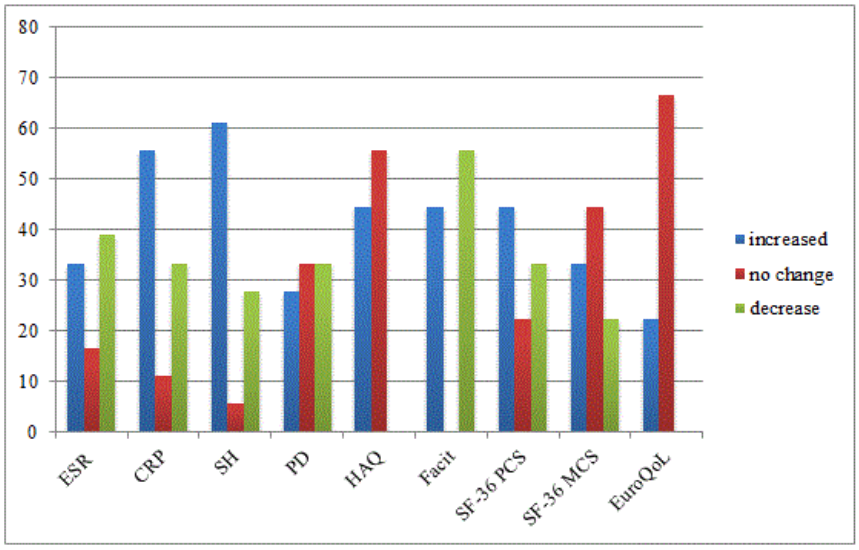

Figure 1. Percentages of all variables changing from week 0 to week 4.

Figure 1. Percentages of all variables changing from week 0 to week 4.

Conclusion: The data of this study which is ongoing, does not show any consistent pattern of variation within 4 weeks prior to RTX retreatment, and baseline assessments at week 0 did not seem to predict stability or worsening of symptoms in the following 4 weeks. The variables increased, decreased or remained the same in almost similar patient numbers. The ESR, CRP and SH on US showed an increase over the 4 week period. All patients with PD on US reported symptoms. Assessment of patients 1 month before preventive retreatment with RTX does not seem to be able to predict which patients are likely to be flaring shortly.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The multi-biomarker disease activity (MBDA) score, which combines 12 serum biomarkers to measure RA disease activity on a scale of 1−100, has been found to be predictive of risk for radiographic progression.[1] The objectives of this study were to evaluate early RA patients from the randomized double-blinded OPERA trial for: 1) associations between baseline (BL) MBDA score and 12-month radiographic outcomes; 2) the value of adding MBDA score to

anti-CCP for predicting radiographic progression.

Methods: In the OPERA trial, treatment-naive early RA patients (N=180) with moderate or high DAS28 were randomized to treatment with oral methotrexate and either adalimumab (ADA) (n=89) or placebo (n=91). Glucocorticoids were injected into up to 4 swollen joints per visit.[2] X-rays of hands and feet (n=164) from months 0 and 12 were assessed with the Sharp van der Heijde Total Sharp Score (TSS). The smallest detectable change (1.8 TSS units) defined radiographic progression (DTSS≥2). Anti-CCP status was dichotomized. MBDA score was determined at 0 and 3 months. Correlations between BL or change (D) MBDA score and radiographic progression were analyzed by Spearman´s rank correlation coefficient (r). Chi-Square test was used for comparisons. A logistic regression model, adjusted for BL demographics and disease activity measures, assessed association between MBDA score and radiographic progression.

Results: Patients had median (range) age 55 (19-86) years, disease duration 84 (42-214) days; 66% were female; 72% were positive for RF and 65% for anti-CCP. Median values at BL were DAS28-CRP 5.6 (3.3-8.6), MBDA score 59 (12-90) and TSS 2 (0-31). 42 patients had DTSS ≥ 2, median DTSS = 3 (2-22)/mean DTSS = 4.52 (3.84). BL MBDA score correlated with DTSS in the placebo (r=0.23, p=0.04) but not the ADA group (r=0.10, P=0.35). ΔMBDA score$_{0\text{-}3\text{months}}$ was not correlated with DTSS. Patients with high BL MBDA score (>44) were more likely to progress radiographically (31%), while only 1/31 (3%) patients with MBDA score ≤44 progressed (p<0.01), and this was significant also for each treatment group. Moderate/high BL DAS28-CRP was not associated with radiographic progression (Figure 1A, B). BL MBDA score (OR=1.03 per unit increase [1.01-1.06]), and anti-CCP (OR=4.45 if positive [1.66-11.95]) were significantly associated with RP in multivariate analyses. 34% of anti-CCP positive and 12% of anti-CCP negative patients had RP (p<0.002). No anti-CCP+ patients with MBDA score ≤44 progressed radiographically, whereas stratifying by DAS28-CRP had no added value to anti-CCP alone (Figure 1C, D)

Conclusion: High BL MBDA score (>44) was a strong, independent predictor of radiographic progression and added value to anti-CCP status. Only 3% of patients with low or moderate BL MBDA score (≤44) progressed radiographically. (1) Hirata et al. Current Biomarker Findings 2015, 5:69-78 (2) Hørslev-Petersen K, et al., Ann Rheum Dis 2014; 73:654-661

Lower Baseline 14-3-3η Levels Are Associated with Better Patient Reported Outcomes in Tocilizumab Treated Patients

Shintaro Hirata[1], Anthony Marotta[2], Kentaro Hanami[1] and Yoshiya Tanaka[3], [1]The First Department of Internal Medicine, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Augurex Life Sciences Corp., Vancouver, BC, Canada, [3]University of Occupational and Environmental Health, Kitakyushu, Japan

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

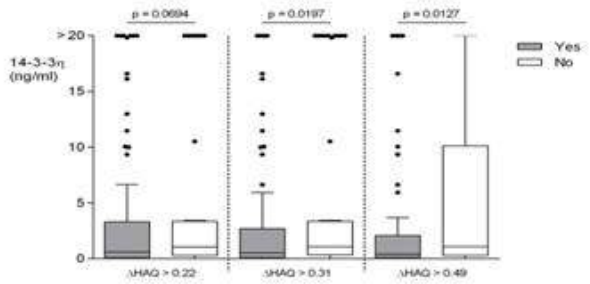
Background/Purpose: Serum 14-3-3η is a mechanistic marker that is involved in the pathogenesis of RA and is a potent up-regulator of IL-6. We previously reported that baseline 14-3-3η levels were significantly lower in a cohort of 49 established RA patients who achieved better clinical outcomes when treated with Tocilizumab. Recently there has been increased interest in assessing therapy response using alternative measures to DAS that are independent of CRP, including patient reported outcomes such as HAQ-DI. The aim of this study was to validate whether lower baseline levels of 14-3-3η is associated with and independently predicts clinical response in RA patients treated with tocilizumab.

Methods: Serum 14-3-3η levels were measured in a cohort of 106 Japanese patients prior to the initiation of tocilizumab therapy (BL). 14-3-3η positivity was defined by the diagnostic cut-off of ≥ 0.19 ng/ml, and 2 and 4 times that, at 0.40 and 0.80 ng/ml, respectively. Patients were sub-grouped according to changes in HAQ-DI based on the minimal clinically important difference (MCID) of ≥ 0.22, ≥ 0.31, and ≥ 0.49. Group differences were assessed by Mann-Whitney U-test. ROC curve analysis was performed to identify the optimal 14-3-3η cut-point for a ΔHAQ-DI ≥ 0.49. Uni- and multi-variable analysis controlling for baseline HAQ-DI was used to assess 14-3-3η's independence of other clinical/serological variables at informing patient reported outcomes.

Results: At baseline, 75 (71%) of the 106 patients were 14-3-3η positive. At year 1, 70 (66%), 58 (55%) and 52 (40%) of the 106 patients achieved changes in HAQ-DI of ≥ 0.22, ≥ 0.31, and ≥ 0.49, respectively. Baseline HAQ-DI values were significantly higher in those patients that achieved a Δ HAQ-DI ≥ 0.22 when compared with those that did not; $p = 0.009$. The HAQ-DI values were also significantly higher at the two other HAQ-DI cut-points (≥ 0.31, and ≥ 0.49), $p < 0.0001$. As shown in the Figure, serum 14-3-3η levels were significantly lower in patients that achieved HAQ-DI MCID of > 0.31 and >0 .49. In patients who achieved a ΔHAQ-DI ≥ 0.49, ROC analysis returned the best cut-off of ≤ 0.18 ng/ml yielding a specificity of 83.3% (95%CI: 70.7-92.1) and sensitivity of 42.3% (95%CI: 28.7-56.8), LR = 2.5. By univariate analysis, all three 14-3-3η cut-points were significantly associated with better clinical outcomes. Multi-variable modeling controlling for BL

HAQ-DI indicated that lower levels of 14-3-3η, age and disease duration, but not CRP, were independent predictors of achieving the HAQ-DI MCID outcomes.

	14-3-3η positivity cut-off					
	≤ 0.19 ng/ml		≤ 0.40 ng/ml		≤ 0.80 ng/ml	
	LR	p-value	LR	p-value	LR	p-value
ΔHAQ 0.22	>6.75	0.0098	2.36	0.0950	0.94	0.2222
ΔHAQ 0.31	>9.57	0.0021	6.18	0.0114	3.56	0.0456
ΔHAQ 0.49	>8.61	0.0034	6.61	0.0090	3.88	0.0382



Conclusion: Lower serum 14-3-3η levels prior to the initiation of therapy independently predicts better patient reported outcomes in patients treated with tocilizumab. The predictive capacity of 14-3-3η at informing therapy response to anti-IL-6 therapy should be investigated across all anti-IL-6 compounds.

Pharmacomicrobiomics of Methotrexate: Baseline Intestinal Microbiota Correlates with Therapeutic Response

Carles Ubeda[1], Shahla Abdollahi-Roodsaz[2], Steven B. Abramson[3] and **Jose U. Scher**[4], [1]Institute for Research in Public Health, Valencia, Spain, [2]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre,

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite significant advances in the therapeutics of inflammatory arthritides, methotrexate (MTX) remains the mainstay of treatment for rheumatoid arthritis (RA) and related conditions worldwide. However, it has a hihgly variable inter-individual bioavailabity (ranging from 20 to 80%) and there is currently no mechanism to predict efficacy. One of the fundamental roles of the intestinal microbiome is to metabolize xenobiotics and synthetic drugs. Here we characterize the effects of oral methotrexate on the gut community composition of patients with RA and the potential role of baseline human microbiota in predicting response to MTX therapy.

Methods: Demographic characteristics, drug use and disease activity scores-28 (DAS28) were recorded from new-onset rheumatoid arthritis (NORA) patients (n=33). For each participant, fecal samples were collected at baseline and at pre-established intervals for at least 3 months after initiation of oral methotrexate (range 3-48 months). 16S rDNA was extracted per protocol (MoBio, USA) and amplicons targeting the hypervariable V4 region were sequenced using 454 and MiSeq (Illumina) platforms to define the microbiota composition. The obtained 16S rRNA sequences were analyzed using the Quantitative Insights into Microbial Ecology (QIIME) pipeline. Taxonomic relative abundance at all hierarchical levels was determined to establish baseline microbiota composition prior to MTX initiation. Two-tailed Wilcoxon non-parametric test was applied to identify significant microbiota taxonomic changes that occur after MTX therapy. The False Discovery Rate (FDR) approach was applied to adjust for multiple hypothesis testing. Changes with a $P<0.05$ and $FDR<0.2$ were considered significant.Spearman correlations between baseline relative composition of intestinal microbiota and clinical response to MTX at each time point were also applied.

Results: To quantify microbiota similarities among fecal samples we used unweighted UniFrac and hierarchical clustering. Samples from MTX-treated patients clustered with their respective baseline samples, indicating that the gut microbiota is stable with inter-individual taxonomic differences maintained for at least 6 months. NORA patients receiving MTX developed minimal changes over time. Intriguingly, however, baseline microbiome signatures in these patients predicted clinical response to MTX at 3 and 6 months, including the overabundance of unclassified *Coriobacteriaceae* ($r=-0.756$; $P<0.01$) and a *Coprococcus*-related OTU ($r=-0.755$; $P=0.022$).

Conclusion: Although oral methotrexate does not induce significant changes in the over all structure of the human intestinal microbiota of NORA patients, the abundance of several taxa at baseline correlate with a significant improvement in clinical disease activity 3 and 6 months into therapy.

Whether specific intestinal commensals can modulate the pharmacokinetics and bioavailability of methotrexate (and other DMARDs), remains to be elucidated. Better understanding of MTX pharamcomicrobiomics will be necessary to achieve precision medicine strategies in RA and related conditions.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Provider adherence to a Treat to Target (TTT) strategy for management of rheumatoid arthritis (RA) requires setting a disease target, regular monitoring of disease activity, shared decision-making, and appropriate adjustment of therapy based on target and disease activity score. We conducted a quality improvement trial to test whether a Learning Collaborative would improve TTT implementation. This analysis examines documented reasons for non-adherence to TTT by providers in the intervention arm.

Methods: Medical record review conducted by trained study staff assessed TTT implementation

based on 4 components: designation of target (remission or low disease activity), disease activity measure (DAM), shared-decision making (when applicable to set target and/or change treatment), and change in treatment based on target and DAM. Within the Learning Collaborative, providers were encouraged to reports reasons for TTT non-adherence when treatment was not changed despite disease activity not achieving target. Provider non-adherence to TTT was defined as no treatment intensification when warranted by disease activity not at pre-determined target. Reasons for non-adherence were categorized as: patient-based preferences (i.e. financial barriers, fear of medication, and reluctance to change), drug side effects, elevated DAM unrelated to RA (i.e. pain from comorbid conditions or irreversible joint damage increases score), no active disease as deemed by provider examination, treatment contraindicated (i.e. pregnancy, renal disease, chemotherapy), medication time-lag (i.e. delayed treatment response), other, and no reason specified. Multiple reasons were possible for each visit. Patient DAM scores were classified based on CDAI or RAPID3.

Results: 81 visits with provider non-adherence to the TTT strategy were observed in 74 patients, distributed throughout the nine month study period. A total of 90 reasons for non-adherence were noted. Patient preference was the most frequently observed reason for provider non-adherence to TTT, cited in 30 (37.1%) visits (see Table 1). Of the 81 visits, 22 (27.2%) visits noted that the DAM was elevated but not due to RA, and 12 (14.8%) had an unspecified reason for non-adherence.

Conclusion: Patient preference was the leading documented reason for provider non-adherence to a TTT strategy in RA, highlighting the importance of patient involvement in the treatment decision-making process. Patients play a critical role within the TTT paradigm.

Table 1: Documented reasons for provider non-adherence to TTT among patients not at target*

Reason	Visits, n (%)†
Patient preference	30 (37.1)
Drug side effects	7 (8.6)
Elevated DAM unrelated to RA	22 (27.2)
No active disease on exam	10 (12.3)
Contraindicated	5 (6.2)
Medication time-lag	4 (4.9)
Unknown	12 (14.8)

*Based on patient disease activity measure (CDAI > 2.8 or weighted RAPID 3 > 1)
†Percent calculated out of total visits; does not equal 100 as multiple reasons possible per one visit

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Therapeutic goal of rheumatoid arthritis (RA) is to achieve disease remission. However, several remission criteria have not always equated to the complete absence of true inflammation. Power Doppler Ultrasonography (PDUS) has been demonstrated to detect subclinical synovitis. The aim of this study was to elucidate the achievement rates of imaging remission and examine characteristics associated with achievement status among RA patients in clinical remission.

Methods: This study was conducted in 90 RA patients who attained clinical remission, defined by DAS28-ESR remission criteria. PDUS was performed in 16 joints and 2 tendons, including both first to third metacarpophalangeal, second and third proximal interphalangeal, radiocarpal (RC), second and third metatarsophalangeal joints and extensor carpi ulnaris tendons and graded on the basis of a dichotomous assessment (presence/absence). The clinical and laboratory data of patients with imaging remission were compared with only clinical remission.

Results: Rate of imaging remission was 51.1% in patients with clinical remission. Forty four patients (48.9%) were PDUS positive. PD was detected most frequently in right RC joint (n=38, 42.4%). In addition, eleven patients have arthralgia on not evaluation joint, PDUS positivity was 91%. PDUS positive patients had higher evaluator global assessment score (p<0.001), and all clinical disease activity score. Rheumatoid factor was correlated with imaging remission with positivity and level. Overall, Patients could not reach imaging remission tend to more tender and swollen joint count, higher patient global assessment score, higher health assessment questionnaire (HAQ) score. They use more nonsteroidal anti-inflammatory drug (NSAID).

Conclusion: Only 51.1% of the patients with RA in clinical remission had PDUS defined imaging remission. Patients who were in imaging remission have lower disease activity, lower pain score

and less frequent use of NSAIDs, compared to patients with only clinical remission.

Table1. Clinical and Demographic Characteristics of Enrolled patients

	DAS28-ESR remission (n=90)
Age, year, mean (SD)	59.25 (±11.64)
Gender	
Male, n (%)	15 (16.7%)
Female, n (%)	75 (83.3%)
Tender joint count, mean (SD)	0.22 (±0.54)

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Guidelines recommend to treat newly diagnosed Early Rheumatoid Arthritis (ERA) with intensive treatment strategies using Methotrexate (MTX) or a combination of csDMARDs and a short course of glucocorticoids (GCs). However, patient characteristics predicting response to such treatments are unknown.

Methods: The Care in ERA (CareRA) trial compares remission induction regimens in a treat-to-target approach. DMARD naïve ERA patients were stratified into a high- or low-risk arm based on classical prognostic markers. High risk patients were randomized to COBRA Classic (MTX + Sulphasalazine + prednisone step-down from 60mg), COBRA Slim (MTX + prednisone step-down from 30mg) or COBRA Avant-Garde (MTX + Leflunomide + prednisone step-down from 30mg). Low risk patients were randomized to MTX tight step-up (MTX-TSU) without oral GCs, or COBRA Slim. Prednisone was tapered down over 6 weeks to 7.5mg in Classic and 5mg in the other COBRA arms. Oral GCs were stopped at week 34. Demographics were routinely registered. Treatment response was defined as achieving remission at Week52 (DAS28(CRP))<2.6). Firstly, differences in age, smoking status, alcohol status, BMI and gender between responders and non-responders were analyzed with χ^2 or Mann Whitney U tests where appropriate. Secondly, these patient characteristics were analyzed in a multivariate logistic regression model predicting response. Treatment strategy was put in the model to correct for any treatment differences. This analysis was intention-to-treat using all patients recruited at baseline and carrying last observation forward in case of missing data. A significance level of 0.05 was used.

Results: This analysis included 379 patients. Remission at Week52 was achieved in 62.3% of patients. The population reflected a typical Belgian ERA cohort aged 51.9 ±13.0 years with an average BMI of 26.4 ±4.2 kg/m², with 69.1% women, 25.6% current smokers and 56.2% drinking alcohol. No differences in gender, smoking status, alcohol status and age were found between responders and non-responders. BMI did however differ (p=0.036): individuals not responding to therapy had a higher BMI compared to responders (27.1 ±4.8 vs 26.0 ±3.8). Multivariate logistic regression confirmed these findings. Only BMI was statistically significantly related to treatment response (p=0.007, Odds Ratio (95%CI) = 0.934 (0.889-0.982)).

Conclusion: Intensive treatment strategies based on MTX or combinations of csDMARDs with short term glucocorticoids lead to high response rates. Chances of patients with a higher BMI to achieve remission after 1 year of treatment with these strategies are however lower. These results should be taken into account when choosing the initial treatment strategy in early RA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The goal of rheumatoid arthritis (RA) strategy is to reach remission or at least a low disease activity. When this goal is reached, no clear guideline exists to manage therapy. Recently, STRASS (Spacing TNF-blocker injections in RA Study) provided evidence of step-down therapeutic strategy with adalimumab or etanercept (1). So, we investigated if drug dosages and their antidrug antibodies (ADAb) could predict relapse during the 18 months of STRASS study.

Methods: We assessed 131 serum among the 137 included in STRASS study (60 and 71 for adalimumab and etanercept, respectively). Sera were collected at the time of randomisation. Adalimumab and etanercept blood concentrations and theirs ADAb were assessed by ELISA (Theradiag, Marne-La-Vallee, France). For this study, relapse was defined as DAS28>2.6 with DAS28 increase >0.6 since the previous study visit. Non parametric analysis was performed.

Results: Characteristics of the 131 patients similar to 137 from the initial STRASS study (data not shown). These RA patient characteristics are summarised in the Table 1 according to TNF blocker used. The median age was 54.5 [48.3-61.8] years. One hundred and two (77%) were female. The median disease duration was 6.5 [4.5-12.4] years. The median DAS28, ESR, and CRP were 2.0 [1.5-2.3], 10 [6-17]mm/hr, and 3 [2-4]mg/mL, respectively. Methotrexate was the main DMARDs

used (n=91; 70%). No baseline characteristics were associated with relapse during tapering or not. Adalimumab or etanercept serum concentrations were not different in case of relapse or not (Table2). Some ADAb against etanercept or adalimumab were detected, but their concentrations were under the positivity threshold. **Table 1. RA patients characteristics**

	Adalimumab (n=60)	Etanercept (n=71)	P values
Age, years	54.1 [44.7-60.3]	58.3 [52.0-62.8]	0.062
Female sex, n (%)	44 (73)	58 (82)	0.294
Disease duration, years	7.9 [4.4-12.7]	5.8 [4.6-9.4]	0.937
IgM RF positivity, n (%)	32 (61.5)	46 (74.2)	0.349
ACPA positivity, n (%)	37 (75.5)	52 (81.2)	0.285
DAS28	2.0 [1.6-2.3]	1.9 [1.4-2.2]	0.275
ESR, mm/1st hour	12.5 [6.7-18]	8.0 [5.0-16.0]	0.470
CRP, mg/mL	3 [2-4]	3 [1-4]	0.728
Monotherapy (%)	18	31	0.110
Time to relapse, (months)	9 [3-12]	6 [3-12]	0.273

Table 2. Adalimumab or etanercept serum concentrations at the time of randomisation according to relapse or not

	Adalimumab			Etanercept		
	Relapse	No relapse		Relapse	No relapse	P value
Number	43	17		35	36	
TNF blockers concentration (µg/ml)	6.90±2.32	6.97±2.42	0.91	4.23±1.39	4.18±1.45	0.89

Conclusion: No difference was observed in adalimumab or etanercept serum concentrations at the time of randomization to predict relapse in RA patients with low disease activity. Further investigations at various time points during the tapering could be useful.

DRUG RETENTION OF BIOLOGICS IN RHEUMATOID ARTHRITIS PATIENTS: THE ROLE OF BASELINE CHARACTERISTICS AND IMPACT OF TIME-VARYING FACTORS

<>D.S. Courvoisier[1], D. Alpizar-Rodriguez[1], JE. Gottenberg[2], F. Iannone[4], E. Lie[5], M.J. Santos[6], K. Pavelka[7], M.L. Hetland[8], C. Turesson[9], X. Mariette[10], D. Choquette[11], A. Finckh[1]. [1]University Hospitals Geneva, Switzerland; [2]Strasbourg University Hospital, France; [4]University Hospital, Bari, Italy; [5]Diakonhjemmet Hospital, Oslo, Norway; [6]Lisbon School of Medicine, Portugal; [7]University Hospital, Prague, Czech Republic; [8]Rigshospitalet, Glostrup, Denmark; [9]Skåne University Hospital, Malmö, Sweden; [10]Hôpitaux Universitaires Paris-Sud, France; [11]Institut de Rhumatologie de Quebec, Canada.

Background/Purpose: While the associations of baseline characteristics with drug effectiveness have often been studied in rheumatoid arthritis (RA), little is known about how the evolution of disease characteristics influences drug retention, a measure integrating both drug's effectiveness and tolerance. Aim: To examine the association of time-varying disease characteristics with drug retention of abatacept (ABA).

Methods: This is a pooled analysis of nine RA registries (ARTIS, ATTRA, RHEUMA DATA, DANBIO, GISEA, NOR-DMARD, ORA, SCQM, Reuma.pt). Inclusion criteria were a diagnosis of RA, initiation of ABA treatment and information on date of visit. Each time-varying variable was divided into baseline assessments and changes from baseline at subsequent visits. The baseline

values capture the inter-individual differences at drug initiation, while the changes over time inform on the intra-individual differences. We used time-varying Cox regression models to examine the association of baseline and time-varying characteristics with drug discontinuation, adjusting for age, sex, seropositivity, disease duration, number of previous conventional synthetic disease modifying antirheumatic drugs (csDMARD), and biologics (bDMARDs), presence of a comorbidity, calendar year of drug initiation, and stratifying by registry.

Results: 5440 patients initiated ABA, contributing 9715.4 patient-years, and 2920 stopped ABA during follow-up. Patients had a mean age of 57.8 years (SD: 13.1), mean RA duration at ABA initiation of 12.5 years (SD: 10.0), and most patients had failed several previous DMARDs (median csDMARD: 2, median bDMARDs: 1).

Median time to ABA discontinuation was 1.40 years. Seropositivity was associated with a lower chance of discontinuing ABA (Table). Previous failure of bDMARDs was associated with ABA discontinuation, whereas there was no such association for previous csDMARDs failure.

For most time-varying characteristics, the change over time (intraindividual evolution) was a stronger predictor of discontinuation than the baseline values (interindividual differences). Overall, ABA discontinuation was most strongly associated with a poor evolution of physician global assessment (HR: 1.62, 95% CI: 1.52-1.72). It was further independently associated with an inadequate progression of DAS28 and patient global assessments. In contrast, only the changes in physician global and patient global assessments were associated with discontinuing ABA for AEs.

Conclusion: The decision to discontinue ABA appears to be mostly influenced by the physician judgment and in particular its evolution over time. The evolution of the patient's appraisal and disease activity over time also play a role above and beyond the impact of the physician's assessment. Table: Multivariable Cox models of discontinuing ABA treatment due to any reason, to ineffectiveness and to adverse event.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of the study was to investigate long-term survival of low-dose etanercept (ETN) (25 mg weekly) and possible predictors of survival.

Methods: We collected retrospectively data of RA patients starting full-dose ETN (25 mg twice a week) between April 2001 and September 2014 who tapered ETN and maintained low-dose ETN for at least 12 months. Patients were evaluated every 3 months with a treat-to-target approach. Patients who achieved and maintained remission (DAS28 <2.6) for at least 6 months with full-dose ETN, tapered ETN. If remission was lost in two consecutive visits the patient returned to full-dose. We recorded the time to achieve remission with full-dose ETN (TTR). We considered two different cut-offs of TTR: <=6 months and <=12 months. We then evaluated survival of low-dose ETN treatment and possible predictors. Variables collected are reported in Table I. Survival was analysed with Cox-regression. Covariates included were those achieving a $p<0.20$ in univariate analysis. A separate Cox regression analysis was run with TTR<=6 months and TTR<=12 months.

Results: Among 532 patients, 276 were excluded because of missing data or because they were lost to follow-up leaving 256 patients eligible. After 11.28±4.05 years, 50/256 (19.5%) returned to full dose because of disease relapse, 55/256 (21.5%) stopped the treatment with ETN, and 151/256 (59.0%) maintained low-dose. TTR<=6 months and TTR<=12 months resulted significant predictors of low-dose survival (OR 1.93, 95% C.I. 1.31-2.85, $p=0.001$ and OR 3.11, 95% C.I. 2.06-4.68; $p<0.001$, respectively) together with a lower mean prednisone daily dose (Table II, Figure 1).

Conclusion: A shorter TTR and a lower mean prednisone daily dose are predictors of long-term survival of low-dose ETN. TTR<=6 months and TTR<=12 months are associated with a 2-fold and 3-fold increased probability of low-dose ETN survival respectively.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase (JAK) inhibitor approved in the USA in November 2012 for the treatment of rheumatoid arthritis (RA). As the first oral JAK inhibitor for RA, little is known about the real-world effects of tofacitinib. Our aim was to compare the effectiveness of traditional disease-modifying antirheumatic drugs (DMARDs), biologic DMARDs and tofacitinib for RA patients with inadequate response to methotrexate.

Methods: We performed a retrospective cohort study using MarketScan Databases from 2011-2014. We studied RA individuals, 18 years or older, previously treated with methotrexate (oral or SQ, at any time) and newly prescribed one of the medications under study (DMARDs, biologics or tofacitinib), between January 2011 and December 2013. The date of first filled prescription or infusion drug was defined as the cohort entry and individuals must have had no prior use of biologics or tofacitinib at any point before cohort entry. We required subjects to be continuously enrolled in the medical and pharmacy plan for 12 months before and 12 months after the cohort entry. A patient's therapy was defined as effective if none of the following occurred during the first year of follow-up: 1) non-adherence, defined as medication possession ratio (MPR) lower than 80% or the number of infusions lower than the minimum expected for each biologic. 2) Switching or adding a new biologic agent or tofacitinib. 3) Switching or adding a new DMARD. 4) Having at least one glucocorticoid joint injection between the months 4 and 12 of follow-up. We presented descriptive analysis of baseline characteristics and the proportion of patients achieving therapy effectiveness and the individual criteria by exposure groups.

Results: 16,962 RA patients were included; 3,033 began therapy with DMARD, 13,843 with biologics and 86 with tofacitinib. Among all patients, 77.4% were female and the mean age was 56.1 years (standard deviation 12.6). Table 1 shows the proportion of patients that failed the effectiveness criteria. Table 1. Proportion and 95% confidence interval (CI) of patients who achieved therapy effectiveness and the individual criteria.

Effectiveness criteria	DMARD		Biologics		Tofacitinib	
	%	95% CI	%	95% CI	%	95% CI
Effective therapy (none of the criteria)	16.6	15.2;17.9	18.1	17.4; 18.7	19.8	11.3;28.2
Non-adherence	74.7	73.2; 76.3	54.4	53.5; 55.2	67.4	57.5; 77.3
Switch/add biologic agent or tofacitinib	15.7	14.4; 17.0	34.7	33.9; 35.4	18.6	10.4; 26.8
Switch/add DMARD	12.8	11.6; 14.0	16.5	15.8; 17.1	15.1	7.5; 22.7
Glucocorticoid joint injection	20.4	19.0; 21.9	27.5	26.7; 28.2	25.6	16.4; 34.8

Conclusion: Similar rates of therapy effectiveness were observed among groups, although the rates for the individual criteria differed. The number of RA patients starting therapy with tofacitinib was relatively low and most of them were non-adherent. Fewer patients using biologic agents were non-adherent compared to DMARD and tofacitinib therapy, while more patients using biologic agents switched to or added a new biologic agent or tofacitinib. The results suggest that tofacitinib are not usually prescribed as a therapy option after inadequate response to methotrexate. At least through the end of 2014, patients initiating tofacitinib before biologics appear quite dissimilar to initiators of first time biologics. Given this pattern of use, further analysis should focus on the comparative effectiveness and safety of tofacitinib and biologic drugs as second and third therapy options for RA

patients.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In 2004 we initiated a cohort of rheumatoid arthritis (RA) patients with recent-onset disease. From 2008 onwards, both construct of compliance, persistence on therapy (P) and adherence with therapy (A) were prospectively assessed through a questionnaire (the CQ) that additionally investigated motivations for non-P, and a visual analogue scale for C (C-VAS). We hypothesized that how a patient subjectively attributed a motivation (patient-dependent vs. patient independent) impacted his/her evaluation of C. **Objectives** were to examine the correlation between compliance assessed as per the CQ and per the VAS, and to investigate if the selection of patient-independent motivation for non-P predicted better score of C.

Methods: Up to January 2016, the cohort comprised 180 patients with variable follow-up. Since 2008, CQ and C-VAS were concomitantly applied at regular six-months apart-intervals. The CQ is a 22-items questionnaire, where item 11 investigates 15 predefined patient´s motivations for non-P

and one open answer; a patient is considered CQ-compliant if A and P. The C-VAS is a 100 mm VAS, where 0 indicates “very good compliance”. Each motivation for non-P was classified as patient-dependent or patient-independent by 50 patients randomly selected and directly interviewed to such purpose (≥70% agreement among the patients interviewed). Multiple regression analysis was used to evaluate patient-independent motivation as a predictor of better compliance. The study was approved by the institution’s internal review board. Written informed consent was obtained.

Results: The final number of patients for which data were analyzed was 160. At inclusion in the cohort, patients were primarily middle-age female (90%), with 5.4±2.6 months of disease duration and high disease activity. The majority had RF (85.6%) and antibodies to cyclic citrullinated peptides (88.1%). To January 2016, the (mean±SD) length of follow-up was 6.7±3.4 years, during which patients completed 1516 pairs of CQ and C-VAS. The C-VAS significantly correlated with the CQ, r=0.468, p=0.001. Cut-off value of C-VAS to predict CQ-compliance was 7.5 mm. During follow-up, there 670 CQs scored as with non-P among whom, 654 had at least one motivation for non-P selected; of them, 549 CQs (70.2%) corresponded to non-P patients who selected only patient-independent motivations and 31 (4.7%) to those who selected only patient-dependent motivations. Patients from the former group had better C-VAS scores than their counterparts. The selection of exclusively independent motivations for non-P predicted C-VAS score and CQ score, ß: -0.15, 95%CI: -19.2 to -6.8, p≤0.001 and ß: 0.79, 95%CI: 0.01-0.819, p=0.045, respectively. Also, the selection of exclusively independent motivations for non-P predicted VAS-compliance (OR: 15.6, 95%CI: 5.4-45.3, p≤0.001) and CQ-compliance (OR: 2.25, 95%CI: 1.062-4.664, p=0.034).

Conclusion: Patient´s motivations for non-P impact how they perceived and scored their compliance; a potential consequence of such behavior is that non-compliant patients may be misidentified.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

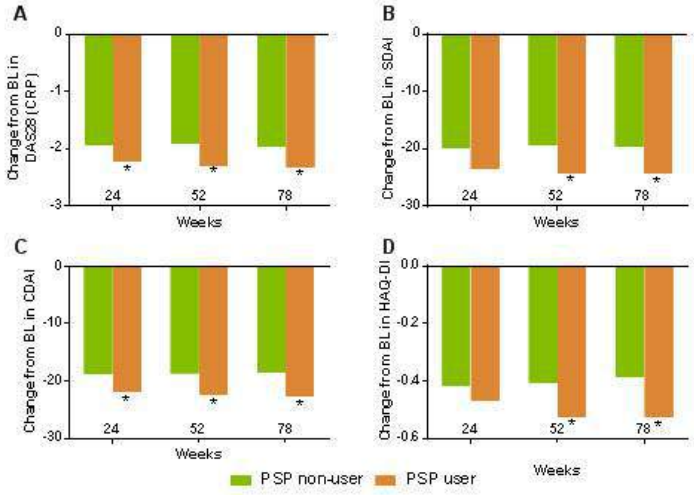
Background/Purpose: Patients (pt) with Rheumatoid arthritis (RA) who are treated with adalimumab (ADA) are offered a Patient Support Program (PSP) with variety of services. To date, no prospective study has been conducted to analyze the acceptance and the impact of these PSPs on treatment effectiveness and pt satisfaction. The purpose of this study was to examine the effectiveness of ADA on rheumatoid arthritis (RA) treatment course in the context of PSP participation.

Methods: PASSION (NCT01383421) was a 78-week (wk) post-marketing observational study of pts with RA receiving ADA in routine clinical care. Pts from the EU, Israel, Mexico, Puerto Rico, and Australia with an insufficient response to ≥1 disease-modifying antirheumatic drug (DMARD) newly initiating ADA (1 prior biologic DMARD was allowed) were enrolled. The primary endpoint was the % of pts achieving the minimal clinically important difference (MCID; improvement of ≥0.22) in the Health Assessment Questionnaire Disability Index (HAQ-DI) at wk 78 vs baseline (BL). Non-responder imputation (NRI) was used to account for the missing values. Secondary clinical parameters included % of pts achieving MCID in HAQ-DI at wks 24 and 52 vs BL and changes in the 28-joint DAS based on CRP (DAS28(CRP)), Simplified Disease Activity Index (SDAI), and Clinical Disease Activity Index (CDAI) at wks 24, 52, and 78 vs BL. Pts were categorized based on their participation in the PSP: ever (PSP users) vs never (PSP non-users) and outcomes were compared after adjusting for corresponding BL values.

Results: 1,025 pts were included in the Intent-to-treat population (BL: mean age, 54.3 years (y); % female, 77.1%; mean RA duration, 7.8 y; mean HAQ-DI, 1.5; mean DAS28(CRP), 5.3; mean SDAI, 35.6; mean CDAI, 33.3; 17.8% pts had received prior biologic DMARD. Overall, 48.7% pts were PSP users. Approximately 72.9 % (as observed) and 42.8% (NRI) of PSP-users surpassed the MCID in HAQ-DI at wk 78. The percentage of pts achieving MCID in the HAQ-DI was higher in PSP users vs PSP non-users (48.1% vs 37.8%, NRI) at wk 78 (P<0.001). Significant changes (P≤0.05) from BL to wk 78 were observed for pts using the PSP vs PSP non-users in HAQ-DI (0.53 vs 0.39), DAS28(CRP) (−2.33 vs −1.97), SDAI (−24.5 vs −19.8), and CDAI (−22.66 vs −18.55) scores **(Figure)**. Study discontinuation rates were significantly (P<0.001) lower among PSP-users vs PSP non- users (25.5% vs 41.6%). Reasons for discontinuations are listed in the **Table**.

Conclusion: The final study results showed that, in pts with moderate to severe RA who initiated ADA, significantly better improvement in functional and clinical outcomes was achieved in the PSP users vs the PSP non-users. Improvements were achieved at early timepoints and continued to increase throughout the study.

Figure: Changes from baseline in DAS28 (CRP) (A), SDAI (B), CDAI (C), and HAQ-DI (D) over time between PSP users and PSP non-users.



*significantly different between PSP users and PSP non-users ($P<0.05$). Data represented by LOCF imputation for intent-to-treat population. Results are adjusted for BL DAS28(CRP), SDAI, CDAI, and HAQ-DI. LOCF=Last Observation Carried Forward.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adherence to disease-modifying antirheumatic drugs (DMARDs) in patients with rheumatoid arthritis (RA) is varied; rates range from 30% to 80%.[1] Adherence to methotrexate (MTX), the most commonly prescribed DMARD in patients with RA, has been incompletely studied; available data come from third-party rather than patient-level sources. We aimed to describe self-reported MTX adherence among an online community of patients with RA and to explore the patient characteristics associated with MTX nonadherence.

Methods: US-based adult patients self-reporting RA were recruited from an online health-sharing network, PatientsLikeMe. Patients were invited to fill out a cross-sectional Web-based survey if they reported an RA diagnosis and current or past (within 6 months) treatment with MTX. Eligible patients were grouped by treatment regimen into 4 MTX groups (MTX alone, MTX with biologic DMARD[s] [bDMARD], MTX with nonbiologic DMARD[s] [nbDMARD], MTX with both bDMARD[s] and nbDMARD[s]), and they completed the 4-item Morisky Medication Adherence Scale (MMAS-4). MTX adherence was classified as high, moderate, or low based on MMAS-4 scoring criteria. Descriptive statistics were used to describe the sample, bivariable statistics were used to test for associations between MTX use and adherence, and multivariable logistic regression modeling with a backward selection procedure was used to identify factors predictive of moderate or low adherence.

Results: Of 745 patients who viewed the invitation, 232 eligible patients participated in the survey, for an online response rate of 31%. Participants were demographically similar to nonparticipants but were slightly older (54.7 vs. 50.5 years; $p<0.0001$). Most survey completers (n=210) were female (90%), white (93%), and, on average, 55 years of age. Thirty-four percent (n=60) took MTX with bDMARD, 28% (n=49) took MTX alone, 25% (n=44) took MTX with nbDMARD, and 13% (n=23) took MTX with both bDMARD and nbDMARD. There was a significant relationship between MTX medication group and nonadherence; of patients taking MTX with bDMARD, 58% were highly adherent compared with 92%, 75%, and 87% in the other MTX medication groups, respectively (overall χ^2 $p=0.0003$). In the final model adjusted for demographics, years since RA diagnosis, duration of MTX treatment, and mode of administration, MTX with bDMARD use was most strongly predictive of lower levels of MTX adherence; the MTX with bDMARD group had 4 times the odds of moderate/low adherence (OR, 4.1; 95% CI, 1.9-8.6; $p=0.0002$) compared to those taking MTX alone.

Conclusion: In this study, there was a strong relationship between MTX with bDMARD use and lower levels of self-reported adherence to MTX. Future research should explore how adherence is related to disease activity and should test whether these findings are replicated in other patient samples. Health care providers should be aware of this potential association and should appropriately counsel patients to optimize RA medication adherence. **Reference:** 1. van den Bemt BJ et al. *Expert Rev Clin Immunol*.2012;8:337-351.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients frequently report concomitant

comorbidities that could worsen their prognosis. Tumor necrosis factor inhibitors (TNFi), the most common biological agents used, have shown efficacy in RA patients, although use in RA patients with certain comorbidities warrant caution (1). Abatacept, a biologic agent with a different mechanism of action, inhibiting the co-stimulation of the T-lymphocyte, has demonstrated differentiated safety profile (2), that could influence the biological agent prescribed in RA patients with some associated comorbidities. Our objective is to analyze differences in the frequency of baseline comorbidities in RA patients treated with abatacept compared with those treated with TNFi

Methods: Patients with RA recruited into the BIOBADASER 2.0 register from January 2008 to December 2014 and treated with abatacept or TNFi with comorbidities were selected. Comorbidity was defined as ≥ 1 of the following at initiation of biological therapy: Ischemic heart disease; lymphoma; malignancy (except lymphoma); diabetes; chronic pulmonary obstructive disease (CPOD); smoking; hypercholesterolemia; hypertension; heart failure; renal failure; osteoporosis; Epstein Barr, hepatitis B or C virus infection; and others. We analyzed the frequency of each comorbiditiy and the differences in the rate of baseline comorbidities between the two groups

Results: From January 2008 to December 2014, 640 and 252 RA patients treated respectively with TNFi or abatacept, were included in the BIOBADASER 2.0 register, of whom 51.6% had ≥ 1 comorbitity at baseline. Frequencies for every basal comorbidity described ere shown in Table 1. There was a significantly higher rate of heart failure in abatacept than in TNFi patients. Other comorbidities showed no significant differences **Table 1**

	Frequency (%)		
Comorbidities	Abatacept	TNFi	p-value
Ischemic heart disease	1(2.3)	14(2.1)	0.940
Malignancy (except lymphoma)	1(2.3)	13(1.9)	0.883
Diabetes	6(13.6)	46(6.9)	0.098
CPOD	2(4.6)	16(2.4)	0.382
Smoking	8(18.2)	109(16.4)	0.757
Hypercholesterolemia	9(20.4)	111(16.7)	0.519
Hypertension	10(22.7)	148(22.3)	0.942
Epstein Barr infection	0(0)	1(0.1)	0.797
Heart failure	**4(9.1)**	**6(0.9)**	**<0.001**
Renal failure	0(0)	8(1.2)	0.464
Lymphoma	0(0)	0(0)	
Osteoporosis	7(15.9)	89(13.4)	0.635
Hepatitis B virus infection	1(2.3)	13(1.9)	0.883
Hepatitis C virus infection	0(0)	1(0.1)	0.797
Others	22(50)	292(43.9)	0.431

Conclusion: RA patients treated with abatacept had a higher baseline frequency of concomitant heart failure compared with patients treated with TNFi, probably reflecting different recommendations on biological drug use. No differences in other baseline comorbidities were found

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Radiographs of hands and feet represent an objective outcome measure of rheumatoid arthritis (RA). Joint damage is a result of cumulative disease activity over years. Unlike other clinical measures, radiographic damage is caused mainly by disease inflammatory activity. Therefore, radiographs provide a proper measure to analyze outcomes of RA over a long term. Our purpose was to analyze radiographic remission of patients with early RA at ten years after diagnosis in a real life setting.

Methods: All 1046 patients who were diagnosed with RA in 1997–2005 at a single rheumatology center were scheduled for a ten year follow-up with radiographs of hands and feet at years 0, 2, 5, and 10. Larsen score (0 -100) was employed including MCPs, wrists and 2-5 MTP joints. Radiographic remission was defined as no new erosions and no worsening of erosions between the baseline (at diagnosis), and ten years. Proportion of patients with radiographic remission/no remission ten years after diagnosis was compared in patients with a new diagnosis of RA in 1997-99, 2000-02, and 2003-05.

Results: Among 1046 patients (66% women, mean age 58, 60% seropositive, 13% with erosions at baseline), 743 patients (70% women, mean age 54, 65% seropositive, 12% with erosions at baseline) were seen at their 10-year follow-up visit. Among 480 seropositive patients, the median (IQR) progression of Larsen score was 3(0, 8) and in 263 seronegative patients 0(0, 2). Radiographic remission was met at the 10-year follow up visit by 31%, 40%, and 56% of seropositive patients who had the diagnosis in 1997-99, 2000-02, and 2003-05 (Figure 1); $p<0.001$. In seronegative patients, the figures were 75%, 79%, and 83%, respectively. Over ten years, anti-rheumatic medications included MTX in 79%, 84%, and 90% of the patients diagnosed in 1997-99, 2000-02, and 2003-05, subcutaneous MTX in 13%, 24%, and 25%, SSZ in 82%, 83%, and 72%, HCQ in 61%, 73%, and 76%, LEF in 13%, 16%, and 14%, im gold in 19%, 11% and 5%, Pred in 63%, 80%, and 82%, and biologic agents in 10%, 16%, and 19% of the patients, respectively. Mortality (a total of 15% of women and 30% of men died over 10 years) was the main reason for missing data.

Conclusion: Proportion of patients who meet radiographic remission at ten years after diagnosis of early RA is increasing over the recent years. A majority of patients with seropositive RA who were seen at the 10-year control in 2013-15 met radiographic remission (Figure 1). Over the observation period, the use of MTX, sc MTX, HCQ, Pred and biologics increased, and the use of SSZ and im gold declined. **Figure 1**. Proportion of patients with radiographic remission/no remission, ten years after diagnosis of early seropositive RA.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Several factors influence pharmacokinetics of TNFinhibitors (TNFi). One relevant factor is the formation of anti drug- antibodies (ADA) associated with low drug levels and a worse clinical response. Recent publications in rheumatoid arthritis (RA) (1,2) have demonstrated a beneficial effect of concomitant use of anti-TNF drugs and methotrexate (MTX), with a dose-dependent effect[¥]. To analyze the MTX influence on the presence of drug and appearance of ADA in a cohort of RA patients treated with Infliximab (Ifx), Adalimumab (Ada) or Etanercept (Etn) with a long follow-up (3 years).

Methods: This is an observational study that analyzed patients with RA treated with Ifx (112 patients), Ada (71 patients) and Etn (110 patients), in a prospective observational biological cohort from the University Hospital La Paz, Madrid, Spain. Patients were grouped according to the use of MTX: no MTX, low dose (≤12.5 mg / week), intermediate dose (15-17.5 mg / week) and high dose (≥20 mg / week). Levels of drug and ADA were measured by capture and bridging. ELISA respectively at baseline, 0.5, 1, 2 and 3 years. All samples were obtained just before drug administration. Statistical analysis was performed using GraphPad Prism 5.0 software.

Results: Out of 293 RA patients with a TNFi treatment; 184 (71 with Ifx, 40 with Ada and 73 with Etn) were included. In this cohort, 111 (61%) were on MTX and 72 (39%) were on monotherapy. Most patients with high dose of MTX had levels of drug over 3 years of treatment (93% with MTX ≥20 mg/week vs 77% without MTX; p = 0.0003) being significant since 0.5years (60% with MTX ≥ 20 mg / week vs 39% without MTX; p = 0.003). To analyze the ADA development, patients treated with Ifx and Ada were grouped and we observed a low development of immunogenicity in the group which did not receive MTX (n = 37) compared to those who received high-dose MTX (n =27) close

to significance (32% vs 19%, p = 0.05). Analysing by separate drugs MTX significantly reduced the immunogenicity of Ada, (53% in patients with MTX vs 12% in monotherapy; p <0.0001).When we study the lack of circulating drug (Ifx, Ada and Etn) as an indicator of immunogenicity, patients who did not receive MTX (n = 56) had higher absence of drug than patients with high-dose MTX (n = 61) (34% vs 10%, respectively; p <0.0001) .This effect was significant since 0.5 years of treatment (16% MTX ≥ 20 mg / week vs 3% without MTX; p =0.001)

Conclusion: In our cohort of RA patients the concomitant use of MTX has a positive effect in the persistence of TNFi levels together with a decrease of immunogenicity. Furthermore, the MTX has a dose-dependent effect being greater at high dose of MTX.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In early rheumatoid arthritis (RA), first assessment by a rheumatologist and/or initiation of disease-modifying anti-rheumatic drugs (DMARD) within 12 weeks of symptom

onset are associated with a significant benefit in long-term disease outcome. Our objective was to determine the proportion of patients with newly diagnosed RA in whom first rheumatology assessment and/or initiation of DMARD therapy was within the desired time frame.

Methods: A retrospective chart review of adult patients diagnosed with RA during years 2014 and 2015 was performed at the rheumatology department of an integrated secondary/tertiary teaching hospital that provides rheumatology services for a population of more than 500.000 residents. Potential cases were identified by searching the electronic medical records for ICD-10 codes M05.* and M06.* Electronic and paper records of patients were then thoroughly reviewed. In addition to demographic and clinical data, dates were recorded for onset of inflammatory joint symptoms, referral to rheumatologist, initial assessment by a rheumatologist and initiation of DMARD therapy. The percentage of patients assessed by a rheumatologist and/or treated with a DMARD within 12 weeks of symptom onset and the median times for delay were then calculated.

Results: Between January 1st 2014 and December 31st2015, 243 new cases of RA were identified at our Department of Rheumatology. Of those, 197 (81.1%) were referred to our early interventional clinic. Within 12 weeks of symptom onset, 111 (45.7%) new RA patients were examined by a rheumatologist and 87 (35.8%) were started on DMARD therapy; the median time from symptom onset to consultation was 13.0 (IQR 4.6–27.8) weeks, median time from referral to consultation was 1 (IQR 1–3) days and median DMARD treatment delay was 15.7 (IQR 8.7–31.9) weeks.

Conclusion: 46% of new RA patients were assessed by a rheumatologist and 36% were treated with a DMARD within the recommended time frame of 12 weeks. Most of the treatment delay was due to the time elapsed between symptom onset and referral to a rheumatologist. These results substantiate the efficacy of our early interventional clinic in diagnosing and treating patients with early RA: despite the heavily protracted nationwide waiting times for first rheumatologist assessment and significantly (40%) lower number of rheumatologists per capita compared to European Union average, the percentage of timely treated patients was comparable to recent reports.

Table: **Demographic data, clinical history, and delays**	
Gender (female/male) (%)	183/60 (75/25)
Age, years (median)	64.2 (IQR, 52.1–75.9)
Patients fulfilling 2010 ACR/EULAR classification criteria for RA, No. (%)	228 (93.8)
DAS28 3v (mean ± SD)	5.3 ± 1.3
Erosive disease (plain radiographs) at first rheumatologist assessment, No. (%)	67 (31.5)
Time from symptom onset to first rheumatologist assessment, weeks (median)	13.0 (IQR, 4.6–27.8)
Time from referral to first rheumatologist assessment, weeks (median)	0.14 (IQR, 0.14-0.43)
Time from symptom onset to glucocorticoid initiation, weeks (median)	13.1 (IQR, 5.6–26.9)
Time from symptom onset to DMARD initiation, weeks (median)	15.7 (IQR, 8.7–31.9)

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic disease-modifying anti-rheumatic drugs (bDMARDs) that target cytokines and cytokine receptors such as tumor necrosis factor (TNF)-alpha and interleukin (IL)-6 have been established as a standard therapy of rheumatoid arthritis (RA) for patients with conventional systemic DMARDs, such as methotrexate (MTX), resistant disease. Currently, TCZ is included as one of the first-line bDMARDs in the latest ACR guideline and European League against Rheumatism (EULAR) recommendations. However, it is unclear whether the effectiveness of TCZ is depended on previous administration of biologics. Therefore, we focused on the retention rate taking into account of both efficacy and safety under the daily setting care, and this study aimed to investigate optimal treatment strategy with TCZ as a first-line bDMARD treatment in comparison with second-line treatment for RA patients.

Methods: All RA patients who treated with TCZ in Osaka City Universityfs RA registry (including 1070 patients with RA and 353 patients using bDMARDs) were included in this analysis. These

patients were divided into two groups that TCZ was used as a first-line bDMARDs (1st group) and a second-line or more treatment (2nd group). Retention rates and clinical efficacy assessed by disease activity score in 28 joints (DAS28; on the basis of the erythrocyte sedimentation rate, ESR) and clinical disease activity index (CDAI) from week 0 to week 52 were assessed. Retention rates of TCZ were evaluated using Kaplan–Meier analysis. Furthermore, the discontinuation ratio of glucocorticoid was also evaluated.

Results: Sixty-two patients in 1st group and 75 patients in 2nd group were analyzed in this study. Retention ratio at week 52 was 82.3% in 1st group and 64.0% in 2nd group (p=0.01). Of 11 discontinued patients in 1st group, only 2 patients were withdrawal due to inadequate response. From the initiation of TCZ use, efficacy of 1st group patients were faster than that of 2nd group patients. DAS28 remission rates were 23.5, 47.0, 49.1, 41.2 and 35.3% in 1st group and 8.3, 22.9, 29.2, 33.3 and 37.5% in 2nd group at week 4, 12, 24, 36 and 52, respectively. Also, CDAI remission rates were 15.7, 13.7, 15.7, 25.5 and 13.7% in 1st group and 0, 6.3, 10.4, 14.6 and 10.4% in 2nd group at week 4, 12, 24, 36 and 52, respectively. During 52 weeks, the dose of glucocorticoid was reduced in 18 patients and withdrawal in 12 patients between 22 patients of 1st group using glucocorticoid at week 0. In 2nd group, the dose of glucocorticoid was reduced in 14 patients and withdrawal in 5 patients between 20 patients of using glucocorticoid at week 0.

Conclusion: High retention rates and clinical efficacy of TCZ as a first-line biologic treatment was found in this research. More than half of glucocorticoid user were able to withdraw glucocorticoid during 52 weeks. This result as 1st line use of TCZ supports for current treatment guidance of the latest ACR guideline and EULAR 2016 recommendations.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: With the availability of multiple biologic agents, each with different modes of action, use of real world registries provide the manner in which to examine comparative effectiveness in the absence of head-to-head clinical trials inform physicians how they might be used for the treatment of rheumatoid arthritis

Methods: Arthritis Registry Monitoring Database (ARMD) has been collecting prospective patient data since 2005 in all patients seen in routine care. Each patient in this setting (with any diagnosis) completes a 2-sided, 1-page MDHAQ (multidimensional health assessment questionnaire) at every visit while waiting to see the physician in the infrastructure of clinical care. The MDHAQ includes scales for physical function, pain, patient global estimate (PATGL), fatigue, and a self-report RADAI painful joint count. Usage of the biologic medication abatacept as well as its route of administration along with self-reported disease activity and clinic measures were abstracted. Time to first response defined as an improvement in RAPID3 of at least 3.6 was calculated; change from abatacept initiation to first response for self-reported disease activity and clinic measures was estimated by administration route. For those individuals with no response, time to last follow-up was calculated.

Results: 2168 encounters were reviewed for this analysis. 198 subjects were abstracted with an average of 10.9 followup encounters. The average age of the cohort was 53.0 years (±15.0), average duration 10.9 years (±9.0), 177 (89%) were female, and average baseline RAPID3 was 14.5 (±5.8). 154 subjects were given abatacept intravenously (IV), while 44 were administered abatacept subcutaneously (SC). PATGL was slightly higher in the SC group compared to IV, but the overall RAPID3 was not different; no other differences between demographics or baseline clinical features were observed (**Table**). However, the SC group had significantly less followup encounters compared to IV (SC 2.5±1.7 versus IV 13.3±13.8, poisson regression P<0.001). Despite the followup disparity, the average time for abatacept subjects to achieve clinical response was approximately six months regardless of administration route (SC 5.8±5.05 versus IV 6.0±7.0).

Conclusion: Our data suggest that there are no major differences in efficacy of the different administration routes of abatacept in time to response when treating RA patients. Further investigation into previous treatment history to determine refractory status and its impact on abatacept efficacy in warranted. **Table**. Demographic and Clinical Features at Abatacept Initiation as well as Followup Outcomes by Route of Administration

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The disease activity score in 28 joints (DAS28) and health assessment questionnaire (HAQ) serve as guides for the treatment of rheumatoid arthritis (RA). Smart System of Disease Management (SSDM) is a series of mobile phone applications for chronic diseases management, which includes interfaces of both physicians' and patients' applications. After entry the results of DAS28 and HAQ self-assessed by patients, all data can be synchronized automatically to the authorized rheumatologist' mobile terminals. We have confirmed in a validation study that Chinese RA patients can master the use of SSDM for accurate DAS28 self-assessments after training. The purpose of this study is to evaluate the susceptible joints and the recovery sequence of

swollen joint counts (SJCs) and tender joint counts (TJCs) based on DAS28 which self-assessed by Chinese RA patients with SSDM, and to describe the association between DAS28 and HAQ.

Methods: From August 2014 to May 2016, 5,756 RA patients did self-management and synchronized their data with the responsible physicians. The data were extracted online from the mobile terminals of 741 rheumatologists in 295 rheumatology centers across China. Patients were trained to self-assess DAS28 and HAQ with SSDM at baseline, and were asked to repeat the assessment once a month during the treatment. Descriptive statistics were performed for patient and disease characteristics. The mean of each variable was analyzed using t-test assuming.

Results: Among 5,756 RA patients, 4,299 (74.7%) women and 1,457 (25.3%) men. The mean age was 46.37 ±13.32 (18 to 99) years and the median disease duration was 2.58 (0 to 51.83) years. Total 8,533 times self-assessment of DAS28 and HAQ were performed. There were 37,501 joints tender and 22,029 joints swollen in the entire cohort. 807 RA patients did repeat self-assessment at least 28 days apart for 1,361 times. At baseline, 3,363 joints were swollen and 5,176 joints were tender. The top three swollen joints were right wrist (25.28%), right middle proximal interphalangeal (PIP) (25.15%) and left wrist (22.92%), and the top three tender joints were right wrist (43.25%), left wrist (42.63%) and right knee (40.40%). After treatment, the recovery rate of TJCs (25.54%) was significantly better than that of SJCs (21.80%), $p < 0.01$. Hand joints recovered more quickly than other joints. In the last assessment, the three worst recovery swollen joints were left shoulder (-15.50%), right shoulder (-1.79%) and right knee (0.00%). At baseline, HAQ score showed that the top two most difficult physical activities were “bending down to pick up clothing from the floor (reaching)” and “washing and dry entire body (hygiene)”. At the last assessment, the total HAQ score was significantly improved than the baseline in the entire group, $p < 0.01$. The top two difficult physical activities changed as “getting in and out of a car” and “reaching”, which match with joints swollen conditions.

Conclusion: In this study, most involved joints in tender and swelling are hand and wrist joints. After treatment, hand joints recovered quickly but shoulders and knees recovered slowlier, which matched with HAQ assessment results. The results will prompt future rehabilitation.

The Longitudinal Impact of Biologic Use on Disability within a RA Registry

N A Shadick[1], Nicole Gerlanc[2], M Frits[1], Bradley S. Stolshek[3], Brenna Brady[2], Christine Iannaccone[4], David Collier[5], Jing Cui[6], Alex Mutebi[7] and Michael Weinblatt[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Health Analytics, LLC, Columbia, MD, [3]Amgen, Thousand Oaks, CA, [4]Rheumatology, Immunology and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [5]Amgen Inc., Thousand Oaks, CA, [6]Rheumatology, Immunology, and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [7]Global Health Economics, Amgen, Thousand Oaks, CA

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologics have become the standard of care for treating moderate to severe rheumatoid arthritis (RA) in patients with an inadequate response to small molecule disease modifying antirheumatic drugs. Although biologics have been proven effective in managing RA symptoms and disease activity, their long term impact on disability remains unclear. Longitudinal data from a cohort of RA patients enrolled from a single academic medical center were used to examine the link between RA patient disability and biologic exposure.

Methods: Linear mixed repeated measures regression was used to model the impact of biologic exposure on changes in disease activity (DAS-28 CRP) and disability (modified Health Assessment Questionnaire [mHAQ]). At each follow up, biologic exposure was quantified as the ratio of a patient's time on a biologic relative to their time participating in the cohort. Patients' yearly biologic exposure, outcome scores, and associated covariates were incorporated over a maximum of 13 years into the longitudinal regression models to identify predictors of disease activity and disability at the population level.

Results: The analysis included 1,395 RA patients, 82.2% female, with a total of 6,783 unique physician visits from 2003 to 2015. Average disease duration at enrollment was 12.7 years. Longer biologic exposure was associated with a significant reduction in annual population means for both disease activity and disability ($p < 0.0001$, *Figure 1*). Patients' DAS-28 or mHAQ score at enrollment was the strongest predictor of disease activity and disability in models, respectively ($p < 0.0001$). While, shorter disease duration ($p < 0.0001$), not using a biologic at enrollment ($p < 0.0001$), and use of methotrexate ($p < 0.0003$) were significant predictors of reduced disease activity and disability in the models.

Conclusion: Longer biologic exposure is associated with reduced disease activity and disability in this longitudinal population of RA patients. Although biologic use improves the functional status of the population, patient RA status at enrollment remains the most significant predictor of disability. The results of the longitudinal models developed here suggest that use of biologics may help to

reduce long term disease activity and disability in the RA population.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at increased risk of falls and fractures. The present study aimed to prospectively determine the incidence of clinical fractures and associated predictors in patients with RA who participated in the TOMORROW study (UMIN000003876) that started in 2010.

Methods: We evaluated anthropometric parameters, bone mineral density (BMD), disease activity, RA medication, and the incidence of clinical fractures over a five-year period in 202 patients with RA (mean age, 58.6 y; medication with biological agents, 54.9%) and 202 age- and sex-matched healthy volunteers (controls; mean age, 57.4 y). We compared the incidence of clinical fractures between patients and controls between 2010 and 2015 and analyzed associated predictors in the patients using cox proportional hazard regression analysis.

Results: The incidence of clinical fractures did not significantly differ between patients with RA (0.042/person-years; py) and controls (0.034/py) within the five-year period ($p = 0.35$). And also, there were no difference in fractures sites between the two groups. Multivariable cox proportional hazard regression analysis adjusted for confounding factors including age, sex, smoking, and body mass index revealed that low BMD of the thoracic vertebrae (< 0.7 g/cm^2) at entry was significantly associated with the incidence of clinical fractures (hazard ratio [HR], 2.63; 95% confidence interval [CI], 1.49 to 4.66; $p = 0.001$) in all participants group (Table 1). Although medication with glucocorticoid (GC) at entry was also a significant risk factor for fractures (HR, 2.14; 95% CI, 1.24 to 3.68; $p = 0.006$), RA morbidity was not (HR, 1.22; 95% CI, 0.74 to 2.01; $p = 0.437$). Among patients with RA, low BMD of the thoracic vertebrae (< 0.7 g/cm^2) at entry was the most prominent risk factor for fractures (HR, 3.53; 95% CI, 1.52 to 8.15; $p = 0.003$). Additionally, medication with GC at entry (HR, 2.46; 95% CI, 1.28 to 4.73; $p = 0.007$) was a significant risk factor for fractures in the patients. A mean GC dosage of ≥ 2 mg/day during the five-year period increased risk for fractures in the patients (HR, 2.67; 95% CI, 1.06 to 6.72; $p = 0.037$).

Conclusion: There were no difference in the incidence of clinical fractures between patients with RA and controls during a period of five years. Low BMD of the thoracic vertebrae and low GC doses (≥ 2 mg/day) are apparently significantly associated with the incidence of clinical fractures among patients with RA.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at increased risk of falls and fractures. The present study prospectively investigates correlations between decreasing dosage of glucocorticoid (GC) and the incidence of clinical fractures in patients with RA based on the five-year findings of the TOMORROW study (UMIN000003876) that started in 2010.

Methods: We evaluated anthropometric parameters, bone mineral density, disease activity, RA medication, and the incidence of clinical fractures over a period of five years in 202 patients with RA (mean age, 58.6 years; mean disease duration, 14.0 years). We also assessed the effects of adjusting GC doses on the incidence of clinical fractures over the same period in patients with RA using cox proportional hazard regression analysis.

Results: The incidence of clinical fractures in patients with RA was 0.042/person-years (py). There were 84 RA patients (41.6%) treated with GC whose incidence rate and number of clinical fractures were significantly higher than those without GC treatment (27.4% vs. 11.9%; p = 0.008; 0.063 vs. 0.012 py; p = 0.012, respectively). After adjusting for confounding factors including age, sex, smoking, and body mass index, multivariable cox proportional hazard regression analysis revealed that GC administered within the five-year period was a significant risk factor for clinical fractures

(hazard ratio [HR], 2.35; 95% confidence interval [CI], 1.18 to 4.68; p = 0.015). An average of GC dose during the 5-year period of ≥ 2 mg/day increased risk for fractures in patients with RA (HR, 2.67; 95% CI, 1.06 to 6.72; p = 0.037). Although only reducing the GC dose did not decrease the risk of clinical fractures in patients with RA (HR, 0.75; 95% CI, 0.31 to 1.82; p = 0.521), risk was significantly decreased when the GC dose was reduced to zero within the five-year period (HR, 0.28; 95% CI, 0.11 to 0.72; p = 0.008).

Conclusion: Medication with GC was a significant risk factor for clinical fractures, and low GC doses (≥ 2 mg/day) are apparently significantly associated with an increased frequency of fractures among patients with RA. However, achieving freedom from GC among RA patients within five-years could decrease the risk for clinical fractures. We concluded that GC medication should be tapered to zero over a period of five years in patients after RA activity is controlled well.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is routinely used among rheumatoid arthritis (RA) patients treated with anti-TNF agents to enhance treatment efficacy and minimize the dose of biologic therapy. The aim of this analysis was to evaluate the risk of infections among patients treated with infliximab (IFX) or golimumab (GLM) in combination with MTX in the first 12 months following the start of biologic therapy.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment with infliximab or GLM for RA, ankylosing spondylitis, or psoriatic arthritis (PsA), or with ustekinumab for PsA. Eligible participants for this analysis included RA patients treated with IFX or GLM enrolled since 2002 and 2010, respectively, in combination or in monotherapy with MTX. Patients were excluded from the analysis if concomitant corticosteroids were used during any time point from baseline to 12 months of treatment. Serious and non-serious infections were assessed with the incidence density rate (IDR) as events /100 patient-years (PY). Poisson regression was used to compare the IDRs of infections between treatments while controlling for baseline disease activity and length of exposure to biologic treatment.

Results: A total of 526 RA patients were included in the analysis. At baseline, 71 (13.5%) were on anti-TNF monotherapy, while 109 (20.7%) were on combination therapy with MTX ≤15mg (low-moderate dose), and 346 (65.8%) with MTX>15mg (high dose). The vast majority (93.3%) of patients were bio-naïve, 73.4% were female, mean (SD) age was 55.7 (13.4) years and disease duration since diagnosis was 7.5 (8.3) years. A total of 163 (37.4 events/100 PY) infections were reported by 104 (19.8%) patients and a total of 10 (2.8 events/100 PY) serious infections. Specifically, the mean (95% CI) adjusted IDR was 23.9 (14.4-39.8) events/100 PY for monotherapy, 30.2 (21.4-42.7) events/100 PY for MTX low-moderate dose, and 30.5 (24.9-37.4) events/100 PY for MTX high dose. Furthermore, among patients treated with MTX, no association between use of other concomitant DMARDs in the treatment regimen and risk of infection was observed while adjusting for MTX dose with mean (95% CI) IDR of 33.6 (25.6-44.1) events/100 PY for DMARDs vs. 33.8 (25.2-45.3) events/100 PY for no DMARDs.

Conclusion: The results of this real-world observational study have shown that, overall, a low incidence of serious infections is observed with anti-TNF treatment. Concomitant use of anti-TNFs and MTX, with or without other DMARDs, is not associated with a higher incidence of total infections.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: After the diagnosis of rheumatoid arthritis (RA), glucocorticoids (GCs) are a common initial treatment in addition to methotrexate (MTX)(1). However, many patients are afraid to gain weight as side effect of the GCs. Therefore, we studied the effect of GCs on body mass index (BMI) after 4 and 12 weeks of treatment.

Methods: Consecutive patients from our early arthritis cohort, with a disease duration of <2 years, at least 2 swollen joints and no prior DMARD treatment were investigated. Patients were divided in two groups: GC-users were treated with MTX and GC (week 1: 30 mg, week 2: 20 mg, week 3: 15 mg, week 4-8: 10 mg, week 9-12: 7,5 mg), and non GC-users were treated with monotherapy MTX. Patients were placed in the GC-users group when they had a high disease activity and/or unfavourable prognostic factors. For this study the 22 non GC-users were matched on age to 22 GC-users. At baseline, week 4 and week 12, weight, height, BMI and a DAS44 were assessed. For statistical analyses, patients with an increase in BMI were compared with patients with a stable or decreased BMI.

Results: Of the 44 early RA patients, 24 were male; mean age was 54 years. Patients with versus without GCs had a mean weight at baseline of 74.2 and 82.3 kg, respectively (table 1). Both groups had a similar, large mean improvement in DAS. After 4 weeks of treatment, BMI increased in 41% of the GC-users versus 32% in de non GC-users, (p= 0.532). After 12 weeks, 55% of the GC-users had an increase in BMI versus 23% in the non GC-users, (p= 0.025, table 2). There is no statistically significant difference in DAS44 between the high and low risk group at baseline or after 12 weeks of treatment.

Conclusion: Early RA patients treated with MTX and GCs more often have an increase in BMI compared to patients treated with MTX monotherapy after 12 weeks of treatment. This difference is not caused by a difference in disease activity. These substantial differences appear to be caused by GC-induced changes in body composition and need to be further investigated during a longer follow-up period. Literature: 1) Boers M et al. Lancet 1997 Aug 2;350(9074):309-18.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Disease Activity Score (DAS) and the European League Against Rheumatism (EULAR) response criteria are commonly used to describe disease activity in Rheumatoid Arthritis (RA) patients(1). This study investigates the relationship between remission perceived by physicians versus patients according to the EULAR response criteria.

Methods: Consecutive RA patients with high disease activity and/or unfavourable prognostic factors and no prior treatment were investigated. Patients were treated with methotrexate and prednisolone (week 1: 30 mg, week 2: 20 mg, week 3: 15 mg, week 4-8: 10 mg, week 9-12: 7,5 mg). After 12 weeks of treatment the EULAR response was determined, according to the DAS44. Physician perceived remission was defined as a physician global assessment ≤ 20 on a visual analogue scale (VAS), phrased: *"How active do you think the rheumatoid arthritis of your patient is today?"*. For patient perceived remission the following question was phrased: *"Would you say that, at this moment, your disease activity is as good as gone? (yes/no)*(2).

Results: In 75 early RA patients the mean (SD) DAS44 decreased from 3.4 (1.2) to 1.5 (1.0) after 12 weeks of therapy. The number of good, moderate and none EULAR responders were 54 (72%), 14 (19%) and 7 (9%) respectively. After 12 weeks 72% of the physicians perceived remission as well as 72% of the patients, see figure 1. The spearman's rho test showed significant correlations between the EULAR response versus perception of physicians, the EULAR response versus the perception of patients and the perception of patients versus physicians, respectively $r=0.645$ ($p<0.001$), $r=0.393$ ($p=0.001$) and $r=0.267$ ($p=0.036$). In 61% of the good EULAR responders the physician as well as the patient perceived remission, but in 33% only the physician perceived remission, see figure 2. Patients who did not perceive remission had a significantly different mean (SD) DAS44 of 1.4 (0.5) compared to 0.9 (0.5) in the patients who perceived remission ($p=0.001$). The difference in DAS44 is caused by tender joint count (TJC) and patient global (PG) but not by swollen joint count or erythrocyte sedimentation rate.

Conclusion: There is a significant correlation between EULAR response and both physicians and patients perceived remission in early RA patients. However, 33% of the patients with a good EULAR response and physician perceived remission, perceive no remission themselves. These patients had a significantly higher DAS44, caused by a higher TJC and PG. Literature:

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic therapy for rheumatoid arthritis (RA) downregulates the immune response. Tumoral immunity is an important host mechanism against cancer progression, and for this reason, biologic therapy is often discontinued when a patient with RA develops cancer. Objectives: To determine the utilization of biologic therapy in patients with RA and cancer, after their cancer diagnosis.

Methods: We performed a retrospective cohort study of patients with RA and cancer seen at National Cancer Institute designated Comprehensive Cancer Center between 2002 and 2014. Patients were initially identified as having RA if they had a claim with a diagnostic code for RA (714) according to the International Classification of Diseases (ICD-9). Two independent reviewers examined all electronic medical records, and selected patients that fulfilled the following criteria in addition to a claim code: age ≥ 18 years, diagnosis of RA by a rheumatologist, and/or current or prior use of a DMARD or biologic agent. Patients with more than one primary or non-melanoma skin cancer were excluded. Descriptive statistics were generated to summarize patient characteristics, biologic use, and time to biologic therapy onset after cancer diagnosis. Kaplan-Meier methods were used to estimate time from biologic therapy onset to recurrence.

Results: 1719 patients met the inclusion criteria. Of these, 563 had received biologic therapy at any time, before and/or after cancer diagnosis. Most were female (72%), with a mean age at cancer

diagnosis of 59 years (±13 years). Eighty-one had a follow-up of less than 3 months after cancer diagnosis and were not included in the analysis; 43 had discontinued biologic therapy before the cancer diagnosis; 313 were receiving biologic therapy at the time of cancer diagnosis, and in this group 225 (72%) discontinued therapy within 3 months of diagnosis, and 88 (28%) continued treatment. In addition, 126 patients initiated biologic therapy after their cancer diagnosis with a median of 8 years (range 0.04-39). Overall, 214/1719 (12%) of the patients with RA received a biologic after their cancer diagnosis. The most common tumor site among the 214 patients was breast (28%) followed by lymphoma and prostate in 7% each, and melanoma in 6%. Biologic therapies included: tumor necrosis factor inhibitors (TNFi) (88%), rituximab (7%), abatacept (4%), and tocilizumab (1%). Almost 20% switched biologic therapy at a later stage. Fifty-seven (27%) patients who received biologic therapy had active cancer or developed a recurrence during follow-up, and 14 (7%) died. Recurrence/active cancer rate was 12% in first year after starting biologic therapy (or after diagnosis of cancer if biologic had been continued), 16% by 2 years, and 33% by 5 years.

Conclusion: Biologic therapy was used in 12% of patients with RA after their cancer diagnosis, most frequently TNFi. One third had active cancer or a recurrence during follow-up. Additional controlled studies are needed to determine if the risk of cancer recurrence is higher in patients with RA receiving biologic therapy after developing cancer.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids (GCs) are frequently and often chronically used for the treatment of rheumatoid arthritis (RA) and other immune diseases and vasculitis. An estimated 0.8–1.2% of the population in developed countries at any moment in time uses GCs. EULAR guidelines state that the adverse effects (AEs) of GC therapy should be considered and discussed with the patient before treatment is initiated.[1] However, reliable quantitative data on cutaneous AEs of low- to medium dose GC's are lacking.

Methods: We performed a study to assess the occurrence of cutaneous AEs of GCs and its association with current and cumulative GC-doses. This cross-sectional study was performed at the outpatient departments of the Charité University Medicine Berlin and the University Medical Center Utrecht; 381 RA-patients were included. Patients were classed into 4 groups, according their mean daily dose during the past 12 months: 0 mg (n=87), <5mg (n=108), 5–7.5 mg (n=130), and >7.5 mg (n=56) of prednisolone equivalent. Cushingoid appearance, ecchymosis, stretch marks, steroid acne, perioral dermatitis, hirsutism, and scalp hair loss were assessed by physical examination using a predefined scoring system, and by patients' self-assessments. Easy bruising, skin atrophy, and impaired wound healing were patients' self-assessed reports. Data were analyzed according GC dose categories and cumulative doses.

Results: Of the 381 patients, 76% was female; 67% was rheumatoid factor positive and 55% had erosive joint disease. The median (quartiles) disease duration was 9 (4-17) years. The mean number of lifetime conventional synthetic DMARDs used was 2.6 and for biological DMARDs it was 1.0. The median (quartiles) total duration of GC use was 4.0 (1.5-10) years, and the mean (sd) cumulative dose was 14 (17) g. Cushingoid habitus, easy bruising, skin atrophy, and impaired wound healing as reported by patients occurred significantly more frequent in those using GC the past 12 months, compared to those not using GC, see figure. At physicians' assessments, only Cushingoid habitus and ecchymosis were more prevalent in GC-users, see figure. The prevalence of these AEs was statistically significantly positively associated with current and cumulative GC dose. There was a low occurrence of abnormal stretch marks, acne, perioral dermatitis, alopecia, and hirsutism in our study, and there were no correlations between these AEs and GC therapy.

Conclusion: Cushingoid habitus, easy bruising, skin atrophy, impairment of wound healing, and ecchymosis are AEs of GC which can be observed relatively frequently in clinical daily practice. They are GC dose-dependent (current and cumulative dose). At the lower GC doses used in RA, abnormal stretch marks, acne, perioral dermatitis, alopecia, and hirsutism are rare AEs of GC.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent trial data from Mariette et al. investigating a single-dose 1g

rituximab regimen as opposed to a double-dose 1g rituximab regimen in patients with RA and a good or moderate EULAR response to an initial double-dose rituximab regimen, demonstrated non-inferiority in terms of a DAS-28 response [1]. There may be potential benefits of a lower dose rituximab regimen to patient safety and care, such as reducing the risk of hypogammaglobulinaemia and serious infection [2] and a reduced delay in repeat treatment time. There are also potential cost savings and health economic implications to a lower dose rituximab regimen. The aims of this audit were to assess whether our department was prescribing rituximab in accordance to National Institute of Clinical Excellence (NICE) guidance [3] and to evaluate the potential cost savings that could be made in a large cohort of patients receiving repeat rituximab treatment for RA.

Methods: Notes were reviewed from a random sample of 50 patients on our electronic biologic database receiving rituximab for RA at the Freeman Hospital, Newcastle-Upon-Tyne between 2013 and 2016. Data on prior biologic exposure, frequency of rituximab infusions and EULAR response to rituximab was recorded.

Results: The electronic database identified 210 patients who were receiving rituximab at least annually. Complete data was available from to audit from 44/50 of the random sample. 37/44 patients had received a prior anti-TNF therapy and 6 patients had documented reasons for not having received anti-TNF therapy (ie history of malignancy or interstitial lung disease). 1 patient had been started on rituximab pre-dating our electronic records. 36/40 (82%) patients had a good or moderate response to rituximab and in the other 8 patients, rituximab was either stopped or were under review pending a management decision. No-one had rituximab infusions more frequently than 6 monthly. This data was in keeping with NICE guidance [3]. In order to estimate the potential cost savings to our department by using a single-dose 1g rituximab regimen rather than a standard double-dose regimen, we calculated the mean number of treatments given to our cohort of patients with RA as 1.66 1g infusions per year. If this infusion number was halved to 0.83 1g infusions per year, the estimated annual saving to our department would be £435,000 (this is based on 210 patients receiving repeat rituximab infusions in 2015/2016 and the price per 1g rituximab infusion plus infusion costs of £2,495).

Conclusion: Current practice in the Freeman Hospital, Newcastle-Upon-Tyne is adherent to NICE guidance [3]. Using a single-dose repeat rituximab regimen rather than a double-dose repeat rituximab regimen has been demonstrated to have non-inferior clincial outcome data [1] and has potential long-term safety benefits to patients. In our trust, which prescribes a large amount of rituximab for RA, we could potentially save around £435,000 per annum by switching to a single-dose rituximab regimen.
