metaplasia, 343 (81.1%) patients were recorded with erosion, 246 (58.2%) were recorded with backfill, and 104 (24.6%) were recorded with backfill. There were no differences of the rates of four kinds of lesions appeared on the left or the right SIJ (all $p>0.05$). Erosion and backfill were more frequently seen in the upper half than in the lower half SIJ (both $p<0.05$). The ilium bones were with more often with erosion and fat metaplasia than the sacrum bones (both $p<0.05$). Interobserver reliability was good for fat metaplasia (ICC 0.70-0.75), also good for erosion (ICC 0.67-0.73), fair to good for backfill (ICC 0.56-0.66), and good to excellent for ankylosis (ICC 0.78-0.88).

Conclusion: The SPARCC MRI SSS method could detect structural changes in the SIJ with acceptable reliability in Chinese patients with axial SpA.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterised by progressive destruction of joint bone and loss of periarticularbone mineral. Hand bone loss (HBL) measured by Digital X-ray Radiogrammetry (DXR) has been proposed as a sensitive outcome measure for treatment effect and as a potential predictor of subsequent radiographic progression in RA patients. We aimed to investigate the effect of adding adalimumab to a methotrexate and intra-articular triamcinolone treat-to-target strategy on one-year hand bone loss ($HBL_{one\text{-}year}$) in early rheumatoid arthritis (RA) and to determine if $HBL_{6months}$ is associated with radiographic progression after two years.

Methods: In a clinical trial (OPERA) of 180 treatment-naive early RA patients (1), bone mineral density (BMD) was estimated from hand radiographs with Digital X-ray radiogrammetry (DXR) at baseline, after 6 months (n=90) and 12 months (n=70) of follow-up. Baseline and two-year radiographs were scored according to the Sharp/van der Heijde method. Baseline characteristics and $HBL_{6months}$ (0-6 months changes in DXR-BMD) were investigated as predictors of structural damage by univariate linear (DTotal Sharp/van der Heijde Score (TSS) as dependent variable) and logistic (+/-radiographic progression (DTSS>0) as dependent variable) regression analyses. Variables with $p<0.10$ were included in multivariable models.

Results: In 70 patients with available $HBL_{one\text{-}year}$ data, $HBL_{one\text{-}year}$ was median (InterQuartileRange(IQR)) -1.9 (-3.3;-0.26 mg/cm^2) in the placebo-group and -1.8 (-3.6;0.06) mg/cm^2 in the adalimumab-group, p=0.98,Mann Whitney (Figure 1). Increased HBL (compared to general population reference values (2)) was found in 26/37 and 23/33 patients in the placebo- and adalimumab-groups, Chi-sq=0.99. In 90 patients with $HBL_{6months}$ data and two-year radiographic data, $HBL_{6months}$ was independently associated with DTSS after two years (β=-0.086 (95% Confidence Interval=-0.15;-0.025) TSS unit/mg/cm^2 increase,p=0.006), and borderline associated with presence of

radiographic progression (DTSS>0) (OR 0.96(0.92-1.0), p=0.10).

Conclusion: In early RA, adding adalimumab to a methotrexate-based treat-to-target strategy had no impact on $HBL_{one\text{-}year}$, which was increased in both treatment groups. $HBL_{6months}$ was independently associated with DTSS after two years. **References:** 1) Hørslev-Petersen et al. *Ann Rheum Dis.* 2015 doi: 10.1136/annrheumdis-2015-208166. 2) Ørnbjerg LM et al. *Arthritis Research & Therapy*.2016,

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There has been increasing interest in hip morphology as a risk factor for OA. There is a need for frequency estimates in the general population (Dickenson OAC 2016). We aimed to provide a description of these measures in a well-characterized community-based cohort.

Methods: This cross-sectional analysis involved data collected during 1991-1997 from the Johnston County OA Project. Hip morphology measures were defined using OxMorf software (Oxford, UK). Radiographic hip OA (rHOA) was defined, at the participant level, if at least one hip had Kellgren-Lawrence grade 2 or more. Descriptive means and 95% confidence intervals for hip measures were obtained from unadjusted regression and logit models, as appropriate, using GEE to account for within-participant hip correlation, stratified by sex and rHOA status; comparisons were qualitative.

Results: Complete data were available for 4519 hips from 2263 individuals, mean age 64 years, mean BMI 29 kg/m^2, 30% African American, 39% male. Several measures although different by sex, did not differ substantially between those with and without rHOA (triangular index height, femoral shaft angle, extrusion index, coxa profunda). Results for those without rHOA are shown in Table 1. Only crossover sign (~20%) and lateral center edge angle (CEA) <=25 degrees (~25%) were more frequently seen in the non-rHOA compared with the rHOA group. Pathologic AP alpha angles over 60 degrees were seen in 20% of men and 7% of women, while only around 1% had a triangular index sign, both signs of cam-type morphology. About a quarter had CEA <=25 degrees, consistent with mild dysplasia. In contrast, several measures were higher in those with rHOA in at least one hip (Table 2), including AP alpha angle, Gosvig ratio, the proportion with triangular index sign, CEA >40 degrees, and protrusio acetabuli. AP alpha angle > 60 degrees was twice as common in those with rHOA (26% overall; 39% of men, 20% of women) versus those without, and 5% had a triangular index sign. Other measures suggestive of cam type deformity (continuous alpha angle and Gosvig ratio) were also higher compared to the non-rHOA group. CEA > 40 degrees was about twice as frequent among men and women with rHOA versus those without. Protrusio was twice as frequent among women with versus women without rHOA, but was rare in men.

Conclusion: One out of 5 men without rHOA, and 2 out of 5 with rHOA, have a pathologic AP alpha angle in this sample. Radiographic assessment of most measures is confounded by morphologic changes due to rHOA; however, some were not. Both cam-type (alpha angle, Gosvig ratio) and pincer-type (protrusio, CEA >40 degrees) were more common in those with rHOA.

Table 1. GEE estimates of means and frequencies (with corresponding 95% confidence intervals), stratified by sex among those WITHOUT rHOA at baseline (KLG 0 or 1, n=1599)

Morphologic measure	Overall (n=1599)	Men (n=661)	Women (n=938)
AP alpha angle, mean°	48.4 (47.9, 48.9)	51.4 (50.6, 52.2)	46.3 (45.7, 46.9)
AP alpha angle >60°, %	12.4% (11.1, 13.9%)	20.2% (17.8, 22.9%)	7.0% (5.7, 8.5%)
Gosvig ratio, mean mm	0.94 (0.93, 0.94)	0.97 (0.97, 0.97)	0.91 (0.91, 0.92)
Triangular index, mean mm	22.8 (22.6, 22.9)	25.7 (25.5, 25.9)	20.7 (20.6, 20.8)
Triangular index sign, %	1.0% (0.6, 1.5%)	2.0% (1.3, 3.1%)	0.2% (0.1, 0.7%)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Increasing body of evidence suggest that alarmins such as S100A8/A9 proteins play a critical role in Rheumatoid Arthritis pathogenesis (RA). We aimed to analyze the association between baseline S100A8/A9 protein plasma levels and radiological progression during the first 36 months of early RA.

Methods: Patients fulfilling the ACR/EULAR criteria in the early arthritis cohort ESPOIR were included in this study. S100A8/A9 (also known as calprotectin) levels were assessed in 813 patients of the early arthritis cohort ESPOIR at baseline. Total Sharp-van der Heijde score was assessed at baseline, year 1, 2 and 3. Univariate Cox regressions were used to evaluate the role of the risks factors to detect total Sharp-van der Heijde score progression ≥ 5 points /year. A multivariate risk model, comprising gender, age, baseline CRP, baseline ACPA, baseline smoking status, baseline DAS28, baseline S100A8/A9 level and treatment with biologic or synthetic DMARD , was constructed using a backward stepwise Cox model. A patient was considered under DMARD treatment when receiving methotrexate≥7.5mg/sem, sulfasalazine, leflunomide or any biological treatment at least 6 months before radiological assessment.

Results: A total of 614 patients were included and analyzed out of 813 patients of the cohort. Significant differences were found between patients with or without radiological progression, in the univariate Cox model : progressors were more likely to be ACPA positive, to be treated biologic or synthetic DMARD and to display high level of baseline CRP and S100A8/A9 proteins (**table**). In the multivariate analysis, S100A8/A9 level was the only predictor of the structural evolution over 3 years, independently of usual marker of inflammation (Hazard ratio 1.06, 95%CI [1.00-1.11], p=0,045). .

Conclusion: These results confirm that S100A8/A9 predicts radiological progression, in a large cohort of early rheumatoid arthritis. The correlation between this new biomarker and radiological progression was moderate but independent from other risk factors.

Table. Predictors of radiological progression with the first 3 years of early Rheumatoid arthritis

N=615	No radiological progression n=290	Radiological progression n=325	Hazard Ratio [95%IC]	P value
Gender, female	79.3% (230)	76.9% (250)	0.95 [0.73 ; 1.23]	0.702
Age, years	48.7 [38 ; 56.3]	52.4 [41.1 ; 58.4]	1.01 [0.99 ; 1.02]	0.082
Baseline CRP	7 [4 ; 18]	12 [5 ; 28]	1.003 [1 ; 1.01]	0.047
Baseline ACPA	29.1% (103)	53.7% (187)	1.94 [1.57 ; 2.39]	<0.001
Baseline DAS28	5.14 ± 1.23	5.25 ± 1.25	1.07 [0.98 ; 1.17]	0.148
Current smoking at baseline	48.3% (140)	46.8% (152)	1.04 [0.84 ; 1.29]	0.732
Baseline S100A8/A9	3.18 [1.83 ; 4.83]	3.85 [2.35 ; 5.31]	1.06 [1.01 ; 1.12]	0.027
DMARD treatment *	77.2% (224)	86.8% (282)	1.5 [1.09 ; 2.07]	0.013

Univariate analysis: Cox model, HR: hazard ratio [confidence interval 95%]. Percentage (Number); mean ± standard deviation or median [25th, 75th percentiles] were appropriate

* A patient was considered under DMARD treatment when receiving methotrexate≥7.5mg/sem, sulfasalazine, leflunomide or any biological treatment at least 6 months before radiological assessment.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have indicated that High Resolution peripheral CT (HR-pQCT) scanning is more sensitive than radiography in detecting cortical interruptions in destructive joint diseases like rheumatoid arthritis (RA)[1-3]. Cortical interruptions are also seen in healthy controls, but the exact nature of these interruptions is not known, and might represent vascular channels (VCs). No previous study has compared histology to HR-pQCT images in finger joints. We hypothesized that VCs seen on histology can also be detected by HR-pQCT imaging.

Methods: Based on HR-pQCT, 4 regions in 3 metacarpophalangeal (MCP) joints from female cadavers with an unknown medical history (mean age 84.7, SD 5.5 years) were selected. These regions were extracted, embedded undecalcified in methylmetacrylate and histologically sectioned (thickness 14µm) parallel to the axial plane. Every second section (n=478) was stained with Goldner Trichrome. VCs were identified as a cortical interruption in one histological section, which contained one or more vessels. Histological sections were matched visually to corresponding axial HR-pQCT images. Per match, it was described if a cortical interruption was observed on HR-pQCT and if this was a VC based on an interruption with a parallel structure present on 2 consecutive slices in 2 planes (axial, and/or sagittal/coronal).

Results: A total of 52 different VCs were identified on histology. All could be matched to a corresponding axial HR-pQCT image. Twenty histologically defined VCs would be defined as VC on HR-pQCT based on the parallel structure, although only 5 were present on 2 consecutive slices and 15 on less than 2 consecutive slices. Twenty-seven interruptions were observed on HR-pQCT, but did not fulfill the definition of a VC. In 5 cases no interruptions could be observed on HR-pQCT. Figure 1 demonstrates 3 examples of histology and matching HR-pQCT images.

Conclusion: VCs were frequently present in MCP joints. Only a minority of histologically defined VCs is interpreted as VC using a pre-specified definition on HR-pQCT images. Small histological VCs were often identified as an interruption but rarely considered a VC on HR-pQCT. Therefore, additional criteria in order to categorize a VC as such on HR-pQCT are warranted.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Concomitant presence of anti-cyclic citrullinated peptide antibodies (ACPA) and rheumatoid factor (RF) is associated with higher erosive disease burden in patients with established rheumatoid arthritis (RA). Even before the clinical onset of arthritis, ACPAs are associated with bone loss. Whether RF also influences bone damage in patients with RA is less well defined. In this study, we aim to determine whether there is an effect of ACPA and RF on the number and volume of bone erosions in early rheumatoid arthritis (ERA) patients.

Methods:

In this cross-sectional study, the second metacarpophalangeal joint (MCP2) in 96 patients with ERA (onset of disease within 2 years) were assessed using high-resolution peripheral quantitative CT (HR-pQCT). Data on demographic (age, sex) and disease-specific parameters including DAS 28, ESR, CRP, ACPA and RF levels were recorded. Erosions were visualized in 73 patients and the number and volume of the erosions were documented. Relationship between erosions, demographic and disease-specific data was evaluated by two multiple linear regression models.

Results:

Amongst the 96 ERA patients, 72.9% were female. The mean age was 53.1±13.8 years, disease duration was 8.0±5.6 months and DAS 28 was 5.0 ±0.9. Out of the 96 patients, 75 were both RF and ACPA positive (ACPA+/RF+), 5 were RF positive only (ACPA-/RF+), 9 were ACPA positive only (ACPA+/RF-) and 7 were double negative (ACPA-/RF-). Erosion volume was higher in the ACPA+/RF+ group compared with the non- ACPA+/RF+ (ACPA-/RF+ or ACPA+/RF- or ACPA-/RF-) group (3.99±3.16 mm^3 vs 2.50±1.24 mm^3, p=0.023). When all patients were subdivided according to RF and ACPA titer, erosion volume was significantly larger in the RF positive (>16 U) group than the RF negative (<16 U) group (4.28±3.42 mm^3 vs 2.66±1.34 mm^3, p=0.019). Similarly, erosion volume was also significantly larger in the ACPA>100U group compared to the ACPA<100U group (2.94±3.19 mm^3 vs 1.64±1.34 mm^3, p=0.010). Erosion volume was also increased in female patients (Beta=0.315, p=0.012). On the other hand, erosion number was associated with increasing age (Beta=0.359, p=0.000), ESR (Beta=0.320, p=0.001) and longer disease duration (Beta=0.251, p=0.014) in the univariate analysis. Using multiple linear regression model, independent explanatory variables associated with erosion volume included RF>16U (p=0.018) and female gender (p=0.011); while erosion number was associated with a longer disease duration (p=0.021), older age (p=0.000) and elevated ESR (p=0.007).

Conclusion:

In RA patients with recent onset of disease, the number of erosion appears to depend on disease activity, while the presence of RF may play a predominant role in the structural deterioration in terms of erosion volume. .

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In RA bone erosions are defined as cortical breaks with adjacent trabecular bone loss. High resolution peripheral quantitative CT (HR-pQCT) is more sensitive than conventional radiography in the detection of erosions in finger joints, but the scoring of erosions on acquired images was performed manually. We thus developed and validated a semi-automatic algorithm for HR-pQCT to detect cortical breaks and adjacent trabecular bone loss. The reproducibility of our algorithm on scan/re-scan (repositioning) data is presented in this study.

Methods: Twenty one subjects (mean (SD); age 49 (11) years) with 17 early RA (n=17, diagnosis <1 year) and undifferentiated arthritis (n=4) were studied. The 2nd and 3rd MCP joints were imaged by HR-pQCT (82µm nominal isotropic voxel size) twice on the same day with repositioning in between the scans. The semi-automatic algorithm was applied to the HR-pQCT images for the detection of cortical breaks. This included automatic detection of the outer contour of the bone, which was verified manually. A cortical mask of 0.33mm from this contour was selected and the remaining inner volume was considered trabecular bone. Cortical breaks with a diameter of >0.16mm, >0.33mm and >0.50mm and trabecular cavities >0.3mm in diameter were extracted, of which only those that were connected to a cortical break remained. Reproducibility for the number of breaks detected, break surface and erosion volumes was calculated per break diameter using intraclass correlation coefficient (ICC).

Results: The algorithm enabled detection of cortical breaks and adjacent trabecular bone loss (Fig. 1). The number of breaks, break surface and erosion volume per joint detected was dependent on the minimal break diameter (Table 1). Excellent reproducibility (ICC ≥0.82) was observed for all outcomes and all break diameters, with the exception of erosion volume for breaks >0.50mm (ICC=0.11). This is explained in figure 1 where an erosion was accurately detected on the 1st scan by all break diameters. However, on the 2nd scan the erosion was not detected for breaks >0.50mm. This subsequently leads to a high discrepancy in the erosion volume.

Conclusion: Our semi-automatic algorithm is highly reproducible in the detection of cortical breaks, break surface and erosion volume in repositioning data on HR-pQCT.The use of HR-pQCT in combination with our algorithm is therefore a promising tool for early detection and monitoring of erosions in finger joints.

Table 1. The mean number of cortical breaks, break surface and erosion volume per joint detected by the algorithm on the 1st and 2nd scan.

break diameter	Number of breaks				ICC	Break Surface (mm^2)				ICC	Erosion Volume (mm^3)				ICC
	1st scan		2nd scan			1st scan		2nd scan			1st scan		2nd scan		
>0.16mm	25.0	(18.5)	25.8	(20.3)	0.93	18.9	(18.4)	19.5	(18.7)	0.95	16.9	(19.5)	16.8	(20.6)	0.88
>0.33mm	3.0	(3.5)	3.2	(3.6)	0.82	4.0	(7.0)	4.4	(7.5)	0.92	4.6	(11.9)	4.4	(11.2)	0.88
>0.50mm	0.9	(1.8)	1.3	(1.9)	0.86	1.5	(3.5)	2.3	(4.5)	0.91	1.1	(3.2)	2.9	(10.5)	0.11

Values are displayed as: mean (SD)
SD = standard deviation
ICC = intraclass correlation coefficient

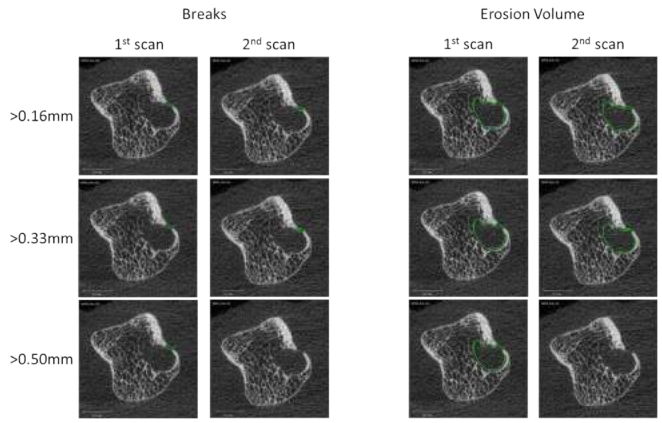

Figure 1. An example of an erosion in a 2D grayscale image. The cortical break and the adjacent trabecular bone loss of the erosion was accurately detected by the algorithm for all break diameters on the 1st scan. However, on the 2nd scan the break was not detected for breaks >0.50mm and therefore no adjacent trabecular bone loss was detected.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing Spondylitis (AS) is a chronic inflammatory disease characterized by new bone growth that leads to syndesmophytes formation. However, AS patients present low bone mineral density (BMD) or osteoporosis that can be associated to systemic inflammation and decreased mobility. Low bone mass diagnosis in AS patients is based on data using dual-energy X-ray absorptiometry (DXA), which may present confusion factor for the presence of syndesmophytes and difficulty in patient positioning on the DXA table.Other limitation of DXA is that it cannot distinguish between bone compartments.Thus, the objective of this study is evaluate bone microarchitecture, cortical and trabecular, at spine and peripheral sites analyzing bone parameters using other images technology in AS patients. Patients and

Methods: Seventy-nine male patients with AS were evaluated compared with age-matched male controls. Demographic, anthropometric, disease duration, disease activity Score (BASDAI) and medication using were recorded. None patient was using bisphosphonates. Bone mineral density (BMD) was evaluated by using dual-energy X-ray absorptiometry (DXA-Hologic). Trabecular bone score (TBS iNsight software) was analyzed from lumbar spine measurement for vertebrae L1–L4 exactly at the same ROI as spine BMD DXA. Trabecular and cortical parameters were measured by High-resolution peripheral quantitative computed tomography (HR-pQCT- Scanco) at distal tibia.

Results: Patients with AS had a mean 42.6 ± 8.9 yrs and a mean disease duration of 17.4 ± 9.7 yrs. Bone mineral density at lumbar spine in AS patients showed higher values compared with control group (1.104 ± 0.206 vs 1.041 ± 0.117g/cm^2, p = 0.023) and lower BMD at total hip (0.951 ± 0.015 vs. 1.003 ± 0.015 g/cm^2, p= 0.017). Differently, TBS analysis showed lower values of this score in patients than control group (1.317 ± 0.121 vs. 1.396 ± 0.070, p <0.001). AS patients had lower values than controls of trabecular parameters as Tb.N (1.82 ± 0.34 vs. 1.94 ± 0.32, p=0.03), Tb.Th (0.07 ± 0.01 vs 0.08 ± 0.01, p= 0.008); cortical parameter as Ct.Th (1.24 ± 0.32 vs 1.36 ± 0.27, p=0.024) and total vBMD parameters (293.2 ± 67.69 vs. 319.15 ± 55.07, p= 0.019) at distal tibia measured by HR-pQCT. The bone strength parameters such as stiffness and stress estimated by finite element analysis were lower in AS patients than controls (p<0.001). In AS patients, TBS correlated negatively with mSASSS (r=-0.325; p=0.003). Furthermore, TBS correlated positively with trabecular thickness (Tb.Th) at tibia (r=0.228; p=0.047).

Conclusion: The TBS and HR-pQCT imaging measurements seems to be a good technologies to analysis the bone microarchitecture parameters in AS patients allowing better interpretation and possible predicting the fracture risk in these patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) synovial tissue has been demonstrated to express high levels of fibroblast activation protein (FAP) using anti-FAP-antibody 28H1. In addition, RA patients show elevated levels of IL-22 and IL-22-producing T helper cells that correlate to erosive disease, suggesting a role for this cytokine in the pathogenesis of RA. The purpose of this study was to determine the feasibility of ^{111}In-28H1 SPECT/CT imaging of FAP-expressing synovium to monitor the therapeutic potential of neutralizing IL-22 during experimental arthritis.

Methods: Collagen-induced arthritis (CIA) was induced in male DBA/1J mice. Mice were treated 3 times per week with anti-IL-22 antibodies (8 mg/kg), while the control group received rat IgG1 isotype control antibodies. To monitor the therapeutic effect after 2 weeks of treatment, SPECT/CT images were acquired 24 h after injection of ^{111}In-labeled DTPA-conjugated anti-FAP antibody, 28H1. After image acquisition, mice were euthanized and dissected. Imaging results were compared with the macroscopic arthritis scores and radiographic bone damage scores acquired by X-ray.

Results: Blocking IL-22 during CIA was a potent approach to prevent arthritis development, reaching a disease incidence of only 50%, versus 100% in the control group. SPECT/CT imaging using indium-labeled anti-FAP antibodies showed that joint uptake of the tracer was significantly reduced ($p = 0.03$) in anti-IL-22-treated mice (4.3 %ID/g) compared to the isotype control group (8.0 %ID/g) (See figure). This was confirmed by the corresponding macroscopic arthritis scores and radiographic bone damage scores that were significantly ($p = 0.047$ and $p = 0.017$ respectively) lower in the anti-IL-22-treated group. Besides its sensitivity, the in vivo FAP-based SPECT/CT had the great advantage to visualize sites of inflammation that were overlooked during clinical scoring, like in knee, hip, elbow and shoulder (See figure).

Conclusion: These findings demonstrate that IL-22 plays an important role in the development of experimental arthritis, and targeting this cytokine seems an attractive new strategy in RA treatment. Most importantly, SPECT/CT imaging of the inflamed synovium using the labeled anti-FAP antibody ^{111}In-DTPA-28H1 can be used to specifically monitor response to therapy in an objective and quantitative way, and is potentially more sensitive in disease monitoring compared to the standard method of clinical arthritis scoring by macroscopic inspection.

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic sclerosis (SSc), a multi-organ fibrotic disease, affects the gastrointestinal tract (GIT) in 90% of patients. An urgent unmet need in the management of SSc GIT involvement is the availability of non-invasive investigations for early diagnosis and monitoring. Development of a new MRI sequence, T1 MOLLI (modified look-locker inversion recovery) mapping, has been applied to cardiac imaging, which enables detection and quantification of diffuse fibrosis without contrast. In this pilot study comparing SSc patients with healthy controls, we investigate FDG-PET/MRI in diagnosing SSc GIT involvement, hypothesizing that (i) MRI T1 MOLLI values, denoting fibrosis, is higher in SSc patients than healthy controls, and (ii) PET detects bowel inflammation associated with early mild GIT involvement.

Methods:

Ten patients fulfilling the 2013 ACR/EULAR criteria for SSc and 10 healthy age and sex matched controls underwent scanning. SSc patients either had early SSc <3 years and asymptomatic to mild GIT symptoms (Group A, n=5), or moderate to severe GIT symptoms regardless of disease duration (Group B, n=5), as determined by a validated questionnaire (Table 1). All subjects fasted 6 hours prior and had non-spicy low-residue diet 3 days prior. SSc patients underwent PET-MRI scan, 60 minutes after injection of 6mCi FDG tracer and immediately after injecting 10mg hyoscine butylbromide (reduce peristalsis). Breath-hold native T1 MOLLI mapping was acquired. Controls underwent the same MRI protocol. FDG uptake was quantified by specific uptake value (SUV). Student t-test and box plots were used to evaluate statistical significance ($p<0.05$).

Results:

Majority were females with a mean age of 48 years. Mean T1 values for the large and small bowels were higher in SSc patients than healthy controls (large bowel: 1206±148ms vs 869±192ms respectively, $p<0.001$; small bowel: 1425±245ms vs 1150±115ms respectively, $p=0.005$) (Table 1).

All SSc patients had high PET uptake in the bowel (on average 25% of their total bowel had SUV >1.5). PET SUV values in the large and small bowels were higher in Group A (mean GIT score 0.11) than Group B (mean GIT score 0.57) patients. In the large bowel, T1 values were higher in the regions of inflamed bowel, as defined by PET SUV >1.5 (Figure 1).

Conclusion:

Our preliminary results suggest the feasibility of using T1 MOLLI to evaluate bowel fibrosis. FDG-PET showed uptake in all SSc cases, with increased bowel inflammation occuring in patients with early mild disease. FDG-PET/MRI is potentially a useful diagnostic and monitoring tool for SSc GIT disease.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Bone formation is an important hallmark of ankylosing spondylitis (AS). Recently, we demonstrated that axial bone formation activity in AS patients can be visualized in vivo by [^{18}F]Fluoride PET-CT. [^{18}F]Fluoride PET-CT may therefore allow monitoring of changes of bone formation in AS during treatment. Therefore we investigated **1.** changes in bone formation activity in AS patients that start anti-TNF treatment using [^{18}F]Fluoride-PET-CT and **2.** Histology of PET identified lesions in spine (small feasibility sub-study).

Methods: We included 12 AS patients (female 7/12; age 39±11) with high disease activity (BASDAI 5.5±1.1). [^{18}F]fluoride PET-CT scans were performed at baseline and 12 weeks of anti-TNF treatment. Two patients only obtained a baseline scan to identify PET^{+} lesions in spine for a subsequent biopsy procedure to collect material of these lesions for immunohistochemistry (IHC). PET scans were assessed visually by two blinded readers. Clinical response was defined according to the ASAS20 at 12 weeks.

Results: Visualization of bone formation by [^{18}F]fluoride PET-CT in spine was supported by osteoid formation and osteoclasts along with cell infiltrate in conjunction areas of bone and connective tissue in PET^{+} lesions, while largely absent in PET- lesions (Figure 1A,B). At baseline, the other 10 patients showed at least one lesion of [^{18}F]Fluoride uptake in spine and/or SI joints. In spine, a total of 94 PET^{+} lesions were observed in 6 patients (range 2-32 p.p.), and ≥1 SI PET^{+} joint in 8/10 patients (Fig. 2). After 12 weeks of anti-TNF treatment, 7/10 patients received ASAS20 response. In spine, in 6/10pts with ≥1 PET^{+} lesion at baseline, the number of PET^{+} lesions decreased from 94 to 66 in 12 weeks. Decrease of spine^{+} lesions was noticed both in clinical responders and non-responders although the remaining number of spine^{+} lesions at 12 weeks tended to be higher in non-responders than in responders (16-21 vs. 1-13, respectively). SI^{+} joints remained visually positive at 12 weeks although at variable intensity.

Conclusion: In AS patients, [^{18}F]Fluoride PET-CT visualizes multiple lesions with bone formation in SI joints and spine. Histological evaluation of PET^{+} lesions supported *in-vivo* identification of bone formation activity by [^{18}F]Fluoride PET-CT. In this preliminary visual analysis of PET data, one third of [^{18}F]Fluoride PET-CT^{+} lesions in spine disappeared after 12 weeks of a-TNF treatment. The relationship between PET outcome and clinical response will be further investigated by quantitative analysis of PET^{+} lesions and clinical follow-up up to 24 weeks, which is currently in progress.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In order to visualize amyloid deposition in the specific organs, the patients with systemic amyloidosis underwent positron-emission tomography (PET) study with 11C-BF-227 that specifically binds to aggregated amyloid fibrils. A PET tracer, 11C-BF-227, was previously developed, and we had success with in vivo detection of amyloid plaques in Alzheimerfs disease brains and cardiac amyloidosis in familial transthyretin-related systemic amyloidosis (Kudo Y. et al. in J Nucl Med 8: 2007, and Furukawa K. et al. in

Circulation.125:2012, respectively).Here, we investigated additional patients with AA and AL amyloidosis, utilizing this strategy.

Methods: We obtained 6 patients who were diagnosed as amyloidosis with tissue biopsies. We got the informed consent from all study subjects. Patients were 2 female, 4 men (average age plus minus SD, 69 plus minus 5.7) , and they were 2 of Sjogrenfs syndrome, 2 of monoclonal gammopathy of undetermined significance (MGUS), 1 of Rheumatoid Arthritis, and 1 of etiology unknown. The types of amyloid are 3 of AA and 3 of AL amyloid. We also evaluated two healthy controls to compare the images. They were taken 11C-BF-227 PET imaging, then collected an anatomic Magnetic Resonance Image (MRI) sequence to identify the specific organ structures. We analyzed the data with PMOD and Dr. view software, merging the PET and MRI images from the same subject into the same three-dimensional space. The region-of-interest (ROI) was placed on individual MRI images in each organ. The ROI information was then copied onto dynamic PET standardized uptake value (SUV) images. The ratio of regional SUV to the intact lung SUV (SUVR) was also calculated.

Results: First, we confirmed the amyloid depositions by biopsies of the knee, lung nodules, skin, heart, kidney, and colon. We analyzed the PET images, and the subjects showed the accumulation of 11C-BF-227 in each organ. The representative PET and MRI image of the patient, having amyloid deposition by the knee biopsy, was shown the strong accumulation of 11C-BF-227as indicated in the Figure. His renal and cardiac functions were normal and did not have any amyloid deposition. Another patient having multiple nodules in the lung with amyloid deposition, indicated an increased SUV in those nodules in the PET image. The patients who had amyloid deposition in the kidney showed relatively higher SUVR in the kidney.

Conclusion: We clarified that our newly developed amyloid pet tracer, 11C-BF-227, can detect the amyloid deposition specifically, and 11C-BF-227-PET is a useful technology to detect the amyloid in the whole bodies, although the sensitivity might be different in each organ.

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We lack a method to quantify severity of inflammation in the pediatric sacroiliac joint. We evaluated the reliability and construct validity of the Spondyloarthritis Research Consortium of Canada (SPARCC) sacroiliac joint inflammation score (SIS) in children with suspected or confirmed juvenile spondyloarthritis (SpA).

Methods: The SIS divides the joint into quadrants and scores the presence, depth, and intensity of bone marrow edema (BME) on short tau inversion recovery (STIR) magnetic resonance imaging (MRI). Six consecutive semicoronal slices through the cartilaginous portion of the joint are scored for BME (total score 0-72). We developed a pediatric training module that included scoring instructions and examples of BME and bright subchondral signal on STIR scans easily confused with inflammation (Figure). After reviewing the module, 5 readers (1 adult and 3 pediatric radiologists, 1 adult rheumatologist), blinded to clinical details except age, scored 30 studies that included semicoronal T1-weighted and STIR sequences. Pain was recorded on a visual analogue scale (0-10). Disease activity was evaluated using the juvenile SpA disease activity (JSpADA) index (range 0-8). Inter-observer reliability was assessed using intraclass correlation coefficient (ICC). Correlation (convergent validity) of the mean SPARCC SIS developers' score with disease activity was tested using Spearman correlation. Discrimination was tested by comparing the mean SPARCC SIS developers' score between children with and without inflammatory back pain using the Mann-Whitney test.

Results: The SIS had face validity and was feasible to score in the 30 pediatric cases. 21 (70%) were male. Median age at the time of imaging was 15.5 years (IQR: 12.7-16.8). Median pain score and JSpADA index were 2 (IQR 0.5-6) and 2 (IQR: 0.5-3), respectively. Of the 150 scores submitted by 5 readers, 114 (76%) of the studies had a SIS >2. Median SIS was 13.5 (IQR: 2-28). ICC for all readers (N=5), SPARCC developers (N=2), and pediatric radiologists (N=3) were 0.69 (95% CI: 0.47-0.83), 0.89 (95% CI: 0.75-0.95), and 0.85 (95% CI: 0.72-0.92), respectively. SIS had low correlation with disease activity as measured by the JSpADA (r=-0.08) and C-reactive protein (r=0.14). SIS score did not discriminate between those with and without inflammatory back pain (p=0.16).

Conclusion: The SIS was feasible to score and had near excellent reliability, even with limited calibration. SIS did not have convergent validity with clinical measures of disease activity, highlighting that imaging and clinical evaluations provide complimentary but non-overlapping information. Responsiveness of the SIS should be evaluated in a prospective cohort of children who start biologic therapy.

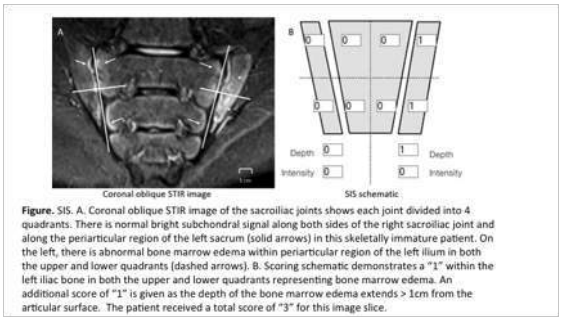

Figure. SIS. A. Coronal oblique STIR image of the sacroiliac joints shows each joint divided into 4 quadrants. There is normal bright subchondral signal along both sides of the right sacroiliac joint and along the periarticular region of the left sacrum (solid arrows) in this skeletally immature patient. On the left, there is abnormal bone marrow edema within periarticular region of the left ilium in both the upper and lower quadrants (dashed arrows). B. Scoring schematic demonstrates a "1" within the left iliac bone in both the upper and lower quadrants representing bone marrow edema. An additional score of "1" is given as the depth of the bone marrow edema extends > 1cm from the articular surface. The patient received a total score of "3" for this image slice.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: There is a critical need for measures to evaluate structural progression in the pediatric sacroiliac joint. We aimed to evaluate the precision and construct validity of the Spondyloarthritis Research Consortium of Canada (SPARCC) sacroiliac joint structural score (SSS) in children with suspected or confirmed juvenile spondyloarthritis.

Methods: The SSS assesses a spectrum of structural lesions of the sacroiliac joint on magnetic resonance imaging (MRI) including fat metaplasia, erosion, backfill, and ankylosis on 5 consecutive slices through the cartilaginous part of the joint. These components are scored 0-20 (backfill and ankylosis) or 0-40 (fat metaplasia, erosion). We developed a pediatric training module that included a detailed description of each SSS component plus sclerosis (0-40), scoring methodology, and numerous examples (Figure). After reviewing the module, 5 readers (1 adult and 3 pediatric radiologists, 1 adult rheumatologist), blinded to clinical details except age, scored 30 studies that included semicoronal T1-weighted sequences. Inter-observer reliability was assessed using intraclass correlation coefficient (ICC). We assessed correlation (construct validity) between the mean SPARCC SSS developers' scores and disease duration with Spearman correlation. Discrimination was tested by comparing the mean SPARCC SSS developers' scores between children with and without limited mobility (retained lumbar lordosis, modified Schober <20 cm, or both).

Results: The SSS had face validity and was feasible to score in the 30 pediatric cases with suspected or confirmed spondyloarthritis. 21 (70%) were male and median age was 15.5 years (IQR 12.7-16.8). Median symptom duration was 30 months (IQR 2.3-74.7). The ICCs for the SSS components are shown in the Table. Erosion, backfill, and ankylosis had good reliability (>0.40) while reliability for fat metaplasia and sclerosis were low. 27 (18%), 106 (70%), 44 (29%), 83 (55%), and 13 (9%) of studies had a score>0 for fat metaplasia, erosion, backfill, sclerosis, and ankylosis, respectively. Correlations of symptom duration with each component of the SSS were low (r range -0.13-0.26). SSS components did not discriminate between children with and without limited back mobility.

Conclusion: The SSS was feasible to score and had acceptable reliability for pediatric sacroiliac joint MRI evaluation. Low ICC for fat metaplasia may reflect low frequency of this feature in pediatric SpA or difficulty in assessment since hematopoietic marrow can appear patchy. Low ICC for fat metaplasia and sclerosis highlight the need for additional calibration.

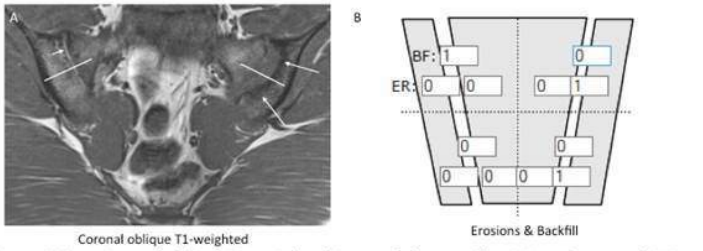

Figure. SSS. A. Coronal oblique T1-weighted image of the sacroiliac joints shows each joint divided into 4 quadrants. There is backfill along the superior aspect of the right sacroiliac joint, as demonstrated by abnormal bright T1 signal adjacent to the articular surface (short arrow). There are erosions within the upper and lower quadrants of the left iliac bone (long arrows). No sclerosis, ankylosis or fat metaplasia. B. Scoring schematic demonstrates a "1" for backfill (BF) within the upper aspect of the right sacroiliac joint and "1" within both the upper and lower quadrants of the left iliac bone representing erosions (ER).

	SSS Median (IQR), All readers	All Readers (N=5) ICC (95% CI)	Pediatric Radiologists (N=3) ICC (95% CI)	SPARCC developers (N=2) ICC (95% CI)
Fat metaplasia (0-40)	0 (0-0)	0.37 (0.21-0.56)	0.46 (0.25, 0.67)	0.89 (0.77-0.95)
Erosion (0-40)	4 (0-10)	0.47 (0.29-0.65)	0.39 (0.15, 0.61)	0.72 (0.48-0.86)
Backfill (0-20)	0 (0-1)	0.54 (0.38-0.71)	0.36 (0.14, 0.58)	0.82 (0.56-0.92)
Sclerosis (0-40)	1 (0-5)	0.39 (0.21-0.59)	0.42 (0.17, 0.65)	0.61 (0.08-0.83)
Ankylosis (0-20)	0 (0-0)	0.59 (0.43-0.74)	0.46 (0.24, 0.66)	0.72 (0.49-0.85)
Table. ICC for SSS components. ICC<0.40 is poor, 0.40≤ICC<0.75 is good and ICC≥0.75 is excellent.

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is not rare and clinically important disease. It is difficult to confirm the diagnosis because IgG4 positive lymphocyte infiltrates various organs. Especially, lymphadenopathy is a common manifestation in IgG4-RD. However, it is difficult for the rheumatologist to distinguish its lymphadenopathy from non IgG4-RD. Elevated serum IgG4 level did not decide diagnosis of IgG4-RD. In 2011, comprehensive diagnostic criteria for IgG4-RD were established by Umehara et al. [1]. This criteria required histopathological findings to diagnose IgG4-RD definite. Recent research has shown FDG-PET/CT is useful modality to select biopsy site [2].

Methods: We enrolled 29 cases which suspected IgG4-RD with lymphadenopathy in our facility between 2008 and 2016. Serum IgG4 level was analyzed all patients which were undertaken whole-body FDG-PET/CT study and biopsy. The diagnosis for IgG4-RD was based on comprehensive diagnostic criteria for IgG4-RD. Laboratory data were retrospectively collected from their medical records. We investigated levels of serum C-reactive protein (CRP) and serum albumin, eosinophil/leukocyte ratio, serum IgG and IgG4 levels, sIL2-R levels, the size and maximum standardized uptake value (SUVmax) and distribution of lymph nodes with abnormal FDG uptake on FDG-PET/CT and pathological findings. We investigate the utility of FDG-PET imaging and serological biomarkers for diagnosing lymphadenopathy of IgG4-RD.

Results: 29 patients were diagnosed into 3 groups (IgG4-RD definite: 12, IgG4-RD possible: 10, non IgG4-RD: 7). Non IgG4-RD group was included infectious disease, systemic lupus erythematosus, eosinophilic granulomatosis with polyangiitis, Sjogren's syndrome,

Castleman's disease, and malignant lymphoma. No significant differences among 3 groups in levels of CRP or sIL-2R were found. In IgG4-RD definite group, serum IgG4 levels and serum IgG4/IgG ratio were higher than other groups. Serum albumin levels were lower in non IgG4 group compared to others. Eosinophil/leukocyte ratio was higher in IgG4-RD definite group than in possible group. We examined about lymph nodes with abnormal FDG uptake. In IgG4-RD definite group, size of lymph nodes were smaller compared to other 2 groups. There is no difference among 3 groups in SUVmax or distribution of abnormal lymph nodes. Lymph node biopsy were performed in 5 patients with IgG4-RD. In 2 patients who diagnosed IgG4-RD definite, sIL-2R levels were higher and size of abnormal lymph nodes were smaller compared with those in 3 patients diagnosed IgG4-RD possible.

Conclusion: In this study, we examined patients which suspected IgG4-RD with lymphadenopathy. Patients with IgG4-RD definite tended to show higher serum IgG4 levels and smaller size of lymph nodes with abnormal FDG uptake on FDG-PET/CT. No significant differences were found among 3 groups in levels of serum CRP, sIL2-R, SUVmax or distribution of lymph nodes with abnormal FDG uptake.

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasound (US) has been demonstrated to be a very sensitive and objective tool for evaluating synovitis in children. However sometimes due to the age variability especially in the vascularization of the epiphysis and short bone cartilage, the distinction between physiological and pathological grey-scale (GS) and power Doppler (PD) findings can be difficult. The aim of the study was to test the intra- and inter-observer reliability of US detected age related vascularization and ossification grade in healthy children.

Methods: Following standardized image acquisition and machine setting protocol, 10 international ultrasound experts examined four joints (wrist, 2ndMCP, knee and ankle) in 12 healthy children (divided in four age groups: 2–4; 5–8; 9–12 and 13–16 years). GS and PD US were used to detect physiological vascularization and ossification grade. Ossification was graded as follow: grade 0 – non-ossified epiphyseal bone, short bones or patella; grade 1 - small ossification centers, dominant cartilage, visible growth plate; grade 2 - large ossification centers, thin cartilage, visible growth plate; grade 3 - completed ossification. PD was defined as any PD signal inside the joint. Kappa statistics were applied for intra- and inter-observer reliability.

Results: According to specific joint and age up to 4 solitary PD signals (mean 1.5/joint) were detected within the joint areas due to the

physiological vascularization localized predominantly in some specific anatomic positions: fat pad, epiphysis, the physis and the short bone cartilage. The kappa values for grading ossification were 0.87 (range 0.85-0.91) for intra-observer and 0.58 for inter-observer reliability respectively. Since the prevalence of the PD detected lesions was not uniformly distributed, we used the bias adjusted kappa, which was 0.71 (range 0.44-1) for intra-observer and 0.69 for inter-observer reliability.

Conclusion: Our study showed that the detection of normal findings (i.e. grading of physiological ossification in the skeletal maturation including physiological vessels) can be high reliable by using clear definitions and a standardized acquisition protocol. These data will permit to develop a reliable and standardized US approach for evaluating pediatric joint pathologies.

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: BehetÕs disease (BD) is a multisystemic disease characterized by recurrent inflammatory manifestations. BD is classified as variable vessel vasculitis. While inflammatory thrombotic venous findings are dominant in patients with vascular-BD, arterial lesions manifesting as aneurysms and occlusive/stenotic lesions can also be seen. In addition to clinical findings, imaging studies with CT, MRI, and Doppler ultrasonography play an important role in the diagnosis of vascular involvement. PET/CT is a relatively new tool being used in the assessment of large-vessel vasculitis, and there are conflicting reports about using PET/CT in patients with BD. We herein aimed to investigate our records for the role of PET-CT in the diagnosis and follow-up of BD patients with vascular involvement.

Methods: We retrospectively reviewed the charts of BD patients who were investigated with PET/CT for any reason related to disease activity. Patients fulfilling the ISG criteria or with a preliminary diagnosis of BD were included for the analysis. Using a standard form, clinical findings, acute phase response including ESR and CRP, and additional imaging findings, such as CT or MRI, performed within the last 2-week of PET/CT scanning were recorded. Vascular FDG uptake was graded using a 4-point semi-quantitative scale. PET/CT scans were considered positive if vascular FDG uptake was ³ 2 (equal to or greater than liver).

Results: We identified 12 patients investigated with PET/CT. The mean age of the patients was 44 years, the mean disease duration was 14 years, and 11 (92%) were male. Demographic and clinical findings are summarized in Table 1. Patients underwent PET-CT due to fever of unknown origin (n=6), fatigue with unexplained high acute phase response (n=3), abdominal pain (n=1), or unexplained neck pain (n=1). Five of them fulfilled the ISG criteria, and 4 had positive PET/CT findings due to aortic involvement or bronchiolitis obliterans organizing pneumonia (n=2). No FDG uptake was detected in one patient with venous lesions. In remaining 7 patients with incomplete manifestations suggesting BD, vascular involvement documented by FDG uptake in aorta and its branches (n=2), pulmonary arteries (n=2), carotid arteries

Table-1.Demographic and clinical findings of patients with Behcet Disease

N	Sex, age	Disease duration (y)	Clinical Finding					Clinical finding before PET	Positive PET-CT findings
			Mucocutaneous	Eye	Arthritis	Vascular	CNS		
1	M,38	4	ROA, GU, PPL, EN	-	-	DVT, right ventricular thrombus	-	Fatigue, High CRP and ESH	Normal
2	M,42	18	ROA, GU, PPL	-	-	Aortitis	-	FUO	Arcus and thoracic aorta involvement
3	M,27	17	ROA, GU, PPL	Uveitis	-	Pulmonary aneurysm and thrombosis	-	FUO	Bronchiolitis obliterans organizing pneumonia
4	M,47	14	ROA, GU, PPL	Uveitis	-	Pulmonary aneurysm	-	FUO	Bronchiolitis obliterans organizing pneumonia
5	M,46	23	ROA, GU, PPL, EN	Panuveitis	-	LAD aneurysm	ACA aneurysm	Fatigue and high ESH	Abdominal aorta involvement
6	M 38	26	ROA, PPL, EN	-	Oligoarthritis	CCA and ICA aneurysm		Neck pain	Carotid involvement
7	M,37	2	ROA	-	Oligoarthritis	DVT, pulmonary aneurysm	-	FUO	Pulmonary artery involvement
8	F,61	13	ROA	-	Oligoarthritis	Arcus aort and abdominal aneurysm	-	FUO	Arcus and abdominal aorta involvement
9	M,47	12	ROA, GU	-	-	-	-	Chest and back pain	Carotid and aortic (arcus, thoracic, abdominal) involvement
10	M,46	12	ROA, GU	-	-	Arcus aort, thoracic and abdominal aneurysm	-	High CRP and ESH	Normal
11	M,59	10	ROA, PPL	-	-	Pulmonary aneurysm	-	FUO	Pulmonary artery involvement
12	M,42	16	ROA, PPL	-	-	Coronary, femoral, and splenic artery aneurysm	Parenchymal infarct	Abdominal pain	Splenic artery involvement

ROA; recurrent oral aphthous ulcers, GU; genital ulcers, PPL, papulopustular skin lesions, DVT; Deep venous thrombosis,

(n=2) and splenic artery (n=1).

Conclusion: In BD patients with unexplained acute phase response, screening for vascular involvement is important, and PET/CT may contribute to diagnostic process by documenting medium-large size arterial activity. FDG uptake by arterial aneurysms and venous involvement in PET/CT is not clear, and several factors such as the size of the vessels and the thickness of vessel wall may affect FDG uptake. Parenchymal lesions possibly induced by small vessel vasculitis may also be another reason for positive PET/CT findings. Role of PET/CT in the diagnosis of patients with incomplete BD manifestations needs to be investigated further, since other disorders with mucocutaneous and vascular findings may mimic BD and cause diagnostic uncertainty.

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-Related Disease (IgG4-RD) is a multisystemic inflammatory disease characterized by fibrous swelling and IgG4+ plasma cells infiltration of affected organs.18-Fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) scan is emerging as a promising imaging technique for diagnosis and staging of IgG4-RD. We aim to correlate the intensity and distribution of FDG-PET uptake with clinical and immunological parameters in patients with active untreated IgG4-RD.

Methods: Patients with active, untreated, biopsy proven IgG4-RD were included in the study. Disease activity was assessed through clinical (IgG4-RD Responder Index (RI)) and immunological (erythrocyte sedimentation rate (ESR), C reactive protein (CRP), serum IgG4, and circulating plasmablasts) parameters. Plasmablasts, a recently characterized disease biomarker, were identified as CD19+CD20-CD27+CD38bright cells on flow cytometry. FDG-PET/CT was performed in all patients at diagnosis. Quantitative assessment of FDG uptake was measured using the mean Standardized Uptake Value corrected for the Partial Volume Effect (PVC-SUV) and with total lesion glycolysis (TLG). Lymph nodes < 1 cm of diameter were excluded from the analysis because of the risk of PVC-SUV over/under-estimation. In patients with multiorgan involvement, the IgG4-RD lesion with the highest PVC-SUV was selected to correlate FGD uptake with clinical and serological parameters.

Results: We studied 19 patients (12 males, 7 females) with a mean age of 61 years (range, 30-78 years). Eleven (58%) patients had

multiorgan IgG4-RD, with a average number of organ affected of 2.2 (range, 1-6). Involved organs were: lymphnodes (8 patients), aorta (6 patients), pancreas (4 patients); lung, parotids and submandibolar glands (3 cases each), paranasal sinuses, palate, orbits, bones and lachrymal glands (2 cases each); meninges, thyroid, subcutaneous nodule and spleen (one case each). The median IgG4-RD RI was 6 (range 6-15; normal < 3). The median levels of ESR, CRP, serum IgG4 and plasmablasts at baseline were 30 mm/h (range 4-121 mm/h, normal <20 mm/h), 9,9 mg/L (range 0.0-48.0 mg/L; normal <6mg/L), 455 mg/dL (range 80-2100 mg/dL, normal <135 mg/dL), and 5365 cells/mL (range 130-40840 cells/mL, normal <650 cells/mL), respectively. The mean PCV-SUV was 10.36 (range, 2.78-39.34) and the mean TLG was 429.24 (range, 91.37-3479.65). Significant positive correlation was found between PVC-SUV and circulating plasmablasts levels (r=.46, p=.004). No statistically significant correlation was found between either PVC-SUV or TLG and CRP, ESR, serum IgG4 levels, IgG4-RD RI at baseline (p>.05), and not even between TLG and circulating plasmablasts (p>.05).

Conclusion: We first demonstrated a positive correlation between circulating plasmablasts and inflammatory activity of IgG4-RD lesions as assessed by PVC-SUV on FDG-PET. Inflammatory markers, serum IgG4 levels, and IgG4-RD RI do not appear to correlate with metabolic activity in IgG4-RD lesions. Our results further strengthen the utility of circulating plasmablasts as a biomarker of IgG4-RD activity.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu arteritis (TA) is a large-vessel vasculitis predominantly affecting the aorta and its main branches. Assessing disease activity is difficult and mainly based on the clinical findings, levels of acute phase reactants and angiography, but these items generally do not correlate well. The aim of the this study was to investigate the role of PET/CT in the diagnosis of the disease and assessing disease activity in TA

Methods: Thirty TA patients fulfilling ACR criteria underwent FDG-PET/CT were retrospectively assessed. Disease activity was defined according to NIH criteria. A nuclear physician who was blinded to clinical and laboratory data examined all PET/CT scans. PET/CT scans were considered negative if vascular FDG uptake relative to liver was grade 0 or 1 and positive if vascular uptake was grade 2 or 3 in at least one vessel area. The levels of C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were measured concomitantly. The correlations between CRP and ESR with SUVmax values of vessels were investigated. CRP levels and ESRs were compared in subjects with or without positive PET/CT scans. Disease activity assessed by PET/CT was compared with the NIH criteria. ROC curve analyses were performed to assess the sensitivity and specificity of CRP and ESR according to PET/CT positivity.

Results: PET/CT was performed for diagnostic purposes early in the disease course in 9 subjects and to assess disease flare in 21 subjects on follow-up. The rate of a positive PET/CT examination tended to be higher in diagnostic/early use (88.9% positive) compared with use for flare-assessment (61.9% positive), although the difference was not significant (Fisher=0.2). Median CRP and ESR tended to be higher in PET/CT positive patients compared with PET/CT negative subjects (median CRP 19 vs. 14, p=0.16; mean ESR 59.8±36.5 vs. 35.2±19.7, p=0.07). ROC curve analysis showed an ESR of 38 mm/h or higher was 68.4% sensitivity and 66.7% specificity to predict a positive PET/CT examination (positive and negative predictive values 81.6% and 50%). A CRP of 14.5 mg/L or higher was 66.7% and 55.6% specific to predict a positive PET/CT examination (positive and negative predictive values 77.8% and 41.7%). While CRP was significantly correlated with mean SUV_{max} value of aorta (r=0.41, p=0.02), ESR was weakly correlated with SUV_{max} value of aorta

(r=0.3, p=0.13). There was moderate agreement between PET-CT and NIH criteria (kappa 0.462, p=0.01, sensivity 81%, spesificity 67%)

Conclusion: These results suggested that clinical benefit of PET/CT may be higher in diagnostic use (early in the disease course) compared with use for flare assessment (after treatment) in TA. There was a moderate association between NIH activity criteria and PET/CT activity. The predictive value of increased ESR and CRP was similar for a positive PET/CT scan with lower negative predictive values. CRP levels had a better correlation with SUVmax levels of aorta compared to ESR. PET/CT is a promising tool in the diagnosis and activity assessment of TA but discrepancies with other activity parameters do exist.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical imaging modalities in rheumatoid arthritis (RA) such as MRI and ultrasound can detect morphologic changes associated with synovial inflammation. ^{18}F-labeled fluorodeoxyglucose positron emission tomography (FDG-PET) can directly assess cellular metabolic activity and has been used to quantify joint inflammation in small studies. We developed a semi-automatic method to evaluate RA disease activity and assessed associations with measures of systemic inflammation.

Methods: Patients with RA underwent static FDG-PET 180 minutes after the intravenous administration of FDG tracer. Regions of interest were drawn around the hips, shoulders, knees, elbows, hands, and feet. An adaptive thresholding algorithm delineated and quantified regions of high tracer uptake in the regions of interest (Figure 1). Of the calculated values, the global partial volume corrected mean standardized uptake value considers all active sites proportional to their active volumes and was considered to best represent overall disease activity as an estimate of total body synovial metabolic activity. Correlations between synovial metabolic activity and systemic inflammation and clinical disease activity were assessed.

Results: A total of 18 patients (13 men) underwent FDG-PET. The average age was 57.7 (12.1) years with a mean DAS28(CRP) of 3.74 (1.29). The mean synovial metabolic activity score was 4.48 (1.78), with a range of 2.35-9.46 units. A significant correlation was observed between synovial metabolic activity and TNF-α, IL-6, and CRP (Figure 2). In contrast there was poor correlation with other measures of clinical disease such as swollen joints, tender joints, and results of the Health Assessment Questionnaire (Table). Among the 6 subjects with low clinical disease activity [DAS28(CRP) <3.2], there was a strong positive correlation between synovial metabolic activity and CRP (Rho=0.89, p=0.01) and IL-6 (Rho=0.89, p=0.02).

Conclusion: This study describes a novel semi-automated methodology to quantify synovial metabolic activity in RA using FDG-PET. This measure strongly correlates with measures of systemic inflammation, even among those with low disease activity. This methodology may have clinical and research utility in the evaluation of RA-specific systemic inflammation.

Figure: FDG-PET images of the whole-body of a patient with rheumatoid arthritis in the upper (a) and lower (b) extremities. The disease activity in these joints was assessed using ROVER software. The pvcSUVmean is presented next to each joint. The global pvcSUVmean was 5.8 for this individual.

Global pvcSUVmean = [∑ (joint pvcSUVmean × joint volume)]/(∑ joint volume)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Positron emission tomography (PET) can be used to identify inflammation using ^{18}F-fluorodeoxyglucose (^{18}F-FDG). ^{18}F-FDG uptake correlates with clinical and laboratory markers of disease activity in adults with rheumatoid arthritis and in one previous study of juvenile idiopathic arthritis (JIA). The purpose of this study was to test the feasibility of combining the metabolic data from ^{18}F-FDG PET with structural and functional data from MRI to assess disease activity in JIA.

Methods: Seven patients with polyarticular JIA according to ILAR criteria (6 RF-positive, 1 RF-negative) underwent ^{18}F-FDG PET/MRI of the whole body and a dedicated scan of 1 joint/region. Each patient had a complete joint exam on the day of the scan. Patients were scanned using a weight-based, low-dose (0.5 megabecquerel/kg) ^{18}F-FDG protocol to minimize radiation exposure, resulting in maximum effective dose less than 0.7 millisievert for patients weighing 55 kg or greater. Images were evaluated qualitatively, and joints were considered positive on PET if ^{18}F-FDG localization was increased above background.

Results: Mean age was 15.1±2.9 yrs and median disease duration was 7.5±2.4 yrs. For 4 out of 7 patients, PET showed more positive joints than physical exam (see table). For 1 patient, physical exam showed 2 positive joints but PET was negative. Joints that showed disagreement between physical exam and PET included hand/wrist, ankle/foot, knee, elbow, and shoulder (see Figure 1). Disagreement between physical exam and PET did not correlate with any clinical characteristics including ESR, BMI, or Juvenile Arthritis Disease Activity Score (JADAS). MRI allowed localization of PET signal, for example allowing diagnosis of tenosynovitis in one patient (see Figure 2).

Conclusion: We found disagreement between physical exam and PET in 5 out of 7 JIA patients. PET detected more joints with inflammation than physical exam, and notably this disagreement often occurred in joints that are easily accessible on physical exam.

Table. Clinical disease activity compared to PET findings

Subject	Clinical disease activity[a]	JADAS[b]	Active joint count by physical exam	PET positive joints
1	Inactive	3.1	0	0
2	Inactive	0	0	5
3	Inactive	4.0	0	0
4	Active	3.0	1	4
5	Active	9.0	2	0
6	Active	9.0	3	4
7	Active	10.0	3	8

[a] ACR provisional criteria for inactive disease in JIA
[b] Juvenile Arthritis Disease Activity Score: Low disease activity ≤ 2.5, Moderate 2.6 – 8.5, High > 8.5

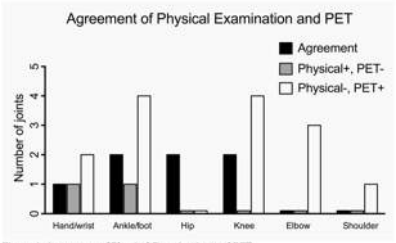

Figure 1: Agreement of Physical Examination and PET

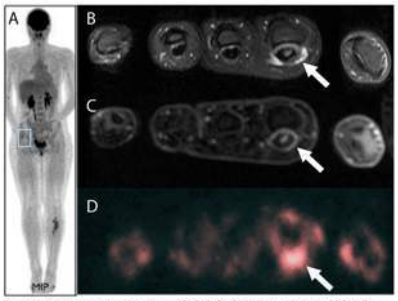

Figure 2: Maximum projection image of whole body PET in a 17-year-old female with JIA shows increased activity in the right hand (box in A). Axial images show tenosynovitis at the right index finger extensor tendon (arrows) on T2-weighted fat saturated MRI (A), T1-weighted fat saturated post-contrast MRI (B), and high resolution PET.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyositis/dermatomyositis (PM/DM) are systemic inflammatory disorders predominantly affecting skeletal muscles and skin respectively. Although muscle biopsy is the most important to the diagnosis of PM/DM, some cases may not have inflammatory lesion in biopsy site. There are some reports that enhanced magnetic resonance imaging (MRI) is useful for decision of biopsy site. However, enhanced MRI could not detect inflammatory lesion of whole body easily.The purpose of this study was to investigate the usefulness of volumetric parameters of the whole-body FDG PET/CT for evaluating disease activity in patients with PM/DM.

Methods: A total of 21 patients with previously untreated PM/DM were examined with whole-body FDG PET/CT. The same number of age- and sex-matched control patients with non-muscular diseases were also identified. The FDG uptake was visually evaluated in 22 regions of the whole-body. Regions with FDG uptake greater than that of the mediastinum blood vessels were considered positive. The semi-quantitative analysis was also performed using a maximum standardized uptake value (SUVmax), metabolic volume (MTV), and total lesion glycolysis (TLG). PET results were compared with those of serum levels of creatine kinase (CK) and aldolase.

Results: On visual analysis, the mean ± SD of number of positive regions in patients with PM/DM was 11 ± 7. The mean value of SUVmax in patients with PM/DM was significantly higher than that in control patients ($p<0.001$). There was a significant correlation between number of positive regions and TLG ($p<0.04$). There was a significant correlation between MTV and aldolase ($p<0.04$) and between TLG and CK ($p<0.009$) and aldolase ($p<0.006$). There was no significant correlation between number of positive regions and CK or aldolase and between SUVmax and CK or aldolase.

Conclusion: These preliminary results suggest that volumetric parameters such as MTV and TLG of whole-body FDG PET/CT may be useful for evaluating disease activity in patients with PM/DM.

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We aimed to assess increased SIJ uptakes on 18-FNa (an osteoblastic tracer) PET/CT and to compare with MRI SIJ assessments for inflammation and structural damage in MRI in a population of 23 patients with SpA. (IDRCB : 2012-A00568-35).

Methods: This prospective study included 23 patients with active SpA according to ASAS and/or modified mNY criteria (males 43%, median age 43 y, median symptom duration 7.7 y, HLA-B27 30%, median CRP 8mg/L, median BASDAI 6.1). Pelvic radiograph, MRI of the SIJ and 18-FNa PET/CT were performed during the same month. For MRI, SIJ were assessed for the presence of inflammation (ASAS criteria) and were quantitatively assessed according to SPARCC methods for scoring inflammation and structural damage. On the PET, SIJ

were scored blinded to MRI and CT by two nuclear physician according to a slice by slice approach. A positive PET was defined when unilateral uptake was observed on 2 consecutive slices or bilateral uptake on a single slice. As for SPARCC MRI methods, quantitative assessment on 18-FNa PET was performed according to SIJ quadrants for six consecutive slices through the cartilaginous region of the joint (PET-activity score). The Standardized Maximal Uptake Value (SUV-max) was measured for each SIJ, corresponding to the highest uptake value of the SIJ.

Results: 7 patients had radiographic sacroiliitis, 9 had inflammatory sacroiliitis on MRI (mean SPARCC 7.65)., 9 had structural sacroiliitis on MRI The concordance between the two readers for a positive PET was good (73.9%) as well as the inter-reader reliabilities for the PET-activity score (ICC= 0.69 (95%CI: 0.40 to 0.86)). 18 patients had a positive PET with a mean PET-activity score of 15.7 (± 14). The mean SUV-max for a positive PET was 1.91 versus 1.27 for a negative one. According to a binary approach, a positive PET did not correlate to both inflammatory and structural damages on MRI. The PET-activity score (r=0.57, p=0.005) and SUV-max ($p<0.05$) correlated with the SPARCC inflammation score .Only backfill score amongst MRI structural lesions correlated negatively with the PET-activity score (r=-0.45 p=0.03). The SUV max was associated with SPARCC inflammation and backfill (r= 0.02; p=0.046) and (r= -0.1; p=0.04), respectively.

Conclusion: In axial SpA, the frequency of a positive 18-FNa PET (78.3%) was higher than the frequency of an ASAS positive MRI for inflammatory sacroiliitis (39.1%). Compared to MRI, PET SIJ uptake had a good correlation with inflammatory sacroiliitis while correlation with structural lesions was absent except for backfill.

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: to assess increased SIJ uptakes on 18-FNa (an osteoblastic tracer) PET/CT according to a qualitative and quantitative approach and to compare with MRI SIJ assessments for inflammation and with CT-scan for structural damage in a population of 23 patients with SpA (IDRCB: 2012-A00568-35).

Methods: This single-center prospective study included 23 patients with active SpA according to ASAS and/or modified mNY criteria (males 43.5%, HLA-B27 30%, years 44, symptom duration 7.7 years, median CRP 8mg/L, median BASDAI 6.1). All patients had a pelvic AP-view radiograph, MRI of the SIJ and 18-FNa PET/CT examinations during the same month. For MRI, SIJ were assessed for the presence/absence of inflammation according to ASAS criteria and were quantitatively assessed according to SPARCC method for scoring inflammation. CT-scans were read by three readers blinded to MRI images. Structural lesions were scored in consecutive slices in SIJ quadrants (erosion, sclerosis) or SIJ halves (ankylosis) on a dichotomous basis (present/absent) using the same anatomical principles for defining SIJ quadrants as developed for the SPARCC MRI SIJ inflammation and structural scores. On the 18-FNa PET, SIJ were scored blinded to MRI and CT images by two nuclear physicians according to a slice by slice approach performed from the anterior to the posterior part of the joint. A positive PET was defined when unilateral (sacral or iliac part) uptake was observed on 2 consecutive slices or when bilateral uptake was depicted on a single slice. As for SPARCC MRI methods, quantitative assessment on 18-FNa PET was performed according to SIJ quadrants for six consecutive slices through the cartilaginous region of the joint (PET-activity score). The

Standardized Maximal Uptake Value (SUV-max) was measured for each SIJ, corresponding to the highest uptake value of the SIJ.

Results: 7 patients had radiographic sacroiliitis, 9 had inflammatory sacroiliitis on MRI (mean SPARCC 7.65). On CT-scan, inter-reader reliabilities for ankylosis, erosion and sclerosis were excellent to mild (ICC=0.95; ICC=0.81; ICC=0.39) respectively. The concordance between the two readers for a positive PET was good (73.9%) as well as the inter-reader reliabilities for the PET-activity score (ICC= 0.69 (95%CI: 0.40 to 0.86)). 18 patients had a positive PET with a mean PET-activity score of 15.7 (± 14). The mean SUV-max for a positive PET was 1.91 versus 1.27 for a negative one. According to a binary approach, a positive PET did not correlate to a positive MRI (ASAS criteria) or to a structural sacroiliitis on CT-scan. The PET-activity score (r=0.57, p=0.005) and SUV-max (r= 0.02, p=0.046) correlated with the SPARCC inflammation score but not with erosion, ankylosis and both ankylosis-erosions scores on CT-scan (ICC=-0.04; p=0.85), (ICC=-0.30; p=0.16) and (ICC=-0.19; p=0.37) respectively.

Conclusion: In axial SpA, the frequency of a positive 18-FNa PET (78.3%) was higher than the frequency of an ASAS positive MRI for inflammatory sacroiliitis (39.1%) and was also higher than the frequency of structural damages on CT-scan (39.1%). PET activity score had a good correlation with inflammatory sacroiliitis but not with structural lesion on CT-scan.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Between 8-39% of patients with cutaneous psoriasis may develop psoriatic arthritis (PsA). Subclinical inflammatory joint disease in patients with psoriasis is common. [i,ii] This study sought to examine the utility of easily accessible office-based eMRI in evaluating inflammation and damage in a subset of psoriasis patients without arthritis, and compare the findings with PsA patients.

Methods: Psoriasis patients recruited from Dermatology and Rheumatology clinics of a tertiary care, teaching institution in southern India were divided into those without arthritis (PsO) and PsA groups. All underwent contrast eMRI of the dominant or most-affected hand. Demographic and physical examination details were noted. PsO patients completed the early arthritis in psoriasis (EARP) questionnaire. MRIs were scored by two trained readers, based on Psoriatic arthritis MRI score (PsAMRIS). One reader (AJM) read all studies and a second reader (JP) read a random subset of 40 cases to assess inter-reader reliability. Reliability of scores was determined using intra-class correlation coefficient. Proportion of patients showing any signs of MRI inflammation (synovitis, osteitis, tenosynovitis, periarticular inflammation) or damage (erosion or bone proliferation) was determined. Mann-Whitney U test was used to compare PsA with PsO patients. Significant values ($p<0.1$) were included in multivariate linear regression to assess their independent contributions to outcome.

Results: 104 patients included 62 PsO and 42 PsA, with 73% males; mean age was 42.08±11.90 years. Inter-reader reliability for all features was very good (ICC >0.7). Thirty-nine (62%) patients in the PsO group exhibited evidence of inflammation and 31 (60%) patients showed evidence of damage by eMRI (Table 1). Flexor tenosynovitis and periarticular inflammation were the most common pathologies identified. PsO patients with nail involvement showed a higher percentage of cases with MRI inflammation ($p = 0.037$). EARP ≥3 (OR 1.9; $p = 0.024$) in PsO group and NAPSI scores ≥20 in PsA group predicted higher MRI inflammation.

Conclusion: This study demonstrates a high proportion of psoriasis patients with subclinical disease and evidence of joint damage. Patients with psoriasis and nail involvement had a higher risk of subclinical disease. Office eMRI provides a potential screening tool for these at-

risk groups. [i] Freeston JE et al. Arthritis Care Res (Hoboken) 2014;66:432-9 [ii] Faustini F et al. Ann Rheum Dis doi:10.1136/annrheumdis-2015-208821 **Table 1:** PsAMRIS variables for MRI inflammation and damage in the PsO and PsA subgroups

Variable	PsO (n = 62)	PsA (n = 42)
Synovitis	11 (17.7%)	23 (54.8%)
Osteitis	3 (4.8%)	11 (26.2%)
Flexor tenosynovitis	25 (40.3%)	33 (78.9%)
Periarticular inflammation	32 (51.6%)	40 (95.2%)
Bone erosion	15 (24.2%)	26 (61.9%)
Bone proliferation	23 (37.1%)	33 (78.6%)

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Antero-posterior (A-P) view radiograph of pelvis was usually used to diagnose sacroiliitis. Magnetic resonance imaging (MRI) can detect lesions in early disease before lesions can be seen on radiography. The oblique views radiographs of pelvis can provide additional information that makes it closer to the findings of MRI than A-P view radiograph. In this study, we attempted to record lesions of sacroiliac joint (SIJ) seen on A-P view and oblique views radiographs and MRI in patients with axial Spondyloarthritis (SpA), and to analyze whether oblique views are better than A-P view radiographs in assessing sacroiliitis.

Methods: All patients fulfilled the 2009 ASAS classification criteria for axial SpA. Three readers blinded (two radiologists and one rheumatologist) investigated the A-P view and oblique views radiographs and MR images from 182 patients with axial SpA. The modified New York criterion was used to grade the sacroiliitis according to the lesions seen on different imaging methods. We analyzed and calculated the sensitivity, specificity, positive and negative likelihood ratio of A-P view and oblique views radiographs for diagnosing axial SpA with MRI as the gold-standard.

Results: The total consistency was higher in oblique views and MRI than in A-P view and MRI (82.8% vs. 71.6%, $p<0.01$). The agreement rates were higher between oblique views and MRI than that between A-P view and MRI in the SIJs graded≤2, especially in patients with symptom duration less than 2 years (all $p<0.01$). But in the SIJs graded>2 and in patients with symptom duration more than 2 years, there were no differences using A-P view or oblique views to assess sacroiliitis (all $p>0.05$). Oblique views had high sensitivity, while A-P view had moderate sensitivity for diagnosing axial SpA in the SIJs graded≤2.

Conclusion: We recorded and analyzed the sacroiliitis assessed by A-P view, oblique views radiographs and MRI and found that oblique views radiographs had some advantages over A-P view radiographs in assessing sacroiliitis in patients with early axial SpA.

The Prevalence of Inflammatory and Structural Lesions on MRI of the Sacroiliac Joints in Patients with Very Early Peripheral Spondyloarthritis

Gaëlle Varkas[1], Philippe Carron[2], Heleen Cypers[1], Dirk Elewaut[1], Lennart Jans[3] and Filip van Den Bosch[4], [1]Laboratory for Molecular Immunology and Inflammation, Department of Rheumatology, VIB, Ghent University and Ghent University Hospital, Ghent, Belgium, [2]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, [3]Department of Radiology, Ghent University Hospital, Ghent, Belgium, [4]Rheumatology, Ghent University Hospital, Ghent, Belgium

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the prevalence of inflammatory and structural lesions on MRI of the sacroiliac joints (SIJ) in patients with peripheral spondyloarthritis (PSpA) in a very early stage of the disease.

Methods: Baseline data originated from the double-blind RCT with golimumab in 60 patients (CRESPA), who were diagnosed with PSpA and had a symptom duration <3 months. MRI SIJ was performed at baseline. Peripheral arthritis, dactylitis or enthesitis combined with ≥1 SpA feature (uveitis, psoriasis, IBD, preceding infection, HLAB27 or sacroiliitis on imaging) was necessary for inclusion. However, all patients already fulfilled the classification criteria without data on imaging of the SIJ. Bone marrow edema (BME) of the SIJ was quantified using the Spondyloarthritis Research Consortium of Canada (SPARCC) scoring system. Besides BME of the SIJ, all MRIs were also scored for other inflammatory lesions such as enthesitis and capsulitis. Structural MRI lesions of the SIJ such as subchondral sclerosis, erosions, periarticular fat and ankylosis were also assessed. Hip evaluation consisted of the presence of joint effusion, BME, enthesitis and cortical aberrations.

Results: Although not the reason for encounter, 7 out of 60 patients reported ever having inflammatory back pain (IBP) at inclusion or in the past, with median Visual analogue scores (VAS) of 2.0 (range 0.0- 9.0) for back pain. Overall, 35% of patients (21/60) exhibited BME of the SIJ and fulfilled the definition of a positive MRI by ASAS, with median SPARCC score of 8.0 (range 2.0-37.0). Only 3 out of 7 patients with IBP exhibited BME on MRI SIJ. Therefore, almost 86% of patients (18/21) with active sacroiliitis did not exhibit symptoms of IBP. Median VAS back pain in patients with sacroiliitis compared to patients without sacroiliitis respectively reached 2.0 and 1.0 (P=NS). Pelvic enthesitis was present in 23.8% (5/21) of patients with an ASAS positive MRI SIJ and in 10.3% (4/39) of patients with negative MRI. None of the patients exhibited enthesitis of the L5 spinous process, iliac crest, anterior superior iliac spine or ramus pubis. None of the patients exhibited thorax enthesitis.

Conclusion: Even in early diagnosed peripheral SpA patients, over 1/3 exhibited BME suggestive of acute sacroiliitis and structural lesions of the SI joints. Our findings underscore the importance of sacroiliitis as the cornerstone feature within the SpA-concept, even in asymptomatic patients.

Quantitative Measurements of Cartilage, Osteophyte, and Bone Marrow Lesion volume in Knee Osteoarthritis

Schaefer L.F., Yin M., Sury, M., Jamieson S., Collins J., Smith S., Duryea J.

Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Clinical trials and other large studies of knee osteoarthritis (OA) require efficient and objective methods to assess disease changes. Magnetic resonance imaging (MRI) offers superb soft tissue contrast and is ideal for visualizing many structures associated with knee OA. We have developed the MRI Osteoarthritis Software Score (MOSS), a software-based method that assesses volume change of osteophytes, cartilage, and bone marrow lesions (BMLs) for knee OA. The goal of our study is to assess all 600 subjects of the OA Biomarkers Consortium FNIH Study. This will further validate the method and demonstrate its suitability for use in highly-powered studies and clinical trials of knee OA.

Methods: The OA Biomarkers Consortium FNIH Study is a case-control study of knee OA progression nested within the Osteoarthritis Initiative (OAI). The study cohort was divided into four subgroups based on radiographic and pain progression: Group 1: radiographic and pain progression (n=194) Group 2: radiographic-only progression (n=103) Group 3: pain-only progression (n=103) Group 4: no radiographic or pain progression (n=200). Double echo steady state (DESS) pulse sequences were used for cartilage and osteophytes, and turbo spin echo (TSE) for BMLs. Baseline to 24 month volume change was analyzed as a predictor of case-control status in univariate models using logistic regression. This highly-powered longitudinal study represents the result of 3,600 individual measurements of OA structures on MRI scans.

Results: Change in volume of cartilage and osteophytes were strongly associated with radiographic progression: decreasing cartilage volume was associated with an increased odds of being a case, while increasing osteophyte and BML volume were associated with an increased odds of being a case. The association of cartilage and osteophyte volume change was lower but significant for pain progression. BMLs showed marginally significant associations with radiographic and pain progression. All three measurements (cartilage, osteophytes, and BMLs) can be performed in a total time of less than 30 minutes per knee, split roughly evenly between a research assistant and an experienced reader. Table 1: Results

	Primary analysis: cases (Group 1) versus controls (Group 2, 3, and 4)		Radiographic (Group 1+2) versus non-radiographic progression (Group 3+4)		Pain progression (Group 1+3) versus no pain progression (Group 2+4)	
Variable	Adjusted OR (95% CI)	p-value	Adjusted OR (95% CI)	p-value	Adjusted OR (95% CI)	p-value
Cartilage	0.55 (0.45-0.67)	<.0001	0.30 (0.22-0.39)	<.0001	0.75 (0.63-0.90)	0.0018
Osteophytes	1.53 (1.27-1.85)	<.0001	2.13 (1.69-2.69)	<.0001	1.21 (1.02-1.45)	0.0329
Bone Marrow Lesions	1.25 (1.04-1.49)	0.0169	1.23 (1.02-1.48)	0.0285	1.21 (1.01-1.44)	0.0375

Conclusion: We have demonstrated that measurements of cartilage, BML, and osteophyte volume using the MOSS method have clinical validity in a case-control study. The method is efficient and ideal for current and future large studies and clinical trials of knee OA requiring assessment of many thousands of MRI scans.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recurrent acute anterior uveitis (rAAU) is associated with spondyloarthritis (SpA). However, it is not known if patients with rAAU, but no back symptoms could have positive findings on sacroiliac joint (SIJ) MRI. **Aim:** To assess the prevalence of definite SpA by combined T1W/STIR MRI (global MRI), to quantify acute and chronic lesions in SIJ using MRI in patients with rAAU with and without back symptoms, and to assess which MRI lesion-based criteria optimally reflect the global MRI designation of definite SpA.

Methods: A total of 50 consecutive patients with rAAU without prior rheumatologic diagnosis were included in this cross-sectional study and were compared to 21 healthy volunteers. MRI scans were read by two rheumatologists according to the SPARCC/MORPHO protocol.

Results: rAAU patients were classified as axial SpA (Group 1, n=20), according to ASAS criteria (2009); non-specific back pain (Group 2, n=6) and asymptomatic (Group 3, n=24). The groups were similar regarding age, sex, ethnicity, age at onset of uveitis, current uveitis activity and duration of eye disease. HLA-B27 was positive in 48% of those with rAAU. Considering only group 3, nine (37.5%) patients had SIJ MRI and/or X-ray positive for axial SpA (5 MRI and x-ray, 1 MRI, 3 x-ray). MRI scans compatible with SpA in groups 1(n=12) and 3 (n=6) were similar regarding acute and chronic lesions analysed according to MORPHO. The best sensitivity/specificity criterion to define a positive global MRI assessment was bone marrow edema (BME) ≥ 3 (92%/94%).

Conclusion: This is the first study evaluating SIJ MRI in patients with rAUU without back symptoms showing positive findings for sacroiliitis, confirming a uvea-axial spine link, and BME ≥ 3 as optimal for a positive MRI.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In clinical trials encompassing axial spondyloarthritis (axSpA) patients, bone marrow edema (BME) in the sacroiliac joints (SIJs) is assessed with standardized and validated semi-quantitative scoring systems such as the Berlin MRI method(1) and the SPARCC method(2), which both are based on the semi-coronal scan plane. However, in routine care the inflammation sensitive MRI sequence (e.g. STIR) is frequently obtained in the semi-axial scan plane. This limits use of routine care MRI for systematic follow-up of assessment and prediction of treatment effect in patients recorded in clinical databases. It is important to investigate such patients, since they represent a broader spectrum of the disease than patients recruited to clinical trials (3). The objective of this study was to develop semi-axial MRI scoring methods for assessment of SIJ BME in patients with axSpA, and to compare the reliability with equivalent semi-coronal scoring methods.

Methods: Two semi-axial MRI scoring methods were based on the principles of the Berlin and SPARCC MRI inflammation methods. The intra-reader and interreader reliability of the semi-axial and semi-coronal methods were assessed with intraclass correlation coefficients (ICC) and smallest detectable change (SDC) as absolute values and percentages of the highest observed score (SDC-HOS) were used to assess reproducibility and sensitivity to change, and linear regression analysis to compare the 2 methods

Results: Inter-reader and intra-reader ICCs for *status scores* were excellent for the semi-axial MRI scoring methods (Berlin: 0.88 and 0.93-0.95; SPARCC: 0.92 and 0.92-0.97) and comparable to the semi-coronal methods (Berlin: 0.92 and 0.96-0.97; SPARCC: 0.92 and 0.96). The ICCs for the semi-axial *change scores* were moderate for the Berlin method (0.50) and good for the SPARCC method (0.78), whereas it was good for the semi-coronal methods (Berlin: 0.87; SPARCC 0.89). The association between semi-axial and semi-coronal scores was high for both the Berlin and SPARCC method (linear regression, R^2=0.93 and 0.88; change: R^2=0.82 and 0.87, respectively, see Figure 1). The SDCs and SDC-HOC for the Berlin vs. SPARCC semi-axial methods were 2.6 and 12.8% vs. 5.5 and 9.8%, respectively, and for the semi-coronal methods 1.4 and 5.9% vs. 3.2 and 6.4%, respectively.

Conclusion: Detection of SIJ BME in the semi-axial scan plane is feasible and reproducible. However, slightly lower reliability and sensitivity to change of the semi-axial methods support the general practice of using the semi-coronal scan plane in therapeutic studies.

Can the 3D-modified Dixon

Methods Replace the Conventional Sacroiliac Joint Magnetic Resonance Imaging?

ABSTRACT

Background/Purpose: The purpose of our study was to assess the diagnostic value of two-point Dixon method compared with conventional magnetic resonance imaging (MRI) including T1-weighted, T2-weighted, fat saturated (FS) T1-weighted, FS T2-weighted, and short tau inversion recovery (STIR) in diagnosing axial spondyloarthritis (SpA). Methods: A total of 67 patients with low back pain and suspected axial SpA who underwent sacroiliac joint MRI in our institution from September 2014 to October 2015 were retrospectively evaluated. Each with two data sets (modified Dixon images, conventional MRI), were independently reviewed by two radiologists as follows: 1) grading of both sacroiliac joints; 2) bone marrow edema; 3) erosion; 4) periarticular fat deposition; 5) ankylosis. Bone marrow edema was evaluated on FS T2-weighted, and STIR images. Structural change and fat deposition were evaluated on T1-weighted image. Erosion was evaluated on T1-weighted and FS T1-weighted images. All variables were determined in a thin slice 3D-Dixon images. Sensitivity, specificity, and intra- and interobserver reliabilities were calculated.

Results: Patients had a mean age of 31.7 ¡¾ 11.1 years and male were 44 (65.7%). 44 of 67 patients (65.7%) had positive HLA-B27. 62 patients were diagnosed with axial SpA based on laboratory and imaging information as well as the Assessment of Spondyloarthritis International Society (ASAS) criteria. One patient was diagnosed with osteitis condensans ilii. Four patients were diagnosed with non-specific mechanical back pain. Sensitivities and specificities of Dixon method and conventional MRI are 97.4%, 14.3% and 94.6%, 10.7%. Both Dixon method and conventional MRI had a good to excellent intraobserver (mean intraclass correlation coefficient [ICC] = 0.680-0.953, 0.886-1.000) and interobserver agreement (mean ICC = 0.860-0.986, 0.792-0.953).

Conclusion: 3D-modified Dixon method might be another practical novel imaging technique as conventional MRI. The Dixon method is more intuitive than conventional MRI to evaluate sacroiliac joint, moreover, it takes less time.

Figure 1. Bilateral sacroiliitis (grade 3) with periarticular fat deposition (arrow head), and edema (arrow) showed in 3D-Dixon methods.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) sensitively detects inflammation, but the clinical relevance of MRI-detected inflammation is undetermined in early arthritis. Therefore, this cross-sectional study investigated the association between MRI-detected inflammation of hands and feet and functional disability in early arthritis.

Methods: 514 early arthritis patients, consecutively included in the Leiden Early Arthritis Clinic, were studied. At baseline, unilateral 1.5T MRI of the wrist, metacarpophalangeal (MCP) and metatarsophalangeal-joints was made and functional disability was measured using the Health Assessment Questionnaire (HAQ). MRIs were scored for tenosynovitis, synovitis and bone marrow oedema (BME) by two readers. The sum of these types of MRI-inflammation yielded the total MRI-inflammation score. Linear and non-linear regression analyses were performed with HAQ as outcome.

Results: The total MRI-inflammation score was associated with the HAQ-score (β=0.014, $p<0.001$), as were tenosynovitis (β=0.046, $p<0.001$), synovitis (β=0.039, $p<0.001$) and BME-scores (β=0.015, $p<0.001$) separately. Analysing these three types of MRI-inflammation in one multivariable model, revealed that only tenosynovitis was independently associated with HAQ-score (β=0.039, $p<0.001$). Also when correcting for age, gender, joint counts, C-reactive protein and auto-antibodies, this association remained significant (β=0.034, $p<0.001$). MRI-detected inflammation at wrists or MCP-joints associated significantly with impairments in hand functioning (e.g. difficulties with opening milk cartons or jars). Exploring the relation between MRI-detected inflammation and HAQ-scores, suggested the presence of a ceiling effect, because after a certain inflammation-level, more inflammation was not associated with higher HAQ-scores.

Conclusion: MRI-detected inflammation, and tenosynovitis in particular, is associated with functional disability in early arthritis. This demonstrates the functional relevance of MRI-detected inflammation in early arthritis.

Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Enthesites and dactylitis are common phenomena in patients with psoriatic arthritis (PsA). Inspite of significant advances in our understanding of PsA pathophysiology in recent years, the structural changes underlying dactylitis in PsA have not been comprehensively assessed. Moreover, it is unknown which components of dactylitis respond best to immunosuppressive therapy. We therefore aim to employ most recently developed small joint MRI coils to generate high-resolution images of the fingers in PsA patients in order to analyse the contribution of the various inflammatory dactylitis lesions of PsA and analysing the responsiveness of these components to immunosuppressive therapy with highly active anti-TNF therapy.

Methods: High resolution MRI scans (3 Tesla) with use of small joint coils of the clinical dominate hand were performed before and 6 months after switch from DMARD to anti-TNF therapy in 12 PsA patients with dactylitis (age 42 ± 18; disease duration 4 ± 3.3 years).

Results: The following sites were most commonly involved in dactylitis: collateral ligament enthesitis 11/12 (92%); extensor tendons enthesitis 5/12 (42%); flexor tenosynovitis 9/12 (75%), periarticulitis (i.e. contrast enhancement in periarticular soft tissue) 9/12 (75%).After 6 months, periarticulitis was improved in 8/9 cases (89%), while residual enthesits at any site persisted in 6/11 patients (55%).

Conclusion: Dactylitis is a digital polyenthesitis with collateral ligaments and the extensor ligaments most frequently involved. Moreover periarticular contrast enhancement as well as tenosynovitis is regularly seen. Periarticulitis responds more readily to TNF-therapy than enthesitis. High-resolution MRI is a valid tool to investigate and monitor pathological findings in dactylitis in PsA patients.

Silent Progression in Patients with Rheumatoid Arthritis: Is DAS28 Remission an Insufficient Goal in RA? Results from the German Remission-PLUS Cohort

Dr. Philipp Sewerin[1], PD Dr. Stefan Vordenbäumen[1], Annika Hoyer[2], Ralph Brinks[1], Dr. Christian Buchbender[3], Dr. Christoph Schleich[4], Sabine Kamp[1], Prof. Dr. Gerald Antoch[3], Prof. Dr. Matthias Schneider[1] and Prof. Dr. Benedikt Ostendorf[1], [1]Department of Rheumatology & Hiller Research Unit, Heinrich-Heine University, Düsseldorf, Germany, [2]Institute for Biometry and Epidemiology, German Diabetes Center, Duesseldorf, Germany, [3]Diagnostic and Interventional Radiology, Heinrich-Heine-University, Düsseldorf, Germany, [4]Dep. for diagnostic and interventional Radiology, Heinrich-Heine-University, Duesseldorf, Germany

SESSION INFORMATION
Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Remission in rheumatoid arthritis (RA) arguably is the ultimate goal of an antirheumatic therapy. With modern therapeutic strategies, this goal can be achieved in the majority of patients with early RA (ERA). It is known, that the number and extend of erosions can increase instead of clinically measurable low disease activity or remission (disease activity score in 28 joints; DAS28). We therefore investigated the value of MRI for the detection of erosive changes in patients with DAS28 improvement and/or remission of the German Remission-plus cohort.

Methods: Data-sets of 80 RA patients from the REMISSION-plus study cohort who fulfilled the following criteria were retrospectively analysed: ACR/EULAR 2010 Criteria for RA according to ACR/EULAR criteria, availability of two consecutive MRI scans (low-field MRI, follow up interval 1 year) of the clinically dominant hand and wrist, and the presence of DAS28 (CRP) scores at both time points. The DAS28 was used to assess disease activity. Changes of disease activity were graded by the following classification criteria: DAS28£ 2.6 = clinical remission, £ 3.2 mild disease activity < 5.2 moderate disease activity and > 5.2 severe disease activity. Therapy response was graded by the following improvement criteria proposed by the EULAR committee DAS28 decrease >1.2 units and endpoint score <3.2 =good response, DAS28 decrease >1.2 units and endpoint score >3.2 or DAS28 decrease 0.6 – 1.2 units and endpoint score <5.1 =moderate response, DAS28 decrease <0.6 or DAS28 decrease 0.6 -1.2 units and endpoint score >5.1 =poor response.

Results: 71 of the 80 investigated patients presented a clinical improvement of the DAS28 after 12 month (T4). After 12 months 73% of the 71 patients who improved in DAS28 showed a lower RAMRIS-Score, while 24% demonstrated an increased score despite DAS28 improvement. 34 of the 71 patients who improved in DAS28 reached EULAR Remission. Despite DAS28 remission, 41% of all patients who attained remission showed in increased Erosion-Subscore in MRI after 12 month (T4). Looking at the 71 patients who improved in DAS28 after 12 month, 7 showed EULAR non-response, 19 presented moderate and 45 good EULAR responses. An increase of erosions was found in 71.4% of non-responders 52.6% of moderate responders and 31.1% of good responder at T4 compared to baseline.

Conclusion: Up to 40% of patients in this study demonstrated a progressive erosive disease course in rheumatoid arthritis detected by MRI despite DAS28 improvement or EULAR remission. These data reflects that DAS28 remission alone might be an insufficient therapy goal in rheumatoid arthritis. MRI should be considered as a secondary outcome measure in interventional therapeutic trials with subsequent observational extension including conventional x-rays to systematically assess this question.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the value of cardiovascular magnetic resonance (CMR) and T2-mapping in patients with systemic lupus erythematosus (SLE) and persistent dyspnoea without sings for pulmonary involvement (conventional x-rays and pulmonary function testing) as a possible sign for myocardial involvement.

Methods: 5 women fulfilling the ACR criteria for SLE (mean age 47.4 (30-69) years, mean disease duration 10.4 (5.3 – 22) years, with persistent dyspnoea (at least NYHA II) but absence of pathological findings in electrocardiogram (ECG) or echocardiography were investigated by CMR. CMR was conducted with a 1.5 Tesla MRI-System (Achieva, Philips, Best, Netherlands) using a 32-channel coil. T2 mapping was done using a respiration navigator gated Gradient-And Spin-Echo sequence (GRASE, 15 T2 echoes separated by 10ms, res: 1x1x10mm², 3 short axis slices). Images were post-processed using software based on the LabView environment for local T2 value generation (T2 mapping). Strain analysis was conducted entering cine-images into myocardial feature tracking (FTI) analysis software (TomTec Imaging Systems, Unterschleißheim, Germany). A cohort five of age and gender matched volunteers served as controls.

Results: All patients showed significantly extended T2 times as a sign of local inflammation compared with age matched healthy controls ($p < 0.05$). Moreover, the global systolic longitudinal strain (GLS) as means by systolic function was significantly decreased. In addition, global early diastolic strain rate displayed diastolic dysfunction in comparison to controls.

Conclusion: SLE patients with persistent dyspnoea in absence of pathological findings in ECG and echocardiography showed significantly extended T2-times in MRI as a sign of local fluid content as a part of myocardial inflammation, reduced GLS and diastolic dysfunction, which would be missed by using conventional technics. CMR and T2-mapping is a possible tool for the investigation of a cardiac involvement in SLE patients and should be investigated in clinical studies.

2D and 3D Measurements of Osteoarthritis Joint Space Width have Good Agreement in Radiographically Normal Knees but Poor Agreement with Advancing Kellgren-Lawrence Grade: Data from the Osteoarthritis Initiative Aaron Ray[1], Michael A Bowes[2], Bright Dube[1], Elizabeth MA Hensor[1], Andrew Barr[1], Philip G Conaghan[1] *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds [2]Imorphics Ltd, Kilburn House, Manchester, UK;*

Background/Purpose: Joint Space Width (JSW) remains the current gold standard in OA structure modification trials, however MRI studies have suggested JS narrowing represents a group of pathologies[1]. We aimed to assess the agreement between sensitive measurements of 3DJSW and standard radiographic 2DJSW to further explore conceptually what inter-bone distance represents, using a large OA knee cohort.

Methods: Analyses were performed on 5622 knees from the Osteoarthritis Initiative. Femur and tibia bones were automatically segmented using active appearance models (AAMs). 3D JSW measurements were taken from 1700 points on the medial tibial plateau across the medial tibiofemoral joint (mTFJ), generating an average measurement ($3DJSW_{mean}$); radiographic 2DJSW was generated centrally using a trainable algorithm-based software tool. 3DJSW was compared to radiographic 2DJSW at a fixed radiographic location. SPSSv21 was used to generate Bland Altman plots and used linear regression to measure agreement between the methods.

Results: Bland Altman plots for 2D vs 3D measurements of JSW demonstrated good agreement in radiographic structurally normal knees (Kellgren-Lawrence (KL) grade 0 variation in bias=0.14 per mm; bias at 5mm = -0.36; limits of agreement (LoA) width = 2.89; see Figure 1a) but as KL grade increased and mean JSW decreased, the variation in bias with mean JSW increased and limits of agreement widened (KL4 variation in bias=0.96 per mm; bias at 5mm = -1.30; LoA width: 4.42; see Figure 1b) with a breakdown of the relationship between the 2D and 3D JSW measurements.

Conclusion: JSN comprises various pathologies that are not visualised in radiographs (which consolidate these changes into a single projection) including asymmetric cartilage loss and meniscal extrusion. Although X-ray assessment of JSW provides a comparable measure of inter-bone distance for normal knees, there is increasing discrepancy between 2D and 3DJSW with increasing KL grade. In KL4 knees, poorer agreement between the methods is seen at lower average JSWs. This suggests that radiographs underestimate JSW when compared to MRI when structural change is most advanced. When radiographs demonstrate 'bone on bone' changes, MRI is able to discern differences in JSW. **FIGURE 1: Bland Altman Plot of Fixed Radiographic JSW vs 3DJSWmean**

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Radiography is often used in RA clinical trials to screen for bone erosions (ERO) to ensure that only patients with the erosive phenotype are enrolled. Despite this fewer than 30% of patients in most RA cohorts show significant progression of joint damage. Osteitis (OST) and synovitis (SYN) on MRI have been shown to predict ERO progression, and may thus offer further opportunity to enrich clinical trial cohorts with patients more likely to progress structurally. However, previous studies examining these MRI parameters were at the patient level, and were thus confounded by the multiplicity of individual joint score combinations that could produce a similar total score. We have examined the association between OST and SYN at baseline and the progression of ERO on follow-up at the level of individual bones and joints in an unplanned sub-analysis of the AC-CUTE trial (NCT01951170).[1]

Methods: 50 patients with active RA who had inadequate response to methotrexate (MTX) or other DMARDs and had at least one ERO on screening radiographs or MRI were included in the sub-analysis. 1.5T MRI of one hand (MCP 1-5) and wrist was acquired at baseline and 24 weeks. Two radiologists scored all images blinded to visit order using the RA MRI Score (RAMRIS); the two radiologists' scores were averaged.

Results: A total of 1245 bones were examined. ERO, OST and SYN at baseline were each associated with ERO progression, with odds ratios (OR) of 9.5, 3.7 and 3.1, respectively (Table). OST was more strongly associated with ERO progression than ERO or SYN were. Among bones with ERO at baseline, a larger proportion of those with concurrent OST, i.e., "active" ERO (OR = 1.6) but not those with adjacent SYN (OR = 1.0) progressed. At the patient level, the OR for progression with active ERO (ERO + OST) versus with ERO alone was 1.7. Screening for ERO originally excluded 6% of patients from participating in the study. Screening for at least one bone with active ERO would have excluded 28% more. Requiring patients also to have SYN adjacent to the bone with active ERO would have raised the screen failure rate to 42%.

Conclusion: Baseline ERO, OST and SYN were each associated with ERO progression at the individual bone and joint level. Screening with MRI for the presence of active ERO may enrich RA trial cohorts with likely progressors more effectively than would screening for ERO, OST or SYN alone. **References:** 1. Bird et al. EULAR 2016, (AB0368). [DOI: 10.1136/annrheumdis-2016-eular.3780]. **Table: Effect of ERO, OST and SYN at baseline on subsequent ERO progression**

MRI Feature	% Bones Involved	% ERO Progression*
- ERO	65.3	1.4
+ ERO	34.7	12.0
- OST	82.6	4.1
+ OST	18.3	14.0
- SYN	37.3	2.8
+ SYN	62.7	8.2
+ ERO - OST	20.0	10.0
+ ERO + OST	14.5	14.9
+ ERO - SYN	18.7	12.6
+ ERO + SYN	46.8	12.2

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) in rheumatoid arthritis (RA) has been shown to be more sensitive than clinical and radiological parameters in evaluating disease activity levels and chronic joint damage. Few studies have illustrated the impact of conventional and biologic DMARDs on the MRI findings of RA, including osteitis (bone marrow edema), synovitis and bone erosions. The objectives of this study were to compare MRI findings among groups of RA patients treated with conventional systemic DMARD (csDMARD) monotherapy, csDMARD multi-therapy and combination biologic and conventional DMARD therapies over a two year study period.

Methods: Magnetic resonance images were acquired of the dominant hand of 51 RA patients from a single rheumatology clinic at baseline and at follow-up over an average time of 23 months. Images were obtained using a 1T magnet, 100nm cylindrical transmit and receive coil and a 3D spoiled gradient echo sequence. RAMRIS scoring for bone marrow edema, synovitis and bone erosion was performed for the 2nd through 5thMCP joints at baseline and follow-up as well as clinical disease activity scores (CDAI). DMARD (biologic and conventional) history for all patients was obtained and the patients were grouped into four categories based on their exposure: 1. DMARD mono-therapy with methotrexate (MTX), 2. DMARD mono-therapy with hydroxychloroquine (HCQ), 3. DMARD multi-therapy (multiDMARD) and 4. Biologic and conventional DMARD multi-therapy (DMARDbio). Multivariable linear regression analyses were conducted to determine differences in synovitis, edema and erosion scores at follow-up. The analyses were adjusted for baseline values.

Results: The MTX, HCQ, DMARDbio and multiDMARD groups had 12, 5, 21 and 13 patients respectively. Average CDAI scores at baseline were 10.9, 7.3, 19.0 and 36.5 for MTX, HCQ, multiDMARD and DMARDbio groups respectively. The average baseline and follow-up RAMRIS scores for all groups are listed in table 1 with asterisks denoting statistical significance ($p < 0.05$) versus MTX group.

	RAMRIS baseline				RAMRIS follow-up			
	Synovitis	Edema	Erosion	Overall	Synovitis	Edema	Erosion	Overall
MTX	3.6	3.3	11.3	18.2	2.4	3.8	8.8	15
HCQ	3.2	2.4	7.2	12.8	2.4	3	8.6	14
multiDMARD	5.2	4.2	13.5	22.9	5.8*	7.3*	15*	28.1
DMARDbio	3.2	3.9	9.8	16.9	4.5*	4.3	11.8	20.6

Table 1: RAMRIS scores at baseline and follow-up (* p value < 0.05 vs MTX)

Conclusion: In this prospective cohort of rheumatoid arthritis patients treated with four different regimens, we noted a significant difference in all RAMRIS scoring over an average 23 month period in the multiDMARD therapy group versus MTX group. The baseline CDAI score of the multiDMARD group was higher than the MTX group. The need for multiple DMARDs during this study period may have been because of the higher disease activity in this group. Despite multiple therapies, there was worsening of disease activity based on the RAMRIS scores in this group, which likely was accounted for by the significantly higher baseline disease activity. The MTX group was a suitable control considering the stable RAMRIS scores from baseline to follow-up. The DMARDbio group had higher clinical disease activity score than all other groups at baseline with a CDAI of 36.5. There was a significant difference in RAMRIS synovitis score in the DMARDbio group over the study period versus MTX group but other RAMRIS scores were not significant. This would suggest that biologic DMARD therapy has higher efficacy in suppressing disease activity versus multiple csDMARD therapy. Further studies will be needed to determine the impact of therapy on disease activity as measured by MRI studies.

Anatomical Patterns Suggest the Involvement of Biomechanical Stress in the Pathogenesis of Erosions in Rheumatoid Arthritis

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is limited data outlining the anatomic characteristics of bone erosions of the small joints in rheumatoid arthritis (RA). In particular, there is minimal utilization of 3-dimensional imaging modalities, such as magnetic resonance imaging (MRI) for the purpose of describing erosion patterns in the metacarpophalangeal (MCP) joints. This is of particular interest for understanding the role of biomechanical forces exerted by the adjacent anatomy in contributing to erosion initiation and progression. Our objective was to describe the anatomical features of erosions in the MCP joints to explore the importance of biomechanical stress in erosion pathogenesis.

Methods: MR images of the 2nd through 5th MCP joints were acquired bilaterally from 22 patients who met early referral criterial for RA. Maximum depth and width of erosions were determined using the semi-automated segmentation software Early Erosions in Rheumatoid Arthritis (EERA). Anatomical features were recorded, including: affected hand and MCP joint, metacarpal head vs. phalangeal base involvement, radial- vs. ulnar-sided cortical breakage, and palmar vs. dorsal cortical breakage. One-way ANOVA was used to compare means across groups. Bivariate correlation between maximum erosion depth and width was calculated as an estimate of erosion geometric sphericity.

Results: Patients were 91% female with mean (SD) age of 55.9 (9.3) years, symptom duration of 4.8 (5.3) years, and disease activity score of 4.8 (1.5). Thirty right-handed and 19 left-handed erosions were identified; all involved the metacarpal head, with none involving the phalangeal base. Erosion frequencies across MCP joints 2 through 5 were: 15, 22, 7 and 5 erosions, respectively. Radial-sided cortical breakage was observed in 42 (86%) erosions, and ulnar-sided breakage was observed in 4 (8%) erosions, 3 of which were on the 5th metacarpal. Palmar cortical breakage was observed in 3 (6%) erosions, and dorsal breakage was observed in 1 (2%) erosion. Mean (SD) maximum erosion depth and width were 4.3 (1.5) mm and 4.6 (2.1) mm, respectively. Maximum depth and width correlated moderately, Pearson's $r = 0.51$ ($p < 0.05$), and with the exclusion of one large erosion outlier, only correlated weakly, $r = 0.36$ ($p < 0.05$). Neither erosion depth nor width were significantly associated with MCP joint number, or location of cortical break ($p > 0.05$ for all comparisons).

Conclusion: Predominance of erosions on the right (mostly dominant) hand, 2nd and 3rd MCP joints (higher stresses compared to 4th and 5th MCP), and the radial side of metacarpal heads (higher stabilizing stress from the adjacent radial collateral ligament) except on the 5th metacarpal, all support the hypothesis that anatomical areas subjected to greater biomechanical stress are more susceptible to erosive damage. The weak to moderate correlation between maximum depth and width reflects the geometric asymmetries and irregularities of erosions of the MCP joints. Application of MRI to characterizing other small joints in RA may provide insight to the unique ways in which biomechanical stresses influence bone erosion pathogenesis and progression.

Session Title: Imaging of Rheumatic Diseases - Poster II: XR/CT/PET/MRI

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Almost all previous clinical trials investigating the drug efficacy in patients with rheumatoid arthritis (RA) on the outcome of MRI were based on scans of a unilateral hand (unilateral approach). The aim of this study is to identify the usefulness of MRI scanning bilateral hands (bilateral approach) of patients with RA in clinical practice.

Methods: Thirty-five RA patients participated in this prospective study and received intravenous abatacept treatment for 12 months. MRI of bilateral hands was performed at baseline and 12 months. MRI images were scored for synovitis, osteitis and bone erosion according to the Rheumatoid Arthritis MRI Scoring System (OMERACT-RAMRIS). Score of unilateral hand was defined as score of hand with higher synovitis score. The smallest detectable changes (SDCs) in MRI scores were calculated to estimate the measurement error and a definite change of MRI score (progression or regression) was defined as a change in the score greater than the SDC cut-off. First, we compared MRI scores between hands at baseline and explored imbalances in the imaging scores for each hand. Next, we compared the treatment results obtained by MRI with the “bilateral approach” to those obtained by MRI with the “unilateral approach”.

Results: Imbalances in the synovitis, osteitis, and erosion scores were identified at baseline in 14%, 51%, and 40% of enrolled patients, respectively. We also found that the hand with the higher synovitis score was different from the hand with the higher osteitis score in 11% of patients and from the hand with the higher erosion score in 37% of patients. After 12-month treatment, higher number of patients with progressive synovitis and osteitis scores was detected in the “bilateral approach” than was detected in the “unilateral approach” (synovitis; one case in the “unilateral approach” /four cases in the “bilateral approach”, osteitis; none case /one case, respectively). No significant difference between two approaches was observed. The number of patients with progressive erosion scores was same (six cases in both approaches).

Conclusion: Our data revealed that high prevalence of imbalances in MRI scores between hands and that MRI by the “bilateral approach” revealed higher number of patients who showed progressions in synovitis and osteitis scores compared to the “unilateral approach”. These results imply that MRI of unilateral hands could make clinicians fail to detect joint damage of the other hand and that scanning bilateral hands provides more reliable information about joint damage of patients with RA in clinical practice.

The Incidence of Sexually Acquired Reactive Arthritis: A Systematic Literature Review

Hayley Denison[1], Elizabeth Curtis[2], Michael Clynes[2], Collette Bromhead[3], Elaine Dennison[2,4] and **Rebecca Grainger**[5], [1]School of Biological Sciences, Victoria University of Wellington, Welington, New Zealand, [2]MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom, [3]Massey Institute of Food Science and Technology, Massey University, Wellington, New Zealand, [4]School of Biological Sciences, Victoria University of Wellington, Wellington, New Zealand, [5]University of Otago Wellington, Wellington, New Zealand

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Reactive Arthritis (ReA) is an inflammatory spondyloarthritis occurring after infection at a distant site.

Chlamydia trachomatis is proposed to be the most common cause of ReA, yet the incidence of sexually-acquired ReA (SARA) has not been well established. We carried out a systematic literature review to collate and critically evaluate the published evidence regarding the incidence of SARA.

Methods: MEDLINE and EMBASE databases were searched using free-text and MeSH terms relating to infection and ReA. The title and abstract of articles returned were screened independently by two reviewers and potentially relevant articles assessed in full. Data were extracted from relevant articles and a risk of bias assessment carried out using a validated tool. Heterogeneity of study methodology and results precluded meta-analysis.

Results: The search yielded a total of 11680 articles, and a further 17 were identified from review articles. After screening, 55 papers were assessed in full, from which 3 met the relevant inclusion criteria for the review. The studies reported an incidence of SARA of 3.0% - 8.1% and were of low to moderate quality.

Conclusion: More studies are required to address the lack of data regarding the incidence of SARA. Specific and sensitive classification criteria must be developed in order for consistent classification and valid conclusions to be drawn. In clinical practice, it is recommended clinicians discuss the possibility of ReA developing at the time of STI diagnosis, and to encourage patients to return if they experience any relevant symptoms.

Session Date: Monday, November 14, 2016

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To describe “chronic chikungunya (CHIK)” manifestations seen during the Caribbean outbreak from December 2013 to January 2015.

Methods: We report our experience as the only Rheumatology Department on Martinique Island. Patients were examined by a senior rheumatologist, using a standard care-report form, and CHIK was diagnosed collectively. The median time from acute CHIK to the first rheumatology consultation was calculated; severity was evaluated based on clinical scales and the degree of joint destruction. Each patient’s therapeutic strategy was recorded.

Results: The median time between acute CHIK and the first rheumatology consultation for the 147 patients analyzed was 8 months. After reviewing each patient’s chart, 19 (12.9%) had been given epidemic-influenced CHIK diagnoses. For the remaining 128 patients, with compatible history and positive serology, 4 distinct rheumatologic patterns were observed: 47 (31.9%) had reactivation of painful chronic mechanical manifestations; 9 (6.1%) had fibromyalgia; 45 (30.6%) met the criteria of spondyloarthritis, known for all before the CHIKV infection, and suffered a flare; and 27 (18.3%), with no history of joint disease, developed de novo bilateral symmetric chronic inflammatory joint disease in response to CHIKV infection.

Conclusion: The term “chronic CHIK syndrome” covers multiple etiologies. Compliance with the French Society of Rheumatology recommendations, careful history-taking and serologic verification help avoid errors inherent to the epidemic context and assure early therapeutic intervention for these patients, who should be managed by rheumatologists as early as possible to avoid late treatment onset.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Management of septic arthritis remains a challenge. The emergence of methicillin-resistant Staphylococcus aureus (MRSA) strains with reduced vancomycin susceptibility and multi drug resistant (MDR) gram negative bacilli (GNB) further complicates treatment. However, no information is available for the incidence and outcomes of septic arthritis due to these organisms.

Methods: We performed a retrospective chart review of all inpatient cases of septic arthritis with positive synovial cultures from 2000 to 2015 at a tertiary medical center. MDR was defined for GNB as resistance to two or more classes/groups of antibiotics. We compared patient demographics, clinical information, antibiotic resistance patterns, and clinical outcomes between the early period (2000-07) and the later period (2008-2015) using Mann Whitney and chi-square tests.

Results: There were 128 cases of septic arthritis; 52 in the period 2000-2007 and 76 in the period 2008-2015. The proportion of MRSA septic arthritis did not differ significantly between the first and second period (17% vs 20% of cases, p-value 0.73) while there was a trend toward more cases of GNB in the second period (4% vs 11%, p-value 0.20). One patient had septic arthritis due to MRSA with a vancomycin minimum inhibitory concentration (MIC) $\geq$ 1.5 ug/mL in each period. There was only 1 case of MDR GNB in the later period. Median length of stay (LOS) was similar between methicillin-sensitive Staphylococcus aureus (MSSA) and MRSA (11 days vs 14 days, p=0.59), but higher than other organisms including streptococci and GNB (p=0.02). The most common joint involved was knee (55%) followed by hip (14%). Six out of 8 (75%) cases of polyarticular septic arthritis occurred in patients with MSSA. In-hospital mortality rate of MSSA and MRSA septic arthritis was 6.7% and 8.3 % respectively while no deaths occurred in patients with streptococci and GNB septic arthritis.

Conclusion: The distribution and sensitivity of pathogens causing septic arthritis, including MRSA and MDR GNB, did not differ between the two study periods in this single-center study. The patient with MDR GNB developed severe sepsis requiring intensive care unit admission. The outcomes of MRSA septic arthritis, including increased vancomycin MIC, did not differ significantly from MSSA septic arthritis. Figure

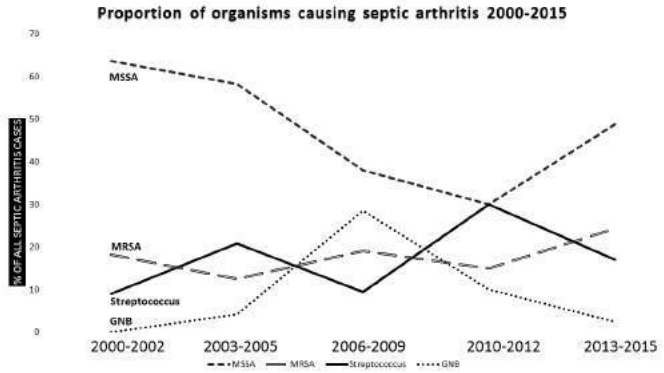

Table Outcomes of septic arthritis across different organisms

	MSSA [a] (N=60)	MRSA [b] (N=24)	CoNS [c] (N=7)	Streptococci (N=22)	Gram negative bacilli (N=10)

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Infection-related Rheumatic Disease - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the incidence of reactive arthritis (ReA), uveitis and conjunctivitis in Japanese patients with bladder cancer following intravesical BCG therapy (iBCG).

Methods: The clinical symptoms, laboratory, and imaging findings of Japanese patients who received iBCG (n=555 (250 and 305 in Kochi Medical School Hospital (KMSH) and Kurashiki Medical Center (KMC), respectively)) for bladder cancer from March 1997 to February 2016 (for 20 years) were retrospectively assessed. Especially, the patients with ReA and conjunctivitis/uveitis were examined.

Results: The backgrounds of patients received iBCG were followings; age 73±10 and 70±11; male/female 198/52 and 240/65 in KMSH and KMC, respectively. ReA was revealed in 5/250 (2.0%) and 6/305 (2.0%), uveitis in 3/250 (1.2%) and 1/305 (0.3%), and conjunctivitis in 18/250 (7.2%) and 15/305 (4.9%) in KMSH and KMC, respectively. As the total evaluation, ReA, uveitis and conjunctivitis were revealed in 11/555 (2.0%), 4/555 (0.7%) and 33/555(5.9%), respectively. All ReA were developed after 3-times of iBCG. Clinical, ultrasound and FDG-PET/CT findings of ReA induced by iBCG showed asymmetric polyarthritis/polyenthesitis. Laboratory examinations showed high CRP (>10mg/dl) in all cases. Notably, there were significant increased frequencies of HLA-B27, B35, B39 and B51 alleles in ReA patients (16.7%, 33.3%, 33.3% and 66.7%, respectively) when compared with healthy subjects (0.3%, 17.0%, 6.0% and 16.0%, respectively).

Conclusion: Despite the positive rate of HLA-B27 in ReA induced by iBCG in our study was 16.7% suggesting lower frequency than 51 to 55% in the Western countries, the incidence of ReA induced by iBCG in Japanese population was 2.0 % which could be more than in the Western countries (0.5 to 1%) from previous reports. High positivity 66.7% and 33.3% of HLA-B51 and B39 in our study might raise the possibility that HLA-B51 or B39, besides B27, also may be associated with ReA induced by iBCG in Japan.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Infection-related Rheumatic Disease - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: HIV infection has been associated with a plethora of rheumatologic diseases, however there are only few studies in the US analyzing the frequency of the different musculoskeletal conditions in patients with HIV on antiretroviral therapy

(ART). The aim of the study was to calculate the proportion of rheumatic manifestations in HIV-infected patients who were receiving antiretroviral treatment and to identify association of the HIV medications with the development of rheumatologic conditions.

Methods: We conducted a review of our electronic medical record database at Maricopa Integrated Health System during the period of 2009 to 2015 using ICD-9 and ICD-10 codes for specific morbidities. We identified 2,996 patients as having chronic HIV infection and on ART that had more than 2 visits in the HIV clinic. A chart review was performed and we identified patients with rheumatologic diseases based on the ACR and EULAR diagnostic criteria. We collected data regarding patient's demographic characteristics, co-morbidities, CD 4 count, HIV viral load and antiretroviral regimen. One hundred fifteen patients with one of the morbidities and 200 randomly selected HIV-infected patients on ART without a diagnosis of rheumatologic disease were used for the analysis. Analytical comparison was based on an aggregate group of patients with any of the four morbidities: autoimmune conditions, avascular necrosis (AVN), musculoskeletal infections, or crystal arthropathies. Group differences were statistically compared and presented using Mann-Whitney U and Fisher's exact test.

Results: Based on the medical record review, 115 out of 2996 HIV patients (3.8%) were found to have a rheumatic condition (mean age of 48.6 years, 83% male). The most frequent musculoskeletal condition was AVN in 39 (1.3%) and the most frequent autoimmune condition was psoriasis in 28 patients (1%). Seven patients had rheumatoid arthritis (0.23%), 6 (0.2%) had psoriatic arthritis and 6 (0.2%) had systemic lupus erythematosus. Ankylosing spondylitis, granulomatosis with polyangiitis and polymyositis were present in one case each. Ten patient were diagnosed with gout (0.35%) and 1 patient had pseudogout. Infectious musculoskeletal conditions were present in 15 patients (0.5%), 12 with osteomyelitis and 3 with septic arthritis. Compared with the 200 HIV patients without any diagnosis of rheumatic disease, the patients with rheumatic conditions were older (median age of 50 vs. 42 years; $p<0.01$) and had a longer duration of HIV infection (median duration of 16 vs. 8 years; $p<0.01$). Those who received integrase inhibitors were more likely (63.3%) to develop rheumatologic manifestations relative to those who never received integrase inhibitors (21.6%; $p<0.01$).

Conclusion: Our study showed that AVN is the most frequent rheumatic complication. Psoriasis was the most frequent autoimmune disease. The proportion of autoimmune rheumatic diseases in HIV patients appears to be comparable to the prevalence in the US population. Older age, longer duration of HIV infection and the use of ART regimens containing integrase inhibitors, appear to increase the risk of developing a rheumatologic condition.

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies showed that arthralgia and myalgia were the most common symptoms among Ebola virus disease (EVD) survivors. Nevertheless specific analyses of rheumatologic sequelea are still lacking.

Methods: The Postebogui study is a prospective multicenter cohort aiming to evaluate the long-term clinical, psychological and socio-behavioral outcomes of EVD survivors infected during the 2014-2015 outbreaks. Of the 216 participants included in October 22th 2015, 44 patients with arthralgia/myalgia underwent a complete examination by a rheumatologist. Data were collected using a

standardized questionnaire and entered in an electronic database.

Results: 43 patients reported joint pain and one patient had myalgia only. 61% were female; median age was 31.5 years; median time from Ebola Treatment Center (ETC) discharge to rheumatologic examination was 8.8 months. Pain manifestations started after Ebola infection in all patients except one. We found similar characteristics in the whole cohort without rheumatologic examination. Morning stiffness was present in 75% of patients. Patients had mechanical pain only (45%), inflammatory pain only (9%) or both (45%). 77% had low back pain and all patients had at least one peripheral joint painful. Large joints were most frequently affected than small joints (73% vs 41%). Oligo and polyarticular presentations were similar and a symmetrical pain distribution was frequent (43-81%). Furthermore, 36 patients (82%) had at least one painful 18-tender point count, most of whom had extensive pain (n=19) and symmetric distribution (91%). Diagnoses were mainly non-specific musculoskeletal disorders (59%) and mechanical back pain (52%). No polyarthritis was observed. We found a higher percentage of depressed patients 42% versus 11% in the remaining Postebogui group ($p<0.001$).

Conclusion: Our study provides an in-depth analysis of rheumatic complaints among a large cohort of EVD survivors. Compared to some other viral infections, synovitis seems rare. Importantly a strong correlation with depression was found highlighting the impact of pain symptoms among survivors

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To describe treatments in patients with chronic post-chikungunya polyarthritis seen during the Caribbean outbreak (December 2013 - January 2015).

Methods: Patients were examined by senior rheumatologists, using a standard care-report form, post-CHIK polyarthritis was diagnosed collectively. Treatments were introduced following recommendation of the French Society of Rheumatology.

Results: Among 147 patients, 45 (30.6%) met criteria of spondyloarthritis. In all cases the rheumatic diseases predated CHIKV infection and exacerbated at the waning of the acute viral infection, despite NSAID(s), justifying further therapeutic intensification with DMARDs (MTX 17/45, mean dose 20 mg/w) and anti- TNF (7/45). Mean follow-up was 6.5 months, during which time the patients' mean BASDAI±SD decreased from 5.1 ± 1.5 at the first visit to 3.8 ± 1.5 at the last one. 27 patients (18.3%), developed de novo polyarthritis in response to CHIKV infection. None had CHIKV-positive PCR during polyarthritis. Biologic inflammation was moderate (mean CRP 25 ± 12 mg/liter), serologic work-up was negative for all patients. All received MTX (mean dose 21 mg/w), with good responses in 21/28, while 7/28 required anti-TNF. Mean follow-up was 7 months, during which mean DAS28score ± SD decreased from 4.8 ± 1.5 at the first visit to 3.3 ± 1.5 at the last one. They received biologics at conventional doses (etanercept 11 and adalimumab 3). Tolerance was good without any recurrence of the viral infection manifestations, as previously described (18). Efficacy

was as expected for this type of pathology.

Conclusion: The term "chronic CHIK syndrome" covers multiple etiologies. These patients should be managed by rheumatologists as early as possible to avoid late treatment onset. Compliance with the French Society of Rheumatology recommendations, assure early therapeutic intervention. *Simon F, Javelle E, Cabie A, Bouquillard E, Troisgros O, Gentile G, et al. Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In developed countries, certain health outcomes are worse among men. For example, in the US, life expectancy for men is 5 years shorter than for women and cardiovascular disease is a major contributor to this discrepancy. Little is known about how clinical features and outcomes of prosthetic joint septic arthritis (PJSA) differ between men and women. This is the first study of its kind to investigate these differences. **Objective**: To compare clinical characteristics and outcomes between women and men with surgically-treated PJSA.

Methods: We conducted a retrospective study that included all patients aged 18 and older admitted to a single, tertiary-care hospital between 1998 and 2015 diagnosed with monoarticular PJSA and treated surgically. We excluded all cases of osteomyelitis, polyarticular infection, septic bursitis, and native joint infection.

Results: Of the 225 patients with PJSA, 122 were female. The frequency of comorbid conditions was similar in men and women [Table 1]. However, a prior history of septic arthritis was more common in men (33 vs 21.3%, p=0.05). While there were no differences in rates of admission early after joint replacement (< 43 days), significantly more men developed late (>365 days after joint replacement) PJSA (59.8 vs 43.9%, p= 0.02). Women had significantly higher mean peripheral WBC counts (11.8 vs 10.3 x 10^9/L, p=0.03) and lower mean synovial fluid polymorphonuclear (PMN) cell counts (82.8 vs 89.9%, p=0.01) than their male counterparts. Males had higher rates of culture positivity (82.5 vs 69.7%, p=0.03) and presence of pus during surgery (68.9 vs 47.1%, p=0.005) but similar rates of MRSA infection [Table 2]. Finally, men were more likely to require ICU stay (17.5 vs 7.4%, p=0.02) and more frequently required multiple operations (29.4 vs 17.4%, p=0.05).

Conclusion: This study suggests there are significant gender differences in clinical features and outcomes of PJSA. Though the presentations were similar, men tended to present later (>1 year post joint replacement), have higher rates of culture positivity and worse outcomes. Further investigation is needed to better understand the causes of these differences and how they might be used to improve treatment. **Table 1. Demographic, comorbidities, and clinical features of patients with PJSA, male vs. female.**

	Female (n=122)	Male (n=103)	p-value

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Do patients with MRSA-positive septic arthritis differ clinically from non-MRSA-positive counterparts? Mary Louise Fowler[3], Kevin Byrne[3], Sarah B. Lieber[1], Andrew Moore[2], Robert H. Shmerling[1], Ziv Paz[1], [1]Beth Israel Deaconess Medical Center, [2]Cambridge Health Alliance, Harvard Medical School, [3]Boston University School of Medicine

Background/Purpose: The incidence of methicillin-resistant Staphylococcus aureus (MRSA) septic arthritis (SA) has increased over the past decade. While MRSA SA is thought to be more severe than non-MRSA SA, there is little published evidence suggesting these patients differ in their presentation and outcomes in the adult population. **Our objective:** To define the epidemiology, clinical characteristics and outcomes of patients with MRSA SA compared to non-MRSA SA patients.

Methods: We conducted a retrospective study that included all patients 18 and older admitted to a single, tertiary-care hospital between 1998 and 2015 diagnosed with culture-positive monoarticular SA and were surgically treated. We excluded cases of osteomyelitis, polyarticular infection or septic bursitis.

Results: Of the 425 patients with SA, 63 (14.8%) were due to MRSA. Compared to patients with non-MRSA SA, those with MRSA SA: were older (63.2 vs 58.3 years, p=0.04); had a higher prevalence of chronic kidney injury (p=0.004); had more end-stage liver disease (p=0.04); and were more likely to have shoulder involvement (p=0.004). In addition, MRSA SA was more likely to affect patients with recent (0-42 days) prosthetic implantation (p=0.05). There were no significant differences in rates of fever or sepsis but mean ESR (87.5 vs 74.3 mm/hour, p=0.04) and mean % of blood polymorphonuclear (PMN) (80.4 vs 77.3%, p= 0.05) were significantly higher in those with MRSA SA. Importantly, the length of hospital stay (LOS) was significantly longer for patients with MRSA SA (12.6 vs 10.4 days, p=0.05), as well as the rates of discharge to rehabilitation was higher (73.7 vs 54%, p=0.005) and expiration within 30 days (11.4 vs 4.4 %, p=0.03).

Conclusion: MRSA SA is common, representing nearly 15% of SA cases. Our study confirms that MRSA SA patients tend to be older, have more comorbidities and worse outcomes than those infected with other organisms. Despite these findings, patients with MRSA SA do not, on average, appear to be sicker at the time of presentation. Table 1. Session Date: Monday, November 14, 2016

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chikungunya virus (CHIKV) caused a large epidemic in Puerto Rico in 2014 with more than 30,000 reported cases. Many of the affected individuals developed chronic arthralgia and/or arthritis months or years after the infection. Animal and human studies have suggested that chronic arthralgia/arthritis is caused by unresolved inflammation responses in joints and persistent infection in macrophages. Thus, the main goal of this study was to identify factors released from macrophages of CHIKV-infected individuals that may play a role in the establishment of the chronic arthralgia/arthritis.

Methods: A cross-sectional study was performed in patients with and without chronic arthralgia/arthritis (chronic and control groups, respectively) associated with CHIKV infection. All patients had laboratory confirmed CHIKV infection by IgG ELISA. Demographic features, health-related behaviors, clinical manifestations, comorbidities, disease activity (per Clinical Disease Activity Index [CDAI]), functional status (per Health Assessment Questionnaire [HAQ]), patient's and physician's global disease assessments by visual analog scales, and pharmacologic treatment were determined. Monocytes-derived macrophages were cultured for 7 days for differentiation. Cytokines and chemokines levels were determined in supernatants collected 3 days after macrophage differentiation

using the Quantibody Inflammation Q3 ELISA array. Variables between chronic and control groups were compared using Fisher's Exact and Mann-Whitney tests. Additional analyses were performed with stratified CDAI data (low < 10 and moderate or high ≥ 10) using Kruskal-Wallis tests with Dunn's multiple comparisons.

Results: Twenty-four patients were studied, 15 with chronic symptoms and 9 controls. The mean age was 47 ± 17 (SD) and 52 ± 11 years old in the chronic and control groups, respectively. A significantly higher proportion of women (13/15) had chronic arthralgia/arthritis than men (2/15, p=0.042). The mean time period between CHIKV infection and study visit was 18 months for both groups. Patients with chronic symptoms had significantly higher CDAI (12.5 ± 10.1 vs. 0.1 ± 0.3, p<0.001) and HAQ scores (0.9 ± 0.66 vs. 0.1 ± 0.29, p=0.002) than the controls. Patients in the chronic group had significantly (p<0.05) lower levels of MCP-1, MCSF, MIP1alpha, TIMP1, and TIMP2 than the controls. Conversely, patients with chronic arthralgias/arthritis were more likely to have significantly (p=0.003) higher levels of I309 than those without chronic symptoms. No differences in cytokine or chemokine levels were observed in chronic patients with low or moderate/high CDAI. Eotaxin, IL-4, IL-11, and IL-12p70 were not detected in any of the samples tested in this study.

Conclusion: Higher levels of chemokines, except for I309, were observed in patients without chronic arthralgia/arthritis suggesting a protective role, in particular of the metalloproteinase inhibitors TIMP1 and TIMP2. Further studies are required to define the mechanism of action of these chemokines in preventing the development of chronic arthralgia/arthritis after CHIKV infection.

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chikungunya fever (CHIKF) is a systemic arboviral disease manifesting with fever, acute arthritis and rash. The acute symptoms can last for days but articular pain and edema can persist and chronify. Objectives: to analyze the clinical manifestations of CHIKF in patients with a previous established articular disease in regular biological (boDMARDs) or conventional DMARDs (cDMARDs) treatment included in BiobadaBrasil register,

Methods: an active search for CHIKF in patients with established rheumatic diseases (ACR criteria) in regular follow up in our database and living in the epidemic area (127.8CHIKFcases/100000 habitants – 18 epidemiological week) was performed; positive cases were identified and submitted to clinical exam and structured interview,

Results: from 358 patients in regular follow up at the 4 centers localized in the epidemic area, CHIKF was diagnosed in 30 (8.4%) patients based on clinical and epidemiological criteria. In this sample, 13 patients were on boDMARDs therapy (4 on adalimumab, 2 on certolizumab and 3 on etanercept, and one on abatacept, infliximabe, golimumabe and rituximab); median treatment

duration 30 months[1-70]) and 17 on cDMARDs. Nearly all patients (85%) lived in urban area, 87% were female, mean age 46(10)yrs; mean disease duration 8 (1-21).yrs. Regarding diagnosis 22 have RA, 7AS and 1 SLE. Remarkable symptoms reported in the table below as well CHIKF treatment with corticoid (CE) *p<0.05.

symptoms	fever	Joint pain	polyarticular	Swollen	Exanthema	paresthesia	CE	Daily dose(mg)
cDMARds n=17 (%)	17 (100)	17 (100)	14 (82)	13 (76)	13* (54)	9* (53)	12 (61)	16.8 (±5.8)
boDMARDs (n=13) %	13 (100)	13 (100)	11 (85)	10 (77)	7 (76)	2 (15)	8 (71)	16.2 (±6.9)

Symptons presented by more than 60% of the patients, with no difference between treatment groups were: myalgia, fatigue, GI complains (diarrhea, nausea, vomit, pain), headache, morning stiffness. Presence of exanthema, paresthesia and neuropatic pain were more frequent in cDMARds treated patients. At the moment of the CHIKF symptoms 76% of the patients in both treatment groups were considered in remission and the articular manifestations were reported as similar to the rheumatic disease only by 15% of the patients on boDMARDs and 18% of the ones on cDMARDs. The pain intensity and localization was reported as different of other acute exacerbations of the previous rheumatic disease. So far, the duration of symptoms were similar with just 23% of the patients having less than 3 months of symptoms. There were no serious complications of CHIKF in any of the treatment groups.

Conclusion: : boDMARDs does not aggravate CHIKF symptoms or persistence. The clinical manifestations of CHIKF in patients with rheumatic diseases are no different from literature reports in health individuals.

Session Date: Monday, November 14, 2016

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chikungunya virus (CHIKV) emerged in Brazil in September 2014. Since then the infection reached epidemic proportions in the country, paticularly in the Northeast region of Brazilian territory. Clinical manifestations of CHIKV infection involve various organs (skin, gastrointestinal tract, vascular system); however, rheumatic manifestations are the most typical features. The disability present in the chronic articular disease in CHIKV infection is an emerging challenge for rheumatologists. **Objectives**: To describe clinical manifestations associated with CHIKV infection in the Brazil population, in patients with previous rheumatic diseases and without previous rheumatic diseases.

Methods: From April to June 2016, 122 patients were enrolled with clinical and epidemiological diagnosis of CHIKV infection, 75

with IGG serology positive for CHIKV (ELISA, Euroimmun®).

Results: Thirty three patients (27.0%) presented a rheumatic disease prior to CHIKV infection (19 rheumatoid arthritis, 8 ankylosing spondylitis and 6 systemic lupus erythematosus). Most of the patients were women (80.3%), non-caucasians (85.0%) and the median age was 53.5 (±11.97) years. Patients had a median time of symptons of 10.8 (±7.46) weeks at the moment of enrollment. All of the patients presented joint pain, 87.0% presented characteristic inflammatory joint stiffness and 87.7% presente arthritis, with an additive polyarticular pattern in most of the cases. Pain intensity measured by visual analogue scale (VAS) was 6.36 (±2.52) and stiffness was 7.44 (±2.11); the median number of painful joints per patient was foi 11.9 (±17.9) and swollen joitns was 7.3 (±9.10). From the 122 patients, 53 (42.63%) had positive CHIKV IgM and 13.9% had a negative result; among the positives, 44.9% retained the positivity after 12 weeks of disease onset. There was significant association between IgM positivity and the number of painful joints by physical examination (p=0.001). There was no difference in clinical manifestations between patients with prior rheumatic diseases and patients whithout prior rheumatic diseases. Most of patients with prior rheumatic diseaes (50%) were under biological therapy (mainly TNF-blockers). There was no association between biological therapy use either with time of symtpons or joint pain characteristics. No disesase complications were observed in patients under immunossuppressor treatment and under disease modifying rheumatic drugs, biological or non-biological.

Conclusion: Initial data of CHIKV infection in brazilian population with prior rheumatic diseases suggest that there are no clinical differences from individuals with no prior rheumatologic disesases. The use of biological drugs seems not to be associated with either clinical complications or changes in the characteristic features of the symptons related to CHIKV infection. The persistence of positivity for IgM beyond 12 weeks may be a factor associated with chronicity of joint symptoms in FC .

Distinguishing Features of Polymicrobial Septic Arthritis

Sarah B. Lieber[1], Andy Moore[2], Robert Shmerling[3], Mary Louise Fowler[4] and Ziv Paz[1], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Division of Rheumatology, Cambridge Health Alliance, Harvard Medical School, Boston, MA, [3]Rheumatology, Beth Israel Deaconess Medical Center, Boston, MA, [4]Boston University School of Medicine, Boston, MA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Little is known about patients with polymicrobial septic arthritis (SA) and how they may differ from those with SA due to a single organism. The purpose of this study is to define the demographic features, clinical characteristics, microbiology, and outcomes of patients with polymicrobial SA as compared to those with monomicrobial SA.

Methods: We conducted a retrospective cohort study of patients 18 years and older admitted to a single tertiary care center from 1998 to 2015 with culture-positive, surgically treated SA affecting one or more joints. Baseline characteristics, clinical features, microbial profile, rate of operative intervention, length of hospital stay (LOS), and 60-day readmission rates were determined. Patients were stratified by presence of SA due to a single organism or more than one organism, identified either in the blood of patients with inflammatory arthritis or in synovial fluid.

Results: Of 511 patients with SA, 52 (10.2%) were found to have polymicrobial SA. Demographic features were similar in the polymicrobial and monomicrobial SA groups. Of those with polymicrobial SA, 6 had polyarticular involvement, similar to the rate of polyarticular involvement in those with monomicrobial SA. Polymicrobial SA was less commonly preceded by joint trauma (5.9% versus 18.1%; p = 0.03). Those with polymicrobial SA tended to have lower synovial fluid white blood cell counts (SF WBC) (71.2 versus 101.4 x 10^9 per liter) with significantly lower % polymorphonuclear (PMN) cells (78.1% versus 88.0%; p = 0.003). Polymicrobial SA occurred most frequently in the knee (n = 27) and hip (n = 13), but no differences in joint distribution were found as

compared to those with SA due to a single organism. Coagulase negative Staphylococcus (32.7% versus 12.0%; p < 0.001), Enterococci (33% versus 2.5%, p <0.001) and Escherichia Coli (15% versus 2.5%, p <0.001) are the three most frequently isolated organism in polymicrobial SA (Figure 1). LOS was longer in those with polymicrobial SA (13.4 versus 10.7 days; p = 0.04), and there was a trend toward more frequent Intensive Care Unit (ICU) stays (25.0% versus 15.9%; p = 0.098). Rates of endocarditis were similar in patients with polymicrobial and monomicrobial SA.

Conclusion: Patients with polymicrobial SA may differ in important ways from patients with monomicrobial SA. Despite lower SF WBC counts and many infections with bacteria of low virulence, patients with polymicrobial SA may have more severe disease, as suggested by a longer LOS and more frequent transfers to the ICU.

Use of biologics in arthritis patients with Hepatitis B and C : a multicentral retrospective case series

Abstract

Background/Purpose: Reactivation of viral hepatitis B (HBV) and C (HCV) has been reported in various case reports in arthritis patients on biological therapy. The objective of the study is to describe clinical characteristics and outcomes of arthritis patients with HBV or HCV treated with biological therapy.

.**Methods:** This is a retrospective case series including 4 centers

Results: Total of 20 arthritis patients with HBV and HCV on biological therapy were identified: 10 cases had (HBV) and 10 cases had (HCV) infection. In the HBV cohort the mean age was 51 (34-85) years, 80% were females. Most patients had Rheumatoid Arthritis (RA) 8(80%), 1 patient had RA/ Systemic lupus erythematosis (SLE) and 1 had HIV related arthritis.A total of 70% were inactive HBsAg carrier and the 3 had chronic hepatitis B. Prophylactic antiviral therapy was given in 9 patients with HBV cases: Entecavir (ETV) 7 , lamivudine and (ETV) 1 and tenofovir 1. The biologics used were Adalimumab (ADA), tociluzumab (TOC), rituximab (RIT) .and etarnercept (ETA). There were 2 cases with chronic HBV had reactivation with no elevation of the transaminases

The mean age in Hepatitis C (HCV) cohort was 54 (23-79) years, all were female RA patients. 5 had detectable HCV RNA before start of biologics. Antiviral treatment was given in 9 (90 %) patients of the hepatitis C cohort: pegylated interferone plus ribavarin (PEG-RIB) 8, PEG-RIB and sofosbuvir plus ribavirin (SOF-RIB) 1pat. The biologics that were used: (ETA, ADA, TOC, RIT, abatacept (ABA) and infliximab (INF). There were 3 patients found to have elevated HCV RNA with elevation of transaminases during followup on biologics meeting criteria for hepatitis C reactivation. All three cases were genotype 4. One of the patients with HCV reactivation was started on SOF-RIB that showed undectable HCV RNA on follow-up.

Conclusion: We report a successful and safe use of biological therapy in patients with arthritis infected with HBV or HCV. Frequent .monitoring is essential to detect reactivation that might occur

Session Title: Infection-related Rheumatic Disease - Poster
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Human parvovirus B19 (HPV-B19) is well known as a cause of erythema infectiosum during childhood, pure red cell aplasia in immunocompromised persons, transient aplastic crisis in patients with hereditary hemolytic anemia, and hydrops fetalis during pregnancy. We sought to describe the characteristics and outcome of the systemic manifestations of HPV-B19 primary infection in adults, whose spectrum is poorly identified and treatment uncodified.

Methods: We conducted an observational, retrospective, multicenter study, with the help of the Société Nationale Française de Médecine Interne and the Club Rhumatismes et Inflammation. Cases was defined by at least one diagnostic criterion of recent HPV-B19 infection: IgM antibodies or viral DNA presence in blood and/or another tissue.

Results: We collected 23 observations over the period 2001-2016. Median patient age at diagnosis was 37.9 years (range: 22.7-83.4). There was a female predominance (sex-ratio: 3.6/1). Median time to diagnosis was 11 days (0-197). Only 2 patients had underlying predisposing condition (sickle cell disease, pregnancy). The most common manifestations were joint involvement (87.0%), with peripheral and symmetrical polyarthralgia in all cases and sometimes arthritis (34.8%) or axial involvement (8.7%). Cutaneous symptoms were also frequent (56.5%) and manifested predominantly by rash (21.7%) with or without classical papular-purpuric gloves and socks syndrome (17.4%); when biopsy was performed, it revealed leucocytoclastic vasculitis in 2/3 cases and neutrophilic dermatosis in 1/3 cases. Four patients (17.4%) had renal involvement, with histological documentation in 2 cases (endocapillary proliferative glomerulonephritis, membranoproliferative glomerulonephritis). Two patients (8.7%) presented with lower limbs myositis, and two others with peripheral nervous system involvement (mononeuritis multiplex, Guillain-Barré syndrome). Other disorders included hemophagocytic lymphohistiocytosis, myopericarditis, pleural effusion, lymphadenopathy and splenomegaly mimicking lymphoma, and spleen infarct. Immunologic abnormalities were frequently observed: anti-nuclear antibodies (43.5%), anti-dsDNA antibodies (21.7%), anti-phospholipid antibodies (17.4%), hypocomplementemia (21.7%), anti-neutrophil cytoplasmic antibodies (13.0%), rheumatoid factor (13.0%), and mixed cryoglobulinemia (8.7%). After 6 months, all patients survived, and 47.8% were in complete remission. In 2 patients, joint involvement evolved into rheumatoid arthritis. Only 5 patients (21.7%) received intravenous immunoglobulin (IVIg), with a good response in the 2 patients with neurological disorders but without efficacy in the 3 others.

Conclusion: HPV-B19 is responsible for a wide variety of systemic manifestations with prominent joint and skin involvement, and diagnosis can be difficult to make. IVIg therapy could be discussed in rare cases whose evolution is not spontaneously favorable, particularly in the setting of peripheral nervous system involvement, but its efficacy should be further investigated in prospective studies.

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Active tuberculosis (TB) is one of the most devastating side effects of biologic agents use. Several guidelines for the prevention of biologic agents-related infections have been published and recommended screening tests for latent tuberculosis

infection (LTBI). However, the evidence for the repeated screening tests for LTBI in areas that have a high incidence of active TB and the incidence rate of positive conversion after starting biologic agents in patients with rheumatic diseases is lacking. The value of LTBI screening in non-TNF biologics and switching biologics use are also unknown. Herein, we repot the result of follow-up interferon-gamma-release assays (IGRAs) in patients with rheumatic disease receiving biologic agents.

Methods: We studied retrospectively all patients who had received biologic agents (TNF and non-TNF agents) for the treatment of rheumatic diseases in our department from April 2007 to March 2016. To evaluate the results of follow-up IGRAs for detection of latent and newly developing tuberculosis, 406 patients with various rheumatic diseases were screened prior to biologic therapy initiation for LTBI with T-SPOT.TB and QuantiFERON-TB Gold In Tube assays.

Results : We assessed 275 patients with follow-up IGRA tests. The analysis of the data showed 2.2% (n=6) of IGRA negative conversion and 4.0% (n=11) of IGRA positive conversion (Table 1). There was no difference in patientfs characteristics between converters and non-converter (Table 2). The incidence of active TB after starting biologic agents was 0 % in this study.

Conclusion : Although the evidence for the repeated IGRA and the positive conversion after starting biologic agents in patients with rheumatic diseases is lacking, follow-up IGRA test may be useful to prevent the activation of LTBI in areas that have a high incidence of active TB such as Japan.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Infection-related Rheumatic Disease - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal complaints are common among survivors of Ebola Virus Disease (EVD) and can have clinical impacts beyond two years post-convalescence. The frequency of these manifestations has been described in several post-convalescent populations, but with very little detail. This study helps detail arthritis manifestations in EVD survivors.

Methods: EVD survivors were evaluated at an established survivors' clinic between 6/29/2015 & 7/2/2015. A trained rheumatologist formally evaluated self-selected survivors, and data were recorded on a standardized form. Summary statistics were then performed.

Results: Forty-six Ebola survivors presented to the survivors' clinic and were evaluated. The mean age was 37.8 years, ranging from 14 to 68 years of age at the time of evaluation. The survivors who presented to the clinic were 54% female and 46% male. Of those whose musculoskeletal complaints could be related to the Ebola infection (i.e., the infection preceded the symptoms), n=42, the mean number of days between being released from the Ebola Treatment Unit (ETU) and development of arthritis symptoms was 46.6 days, SD of 81.5 days. The most striking feature of the Ebola survivors' musculoskeletal symptoms is the high prevalence of enthesitis. Of those examined, 43% had enthesitis in at least one site identified for formal spondyloarthritis examinations after a mean of 202 days of symptoms. Only 7% had one or more swollen joints. Sacroiliac joint tenderness was not a common feature, with only 5% with a positive exam. Twenty-six percent espoused past or present uveitis.

Conclusion: Musculoskeletal complaints are reportedly common among EVD survivors. In a self-selected survivor population, the musculoskeletal complaints are most notable for a predominance of enthesitis with an absence of signs of inflammatory arthritis and sacroiliitis.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Infection-related Rheumatic Disease - Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Lyme arthritis (LA) usually responds to antibiotic therapy, though immune-mediated synovitis may persist after antibiotic treatment, usually confined to a previously infected joint, without systemic symptoms. In contrast, systemic autoimmune arthritides following Lyme disease have not been described. We report here a cohort of 30 patients who developed new-onset rheumatoid arthritis (RA), psoriatic arthritis or peripheral spondyloarthropathy (PsA/SpA), after antibiotic treatment for Lyme disease.

Methods: We reviewed records of all adult patients referred to our Lyme arthritis (LA) clinic over a 13-year period in whom we diagnosed systemic autoimmune arthritis occurring within 2 years of Lyme disease, the interval in which LA may develop after erythema migrans (EM). For comparison, 43 patients enrolled in our LA cohort over a 2-year period were analyzed. IgG antibodies to *Borrelia burgdorferi* and to 3 Lyme-associated autoantigens, endothelial cell growth factor (ECGF), apolipoproteinB-100, and matrix metalloproteinase-10, were measured.

Results: We identified 30 patients who developed new-onset systemic arthritis a median of 4 months after Lyme disease; 60% were seen in the past 3 years. Fifteen had RA, 13 had PsA, and 2 had peripheral SpA. The majority (80%) had prior early Lyme disease, usually EM; all had been treated appropriately with antibiotics. In contrast, only 2 of 43 LA patients had prior EM ($P<0.0001$), and no

patient received antibiotics prior to arthritis onset. All 15 RA patients had symmetrical polyarthritis; 6 had RF or anti-CCP antibodies. The 15 PsA/SpA patients often had axial arthritis, dactylitis, or enthesitis. Of the PsA patients, 9 had skin psoriasis prior to Lyme disease, whereas 4 developed new-onset skin psoriasis and arthritis after the infection. In contrast, the LA patients had monoarticular or oligoarticular arthritis, usually of knees, without SpA features or RA autoantibodies. Most systemic autoimmune patients had positive tests for *B. burgdorferi* IgG antibodies by ELISA, but had much lower titers than LA patients ($P<0.0001$). Moreover they had lower frequencies and levels of Lyme-associated autoantibodies, particularly anti-ECGF ($P\leq0.02$). Prior to our evaluation, the patients often received additional antibiotics for presumed Lyme arthritis without benefit. We prescribed anti-inflammatory therapies, usually DMARDs, resulting in improvement.

Conclusion: Although systemic autoimmune arthritis may follow Lyme disease by chance, onset within months suggests that *B. burgdorferi* infection may be a pro-inflammatory trigger. Thus, when inflammatory arthritis develops in the context of Lyme disease, clinicians need to distinguish among three possibilities: patients who have active infection in joints, those who have post-infectious Lyme arthritis, and those who have developed another form of arthritis. Onset of polyarthritis after antibiotic-treated EM, prior psoriasis, or low-titer *B. burgdorferi* antibodies may be distinguishing features. As Lyme disease is now epidemic in parts of the U.S., awareness of this arthritis spectrum is essential in preventing delays in appropriate diagnosis and treatment.

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chikungunya fever (CHIK) is an arboviral disease characterized by sudden onset of fever and incapacitating polyarthralgia. Some patients develop chronic articular symptoms but the mechanisms by which this occurs and possible biomarkers are poorly understood. Interleukin (IL)-17A, IL-21, IL-22, IL-27 and IL-29 have been implicated in the pathogenesis of inflammatory joint diseases, such as rheumatoid arthritis. Therefore, the purpose of this study was to assess the serum levels of these cytokines and to verify any association with clinical manifestations in CHIK-patients.

Methods: We evaluated 75 patients (58 female, mean age 52.7 ± 13.4 years old) with clinical manifestations of Chikungunya fever and sorological confirmation with IgM and/or IgG CHIK antibodies. All included patients had articular manifestation on the evaluation. From these patients, 30 had previous inflammatory rheumatologic diseases (17 rheumatoid arthritis, 6 systemic lupus erythematosus and 7 spondyloarthritis). Forty-nine age and gender matched healthy individuals served as controls.

Anti-CHIKV IgM and IgG antibodies were tested by ELISA (Euroimmun). IL-17A, IL-21, IL-22, IL-27 and IL-29 serum levels were measured with specific ELISA kits (eBioscience), according to the manufacturer's protocol. The association between cytokines levels and clinical parameters were analyzed. Statistical analyses were performed using GraphPad Prism (version 6.0) and results are expressed as the median and interquartile range.

Results: Serum IL-17A, IL-27 and IL-29 were detected in most of the patients but not in controls. Instead, IL-21 was only detected in healthy individuals' serum but not in CHIK-patients. Serum IL-22 was not detected in both groups. There were no differences in IL-17A, IL-27 and IL-29 levels between rheumatic and non-rheumatic patients.

IL-27 serum levels were higher in patients with chronic symptoms (median 395.9 [62.5-1065] pg/ml) compared with acute/subacute patients (median 62.5 [62.5-451.3] pg/ml), p=0.008). In CHIK-patients, we found significant correlations between IL-27 levels and tender joints (r=0.32, p=0.006) and swollen joints (r=0.26, p=0.03). Also IL-17A levels were associated with swollen joints (r=0.32, p=0.006). Furthermore, patients who reported arthritis had higher IL-17 A levels (median 24.14 [20.6-27.1] pg/ml) than those who did not (median 20.15 [3.9-22.5] pg/ml).

Conclusion: Increased serum levels of IL-17 A, IL-27, and IL-29 were present in CHIK-patients and there was an important association with articular manifestations. This finding may reflect the inflammatory nature of CHIK infection in patients with joint symptons and may implicate the role of these cytokines in the pathophysiology of the disease, similar to what occurs in other inflammatory arthritis.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Infection-related Rheumatic Disease - Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Echocardiogram is frequently performed on patients presenting with septic arthritis (SA) but rarely demonstrates evidence of infective endocarditis (IE). Similarly, while patients with IE often develop musculoskeletal manifestations (including arthralgias, myalgias, and osteomyelitis) concomitant SA and IE is uncommon. The prevalence and presenting features of IE among patients with SA have not been well-defined. The purpose of this study is to describe the utilization of echocardiogram and clinical features and outcomes of patients with SA found to have endocarditis.

Methods: We conducted a retrospective cohort study of patients 18 years and older admitted to a single tertiary care center from 1998 to 2015 with septic arthritis. Baseline characteristics, clinical features, microbial profiles, rates of operative intervention, length of hospital stays (LOS), and 60-day readmission rates were determined. Patients were stratified on the basis of whether echocardiogram was performed and whether it demonstrated evidence of IE.

Results: Of 750 patients with SA, transthoracic echocardiogram (TTE) or transesophageal echocardiogram (TEE) was performed in 293 patients (39%) and found to be positive in 16 patients (2%). TTE and TEE were obtained more often in older patients (mean age 60.4 versus 56.6; p = 0.004) with higher peripheral white blood cell (WBC) counts (12.8 versus 10.6; p <0.0001) and synovial fluid WBC counts (106.8 versus 70.6; p = 0.003 (Table1). TTE and TEE were more frequently performed for those with longer LOS (13.7 versus 7.4 days; p <0.0001) who underwent operative intervention (p = 0.05), were discharged to rehabilitation (p <0.001), and died within 30 days post-discharge (p < 0.001). Presenting features, comorbidities, and outcomes did not differ significantly between those with and without IE. Echocardiograms were more frequently positive in those with SA transferred from outside hospitals as compared to those who were not (68.75% versus 31.25%; p = 0.002). Methicillin sensitive Staph aureus (MSSA) was the most bacterial cause of SA with associated endocarditis.

Conclusion: In this study of SA, we were unable to identify clinical features and outcomes that distinguished those with or without IE other than higher rates of MSSA infection and preceding outside hospital transfers. Echocardiograms were more frequently obtained in sicker patients as implied by their presentation and eventual outcomes; however, IE was not more frequently identified in such patients. Additional study is needed to determine which factors may predict the presence of IE in patients with SA and which may benefit most from echocardiography.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: No study has compared the efficacy and the safety of biologics in a large relapsing polychondritis (RP) cohort. This is the aim of the present study.

Methods: We conducted a national multicenter retrospective study in France including adult patients treated with biologics for RP from 2001 until July, 2015. Data were recorded at the time of biologic exposure (T0), at 3 and 6 months, and then every 6 months. Follow-up ended at biologic discontinuation or at the date of last available data. Efficacy outcomes were the intention-to-treat rates of partial (PR, defined by clinical improvement with persistent disease activity) or complete response (CR, defined by no clinical activity) during the first 6 months of exposure, and the evolution of the corticosteroid (CS) doses between T0 and month 6 for patients having a >6-month exposure to each biologic. Adverse drug reactions (ADRs) were described. We also compared the persistence of biologics (excluding rituximab) through Kaplan-Meier curves and the reasons for discontinuation. Factors associated to a PR or CR during the first 6 months of exposure to first-line biologics were investigated using a multivariate logistic regression model.

Results: The cohort included 41 patients. Mean age was 46.9 ± 12.5 years and 53.6% were females. Median time from RP diagnosis to

first-line biologic T0 was 26.5 months. All patients satisfied to McAdam, Damiani and Michet diagnostic criteria. All but 2 patients had an active disease at first biologic prescription. Reasons for biologic initiation were CS dependency (n=28), CS resistance (n=11) or ADR to previous treatments (n=3). First-line biologics were TNF inhibitors (n=30), tocilizumab (n=5), rituximab (n=4), anakinra and abatacept (n=1 each). Twenty-eight patients were exposed to at least 2 lines of biologics (because of insufficient efficacy in14, relapses in 8 or adverse drug reactions in 9). In total, 105 biologic prescriptions were recorded (TNF inhibitors, n=60; tocilizumab, n=17; anakinra, n=15; rituximab, n=7; abatacept, n=6). Outcomes are presented in Table 1. PR or CR rate during the first 6 months was 62.9% while CR rate was 19.0%. There was only a modest reduction in the median CS dose. ADRs were mostly infections (n=42) and reaction at site of injection for subcutaneous biologics (n=12). Persistence was comparable among biologic classes (p=0.77). Among TNF inhibitors, the highest persistence was observed on adalimumab and the lowest for etanercept (log-rank test: p=0.02). In multivariate analysis, the single factor associated to PR or CR during the first 6 months of exposure to first-line biologic treatment was a history of chondro-sternal inflammation (OR: 5.75; 95% CI: 1.27-26.07; p=0.02) and there was a trend for nasal or auricular inflammation at biologic initiation (OR: 4.30; 95% CI: 0.93-19.78, p=0.09).

Conclusion: Overall, biologics are an interesting option for RP treatment.

Table 1. Efficacy and adverse drug reactions of biologics prescribed for relapsing polychondritis in 41 patients.

Biologics	PR or CR at 6 months, n (%)	CR at 6 months, n (%)	Variation in CS dose at M6, mg PEQ, median (range)	Follow-up, months, median (range)	Discontinuation of biologic				
					Overall	Insufficient efficacy	Loss of efficacy	ADR	Stable CR
Overall (n=105)	66 (62.9%)	20 (19.0%)	-5.0 (-72.5; +70.0)	6.0 (0.1-80.8)	77 (73.3%)	36 (34.3%)	19 (18.1%)	22 (20.9%)	1

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a rare and in some cases fatal autoimmune disease that can affect multiple organs including cartilaginous structures. The disease is unpredictable and clinical manifestations may be variable resulting in a delay to diagnosis. Patients may have involvement of organs other than the nasal bridge and ear, including larynx, tracheobronchial tree, joints, vasculature, heart valves and kidneys. In this report we present the results of the largest survey to date evaluating disease patterns in an international cohort.

Methods: Data was acquired using an internet-based questionnaire aimed at cataloguing a variety of possible clinical presentations of RP. We obtained an Office of Human Subjects Research Protections 'Exclusion from IRB Review' certificate. The data was anonymous therefore met criteria for exclusion per the requirements of 45 CFR 46 and NIH policy. The Relapsing Polychondritis Awareness and Support Foundation administered the survey by email solicitation to patients that previously agreed to be contacted and by posting the link online. The survey was open to the public on 2/23/2016 and the data for this analysis was extracted on 4/11/2016.

Results: 193 surveys total were captured and 13 were excluded either for age less than 18 or no age reported**.** 180 surveys were included in this analysis. The mean age was 49.5 (SD 11.9). 86.5% were female. 91% identified as "white" and 31.5% reported country of origin other than the USA. The approximate mean age at diagnosis was 43.4 years (SD 12.7). A non-rheumatologist physician made the diagnosed in 47.5%. 54% of the patients saw more than 3 physicians prior to establishing a diagnosis and only 15% underwent cartilage biopsy to support the diagnosis. 49% of the patients had symptoms for more than 3 year before diagnosis. 55% of patients went to the emergency room prior to diagnosis because of RP symptoms. Common initial symptoms included dizziness, eye inflammation, constochondritis, and shortness of breath, nose pain, and voice changes. Some patients also reported fatigue, flu-like symptoms, fever and difficulty swallowing as initial symptoms. Complications of RP included disability (25%), tracheomalacia (16%) and intubation related to RP (12%).

Conclusion: This is the largest RP study to collate patient and disease characteristics in an international self-reported cohort. We found that the majority was female and there was a high incidence of initial symptoms other than ear and nose inflammation. The time to diagnosis was greater than 5 years. We learned that non-rheumatologist physicians commonly encounter patients with RP and sometimes these encounters occur in the emergency room. We also found that RP could have devastating complications including tracheomalacia and disability. Physicians must be alert to underappreciated presenting symptoms such as voice changes and shortness of breath. The limitations of this study include both the inability to validate self-reported claims of a diagnosis of RP and recall bias. The strength of our study includes the anonymous web-based strategy, which enabled us to capture a larger, and less geographically constrained, population.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a rare autoimmune disorder characterized by cartilage inflammation and damage. Chronic RP may lead to sequelae due to cartilage tissue damage. There is no diagnostic test for RP and prompt diagnosis remains a challenge due to the marked variation in initial clinical presentation. We describe disease patterns amongst patients with RP, and identify factors that correlate with diagnostic delay and poor outcome.

Methods: This was a retrospective cohort study of RP patients followed up for 20 years in our systemic vasculitis clinic. Patient data was retrieved from June 1995 until 31stDecember 2015, or until patient's last follow-up date. Data recorded include patients' demographic, initial clinical presentations, therapeutic regimes, and long-term outcome. Data analysis was performed using SPSS Version 23.0

Results: 45 patients were identified. 68.9% were female. 39 patients (86.7%) were Caucasian, 5 (11.1%) Afro-Caribbean and 1 (2.2%) Asian. Median age of disease onset was 39.0 (29.5, 54.0) years. Median age of RP diagnosis was 42.0 (34.5, 60.5) years. Median diagnosis delay was 19.0 (5.0, 65.0) months. Most had ear involvement at presentation (73.3%, n=33), followed by chest wall or peripheral joint pain (57.8%), eyes (53.3%), nose (42.2%), and airways (28.9%). Mean number of initial organ presentation was 2.6 ± 1.04. All patients received steroid as therapeutic agent. There was wide heterogeneity in terms of therapeutic agents used, including methotrexate (31.1%), azathioprine (26.7%), hydroxychloroquine (13.3%), mycophenolate (13.3%), and IV cyclophosphamide (11.1%). Mean number of drugs used at any time was 1.9 ± 1.00. Long-term sequelae involved chronic pain (64.4%) and drugs related complications (57.8%). 57.8% had ears damages, followed by eyes damages (42.2%), and airway damages (40%). Mean number of organ damages was 1.7 ± 1.37. Higher number of initial organ presentation (r= 0.34, p= 0.022) and younger age of disease onset (r= -0.40, p= 0.006) correlated with diagnosis delay. Male gender correlated with airway involvement (r= 0.42, p= 0.004). There was positive correlation between airway involvement with higher number of organ damage (r= 0.30, p= 0.047). A weak correlation was noted between initial involvement of chest wall or peripheral joint pain with chronic pain complication (r= 0.34, p= 0.024). 30 patients (66.7%) remained under active follow-up, with 11 patients (24.4%) lost to follow-up, and 4 deaths occurred with cause unknown (8.9%).

Conclusion: Our study revealed higher number of initial organ presentation, and younger age of disease onset correlated with potential diagnosis delay. Male gender with airway involvements correlated with higher number of organ damages and poorer outcome. Multicenter registries may lead to a better understanding of this disease.

Severe Complications and Immunosuppressive Treatments in 33 Patients with Relapsing Polychondritis

Toshiki Nakajima[1], Hajime Yoshifuji[1], Chikashi Terao[2], Kosaku Murakami[1], Nobuo Kuramoto[1], Ran Nakashima[1], Yoshitaka Imura[3], Masao Tanaka[1], Koichiro Ohmura[1] and Tsuneyo Mimori[1], [1]Department of Rheumatology and Clinical Immunology, Kyoto University Graduate School of Medicine, Kyoto, Japan, [2]Genomic Center, Center for Genomic Medicine, Kyoto University Graduate School of Medicine, Kyoto, Japan, [3]Rheumatology and Clinical Immunology, Kyoto University Graduate School of Medicine, Kyoto, Japan
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Since relapsing polychondritis (RP) is a rare disease as the prevalence rate is 0.0004% in Japan, its severe

complications, prognosis and immunosuppressive therapies have not been fully understood or established. We recently reported association of disease onset and 3 HLA haplotypes (DQB1*05:02, B*67:01 and DRB1*16:02 in linkage disequilibrium) in 102 patients with RP (Terao C et al. Rheumatology (Oxford) doi: 10.1093/rheumatology/kew233), however, we did not survey clinical information such as treatment course. In the present study, we investigated detailed clinical information of 33 patients in a single center.

Methods: We examined medical records of 33 patients with RP who satisfied Damiani's criteria. HLA haplotypes and anti-type II collagen antibodies were assayed in some of these patients.

Results: Tracheobronchial (TB), central nerve system (CNS), and aortic complications were seen in 17 (51.5%), 4 (9.1%), and 2 (6.0%) patients, respectively. One (3.0%) died, and two (6.0%) with CNS lesions failed into bed-bound status. Recurrence was seen in 25 (75.8%). Positivity of HLA-DQB1 05:02 was 17.6% (3/17), higher than 2.6% in healthy Japanese. Two of the 3 patients with DQB1 05:02 had TB lesions and one needed TCZ. B 67:01 and DRB1 16:02 were positive in 2 patients (11.8%) and linked with DQB1 05:02. Anti-type II collagen antibodies were seen in 29.2% (7/24). Methotrexate (MTX), azathioprine (AZP), intravenous cyclophosphamide (IVCY), infliximab (IFX) and tocilizumab (TCZ) were used along with glucocorticoid in 10 (30.3%), 8 (24.2%), 5 (15.2%), 5 (15.2%) and 4 (12.1%), respectively. Three patients with TB lesions and 2 with CNS lesions were treated with IVCY, and response rates were 100% and 50%, respectively. IFX was used and partially effective in 1 with TB lesion, 1 with CNS lesion, and 3 patients complicated with Behçet disease. TCZ was used in 3 patients with TB lesions, and response rate was 33%.

Conclusion: The linkage with certain haplotypes of HLA and the positivity of autoantibodies (~30%) consolidate that RP is an autoimmune disease. IVCY showed a good response in patients with TB lesions in the present study. The prognosis of patients with CNS lesions was poor. Further collection of cases is required to elucidate pathophysiology and improve treatments.

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Findings of ophthalmologic examination can guide the diagnostic management of uveitis. Granulomatous presentation is commonly associated with peculiar causes, including infections, eye-restricted diseases, or systemic diseases such as sarcoidosis, multiple sclerosis or bowel inflammatory diseases, but large series are lacking to confirm this trend. The present study aimed to evaluate relevance of granulomatous presentation for the etiological diagnosis of uveitis.

Methods: Single-centre retrospective study including patients referred from the Ophthalmology department to Internal Medicine practitioners for etiological diagnosis of uveitis. Uveitis related to pure ophthalmological diseases or occurring during the course of an already diagnosed pathology were excluded. Granulomatous presentation was defined by the aspect of keratic precipitates and/or the presence of iris nodules. Granulomatous uveitis were compared to non-granulomatous uveitis.

Results: One hundred and thirty-one consecutive granulomatous uveitis were compared to 120 non-granulomatous uveitis. Mains ophthalmologic findings (i.e. (bilateralism, topography, frequency of panuveitis, cystoid macular edema and chronicity)) were

comparable between both subgroups. In contrast, vitreous snowballs were more frequent in granulomatous uveitis compared to non-granulomatous uveitis (32% vs. 21%, p=0.04). Increased serum angiotensin-converting enzyme titer, a positive latent tuberculosis test (purified protein derivative skin test or Interferon-gamma releasing assay) and chest CT scan findings were comparable between both groups. The frequency of lymphocytic alveolitis on bronchoalveolar lavage and granulomas on bronchial biopsies were also similar. At the end of the diagnostic workup which was comparable between groups, the rate of uveitis of undetermined origin was similar between both groups (35% vs. 32%, p=0.68), as well as the spectrum of causes: sarcoidosis (16% vs. 10%, p=0.19) and uveitis associated with latent tuberculosis (34% vs. 23%, p=0.09). In contrast, uveitis associated with HLA B27 antigen (6% vs. 0%, p=0.006) and Behçet's disease (9% vs. 0%, p<0.001) were only observed in the non-granulomatous group. Rather than the granulomatous presentation of the anterior chamber, the combination of granulomatous uveitis with vitreous snowballs or with peripheral multifocal choroiditis was significantly associated with proven or presumed sarcoidosis (p=0.001 and p=0.006, respectively). Finally, response to treatment and relapse rate were comparable between both groups.

Conclusion: The granulomatous presentation of uveitis alone is not sufficient to guide the diagnostic management of uveitis and does not impact treatment response and outcome. In contrast, its association with vitreous snowballs or peripheral multifocal choroiditis are highly suggestive of sarcoidosis.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis represents a diagnostic and therapeutic challenge, as well as an economic one, due to its heterogeneous presentation, multiple underlying causes and lack of well-codified diagnostic procedures. Furthermore, a third of uveitis is considered idiopathic. The aim of this study was to evaluate the contribution of diagnostic investigations in the management of uveitis in a specialized centre.

Methods: Single-centre retrospective study including patients referred from the Ophthalmology department to Internal Medicine practitioners for etiological diagnosis of uveitis. Uveitis related to pure ophthalmological diseases or occurring during the course of an already diagnosed pathology were excluded. All patients had a complete ophthalmologic examination followed by clinical and paraclinical exams. All diagnoses were established according to recent international diagnostic criteria.

Results: Three hundred consecutive patients were included (mean age 48 ± 30 years, men 49%). The main features of uveitis were: bilateral 56%, anterior 33%, posterior 8%, panuveitis 30%, granulomatous 44%, chronic 39%. Forty-three percent of patients had at least one clinical extra-ophthalmologic manifestation, such as arthralgia (17%) or general symptoms (15%). Regarding paraclinical exams, chest CT scan was performed in 94% of cases, and showed abnormal findings suggestive of pulmonary or mediastinal sarcoidosis in 39%. Factors associated with having an abnormal CT scan were blood lymphocytopenia (p=0.002) and increased angiotensin-converting enzyme (ACE) over 1.5 the upper limit of normal (ULN) (p=0.007). Salivary gland biopsy, performed in 76% of cases, led to the identification of granuloma in only 6%. Bronchoscopy was performed in 61% of cases, with bronchial biopsies showing granuloma in only 8% whereas bronchoalveolar lavage fluid (BALF) analysis revealed alveolar lymphocytosis suggestive of

sarcoidosis (lymphocytes >15% and/or CD4/CD8 ratio >3.5) in 27%. Patients with granuloma on biopsies always had abnormalities on CT scan whereas 37% of patients with alveolar lymphocytosis had normal CT scan. Factors associated with having contributive BALF were vitreous snowballs (p=0.003), peripheral multifocal choroiditis (p=0.002), lymphocytopenia (p=0.03), and a >1.5 ULN ACE titer (p<0.0001). Cerebral MRI was performed in 56% of cases and was abnormal in 14%. Factors associated with abnormal MRI were retinal vasculitis (p=0.03) and a >1.5 ULN ACE titer. Lumbar puncture was performed in 44% but mainly showed non relevant abnormalities in 31%. Finally, at the end of the diagnostic workup, the main causes identified were uveitis associated with latent tuberculosis in 25%, sarcoidosis in 18% or Behçet's disease in 5%. However, 37% of uveitis remained of undetermined origin. Baseline features from the latter did not differ from those in which a specific diagnosis was retained.

Conclusion: Despite an extensive clinical and paraclinical workup, an important proportion of uveitis remains of undetermined origin. Identification of factors associated with abnormal investigations might improve the optimal diagnostic workup adapted to each patient's characteristics.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the long-term safety and efficacy of adalimumab (Humira®) in patients with non-infectious intermediate, posterior, or panuveitis (NIPPU) in an open-label clinical trial extension, VISUAL-III.

Methods: Adults who met treatment failure or study completion criteria in VISUAL-I/VISUAL-II and opted to enroll in VISUAL-III received adalimumab 40-mg every other week. Corticosteroids and/or immunosuppressive therapy were permitted as needed. Patients that discontinued VISUAL-I/VISUAL-II due to treatment failure had active disease at VISUAL-III entry. Efficacy endpoints included new inflammatory lesions, anterior chamber (AC) cell, and vitreous haze (VH) grades from study entry (week-0) through week-54 (inactive uveitis) and week-78 (active uveitis). Corticosteroid daily dose was measured over time. Adverse event rates were reported from first adalimumab dose in VISUAL-I/II/III until the data cutoff of 31-August-2015.

Results: Intent-to-treat analyses included 243 (active) and 128 (inactive) uveitis patients at study entry. At week-54, no new

inflammatory lesions relative to baseline, AC cell and VH grades of ≤0.5+ were observed in 98.5%, 98.5% and 92.6% of inactive uveitis patients, respectively. At week-78, no new inflammatory lesions relative to week-8, AC cell and VH grades of ≤0.5+ were observed in 96.3%, 91.0% and 87.8% of active uveitis patients, respectively. Mean systemic corticosteroid daily dose decreased from 12.7 to 3.68 prednisone equivalents by year 1 for patients with active uveitis and remained stable from 1.48 to 1.21 prednisone equivalents for inactive patients. Adverse events rates (577 AE/100PY and 19.6 SAE/100PY) were comparable to the VISUAL-I and VISUAL-II trials.

Conclusion: Long-term adalimumab treatment reduced ocular inflammation and corticosteroid burden in NIPPU patients and demonstrated a safety profile consistent with other indications and previous VISUAL studies.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Our objective was to evaluate the efficacy and safety of Tocilizumab (TCZ) in a series of patients with refractory CME.

Methods: A Multicenter study of 25 patients with CME secondary to non-infectious uveitis who had inadequate response or intolerance to traditional treatment with corticosteroids and at least one conventional immunosuppressive drug including in most cases biological therapy. CME was defined by (OCT >300 µm). The outcome variables were the degree of inflammation of the anterior chamber and vitreous, visual acuity and macular thickness. Comparison of continuous variables was performed using theWilcoxon test.

Results: 25 patients (17 females/8 males) with CME were studied. Mean age of 33.6±18.9 years. The associated disease was: juvenile idiopathic arthritis (n=9), Behçet's disease (n=7), Birdshot retinochoroidopathy (n=4), idiopathic (n=4), sarcoidosis (n=1). The ocular pattern was: panuveitis (n=9), anterior uveitis (n=7), posterior uveitis (n=5), intermediate uveitis (n=4). Most patients had bilateral involvement (n=24). Prior to TCZ patients received: intraocular corticosteroids (n=22), iv. methylprednisolone (n=7), methotrexate (MTX) (n=19), cyclosporine A (CSA) (n=17), mycophenolate (n=4), azathioprine (n=2), cyclophosphamide (n=1), sulfasalazine (n=1), daclizumab (n=1), acetazolamide (n=1), thalidomide (n=1), leflunomide (n=2), infliximab (n=8), adalimumab (n=19), etanercept (n=2), golimumab (n=2), rituximab (n=2), abatacept (n=3), anakinra (n=1). TCZ administration schedule was 8 mg/kg/4 weeks iv. in all patients except in one that was administered every 2 weeks. TCZ was used in monotherapy (n=11) or combined with conventional immunosuppressive: MTX (n=6), CsA (n=5) and leflunomide (n=1). A statistically significant reduction was observed in macular thickness from 415.68±177.15 to 259.1±499.5 microns; p=0.00009 during the first year of treatment with TCZ. Most of intraocular inflammation parameters showed also a rapid improvement after initiation of TCZ (TABLE). Visual acuity improved in a statistically significant way from 0.39±0.31 at baseline to 0.54±0.33 after one year of treatment (p =0.0002). After a mean follow up of 12.7±8.34 months only minor side effects were observed: nausea (n=1), viral conjunctivitis and bullous impetigo (n=1). Remission was achieved in 14 patients. The prednisone dose was reduced from 15.9±13.6 at baseline to 3.1±2.3 after a year of treatment; p=0.002.

Conclusion: Treatment with TCZ seems an effective and safe treatment in patients with uveitic CME refractory to other synthetic and biological immunosuppressive drugs **TABLE**

	Baseline	1st week	2nd week	1st month	3rd month	6th month	1st year
Visual acuity mean ± SD	0.39±0.31	0.4±0.31	0.45±0.31*	0.51±0.3*	0.57±0.32*	0.56±0.33*	0.54±0.34*

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Refractory uveitis may requiere the use of biological therapy, especially tumour necrosis factors inhibitors (TNFi), being the most currently used infliximab and adalimumab. However, in cases of failure or adverse events related to these drugs, another TNFi such as certolizumab pegol (CZP) could be an effective option (1) as we have previously reported (2). Moreover, given that CZP does not cross the placental barrier (3), this drug could be a safer option in women considering pregnancy. Our purpose is to study the efficacy and safety of CZP in patients with uveitis refractory to other immunomodulatory treatments

Methods: Observational, multicentric, retrospective study. All the patients with a diagnosis of uveitis, confirmed by an Ophtalmologist, treated with CZP for at least 6 months were included. Variables analyzed: age, sex, diagnosis, type of uveitis and duration since the first uveitis episode; previous treatment (NSAID, disease-modifying anti-rheumatic drugs (DMARDs), immunossuppressive or biological therapy); outcome and time to follow-up

Results: Forty eyes of 22 patients (10 women); age 44.6 ± 12.6 (range 29-71 years) were included in the study. Diagnosis were: 8 ankylosing spondylitis; 5 Behçet disease; 4 psoriatic arthritis; and one of each of the following (nonradiographic axial spondyloarthritis, rheumatoid arthritis, juvenile idiopathic arthritis, punctate inner coroiditis, and idiopathic panuveitis). Type of uveitis: 10 anterior, 7 panuveitis, 4 posterior and 1 intermediate; mean disease duration of 139.8 ± 112.9 months (range 5-420). 86.4% patients had received previous biological therapy (59% ≥ 2 biological agents). 72.7% received CZP with no concomitant DMARD treatment (only 6 patients received concomitant DMARD: 3 methotrexate and 3 azathioprine). In four women CZP was indicated due to pregnancy desire. In the remaining cases CZP was started due to inefficacy to previous treatment except for 2 cases that was by adverse event. After a follow-up of 17.3 ± 11.6 months (range 6-48), 16 patients are still on CZP treatment. Eighteen eyes showed improvement of visual acuity (45%), 17 remained stable and 5 worsened. One patient had retinal vasculitis at baseline that resolved after 1 month of CZP. During the follow-up only 3 patients suffered 7 uveitis flares and 2 required switch to tocilizumab. No serious adverse events were reported. Only 4 cases withdrawn treatment: 2 due to worsening of articular symptoms but with no uveitis activity; 1 due to macular edema and 1 due to persistent uveitis activity

Conclusion: CZP has demonstrated effectiveness in patients with refractory uveitis to previous TNFi treatment, showing a safety profile that even allows its use in patients with pregnancy desire References: 1. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmune Inner Ear Disease (AIED) is characterized by rapidly progressive sensorineural hearing loss accompanied by tinnitus, with or without vertigo, which may progress to deafness if untreated. While corticosteroid (CS) therapy may

be effective in 50-70% of cases, there is often difficulty in tapering CS without decline in hearing and there are significant associated side effects. Multiple immunosuppressive regimens have been used with mixed results. A recent open label trial demonstrated intratympanic (TM) Golimumab, a tumor necrosis-α inhibitor, to be effective in stabilizing hearing loss and allow 7 of 10 long-term CS-dependent patients to completely taper off of prednisone. In this retrospective case series, we report our experience with the use of subcutaneous (SC) Golimumab.

Methods: Patients were diagnosed by experienced Otologists at House Ear Clinic and followed by Rheumatology at Cedars-Sinai for co-management of immunomodulatory therapy, from January 2013 to April 2016. Medication lists and hearing tests were reviewed throughout treatment with off-label SC Golimumab.

Results: Five patients were identified with AIED with hearing loss initially responsive to CS and difficulty with sustaining hearing with taper. There were 3 male and 2 female patients, with a mean age of 57.4. In 2 patients, 1 male and 1 female, there was previous success with steroid taper and hearing stability during the TM Golimumab trial in 2012. Patient 1 was steroid dependent (30 mg QD) for 7 years prior to trial and was able to taper off. Once hearing declined after 15 months, she was started on SC Golimumab. She continues to be maintained off steroids and showed improvement in left ear word recognition scores. Patient 2 was able to taper off steroids in the TM trial. He needed to restart steroids 16 months after trial at 60 mg due to worsening hearing loss and tinnitus. He started SC Golimumab and was able to taper off steroids within 13 months with improvements in both hearing loss and tinnitus. Patient 3 required steroids off and on for 8 years due to hearing loss and severe attacks of vertigo. When he started SC Golimumab he was on Prednisone 20 mg and was able to taper to 4 mg in 11 months, with improvement in speech recognition in both ears. He has been free of severe vertigo attacks, now with only mild episodes. Patient 4 had symptoms of hearing loss, tinnitus and vertigo and was on Prednisone 11 mg when she started SC Golimumab. She was able to taper off completely within 12 months, with improvement in speech discrimination score in both ears and improvement in all her symptoms. Patient 5 was on and off steroids for several years due to hearing loss and vertigo. After initiation of SC Golimumab, he noted increase in speech recognition in the 2ndmonth of therapy, improvement in vertigo and has been maintained off steroids. Golimumab was well-tolerated in all patients without significant complications or side effects to date.

Conclusion: The preliminary data suggests that treatment with SC Golimumab may be considered a therapeutic option for patients with AIED, and is useful as a steroid-sparing agent. Larger studies are warranted to further explore the therapeutic potential of Golimumab in AIED.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The introduction of immunotherapy with biologic agents targeting immunologic checkpoints (i.e. CTLA4 and PD-1/PDL-1) have yielded impressive gains for cancer patients. These agents exploit suppressor and regulatory pathways boosting integrated immunity against tumors but are attended by a spectrum of immune related adverse events (irAEs) most notably affecting dermatologic, pulmonary, gastrointestinal and endocrine systems. Reports of rheumatic complications have been sparse and not systematically reported. We have developed a multidisciplinary virtual clinic to evaluate and manage irAEs and now report our initial findings.

Methods: In February 2016 an interdisciplinary group was created to manage irAEs resulting from patients on approved and

experimental immune based therapies for cancer. Patients were identified by treating oncologist and then triaged by a designated advanced practitioner and seen in a facilitated fashion. Two designated rheumatologists saw all patients. A detailed retrospective review of the EMR was performed, including: gender, date of birth, age at diagnosis of malignancy, type and stage of malignancy, prior treatment (chemotherapy, radiation, surgery), checkpoint inhibitor (drug(s), date started, date of last dose), pre-existing autoimmune history, nosology of irAE (type, date of onset, diagnostic testing), irAE treatment and global response to treatment, prior autoimmune serologies.

Results: IrAEs were evaluated in 12 patients. 9 had no pre-existing autoimmune disease (AID) and 3 with AID (2 rheumatoid arthritis, 1 psoriatic arthritis) were evaluated pre-emptively prior to starting immunotherapy. In the group without AID average age at rheumatologic evaluation was 61.2 years. 5 patients had melanoma, 2 lung adenocarcinoma and 2 renal cell. All had previous treatments with either surgery, chemotherapy, radiation or in combination. Rheumatic irAEs included 4 inflammatory arthritis, 2 polymyalgia rheumatica, 5 sicca and 1 myositis. The majority of patients had more than one irAE, including hypophysitis, thyroiditis and rash. With the exception of one patient who experienced irAE 1 year after starting immunotherapy, the average time to irAE was 52 days. Rheumatic irAEs led to holding of immunotherapy in all but one patient. All cases were treated with glucocorticoids, and 3 required additional therapy with anti-tumor necrosis alpha, intravenous immunoglobulin or hydroxychloroquine. Treatment of irAEs led to significant improvement in 5 patients and only moderate improvement in 3. The lone patient with myositis developed life-threatening muscle involvement requiring hospitalization for aggressive immunosuppression. Of the 3 patients with pre-established AID, 2 experienced flares of their disease after starting immunotherapy.

Conclusion: Attendant to immunotherapy for malignancy are a growing number of newly defined rheumatic complications. These complications may require aggressive immunosuppression or even cessation of immunotherapy. The epidemiology, natural history and pathophysiology remains undefined. Rheumatologists must be increasingly aware of this spectrum so they may participate in optimal management.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although immune checkpoint inhibitors improve survival in patients with melanoma and other cancers, the alterations to the immune system induced by these medications can trigger immune-related adverse reactions. Documented immune-related adverse reactions of pembrolizumab include pneumonitis, immune-mediated colitis, hepatitis, endocrinopathies, and nephritis. The purpose of this abstract is to identify the type and frequency of immune-related adverse reactions in patients treated with pembrolizumab at our institution.

Methods: We conducted a retrospective chart review of 74 patients who received pembrolizumab therapy to treat melanoma at our institution between September 2014 and May 2016. The notes from the patients' initial oncologic evaluations and all subsequent follow-up visit notes during their treatments with pembrolizumab were evaluated. We focused on patient complaints, symptoms, physical exam results, and treatment plans. Referrals to subspecialists and hospitalization records were also reviewed if applicable and available. Complaints and adverse reactions were grouped by organ system for detailed analysis. Treatment with glucocorticoids was also recorded.

Results: Seventy-four charts were reviewed, and 69 patients had advanced melanoma and were treated with at least 1 cycle of pembrolizumab. Please refer to the table below for the type and frequency of identified immune-related adverse reactions. Rheumatology was consulted on 3 patients. One patient with a history of Raynaud's disease was evaluated for hand pain with swelling. This patient was treated with prednisone prior to evaluation, which effectively treated the pain, but there was still residual, diffuse swelling of the hands and limited extension of the wrists bilaterally, but no synovitis was identified. This patient had elevated ANA 1.1 and anti-histone antibody 1.1. Another patient had recurrent episodes of diarrhea and abdominal pain that required admission to the hospital for large-vessel vasculitis after a computed tomography scan showed thickening of the abdominal aorta and ileum as well as ileal dilation that was suggestive of ischemia due to vasculitis of the superior mesenteric artery. Finally, one patient had history of seronegative rheumatoid arthritis who was in remission and no longer taking hydroxychloroquine and had no flare ups during pembrolizumab treatment.

Conclusion: We found that the incidence of significant adverse events was higher than reported in the populations treated with pembrolizumab, including a never-reported case of large-vessel vasculitis. **Table 1: Selected Adverse Immune-Reactions Occurring in Patients Treated with Pembrolizumab**

Total Patients with Advanced Melanoma	69	
Female	27	39%

Rheumatic and Musculoskeletal Immune-Related Adverse Events due to Immune Checkpoint Inhibitors: A Systematic Literature Review

Background/Purpose: Immune checkpoint inhibitors (ICI) are effective treatments for advanced solid tumors that act by blocking negative costimulation of T-cells leading to an anti-tumor response. ICIs also cause non-specific immunologic activation leading to immune-related adverse events (IRAE), including colitis, pneumonitis, and hepatitis. Rheumatic and musculoskeletal events have been described in clinical trials, case reports, and observational studies, but have not been summarized or reviewed. This topic will become important to rheumatologists as the number of ICIs and indications for their use increase.

Methods: We conducted a systematic review of published literature (Medline, CENTRAL databases) reporting rheumatic and musculoskeletal IRAE secondary to inhibition of PD-1, CTLA-4, or PD-L1.

Results were screened for relevance and inclusion of original data. Studies were grouped by type: case series or reports, observational studies, and clinical trials. Data extraction was performed in duplicate. **Results**: Searches yielded 1725 unique results; 233 abstracts contained original data, which went on to full text screening. Of these, 51 mentioned a musculoskeletal or rheumatic IRAE and were included. Among 33 clinical trials, the incidence of arthralgia ranged from 1-43 %, while myalgia was reported in 2-20%. True rheumatic IRAE were reported less often in trials with rates of arthritis reported in 5/33 (incidence 1-7%) and vasculitis in 2/33 (incidence 2-3%). In 1 of 3 observational studies, the incidence of arthritis was 2% in patients receiving ipilimumab for renal cell carcinoma or melanoma. In case series and reports, inflammatory arthritis, inflammatory myopathy, eosinophilic fasciitis, vasculitis, and lupus nephritis secondary to ICIs were described (Table 1). No evidence-based information about treatment of rheumatic IRAE or studies evaluating specific pathogenesis was found.

Conclusion: Arthralgia and myalgia are common in patients treated with ICIs. The incidence of true rheumatic IRAEs, like inflammatory arthritis, is less clear from trials, partly due to lack of consensus on event coding and reporting of adverse events only of grade 3 or higher severity. There have been no prospective cohort studies to date that evaluate rheumatic IRAE, but more comprehensive data concerning pathogenesis, evaluation, and management are critical to inform rheumatologists, who will increasingly be referred patients for these complications of cancer therapy.

Table 1: Case reports and series describing rheumatic IRAE.

Author	ICI Drug	Indication	Clinical Presentation/s	Lab/imaging/biopsy	Treatment
Chan	PEM	Melanoma	2 cases polyarticular arthritis (wrist, knee, ankles; PIPs, wrist, elbow, knees)	ANA, RF, CCP negative; MRI: Synovitis/ tenosynovitis	NSAIDs. Pamidronate in 1, HCQ in 1
Conry	IPI	Melanoma	Arthralgia, myalgia, fever, neuro symptoms	ANA, dsDNA, RF negative	High dose IV steroids
De Valasco	NIVO	Renal cell	Joint pain/stiff, swan neck, uveitis	Hand X-Ray: no erosions	Arthropathy no report; Intraocular steroids
Fadel	IPI	Melanoma	Nephrotic proteinuria, microscopic hematuria, renal thrombosis	Positive ANA (1:100) and dsDNA; Biopsy: IgG, IgM, C3,C1q	Prednisone 1 mg/kg, anticoagulation
Golstein	IPI	Melanoma	2 cases PMR/GCA. 1 with arthralgia	↑ CRP; TA biopsies: intimal proliferation/lamina disruption	Prednisone 50-60 mg/d
Henderson	IPI	Melanoma	Orbital inflammation, conjunctival injection, foreign body sensation, limited ocular range of motion	MRI: proptosis, enlarged extraocular muscles	Prednisone: dose/duration not stated
Izzedine	IPI	Melanoma	2 cases Acute Interstitial Nephritis; Prior Sjogrens syndrome in 1 patient	Negative ANA; Renal biopsies: interstitial inflammation in both, tubular injury in 1	Prednisone 1 mg/kg then taper
Khoja	PEM	Melanoma	Myalgias, muscle ÒheavinessÓ, eosinophilic fasciitis, encephalopathy	Peripheral eosinophilia, MRI: fascial edema	Methylprednisolone 1 gm daily x 10 d, then taper
Manusow	PEM	Melanoma	Retinal vasculitis (in setting of ocular metastasis)	Fluoroscein angiography showed retinal vasculitis	Vitrectomy
Minor	IPI	Melanoma	Uterine lymphocytic vasculitis, pelvic mass and lymphadenopathy	ANA negative; Lymphocytic vasculitis uterine and ovarian vessels	Hysterectomy
Sheikh Ali	IPI	Melanoma	Dermatomyositis, Rash (eyelid, upper chest, back, knuckle erythema), proximal muscle weakness.	ANA 1:640 speckled; Anti-Jo1 negative; CK 1854 U/L	IV methylprednisolone 80 mg/day, then prednisone taper
Yoshioka	NIVO	Melanoma	Polymyositis, lung involvement, proximal muscle weakness, dyspnea	CK 2812 U/L; Decreased FVC	Prednisolone 30 mg/day, D/C NIVO
PEM: pembrolizumab; IPI: Ipilimumab; NIVO: nivolumab

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A systematic review of case reports to summarize the existing evidence on the use of checkpoint inhibitors in patients with cancer and preexisting autoimmune diseases.

Methods: We searched Medline, EMBASE, Web of Science, PubMed ePubs, and the Cochrane Central Register of Controlled Trials (CENTRAL) through January 2016 with no restrictions. References cited in the included articles were searched manually. We included case reports describing patients with cancer and autoimmune disease diagnosed before starting treatment with the checkpoint inhibitors. We extracted data on patient's characteristics, type of checkpoint inhibitors, reported immune related adverse events (irAEs), how they were managed, and their clinical outcome, if discontinuation of immunotherapy was required, and if treatment rechallenge was reported.

Results: Fourteen publications met inclusion criteria, reporting on 45 cases. Age of the cases ranged from 30 to 80 years; 25 patients (55.6%) were male. Forty three cases (95.6%) had melanoma. Preexisting autoimmune diseases included autoimmune thyroid diseases, rheumatoid arthritis, ulcerative colitis, psoriasis (two with psoriatic arthritis), multiple sclerosis, Crohn's disease, sarcoidosis, systemic lupus, Behcet disease, inflammatory arthritis, reactive arthritis, rheumatic fever, Sjogren's syndrome, transverse myelitis, and celiac disease. Of the 45 cases, 86.8% received concomitant treatment (corticosteroids, DMARDs, and biologics) for their autoimmune disease; 53.9% were still active at the time of immune checkpoint inhibitor therapy. Most received ipilimumab (88.9%). After immunotherapy: 1) 40.0% reported de novo irAEs, 2) 28.9% reported exacerbation of the preexisting autoimmune disease, 3) 8.9% reported both, and 4) 40.0% did not report any adverse events. Hypophysitis and colitis occurred in most cases (27.8% each) with de novo irAEs. Autoimmune thyroiditis, diabetes, glaucoma, interstitial nephritis, skin itching, and toxic epidermal necrolysis were also reported. Those with exacerbation of the preexisting autoimmune disease, had manifestations similar to those occurring before checkpoint therapy, and none developed new disease features. Patients were treated with corticosteroids and hormonal replacement therapy. Therapy with azathioprine, sulfasalazine, or infliximab was also reported. Discontinuation of immunotherapy was recommended in 33.3%, and resolution of irAEs was achieved in the majority of cases. Death was reported in one case with toxic epidermal necrolysis and in another with severe colitis. Treatment rechallenge was reported in a patient with ulcerative colitis who developed exacerbation of his colitis after initial use of ipilimumab. Upon rechallenge, he reported grade III anterior panhypopitutarism and tracheobronchitis. In a patient with pulmonary sarcoidosis, ipilimumab rechallenge was not associated with significant clinical symptoms.

Conclusion: Forty percent of the cases did not experience irAE or disease exacerbation, despite many having active autoimmune disease at the time of checkpoint inhibition. Further studies are needed to establish the risk-benefit profile of this novel therapy in this population.

Session Date: Monday, November 14, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: This study analyze the safety and efficiency of biologics (TNF-α antagonists, tocilizumab, rituximab and IL-1 inhibitors) in patients with autoimmune systemic diseases (SAIDs) associated to myelodysplastic syndrome (MDS).

Methods: In a French multicenter retrospective study, 28 patients with both MDS and SAID treated with at least one biological-targeted treatment were analyzed. Clinical, biological and overall treatment response was considered as complete (no more symptoms), partial (at least 50% improvement) or non-response. In patients with several lines of treatment, data were analyzed before and at the end of each line and pooled to compare overall response between steroids, DMARDs and biologics

Results: 28 patients with median age 66 [19-85] years, 11% of females were included. MDS most frequent subtypes were CMML (18%), AREB-1 (32%), CRDM (32%), 5q-(7%) with median marrow blasts 2% (0-10), normal karyotype in 12/24 (50%) cases and IPSS 0.5 (0-1). The associated SAIDs were arthritis (undifferentiated and rheumatoid arthritis in 3 (10%) cases each), Behcet's disease in 2 (7%) cases, cryoglobulinemic vasculitis in 2 (7%) cases, giant cell arteritis in 1 (4%), relapsing polychondritis in 8 (30%) cases, Sweet's disease in 3 (10%) cases and others (18%). During the follow-up of 3 (1.3-4.5) years, 112 lines of treatments were used, consisting in steroids alone (23%), DMARDs (25%), TNF-α antagonists (15%), anakinra (11%), rituximab (10%) and tocilizumab (7%). The median number of lines was 3 (1-9) and more than 5 lines were used in 13 (46%) of patients. Specific MDS treatment was used for SAIDs in 10 patients (9%) (azacytidine). Considering all 112 lines, overall response (complete and partial) occurred in 54% cases. Comparing the treatments, overall response was noted more frequently under steroids (76%) and rituximab (54%), than DMARDs (45%) and TNF-α antagonists, tocilizumab and anakinra (31%)($p<0.05$). Azacytidine allowed 71% response in steroid-dependent SAIDs. Steroid dependence occured in 25 cases with mean steroid dose 27 mg/day (10-120). During the follow-up, 20 (71%) patients presented at least one severe infection. Table 1

N=112	DMARDs N=29 (26%)	Biologics N=36 (32%)	Rituximab N=11 (10%)	Steroids N=26 (24%)	Azacytidine/BMT N=10 (9%)
Treatments					
Steroids	21 (95%)	36 (95%)	11(91%)	25 (100%)	10 (100%)
Prednisone (mg/day) before/at the end	25 (18-38) 25 (15-28)	25 (20-30) 22.5 (10-30)	20 (15-30) 18 (9-24)	60 (40-60) 25 (20-40)	25 (18-28) 20 (5-23)
Type of immunosuppressive agents	MTX 7 (24%)	Anakinra 14 (39%)	-	-	-
	CYC 4 (13%)	TNF-a antagonists 15 (42%)	-	-	-
	AZA 4 (13%)	Tocilizumab 7 (19%)	-	-	-
	MMF 5 (18%)	-	-	-	-
	CICLO 5 (18%)	-	-	-	-
	HCQ 4(14%)				
Treatment duration (months)	9 (4-21)	2.5 (1-7)	6 (4-32)	9 (2-12)	8 (3-22)
C-reactive protein level (mg/l) before/at the end	53 (39-140) 18 (3-200)	60 (22-90) / 60 (26-99)	18 (5-50) 30 (7-50)	90 (45-117) 32 (4-90)	53 (36-79) 9 (3-20)
SAID response					
SAIDs partial response	1/20 (5%)	8/30(25%)	4/11 (36%)	1/23 (4%)	5/7 (71%)
SAIDs complete response	8/20(40%)	2/30 (6%)	2/11 (18%)	18/23 (78%)	0
SAIDs non response	11/20 (55%)	21/30 (69%)	5/10 (46%)	4/23 (18%)	2/7 (29%)

Conclusion: This nationwide study demonstrates the efficiency of steroids for SAID associated to MDS, the frequency of steroid dependence and poor response to biologics, except rituximab. The efficiency of azacytidine for MDS-related SAIDs should be considered in patients with inefficacy of other strategies and steroid dependence.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: pulmonary hemorrhage (PH) may complicate systemic disease. The main objective of this study was to describe characteristics, treatment and outcome of patients presenting severe PH related to systemic disease.

Methods: we performed a French multicentric retrospective study including all cases of adult patients presenting severe PH related to systemic disease from 2000 to 2016. Severe PH was defined as PH requiring intensive care unit (ICU) admission. Data concerning clinical, biological and radiological findings were collected, as well as treatments.

Results: we identified 70 patients (52.9% men) admitted with severe PH due to a systemic disease with a median age of 48 (29.8-66.3), in 7 centers. Among these patients, 21 (30%) had a past medical history of systemic disease. Main symptom for consultation was dyspnea in 69 (98.6%) cases. Patients were hospitalized 27.5 (10-66) days after the first symptoms and 6.5 (1-29) days after the beginning of respiratory symptoms. There was evidence a pulmonary-renal syndrome in 54 (78.3%) cases, articular manifestations in 9 (13.0%) cases, skin manifestations in 16 (23.2%) cases, nervous manifestations in 12 (17.4%) cases, and digestive manifestations in 5 (7.2%) cases. ICU admission occurred 4 (1-11.5) days after hospital admission. All patients presented anemia with a median hemoglobin level of 8.2 (6.9-9.4) g/dl. Median blood creatinine level was 222 (91-429) µmol/l. Chest X-ray was normal in 3 (4.6%) patients, there was bilateral alveolar condensations in 51 (78.5%) patients and bilateral interstitial pattern in 28 (43%) patients. CT-scan was realized for 50 (71.4%) patients and was never normal. Main findings included ground glass opacities in 44 (88%) cases, nodules in 11 (22%) cases, and a pleural effusion in 6 (12%) cases. Sixty-one (87.1%) patients underwent a bronchial fibroscopy showing PH for all patients (100%). Diagnosis was made 31 (10.5-62.5) days after the first symptoms and 5 (2-10) days after hospitalization. A vasculitis diagnosis was made for 40 (57.1%) patients with ANCA, IgA and cryoglobulinemic vasculitis in 33 (47.1%), 3 (5.7%), and 4 (5.7%) cases, respectively. A connective tissue disorder was diagnosed for 21 (30%) patients, mainly with lupus and antiphospholipid syndrome (APS) in 9 (12.9%) and 6 (8.6%), respectively. Anti-MBG disease (Goodpasture syndrome) was diagnosed in 9 (12.9%) cases. Steroids were used in 69 (98.6%) patients with bolus in 61 (87.1%) patients. Cyclophosphamide and Rituximab were used for 49 (70%) and 8 (11.4%) patients, respectively. Plasmapheresis was used in 38 (54.3%) patients. During ICU stay, 67 (95.7%) patients required oxygen therapy, 34 (48.6%) were intubated with a median ventilation length of 12 (6.3-25.3) days, 40 (57.1%) required renal replacement therapy, and 25 (35.7%) vasopressive drugs. Median ICU and hospital length of stay were 11 (6.8-19.3%) and 39 (21.3-64) days. Twelve (17.1%) patients died. After a median follow-up of 7.5 (2-34) months, 17 (39.5%) patients required renal replacement therapy, and 3 (7.6%) had a chronic lung disease.

Conclusion: PH is a serious complication of systemic disease accounting for 17% of deaths. Even if the use of steroids, immunosuppressive therapy, and plasmapheresis seem to be effective, the best regimen remains to be determined.

Undifferentiated Connective Tissue Disease: A 121 Patients Audit Focusing on Initial Diagnosis and Changes over Time

Maria Leandro[1,2] and Raluca Ionescu[3,4], [1]Rheumatology, University College London Hospitals, London, United Kingdom, [2]University College London, London, Uruguay, [3]University College London Hospitals, London, United Kingdom, [4]Sfanta Maria Hospital, Bucharest, Romania

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis of Undifferentiated Connective Tissue Disease (UCTD) has raised controversy over the years regarding making the diagnosis, evolution and prognosis. Le Roy et al[1] in 1980 and most recently Mosca et al[2]in 2014 proposed classification criteria for UCTD, but confusion still exists regarding making the diagnosis of UCTD, evolution and prognosis of the syndrome and how the patient should be followed up over time.

Methods: This was a retrospective study of patients followed up in a specialist clinic in a tertiary referral centre (University College London Hospitals) with a diagnosis of UCTD, focusing on clinical and serological features, treatment, follow up and disease evolution over time.

Results: A total of 121 patients were included in the study: 93% were females; the mean age at disease onset was 39 years (range 20 to 80); and the patients were followed up for at least 1 year (mean 12 years, range 1 to 40). 78% of these patients had a stable diagnosis of UCTD, while in 22% diagnosis changed over time: 9% evolved into a specific connective tissue disease (CTD) - 4 Systemic Lupus Erythematosus, 3 Sjogren's Syndrome, 1 Rheumatoid Arthritis, 1 Systemic sclerosis and 1 Anti-synthetase Syndrome -, 7% had a change of diagnosis from a specific CTD to UCTD, 4% evolved into an overlap syndrome and 2% of the patients were no longer diagnosed as having any CTD at the end of the study. The most prevalent manifestations were joint pain (arthralgia/arthritis) in 89% of the patients, fatigue 80%, Raynaud's phenomenon 63%, skin rashes 49% and sicca symptoms 45%. Lung involvement was observed in 11% of the patients within which 8% had a nonspecific interstitial pneumonia (NSIP) and 3% had a usual interstitial pneumonia (UIP) pattern. 36% of the patients were noted to have associated gastro-oesophageal reflux disease. Serological features included positive ANA in 98%, anti-RNP 33%, anti-Ro 32%, Rheumatoid Factor 20% and hypocomplementemia was observed in 19% of the patients. 7% of the patients did not require any treatment for their UCTD, but the majority of patients were treated with Hydroxychloroquine only (75%), and the rest with other immunosupressants/immunomodulators.

Conclusion: In our study the majority of patients initially diagnosed with UCTD kept this diagnosis over time but 13% of patients evolved to a defined CTD or an overlap syndrome and in 2% of patients, symptoms and serological features eventually resolved. Although, UCTD is often mild, significant major organ involvement such as interstitial lung disease can occur, as well as evolution to a defined CTD or overlap syndrome. This should guide follow up of these patients in clinic.

Factors That Influence Therapy in Patients with Undifferentiated Connective Tissue Disease

Diana P. Pena[1] and Anca D. Askanase[2], [1]Rheumatology, Universidad Militar Nueva Granada, Bogotá, Colombia, [2]Department of Medicine, Rheumatology, Columbia University College of Physicians & Surgeons, New York, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare clinical and immunological characteristics in patients with undifferentiated connective tissue disease (UCTD) treated with hydroxycholoroquine (HCQ) in a large academic clinical practice.

Methods : This cross-sectional study included all patients diagnosed with UCTD according to the preliminary classification criteria(1), seen at the Columbia University Lupus Center in New York, from January to December 2015. Clinical and immunological variables were ascertained. Chi squared tests were used to compare the following characteristic between treated and untreated patients: demographic characteristics, number of ACR criteria, SLICC criteria, individual symptoms and laboratory values.

Results : Eighty-three patients were identified; 93% were female, mean age at diagnosis of 44 years ±14.9; 67% were Caucasian, 20% Hispanic and 11% Black/African American; median disease duration of 3.91 years±5.35 (1-27). The most prevalent symptoms that required medical attention are described in the Figure 1.

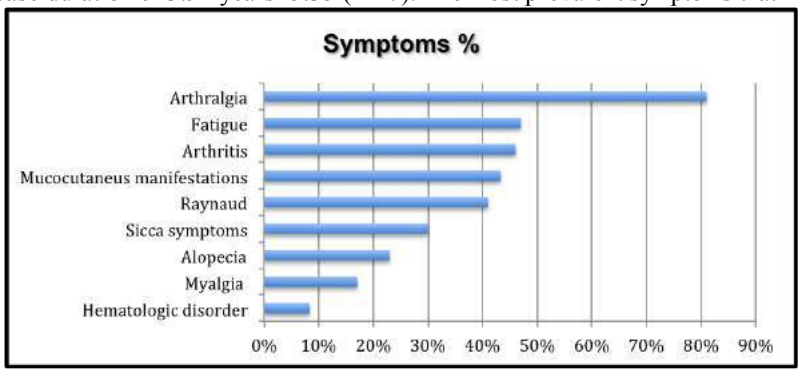

Figure 1. 49.4% of patients had a family history of autoimmune diseases. 95% of patients had positive antinuclear antibody (ANA) titers and 5% were ANA negative Ro/SSA+, 88% had titers ≥ 1:160, with speckled pattern in 69% of patients. 16% of the patients studied met SLICC SLE criteria. Half of the patients, 42(51%) were treated with HCQ and 41(49.3%) were not treated. The patients treated with HCQ were more likely to also meet SLICC criteria (10 vs. 3, respectively; p=0.03), have a history of arthralgia (38 vs. 29; p=0.02), arthritis (28 vs. 10; p=0.0001), and fatigue (25 vs. 14; p=0.02). A history of low complement was more prevalent in the treated group (12 vs. 3; p=0.01). 38 patients had folllow-up greater than 3 years; of these 18 had a strong family history of autoimmune diseases. While only 17(45%) patients had been treated with HCQ, we did not observe any increase in the titer and/or number of autoantibodies or clinical manifestations over the 3 years of follow-up in any of these 38 patients.

Conclusion : Data from this single-center cohort of patients with UCTD show that patients treated with HCQ by their rheumatologist are more likely to have multiple clinical criteria and low complement compared to those that were not treated. These data suggest that rheumatologists treat pre-clinical autoimmunity in the setting of clinical symptoms. None of patients were treated based on serologies alone. Longitudinal studies are needed to evaluate the long-term impact of HCQ on clinical and seologic outcomes of patients with UCTD. **References:** (1) Mosca M, et al. SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Steroid-responsive encephalopathy and associated autoimmune thyroiditis (SREAT) is characterized by encephalopathy and the presence of antithyroid antibodies. We describe the clinical presentation, outcome and treatments for SREAT by a systematic review of the literature.

Methods: MEDLINE via PubMed, Web of Science and the Cochrane Library were searched for articles published until 2015. Inclusion criteria were unexplained encephalopathy with antithyroid antibodies.

Results: We found reports of 251 patients (median age 52 years [range 18–86], 73% females, 80 [32%] with preexisting thyroiditis). Patients presented encephalitis signs with convulsions (n=117; 47%), confusion (n=115, 46%), speech disorder (n=91, 37%), memory impairment (n=107, 43%), gait disturbance (n= 67, 27%) and persecutory delusions (n=61, 25%). 28 patients (11%) presented progressive memory impairment and 26 (10%) isolated psychiatric disorders. In serum, 34% of patients were positive for anti-thyroid peroxidase (TPO) antibodies, 7% for anti-thyroglobulin (TG) antibodies, and 69% both. Thyroid-stimulating hormone levels were usually normal, at 2 UI/ml [0.001–205]. Cerebrospinal fluid analysis showed mild to moderate hyperproteinorachia in 107/131 patients (82%), with median level 0.71 g/l [0.13–7.65]. Cerebrospinal fluid from 10/53 patients (19%) was positive for anti-TPO antibodies, 2/53 (4%) anti-TG antibodies and 28 (53%) both. Electroencephalography findings were abnormal for 82% of patients, showing diffuse slowing consistent with encephalopathy (70%) or epileptic activity (14%). The first-line treatment was steroids in 193 patients and other immunosuppressive drugs in 10 (intravenous immunoglobulin (n=4), azathioprine (n=2), plasma exchange (n=2), rituximab (n=1) or hydroxychloroquine (n=1). Among 146 patients evaluated within a median delay of 5 days [1-20], 134/146 (92%) showed neurological response. At a median final follow-up of 12 months [range 0.2–110], 91% of patients showed complete or partial neurological response, with anti-TPO and -TG antibody titers at 347 UI/ml [0–825000] and 110 UI/ml 0–50892], respectively. During follow-up, 40 patients (16%) experienced at least one relapse. Relapse was more frequent in patients with initial coma (26% vs 13%, p=0.08).

Conclusion:

SREAT is a rare syndrome with various clinical presentations that should be considered in any patient with acute or subacute encephalopathy without obvious etiology but also with progressive cognitive impairment and psychiatric signs, to quickly start corticosteroid treatment. The benefit of other immunosuppressive drugs remains to be determined. Table 1:

Table 1. General characteristics of 251 patients with steroid-responsive encephalopathy associated with autoimmune thyroiditis (SREAT).

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Neuromyelitis optica (NMO) is an immune-mediated inflammatory disorder of the central nervous system that has been associated with systemic autoimmunity often cared for by rheumatologists. We examined whether clinical characteristics and treatments differed among patients with NMO treated by rheumatologists compared to non-rheumatologists.

Methods: We performed a retrospective cohort study using a large national health plan database from May 1, 2000 - June 30, 2013. Data collected included inpatient, outpatient, and pharmacy claims. Subjects were identified by having at least one *International Classification of Disease, Ninth Revision, Clinical Modification* (ID-9-CM) code for NMO, receipt of glucocorticoids, and an inpatient/acute care visit within 90 days of the index date (defined as the first documented code for NMO). Subjects <1 year of age and with ≥2 codes for multiple sclerosis were excluded. Subjects required continuous health plan enrollment for 6 months prior to and 12 months after the index date. The exposed group included subjects with ≥ 1 NMO diagnosis code documented by a rheumatologist. Systemic autoimmune conditions were identified by their respective ICD-9-CM codes. Pharmacy claims (via National Drug Code) were used to identify medication use. We were unable to reliably assess intravenous medications.

Results : 156 subjects met study criteria. Subjects were predominantly adult (90%), female (63%) and Caucasian (66%). Median age among the pediatric (<18 years old) group (N=15) was 12 years (IQR: 4-15) and among the adult cohort was 49 years (IQR: 38-64). 41% of subjects had at least one systemic autoimmune condition. A rheumatologist documented at least one NMO ICD-9-CM code for 27% of the subjects (N=41). Table 1 shows demographics, clinical characteristics and treatment regimens for subjects treated by a rheumatologist versus non-rheumatologist. There was no statistically significant difference in the proportion of subjects with a concomitant systemic autoimmune disease between the two groups (all p>0.05). Use of any non-glucocorticoid immunosuppressant was more common in the rheumatologist group (p<0.01). This finding persisted when restricted to the adult cohort (p<0.01) but was not true for the pediatric cohort (p=1.00). Azathioprine and mycophenolate mofetil were significantly more common in the rheumatologist group (p=0.02 and p=0.01, respectively). Methotrexate was more common among rheumatologists (4.9% vs. 0%) but was only marginally significant (p=0.07).

Conclusion: Patients with NMO cared for by a rheumatologist were more likely to receive non-glucocorticoid immunosuppressive agents. The most commonly used medications were azathioprine and mycophenolate mofetil. Future studies should address the use and effectiveness of non-glucocorticoid medications in the rheumatologic management of pediatric NMO.

Clinical Analysis of Hypertrophic Pachymeningitis

Risa Wakiya, Atsushi Kondo, Hiroki Ozaki, Hiromi Shimada, Shusaku Nakashima, Miharu Izumikawa, Tomohiro Kameda and Hiroaki Dobashi, Internal Medicine Division of Hematology, Rheumatology, and Respiratory Medicine, Kagawa University, Kagawa, Japan

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hypertrophic pachymeningitis (HP) is a rare, chronic and inflammatory disorder. HP is characterized by thickening of the cranial dura mater. The cause of HP was reported to be associated with some disorders such as infectious disease, connective tissue disease (CTD) and malignant tumor[1)]. Recently, some reports showed that some patients with hypertrophic pachymeningitis may have myeloperoxidase anti-neutrophil cytoplasmic antibody (MPO-ANCA)-positive status[2)]. However, the clinical characteristics and specific treatments for CTD associated hypertrophic pachymeningitis remain elusive. Because of its low incidence of HP, clinical course such as symptom, laboratory data and treatment strategy was unclear. [1) 2)] Previous reports have shown that HP patients usually respond to glucocorticoid (GC), but not some patients were recurred during steroid tapering [3)]. We extract the clinical features and treatment regimen, and investigate the clinical characteristics of HP. We examined HP patients in our institution in order to reveal the incidence of CTD complication and the efficacy of treatment.

Methods: We enrolled the 6 patients (M/F: 2/4) with HP diagnosed and treated in our facility between 2000 and 2015. We extract the subjects as follow; initial symptom, underlying disorder, initial intervention and the efficacy of treatment.

Results: The mean age at diagnosis of HP was 43.7 years old (range; 18-73). The initial symptom of HP was headache in 5 cases, eye manifestation in 3 cases, fever in 2 cases, nausea in 1 case and tinnitus in 1 case. Underlying disorders complicated HP existed in 4 of 6 cases and all 4 cases diagnosed CTD (two only Sjögren's syndrome, one mixed connective tissue disease and Sjögren's syndrome, one granulomatosis with polyangitis). Performed meningeal biopsy was only 1 case. Infiltration of lymphocytes and anti-IgG4-positive plasma cells (IgG4/IgG≧40%), but we couldn't diagnose IgG4-related disease. The intervention was conducted with glucocorticoid (GC) treatment in all HP patients. 3 cases were taken methylprednisolone-pulse. Two third of 6 HP patients had well responded to initial GC treatment. However two patients were refractory treatment. One case treated with methotrexate combined with GC, and another case cyclosporine A.

Conclusion: In HP patients in our institution complicated with CTD, headache and eye manifestation often observed as initial symptoms. Several reports showed that serum IgG4 level was normal in IgG4-related HP as this case. Sjögren's syndrome is most frequent complication in our hospital and these HP patients are refractoriness to GC. It is necessary for refractory HP patients to treat using immunosuppressive therapy with combined GC.

Asymptomatic Coccidioidomycosis in Patients with Rheumatic Disease: 8 Years of Experience

Usman Ajaz[1], Jeffrey R. Lisse[2], Neil M. Ampel[3] and **Dominick Sudano**[4], [1]Department of Medicine, University of Arizona, Tucson, AZ, [2]Arizona Arthritis Center, University of Arizona, Tucson, AZ, [3]Department of Infectious Disease, Southern AZ VA Medical Center, Tucson, AZ, [4]Department of Rheumatology, University of Arizona, Tucson, AZ
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Coccidioidomycosis (valley fever) is an endemic fungal infection that typically causes a self-limited pulmonary illness in the Southwestern United States,. Immunosuppressed patients are at higher risk of more severe infection, and this includes patients with rheumatic disease on disease-modifying antirheumatic drugs (DMARD) or biologic response modifiers (BRM). At our institution, the routine practice is to screen patients for coccidioidomycosis before initiating BRM therapy, and then annually thereafter. Through this process, we have identified asymptomatic patients with positive serologies. This is concerning as it indicates a recent infection. A 2012 retrospective study proposed a protocol that suggested continuing antirheumatic therapy rather than stopping it in asymptomatic patients. Following this protocol has not resulted in the development of a more severe infection in asymptomatic patients.

Methods: A cohort study at two centers in Tucson, Arizona identified patients who developed coccidioidomycosis while on DMARD or BRM therapy. Several patients had asymptomatic illness as defined as a positive serology found on surveillance labs, not ordered in response to symptoms, and no concurrent signs or symptoms of active disease. Patients were seen at least once between 2007 and 2015. The study emphasized management of BRM/DMARD therapy, as well as antifungal therapy and duration.

Results: Seventy one patients with rheumatic disease were diagnosed with coccidioidomycosis, and 19 of them had positive serologies and no symptoms. Most (17/19) had rheumatoid arthritis, 1 had psoriatic arthritis, and 1 had dermatomyositis. Sixteen patients were identified during routine annual surveillance, and three were identified during pre-BRM therapy screening. Eight patients were on BRM alone, 9 on BRM with a DMARD, and 2 on a DMARD alone. Three patients were also on prednisone. Six patients stopped their antirheumatic therapy, while the rest continued without interuption. BRM therapy was restarted in 5 of these patients, most resuming therapy within 1 month of infection (range 0.5 – 12 mos). One did not resume therapy due to osteonecrosis of the jaw. Six patients received fluconazole, duration ranging from 8 to 73 months (median 30.5 mos). Ten patients neither reduced antirheumatic therapy, nor started antifungal treatment. The median follow up is 43 months, and no patients have developed symptomatic illness. Three patients have been lost to follow up, and one died from unrelated causes.

Conclusion: Positive coccidioidomycosis serologies in asymptomatic patients are concerning as they are indicative of a recent active infection. This cohort supports the management strategy of continuing DMARD and BRM therapy in patient with asymptomatic disease. It also suggests that in patients with persistently positive serologies, antifungal therapy should be considered. In the past 8 years there have been no complications in the asymptomatic cocci patients who continued BRM and DMARD. The management strategy implemented may be effective in guiding therapy.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Pneumocystis pneumonia (PCP) is one of the severe opportunistic infections in immunocompromised patients. PCP is still a leading cause of death in patients with connective tissue diseases treated with glucocorticoid, immunosuppressant and biologic agents. However, the mortality rate and factors related to death for PCP remain unclear. The aim of this study is to identify the prognostic factors for PCP in immunosuppressed patients with connective tissue diseases.

Methods: A total of 52 patients with connective tissue diseases developing PCP were included in this study. PCP was diagnosed by clinical symptoms, radiological findings, respiratory specimens (the microscopic demonstration of Pneumocystis jirovecii or pneumocystis-specific nested polymerase chain reaction) and serum β-D glucan. The patients were divided into two groups according to the outcome (Survivors group or Non-survivors group). Baseline demographics, treatment for the underlying connective tissue disease, laboratory findings at the diagnosis of PCP, and treatment for PCP were compared between the two groups.

Results: Of 52 patients with PCP, 6 deceased and a mortality rate was 11.5%. There were no significant differences in age, gender, type of connective tissue disease, previous immunosuppressive treatments between survivors and non-survivors. The treatment regimen for PCP was not different between the two groups. The initial trimethoprim-sulfamethoxazole treatment failure was also not statistically different between the two groups. In univariate analysis, while the levels of serum β-D glucan, KL-6, IgG and PaO2, and the number of lymphocytes were not statistically different, the lower level of serum albumin, and higher levels of serum C-reactive protein and lactate dehydrogenase were significantly associated with mortality. Multivariate analysis showed that the lower level of serum albumin was an independent poor prognostic factor for the death with PCP.

Conclusion: The low serum albumin is an independent prognostic factor for mortality in PCP developed in immunosuppressed patients with connective tissue diseases.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Immunosuppressive therapy, which is frequently used to treat various rheumatic diseases, increases risk of opportunistic infection. However, few reports were available on the prognosis of CMV infection in rheumatic diseases. While prognosis of CMV infection without end-organ involvement is excellent, there is a clinical dilemma to start anti-viral treatment because it is difficult to assess end-organ involvement of CMV due to systemic manifestations of underlying disease or co-existence of other

infections. This study aimed to assess the predictors of mortality in rheumatic diseases patients with CMV infection.

Methods: We retrospectively reviewed the Severance Hospital¡¯s electronic medical records of rheumatic disease patients with CMV infection between 2005 and 2016. Clinical and laboratory data on patients including immunosuppresive treatment, CMV titer by real time PCR, anti-viral treatment were collected. Statistic analysis was done using internet based "R" software. Characterization of the features was analyzed using descriptive statistics and Fisher's exact test. Separate analyses of variance (Kai analysis) examined. Mortality was compared across the tertiles by CMV titer.

Results: A total of 68 rheumatic disease patients with CMV infection were evaluated (mean age 56.6 years, 45 women(68%), mean disease duration 6.4 years, 22 deaths). Rheumatic disease¡¯s distribution was like table 1. Mortality rate was significantly higher for the upper tertile CMV group than lower tertile CMV group (table 2, p<0.05). Comparison of the death group and the survival group revealed CMV count (239,252.2 ¡¾ 389,940.3 vs. 63,126.1 ¡¾ 197,791.7, p=0.056), lymphocyte count (917.0 ¡¾ 1,914.6 vs. 682.0 ¡¾ 911.0, P=0.589), using ganciclorvir (10 (45.5%) vs. 15 (32.6%), p=0.448) and using mechanical ventilation (13 (59.1%) vs. 3 (6.5%), p<0.0001).

Conclusion: High CMV titer is associated with mortality in rheumatic disease patients even though anti-viral treatment was not associated with mortality. It is still unknown whether high CMV titer is the direct cause of mortality or the result of critical condition. Larger studies are needed to confirm the findings.

Table 1. Distribution of Rheumatic disease

outcome	Death (N=22)	Survival (N=46)
ANCA associated GN	1 (4.5%)	1 (2.2%)
AOSD	1 (4.5%)	1 (2.2%)
Behcet's disease	0 (0.0%)	3 (6.5%)
Churg-Strauss syndrome	0 (0.0%)	2 (4.3%)
Dermatomyositis	2 (9.1%)	3 (6.5%)
Microscopic polyangiitis	1 (4.5%)	1 (2.2%)
Polymyositis	1 (4.5%)	2 (4.3%)
RA	6 (27.3%)	11 (23.9%)
Sjogren syndrome	1 (4.5%)	0 (0.0%)
SLE	6 (27.3%)	19 (41.3%)
Takayasu's disease	1 (4.5%)	0 (0.0%)
undifferentiated arthritis	0 (0.0%)	1 (2.2%)
Wegener's granulomatosis	2 (9.1%)	2 (4.3%)

Table 2. Outcome comparison of the upper and lower tertile group by CMV titer

	Upper tertile (N=22)	Lower tertile (N=22)	p
outcome			0.028
death	12 (54.5%)	4 (18.2%)	
survival	10 (45.5%)	18 (81.8%)

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary MAC disease is caused by MAC and the incidence is increasing in Japan. It is also becoming a great concern in the field of rheumatology because there are no drugs which show good anti-MAC activity. Another problem is diagnostic criteria for pulmonary MAC disease that has been revised many times, in which positive sputum culture more than twice is included. However, it takes long time to get culture positive twice. Measurement of anti-MAC antibody was developed by Kitada, et al (Am J Respir Crir Care Med 2008) and is commercially available (Capilia MAC, TM), and the sensitivity has been reported to be 70 - 80 % with very good specificity. We aimed to detect risk factors for pulmonary MAC disease in patients with rheumatic diseases and the significance of the measurement ant-MAC antibody.

Methods: Subjects were 88 patients with various rheumatic diseases whose chest CT findings showed small nodular opacities, bronchiectasis, and, in cases, cavities which are difficult to distinguish from pulmonary lesions due to rheumatic diseases itself. Sputum culture was done more than twice, and blood was drawn for anti-MAC antibody detection. PCR test for MAC in sputum samples was done in most of the patients. Fourteen clinical factors, such as age, gender, BMI, underlying diseases, dose of PSL and MTX, and others, were collected and multivariate analysis was done to find risk factors of pulmonary MAC disease.

Results: Out of 88 patients, 12 patients fulfilled the criteria for pulmonary MAC disease. However, 2 patients showed sputum culture positive once and PCR test for MAC in another sample was positive, and these patients were treated as pulmonary MAC disease resulting in good response. Therefore, we included these 2 patients into pulmonary MAC disease. Multivariate analysis found only one significant risk factor, low BMI. The mean BMI with and without pulmonary MAC disease were 17.5 +/- 2.3 and 21.3 +/- 3.7, respectively ($p < 0.0005$). In patients with BMI less than 18.5, OR of developing pulmonary MAC diseases was 12.3. Anti-MAC antibody was positive in 11 patients. In 14 patients diagnosed as pulmonary MAC disease, ant-MAC antibody was positive in 9, and 2 patients not diagnosed as MAC disease were positive for anti-MAC antibody. The sensitivity, specificity, PPV and NPV of ant-MAC antibody for pulmonary MAC disease were 64.3 %, 97.3 %, 81.8 %, and 93.9 %, respectively.

Conclusion: Low BMI was only one risk factor of developing pulmonary MAC disease in patients with rheumatic diseases, which is consistent with that in general populations. Measurement of anti-MAC antibody can be a replacement of one positive sputum culture, but further study is definitely needed.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To study inflammatory and structural ultrasound lesions in patients with hereditary hemochromatosis (HH) with and without arthropathy

Methods: Cross-sectional study of 50 patients with HH [mean age 57.5 (±SD 11.6) years years, 26.0% female, median disease duration 8.8 (range 0.8-27.6) years] recruited at medical centers in Graz, Oberndorf and Vienna. HH arthropathy (HH-A) was defined as the presence of hand pain (VAS>10mm and/or ≥1 tender joint) plus ≥1 radiographic finding compatible with HH-A. Thirty-eight patients with hand osteoarthritis (HOA, according to ACR criteria) were studied for comparison [mean age, 60.1 (±SD 9.4), 89.5% female). Clinical examination was performed at 68 joints, and we retrieved data on hand function, pain and overall health status (all using a VAS), morning stiffness, ferritin levels and phlebotomy. Ultrasound was conducted at 40 joints (hand joints, hips, knees, ankles) by one rheumatologist blinded to clinical data using an ESAOTE Twice ultrasound device. Synovial hypertrophy and/or joint effusion (SH/E), Power Doppler (PD), osteophytes and erosions were subjectively graded from 0 to 3 in accordance with prior publications.

Results: Twenty-six (52.0%) HH patients were classified as HH-A. Mean age [57.1 (±SD 13.0) vs. 57.8 (±SD 9.7) years], median disease duration [7.5 (3.2-22.8) vs. 10.3 (0.8-27.6) years), median ferritin levels [83.6 (23-1060) vs. 66.1 ng/ml (14-853) as well as median duration [6.0 (0-23) vs. 6.0 (0-26) years] and number of phlebotomies/year [3 (0-5) vs. (2.5 (0-12)] were comparable between HH patients Without Arthropathy (HH-WA) and HH-A patients.<span">Patients with HH-A and HOA had a similar number of tender [4 (0-29) vs. 3 (0-40)] and swollen joints [0 (0-7) vs. 0 (0-6)], and similar scores for hand function [39.5 (0-100) vs. 47.0 (0-92) mm] and hand pain [31.0 (0-72) vs. 23.0 (0-86) mm]. These findings were absent/low in HH-WA patients by definition.Using ultrasound, we observed ≥1 erosion in 10 (41.7%) HH-WA patients, 12 (46.2%) HH-A, and 21 (55.3) HOA patients (p>0.2). Similarly, ≥1 osteophyte was observed in 23 (95.8%), 26 (100%) and 38 (100%) patients, respectively (p>0.2); median osteophyte score, however, was higher in HH-A than in HH-WA patients [19 (0-53) vs. 30 (3-69), p=0.019] and comparable between HH-A and HOA [36 (8-68)]. SH/E were observed in a high portion of HH-WA, HH-A and HOA patients [20 (83.3%), 25 (96.2%) and 38 (100%), respectively] whereas PD-findings were more common in the HH-A [n=21 (80.8%)] and the HOA [n=31 (81.6%)] than in the HH-WA group [n=12 (50.0%), p<0.05]. Also, SH/E scores were comparable between the three groups [HH-WA: 6.5 (0-25), HH-A 9 (0-32) and HOA 11.5 (1-30)] whereas PD-scores were higher in HH-A [2.5 (0-17] and HOA [2 (0-17] than in HH-WA cases [0.5 (0-9), p<0.05). In HH-A patients, there was a weak correlation between PD-score and hand function (0.23, p=0.031), whereas the other clinical parameters were unrelated to ultrasound results.

Conclusion: A high prevalence of ultrasound verified inflammatory and structural lesions were found in patients with hereditary hemochromatosis. Higher PD scores were observed in patients with arthropathy, and these were related to limited hand function.

ASAH1 Gene Mutations Cause Acid Ceramidase Deficiency (Farber Disease), with Symptoms Including Arthritis and Subcutaneous Nodules. Patients Are Often Misdiagnosed with JIA, and Slowly Progressive Disease May Only be Diagnosed in Adulthood

Alexander Solyom[1], Calogera Simonaro[2] and Edward Schuchman[3], [1]Roivant Sciences, New York, NY, [2]Genetics & Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, [3]Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mutations in the *ASAH1* gene cause acid ceramidase deficiency, accumulation of the pro-inflammatory and pro-apoptotic lipid ceramide, and a distinct set of clinical features, which can vary greatly in severity (Farber disease). Typically, Farber disease presents in childhood with polyarticular arthritis or joint contractures, subcutaneous nodules and a hoarse or weak voice due to nodule formation in the larynx. A recent report of patients diagnosed at over 40 years of age indicates that peripheral osteolysis can also

be caused by *ASAH1* mutations, and reinforces the fact that mild forms of the disease may only be diagnosed in adulthood. The prevalence of Farber disease is currently unknown, but it is likely underdiagnosed due to lack of awareness of the clinical presentation and of the availability of diagnostic testing. All known phenotypes are associated with autosomal recessive inheritance. Acid ceramidase enzyme replacement therapy is currently under development.

Methods: Using physician reporting and retrospective chart review, data from 22 recently diagnosed Farber disease patients has been collected to explore the spectrum of symptoms and disease severity associated with acid ceramidase deficiency. When available, data on previous diagnosis, presence of specific symptoms, age at presentation of first symptom, and time between presentation of each additional symptom was compared between patients with severe, moderate and attenuated phenotypes.

Results: Data indicates that Farber disease represents a broad clinical spectrum, with first symptoms presenting most often from infancy through late childhood, with a mean age at onset of 1.2 months for the most severe form in this group of patients, and reinforces the validity of the characteristic features of Farber disease: polyarticular arthritis, subcutaneous nodules and a hoarse or weak voice. However, there are patients who present with only one or two of these symptoms, and the spectrum of disease includes remarkably attenuated forms (mean age at onset of 4.5 years). 10 of 14 patients (71%) with moderate or attenuated disease were initially misdiagnosed with JIA. Treatment with anti-inflammatory therapies or disease modifying anti-rheumatic drugs (including biologics) may have some effect on the severity of pain and inflammation in Farber disease patients, and this can initially reinforce a misdiagnosis. Such treatments cannot resolve the major symptoms of Farber disease, or prevent disease progression.

Conclusion: The broad spectrum of phenotypes associated with *ASAH1* mutations indicate that Farber disease should be considered in the differential diagnosis of therapy resistant arthritis in childhood and adulthood, as well as in cases of peripheral osteolysis. A better understanding of the clinical symptoms associated with *ASAH1* mutations, and the availability of biochemical and genetic diagnostic testing, means that screening programs can be initiated to identify patients with Farber disease from among those currently treated by adult and pediatric rheumatologists around the world.

Abstract Number: 1356

Correlation of Erythrocyte Sedimentation Rate with Glycohemoglobin Values and Other Patient Factors

Brian LaMoreaux, Dept of Internal Medicine, Division of Rheumatology, The Ohio State University, Columbus, OH
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The erythrocyte sedimentation rate (ESR) is a laboratory test commonly used in clinical practice as an assessment of systemic inflammation. The glycohemoglobin (A1c) measures long-term serum glucose levels to screen for diabetes and evaluate glycemic control. Both of these tests use red blood cells to determine their values. The result of the ESR test is nonspecific and varies with factors including patient age, gender, body size, pregnancy, anemia, albumin, and more. This project sought to determine the correlation of A1c to ESR values while accounting for other relevant clinical factors.

Methods: Historical biomedical data from 2011 to 2014 were collected and analyzed. Patients with ESR values resulted within a 30-day period of glycohemoglobin values were included, with a total sample size of 22,984. Additional information was collected including age, gender, body mass index, smoking status, platelets, WBCs, C-reactive protein and hemoglobin. The dataset was then analyzed to determine the correlation of ESR values with glycohemoglobin values. Additional analyses evaluated the impact of other variables on the ESR value and construct a model based on this using forward selection methods.

Results: The correlation between ESR and A1c levels was 0.268, with a p-value of 2.2e-16 indicating a strong positive correlation.

Other variables that were significantly associated with the ESR level included hemoglobin, gender, creatinine, platelets, white blood cells (WBCs), and age (see **table 1**).

Table 1: Effect of Individual Variables on ESR Values.

Variable	Estimate	Standard Error	p-value
Intercept	37.6	1.26	<0.00001
Hemoglobin	-3.5	0.06	<0.00001
Glycohemoglobin	2.15	0.08	<0.00001
Creatinine	2.17	0.09	<0.00001
Platelets	0.02	0.001	<0.00001
WBC	0.24	0.03	<0.00001
Age	0.24	0.03	<0.00001
Male gender	-2	0.3	<0.00001

Fitting the full model using significant predicting variables yielded the following: **Model:** Expected (ESR) = 37.6 – 3.5(hemoglobin) + 2.15(glycohemoglobin) + 2.17(creatinine) + 0.02(platelets) + 0.24(WBCs) + 0.24(Age) – 2(Male) This model had an overall F-statistic of 1418 with a p-value of 2.2e-16, indicating a highly significant model. The R squared value for this model was 0.3102, indicating that 31% of the variability of ESR was explained by the model.

Conclusion: The traditional model used in interpreting erythrocyte sedimentation rates (ESR) is age divided by two plus five for males, though this is understood to be an incomplete model. It is established that many factors effect ESR values, and this project sought to quantify the effect of these variables on actual ESR values using a retrospectively collected large biomedical dataset. The variables that had a significant effect on ESR levels are shown in **table 1** and in the **model**. The most significant variable was hemoglobin, which had an inverse association with ESR. Other variables had a direct correlation to ESR. Elevated ESR values often result in referrals to rheumatology, and if there was a more accurate way to reliably interpret what an 'average' ESR level would be given a set of specific clinical factors it may help physicians and rheumatologists to frame and understand the significance of a given patients' ESR value.

Clinical Description of Patients with Cytoplasmic Discrete Speckles on Indirect Immunofluorescence on HEp-2 Cells in a Universitary Hospital

Martin Brom[1], Carolina Eva Carrizo[2], Roberto Arana[3] and Cecilia N. Pisoni[3], [1]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]CEMIC, Buenos Aires, Argentina, [3]Rheumatology and Immunology, CEMIC, Buenos Aires, Argentina

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Indirect Immunofluorescence (IIF) shows different nuclear and cytoplasmic fluorescence patterns depending on the antibodies present in the cell. Cytoplasmic patterns are an unusual finding. Their study is not standardized and their clinical value is unknown. The Cytoplasmic Discrete Speckles (CDS) pattern comprises several antigens distributed in the endosomes, lysosomes and GW bodies. The purpose of this study is to describe demographic and clinical characteristics of patients with CDS pattern on IIF in a cohort of patients.

Methods: This is a retrospective descriptive study. We included all patients with a CDS pattern on IIF on HEp-2 cells with a titer equal or greater than 1/80, using a database of all IIF performed in a referral laboratory of a universitary hospital between 2007 and 2015.

We analyzed demographical and clinical information available on their clinical records. We included sex, age, health history and symptoms compatible with autoimmune diseases.

Results: In that period of time, 7085 IIF studies were performed and 21 patients showed CDS pattern (0.29%). We reviewed 17 out of 21 clinical records. We excluded 4 patients that did not have clinical records at the hospital. All patients were female, with a median age of 62 (range 50-81 years). Demographics and clinical characteristics are shown in table 1. We found no relationship between the IIF titer, health history and symptoms compatible with autoimmune diseases. Fourteen of the patients (82%) had at least one symptom of autoimmune disease. Eight of the patients (47%) had an autoimmune disease, being Hashimoto Thyroiditis the most frequent one (50%).

A high rate of respiratory symptoms was observed among these patients. Six of them (34%) referred dyspnea and dry cough. They had different underlying causes, including chronic obstructive pulmonary disease (COPD). Symptoms description is shown in table 2.

Conclusion: CDS pattern is uncommon. We found no association with any particular disease, and none of our patients had any of the diseases described in other studies. Taking into account the low prevalence of this pattern and the heterogeneity of symptoms, the study of antibodies underlying this IIF pattern seems more useful for cell biology study than for clinical use.

Table 1.

	Age	Sex	IIF titer	Health History	Sum of symptoms compatible with autoimmune disease
1	56	Female	1280	No	0
2	70	Female	1280	Hypothyroidism (antibodies lacking), gout, scleroderma, pulmonary hypertension, restrictive cardiopathy	4

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Response of Hidradenitis Suppurativa to Biologic Therapy

Background/Purpose: Hidradenitis suppurativa (HS) is a chronic, debilitating inflammatory disease of apocrine sweat glands, characterized by recurrent abscessing inflammation. The prevalence is around 1-4% in young adults. Despite the prevalence of HS in the US it largely unstudied and treatment is extrapolated from studies done in a northern European population. Molecular drivers of HS are poorly understood, and traditional disease modifying anti-rheumatic (DMARD) therapies have been largely ineffective. Targeted biologic therapies including TNF-α inhibitors have been used with some success. Adjuvant biologic therapy after radical resection has been shown to reduce risk of recurrence in HS. The purpose of this study is to analyze the outcomes of patients with HS followed in our dedicated HS clinic and to assess how treatment with biologic agents affects disease activity scores including Hidradenitis Sartorius Score (HSS) and Hurley Stage in a US population.

Methods: This research was conducted through the Wound Etiology and Healing Study (WE-HEAL Study), an IRB approved biospecimen and data repository. All subjects gave written informed consent for longitudinal collection of their data while they receive treatment according to standard of care. At the time of data lock, of the 565 patients enrolled in the WE-HEAL study, 67 had HS. Modified Hidradenitis Sartorius Score (HSS) and Hurley Stage were analyzed according to medication exposures.

Results: Consistent with the known demographics of HS, the mean age of HS patients in this cohort was 40.12 ± 13.82 years, and they were 67.2% female and 71.6% African American. Mean HSS score at the first visit was 62.48 ± 47.45, and 67.2% were Hurley Stage III at the time of first visit. In this cohort patients treated with TNF inhibitor showed significant reduction in HSS score after treatment (mean HSS 74.88 ± 49.87 pre-treatment and 30.48 ± 42.18 post-treatment, p=0.0002).

Conclusion: The cohort of HS patients followed in the WE-HEAL study is representative of the population affected in the US with a high prevalence of women and African Americans. Treatment with TNF-α inhibitors was associated with significant improvement in disease activity scores in this population.

New Markers for Celiac Disease: Anti-Neo-Epitope Human and Microbial Transglutaminases

Torsten Matthias[1], Sandra Neidhöfer[2], Patricia Jeremias[1] and Aaron Lerner[3], [1]Aesku.Kipp.Institute, Wendelsheim, Germany, [2]AESKU.KIPP.Stitute, Wendelsheim, Germany, [3]B. Rappaport School of Medicine, Technion-Israel Institute of Technology, Haifa, Israel

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Microbial transglutaminase (mTg) and human tissue Tg (tTg) complexed to gliadin peptides present neo-epitopes. Antibodies against these complexes are called tTg neo-epitope and mTg neo-epitope. Reliability of antibodies against the

non-complexed and complexed forms of both transglutaminases to reflect intestinal damage and to diagnose the pediatric Celiac Disease (PCD) was compared.

Methods: 95 PCD patients, 99 normal children (NC) and 79 normal adults (NA) were tested using the following ELISAs detecting IgA, IgG or both IgA+IgG combined: *AESKULISA*® tTg (tTg, RUO), *AESKULISA*® tTg New Generation (tTg neo-epitope (tTg-neo)), *AESKULISA*® mTg (RUO) and *AESKULISA*® mTg neo-epitope (mTg-neo, RUO). Marsh criteria were used for the degree of intestinal injury.

Results: All anti-mTg-neo and anti-tTg-neo levels were higher ($p<0.001$) compared to the single antigens. tTg-neo IgA and IgG+IgA were higher than mTg-neo IgA and IgA+IgG ($p<0.0001$). The antibody activities reflecting best the increased intestinal damage were: mTg-neo IgA> mTg-neo IgA+IgG > tTg-neo IgG ≥ mTg-neo IgG > tTg-neo IgA> tTg-neo IgA+IgG. Taken together, mTg-neo IgG and tTg-neo IgA & IgA+IgG correlated best with intestinal pathology ($r=0.5633$, $r=0.6165$ & $r= 0.6492$; $p<0.0001$, $p<0.0001$ & $p<0.0001$ respectively).

Conclusion: The complexed forms of both transglutaminases exhibited a higher OD activity and better reflected intestinal damage in PCD, compared to the non-complexed forms. mTg is immunogenic in children with CD and by complexing to gliadin its immunogenicity and pathology reflection is enhanced.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze discontinuation causes of biologics therapies (bDMARDs) in patients who are registered in the database BIOBADASAR.

Methods: Database included demographics of patients, type and duration of treatments and clinical information of adverse events. A control group was included for comparison consisting of patients not treated with bDMARDs but similar demographics. Values are expressed as mean±standard deviation, median (ranges), and frequencies (percentages), as appropriate. Student's t-test and the chi-squared test were applied and Fisher's exact test was used where necessary. Multivariate cause-specific regression models were used to measure the association with discontinuation. Values of $p < 0.05$ were considered to be statistically significant.

Results: From August 2010 to January 2016, 3483 patients were registered in BIOBADASAR; mean age:56.115.7 yrs; 78.9% females; 2745 (78.6%) had RA, 395 (11.3%) PsA, 150 (4.3%) JIA, 144 (4.1%) SLE, 107 (3.07%) AS. Therapy with non-bDMARDS included 2011(57.7%) patients. Different bDMARDs were used in 1472 (42.3%) patients for a total of 2736 (1.85/patients) treatments cycles. Of these, 1184 (45.8%) were discontinued; etanercept 43.6% (521/1193), infliximab 64.1% (109/156), abatacept 43.5% (123/283), adalimumab 41.2% (262/626), rituximab 34.5% (78/226), belumimab 29.2% (7/24), golimumab 21.6% (11/51), certolizumab 16.6% (20/120) and tofacitinib 8.8% (5/57). The main reasons for bDMARD discontinuation were: Inefficacy: 450 (38%); adverse events 368 (31.1%); lack of insurance: 239 (20.2%) Discontinuation due to inefficacy was significantly higher in patients who were treated with infliximab; and tofacinitib showed a higher frequency of switching due to adverse events in comparison with the rest of biological agents (Table 1). In a logistic regression model, predictors associated with discontinuation of bDMARD treatment were: older age (OR 1.01 95% CI 1.01-1.02), concomitant use of corticoids (OR 1.72, 95% CI 1.44-2.04) and use of infliximab (OR 2.17, 95%CI 1.53-3.08). However, use of tofacitinib (OR 0.14, 95%CI 0.04-0.48, p=0.002), certolizumab (OR 0.21, 95%CI 0.11-0.39, $p \leq 0.00001$), golimumab (OR 0.34, 95%CI 0.15-0.80, p=0.014) and rituximab (OR 0.68, 95%CI 0.49-0.95, p=0.026) showed less discontinuation rate. **Table 1.** Discontinuation causes of biologics therapies in BIOBADASAR

Reason for discontinuation	Abatacept n (%)	Adalimumab n (%)	Belimumab n (%)	Certolizumab n (%)	Etanercept n (%)	Golimumab n (%)	Infliximab n (%)	Rituximab n (%)	Tocilizumab n (%)	Tofacitinib n (%)
Adverse event	32(26)	86(32.8)	1(14.3)	8 (40)	152(29.2)	5(45.5)	34(31.2)	28(35.9)	18(37.5)	4 (80) a

The Role of Von Willebrand Factor Antigen As a Disease Biomarker in the Clinical

Assessment of Children with Juvenile Dermatomyositis

Dawn Wahezi[1], Vito Arena[2], Jaeun Choi[2] and Qi Gao[2], [1]Pediatric Rheumatology, The Children's Hospital at Montefiore, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: With the advent of new therapies, outcomes for children with juvenile dermatomyositis (JDM) have significantly improved. Accurate markers of clinically *inactive*disease are thus fundamental in the effort to reduce unnecessary prolongation of treatment. Muscle enzymes are frequently monitored, however individual enzyme levels do not always correlate with disease activity. Von Willebrand factor (vWF) antigen has been shown to be elevated in children with active JDM, albeit without specificity and absolute consistency. This study aims to evaluate the utility of normal vWF antigen as an indicator of disease quiescence, as well as the usefulness of vWF antigen levels in the assessment of disease flare.

Methods: This longitudinal, retrospective cohort study analyzed disease activity of children with JDM from January 2009 to April 2014, evaluating serial clinical and laboratory measurements. Disease flare was defined by the presence of 2 or more of the following: elevation in muscle enzymes, worsening muscle strength (manual muscle testing - MMT) or functional ability (Childhood Myositis Assessment Scale - CMAS), worsening extramuscular manifestations or worsening physician global assessment of disease activity (PhyGloVAS). Disease inactivity was defined according to modified PRINTO criteria: 3 of the 4 following elements: creatine kinase≤150, CMAS score≥48, MMT≥78 and PhyGloVAS≤0.2.

Results: A total of 357 visits were evaluated from 22 patients. The median number of visits per patient was 12 (IQR: 7-17). Using modified PRINTO criteria, 77/357 (22%) visits met criteria for disease inactivity. In multivariate analysis, the odds of children with normal vWF antigen levels to be in a state of disease quiescence was 3 times greater than the odds of those with abnormal levels after controlling for age, gender and disease duration (p<0.0001) (Table 1). Laboratory values taken from a previous visit (within 3 months duration of a flare) were assessed in separate multivariate analyses as predictors of the upcoming flare (Table 2).

Table 1: Factors predictive of disease quiescence

	OR	CI	p-value
Age (years) at visit	1.1495	1.0368, 1.2743	0.0081
Female gender	0.3924	0.2316, 0.6647	0.0005
Disease Duration	0.9969	0.9799, 1.0142	0.7232
Normal vWF antigen	3.0750	1.8009, 5.2504	<.0001

Table 2: Recent biomarker assessment as predictors of disease flare*

	OR	CI	p-value
Prior vWF antigen	2.4298	1.5287, 3.8621	0.0002
Prior LDH	3.2687	1.8245, 5.8556	<.0001
Prior CPK	1.3715	0.7933, 2.3707	0.2580
Prior AST	1.7859	1.0720, 2.9752	0.0260
Prior Aldolase	0.6452	0.4519, 0.9214	0.0159

* Individual biomarker results are each from separate multivariable analyses of which each adjusts for the other variables which are not presented in the table (age, gender and disease duration)

Conclusion: With improved therapies, clinical remission in JDM is an achievable goal. Accurately identifying children with inactive disease is critical in reducing long-term treatment toxicity and overall morbidity. This data supports the use of vWF antigen, LDH and AST as predictors of disease flare; while traditional markers, CPK and aldolase, were less reliable markers of flare. To our knowledge, this is the first study to demonstrate the utility of normalization of vWF antigen in defining clinically inactive disease.

Associations Between 25-Hydroxyvitamin D, Parathyroid Hormone, and Cathelicidin Concentrations with Inflammation and Cardiovascular Risk in Subjects with Pediatric Systemic Lupus Erythematosus

Varsha Gupta[1], Vin Tangpricha[2], Eric Yow[3], Grace McComsey[4], Laura E. Schanberg[5], Angela B. Robinson[6] and APPLE Investigators Group, [1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]Medicine, Emory University School of Medicine, Atlanta, GA, [3]Biostatistics, Duke Clinical Research Institute, Durham, NC, [4]Pediatric Infectious Diseases, Rheumatology, and Geographic Medicine, Rainbow Babies and Children's Hospital / Case Medical Center, Cleveland, OH, [5]Department of Pediatrics, Duke University Medical Center, Durham, NC, [6]Pediatric Rheumatology, Rainbow Babies and Childrens Hospital, Cleveland, OH
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown associations between reduced serum 25-hydroxyvitamin D (25OHD) levels, inflammation, and disease activity in pediatric systemic lupus erythematosus (pSLE). The goal of this study was to assess the role of parathyroid hormone (PTH) in its relationship with vitamin D and inflammation, and to better understand the role of human cathelicidin (LL-37) in pSLE. LL-37 is upregulated by activated vitamin D and has antimicrobial and immunomodulatory properties. We examined the relationship between 25OHD and LL-37 concentrations to determine whether LL-37 concentrations are associated with the chronic inflammation seen in pSLE.

Methods: Available frozen serum samples from the 3-year APPLE study (n=221 participants) were used to determine 25OHD, PTH, and LL-37 levels at study entry. Pearson's correlations and Chi-square tests were used to evaluate the relationships between 25OHD, PTH, LL-37, inflammation, disease activity, and infection using baseline values collected as part of the study.

Results: 201/221 APPLE participants had serum available for analysis. 61/201 had vitamin D deficiency at baseline. Serum 25OHD was inversely associated with PTH, $r = -0.39$ ($p < 0.01$), but not with LL-37 ($p = 0.58$). LL-37 levels ranged from 18.3 to 289.2 ng/mL, with a mean level of 57.2 (SD 30.6) ng/mL. PTH was not associated with hsCRP, carotid IMT, or HDL- or LDL-cholesterol, but was negatively associated with lipoprotein(a) levels, $r = -0.15$ ($p = 0.03$). Despite no association with serum 25OHD, LL-37 was negatively associated with total cholesterol, HDL- and LDL-cholesterol, and positively associated with age (Table 1). There was no significant difference in mean LL-37 levels in participants with reported infection as an adverse event during the 3 years of study.

Conclusion: As expected, PTH was negatively associated with 25OHD, but interestingly, LL-37 levels were not associated with 25OHD. Serum levels may not reflect the interaction of 25OHD and LL-37 at a cellular level. Notably, many LL-37 levels were significantly elevated over normal. There may be an association between LL-37 and cardiovascular risk (via cholesterol). These exploratory results addressing the role of LL-37 levels in pSLE inflammation and infection appear worthy of future study. Table 1:

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We have earlier demonstrated redistribution of adipose tissue in JDM patients. There is an increase in visceral adipose tissue (VAT), a highly active metabolic organ producing adipokines which are involved in many inflammatory responses and cardiovascular complications. We aimed to investigate serum adipokine levels in JDM patients and controls, and explore the associations with disease activity and damage, VAT and cardiac function.

Methods: Fifty-nine patients with JDM and 59 age- and sex matched controls were included in a cross sectional study median 16.8years after disease onset. Body composition was analyzed by total body dual-energy X-ray absorptiometry (DXA). VAT (g) was quantified (DXA) only in individuals above 18 years. Serum adipokines, including pro-inflammatory (leptin and visfatin) and anti-inflammatory (adiponectin and apelin-12) analyzed by ELISA, were measured in serum drawn at follow-up. Long axis strain (LAS) and early diastolic tissue velocity (E') assessed by echocardiography were used as markers for systolic and diastolic cardiac function, respectively. Inactive disease was measured by the PRINTO criteria, disease activity by DAS and disease damage by myositis damage index (MDI).

Results: Leptin levels were higher in patients compared with controls (11.0ng/ml (IQR 4.4-25.2) vs 5.8ng/ml (IQR 3,0-14.7), p=0.010). Adiponectin was lower, but not significant in patients vs. controls (IQR 4.3microgr/ml (IQR 2.7-6.1) vs 5.5microgr/ml (IQR 3.7-6.9), p 0.091). Apelin-12 (0.8 ng/ml (IQR 0.7-1.3) vs 0.7 (IQR 0.6-0.9), p=0.005) and visfatin levels (5.7ng/ml (IQR 4.1-8.1) vs 4.2 (IQR 4.0-6.0), p=0.032) were higher in patients with active than inactive disease. Disease duration, lipodystrophy and calcinosis at follow-up correlated negatively with adiponectin (rsp-0.464, p=0.000; rsp -0.447, p=0.000 and rsp-0.358, p=0.005). Leptin correlated with DAS muscle at follow-up (rsp 0.284, p=0.029). MDI total at follow-up correlated negatively with adiponectin (rsp -0.315, p=0.015). VAT correlated negatively with adiponectin in all patients, with active and inactive disease and also with controls (rsp -0.578, p=0.000; rsp -0.647, p=0.004; rsp -0.492, p=0.028 and rsp -0.445, p=0.007 respectively). LAS and E' correlated positively with both adiponectin (rsp 0.534, p=0.008 and rsp 0.435, p=0.001) and apelin-12 (rsp 0.347, p=0.007 and rsp 0.279, p=0.034). Leptin correlated with diastolic blood pressure (BP), whereas adiponectin correlated negatively with systolic and diastolic BP, numbers not given.

Conclusion: The pro-inflammatory adipokines leptin and visfatin are elevated in JDM patients and in the subgroup with active disease, respectively. Leptin is associated with higher DAS and elevated blood pressure. Lower levels of anti-inflammatory adipokines (adiponectin and apelin-12) were associated with higher VAT, higher disease activity, higher BP and impaired cardiac function. Our finding suggests that increased VAT and imbalanced adipokine secretion is involved in disease activity and cardiovascular abnormalities in JDM.

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Some patients with juvenile dermatomyositis (JDM) have a disease course which is refractory to multiple drug treatments. There is evidence that prolonged disease activity is associated with increased mortality and morbidity. High levels of TNFα have been reported in JDM patients with a long disease course, suggesting it may play a significant role in refractory disease. There are no published clinical trials of this therapy but some are in progress. The aim of this study was to evaluate the efficacy and safety of anti-TNF treatment in UK JDM Cohort and Biomarker Study patients.

Methods: Data were analysed from children who were recruited to the UK JDM Cohort and Biomarker Study, met Bohan-Peter criteria and were on anti-TNF treatment at the time of analysis, and had had at least 3 months of therapy. Childhood Myositis Assessment Scale (CMAS), Manual Muscle Testing (MMT8), muscle enzymes and physicians global assessment (PGA) were recorded. Skin disease was assessed using modified skin Disease activity score (DAS).

Results: 67 patients with JDM actively treated with anti-TNF agents were analyzed. 41 patients were female (61%). The median [IQR] age at disease onset was 5.2 [3.4-9.5] years and the median age at beginning of anti-TNF was 10.1 [6.5-14] years. The median disease duration at beginning of anti-TNF was 3.2 [1.8-5.3] years and the median duration on anti-TNF was of 2.55 [1.5-3.9] years. Muscle involvement significantly improved, with median [IQR] CMAS and MMT8 values at initiation of anti-TNF therapy of 45.50 [39.75-52.25] and 74 [59.5-79.5] respectively, and at current evaluation (or date of anti-TNF treatment completion) of 53 [50-53] and 79 [74.580] ($p<0.0001$ and $p=0.0097$; Mann Whitney test), respectively. For skin involvement the initial modified DAS was 4 [2-5] and final 1 [0-3] ($p<0.0001$; Mann Whitney test). Assessing global disease activity the initial PGA was 2.9 [1.3-4.3] and final 0.5 [0-1.45] ($p<0.0001$; Mann Whitney test). Sixteen patients (24%) switched their anti-TNF treatment. 62.5% of the switches were due to therapy failure, 25% due to adverse events and 12.5% for patient preference in subcutaneous administration. Of 31 adverse events registered (13.3 adverse events per 100 patient-years), 12 were considered severe. One patient died due to small bowel perforation (not felt to be related to the use of TNF antagonists). The remaining adverse reactions were not severe and 79% (n=15) of them were due to infections causes. In 5 of the mild to moderate adverse reactions the drug had to be discontinued and switched to another TNF antagonist, while in the remaining patients temporarily withholding the drug proved sufficient. No malignancies or tuberculosis were reported.

Conclusion: This study is one of the largest to explore the efficacy and safety of TNF antagonist treatment in a large independent cohort of JDM patients. Both muscle and skin involvement appeared to improve after anti-TNF treatment.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a systemic autoimmune disease with characteristic rashes and chronic muscle inflammation. Because of its rarity, most therapeutic choices are based on small trials or retrospective series. The purpose of this study was to evaluate changes in treatment over time, and factors associated with medication choices in JDM.

Methods: We performed a retrospective review of therapies received by 334 patients with probable or definite JDM enrolled in the Childhood Myositis Heterogeneity Study. Patients were diagnosed from November 1965 to September 2014 (median August 1994). We evaluated the number and type of medications received and their durations, including differences by year of diagnosis, onset severity, and myositis autoantibodies (MSAs). Logistic regression and ROC analysis determined 1997 as a cut point for increasing usage of drugs other than prednisone.

Results: The median follow-up duration was 46 months and treatment duration was 33 months. Oral prednisone (PRED) was the primary therapy used by 99.4% of JDM patients, but was used as monotherapy in only 49% of patients diagnosed after 1997 vs. 85% before 1997 (P<0.001). Other medications were used more frequently in patients diagnosed after 1997 vs. before, including methotrexate (MTX) (95% vs. 60%), Intravenous Immunoglobulin (IVIG) (64% vs. 25%), hydroxychloroquine (HCQ) (70% vs. 37%), other DMARDs (41% vs. 14%) and cytotoxics/biologics (28% vs. 6%, P<0.001 for all). Patients diagnosed after 1997 had a greater number of drug trials per year (median 2.3 vs. 1.0) and a longer percentage of follow-up time on treatment compared to patients diagnosed before 1997. The median daily maximum PRED dose was 2.0 mg/kg/d [IQR 1.2-2.0], and did not differ by onset severity or MSAs. However, the median time to half the initial PRED dose was shorter in patients diagnosed after vs. before 1997 (11 vs. 22 months, P<0.01). The median time to discontinuation of PRED was 47 months [IQ 24-104] and for MTX was 50 months [IQ 24-86] by Kaplan-Meier analysis. Thirty-seven percent of patients discontinued all medications at last follow-up, with a median time to discontinuation of 85 months. There were no significant differences in time to discontinuation of PRED, MTX, or other medications by onset severity or MSAs, but there was a longer time to discontinuation for IVMP, MTX and IVIG in patients diagnosed after 1997 (P<0.01). We examined factors for use of IVMP, MTX, IVIG, and HCQ by multiple logistic regression. All drugs had greater usage in patients diagnosed after 1997 (OR 2.2-13.4). IVMP was more frequently used in patients with severe onset (OR 3.0), with anti-p155/140 and anti-MJ Abs (OR 2.7 and 2.5), and with a higher total initial symptom score (OR 21.9). HCQ was used more commonly in patients with anti-p155/140 Abs (OR 2.2). MTX was more frequently used in older patients at diagnosis (OR 1.1).

Conclusion: PRED is the mainstay of therapy in JDM. There is increasing use of MTX, IVIG and other drugs/biologics in combination after 1997, and PRED was reduced faster for this group compared with patients diagnosed before 1997. Diagnosis year, onset severity, age at diagnosis, and MSAs were associated with specific medication usage in JDM.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Corticosteroids in juvenile dermatomyositis (JDM) alone or in association with other immunosuppressive drugs, namely methotrexate (MTX) and cyclosporine (CSA), represent the first-line treatment option for new onset JDM. No clear evidence based guidelines are actually available to standardize the tapering and discontinuation of corticosteroids in JDM. The purpose of the study was to provide an evidence-based approach for corticosteroid tapering/discontinuation through the analysis of the patients in the PRINTO new onset JDM trial.

Methods: New onset JDM children were randomized to receive either prednisone (PDN) alone or in combination with MTX or CSA. All children were given initially three daily pulses of intravenous methylprednisolone (30 mg/kg/pulse), and then PDN 2 mg/kg/day. After 1 month PDN was tapered to 1 mg/kg/day, from month 2 to 6 was tapered to 0.2, at month 12 to 0.1, and then discontinued at month 24. Major therapeutic changes were defined as the addition or major increase in the dose of MTX/CSA/other drugs or any other reasons for which the patient was dropped from the trial (adverse events, lost to follow-up, etc). Patients who followed the steroid tapering protocol and discontinued PDN at month 24 with no major therapeutic change (group 1) represented the reference standard for the best clinical outcome. Group 1 was compared with those following the steroid protocol, but with other major therapeutic changes (group 2), and with the group who deviated from the steroid protocol with/without major therapeutic changes (group 3). JDM core set measures (CSM) were compared in the 3 groups at 6-12-18 and 24 months (Table).

Results: 139 children were enrolled in the trial: 47 on PDN, 46 on PDN+CSA and 46 on PDN+MTX. We identified 57 (41%) patients for group 1, 24 (17%) for group 2 and 58 (42%) for group 3. At baseline all 3 groups had a high level of disease activity with no differences in the CSM. In group 1 (PND off no failure) there were 12 (21%) patients randomized to PDN alone, 21 (37%) to PDN+CSA and 24 (42%) to PDN+MTX. When we compared the three groups, significant differences were found in all CSM at each time point of analysis ($p<0.0001$). In particular Group 1, when compared to Group 2 and 3, had the lowest level of disease activity at all time points; the decrease of disease activity was primarily within the first 6 months of treatment. Group 2 and 3 were overlapping in the levels of disease activity reached at all the time points and were globally higher when compared to group 1. **Table: Core set measures values at different time points in the 3 groups of patients (only key results are reported).**

	OFF PDN Failure: No Group 1 N=57	OFF PDN Failure: Yes Group 2 N=24	PDN ON Failure Yes or No Group 3 N=58	P value
Month 6: MD global	0.5 (0-2)	2.6 (0.8-5)	3 (0.6-6)	<0.0001
Parent global	1 (0-1.8)	3.1 (0.5-5)	2.5 (0.8-5.8)	0.0002
CHAQ	0.1 (0-0.5)	0.1 (0-0.9)	0.5 (0-1.9)	0.0007
DAS	3 (0-5)	6.5 (1-11.5)	8 (4-12)	<0.0001
CMAS	47 (42-51)	45 (35-48.5)	35 (21.5-47)	0.0001
CHQ-PhS	51.8 (46.2-54.9)	47.5 (20.3-54.1)	36.3 (16.6-50.6)	<0.0001
MMT	77 (70-80)	70 (59-78.5)	64 (51-75)	<0.0001
Month 12: MD global	0 (0-1)	2.6 (1-5.5)	3 (0.6-6)	<0.0001
Month 18 DAS	0 (0-3)	6 (2.5-11.5)	9 (2-12)	<0.0001
Month 24: CMAS	50 (48-52)	42 (36-50)	36.5 (21.5-48)	<0.0001

Conclusion: The PRINTO protocol from the trial in new onset JDM might constitute the reference evidence-based approach for corticosteroid tapering for possible use in current clinical practice.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the long-term outcomes and prognostic factors for pts with juvenile-onset idiopathic inflammatory myopathies (JIIM) who are currently adults.

Methods: Adults with JIIM were assessed at two referral centers between 1994 and 2016. Predictor variables included demographics, clinical symptom scores, disease course, worst ACR functional status, drug therapies and co-morbid conditions. Outcomes included physician global activity (PGA) and damage (PGD), Myositis Damage Index (MDI), HAQ, muscle strength testing (MMT26), and total

number of drugs at last visit. The analysis was done in GraphPad Prysm (version 7.0a).

Results: Forty-nine pts with probable or definite JIIM (42 dermatomyositis, 5 polymyositis, 2 overlap myositis) had a median age of 22 yrs. and median disease duration of 11 yrs.; 47% were Caucasian, 82% female. Among these, 55% had a chronic course, 31% polycyclic,10% a monocyclic illness course, 4% undefined. Review of treatment revealed past use of daily prednisone in 84% and current use in 58%; 56% received IV steroids in past and 16% still required IV steroids. Methotrexate (MTX) was the most commonly used DMARD with 79% receiving it in the past and 40% with continued use; 32% used biologics or cytotoxic therapies and 7% remained on these. Median assessment scores at final visit included PGA 1.6 of 10 [IQR 1.0-3.7]; PGD 3.0 [IQR 2-4.4], HAQ 0.4 of 3, and MMT26 229 of 260 [IQR 212-257]. Damage was present in 96% with a median MDI score of 7 [IQR 4-10]. Cutaneous (80%) and muscle (78%) damage were most frequent and most severe (median cutaneous 3 [IQR 1-5], muscle 2 [IQR 1-3]). The most frequent damage features included persistent weakness (71%), muscle dysfunction (68%), contractures (67%), cutaneous scarring/atrophy (61%), calcinosis (57%), muscle atrophy (49%), and lipodystrophy (32%). The most frequent co-morbid conditions included hyperlipidemia (18%), depression or anxiety (18%), and fibromyalgia (6%). Significant univariable predictors of cutaneous damage included disease duration, ACR functional class and prior use of MTX (p 0.016–0.046), whereas for muscle damage, predictors included the past muscle symptom score, earlier year of diagnosis, and prior MTX use (p=0.004-0.025). Predictors of total MDI score included past GI symptom score, younger age at diagnosis, disease duration and ACR functional class (p=0.0004-0.032). Predictors of final PGA scores included past GI and pulmonary symptom scores, chronic disease course, and past use of biologics/cytotoxics (p=0.007-0.028). Pts were receiving a greater number of drugs at last visit if they were younger at time of enrollment, had a shorter disease duration, and had co-morbid depression or anxiety (p=0.0001-0.033).

Conclusion: This is one of the largest cohorts of patients with JIIM evaluated for long-term outcomes. Our results showed the majority of JIIM pts in this referral-based population have ongoing disease activity and significant disease damage, especially in the cutaneous and muscle systems, and frequent use of prednisone and other drug therapies as adults. Predictors of poor outcomes included disease duration, medication usage, and clinical symptom scores.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a chronic inflammatory disorder of the skin and striated muscle. A subset of patients can present with rash only, labeled as *skin predominant JDM* (spJDM) for this study. The natural course of patients with spJDM and optimal treatment is unknown. The purpose of this study is to describe the clinical course of spJDM patients and assess for early indicators that may predict progression to classic JDM.

Methods: A chart review to identify patients presenting with spJDM was performed on all patients with the diagnosis code for dermatomyositis seen at 3 sites (Children's Hospital of Wisconsin, Boston Children's Hospital, IWK Health Centre). Data collected included patient demographics, presenting symptoms and exam findings, initial treatment, muscle enzymes, muscle biopsy,

electromyography, and magnetic resonance imaging (MRI). Patients were categorized as either amyopathic (no weakness on exam and no diagnostic studies consistent with myositis) or hypomyopathic (no weakness but diagnostic studies showed subclinical myositis). Follow up visits were reviewed for development of weakness.

Results: Twenty-four patients presented with spJDM: 8 (33%) were amyopathic on initial evaluation, while 16 (67%) were hypomyopathic. None of the amyopathic patients later developed weakness (follow up 3-144 months, median 31 months). Six (38%) hypomyopathic patients later evolved into classic JDM with weakness (follow up 10-85 months, median 45 months). Time to development of weakness ranged from 3 to 24 months after onset of rash. Patients who developed weakness had varying degrees of subclinical myositis as evidenced by lab or MRI. MRI was abnormal in 7 of 20 patients (35%) at baseline. Only 2 of these 7 patients (29%) later developed weakness. Patients with an abnormal MRI were more likely to receive systemic corticosteroids and/or methotrexate as part of initial therapy (43% vs 8%). The combination of hydroxychloroquine (HCQ) with a topical calcineurin inhibitor was the most common first line agent (21%). However, whether alone or in combination with a topical agent, HCQ was initiated in 46% of patients. Nine percent of patients treated with HCQ with or without topical agents developed weakness, while 50% treated with topical agents alone and 40% treated with systemic steroids developed weakness. Methotrexate was always started in conjunction with systemic steroids (4/24). Two patients with no initial treatment were later treated with HCQ or topical steroid for persistent skin disease and never had weakness.

Conclusion: Our work suggests that topical therapies do not prevent the development of weakness, but systemic treatment with HCQ may diminish the development of weakness in spJDM (50% vs 9%). No amyopathic patient progressed to develop weakness, while 38% of hypomyopathic patients developed weakness. This suggests the importance of comprehensive baseline testing using clinical, lab and MRI assessments, and that hypomyopathic patients should be followed more closely to assess for disease progression over time. Larger trials are needed to identify long term outcomes, optimal treatment, and whether treatment of spJDM prevents weakness.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinically Amyopathic Juvenile Dermatomyositis **(**CAJDM) is a distinct clinical phenotype of JDM in which patients (pts) often have characteristic JDM rashes with little to no evidence of muscle involvement. Our purpose was to investigate features distinguishing CAJDM from JDM.

Methods: Demographic, clinical, laboratory, and treatment data from 13 (10 hypo- and 3 amyopathic) pts meeting Sontheimer's criteria for CAJDM and from 65 myositis autoantibody (MSA)-matched (1:5) JDM pts meeting probable or definite Bohan and Peter criteria were examined. Differences were evaluated by Fisher's exact and Mann-Whitney tests and significant univariable results were examined in multivariable logistic regression. MSAs were tested by standard immunoprecipitation methods. Scores for each organ system were based on the number of signs/symptoms present at diagnosis vs. the number assessed.

Results: Sixty-nine percent of CAJDM had anti-p155/140 Abs, 2 each (15.4%) had anti-MDA5 or were MSA negative. CAJDM more

frequently had p155/150 Abs than the full cohort of 400 JDM (37.4% p155/140 Ab, p=0.038). CAJDM were younger at diagnosis vs. Ab-matched JDM (median 4.2 vs. 8.0 yrs, p=0.004). CAJDM tended to more often have a family history of autoimmune disease compared to JDM (83% vs. 48%, p=0.07). Gottron's papules were most often the first rash in CAJDM (54% vs.14%, p=0.004) whereas combination of heliotrope and Gottron's papules was most often the first rash in JDM (82% vs. 8%, p=0.0001). CAJDM more frequently had mild illness severity at onset (77% vs. 11%, p<0.0001). There were no differences in speed of disease onset, environmental factors preceding diagnosis, or median UV index scores (average and highest) based on residential location at time of diagnosis between the two groups. CAJDM less frequently had myalgias (7.7% vs. 63%, p=0.0004), arthralgias (15.4% vs. 56.9%, p=0.013), mucous membrane lesions (7.7% vs. 45%, p=0.012), calcinosis (0 vs. 35.4%, p=0.008), and fatigue (38.5% vs. 84.6%, p=0.0012) than JDM, and no ILD. The median muscle (0.0 vs. 0.29), skeletal (0 vs. 0.5) and overall (0.07 vs. 0.20) clinical symptom scores at diagnosis were lower in CAJDM than JDM ($p \leq 0.001$ for each). Muscle enzyme levels were less frequently increased in CAJDM (10-38% vs. 60-87%, $p \leq 0.005$); peak CK levels were lower (median 158 vs. 394 U/L, p=0.005) in CAJDM. CAJDM received less treatment, including fewer drug therapies (median 2 vs. 4, p=0.003) and treatment trials (median 2.5 vs. 5, p=0.004), had shorter durations on steroids (median 3.6 vs. 24 months, p=0.003), and less frequent use of prednisone (60% vs. 100%, p=0.0003). Multivariate logistic regression revealed a lower median muscle system score (p=0.009) was the only significant predictor of CAJDM compared to JDM. At a median f/up duration of 2.5 yrs, all CAJDM were ACR functional class I, 62% had rash, and none developed clinically significant muscle weakness or calcinosis vs. JDM ($p \leq 0.03$).

Conclusion: CAJDM may be distinguished from JDM in that they more likely have p155/140 Abs, are younger at diagnosis, have fewer clinical manifestations, especially muscle symptoms, lower muscle enzyme levels, receive less therapy including oral prednisone and have more favorable outcomes.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: JDM is a multisystem vasculopathic disease that primarily affects the skin and muscles. Most tools for assessment of disease activity in JDM are lenghty, complex, and centered on physician's evaluation. We aim to develop a composite disease activity score for JDM and provide preliminary evidence of its validity.

Methods: A panel of experts devised the score, named Juvenile DermatoMyositis Activity Index (JDMAI), based on their clinical experience and a literature review. The JDMAI is composed of 4 clinical domains: 1) physician's global assessment of overall disease activity on a 0-10 visual analog scale (VAS); 2) parent's/child's global assessment of child's wellbeing on a 0-10 VAS; 3) muscle strength/endurance; 4) skin disease activity. Eight versions of the JDMAI were tested, which differed in the tools used to assess items 3 and 4. For item 3, two versions included the hybrid MMT/CMAS (hMC) with score in deciles (0-10), two the hMC with its original score (0-100), two the MMT-8 (0-80), and two the CMAS (0-52). For item 4, four versions included physician's global rating of skin disease activity on a 0-10 VAS, and four included the cutaneous domain of the Disease Activity Score (DAS) (0-9). Validation was conducted on 275 patients included in a multinational dataset, evaluated at baseline and at 6, 12, and 24 months. Construct validity was assessed by calculating between-subject and within-subject correlations with JDM outcome measures not included in the JDMAI; internal consistency was assessed with Cronbach α and responsiveness to change with standardized response mean (SRM).

Discriminant ability was determined in a different multinational dataset of 142 patients, by assessing the JDMAI score in patients rated in remission, low, moderate, or high disease activity by the attending physician.

Results: In between-subject exercise, all JDMAI versions showed strong (r>0.7) correlations with CHAQ (0.72-0.82), muscle VAS (0.77-0.87), muscle DAS (0.76-0.86) and total DAS (0.68-0.90), and moderate correlations (r=0.4-0.7) with pain VAS (0.50-0.57) and Myositis Damage Index (MDI) (0.51-0.60). Owing to the interrelatedness of longitudinal data from an individual patient, within-subject correlations were higher and were all strong (r=0.76-0.97). SRM was good (1.09-1.57) and was higher for JDMAI 1 and 2. Cronbach's alpha was fair (0.70 and 0.69) for JDMAI 1 and 2, and poor for other JDMAI versions. All JDMAI versions discriminated strongly between patients in different disease activity states (Kruskal-Wallis test, $p < 0.001$).

Conclusion: Overall, the JDMAI1 and JDMAI2 revealed the best measurement properties in validation analyses. The JDMAI1 (score range: 0-40) may be preferred over the JDMAI2 as it weights equally its 4 components, whereas in the JDMAI2 (score range: 0-39) items 1 to 3 are scored on a 0-10 scale and skin disease on a 0-9 scale.

JDMAI 1	JDMAI 2	JDMAI 3	JDMAI 4	JDMAI 5	JDMAI 6	JDMAI 7	JDMAI 8
Physician's global assessment (0-10)

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient reported outcomes (PROs) are becoming increasingly recognized as important in the care of patients with chronic diseases, such as Juvenile Dermatomyositis (JDM); however, the correlation of PROs to physician (MD) reported scores in clinical practice is unclear. We sought to assess the correlation between patient (PT) and MD reported global disease activity in JDM and examine factors associated with disparate scores.

Methods: We identified a cohort of patients with physician-diagnosed JDM through the Childhood Arthritis and Rheumatology Research Alliance registry, an IRB approved, multi-center registry developed to capture data about children with rheumatic diseases. Data were abstracted using a standardized form, including demographics, medication history, PRO measures (global disease activity on a 10 point visual analog scale (VAS), childhood health assessment questionnaire (CHAQ), pain and overall quality of life scores), and physician reported outcome measures (global disease activity VAS, subjective weakness, muscle strength scoring, muscle enzyme

testing, examination findings and associated co-morbidities). We assessed the discordance between PT and MD global disease activity VAS, and defined ≥3 point difference as discordant. We then evaluated factors associated with discordance. Variables were compared using chi-square for categorical and Kruskal-Wallis analysis for continuous, with significance $p<0.01$.

Results: In the registry, 563 patients with JDM were identified. Mean age was 10.6 years (range 6.9-14.7) with average age of onset 5.5 (3.6-9.3). Most patients were female (403, 72%), white (442, 79%) and non-Hispanic (471, 84%). Overall, PT and MD global disease activity VAS were similar in 78% of cases. Of discordant scores, 16% of PT rated VAS ≥3 points above MD (indicating greater disease activity), while 6% of MD VAS were higher than PT VAS. When PT VAS was ≥3 points above MD, these patients had significantly worse CHAQ scores, higher pain scores, and more frequently reported poor quality of life (all $p<0.01$). When MD VAS was ≥3 points above PT, these patients had more frequent muscle enzyme abnormalities, weakness and lower strength score, rash, nail fold changes, calcinosis, joint involvement, and current steroid treatment (all $p<0.01$). Prevalence of GI/cardiac involvement tended to be higher with discordance in either direction. There was no statistical evidence that demographic factors (current age, age of onset, gender, race or ethnicity, or income level) were associated with discordant VAS scores.

Conclusion: While patients and physicians frequently agree on global disease activity VAS ratings in JDM, discordance is seen in over 20%. When patients report discordantly worse/higher scores, this is associated with worse PRO measures of functional status, pain and quality of life. When physicians report higher scores, this is associated with poorer objective measures of strength, abnormal muscle enzyme testing, more co-morbidities and physical exam findings. This study highlights the importance of incorporating PROs into the routine assessment of patients with JDM.

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a systemic autoimmune disease characterized by chronic skeletal muscle inflammation with weakness and skin involvement. The Paediatric Rheumatology INternational Trials Organisation (PRINTO) and the International Myositis and Clinical Studies Group (IMACS) developed criteria to evaluate response in clinical trials which have been recently updated and validated. We compared the PRINTO 2010 (JDM 2010 response criteria) with PRINTO/IMACS 2016 response criteria (JDM 2016 criteria) for improvement in the PRINTO new onset JDM trial.

Methods: New onset JDM children were randomized to receive either prednisone (PDN) alone or in combination with methotrexate (MTX) or cyclosporine A (CSA). Patients were evaluated at months 6, 12, 18 and 24 with different levels of JDM 2010 criteria (improvement of 20-50-70 or 90% in at least three of the 6 core set measures and worsening <30% in no more than one). The same

patients were re-analyzed with the continuous JDM 2016 criteria which evaluate absolute percent change into three categories (total score 0-100): minimal (≥30), moderate (≥45), major (≥70) improvement. Clinical trials data were analyzed according to the intention-to-treat (ITT) principle with patients discontinuing (lack of efficacy, safety, etc.) considered as non-responders from that point onwards.

Results: 139 children were enrolled in the trial: 47 on PDN, 46 on PDN+CSA and 46 on PDN+MTX. The two sets of criteria showed a similar capacity to recognize different levels of improvement of the disease at 6, 12, 18 and 24 months, after treatment with PDN, PDN+CSA or PDN+MTX as shown by the overlapping 95% CI intervals at various time points (Table). In particular, at month 6, 51% patients on PDN versus 72% on PDN+CSA or PDN+MTX achieved at least JDM 2010 20% improvement (p=0.023) as compared to 55% and 74% with the JDM 2016 minimal improvement (p=0.027). At month 24, 38% patients on PDN versus 60% on PDN+CSA or PDN+MTX achieved at least JDM 2010 20% improvement (p=0.016) as opposed to 38% and 61% with JDM 2016 minimal improvement (p=0.012). Kappa agreement between the two criteria with ITT approach were at least in the moderate range (0.61-0.8) as follows: 0.75, 0.75, 0.77, 0.79 at 6-12-18 and 24 months, respectively. The JDM 2016 criteria, similar to the 2010 criteria, confirmed the superior efficacy of combined treatment with PDN+CSA or PDN+MTX versus treatment with PDN alone. **Table 1.** 2010 and 2016 improvement criteria after 6, 18 and 24 months of treatment with PDN or PDN+MTX or PDN+CSA (only few examples are reported)

2010 or 2016 criteria of improvement	**PDN**	**PDN+CSA**	**PDN+MTX**	
	N=47	***N=46***	**N=46**	**P values**
	N (%) [95%CI]	**N (%) [95%CI]**	**N (%) [95%CI]**	
Month 6				
2010 ≥20%	24 (51%) [36-66]	32 (70%) [54-82]	33 (72%) [56-84]	**0.023**
2016 at least minimal	26 (55 %) [40-70]	34 (74%) [59-86]	34 (74%) [59-86]	**0.027**
Month 18				
2010 ≥50%	20 (42%) [28-58]	30 (65%) [50-79]	29 (63%) [47-77]	**0.015**
2016 at least moderate	21 (45%) [30-60]	30 (65%) [50-79]	30 (65%) [50-79]	**0.020**
Month 24				
2010 ≥70%	18 (38%) [24-54]	26 (56%) [41-71]	26 (56%) [41-71]	**0.042**
2016 at least major	17 (36%) [23-51]	27 (59%) [43-73]	27 (59%) [43-73]	**0.012**

Conclusion: Both response criteria have shown a similar discrimination in evaluating different levels of improvement in new onset JDM patients treated with 3 alternative treatment strategies.

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) and Cutaneous Assessment Tool-Binary Method (CAT-BM) have been shown to be reliable and valid outcome measures to assess cutaneous disease in adult dermatomyositis (DM) and juvenile DM (JDM), respectively. This study compared the CDASI and CAT-BM for use by pediatric dermatologists, pediatric rheumatologists, and pediatric neurologists in patients with JDM.

Methods: Five pediatric dermatologists, five pediatric rheumatologists, and five pediatric neurologists each evaluated 14 patients with JDM using the CDASI, CAT-BM, and skin Physician Global Assessment (PGA) scales. Inter-rater, intra-rater reliability, construct validity, and completion time were compared.

Results: Inter-rater reliability for CDASI activity and damage scores was good to moderate for pediatric dermatologists and rheumatologists, but poor for pediatric neurologists. The inter-rater reliability for CAT-BM activity scores was moderate for pediatric dermatologists and rheumatologists, but poor for pediatric neurologists and poor across all specialties for damage scores. Intra-rater reliability for the CDASI and CAT-BM activity and damage scores was moderate to excellent for pediatric dermatologists, rheumatologists, and neurologists. Strong associations were found between skin PGA activity and damage scores and CDASI or CAT-BM activity and damage scores, respectively ($p<0.002$). The CDASI had a mean completion time of 5.1 minutes versus the CAT-BM of 2.8 minutes.

Conclusion: Our data confirm the reliability of the CDASI activity and damage scores and the CAT-BM activity scores when used by pediatric dermatologists and rheumatologists in assessing JDM. Significant variation existed in the pediatric neurologistsÕ scores.

Table 1. Inter-rater reliability of Skin Assessment Tool Scores in JDM patients among pediatric specialists*

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Determinants of changes in disease activity among patients with juvenile dermatomyositis (JDM) are unknown. Our objective was to develop scores to predict changes in disease activity over the next 6 months among children with active disease at baseline using the CARRA registry.

Methods: The CARRA registry included 658 subjects enrolled between May 2010 and October 2014 with definite or probably JDM defined based on Bohan and Peter criteria, which were modified to include magnetic resonance imaging. Among the 297 subjects with at least one follow-up visit between 4 and 10 months (median 6 months) after baseline, we studied the 65 subjects with active disease at baseline(defined as physician global ≥3 of 10). Linear regression models were used to build risk scores for changes in disease activity adjusted for baseline disease activity, age, sex and disease duration.

Results: The study population included 65 patients (mean age at baseline: 9.3 (SD 4.4) years; 66% female; 72% white) with median disease duration of 1.7 (range: 0.1 to 15.2) years. Disease activity improved significantly from baseline to 6 month follow-up as measured by patient global health score (median 4; IQR 2-6 at baseline vs median 2; IQR 1-5 at follow-up; p=0.008), patient pain score (median 2; IQR 0-5.5 to median 1.0, IQR 0=4; p=0.014), physician global (median: 4, IQR: 3-6 to 2, IQR 1-3; p<0.001) and Childhood Myositis Assessment Scale (CMAS) (median 41, IQR 33-47 to median 47, IQR 43-51; p<0.001). Anti-nuclear antibodies (p=0.013) and hydroxychloroquine use (p=0.045) were significant predictors of less improvement in patient global after adjusting for age, sex, disease duration and baseline patient global (R-square improved from 0.19 for adjustors alone to 0.34 for the full model). Anti-nuclear antibodies (p=0.001) and V/shawl sign (p=0.005) were significant predictors of less improvement in patient pain after adjusting for age, sex, disease duration and baseline patient pain (R-square improved from 0.29 for adjustors alone to 0.46 for the full model). There were no identified risk factors for improvement in physician global after adjustment for physician global at baseline, age, sex and disease duration. Small joint arthritis (p<0.01) predicted less improvement and dysphagia/dysphonia (p=0.033) predicted greater improvement in CMAS after adjusting for age, sex, disease duration and baseline CMAS (R-square improved from 0.73 for adjustors alone to 0.86 for the full model).

Conclusion: Disease characteristics can help identify patients who are less likely to improve over time. Risk scores to predict future changes in disease activity could be used to trigger more aggressive treatment earlier in the disease course.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Children with juvenile myositis (JM) have a variable disease course, in part associated with myositis specific/associated antibodies (MSA). Time to off medications has not been well documented. Published reports show 18-55% develop calcifications, but little is known about disease course and damage after 60 observation months. Objective: To examine the records of children with JM at specific time points over 5 years to determine disease activity, therapy duration and evidence of damage.

Methods: After obtaining informed consent, 102 children were enrolled. 65 were treated elsewhere then transferred care (TR). 37 were diagnosed at our center, untreated at first visit (UTR). MSAs (Oklahoma Medical Research Foundation Clinical Immunology Laboratory) were determined by immunodiffusion and immunoprecipitation. Disease Activity Scores (DAS) for skin and muscle involvement, nailfold capillary end row loop (ERL) number, reported cataracts and BMI were obtained at months 0 (first visit to our center) 6, 12, 24, 36 and 60, as well as periodic bone density (DXA) evaluation. Data was analyzed using ANOVA or t tests.

Results: Table 1 describes patient features. TR and UTR groups were similar for race and age at disease onset. TR patients presented after a mean of 12.7 months of treatment (SD 17.23). At first visit, the DAS was essentially equivalent for both groups but at 60 months was significantly lower for UTR ($p=0.04$). Mean time to off medication was 3.8 years (SD 1.54). Calcifications were present in 4 (10.8%) UTR and 8 (12.3%) TR. Cataracts were reported in 13 (35.1%) UTR and 19 (29.2%) TR. TR had a lower average lumbar Z-score at months 0 and 60 than UTR, though not statistically significant. At 60 months, the mean BMI percentile of each group was 66th. ERL number improved in both groups, approaching the normal value of 7. MSA distribution was: p155/140 (29.4%), none (27.5%), Mi-2 (5.9%), MJ (3.9%), MDA5 (1%), Ro (2.9%), Ro plus another MSA (6.9%), three antibodies (12.7%) and antibodies seen in overlapping connective tissue disease ± MSA (9.8%). TR patients with ≥1 MSA trended to have the lowest lumbar Z-score ($p=0.085$) but groups were too small for further analysis.

Conclusion: Between TR and UTR patients, there were few differences at first visit and at 60 months. TR patients had a higher DAS total and muscle at 60 months, possibly reflecting more severe disease, thus prompting referral to our center. MSA distribution was similar to previously reported frequencies but only 11.8% had calcifications, much less than previously reported. Mean lumbar spine Z-scores were below average for age and cataracts occurred in 31.4% of patients, supporting the need for steroid-sparing JM treatments. Our study describes a large JM patient cohort through 60+ treatment months, a middle-term outcome rarely reported in JM literature.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: All previous studies of disease outcome in juvenile dermatomyositis (JDM) patients have been based on retrospective data or cross sectional examination. We aimed to examine if disease activity, muscle strength and organ damage changed over time in an unselected cohort of JDM patients reassessed after long-term follow-up.

Methods: Patients who were included in a cross-sectional examination in 2005-2008 (visit 1) were invited for a re examination in 2013-2015 (visit 2). Patients were divided in active and inactive disease by the Paediatric Rheumatology International Trials Organisation (PRINTO) criteria. Disease Activity Score (DAS) was used to measure disease activity in skin and muscle, while the myositis damage index (MDI) was used to assess cumulative organ damage. The manual muscle test (MMT) and child myositis assessment scale (CMAS) were used to measure muscle strength/endurance, respectively. Also, use of anti-inflammatory medication was assessed.

Results: 42 patients (62% female) participated in both visits. Duration between the visits was mean 7.5 (1.0) years, and disease duration from symptom onset was median 21.5 years, (range 7.6-42.7). No difference in cumulative organ damage, muscle strength / endurance or disease activity measures was found between the visits, except that DAS muscle was higher in visit 2 (Table 1). By the PRINTO criteria, 25(60%) had inactive disease at visit 2; 4 of those used anti-inflammatory medication. Of the 17 (40%) active patients, only 3 used anti-inflammatory medication. 29 patients remained in the same PRINTO category at both visits (18 inactive and 11 active), whereas 7 active patients became inactive and 5 inactive patients became active between the visits.

Conclusion: Despite 40 % of JDM patients still had active disease after median 21.5 years follow-up and the majority of active patients were not on anti-inflammatory medication, no increase in cumulative organ damage was found over a 7.5 years time period.

Table 1: Disease characteristics in 42 JDM patients at visit 1 and visit 2

	Visit 1	**Visit 2**	P value
Follow-up time, years	13.4 (2.0-34.6)	21.5 (7.6-42.7)	NA
DAS muscle (0-11)	1.2 (1.2)	1.8 (1.6)	0.007
DAS skin (0-9)	3.3 (2.2)	2.7 (2.0)	NS
DAS total (0-20)	4.5 (2.7)	4.5 (2.6)	NS
MDI (0-40)	3.5 (2.5)	3.2 (1.9)	NS
PRINTO inactive, n (%)	23 (56)	25 (60)	NS
CMAS (0-52)	50 (28-42)	49 (39-52)	NS
MMT-8 (0-80)	79 (61-80)	78 (50-80)	NS
On prednisolone, n (%)	6 (14)	3 (7)	NS
On methotrexate, n (%)	9 (21)	7 (17)	NS

Numbers are mean (SD) or median (range) if not otherwise stated; NA, not assessed; NS, non-significant

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : The course of juvenile dermatomyositis (JDM) has improved greatly over the last 70 years with early and aggressive use of corticosteroids, immunosuppressive medications, and biologics. Yet it remains difficult to detect disease flare-up because symptoms may be mild, signs of the rash and muscle weakness vary widely and are often equivocal, and laboratory tests, including muscle enzyme levels are often normal. Electromyography and muscle biopsy are invasive and not reliable so alternative tools are needed to detect disease flare-up and decide if further treatment is needed. The objective of this study is to determine the effectiveness of muscle Magnetic Resonance Imaging (MRI) in detecting JDM flare-up and affecting physician's decision-making regarding treatment.

Methods: Approval was obtained from the Internal Review Board of Nationwide Children's Hospital. Subjects were included if they met the modified Bohan and Peter dermatomyositis criteria and were seen between 1/2005 and 6/2015. The MRI was performed on both lower extremities without contrast with the following sequences: Axial T1, axial T2 fat saturation, axial and coronal inversion recovery, and axial diffusion weighted. The physician decision that a subject with JDM was in a flare-up was considered as the gold standard, using rash, muscle weakness by childhood myositis assessment scale, muscle enzymes, and myositis on MRI. We compared the MRI result with the physician's decision of relapse or not and evaluated whether there was a concordance or discordance between the MRI findings and the subsequent treatment decision.

Results: Forty-five JDM children were identified, of which 32 were females. The median age at diagnosis was 5.8 years. Eighty percent had weakness at diagnosis, 100% typical rash, 73% typical nail fold capillary changes. At diagnosis, muscle enzymes were compatible with JDM generally (CK 52%, LDH 62%, aldolase 72%, AST 54% abnormal), EMG abnormal in 3/8, muscle biopsy typical of JDM in 10/11, and MRI abnormal demonstrating myositis in 31/40. Thirteen of the 45 subjects had a repeat MRI for a possible flare-up with differing indications: general proximal weakness in 4 subjects, hip, thigh or calf pain in 3 subjects, rash in 3 subjects, worsening nail fold changes in one subject, elevated enzymes in one subject, and to confirm remission in one subject. Three of 13 repeat MRI's were abnormal, demonstrating myositis. There was moderate agreement between the flare-up MRI findings and the physician's treatment decision (kappa=0.59); in each abnormal MRI case the physician decided to increase treatment (Bayes rule 100% agreement). When the MRI was negative for myositis in 10 patients, 7/10 physicians chose to continue same medications or to taper medications (70% agreement).

Conclusion: Our study suggests that MRI at a time of a JDM flare-up is useful, yielding a sensitivity of 50% and a specificity of 100% for flare-up using a physician's assessment of disease flare-up as the gold standard. Using Bayes rule, when an MRI shows myositis, physicians tend to treat 100% of the time and when an MRI shows no myositis, physicians in this study continued the same medications or tapered medications 70% of the time.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a persistent or remitting-relapsing autoimmune disease that handled in the context of connective tissue diseases and also vasculitides. Although there are commonly used biomarkers of active kidney disease and central nervous system disease, there is not a specific marker for vasculitic involvement. Pentraxin-3 (PTX3) is derived primarily from vascular endothelium and innate immunity cells in response to local inflammation and plays an important role locally at the site of inflammation. Thus PTX3 seems to be a useful biomarker directly reflecting local inflammation and local vasculitis. To the best of our knowledge PTX-3 was not studied in children with SLE. In the present study, we aimed to compare the concentrations of plasma PTX-3 among childhood-onset SLE (c-SLE) patients and control groups and to assess the association of PTX-3 levels with SLEDAI-2K, clinical manifestations and laboratory results.

Methods: From October 2015 to May 2016, 76 c-SLE patients without active infection sign and symptom were eligible for this cross-sectional single center study. We have also measured pentraxin-3 level in 41 healthy and age-matched controls. Both the cumulative and current organ involvement and manifestations were recorded from patient records and from the last examination at that moment, respectively. All of the laboratory analyses were studied concurrently with PTX-3 levels. PedSDI and SLEDAI-2K scores at disease onset, at the most severe flare and at the last examination were calculated. Serum pentraxin-3 levels were measured by a commercially available enzyme-linked immunosorbent assay kit.

Results: Plasma PTX3 concentrations were measured in 76 patients with c-SLE and 41 control subjects. Plasma PTX3 concentration of the SLE patients was significantly higher than that of the healthy controls (mean 10.6 ± 8.2 vs. 2.7 ± 1.3 ng/mL, $p<0.001$). The ratio of females to males with c-SLE was 5.3:1. The mean SLEDAI scores decreased from 10.3±4.8 (at disease onset) to 5.2± 5.3 (at last examination). Additionally, only 10.5% (n=8) and 3.9% (n=3) of the cohort were displaying the signs of active nephritis and active neuropsychiatric disease at last examination. In patients with SLE, PTX3 concentrations were correlated with SLEDAI-2K ($p<0.001$), active vasculitis ($p<0.001$), Raynaud's phenomenon ($p = 0.006$) and active mucocutaneous involvement ($p<0.001$). PTX3 level was not associated with disease duration, anti-ds DNA antibody, decreased complement levels, PedSDI, active nephritis, active neuropsychiatric involvement, musculoskeletal involvement, hematological involvement, ESR,CRP, procalcitonin levels.

Conclusion: In brief, PTX3 levels were significantly correlated with SLEDAI scores. Additionally, its levels are found to be substantially increased in the presence of Raynaud's phenomenon and vasculitic manifestations. Thus predicting the vascular involvement early and quantitatively in a c-SLE patient with presumed clinically inactive, will provide a better management of the disease. In conclusion, as in other vasculitides, PTX3 may represent a potential biomarker for vascular involvement in c-SLE.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Childhood-onset systemic lupus erythematosus (cSLE) is a heterogeneous disease with differing levels of disease activity and organ-specific disease manifestations in each individual. In particular, lupus nephritis (LN) persists as a leading cause of morbidity. We largely lack effective, non-invasive biomarkers to accurately detect LN activity and also to predict children at greatest risk for poor prognosis with LN. S100 proteins are a diverse group of calcium-binding proteins that can promote inflammation and be elevated in varied etiologies of nephritis. The purpose of this cross-sectional study was to evaluate five S100 proteins (S100A4, S100A6, S100A8/9 and S100A12) in both the serum and urine as potential biomarkers of global and renal-specific disease activity in a cohort of cSLE patients.

Methods: Patients were selected for inclusion from an ongoing cSLE Clinical and Research Database based on available serum at an active disease visit, designated by a SLE Disease Activity Index 2000 (SLEDAI-2K) ≥ 8. We then searched for an accompanying paired serum sample from a less active and ideally inactive visit if available. Serum and urine from the active and less active visits were analyzed for protein levels of S100A4, A6, A8/9 and A12 using commercial ELISAs (BÜHLMANN MRP8/14 and Circulex S100A12/EN-RAGE, S100A4, S100A6). Clinical characteristics were also collected on all patients for each visit, including demographics, standard lab values, organ specific disease activity and current medications.

Results: Serum S100 levels did not differ significantly between either paired or independent active/inactive visits, although S100A4 levels trended toward significance. Urine S100A4, A6 and A12 levels were elevated in cSLE patients with active LN, as defined by a renal SLEDAI ≥ 4, when compared to both cSLE patients with active disease but no LN and cSLE patients with inactive disease (refer to table for median S100 levels). Urine S100A4, A6 and A12 levels also differed by the degree of LN activity. In the paired sample analysis, only urine S100A4 levels differed significantly in patients with active LN, increasing by a median value of 4.98 ng/mL from inactive to active visits.

Conclusion: Higher levels of S100 proteins in the urine are associated with LN activity in our cSLE cohort. In particular, S100A4 and A6 levels are much higher in the urine than in the serum, suggesting the possibility of localized production within the kidney and a potential role in LN pathogenesis. S100 proteins could serve as novel biomarkers of LN; however, it will first be necessary to establish that elevation of urine S100 proteins is specific to LN. Further studies are required to validate urine S100 levels as a marker of LN activity in a separate cSLE cohort and to study the possible role of S100 proteins in LN pathogenesis.

Table 1. Summary Table for S100 Serum and Urine Protein Levels in Unpaired cSLE Samples

	(1)	(2)	(3)	(4)	(5)	(6)	P-value	P-value	P-value	P-value	P-value

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus,

Sjögren's Syndrome
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

HER2 (Human Epidermal Growth Factor Receptor 2) is dramatically overexpressed in the glomeruli and in the tubular compartment of patients with lupus nephritis, but not in other proliferative glomerulonephritides. HER2 expression is also increased in NZM2410 mice and it correlates with disease activity. In human mesangial cells, α-interferon increases HER2 expression, which regulates miR-26a and miR-30b levels. These miRNAs control the expression of cell cycle related genes and consequently regulate mesangial cell proliferation. The dysregulation of this pathway contributes, therefore, to the aberrant mesangial cell proliferation seen in lupus nephritis. Furthermore, in an adult cohort, it was recently shown that urinary HER2 levels were increased in patients with active lupus nephritis and correlated with MCP-1 and VCAM-1 levels.

The goal of this study is to determine the role of HER2 as a urinary biomarker for lupus nephritis activity.

Methods: This is an interim analysis of a prospective study of patients with biopsy-proven lupus nephritis. Data were collected from one adult and four pediatric centers. Urine samples were collected from patients at every clinical visit and also from age-sex matched controls. Urine supernatants were analyzed by enzyme-linked immunosorbent assays for HER2. Clinical data were also collected. The activity of lupus nephritis was measured using renal SLEDAI.

Results: HER2 levels were significantly increased in the urine of lupus nephritis patients (N=135) when compared to controls (N=61) (p=0.003). Moreover, our preliminary prospective data from patients with lupus nephritis analyzed at different visits showed that HER2 levels tend to reflect a renal flare (N=22).

Conclusion: The urinary HER2 levels were significantly increased in patients with lupus nephritis and reflected renal disease activity. This evolving study will further analyse if HER2 levels can be clinically useful, namely if they can predict the occurrence of a flare. Finally, this work also establishes strong foundations to study the use of anti-HER2 drugs to control cell proliferation and damage in lupus nephritis.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Pertussis cases have increased worldwide and knowledge on immune response and cytokine profile after adult Tdap vaccine is scarce. This study evaluated the humoral and cellular response through antibodies and cytokine profile after Tdap in juvenile systemic lupus erythematosus (jSLE) and controls.

Methods: After written informed consent, jSLE (n=20) and healthy adolescents (n=8) who received three whole-cell DTP vaccine (DTwP) plus two booster doses and had lymphocytes count > 500 received a Tdap dose. Blood samples were collected immediately before and 28 days after the vaccine. *In vitro* culture was performed with whole blood stimulated with tetanus toxoid, *Bordetella pertussis* or medium. Supernatants were collected after 7 days, kept frozen and subsequently assayed for cytokines secretion by xMAP-Luminex platform. Tetanus, diphtheria and pertussis antibodies were tested by ELISA.

Results: jSLE patients group median age was 14y (9-18y) and control group, 15.2y (9-15.6y). Both control group and jSLE presented an increase in response to tetanus ($p<0.01$), diphtheria ($p<0.001$) and pertussis ($p=0.01$) antibodies after Tdap booster dose on day 28. *Pertussis cellular immune response* on day 28 was stronger in control group, with significantly higher cytokine levels for **IL-2, IL-6, IL12p70, IFN-gamma,** and **TNF-alpha**; by contrast, **IL-4** concentration was higher in jSLE. *Tetanus cellular immune response* on day 28 was also stronger in control group, with significantly higher cytokine concentrations for **IL-2, IL-4,** and **IFN-gamma**; however, **IL-12p70** and **TNF-alpha** were higher in jSLE group. The cytokine levels and p-values are shown in table 1.

Table 1 - Cytokine levels for pertussis and tetanus cellular immune response

	Pertussis				
	jSLE D0	jSLE D 28	Control D0	Control D28	D28 p-value
IL-2	2.26	0.28	1.29	1.16	0.0201
IL-4	2,276.37	1,293.05	0.83	1.1	0.0019
IL-6	281.92	265.69	1,928.02	2,913.48	0.0019
IL-10	61.16	43.92	33.88	53.24	0.5186
IL-12p70	13.36	2.34	1.69	9.33	0.014
IFN-gamma	18.99	46.16	186.21	536.04	0.0098
TNF-alpha	21.63	14.81	158.72	228.49	0.0019
	Tetanus				
	jSLE D0	jSLE D 28	Control D0	Control D28	D28 p-value
IL-2	3.19	1.59	4.33	10.22	0.0528
IL-4	2,451.86	1,323	2,291.08	3,784	0.0142
IL-6	361.79	219	172.14	359	0.1556
IL-12p70	21.73	11.61	2.16	2.25	0.0067
IL-10	49.24	41.46	24.95	57.09	0.2453
IFN-gamma	29.43	54.31	219.05	2,152.06	0.0067
TNF-alpha	18.02	12.47	2.27	1.3	0.0142

Conclusion: In this preliminary study, children and adolescents with jSLE and healthy controls showed adequate humoral immune response to tetanus, diphtheria and pertussis after Tdap. However, jSLE adolescents showed a Th2 pertussis immune response profile, what might not be adequate to control *B. pertussis* infection.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interpretation of coagulation tests remain a challenge in jSLE with positive aPL. Lupus anticoagulant (LA) can mimic bleeding diathesis and its effect on prolonged aPTT is well documented. Rotational thromboelastometry (ROTEM) is a recently approved tool that assesses primary and secondary hemostasis. It has gained utility in the surgical setting and helps guide therapeutic transfusion decisions. The utility of ROTEM for patients with jSLE who have a positive LA has not been defined. We hypothesized that LA affects ROTEM parameters, especially clotting time (CT) and maximum clot firmness (MCF).

Methods: A prospective observational study was conducted from 12/1/15 to 05/30/16 in a pediatric rheumatology clinic after IRB approval was obtained. jSLE patients with current or previous LA positivity were included. Positive LA was defined by positivity of either a hexagonal phase neutralization procedure or dilute Russell's viper venom test. ROTEM was performed using 3 different assays reflective of coagulation pathways; INTEM (intrinsic), EXTEM (extrinsic) and FIBTEM (platelet-inhibited extrinsic pathway). When clotting time (CT) of INTEM was prolonged, the sample was incubated with phospholipids and CT measured again. Correlation between ROTEM results with standard coagulation tests were done by using Pearson's correlation coefficient. Clinical data was presented in mean ± standard deviation. We compared CT parameters in patients with and without aPL mediated clinical features (MS Excel, 2013).

Results: Twelve jSLE patients were recruited; 83% (10) were female, mean age was 16 ± 2.5 years. Ten were Hispanics, duration of disease was 3.25 ± 3 years, SLEDAI score was 3.8 ± 3. Five (42%) patients had aPL mediated clinical features: RP (1), livedo reticularis (1), thrombocytopenia (1), cutaneous ulceration (1), and pulmonary embolism (1). Two patients were on anticoagulation for history of thrombotic events. Immunomodulatory therapy as indicated by the disease severity included CYC (4), Rituximab (5), MTX (3), AZA (5) and MMF (2). All patients were on HCQ and ASA. Mean prednisone dose was 16.8 ± 15 mg/day. A total of 13 samples were obtained, 6 patients had a positive LA. In all children with strong LA, a positive correlation between aPTT and CT prolongation in both INTEM (r= 0.97; p 0.003) and EXTEM (r=0.988; p 0.001) was seen. Comparison between CT prolongation of ROTEM parameters and aPL mediated clinical features were not statistically significant. Elevation in MCF did not correlate with strong LA. Phospholipid incubation did correct all INTEM CT prolongation abnormalities (Figure 1).

Conclusion: LA affects ROTEM by prolonging clotting times as it does other traditional assays. Pediatric rheumatologists should interpret ROTEM coagulation tests with caution in jSLE patients undergoing surgical intervention or presenting with bleeding.

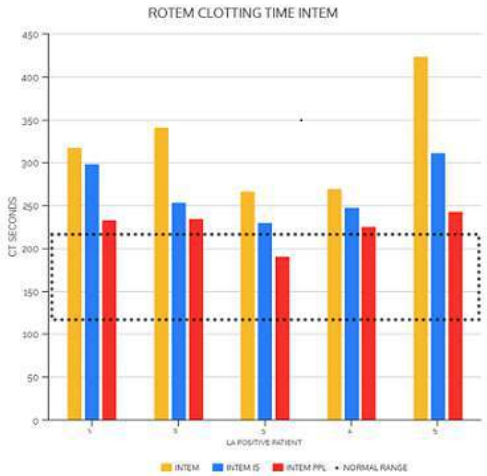

Figure 1. CT INTEM was prolonged in LA positive patients. Samples were incubated in isotonic solution (IS) and phospholipid (PPL). Shortening of CT INTEM close to upper limit resulted from PPL incubation.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-Ro/SSA and anti-La/SSB antibodies were reported in 30-50% and 10-30% of adult SLE patients, associated mainly with cutaneous manifestations. However, to our knowledge there are no studies assessing these autoantibodies in a large population of childhood SLE (cSLE) patients. Therefore, the aim of this multicenter cohort study was to evaluate demographic, clinical and laboratorial features in cSLE patients with and without the presence of anti-Ro/SSA and anti-La/SSB antibodies.

Methods: This was a retrospective multicenter study performed in 10 Pediatric Rheumatology services of São Paulo state, Brazil. Anti-SSA/Ro and anti-SSB/La antibodies were measured by either contraimmunoelectrophoresis or enzyme linked immuno sorbent assay (ELISA) in 645 patients cSLE patients. Other autoantibody analysis was performed according to the routine laboratory of each Center. Demographic data, cumulative clinical and laboratorial features and disease damage (SLICC/ACR-DI) at last visit were evaluated. Juvenile Sjögren's syndrome was established according to the American-European Consensus Group.

Results: Anti-Ro/SSA and anti-La/SSB antibodies were evidenced in 209/645 (32%) and 102/645 (16%) of cSLE patients, respectively. Analysis of cSLE patients with and without anti-Ro/SSA antibodies revealed higher frequencies of malar rash (79% vs. 71%, p=0.032), photosensitivity (73% vs. 65% p=0.035), cutaneous vasculitis (43% vs. 35%, p=0.046), musculoskeletal involvement (82% vs. 75%, p=0.046) in spite of long and comparable disease duration in both groups (4.25 vs. 4.58 years, p=0.973). Sjögren syndrome was rare and observed in only five patients with this antibody (2.5% vs. 0%, p=0.0035), two of them with concomitant anti-La/SSB. The presence of associated autoantibodies: anti-Sm (50% vs. 30%, p<0.0001), anti-RNP (39% vs. 21%, p<0.0001) and anti-ribossomal P protein (46% vs. 21%, p=0.002) were also significantly higher in patients with the presence of anti-Ro/SAA antibodies. Female gender, multi-organ involvement and SLICC/ACR-DI, including skin damage, were similar in both groups (p>0.05). Further evaluation of cSLE patients with the presence of anti-La/SSB antibodies compared to those without these autoantibodies showed that the frequency of alopecia (70% vs. 51%, p=0.0005) anti-Sm (59% vs. 31%, p<0.0001), anti-RNP (42% vs. 23%, p<0.0001) were significantly higher in the former group. Further evaluation of cSLE patients with and without concomitant anti-Ro/SSA and anti-La/SSB antibodies showed a lower frequency of anti-dsDNA (55% vs. 70%, p=0.009), whereas alopecia (71% vs. 51%, p=0.0008), anti-Sm (59% vs. 29%, p=0.0001) and anti-RNP (45% vs. 21%, p=0.0001) were more frequent in patients with these antibodies.

Conclusion: Our large multicenter study provided novel evidence in cSLE that anti-Ro/SSA and/or anti-La/SSB antibodies were associated with mild manifestations, particularly cutaneous and musculoskeletal. Sjögren syndrome was rarely diagnosed in these patients, in spite of the comparable frequencies of anti-Ro/SSA and/or anti-La/SSB reported for adult SLE.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Childhood-onset systemic lupus erythematosus (cSLE) is a chronic autoimmune disease, which can affect any organ system. cSLE is associated with significant morbidity, including diverse types of disease-related organ damage: up to 58% of children have apparent damage at 5 years after diagnosis. The Systemic Lupus Collaborating Clinics-Damage Index (SDI) is the only widely-used damage measure in patients with SLE (and cSLE), but was designed to list extant types of damage, not quantify severity. We sought to determine how this "listing" approach compared to a physician global assessment of disease-related damage in an international registry of cSLE patients.

Methods: The PRINTO (Pediatric Rheumatology International Trials Organization) cSLE registry includes longitudinal follow-up (mean approximately 3 years) of patients meeting revised American College of Rheumatology criteria for classification of SLE. Data from 557 patients, with a total of 1820 visits, was available for review. Data included SDI item and total scores, as well as a physician visual analog scale rating damage from 0 to 10. First, frequency of SDI summary scores was determined. The total SDI score and physician global rating of disease damage were then examined for correlation via Spearman rank-order testing. Finally, a mixed-effect model was used to determine the association of individual items with the physician damage global assessment.

Results: Out of 1820 visits, 1268 visits were assigned a SDI score of zero, while 552 (30.3%) had a non-zero score. Of non-zero scores, 331 visits received a score of one, 116 a score of two, 48 a score of three, 18 each a score of four or five, and 11 a score of six. A further 10 visits were assigned a SDI score of greater than 6. Spearman correlation of non-zero SDI scores with damage VAS was moderate at 0.496 (p value <0.0001). When visits with a SDI score of zero were included, the correlation coefficient was strong at 0.71 (p value <0.0001). Interestingly, of visits with a SDI score of zero (n=1268) 23.7% (n=301) were assigned a physician damage global greater than zero. Mixed effect analysis revealed that only 4 of the 41 SDI items were significantly associated with the physician damage global rating (Pulmonary Fibrosis, Shrinking Lung Syndrome, Chronic Pericarditis, Extensive Cutaneous Scar).

Conclusion: Our analysis revealed that a significant number of cSLE patients were found to have disease-related damage, even within the relatively limited follow-up period. It is also interesting to note the significant discrepancy between SDI scores of zero with non-zero physician global assessments, which could suggest either misunderstanding of the scale by raters, or damage items not captured by the SDI. The moderate correlation between non-zero SLICC-DI scores and the physician damage assessment suggests the need for a new or modified scale to specifically address damage severity. Finally, the lack of an association between the great majority of damage items and the physician damage assessment implies that item weightings alone would be insufficient to improve capture of damage severity.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Childhood-Onset Systemic Lupus Erythematosus (cSLE) is a chronic, multi-system autoimmune disease. In addition to active inflammation, cSLE may result in irreversible damage to affected tissues: up to 58% of children will demonstrate evidence of organ damage by 5 years after diagnosis. The Systemic Lupus Collaborating Clinics-Damage Index (SDI) lists 41 damage items, and is the only widely used measure of damage in patients with cSLE. As the index was originally created to reflect damage seen in adults, we sought to find the frequency of SDI items in three cSLE cohorts, and determine if a reduction in the number of items might be justified for cSLE.

Methods:

The United Kingdom Juvenile-onset SLE Cohort Study (UK) is a longitudinal cohort of 350 cSLE patients (1,375 visits), with a mean follow-up of 4 years. Additionally, the Cincinnati ChildrenÕs cSLE registry (Cincinnati) includes data from 163 patients (243 visits). Finally, the Pediatric Rheumatology International Trials Organization (PRINTO) cSLE cohort includes data from 559 patients (1,832 visits), with mean follow-up of 3 years. Gender distribution, as well as mean and standard deviation for age at diagnosis, disease duration, and final-visit SDI score were determined for each cohort, and the combined dataset. Age at onset, disease duration, and mean SDI score were tested for differences between cohorts via one-way ANOVA. Frequency of each SDI item was also determined, in individual cohorts and overall.

Results: *See table for detailed results.* Mean age at diagnosis was significantly higher in the Cincinnati cohort (14.45 vs. 11.98 for PRINTO and 12.02 for UK, $p < 0.0001$), as was mean disease duration (6.05 years vs. 3.46 for PRINTO and 3.82 for UK, $p< 0.0001$). Mean final-visit SDI score was significantly lower in the UK cohort (0.56 vs. 0.92 for Cincinnati and 1.16 for PRINTO, $p < 0.0001$). The mean SDI of the combined dataset was 0.93, while 602 patients (56.2%) had a final-visit SDI of zero. When SDI item scores were

considered, pulmonary infarct was the only item absent from all cohorts. When all datasets were combined, an additional 17 items were found to have occurred in fewer than 1% of the 1,072 patients, with 4 occurring in only a single case (tendon rupture, angina, myocardial infarct, and mesenteric insufficiency). The most common item in the combined dataset was proteinuria, (found in 103 patients or 9.6%), followed by alopecia (96 patients, 8.9%), and cognitive impairment (91 patients, 8.49 %).

Conclusion:

While many items are relatively rare (occurring in less than 1% of patients), all but one were observed at least once in the combined dataset. This is particularly noteworthy given the relatively brief disease duration (between 3.5 and 6.1 years), and diversity of manifestations described in the SDI. Our analyses do not support a substantial reduction in the number of SDI items considered for cSLE, but do underscore the rarity of many items in childhood-onset disease.

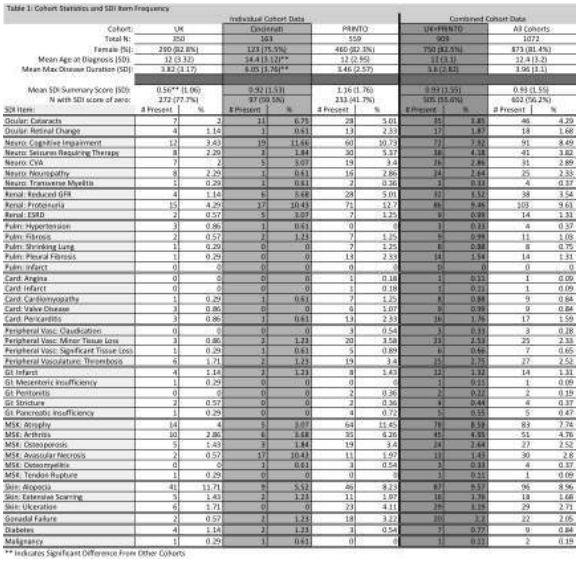

Table 1: Cohort Statistics and SDI Item Frequency

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A recent large study comparing childhood systemic lupus erythematosus (cSLE) with adult-onset SLE revealed a more aggressive and worse outcome in the former group. However, analysis of age-related differences regarding outcome focused on pediatric patients and particularly assessing early-onset cSLE patients (<6 years) is limited to very small sample size precluding a definitive conclusion about their findings. Therefore, the objective of this large multicenter study was to compare cumulative clinical/laboratory features, disease damage and death in three different age groups.

Methods: A retrospective multicenter study was performed in 847 cSLE patients from 10 Pediatric Rheumatology Divisions of São Paulo State, Brazil. Patients were divided in three age-related cSLE groups at diagnosis: A - early-onset (<6 years), B - school age (≥6 and <12 years) and C - adolescent (≥12 and < 18 years). An investigator meeting was held to define the protocol and to standardize disease parameters definitions. Demographic data, clinical and laboratorial features, disease damage (SLICC/ACR-DI) and death were evaluated at last visit.

Results: Groups of cSLE patients were divided according to the age at diagnosis: A=39 (4%), B=395 (47%) and C=413 (49%). Median disease duration was significantly higher in group A compared to groups B and C [8.3(0.1-23.4) vs. 6.2(0-17) vs. 3.3(0-14.6) years,p<0.0001]. The median SLICC/ACR-DI [0(0-9) vs. 0(0-6) vs. 0(0-7),p=0.065] was comparable in the three groups. Further analysis of organ/system damage revealed that frequencies of neuropsychiatric (21% vs. 10% vs. 7%,p=0.007), skin (10% vs. 1% vs. 3%,p=0.002) and peripheral vascular (5% vs. 3% vs. 0.3%,p=0.008) were more often observed in group A compared to B and C. Frequencies of severe cumulative lupus manifestations such as nephritis, thrombocytopenia, hemolytic anemia and vasculitis were alike in all groups(p>0.05). Death was significantly higher in group A compared to groups B and C (15% vs. 10% vs. 6%,p=0.028). Among 69 deaths, 8/33(24%) occurred at first month after diagnosis. Infection accounted for 54/69 (78%) of the overall deaths and 38/54 (70%) had concomitant disease activity. Other causes of death were nephritis (acute kidney injury or chronic renal disease) in 6 (9%), alveolar hemorrhage in 3 (4%), massive intracranial bleeding in 1 (1.4%), multiple thrombosis due to catastrophic antiphospholipid syndrome in 1 (1.4%), B-cell lymphoma in 1 (1.4%) and unknown 3 (4%).

Conclusion: This large multicenter study provided evidence that early-onset cSLE group had distinct outcomes. This group was characterized by higher mortality rate and neuropsychiatric/vascular/skin organ damages in spite of comparable frequencies of severe cumulative lupus manifestations. We also identified that overall death in cSLE was an early event mainly attributed to infection with associated disease activity.

Evaluation of Mild to Moderate SLE Flare in Patients with Childhood-Onset Disease

Malki Peskin[1], Dawn Wahezi[2,3], Chaim Putterman[4], Tamar Rubinstein[5,6] and Nicole Jordan[4,7], [1]Pediatrics, Albert Einstein College of Medicine, Bronx, NY, [2]Pediatric Rheumatology, The Children's Hospital at Montefiore, Bronx, NY, [3]Pediatric Rheumatology, Albert Einstein College of Medicine, Bronx, NY, [4]Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY, [5]Pediatric Rheumatology, Children's Hospital at Montefiore, Bronx, NY, [6]Rheumatology, Albert Einstein College of Medicine, Bronx, NY, [7]Montefiore Medical Center, New York, NY

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: One aspect of childhood SLE lacking understanding is the prediction of disease flares. The objective of this study is to identify predictors of mild to moderate flare in pediatric patients with SLE. The specific aims of this study are to investigate predictors of SLE flare in a high risk, urban, minority population. We aim to use this information to formulate a way to better predict and prevent flares among the pediatric population.

Methods: Included participants were enrolled in the pediatric Einstein Lupus Cohort (a database created in 2009 of patients meeting ACR criteria for SLE at the Children's Hospital at Montefiore), have evidence of mild to moderate flare during participation in the cohort, and have data recorded 1, 6, and 12 months prior to flare. To investigate predictors of flare within our population, we evaluated demographic variables including age, gender, race, ethnicity, education, household income, original criteria for diagnosis, and autoantibody profile. We also evaluated disease specific measures such as disease duration, medication usage, SELENA SLEDAI score, BILAG score and SLICC damage index. Laboratory variables assessed include ANA titer, anti-dsDNA antibodies, C3, C4, CBC, albumin, creatinine and urinalysis. Mild to moderate flare wass defined based on the following parameters: (1) Change in SELENA SLEDAI of ≥3 points OR (2) development of 1 new BILAG A score or 2 new BILAG B scores. All predictors identified in univariate analyses with $p<0.25$ were included into a multivariate model.

Results: We enrolled 102 pediatric patients with SLE (as defined by ACR criteria) and have data recorded for over 369 follow-up visits. General demographics for included participants are listed in Table 1. In multivariate analysis, elevated dsDNA antibodies, low WBC and sledai score were identified as independent predictors of disease flare at the next visit (within 6 months) (Table 2).

Conclusion: We have identified elevated dsDNA and low WBC count as important predictors of upcoming disease flare in pediatric patients with SLE. Interestingly, conventional markers including C3 and C4 were not found to be predictive. With this research, we hope to be able to identify flares before they manifest and ultimately be able to reduce disease burden among the pediatric SLE population.

Table 1: Demographics

Total patients enrolled	102
Total # of specimens collected	369
Mean age at Diagnosis	14.2 ± 3.7 (range 6-20)
Gender	Females: 83 (81.4%) Males: 19 (18.6%)
Race	African American: 41 (40.2%) Asian: 5 (4.9%) White: 5 (4.9%) Other: 4 (3.9%)
Ethnicity	Hispanic: 45 (44.1%) Non-Hispanic: 51 (51.0%)
Patient Level of Education	Grammar School: 11 (11%) High School: 55 (54%) College: 24 (24%)
Household Income	Less than $25,000: 21 (20.1%) $25-75,000: 12 (11.8%) Greater than $75,000: 9 (9%) Deferred: 43 (42.1%)
Patients with a family history of SLE	30 (29%)
Patients with renal disease	61 (59.8%)
Class of renal disease	Class II – 9 (8.8%) Class III – 21 (20.1%) Class IV – 15 (14.7%) Class V – 22 (21.6%)
Patients on Steroids	89 (87.3%)
Patients currently on an additional oral immunosuppressive therapy	37 (36.2%) 9% azathioprine 21% MMF 6% methotrexate
Patients previously received immunosuppressive infusions	39 (38.2%) cyclophosphamide 23 (22.5%) rituximab 7 (6.8%) IVIG 8 (7.8%) belimumab 3 (2.9%) abatacept

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hematologic abnormalities are common manifestations in systemic lupus erythematosus (SLE) patients. Several studies have demonstrated a higher frequency of immune thrombocytopenic purpura (ITP) in pediatric compared to adult lupus but none evaluated ITP at lupus diagnosis in both age groups. Simultaneous diagnosis of these two conditions is challenging and analysis of clinical correlates of ITP in pediatric and adults at lupus presentation may provide a more appropriate time frame from diagnosis to treatment in these patients. Therefore, the objectives of this study were to compare clinical and laboratorial features between pediatric and adult patients at concomitant diagnosis of ITP and SLE.

Methods: This was a retrospective study evaluating 336 cSLE and 1,830 aSLE patients from 1983 to 2014 regularly followed at the Pediatric Rheumatology Unit and the Rheumatology Division of the same University hospital. ITP was defined as platelets count $<100,000/mm^3$ in the absence of other causes often with the characteristic purpuric rash. Data were obtained from medical charts assessed at ITP and SLE diagnosis, including demographic characteristics, clinical and laboratorial findings of SLE, disease activity and initial treatment.

Results: The median current age was 11.6 years and 27.3 years, respectively. The frequencies of female gender and Caucasian race were similar in both groups ($p > 0.05$). cSLE had a higher frequency of ITP compared to aSLE (17% vs. 4%, $p<0.0001$) and the former group had more hemorrhagic manifestations (59% vs. 34%, $p=0.007$). Simultaneous severe lupus manifestations such as pericarditis (25% vs. 10%, $p=0.029$) and central nervous system involvement (30% vs. 14%, $p=0.029$) were more common in cSLE. Concomitant constitutional symptoms (fever and weight loss) and reticuloendothelial manifestations (adenomegaly, hepatomegaly and splenomegaly) were also more frequent in this age group ($p<0.05$), whereas cutaneous and articular involvements were less often observed in cSLE patients ($p<0.05$). A trend for a higher SLEDAI score was observed in pediatric patients (18 vs. 13, $p=0.072$). Analysis of autoantibodies showed a lower frequency of anti-Ro (11% vs. 27%, $p=0.026$) in cSLE patients compared to adults. Concerning treatment, intravenous methylprednisolone, intravenous immunoglobulin, blood transfusion and platelets transfusion were more frequently used in the pediatric population ($p < 0.05$).

Conclusion: ITP at cSLE presentation is more severe than in aSLE with distinct features characterized by major organ involvements and constitutional/reticuloendothelial manifestations. These findings reinforce the need for a more aggressive treatment in this age group.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The association between disease activity and nailfold capillaroscopy (NC) alterations has been described in systemic lupus erythematosus (SLE). However, data on longitudinal assessment of NC are scarce in childhood-onset SLE (cSLE), especially concerning its association with clinical and laboratory parameters. Therefore, the objectives of this study were to perform a prospective evaluation of nailfold capillaries in childhood-onset SLE (cSLE) and to assess the possible influence of clinical and laboratory manifestations, disease activity and treatment on altered NC.

Methods: This prospective study included cSLE patients regularly followed at the Rheumatology Outpatient clinic, University of Sao Paulo. NC was performed at inclusion and after 18 months and the results were classified as normal (no morphologic alterations and more than 7 loops per linear millimeter) or abnormal (slightly decreased capillary density with the presence of mild to moderate micro-hemorrhages or scleroderma pattern). Clinical and laboratory findings, disease activity score and treatment were evaluated at each NC.

Results: Forty-four patients were initially included and 33 patients repeated NC after 18 months. Thirty-eight (86%) were female and the median age at baseline was 20.4±3.7 years with mean disease duration of 7.8±4.7 years. Clinical manifestations of lupus since diagnosis included arthritis in 84% of patients, mucocutaneous involvement in 39%, hematologic in 32% and nephritis in 64%. Thirty-eight (86%) patients were positive for anti-dsDNA, 50% anti-Sm, 9% anti-RNP, 39% anti-Ro, 11% anti-La, 52% anti-P and 23% antiphospholipid antibodies. At baseline, the median of SLEDAI was 3.5 (0-16), predominantly for renal activity (30%), leucopenia (14%), positive anti-dsDNA (39%) and hypocomplementemia (45%). Thirty-four (77%) patients were under prednisone, 18% azathioprine, 11% cyclophosphamide, 50% micofenolate mofetil and 11% methotrexate. Comparison of patients with altered and normal NC showed a higher frequency of serositis in the former group (63 vs. 21%, p=0.01), particularly pericarditis (50 vs. 14%, p=0.016), as well as a trend for more cutaneous vasculitis (56 vs. 25%, p=0.054) any time since lupus diagnosis. At baseline, the group with abnormal NC had more mucocutaneous activity (19% vs. 0, p=0.042). No differences were observed in other clinical manifestations, autoantibodies profile, SLEDAI and treatment at the moment of NC (p>0.05). After 18 months, 21/33 (64%) patients maintained the same NC findings and 3/33 (9%) presented new abnormalities or intensified previous alterations. One of the latter also presented new capillary enlargement with a concomitant lupus nephritis, requiring higher doses of immunosuppressive drugs. Among the 9/33 (27%) patients who showed less alterations on NC after 18 months, six had stable disease/SLEDAI and were on prednisone tapering.

Conclusion: This study reinforces the dynamic characteristics of nailfold capillaries in lupus and strengthens the role of NC as a useful

tool for the follow-up of cSLE patients, especially concerning disease activity assessment.

Novel Electronic Health Record-Based Method Confirms Increased Renal Disease Burden in Pediatric-Onset Vs. Adult-Onset Patients with Systemic Lupus Erythematosus

April Barnado[1], Robert Carroll[2], Carolyn Casey[1], Joshua C. Denny[2] and Leslie J. Crofford[3], [1]Medicine, Vanderbilt University Medical Center, Nashville, TN, [2]Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN, [3]Medicine, Vanderbilt University Medical Center, Nasville, TN

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Children with Systemic Lupus Erythematosus (SLE) are often understudied compared with adults. Using the electronic health record (EHR) can increase sample size and the diversity of SLE patients while providing longitudinal data on comorbidities. We assessed differences in comorbidities in pediatric vs. adult-onset SLE using an EHR-based phenome-wide association study (PheWAS). PheWAS is a systematic and efficient approach that compares two groups using ICD-9 codes.

Methods: We used our validated algorithm of ≥ 4 counts of the SLE ICD-9 code (710.0) and ANA positive ≥ 1:160 while excluding dermatomyositis and systemic sclerosis ICD-9 codes to identify SLE cases in a de-identified EHR called the Synthetic Derivative (SD). The SD contains over 2.5 million subjects with longitudinal clinical data. Our algorithm has an internally validated positive predictive value of 94% and a sensitivity of 86%. Pediatric-onset SLE was defined as ≤ 18 years at first use of the SLE ICD-9 code vs. adult-onset ≥ 19. PheWAS was performed in pediatric vs. adult-onset adjusting for sex and race in logistic regression models and correcting for multiple testing using Bonferroni. PheWAS excludes subjects that have a one time count for a code to minimize the effect of coding errors.

Results: We identified 93 pediatric-onset and 1005 adult-onset patients with SLE. Pediatric-onset patients had a mean age at first SLE code of 15 ± 3 years versus adult-onset at 43 ±15. Both pediatric and adult-onset patients were predominantly female (87% vs. 90%, $p = 0.34$). Pediatric-onset patients were more likely African Americans (49% African American, 40% Caucasian, 8% Asian, and 3% Hispanic) vs. adult-onset (72% Caucasian, 24% African American, 3% Hispanic, and 1% Asian), ($p < 0.001$). Adjusting for sex and race, pediatric-onset patients had 13 codes that met the Bonferroni threshold for significance ($p < 1.26 \times 10^{-4}$) including mostly nephritis codes (Table 1, Figure 1). Compared to adult-onset, pediatric-onset patients had more codes related to other SLE ACR criteria such as pleurisy/pleural effusion, pericarditis, thrombocytopenia, aplastic anemia, pancytopenia, convulsions, and non-infectious encephalitis (all $p < 0.05$).

Conclusion: Using a large EHR, pediatric-onset patients had an increased SLE disease burden with more ICD-9 codes related to ACR SLE criteria, particularly renal disease. These findings demonstrate the ability of PheWAS to replicate epidemiologic associations

within subgroups of SLE patients and to function as an efficient discovery tool in the EHR.

Table 1.

ICD-9 Codes	Code Present	Code Absent	Adjusted Odds Ratio for sex and race (95% CI)	p value
Nephritis and nephropathy without mention of glomerulonephritis (580.3)	176	664	Pediatric-onset: 4.29 (2.62 – 7.02) Adult-onset: 1.00 (ref)	$p = 0.49 \times 10^{-9}$
Nephritis and nephropathy in diseases classified elsewhere (580.31)	164	664	4.25 (2.57 – 7.03)	$p = 1.80 \times 10^{-8}$
Nephritis and nephropathy with pathological lesion (580.32)	60	664	5.99 (3.10 – 11.57)	$p = 1.04 \times 10^{-8}$
Nephritis, nephrosis, renal sclerosis (580)	215	664	3.50 (2.16 – 5.66)	$p = 3.64 \times 10^{-7}$
Abnormal findings on examination of urine (398)	135	891	3.58 (2.13 – 5.94)	$p = 8.68 \times 10^{-7}$
Other hypertensive complications (401.3)	20	566	9.66 (3.47 – 26.87)	$p = 1.38 \times 10^{-5}$
Disorders of phosphorus metabolism (275.53)	27	987	6.39 (2.76 – 14.75)	$p = 1.42 \times 10^{-5}$
Thrombocytopenia (287.3)	98	660	3.77 (2.00 – 7.09)	$p = 3.94 \times 10^{-5}$
Glomerulonephritis (580.1)	99	664	3.51 (1.91 – 6.43)	$p = 5.14 \times 10^{-5}$
Coagulation defects (286)	167	660	3.15 (1.80 – 5.50)	$p = 5.58 \times 10^{-5}$
Pericarditis (420.2)	78	922	3.47 (1.89 – 6.40)	$p = 6.42 \times 10^{-5}$
Purpura and other hemorrhagic conditions (287)	104	660	3.57 (1.90 – 6.68)	$p = 7.30 \times 10^{-5}$
Primary thrombocytopenia (287.31)	27	660	6.42 (2.48 – 16.60)	$p = 1.24 \times 10^{-4}$

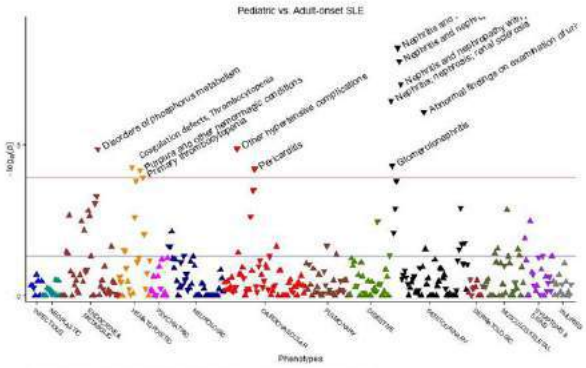

Figure 1. PheWAS of pediatric vs. adult-onset SLE.
The x axis represents the PheWAS codes that are mapped to ICD-9 codes organized by organ system. The y axis represents the level of significance. Adult-onset patients are the reference group. The lower horizontal line represents the $p < 0.05$ significance threshold. The upper horizontal line represents the Bonferroni threshold ($p < 1.26 \times 10^{-4}$). The thirteen codes that met the Bonferroni threshold are labeled above.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Genetic factors play a role in SLE, evidenced by the high sibling risk ratio (λs=8–29) and higher concordance rates between monozygotic twins (>35%) compared to dizygotic twins (2-5%). It is clear that the genetic basis of disease differs to some degree between ancestral backgrounds, and is less well understood in non-European ancestry subjects. In this study, we assessed the familial occurrence autoimmune disease in childhood-onset SLE (cSLE) and adult-onset SLE (aSLE) relatives in a large Brazilian cohort.

Methods: cSLE patients (disease-onset ≤18 years) and aSLE patients (disease-onset >18 years) followed in the Pediatric and Adult Rheumatology Outpatient Clinic of the State University of Campinas were included. Each patient was personally interviewed regarding history of autoimmune diseases in three family generations (grandparents, parents and uncles/aunts, cousins and siblings). Recurrence rates were then calculated for each reported disease.

Results: We included 112 cSLE patients [96 (85.7%) women] and 266 aSLE patients [247 (92.9%) women]. In cSLE patients we identified 3812 relatives. In the first-degree kinship we observed 10 relatives with SLE, with a recurrence rate of 25.3 (25-fold greater risk of SLE than the general population). In the second-degree kinship we observed 10 relatives with SLE and 1193 relatives without, with a recurrence rate of 8.3. In the third-degree kinship we observed a recurrence rate of 0.9 (no increase over general population). In aSLE patients we identified 10584 relatives. In the first-degree kinship we observed a recurrence rate of 18.8. In the second-degree kinship the recurrence rate was4.6. The most frequent non-SLE autoimmune diseases observed in the family members were: hypothyroidism, hyperthyroidism, vitiligo, rheumatoid arthritis, psoriasis, systemic sclerosis, ankylosing spondylitis, inflammatory myopathy, Sjögren syndrome, Crohn's disease.

Conclusion: SLE recurrence rate is higher among first-degree relatives in both cSLE and aSLE patients, and steadily decreases between generations as would be expected for complex inheritance. Familial tendency toward SLE was higher in families with a cSLE patient, and recurrence rates were comparable or higher than those reported in European ancestry.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mycophenolic acid (MPA) is the biologically active metabolite of mycophenolate mofetil (MMF), a widely used immunosuppressant in the treatment of childhood-onset systemic lupus erythematosus (cSLE). In our center, 54% of our cSLE patients are of Hispanic ethnicity. Hispanic cSLE patients are predisposed to higher SLE disease activity and risk for increased

morbidity but have also been found to respond well to MMF. Published cSLE MPA PK studies include mainly Caucasian or African-American patients. The objective of this ongoing study is to describe the pharmacokinetics (PK) of MPA in a cohort of Hispanic cSLE patients at a single center.

Methods: The PK of MPA and its glucuronide metabolites (MPA glucuronide/ MPAG and Acyl MPA glucuronide/ AcMPAG) was evaluated in cSLE patients (n=6; all female and Hispanic; age 13-18 years) on a stable MMF regimen (1,500-2,000 mg/day) (*Table 1*). Blood samples for PK analysis were collected at 4 time points: prior to MMF morning dose administration (trough), 20 minutes, 1 hour, and 3 hours post-MMF administration. Exposure to drug (PK) was measured by the area under the curve of MPA concentration plotted against time. Disease activity was assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI).

Results: The plasma concentration-time profiles of MPA, MPAG, and AcMPAG are shown in Figure 1. The PK parameters (mean ± SD) were: maximum MPA concentration (C_{max}) of 12.8 ± 7 µg/ml (55% coefficient of variation, CV), time to reach C_{max} (T_{max}) of 0.8 ± 0.4 hrs (44.5% CV), and $AUC_{0\text{-}3\ h}$ of 23.7 ± 12.3 µg*hr/ml (51.9% CV). There was noted improvement and decline in SLEDAI scores averaged over time after MMF therapy initiation (*Table 1*).

Conclusion: Our study in an all-Hispanic cSLE patient cohort demonstrated MPA PK parameters which are consistent with currently published literature on MPA PK in cSLE patients. Substantial inter-patient variability in MPA PK was observed, highlighting the need for further studies on individualized MMF dosing strategies in cSLE.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Childhood-onset systemic lupus erythematous (cSLE) patients are at higher risk for renal disease than those with adult-onset disease. Mycophenolate mofetil (MMF) and intravenous cyclophosphamide (CYC), commonly used for induction immunosuppression therapy of proliferative lupus nephritis (LN), are considered equally efficacious in adults. Comparative data in the pediatric population are lacking. To reduce treatment variability and facilitate comparative effectiveness studies, the Childhood Arthritis and Rheumatology Research Alliance (CARRA) published a consensus treatment plan (CTP) for induction therapy in childhood proliferative LN. The CTP recommended treatment with MMF or IV CYC and one of three steroid regimens: primarily oral, primarily IV, or mixed oral/IV. We report treatment group allocation and provider adherence for induction agents and steroid regimens in a multi-center pilot feasibility study.

Methods: This observational study enrolled 41 cSLE patients from 10 CARRA sites. Subjects had new-onset biopsy proven class III or IV proliferative LN and were starting induction therapy with MMF or IV CYC and steroids. Baseline demographics, disease-related features, physician decision-making regarding choice of induction agent and steroid regimen were reported. Subjects were followed for up to 24 months. Providers reported adherence to the CTP for induction agents and steroid regimen at 3 and 6 month visits. Complete renal response (CRR), defined as normal renal function, inactive urine sediment, and urine protein to creatinine ratio of < 0.2, was reported at 6 months.

Results: A majority of participants were female (83%) with a median age of 14 years. There were no significant differences in demographics between MMF or CYC groups or among the three steroid regimens. However, 78% (18/23) of those treated with CYC had class IV nephritis versus 33% (6/18) of those treated with MMF (p = 0.004). Physicians reported adherence concerns as a reason for selecting treatment for 5 of the patients in the CYC group but none in the MMF group (22% versus 0%, p = 0.04). MMF or CYC regimen was followed as intended per the CTP in 75% of subjects at 3 months and 56% at 6 months. CRR at 6 months was achieved for 56% with MMF and 64% with IV CYC (p = 0.6); the study was not powered to evaluate treatment efficacy. Steroid regimen chosen differed significantly by induction agent; those treated with MMF were more likely to receive the primarily oral steroid regimen and those treated with CYC were more likely to receive the mixed oral/IV regimen. Steroid regimen was followed as intended per the CTP in 59% of patients at 3 months and 37% of patients at 6 months.

Conclusion: This feasibility study revealed two important issues. First, there was confounding by indication present as patients with class IV nephritis (vs class III) were more likely to receive CYC. Second, a substantial number of patients did not continue treatment according to the CTP. For future comparative effectiveness studies using observational methodologies, large sample sizes may be needed to allow sufficient adjustment for confounders and modification of the CTP regimens may needed to ensure better usability.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Neuropsychiatric SLE in children and adolescents presents diagnostic challenge due to limitations of conventional magnetic resonance imaging (MRI) to detect clinically relevant brain changes. We examined structural brain abnormalities in pediatric-onset SLE (pSLE) utilizing advanced MRI techniques.

Methods: We conducted a cross-sectional analysis of clinically-obtained brain MRI images from subjects with pSLE, and compared them to existing brain MRI images from age and sex-matched controls from another study. All images were obtained between 2007 and 2015 on the same scanner at 3T using a T1-weighted MPRAGE (magnetization-prepared rapid, acquisition gradient echo) protocol. We used an advanced multi-atlas segmentation algorithm to divide the brain into 154 anatomical regions of interest (ROIs), organized hierarchically within larger brain structures. We calculated volumes of individual ROIs and larger brain structures, and compared volumetric measurements from pSLE and control subjects using univariate paired t-tests. ROIs with significant group differences after Bonferroni correction for multiple comparisons ($q<0.01$, where $q=p/\#ROIs$ tested) were reported. A neuroradiologist, blinded to the volumetric results, performed conventional re-reads of MRIs for pSLE subjects.

Results: We matched 29 SLE adolescents to 29 controls, comprised of 90% females with a mean age of 15.9 (SD=3.6). Median disease duration for SLE subjects was 1.1 years (interquartile range, IQR= 0.2, 2.8), and there was a history of nephritis in 11 (39%), seizures and/or stroke in 5 (18%), anti-phospholipid syndrome in 5 (18%), depression and/or anxiety in 15 (54%). Glucocorticoids were used by 86% of pSLE subjects at the time of MRI (median prednisone dose=10 mg, IQR=6,25). Conventional pSLE MRI reads indicated T2 hyperintensities in 14 (48%) and mild diffuse volume loss in 8 (28%). Using advanced segmentation, total brain volume did not differ between groups, but volumes in specific gray matter ROIs were significantly decreased in pSLE subjects compared to controls ($q<0.01$) (Figure). These ROIs are involved in: decision-making, memory, and social cognition (right medial frontal cortex); empathy, emotional memory and processing (right temporal pole, left anterior cingulate gyrus); topographical and facial recognition (right lingual gyrus); language processing (left parietal lateral cortex, bilateral planum polare, frontal operculum); visual and spatial attention (bilateral cuneus). SLE subjects also had significantly larger lateral ventricles.

Conclusion: Compared to healthy peers, children and adolescents with SLE have decreased gray matter volumes in regions involved in executive function, social cognition, language and emotional processing. Future study should examine the functional correlates of these structural brain abnormalities.

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Children with lupus nephritis (LN) are at risk for cognitive impairment due to effects on the brain from systemic inflammation and from potential effects of chronic kidney disease (CKD). We aimed to determine the risk for neurocognitive dysfunction for children with LN compared to children with other etiologies of glomerular CKD, hypothesizing a higher risk for those with LN, and examined the relationship of cognitive function to quality of life (QOL).

Methods: We conducted a cross-sectional analysis of the Chronic Kidney Disease in Children (CKiD) cohort, a 54-center prospective observational study of pediatric CKD patients with mild/moderate renal dysfunction. We determined neurocognitive outcomes using baseline measures after study entry for standardized tests of intelligence, academic achievement, attention/inhibitory control, memory, and executive function. QOL was measured using parent and child reports of the Pediatric Inventory of Quality of Life Core Scales 4.0. We used inverse probability weighting in a logistic model for propensity score analysis to achieve balance between children with LN and those with other glomerular CKD for the following variables: age, sex, height, race, ethnicity, maternal education, glomerular filtration rate, proteinuria, systolic blood pressure, and anemia. We used linear regression models to: i) compare neurocognitive outcomes between exposure groups, adjusting for prednisone use (yes/no), and testing for an interaction between prednisone use and LN, and ii) test for an association between cognitive function and QOL.

Results: Compared to subjects with other glomerular CKD (n=171), those with LN (n=34) had shorter median CKD duration (1.6 vs 4.0 years) and higher prednisone use (59% vs 23%). In adjusted analyses, subjects with LN had higher intelligence (p=0.07), academic achievement (p=0.03), and better performance for attention (p=<0.01) and inhibitory control (p=0.07) (Table). There were no differences for the other cognitive measures, and no significant interactions between prednisone use and LN. Prednisone use was independently associated with better achievement (p=0.05), but worse attention (p=0.01). Lower executive function was associated with worse parent (p<0.001) and child-reported QOL (p<0.001), and lower attention (p<0.01) and inhibitory control (p<0.01) with worse child-reported QOL.

Conclusion: Contrary to our hypothesis, children with LN early in their disease course have comparable or better cognitive function than their peers with other glomerular CKD, possibly due to shorter disease duration and/or more immunosuppressive treatment. Further study should examine the association of disease duration and immunosuppression in cognitive function for children with LN, as well as strategies to mitigate adverse effects of cognitive dysfunction on QOL in children with CKD.

Table: Neurocognitive Outcomes for Children with Lupus Nephritis vs Other Glomerular Chronic Kidney Diseases				
Neurocognitive Outcome	**Median T-score (IQR)**		**Adjusted Effect of LN**	
	LN n=34	**Other CKD n=171**	**Estimate (95% CI)**	**p-value**
Intelligence (WASI)*	103 (90.5, 114)	93.5 (83, 104)	7.63 (-0.69, 15.95)	0.07
Academic achievement (WIAT-II-A)*	100 (93, 122)	89.5 (77, 100)	8.29 (-3.05, 19.64)	0.15
Memory (WISC-IV)*

Correlation and Responsiveness of Cutaneous Lupus Disease Area and Severity Index (CLASI) and Skindex-29 with Cutaneous Childhood Lupus Erythematosus (cSLE) **Ashwaq AlEÕed, **Nora Al Mutairi , **Sulaiman M Al-Mayouf, $Hafize Emine Sšnmez, $Seza Ozen, Jennifer L. Huggins,*Hermine I Brunner.* *Division of Rheumatology, Cincinnati ChildrenÕs Hospital Medical Center, Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, USA. **Department of Pediatrics Rheumatology, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia. $Department of Pediatric Rheumatology Hacettepe University Faculty of Medicine Ankara, Turkey.

Background/Purpose: Mucocutaneous lupus is a common manifestation in both adult and children with lupus (60-85%). The *Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI)* allows for measuring active inflammation(CLASI-A;range 0-70)and chronic damage (CLASI_D; range 0-59)has been developed and validated for use in adults. The Skindex is a skin-specific Quality of Life (QoL; range 0–100; 100=worst QoL). Neither the CLASI nor the Skindex-29 has been validated for use in cSLE. The objective of this study was to assess the validity of the CLASI and Skindex29 in cSLE.

Methods : In this ongoing study, 33 cSLE patients were enrolled to date. Besides the CLASI, physicians-rated cSLE activity (SLEDAI) and completed the SLICC/ACR damage index (SDI). The Skindex was modified to a 28-item scale given difference between the adult and children life styles. PatientsÕ QoL was rated using the PedsQL Generic Core (GC) scale and the Rheumatology Module (RM) and the Skindex29.

Results: Patients (age: 3-18years; 87% females) had moderately active cSLE (mean± SD; SLEDAI 9.6 ± 7.4), 44.4% had a SDI score>0; and PedsQL-GC/RM scores 75±17.06/74.2±14.8, respectively. The mucocutaneous (MC)scores were 2.6 ± 1.5 for SLEDAI-MC and 0.36 ±0.55 for SDI-MC. As shown in **Table 1/Figure1**,cSLE activity (SLEDAI, SLEDAI-MC), damage (SDI, SDI-MC) and QoL(PedsQL-GC/MC)were moderately associated with CLASI-A, CLASI-D and Skindex scores, respectively.

Conclusion: We found the CLASI and the modified Skindex feasible and to show construct validity when used in cSLE. Additional research is needed to confirm the responsiveness to change of these two indices when use in cSLE.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Discoid lupus erythematosus (DLE) is rare in children. There are no consensus guidelines for management or screening for evolution to systemic lupus erythematosus (SLE). This study compared screening and treatment practice patterns among pediatric dermatologists and pediatric rheumatologists caring for children with DLE.

Methods: A survey was e-mailed to 292 pediatric rheumatologists (Childhood Arthritis & Rheumatology Research Alliance [CARRA]) and 200 pediatric dermatologists (Pediatric Dermatology Research Alliance [PeDRA]). The survey addressed the following domains: laboratory screening for SLE (at time of DLE diagnosis); risk factors impacting screening strategy for SLE; first/second-line systemic therapies; and topical therapies. Consensus was pre-defined as ≥70% agreement from both subspecialties.

Results: Fifty-three pediatric rheumatologists and 69 pediatric dermatologists were included (18% and 35% response rates respectively). Both groups reported treating pediatric DLE (rheum n =48 [91%]; derm n= 65 [94%]), but >90% of respondents reported <10 DLE patients in their current practice. There was no consensus on the choice of labs for initial screening for SLE, but most respondents (rheum n = 42 [79%] vs derm n = 28 [41%]) chose the following panel: CBC/diff, renal/hepatic function, ESR, CRP, urine studies, complements, autoantibodies (i.e. dsDNA, SSA, SSB, RNP, Smith), anti-phospholipid antibodies. Of those who selected a partial laboratory work up (rheum n = 9 [17%]; derm n = 33 [48%]), only CBC (rheum n = 9 [100%]; derm n =32 [97%] and urinalysis (rheum n = 7 [78%]; derm n = 24 [73%]) achieved consensus as defined above. Other laboratory studies are listed in Table 1. There was consensus that the following baseline clinical features warrant more thorough SLE screening: 1st degree relative with SLE, positive autoantibodies, arthritis and nephritis. Rheumatologists more often initiated hydroxychloroquine as first-line therapy (rheum n = 24 [45%]; derm n = 9 [13%]) while dermatologists more frequently started with topical therapy (rheum n = 16 [30%]; derm n = 50 [72%]). There was no consensus regarding appropriate choice of second-line systemic agents.

Conclusion: This study reveals lack of consensus between and among pediatric dermatologists and rheumatologists caring for children with DLE, underscoring the need for future study and collaboration. Knowledge gaps include risk factors for SLE, screening for SLE, optimal therapy, and patient outcomes. Collection of robust longitudinal observational data will aid in developing consensus for management of pediatric-onset DLE. Table 1. Laboratory studies selected for partial screening

	Rheum (9) n, (%)	Derm (33) n, (%)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pediatric rheumatologists have successfully improved the life expectancy and quality of life of children with systemic lupus (cSLE). cSLE has higher morbidity and mortality than adult SLE; the young adult with SLE may have severe system involvement at the time of transition. The consequences of poor transition in this at-risk population are loss of continuity in care and medication regimen, as well as worse disease activity and damage. As data are scarce on successful transition of cSLE patients to adult care, we conducted a pilot study to better understand how to facilitate this transition.

Methods: Patients with cSLE ≥14 years old who fulfilled ACR SLE criteria were evaluated using a 29-item Transition Readiness Questionnaire (SLE-TRQ) adapted from transitioning questionnaires in other chronic disease. It included medical and life skills, medical knowledge and independent living, and feelings/stress about transition. A protocol based on the American Academy of Pediatrics guidelines for successful transition was implemented for patients ≥18 years old. All patients met with the adult rheumatologist in the pediatric clinic and were accompanied to their first adult clinic visit by the Pediatric Rheumatology nurse. Successful transition was defined as ≥ 3 visits with the adult rheumatologist. All successfully transitioned patients were asked to complete a Satisfaction Questionnaire (SQ).

Results: 40 patients with a mean age of 18.4 years completed the SLE-TRQ. The mean disease duration was 5.25 years; 75% were female; 45% Hispanic, 40% African American, 7% Caucasian. There were 93% who had major organ involvement, 19 (48%) renal disease, 8 (20%) neuropsychiatric lupus, 3 (10%) abnormal pulmonary function tests and 2 (5%) anti-phospholipid syndrome. Eleven patients were on prednisone, median dose 20 mg/day at the time of enrollment. Over 50% were non-adherent at least on one occasion with medications and appointments. On the SLE-TRQ, 27 patients reported good medical and life skills, and 14 had good knowledge. However, 16/40 admitted to uneasiness/unreadiness for transition. The mean scores were: skills- 1.39, knowledge- 2.4 and feelings about transition- 2.3, where scores of 4-5 identify patients that are not ready, 2-3 patients in preparation and 0-1 ready for transition. Of the 20 patients scheduled to transition, 12 were successfully transferred, and 8 remain under pediatric care, scheduled to transition at a later date. The mean SLEDAI at the last pediatric visit was 5.6 and at the third adult visit 5.25. Three patients were on prednisone (mean dose 13.8 mg/day). Nine patients completed the SQ, reporting satisfaction with the transition process.

Conclusion: This is the first study evaluating self-reported pre-transition readiness in cSLE and satisfaction with the transition process. Patients had good medical knowledge and independent living skills but were not psychologically ready to transition. We were able to successfully transition 60% of the patients with good satisfaction. However, 40% were not transitioned, suggesting adolescents with cSLE and major organ involvement need additional support in the transition to adult rheumatology.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile systemic lupus erythematosus (SLE) is a chronic multisystemic disease with an episodic course which is prevalent in all cultures with wide-ranging effects on their health-related quality of life (HRQOL). In order to detect the effect of SLE on pediatric population and their parents; a disease specific HRQOL tool, called Simple Measure of Impact of Lupus Erythematosus in Youngsters (SMILEY), was developed, translated into different languages and validated in several languages. To determine the validity and reliability of the Turkish SMILEY in our center. Here we are presenting the preliminary data of our single-center research.

Methods: In our cross-sectional study, Turkish children and adolescents 8–18 years of age with SLE and their parents were enrolled. Pediatric SLE patients and parents completed child and parent reports of Turkish SMILEY and Turkish Pediatric Quality of Life Inventory (PedsQL^{TM}) Generic module. Parents also completed the Childhood Health Assessment Questionnaire (CHAQ) regarding disability which affects HRQOL. Disease activity was estimated by examining physicians with usage of the SLE disease activity index (SLEDAI) and Physician's Global Assessment of disease activity (PGA); chronic damage with the Systemic Lupus Erythematosus International Collaborating Clinics ACR Damage Index (SDI). Additional information including child's age, gender, co-morbidity, date of disease onset, disease duration and medical treatment history were also noted. Test-retest reliability, agreement between child and parent reports of the Turkish SMILEY and validity modalities were examined.

Results: 70 children with SLE (Male/Female 11/59; mean age at investigation 15.4±2.8 years, mean disease duration 41.4±29.4 months) were recruited into the study. Our patients have a median SLEDAI of 4 (range 0-23), and median SDI of 0 (0-5), and median PGA was 1 (0-4) and 80% of these were active (SLEDAI > 0). Out of 70 children, only one child didn't complete the child report SMILEY scale; but all of seventy parents were able to fulfill their corresponding report of the Turkish SMILEY. 59 child subjects and 60 parent subjects solved the Turkish SMILEY again 14 days later. The ICC for all domains and total scores of child report (0.7-0.9, P<0.001) and parent report (0.6-0.9, P<0.001) was significant, thus confirming excellent test-retest reliability. Agreement between children and their parents was found to be favoring. For the existing child-parent pairs (n=69), moderate rho (0.4-0.6, P<0.001) and significant ICC (0.6 - 0.8, P<0.001) values were seen between the child and parent SMILEY total and domain scores. For children; the mean SMILEY total score was 70.3±13.4 and the mean PedsQL^{TM} Generic module score was 78±15.7. For the parents they were calculated as 70.1±13.4 and 77±16.5 respectively. There was a significant correlation between these scores both for the children (r=0.5, P<0.001) and the parents (r=0.4, P<0.001). In our study; important Spearman's correlations were found between child report of Turkish SMILEY and factors affecting morbidity, mortality. The child SMILEY total score (n=69) correlated remarkably with the PGA (r=0.7, P<0.001), SLEDAI (r=0.4, P<0.001), and SDI (r=0.5, P<0.001). The children with lower disease activity and damage were discovered to have higher scores in their corresponding SMILEY report, hereby emphasizing better QOL. This relationship was especially noticeable in total score and the limitation domain of SMILEY.

Conclusion: This first validation study about HRQOL of pediatric SLE patients in Turkey showed that; Turkish SMILEY is a useful, valid and a reliable disease-specific questionnaire which can be further used as a beneficial research tool in our country.

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - Poster II: Myositis, Systemic Lupus Erythematosus, Sjögren's Syndrome

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile Sjögren's syndrome (jSS) is a rare, poorly defined and possibly underdiagnosed condition. Mean age of diagnosis is approximately 10 years, with major salivary gland swelling as a common initial symptom. Extraglandular manifestations occur in approximately 50% of patients with jSS. Salivary gland ultrasonography (SGUS) is a non-invasive, non-irradiating imaging method. With regard to the late onset of sicca symptoms, the current lack of diagnostic criteria and the need for an alternative or supplement to the lip biopsy, a non-invasive diagnostic tool is especially important in the younger population. The aim of this study was to characterize symptoms and clinical findings of jSS and to investigate SGUS as a diagnostic method.

Methods: Patients were recruited from the Departments of Rheumatology at Haukeland University Hospital, Bergen, Norway, and Oslo University Hospital, Oslo, Norway. Patients were previously diagnosed with jSS by a specialist in rheumatology and had received the diagnosis before 18 years of age. Clinical examination, sialometry, Schirmers Itest and SGUS were performed in all patients, and information regarding autoantibodies and biopsy results obtained from the patients' medical journal. The SGUS examination of the parotid and submandibular glands was performed using a GE LogiqE9 with a linear high-frequency transducer (6-15 MHz). Representative images were stored digitally and blindly evaluated by two investigators (DH and MVJ). Glandular homogeneity and presence of hypoechogenic areas were evaluated and glands characterized as normal or SS-like.

Results: Mean age at jSS diagnosis was 13.6 years (range 7-16), with first symptoms occurring at 11 years (range 6-17). Sicca symptoms were reported in 4/10 patients. Reduced secretion of tears (Schirmer I-test ≤ 5 mm/5 minutes) was detected in 3/10 patients, and hyposalivation (unstimulated whole saliva ≤ 1.5 ml/15 minutes) in 4/10 patients. Minor salivary gland lip biopsy had been performed and focus score determined in 8/10 patients; 7/8 biopsies had a focus score ≥ 1. All patients were positive for ANA and anti-Ro/SSA; 6/10 were also anti-La/SSB positive, and 6/10 were rheumatoid factor positive. Salivary gland enlargement had been experienced by 6/10 patients; 1/6 had also experienced lacrimal gland enlargement. Lymphadenopathy was noted in 3/10 patients, and articular involvement in 3/10 patients. Current treatment with hydroxychloroquine was noted in 7/10 patients, and previous treatment in two patients. Interestingly, SGUS revealed that all investigated patients (n=10) had pathological findings consistent with pSS in at least 1 out of 4 major salivary glands, whereas the American-European Consensus Group (AECG) criteria was fulfilled by only 6/10 patients.

Conclusion: The majority of patients in this jSS cohort present with autoantibodies and pathological SGUS findings. Major salivary gland swelling was commonly reported, whereas sicca symptoms were rare. Although further studies are warranted in larger cohorts, findings indicate SGUS as a suitable imaging method in the diagnosis of jSS, possibly enabling an early diagnosis of this rare clinical condition.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects - ARHP Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Evidence based recommendations for transitional programs are available. Despite this, half of Young People (YP) do not make a successful transfer and implementation of transitional care is not widespread. Therefore, it is important to improve transitional care for YP with an autoimmune disease (AID). A potential tool could be the institution of a clinical transition pathway (CTP). The aim of this study was i) to explore how YP with an AID and their parent(s) experience care during the preparation for the upcoming transfer to adult care, ii) to develop a CTP.

Methods: A survey was conducted among YP with an AID (n=48), age 14-20 years with a separate survey for parents (n=48). Subjects of the 38 survey-questions involved demographics, achievement of self-management skills, experience with preparation for transfer and questioning for topics that were not discussed but should have been in clinic. The CTP was built based on principles of vanHaecht & Sermeus[1], results of the surveys were incorporated into the CTP.

Results: Response rate was 67% for YP and 69% for parents. It appeared that almost all YP attended the consultation with parents (88%). Training self-management skills was neglected and only 25% of YP were ordering medication or made appointments independently (15 %). Transition was not a topic in the consultation according to half of the YP. One third of all parents had feelings of anxiety about the upcoming transfer. Almost half of the YP needed discussing topics that were never mentioned during consultation like education, vocational, and alcohol. Results were used to built the CTP (figure 1). Most important points are an early start , with focus on self-management skills and independency using an individual transition plan (ITP) for each patient, joint consultations with professionals from both pediatric and adult rheumatology departments and supporting parents in letting go. The ITP (developed using 'DREAM TEAM UK' [2]) was divided into 3 age-categories (12-14;14-16;16-18+), with final checklist regarding different domains and per category targets that needed to be met.

Conclusion: Current care in general does not meet the needs of YP in the process of transition to adult rheumatology care. The developed CTP is a tool to improve this process with provision of care appropriate to the developmental stage of YP, focus on achievement of self-management skills and self-reliance and supporting parents during this process. Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The ACR practice guidelines establish U.S. and international treatment recommendations. We sought to characterize the quality of the guidelines using the Appraisal of Guidelines for Research and Evaluation (AGREE) II instrument with the aim of identifying potential areas for improvement.

Methods: Using the AGREE II online tool, four independent reviewers appraised the ACR practice guidelines available at the ACR website and their immediate previous version. AGREE II consists of 23 questions that examine six quality domains: Scope and Purpose, Stakeholder Involvement, Rigor of the Methodology, Clarity of Presentation, Applicability and Editorial Independence. To avoid sequencing effects, the order of appraisal was randomly assigned across reviewers. The quality scores of each domain were calculated by summing up the individual item scores in a domain and then dividing that sum by the maximum possible score for that domain. We summarized the domain scores for each guideline and examined trends over time.

Results: The 9 guidelines (Glucocorticoid Induced Osteoporosis (GIOP); JIA; Gout; LN; OA; SpA; PMR; RA) listed at the ACR website as of April 2016 and 4 previous versions (SLE 1999, OA 2000, GIOP 2000 and RA 2008) were appraised using the AGREE II instrument. All guidelines were published between 1999 and 2015. The Table shows the percentages of the total possible score for each guideline. The minimum and maximum for each domain were 53-99 for Scope and Purpose; 47-99 for Stakeholder Involvement; 31-96 for Rigor of the Methodology; 50-99 for Clarity of Presentation; 26-78 for Applicability; 25-85 for Editorial Independence and 42-96 overall. The Figure displays the trend in score changes over time. The average quality of guidelines improved over each time period, especially in the Scope and Purpose, Rigor of the Methodology, Stakeholder Involvement and Clarity of Presentation. In contrast Applicability and Editorial Independence domains improved but not to the levels of the other domains. For the 4 guidelines with previous versions, the mean (SD) absolute improvements for each domain were 18 (±11) for Scope and Purpose; 13 (±8) for Stakeholder Involvement; 38 (±22) for Rigor of the Methodology ; 25 (±15) for Clarity of Presentation; 22 (±12) for Applicability; 24 (±17) for Editorial Independence and 31 (±5) overall.

Conclusion: Based on the AGREE II instrument, the quality of ACR guidelines has improved over the past 16 years. There remains potential for improvement in the applicability and editorial independence domains.

Table: AGREE II Quality Score

	Domain 1. Scope and Purpose	Domain 2. Stakeholder involvement	Domain 3. Rigor of Development	Domain 4. Clarity of Presentation	Domain 5. Applicability	Domain 6. Editorial Independence	Overall score

Systematic Review and Appraisal of Quality Measures for Inflammatory Arthritis

Matthew Cooper[1] and Claire E H Barber[2], [1]University of Calgary, Calgary, AB, Canada, [2]Rheumatology, University of Calgary, Calgary, AB, Canada

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Quality measures are metrics health professionals can monitor to improve care delivery and patient outcomes. To be measurable they must include a specified numerator, denominator for a defined population, capture best-practices and be feasible to measure. The objective of this study was to conduct a systematic review and quality appraisal of measures for inflammatory arthritis (IA).

Methods: A search strategy was developed in consultation with a medical librarian using MeSH terms for IA (SpA [AS, PsA, ReA, and IBD-related arthritis], RA, and JIA) and quality measures. EMBASE, MEDLINE and CINAHL were searched from January 1, 2000 to Jan 17, 2016. A "grey literature" review of international arthritis organizations and quality measure libraries was also conducted. Two reviewers independently considered the papers for inclusion with disagreements resolved by consensus. A modified guideline appraisal tool (AGREE-II) was used to evaluate 6 domains of measure development on a 7 point Likert scale: scope and purpose, stakeholder involvement, rigor of development, clarity of presentation, applicability, editorial independence and an overall quality assessment which determined inclusion. Measures were abstracted in duplicate and categorized into themes, indicator type (process, structure, outcome) and based on 6 domains of quality (acceptability, accessibility, appropriateness, effectiveness, efficiency, safety).

Results: 3417 unique citations were found and 483 were selected for full-text review, 8 measurement sets were eligible for inclusion. An additional 2 sets were included that were published after the search and 5 sets from the grey literature review. Two sets did not meet AGREE II criteria leaving a total of 13 measurement sets. The measure sets were from 4 countries (USA, Canada, UK, Netherlands) and one European consortium. They included 10 sets on RA and 1 each for PsA, IA and JIA. There were a total of 161 unique individual measures (136 process, 20 structure and 5 outcome). Measures were found covering each of the 6 domains of quality. Frequent themes included assessment, management (including medications and comorbidities), wait times and education. Measure sets were developed based on systematic reviews of guidelines and measures, individual guidelines or on information from targeted literature reviews. Evaluation of development methods for the measurement sets revealed a variety of consensus techniques including: RAND-UCLA appropriateness methodology, prioritization exercises or other modified-Delphi methods. Inclusion of patients occurred

in 62% of development groups. Discussion of barriers to measurement was infrequent.

Conclusion: This review highlights that IA quality measures cover a diversity of themes encompassing process, structure and outcome measures across the 6 domains of quality. However, between organizations measure development is not standardized, highlighting the need for a standardized assessment tool for evaluation of development methods. As well, local assessment of measurement feasibility through pilot testing before implementation and use outside the original development context is recommended.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To identify published quality measures in rheumatoid arthritis (RA), osteoarthritis (OA), osteoporosis, spondyloarthropathy (SpA) and gout for the purpose of summarizing the existing measures and identifying gaps for improving care.

Methods: We performed a systematic review of English language articles in PubMed and Embase published before 2/11/2016 on the topic of quality measures in RA, OA, osteoporosis, SpA (psoriatic arthritis and ankylosing spondylitis) and gout. To be included, the quality measure applied to a clearly stated study population and had a description of its development, a measurable change, and an identifiable numerator and denominator. When articles referenced a website as the primary source of a quality measure, we reviewed the website for additional references; opinion articles were excluded. If measures were published on an annual basis, we evaluated the most recent measure set. We categorized individual measures by disease, publication year, domain (structure, process or outcome), country of origin, and endorsement. We analyzed identified quality measures across disease categories to draw summative conclusions and identify gaps.

Results: The literature search identified 4831 relevant abstracts. Detailed screening by 3 reviewers identified 22 abstracts meeting the inclusion criteria; 6 quality measure sets were found only on websites with no primary source in the scientific literature. Most of the published measures were specific for RA and OA (Table) and published after 2010 (n = 24, 62%). Not unexpectedly, most of the measures were related to the health care delivery process (82.3%), while relatively few were in the domains of structure (16%) and outcome (1.7%). Quality measures often originated from organizations and investigators in the United States (US) and United Kingdom (UK). Within the US, ACR (3 sets), Centers for Medicare and Medicaid Services (CMS) (3 sets), and the National Committee for Quality Assurance (NCQA) (2 sets) produced the greatest number of measure sets.

Conclusion: Most of the quality measures in rheumatology relate to the care of patients with RA and OA and focus on process rather than outcomes or structure. These results highlight the gaps in our ability to measure quality of care across the full spectrum of common rheumatologic diseases. Further work is needed to expand the development of quality measures to other common rheumatologic diseases and to address quality of care from the perspective of structure and outcomes.

Quality measures by High Priority Rheumatologic Disease

Disease	Year of Publication (n)	Number of Measure Sets	Number of Individual Measures	Origins of publications (n)	Domains of Individual Measures
Rheumatoid Arthritis (RA)	2004-2010 (4); 2011-2016 (9)	13	142	US (6); Canada (2); UK (2); Netherlands (1); PANLAR (1); EULAR (1)	Structure: 25 (18%) Process: 114 (80%) Outcome: 3 (2%)
Osteoarthritis (OA)	2001-2010 (5); 2011-2015 (6)	11	104	US (5); UK (2); Canada (1); Mexico (1); Belgium (1); EULAR (1)	Structure: 17 (16%) Process: 85 (82%) Outcome: 2 (2%)
Osteoporosis	2001-2010 (3); 2011-2013 (4)	7	40	US (7)	Process: 40 (100%)
Spondyloarthropathy (SpA)* and Generic Inflammatory arthritis[#]	2004-2010 (1); 2011-2016 (3)	4	38	US (2); UK (1); Canada (1)	Structure: 11 (29%) Process: 27 (71%)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Collaborative research is compromised by heterogeneity of data collection in observational rheumatoid arthritis (RA) databases. Therefore a EULAR taskforce has been convened to develop a minimum core dataset (MCD) of data items (i.e. Ôwhat to collectÕ) and instruments for data collection (i.e. Ôhow to collectÕ) to 1) harmonize future data collection 2) act as a common data model to which existing databases can be mapped 3) serve as a template for standardized data collection for RA research in routine clinical practice.

Methods: The task force comprised a study steering committee, a task force working group and a pan-European expert panel. The project involved a multi-step process (Figure): 1) a hierarchical literature review to identify data items and instruments of existing RA cohorts and registers 2) an online survey to capture information on perceived importance of extracted items and instruments for possible inclusion 3) two face-to-face (F2F) meetings of the working group with discussion and voting on content (items) and structure (instruments) of the MCD. The voting of the F2F meetings were confirmed and consolidated by a ratification survey and work performed by the steering group between the two F2F meetings.

Results: Published articles from 67 different European registers and cohorts were included for data extraction. The number of patients recruited in each register ranged from 130 to more than 50,000. A total of 40 different items and 125 instruments were identified in literature; 7 items felt to be missing were added by the steering group. A total of 90 experts from 28 different European countries, including patients (18%), health professionals (18%), physicians (55%) and researchers or other experts (10%) participated in the online survey. 27/47 (57%) items were regarded to be important for inclusion in a MCD by >80% of responders. At the first F2F meeting 22/47 items were voted to be INCLUDED, 24/47 to be EXCLUDED in a MCD; for 2 items no consensus was reached. Ratification survey and second F2F meeting revealed consensus to include 21/47 items and their instruments (Table). Remaining work in the task force pertains to instruments for two items (ÔglucocorticoidsÕ and ÔcomorbiditiesÕ).

Conclusion: Based on the multistep process, a first draft of a MCD was developed which has to be tested for feasibility in clinical settings and applicability to answer important research questions. Figure: Flowchart of the multistep process of the project

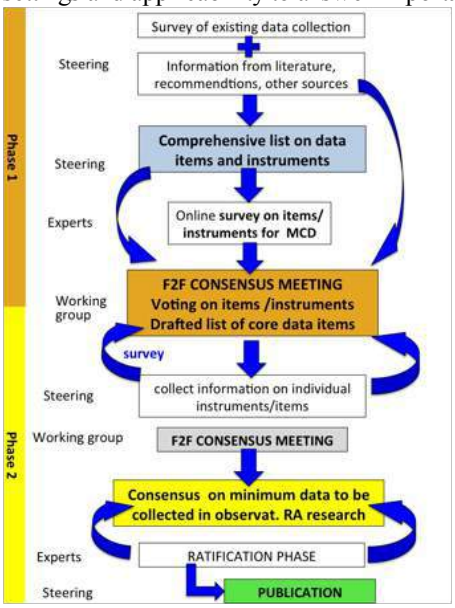

Table: Content of minimum core dataset

INCLUDED ITEM	PROPOSED INSTRUMENTS
AGE	date of birth
GENDER	male /female
DIAGNOISIS OF RA	rheumatologist reported diagnosis of RA
DISEASE DURATION	date of diagnosis
SMOKING	current / previous / never
BMI	weight / height
COMPOSITE SCORE	Clinical disease activity index (CDAI), simplified disease activity index (SDAI), disease activity score 28 joints (DAS28) EULAR and ACR response
TENDER JOINT COUNT	28 joint count
SWOLLEN JOINT COUNT	28 joint count
PATIENT GLOBAL	capture: 1) global assessment of disease activity, 2)related to arthritis,3) today and use of visual analogue scale (VAS) or numeric rating scale (NRS)
EVALUATOR GLOBAL	capture: 1) global assessment of disease activity, 2)related to arthritis,3) today and use of VAS or NRS
PAIN	capture: 1) pain, 2)related to arthritis, 3) last week and use of VAS or NRS
PHYSICAL FUNCTION	Health assessment questionnaire (HAQ)
ACUTE PHASE REACTANTS	C-reactive protein (CRP) AND erythrocyte sedimentation rate (ESR)
SEROLOGY	Rheumatoid factor AND ACPA
ONGOING/MOST RECENT DMARD	1) type of DMARD, 2) start and stop date, 3) reason for discontinuation (if applicable)
DMARD HISTORY	name of previous DMARD(s) (including biological, conventional synthetic and targeted synthetic DMARDs)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Custom-built software applications (apps) have become an integral part of medical practice today to help physicians be more efficient. They are being widely used for diagnostic purposes and for monitoring chronic conditions. In rheumatology, medical apps may help health professionals track disease activity and aid treatment decision in real-time to achieve optimal patient outcomes. The objective was to assess the need of a digital disease tracker to monitor disease activity in rheumatoid arthritis (RA) patients and psoriatic arthritis (PsA).

Methods: A needs assessment survey of Canadian rheumatologists was conducted in the spring of 2015. Our goals were to understand their views about Treat to Target strategies, and their perceptions of digital trackers to provide benefit to their patients and practice.

Results: Of 410 surveys sent via Survey Monkey, we received 70 responses (17% response rate). Responders were representative of the distribution of rheumatologists in Canada with the majority being in Ontario and Quebec. Among responders, 67% had practiced for 15 to 20 years and were serving predominantly urban patient populations (86%). The majority (56%) utilize both paper and electronic medical records (EMR). An additional 31% use EMR only. The vast majority (87%) accessed EMR via desktop/laptop computer with only 15.7% also utilizing tablets or smart phones. Clinical practice guidelines were widely used (87%) to make treatment decisions. CRA guidelines were mostly commonly selected, followed by ACR then EULAR. Treat to target strategies were employed by 92.86% of respondents, with swollen joint count (85.94%), physician global assessment (69.35%) and patient global assessment (57.14%) being the most common targets while DAS28 (45.45%) and SDAI (42%) were used less frequently . Over 80% of respondents do not use an RA disease tracking tool at this time. However 54.3% of respondents were very interested in having access to an efficient, user-friendly electronic device or app to help assess RA patients' disease activity at each visit, and track it over time. Many strongly believed such an app would benefit their practice (48.57%) and their patients (44.93%) and felt it was very important that the tracker be integrated with EMR (62.86%). Similar to accessing EMRs most respondents selected desktop/laptop as their preferred device for use of a digital RA Tracker.

Conclusion: Our survey found that most Rheumatologist apply Treat to Target strategies but are not currently using an RA disease tracking tools in their practice. An easy to use digital RA disease assessment tracker may be of value to Rheumatologists in Canada.

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient (pt) Support Program (PSP) is offered to pts who are prescribed adalimumab (ADA) for their Rheumatoid arthritis (RA). How participation in a PSP may impact pt-reported outcomes (PROs) has not been explored extensively in a prospective study. The purpose of this analysis was to assess the effect of ADA PSP participation on PROs among RA pts initiating ADA.

Methods: In this multi-country, ex-US, 78 week (wk) study, pts were offered a panel of "Core elements" (starter pack, call center/hotline, nursing services, educational material, and injection guide; offered in all participating countries) and "Other elements" (e.g, refill reminders, email, newsletters, support groups, home delivery, and financial assistance; vary by country) of PSP. Pts were divided in 2 groups on the basis of their participation in the PSP: ever (PSP users) vs never (PSP non-users). The following PROs were assessed over time to analyze the effectiveness of ADA in context of PSP utilization: Patient Activation Measure-13 (PAM-13, evaluates knowledge, skills, and confidence essential to a pt managing his/her own health; scores classified *a priori* into 4 levels [higher level = greater pt involvement in disease management]), Work Productivity and Activity Impairment (WPAI, evaluates absenteeism, presenteesism, work productivity loss, and activity impairment), Compliance Questionnaire Rheumatology (CQR, measures compliance to drug regimen), and Treatment Satisfaction Questionnaire for Medication (TSQM, evaluates convenience, effectiveness, side effects and global satisfaction). Change in pt perceptions was measured by the Beliefs about Medicines Questionnaire (BMQ, necessity and concern scales).

Results: Percentage (%) of pts that demonstrated improvement in PAM-13 levels were significantly higher among PSP users vs PSP non-users at wk 78 compared to BL (35.7% vs 28.1%, *P*=0.01). Additionally, compared to PSP non-users, PSP users had a significantly higher % of pts that started at level 4 at BL and remained at level 4 at wk 78 of ADA treatment (52.4% vs 28.9%, *P*=0.001); and % of pts that started at level 3 at BL and stayed at level 3 or improved to level 4 at wk 78 (64.5% vs 53.8%, *P*=0.028). PSP users had lower activity impairment (WPAI), higher convenience and global satisfaction (TSQM), and showed improvement in the necessity scale (BMQ) at all measured time points. Only numerical improvement in the favor of PSP users was observed for CQR **(Table)**.

Conclusion: In pts with moderate to severe RA, PSP users reported significant improvements after 78 wks of ADA initiation in managing their health and had skills and confidence to do so as evidenced by higher PAM-13 levels compared to the PSP non-users. Additionally, PSP users had significantly lower activity impairment, improved convenience and global satisfaction, and felt higher necessity for prescribed medication in comparison to the PSP non-users.

Table: Patient-reported outcomes by PSP utilization category

Patient-Reported Outcomes mean change from BL, (n)	24 weeks		52 weeks		78 weeks

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: International guidelines and studies recommend rheumatologists to use validated measures to monitor disease activity, such as the Disease Activity Score of 28 joints (DAS28). However, based on previous research, that recommendation was marginally followed in daily clinical practice. Before the dissemination of the Dutch guideline, it was found that in 16% of the patient's visits a measure for disease activity was obtained.[1] Up till now it is unknown whether adherence to tight control increased since the dissemination of the Dutch guideline in 2009. This study aims to evaluate whether the use of validated disease activity scores has changed since 2007.

Methods: To increase the precision of the study, Dutch rheumatologists that participated in the study of 2007 were invited to re-enter the study, If necessary, data were supplemented with data from colleagues and 'new' rheumatologists. Per rheumatologist, data was collected from the first 30 consecutive patients that visited the outpatient clinic. Per patient, data from four consecutive rheumatologist visits were collected. Data were collected by local nurses or by a research assistant, using case record forms. Disease activity was considered to be measured when either a validated score was reported in patients' medical chart, or when the researchers could calculate a validated score from the reported data (see figure 1). To allow comparison, this definition is the same as van Hulst et al. used in their 2007 measurement.[1]

Results: At this phase of the study, a medical chart review was performed on a sample of 1044 visits, within 10 rheumatologists, within 7 Dutch rheumatology outpatient clinics. These preliminary results show that in 84.0% (877/1044) of the visits a RA disease activity score was reported. Of those visits, a DAS28 score was reported in 49.6%(435/877) of the cases, a DAS28-CRP score was reported in 13.5% (118/877) of the cases, and a DAS score was reported in 2.6% (23/877) of the cases. In the remaining 34.3% (301/877) of the cases, another disease activity score was used (see figure 1).

Conclusion: Based on the preliminary results, the use of validated disease activity scores has increased since 2007. Currently, a medical chart review on a sample of 35 Dutch rheumatologists is still ongoing. Ultimately, we will present data on their use of validated disease activity scores, as well as on medication regimen changes based on disease activity. Session Title: Quality Measures and Quality of Care - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA can be trained in self-assessment of disease activity by a self-assessment of their joints and calculation of the Disease activity Score 28 (DAS28) (ref). **Objective:** To assess if such an auto-DAS assessment is a feasible measure over the long-term (i.e., do patients adhere to such an assessment?) and to determine the characteristics of patients related to adherence to auto-DAS.

Methods: This was an open long term (2-4 years) extension of the 6 month randomized controlled COMEDRA trial of patients with definite, stable RA. Patients were trained to perform auto-DAS by a nurse, using a video and teaching of self-assessment of joints (the training took approximately 30 minutes) and nurses provided the advice to perform the auto-DAS regularly in a dedicated booklet. 2-4 years after the end of the trial, patients were seen in a face-to-face interview with a nurse and the frequency of auto-DAS was assessed through the auto-DAS booklet and if unavailable, from patient questioning. Adherence to auto-DAS was defined as the performance of at least one auto-DAS more than 6 months after the end of the trial. Characteristics of adherent versus non adherent patients were compared by univariate and multivariate logistic regression analyses and included demographic and disease activity variables as well as the centre (higher versus lower than median inclusion number).

Results: Of the 970 recruited patients, 771 (79.5%) were followed up 3 years and had available data regarding auto-DAS: mean (±SD) age 61 (±11) years, median [IQR] disease duration 15 [9 - 23] years; 615 (80%) were women and 82% had received a biologic. The mean (±SD) baseline and 3-year DAS28 scores were respectively 3.1±1.3 and 2.8±1.4. After 3 years, 354 (46%) patients were adherent to auto-DAS (i.e., had at least one auto-DAS completed more than 6 months after the end of the trial). For adherent patients the median [IQR] number of auto-DAS performed was 5.4 [1.7 – 12.8] overall, i.e. 2.3 [0.8 – 5.9] per year. However among the adherent population, the number of patients who completed their autoDAS booklet at least once per year decreased over time, with 351 (99%), 162 (46%) and 118 (33%) patients respectively for 2012, 2013 and 2014 ($p<0.0001$). In the multivariate analysis, only larger inclusion centres were significantly associated to an adherent behaviour (OR [95% CI] 2.9 [2.0 – 4.1], $p<0.0001$).

Conclusion: After a short training, many of these long-standing, moderately active RA patients continued to perform an auto-DAS, though the performance of auto-DAS decreased over time in this cohort where patients did not receive any ongoing positive feedback on their auto-DAS. In the larger inclusions centres, autoDAS adherence was higher, perhaps related to more patient/physician interactions around autoDAS results. Self-assessment of disease activity is feasible in RA but positive reinforcement appears necessary. Further studies should analyse if outcomes are better for patients who self-assess.

Abstract Number: 1411

An Electronic MDHAQ (multidimensional health assessment questionnaire) Beyond an Electronic RAPID (routine assessment of patient index data): 21.3% of Rheumatoid Arthritis Patients Identified As Having Secondary Fibromyalgia Versus 3.5% By Clinicians

Theodore Pincus and Nathaniel Cook, Rheumatology, Rush University Medical Center, Chicago, IL
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Quality Measures and Quality of Care - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: A major impediment to use of patient questionnaires in routine clinical care has been the absence of electronic entry for patients and for doctors to introduce data into electronic medical records (EMR), particularly as most EMRs are incompatible with each other. RAPID3 (routine assessment of patient index data) on a multi-dimensional health assessment questionnaire (MDHAQ) has been found as useful in rheumatoid arthritis (RA) clinical trials as indices which require a formal joint count, such as disease activity score 28 (DAS28) or clinical disease activity index (CDAI), to distinguish active from control treatments, and to monitor clinical care. RAPID3 also is informative to recognize improvement in patients with osteoarthritis, systemic lupus erythematosus, spondyloarthropathies, vasculitis, and gout. Therefore, a number of organizations have developed electronic versions of RAPID3, often for demonstration projects and to provide quality indicators in routine clinical care. Most electronic versions mimic EMRs in being incompatible with one another, and therefore not easily merged with one another to study patient courses and outcomes, and invovling considerable expense. A common electronic version of MDHAQ used by many rheumatologists can be merged easily for collaborative research, and rendered compatible with any EMR through mandated HL7 and SMART on FHIR interfaces. We sought to develop an electronic MDHAQ/RAPID3 to be compatible with any EMR, although requiring initial collaboration with the EMR vendor, for routine clinical care.

Methods: A developer was identified with expertise in HL7 and SMART on FHIR interfaces and cloud-based storage, meeting all government privacy and security requirements. The developer has worked closely with rheumatologists to develop a user-friendly electronic MDHAQ, including RAPID3 and many additional scales (Table).

Results: The electronic MDHAQ functions quite effectively, providing RAPID3 and much additional information beyond RAPID3 (Table). For example, among 287 patients with RA in one clinical setting, secondary fibromyalgia (FM) was diagnosed in the EMR by rheumatologists in 10 patients (3.5%), while scores on a MDHAQ-FM index composed of pain, RADAI self-report joint count, and symptom checklist, indicated secondary FM in 61 patients (21.2%), of whom only 6 were identified by rheumatologist. An interface with an EMR through HL7 and SMART on FHIR is available, although requiring collaborative interactions to establish the interface.

Conclusion: An electronic MDHAQ offers considerably more information then only an electronic RAPID3, with no extra work on the part of the physician, while saving time with far better documentation, particularly with establishment of an interface to the EMR through HL HL7 and SMART on FHIR. Rheumatologists and organizations are encouraged to implement an electronic MDHAQ/RAPID3, rather than simply an electronic RAPID3.

Features of electronic MDHAQ/RAPID3 for routine rheumatology care	
Feature	Advantage(s)
RAPID3	Informative in RA, OA, AS, vasculitis, SLE, gout
Fatigue	Higher in SLE, FM than RA
Psychological variables: sleep, anxiety, depression	Screen for frequent source of patient problems
RADAI Self-report joint count	Correlated r>0.04-0.06 with TJC, SJC, in range of ESR vs CRP
Symptom checklist	Most effective screening tool reported for FM -
Recent medical history	Updates recent illness, surgery, adverse events, etc. for clinician
Calculations	Calculates RAPID3, RADAI, # symptoms, psych HAQ; MDHAQ FM index of pain>6, RADAI>16, symptoms>16/60; also DAS28, CDAI, if joint count and lab test available

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Stanford Health Assessment Questionnaire Disability Index (HAQ-DI) is a widely used patient reported outcome for functional disability in RA. Minimal clinically important differences (MCIDs) have previously been calculated based on the original ordinal HAQ-DI scores resulting in a dependence of the MCIDs on baseline scores(1), causesing limited generalizability and validity of the proposed MCIDs. The Rasch model provides a transformation of ordinal scores to an underlying latent scale with interval scale properties. This requires adequate fit of HAQ-DI data to the model. We aimed to 1) examine internal construct validity of the Danish version of the HAQ-DI (scored without correction for devices) and 2) determine a MCID of the HAQ-DI in a cohort of RA patients initiating anti-rheumatic treatment in clinical practice based on the transformed linear logit scale.

Methods: RA patients registered in the DANBIO registry at Center for Rheumatology and Spine Diseases, Copenhagen, Denmark were included in the study if HAQ-DI and Patient Global Visual Analogue Scores (PtGl) scores were available at a baseline visit and after > three months of follow-up after initiation of a) first synthetic Disease Modifying Anti Rheumatic Drug (sDMARD) (disease duration <

12 months) or 2) first biological drug (disease duration > 12 months). The Rasch model was fitted to HAQ-DI data at baseline and follow-up and item fit evaluated in separate analyses by comparing observed and expected item-restscore correlations (2). MCID was calculated as the median changes of A) the original and B) logit HAQ-DI score in the group of patients who had improved by 15-30 mm (ie. minimal improvement) on a 0-100 mm PtGl scale.

Results: 362 RA patients were included in the study. HAQ-DI data showed acceptable fit to the Rasch model as no significant evidence of misfit was disclosed at baseline and only a single misfitting item (the "Grip" sub-item, p=0.01) was identified at follow-up. Consistent item ranking across time indicated instrument invariance. Changes in ordinal and logit HAQ-DI scores were strongly correlated (Spearmans rho = 0.935, p <0.001), but the association between them is not completely linear. Sixty-one patients had an improvement > MCID on the logit scale (0.48), but no improvement on the ordinal scale (MCID 0.250), while no patients had the opposite pattern.

Conclusion: The Danish version of the HAQ-DI scored without correcting for devices showed acceptable internal construct validity and thus a MCID based on a linear transformed scale could be calculated for this study (0.48). Application of the logit MCID classified an additional 17% of patients as having achieved a MCID compared to the MCID calculated on the ordinal scale. This finding has potential implications for the use of ordinal-based MCID and the powering of future studies. References:

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Different patient reported outcome [PRO] measures are used for rheumatic diseases [RD], and there is lack of uniform generic illness measures across the disease spectrum. The aims of this study are – (1) Identify PROMISÒ health domains most relevant to care of patients with RD, (2) Collect T-Score metrics for these domains, (3) Identify clinically meaningful cut-points for these domains.

Methods: A convenience sample of RD patients aged 18 and over, were recruited consecutively at the time of routine clinic visits, to complete computer-adaptive tests on thirteen Patient-Reported Outcomes Measurement Information System (PROMIS®) instruments as part of an approved IRB. Based on the severity of the T-score metrics and discussion with clinical providers, four measures were chosen to be relevant to RD patients. A common educational method for establishing "proficiency" was borrowed to determine severity of the domains. Data from these patients were used to develop clinical vignettes across a range of symptom severity. Vignettes were created based on most likely item responses at different levels on the T-score metric (mean = 50; SD = 10). Vignettes were anchored at 5-point intervals (0.5 SDs). Patients with RD (N=9) and clinical providers (N=10) participated as expert panelists in separate one-day meetings. Vignettes were ordered and placed on cards. Panelists identified adjacent vignettes considered to represent upper and lower boundaries separating category cut points. In other words, for each domain these cut-points were used to classify the severity of symptoms – no symptoms, mild symptoms, moderate symptoms, and severe symptoms. Cut scores were defined as mean score for boundary vignettes.

Results: Four domains (physical function, pain interference, sleep disturbance, depression) were selected for their importance in RD, and that are actionable at the point of care, as determined in previous focus groups with clinical providers[1]. For all domains, patients set lower cut points for severity than clinical providers, by 0.5 to 1 SD (Table1). Patient and providers had the most overlap in their cut-scores for the pain interference domain.

Conclusion: We used a modified educational standard setting method to estimate clinically relevant cut points to classify severity for PROMIS measures of physical function, pain interference, sleep disturbance, and depression in patients with RD. Parallel exercises identified the cut points from the perspectives of patients with RD, and clinical providers who treat rheumatic diseases. This allows for meaningful interpretation of PROMIS® measures in a clinical setting in RD populations. Further work is focused on incorporating these cut points in clinical practice and assessing their impact on clinical care. **Table 1: Consensus cut-scores by domains and expert panel**

Domain	Severity categories	T-score cut points	
		Patient classification	Provider classification
Physical function*	No symptoms	>65	>60
	Mild symptoms	45-65	45-60
	Moderate symptoms	35-45	25-45
	Severe symptoms	<35	<25
Pain interference**	No symptoms	<50	<50
	Mild symptoms	50-60	50-60
	Moderate symptoms	60-65	60-70
	Severe symptoms	>65	>70
Sleep disturbance**	No symptoms	<35	<45
	Mild symptoms	35-45	45-55
	Moderate symptoms	45-60	55-65
	Severe symptoms	>60	>65
Depression**	No symptoms	<45	<55
	Mild symptoms	45-55	55-60
	Moderate symptoms	55-60	60-65
	Severe symptoms	>60	>65

*Higher score denotes better physical function ** Higher scores denote more [or worse] symptoms

Session Title: Quality Measures and Quality of Care - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Electronic (e)-health is a rapidly evolving field. Interactive online services are available and may be useful for patients with chronic diseases such as rheumatoid arthritis (RA), but have not been properly assessed. Sanoia is a secure and independent patient e-health and mobile (m)-health platform, developed to allow self-assessment, storage of questions to ask physicians and self-monitoring of disease status. The platform offers a dedicated set of scores, patient-reported outcomes and information for diseases, including RA. The objective of the trial was to assess the effect of access to the Sanoia e-health platform on patient-physician interaction efficacy after 12 months.

Methods: This 12-month, French, multi-center, randomized controlled trial (NCT02200068) included patients diagnosed with RA, recruited by their tertiary care center physician. Patients were allocated to 2 groups: a) possibility of access to the Sanoia platform, or b) usual care (continuation of normal internet use without Sanoia access). Follow-up was performed over 12 months by a home-based e-CRF. Primary outcome was change over 12 months of Perceived Efficacy in Patient-Physician Interactions Questionnaire (PEPPI).[1] The PEPPI-5 consists of 5 items, each starting with ''How confident are you in your ability to…" (eg. "...know what questions to ask a doctor?''). Patients rated each item on an 11-point scale; 0=not at all confident, 10=very confident. Total PEPPI-5 scores range from 0–50, with higher scores representing higher perceived self-efficacy in patient-physician interactions. Other outcomes measured included numeric rating scale (NRS) to assess perceived quality of care, and RA Impact of Disease (RAID) score to assess patient-perceived impact of RA. Analyses were non-parametric comparisons and used LOCF imputation on the intention-to-treat (ITT) population.

Results: Of 320 RA patients (159 vs 161, Sanoia vs usual care), mean (SD) age was 57.0 (12.7) years, mean (SD) disease duration was 14.6 (11.1) years and 253 (79.1%) were female. DAS28 was 2.65 (1.20), 54.1% were in DAS28 remission (<2.6), 216 (67.5%) were taking a biologic and 21.9% had previous therapeutic education sessions. 12-month data were available for 244 patients (76.0%). In ITT analyses, mean (SD) changes in PEPPI from baseline to 12 months were 38.6 (8.2) to 39.2 (8.0) (delta=+0.60 [5.52]) vs 39.7 (7.3) to 38.8 (8.0) (delta=-0.91 [6.08]) in Sanoia vs control group (p=0.01). Mean (SD) changes in quality of care NRS from baseline to 12 months were 8.2 (1.7) to 8.3 (1.6) (delta=+0.06 [1.44]) vs 8.2 (1.6) to 7.8 (1.9) (delta=-0.42[1.63]) in Sanoia vs control group (p=0.02). RAID changes did not differ between groups (data not shown).

Conclusion: In this randomized trial, giving RA patients access to the interactive Sanoia e-health platform led to a statistically significant, although small, improvement in patient-perceived patient-physician interactions and patient-perceived quality of care. This confirms the usefulness of an e-health intervention complementary to physician care in RA. **References:** ten Klooster P. Patient Educ Couns 2012;87(1):125–30.

Session Title: Quality Measures and Quality of Care - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Since 2008 the Center for Medicare and Medicaid Services (CMS) has been in the process of changing patient care to quality-valued healthcare. In order to comply with the six RA performance improvement care measures, we created the Clinical Disease Activity Index (CDAI) calculator with the efforts of a multidisciplinary team for use in the electronic medical record (EMR). The goal of this pilot study was to review the utility, adoption, and impact of the CDAI in an academic clinical practice. We investigated distribution of disease categories, the correlation and agreement of the CDAI and Simple Disease Activity Index (SDAI) values and categories, and finally examined longitudinal trends in disease activity and associated factors in our cohort.

Methods: 179 patients were analyzed over 16 months (n= 663 clinical encounters). Intraclass correlation was computed for CDAI and SDAI scores. The Kappa agreement and McNemar's test were conducted for the agreement of CDAI and SDAI disease categories. A logistic mixed effect model was used to assess the effect of the cofactors on CDAI and SDAI disease categories recorded for patients over time. The Cox proportional hazards model was used to assess the time to initial remission and low disease categories.

Results: After 3 months of launching the calculator we maintained >70 % EMR documentation rate throughout the study period. Our study was conducted in an 84.27% Hispanic population with 84.27% being female. Of total, 72% of subjects improved or remained stable in remission or low CDAI status, while 28% deteriorated or remained in high or moderate status. The intraclass correlation for CDAI and SDAI scores was found to be very high 0.99 (p-value <0.0001). The test of concordance for SDAI and CDAI categories showed no significant difference between discordant pairs (p-value 0.3352). The rate of change to remission or low stage was 7% likely to be obtained in an individual over the follow up period (OR: 1.07; 95% CI: 0.92-1.26, p=0.37). A median time to initial remission or low disease status was estimated as 5.8 months for patients in the cohort that started with either a moderate or high disease status (n=22) based on using the Kaplan-Meier method.

Conclusion: An excellent concordance was found between CDAI and SDAI, therefore CDAI could be used regardless of CRP values. Upon implementation of the CDAI in the clinic a small trend towards improvement in disease control over time could be seen, but could not reach a statistically significant level. Further analysis is needed to study the utility of clinical disease indices in the ambulatory setting. This study has established a quick and easy way to document periodic assessment of disease activity for future epidemiological review and classification of RA disease prognosis.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Quality Measures and Quality of Care - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Measurement of disease activity is considered a quality measure for management of rheumatoid arthritis (RA) patients. One validated measure of RA disease activity is the Routine Assessment of Patient Index Data 3 (RAPID3) score. We developed a quality improvement project to improve our clinic's adherence to use of the RAPID3 score in our patients with RA, with the goal of increasing documentation by 25% from baseline.

Methods: In our academic practice, we surveyed providers regarding their preferred disease activity measurement; the RAPID3,

already utilized in our clinic, was preferred by the majority of providers. Patient charts were screened for presence or absence of RAPID3 score within providers' notes. Using Plan-Do-Study-Act (PDSA) methodology, we introduced the following interventions to improve provider documentation: education through Divisional Grand Rounds, direct modification of electronic medical record (EMR) templates, and posted reminders in clinic. Chart review was conducted between interventions and at the conclusion of all interventions. A repeat survey of providers assessed providers' responses to the interventions and utilization of the RAPID3 in clinical decision making.

Results: Review of 3054 charts identified 632 patients with RA. At baseline, an average of 65% of provider progress notes documented a RAPID3 score. For the 3 months following the last intervention, the provider documentation rate had increased to an average of 90%, a 38% increase from baseline (see figure). Reasons for missing RAPID3 documentation include incomplete data entry during check-in. Providers noted the most helpful interventions to be changing their note template in the EMR (40%), Grand Rounds discussions (33%), and posted clinic reminders (13%). At the conclusion of the QI initiative, 20% of providers reported using the Rapid3 for clinical decision making in 50-74% of cases, while 53% used the Rapid3 25-49% of the time, and 27% reported using the Rapid3 <25% of the time; no one reported never using the Rapid 3 for clinical decision making, and no one reported using it >75% of the time.

Conclusion: We demonstrated sustained improvement in documentation of RAPID3 scores, increasing documentation rates by 38%. One barrier to successful implementation of this score was correct calculation within the EMR, which was challenging to rectify. Once corrected, documentation of the disease activity measure increased. However, we found that the majority of clinicians reported using the RAPID3 in their medical decision making less than 50% of the time, despite stating a preference for this measure in the practice. With the RAPID3 now incorporated into our practice's daily use, assessment of overall clinical response rate will be possible along with ongoing efforts to increase utilization of this quality measure for medical decision making to improve quality of patient care in RA.

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) definition of remission in rheumatoid arthritis (RA) [1] lacks information on patient perceived remission [2]. Qualitative research identified 'returning back to normal' as one of three themes of patient perceived remission [3]. A questionnaire to measure this 'normality' was developed in Bristol and investigated for its discriminative ability [4].

Objectives: This study investigated the relationship between patient perceived concepts of normality and remission, and the ability of the normality questionnaire to discriminate between remission and non-remission states.

Methods: Newly diagnosed RA patients with a high disease activity and/or unfavourable prognostic factors, were treated according a treat-to-target regime. Initially, all patients were treated with methotrexate and prednisolone, for patients not achieving a good EULAR response after 13 weeks treatment was intensified. At baseline and after 13 and 26 weeks of treatment different measures were collected, including the 'normality scale' to measure the perception of normality (7 items, range 7-36, higher scores indicating higher feeling of normality), Disease Activity Score of 28 joints (DAS28), and remission. Remission was measured in two ways: 1) patient perceived remission using the question *"Would you say that, at this moment, your disease activity is as good as gone? (yes/no)"*; and 2) ACR/EULAR Boolean-based definition of remission.

Results: Forty-seven patients completed all assessments, of whom 34 (72%) were female with a mean ± SD age of 50 ± 14 years. At baseline, mean ± SD DAS28 was 4.5 ± 1.1 and the normality score was 20 ± 7. After 13 weeks of therapy, DAS28 significantly decreased to 2.5 ± 1.0 ($p<0.001$), and further to 2.2 ± 0.7 after 26 weeks ($p<0.001$). The feeling of normality was significantly increased to 23 ± 8 in week 13 ($p=0.001$) and 24 ± 8 in week 26 ($p<0.001$) compared to baseline. As shown in Figure 1, patients in self-perceived remission had a significantly higher feeling of normality at week 13 ($p<0.001$) and week 26 ($p=0.007$) compared to patients not in self-perceived remission, while patients in Boolean remission had only a significantly higher feeling of normality at week 26 ($p<0.001$) compared to patients not in Boolean remission.

Conclusion: Self-perceived remission is significantly associated with higher normality perceptions after 13 and 26 weeks of therapy; Boolean remission only after 26 weeks of therapy. The normality scale has the ability to discriminate between patients in and not in remission.

Session Title: Quality Measures and Quality of Care - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: International and national bodies have given evidence-based recommendations for rheumatoid arthritis (RA) treatment. We assessed the general uptake of these recommendations by asking rheumatologists about their initial treatment preferences in case they themselves developed RA.

Methods: An online survey was disseminated to practicing rheumatologists across the continents and also made accessible on social media platforms between April and June 2016. Survey questions included following: 1. If you fell ill with seropositive active rheumatoid arthritis, what medications would you start as the first option? 2. At 3 months: if the first option does not - work, what would you take next? 3. At 3 months: if the first option would work, but you cannot really take it for disturbing side effects, what would you take next? Response options, to select one or more, included NSAIDs, Glucocorticoids (GC), and all DMARDs. Background information included age, gender, type and country of practice, and whether the participant was involved in national or international task force of guidelines/recommendations for RA.

Results: A total of 717 rheumatologists (49% female, 50% <50 years old) participated in the survey from 46 countries on 5 continents. The first preferred medication for early active seropositive RA included: MTX monotherapy 69% (sc 36%), MTX-based combination therapy 22%, another cDMARD(s) 2.7%, and biologic agent 6.2% (Figure 1). Furthermore, 53% would take NSAIDs and 84% GC including 6.3% im, 36% ia, 41% low dose GC, 28% medium dose GC, 1.8% high dose GC, and 16% would not take any GC. In case of inefficacy, options would be MTX monotherapy 15% (sc 78%), MTX-based combination 16%, another cDMARD(s) 8%, biologic agent 60%, and in case of side effects: MTX monotherapy 5.5% (sc 80%), MTX-based combination 4.6%, another cDMARD(s) 20%, biologic agent 70% (Figure 1). The EULAR 2016 recommendation of starting with MTX monotherapy and in case of inefficacy, switching to another cDMARD or adding a biologic was followed by 49% of respondents.

Conclusion: To our knowledge this is the first international effort to evaluate how rheumatologists would treat themselves if they were patients with early seropositive RA. Not surprisingly, biologics are the preferred option in the majority in the case of inefficacy or intolerance to first treatment. Sc MTX administration is preferred by 36% of rheumatologists as first option, despite rarely mentioned in recommendations. This may be a reflection of positive clinical experience using sc MTX. Limitations of the survey include a relatively small number of respondents and better coverage in many countries would be preferred. **Figure 1.** Preferred DMARD therapy for early active seropositive RA at the initiation, in case of inefficacy or side effects at 3 months, among 717 rheumatologists around the globe.

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

To assess validity and reliability of French LupusPRO in France.

Methods:

After cross-cultural adaptation and harmonization for France, the LupusPRO was administered along with a generic PRO tool (the Short Form health survey 36 [SF-36]) in a prospective, multicenter study in France. SLE patients (ACR 1997 criteria) filled the

questionnaires at baseline, and 3 months later. Demographics, disease activity and damage where recorded by the physicians at baseline. We performed a confirmatory factory analysis of the French LupusPRO and evaluated test-rest reliability and internal consistency. External validity was then explored as the correlation between LupusPRO scores and SF-36 scores or disease activity. Test-retest reliability was assessed by the mean of intra-class correlation between baseline and M3 scores among patients who did not report change in their quality of life during this period.

Results:

Among 269 patients participating to the study, 90% were women, with a mean age (SD) of 42 (12) years. Mean baseline activity was low, median (range) SELENA-SLEDAI (SS) score was 2 (0-19), 26% of patients having a moderate or severe flare at baseline according to SELENA-SLEDAI flare index revised (SFI-R). The fit of the data to the conceptual model of LupusPRO was acceptable: RMSEA, CFI, chi-square/degrees of freedom were 0.073, 0.97 and 2.6 respectively (with desirable values of <0.08, >0.95 and <3). Factor loading was over 0.7 for all items in their own dimension except for 3 out of 43 : 0.45 for item #1 ("Loss of hair" in "Lupus Symptoms" dimension), 0.36 for item #38 ("I learned to live with my lupus") , and 0.35 for item #39 ("I received comfort/strength from my religious or spiritual beliefs") , both in "coping" dimension. Cronbach's alpha (Table 1) exceeded 0.7 except for "Lupus symptoms" (alpha=0.6) and "coping" dimensions (alpha=0.4). Test retest reliability -ICC ranged from 0.4 to 0.9 between baseline and M3. External validity was supported by a significant lower score in PRO among patients reporting a low health status according to SF-36 first question ($p<0.0001$ except for "procreation", "coping", and "satisfaction with care"), a high correlation with corresponding SF-36 domains and a low but significant correlation with disease activity.

Conclusion:

The French version of the LupusPRO is valid and reliable. Further study is needed to investigate whether the low fit of the items of "coping" domain is due to cultural difference between French and US patients.

Table 1. Reliability and external validity of French LupusPRO

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease Specific Patient reported outcome measures capture unique domains relevant to patients with a specific disease. LupusPRO is targeted towards measuring health (HRQOL) and non-health related quality of life (Non HRQOL) among patients with systemic lupus erythematosus (SLE). LupusPRO V 1.7 and its translated versions in various languages have measurement equivalence and are responsive to changes in changes in patient reported changes in health and physician-based disease activity assessments. LupusPRO v1.8 has separate domains of sleep, pain and vitality, and has shown good reliability and validity among 50 SLE patients[1]. Herein, we present the confirmation of the psychometric properties of LupusPRO v1.8 in a larger sample size.

Methods: 122 consecutive SLE patients fulfilling ACR classification criteria were given self-administered surveys (MOS SF36 FACIT-Fatigue, Pain, Insomnia Severity Index for sleep, Perceived Stress Scale (PSS)-4, Patient Health Questionnaire-9 (PHQ-9) for depression, LupusPRO V 1.8) to complete at routine care visit. Disease activity and damage were assessed at visit using SELENA-SLEDAI (SS), numeric BILAG and SLICC-SDI/ACR (SDI). Internal consistency reliability (ICR) for each domain was obtained using Cronbach alpha. Convergent construct validity (CV) with corresponding domains of SF36 was tested using Spearman correlation coefficient.

Results: Mean (SD) age was 40.7±14 yrs., 90% of participants were women, and mean disease duration was 8.7 years. Ethnic background was as follows: 56% Blacks, 24% Whites, 10% Asians and 10% others. Median (IQR) values of PGA, total SS, and SDI were 0.5 (0.6), 4.0(6.0) and 0.0(1.0), respectively. Results for LupusPRO V1.8 domains descriptives, ICR and CV are shown in Table 1. Several domains, HRQOL and QOL scores were associated with disease activity. LupusPRO Sleep domain scores strongly correlated with the Insomnia severity index scores, while LupusPRO Vitality correlated strongly with FACIT-Fatigue and SF36 Vitality scores. LupusPRO Pain domain correlated strongly with the Pain score and SF36 Bodily pain domain. Lupus symptom domain (3 items) showed significant correlation with PGA and SS, but not with SDI. Similarly, LupusPRO domains of Physical and Emotional Health had good ICR and significant correlation with corresponding SF36 domains (Table 1). ICR for HRQOL and non HRQOL were 0.96 and 0.81.

Conclusion: LupusPRO V1.8 (including its sleep, vitality and pain domains) has acceptable reliability and validity. Use of lupusPRO as an outcome measure in clinical trials would facilitate responsiveness evaluation and provide important insight into patients' assessment concerning the test therapies.

Responsiveness of Lupus Impact Tracker Among Chinese Patients with Lupus

Chi Chiu Mok[1], **Meenakshi Jolly**[2] and Joel Block[3], [1]Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Rush, Chicago, IL, [3]Rheumatology, Rush University Medical Center, Chicago, IL

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus Impact Tracker (LIT), a 10 item, patient reported outcome tool for patients with systemic lupus erythematosus (SLE) has undergone psychometric validation and responsiveness studies in the US and Europe. Herein we report results on responsiveness of this tool among ethnic Chinese patients with SLE.

Methods: 430 patients with SLE meeting the ACR classification criteria were recruited in Hong Kong, China at a single center. LIT scores from two visits one year apart were analyzed for responsiveness and Minimal Clinically Important Difference (MCID) against patient report and physician assessed anchors of changes in health. Two patient reported anchors were used (Global change in health and item 2 of Short Form 36 form). Physician assessed anchors of change in health were disease activity (Physician global assessment-PGA, SELENA-SLEDAI) and damage (SLICC-SDI/ACR). Change in PGA of ≥ 0.3 and SELENA-SLEDAI of ≥ 4 in either direction was used to define worsening in disease activity. Analysis of variance was used to compare changes in LIT score against the anchors.

Results: Mean (SD) age of participants was 42 (14) years. Ninety five percent were women. Mean (SD) PGA, SELENA-SLEDAI and SDI at baseline were 0.5 (0.5), 2.9 (3.0) and 0.7 (1.2) respectively. Mean (SD) LIT score at baseline was 27.8 (18.2). Mean changes in LIT scores in response to worsening, no change or improvement based on patient report and physician assessments are shown in Table 1. MCID for “some worsening” were -4.0 and -3.9 on patient reported health question and SF36 question 2 respectively.

Conclusion: LIT changes in response to changes in both patient-reported and physician assessed changes in health status among ethnic Chinese SLE patients.

Table 1:

Anchor	Change	N	Mean Change in LIT	p-value
Patient Reported Change				
SF36-Q2	Worse	118	-4.7	<0.001
	No Change	153	0.3	
	Much Better	157	7.5	
Global Change in Health Status	Worse	118	-4.7	<0.001
	No Change	153	0.3	
	Better	157	7.5	
Patient Assessed Change				
PGA	Increase of ≥0.3	72	-2.8	0.02
	Stable	293	-1.8	
	Decrease of ≥0.3	104	2.7	
SELENA- SLEDAI	Increase of ≥4	48	-3.5	0.005
	Stable	348	-0.6	
	Decrease of ≥4	41	8.0

Identifying generic and specific patients' perspectives on disease- and treatment-related issues in rheumatoid arthritis, psoriatic arthritis, and psoriasis: a qualitative concept mapping study

T.S. Jørgensen[1], L. Klokker[1], H. Gudbergsen[1], S.F. Thomsen[2], R. Christensen[1], H. Bliddal[1], and L.E. Kristensen[1]. [1]The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen, Denmark [2]Department of Dermatology, Bispebjerg Hospital & Department of Biomedical Sciences, University of Copenhagen, Copenhagen, Denmark.

Background/Purpose: Considering the patients' perspectives is necessary to promote patient empowerment and adherence to treatment, and thereby optimizing disease management. Specifically, it is essential to identify issues of importance to patients to help guide selection of value based treatment targets and outcomes. The aim of this study was to qualitatively explore disease- and treatment-related issues and concerns experienced by patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and psoriasis (PsO), and to rate the clinical importance of these. A secondary aim was to explore whether these factors were generic or disease specific.

Methods: Concept Mapping, a structured group process, was used to identify and organize disease- and treatment-related issues and concerns. Data were elicited through a nominal group technique and then organized using participants' themes, multidimensional scaling, cluster analysis, participant validation, rating of clinical importance, and thematic analyses, to generate a conceptual model of disease-related concerns experienced in patients with RA, PsA, and PsO.

Results: 17 RA patients, 8 PsA patients, and 9 PsO patients contributed to generating the conceptual model. 8 RA clusters, 7 PsA clusters, and 7 PsO clusters, with each cluster having sub-clusters, emerged from the workshops producing 292 RA statements, 160 PsA

statements, and 187 PsO statements. Some clusters were generic: ‘concerns about the disease and the future’, ‘consequences of the disease’, ‘relationship with partner and others’, ‘acceptance of the disease’, ‘medication and treatment’, and ‘at the doctor’ (Figure). Specific clusters were; for RA: ‘Daily practical problems and disappointments’, for RA/PsA: ‘Meeting the system (municipality)’ and ‘Difficult to have an invisible disease’, and for PsO: ‘Ashamed (about appearance)’ (Figure). RA and PsA patients ranked “Meeting the system (municipality)” as being the most important concept, whereas PsO patients ranked “Ashamed (about appearance)” as being the most important concept.

Conclusion: Patients across chronic inflammatory diseases agreed largely on the concepts, with a few of them being disease specific. The relative ranking of importance showed considerable differences, highlighting the importance of patient involvement. These data offer new knowledge to guide selection of clinically relevant and value based treatment targets and outcomes for patients impacted by RA, PsA and PsO. **Acknowledgements:** This study was funded by The Oak foundation, Roche (Denmark) and Novartis (Denmark). **Disclosure of Interest:** T.S. SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Quality Measures and Quality of Care - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is a debilitating disease with significant impact on patient quality of life (QoL). While patient reported outcome (PRO) instruments broadly capture patient experiences with PsA, they may not identify the full extent of issues patients face. In this study, we compared the types of experiences patients self-report online to concepts captured within commonly used PRO instruments in PsA.

Methods: We collected unguided patient narratives reported between January 2010 and May 2016 from 31 online sources. 56% of narratives were from health social networking sites, 22% from disease-specific patient forums, 9.9% from general health forums, and 0.1% from mainstream social media. Using natural language processing combined with manual curation, we evaluated patient reported experiences within narratives and categorized them into 5 high level themes: **S**ocial (e.g. family burden), **P**hysical (e.g. pain), **E**motional (e.g. anxiety), **C**ognitive (e.g. memory), and **R**ole Activity (e.g. work), or SPEC-R. For comparison, the same SPEC-R categorization was applied to 3 PRO instruments: the Psoriatic Arthritis Quality of Life tool (PsAQoL), Psoriatic Arthritis Impact of Disease tool (PSAID), and Short Form 36 Health Survey (SF-36). The instruments were then evaluated based on their capacity to capture the concepts and sub-concepts extracted from patient narratives.

Results: 15,390 narratives from 3,139 patients were qualified into the sample for analysis. Across the SPEC-R categories, Physical concepts were reported by 81.6% of patients, Emotional concepts by 60.7%, Cognitive concepts by 20.0%, Role Activity concepts by 8.1%, and Social concepts by 5.6%. In addition, 66.8% of patients reported general concepts (e.g. “Feeling unwell”) that could not otherwise be classified into the SPEC-R categories. Pain and dermatology related issues were the most reported physical sub-concepts (66% and 26%, respectively). Emotional concepts were mainly comprised of anxiety (60%) and depression (38%). Cognitive concepts were characterized by impulsive behavior (25%) and balance/coordination issues (12%). Patients reporting Role Activity concepts focused on work/school performance (55%) and parenting (17%). Among patients reporting Social concepts, family burden (50%) and relationships with spouses (27%) were most frequent. While PRO instruments capture many physical and social concepts and sub-concepts, many sub-concepts within other SPEC-R categories were not captured by either PsA-specific or general health related PRO instruments (see table).

Conclusion: This study offers insight into a variety of patient experiences with PsA. The physical and emotional impact of PsA dominates self-reported patient experiences. PROs capture many of the physical and emotional impairments of PsA, but may miss key cognitive and role activity issues that affect patient QoL. **Table 1. Fit/Gap Analysis of PsA PRO Tools with regards to Reported SPEC-R Concepts and Sub-concepts**

SPEC-R Category (% of patients)	Top 3 Reported Sub-concepts	% of SPEC-R Category	PsAQoL	SF-36	PSAID

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Physical activity is recommended and is an important part of the management of inflammatory arthritis and in particular RA and axSpA. Activity trackers, and in particular connected devices, are more and more used to assess physical activity and motivate people to increase their activity level in the general population, and in chronic conditions. However there may be technical issues for arthritic patients and a rapid loss of motivation. The objective of this study was to assess the acceptability of a physical activity connected device in RA/AxSpA patients.

Methods: In this prospective multicenter observational study patients had definite axSpA (ASAS criteria) or RA (ACR/EULAR criteria), and owned a smartphone. All patients were provided with an activity tracker (a watch) connected by Bluetooth and were instructed to wear it every day for 3 months. Acceptability was assessed by the mean number of days the tracker was worn over the 3 months (ie adherence). We considered that the tracker was worn a day if at least 8 hours of physical activity were recorded between the first and the last step. Then predictors of adherence were explored by comparing in univariate and multivariate analyses the adherent patients (ie bracelet worn at least 80/90 days) to non-adherent patients. Acceptability to the use of the activity tracker were assessed by a questionnaire.

Results: 92 patients (49 RA and 43 axSpA patients) were included: 39 (42.4%) were males, with a mean age of 46.6 (±12.3) and a mean disease duration of 10.8 (±7.8) years; 52 (56.5%) were receiving a biologic. RA and axSpA patients had respectively a mean DAS 28 of 2.2 (±1.0) and a mean BASDAI of 3.4 (±2.1). Patients wore the activity trackers 91.3% of the time, during 80.7 (±13.5) days on average and 64 (69.6%) patients wore it at least 80/90 days; 81 (88.0%) patients still wore the device at the end of the 3-month period (Figure). Adherent patients were more often men (OR=7.69, p<0.01), had more often RA (OR=5.56, p=0.02) and were more likely to be treated with biologics (OR=5.00, p<0.01). Overall 69 (75%) patients reported no technical issues related to the use of the device though 17 (18%) needed helped to set the device; 2 (2.2%) patients reported issues to wear the device because of their arthritis. The acceptability of the activity tracker was scored on average at 9 on a 0 to 10 scale.

Conclusion: Acceptability of a connected device in RA and axSpA is high in a population of selected patients accepting to participate in this 3 months study. Studies using connected devices in rheumatology are feasible, but long-term assessments are needed.

Figure: Proportion of patients wearing the tracker throughout the study

Validation of a Patient Reported Experience Measure (PREM) in Patients with Axial

Spondyloarthropathies (AxSpA)

Clare Longton[1], Marco Massarotti[2] and **Marwan Bukhari**[3], [1]Rheumatology, Royal Lancaster Infirmary, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, [2]Rheumatology, Royal Lancaster Infirmary, University Hospital of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, [3]Royal Lancaster Infirmary, Lancaster, United Kingdom

Session Date: Monday, November 14, 2016
Session Title: Quality Measures and Quality of Care - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Improving patient experience is important in all diseases, but most important in patients with chronic rheumatic diseases like the axial spondyloarthropathies (AxSpa). The Commissioning for Quality in Rheumatoid Arthritis (CQRA), a British multidisciplinary group of stakeholders, developed a PREM questionnaire to evaluate patient satisfaction in rheumatology. The questionnaire comprises 8 domains that have been evidenced as being most important to patients' experiences of National Health Service (NHS) services. All questions were graded from very satisfied to very unsatisfied on a five point scale. This PREM was validated within Rheumatoid Arthritis and a variety of rheumatic conditions in a previous publication (Bosworth A et al. 2015). This has not yet been published and validated within a cohort of patients with AxSpa. Our aim was to determine the validity of the PREM questionnaire developed by the CQRA group in a single centre AxSpa clinic.

Methods: Cronbachs alpha was used to check internal consistency within groups of scores in each domain if it contained more than one question and whether it was reasonable to combine scores within groups into a numerical scale. Additionally for each question the percentage agreement with the overall assessment on the five point scale was calculated, in case of multiple questions per domain, the responses are shown as a range.

Results: 64 patients were included in the analysis (mean age 51.6 ± SD11.7; M 58/64, 87.5%). Duration of disease equated >10years in 71.9%. The Cronbach alpha co-efficients within the multi-question domains and their percentage agreement with the question on overall care are shown in the table below. **Table.** Result of Cronbach's alpha analysis and their agreement with overall care

Domain	Number of questions	Alpha Within domain	%Agreement with overall care
Needs and preferences	5	0.71	0.75
Co-ordination of care	4	0.81	0.84
Information about care	4	0.88	0.87
Daily living	2	0.25	0.52
Emotional aspects	2	0.81	0.75
Family and friends	1	NA	0.34
Access to care	1	NA	0.61

Conclusion: The PREM has good construct validity and is a valid tool for measuring AxSpa patient experience. Some domains have higher agreement with overall patient experience. This could provide a useful future tool for measuring patient experience.

Using Self-Reported Patient Experiences to Understand Patient Burden: Learnings from Digital Patient Communities in Ankylosing Spondylitis

Prashanth Sunkureddi[1], Dawn Gibson[2], Stephen Doogan[3], John Heid[4], Samir Benosman[5] and Yujin Park[6], [1]Rheumatology, Clear Lake Rheumatology Center, Nassau Bay, TX, [2]The Global Healthy Living Foundation, Upper Nyack, NY, [3]Real Life Sciences, New York, NY, [4]Kinapse, Inc, London, United Kingdom, [5]Advisory Services, Kinapse, Inc, London, United Kingdom, [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing Spondylitis (AS) is a chronic inflammatory disorder of the spinal joints that can lead to severe, chronic pain and discomfort. There is a substantial disease burden on AS patients as they experience reduction in physical function, increased risk of unemployment, and increased direct and indirect health costs. This study aimed to better understand AS disease burden by describing patient experiences reported online and making comparison to existing patient-reported outcome (PRO) instruments to identify potential gaps.

Methods: Patient narratives between Jan 2010 and May 2016 from 52 online sources were collected; of the online sources, 46.6% were patient health networking sites, 24.9% disease-specific patient forums, 13.5% general health forums, 8.3% treatment reviews, 6.0% Doctor Q&A, and 0.6% mainstream social media. Using a natural language processing platform and manual curation, functional impairments and symptoms related to AS were evaluated and grouped into 6 high-level concepts: Social, Physical, Emotional, Cognitive, Role Activity (SPEC-R), and General (consisting of non-specific narratives, e.g. feeling unwell). These broad categories provided a starting point for organizing the data, with additional levels of detail added through sub-concept groupings. For comparison, the same SPEC-R categorization was applied to 5 AS-specific PRO instruments: ASQoL, ASAS-HI, BASDAI, HAQ-S, and BASFI (81 PRO questions curated, 40 total sub-concepts identified). PRO Instruments were then compared to key concepts and sub-concepts extracted from patient narratives.

Results: A total of 34,780 unguided narratives from 3,449 patients were collected for analysis: 86.7% of patient narratives correlated to the Physical concept, 32.5% to Emotional, 23.6% to Cognitive, 8.7% to Role Activity, 5.6% to Social, and 69.1% to General (Table 1). Some of the common concepts reported by patients, such as pain (65%), muscle weakness (20%), and musculoskeletal impairment (20%), depression (10%), and anger/frustration (5%) were effectively captured by more than 2 of the PRO instruments. However, commonly reported emotional concepts, such as anxiety (19%), and cognitive concepts, such as mental impairment (3.2%), were not captured in the PRO instruments evaluated in this analysis.

Conclusion: Analysis of self-reported patient narratives from online sources showed that some physical and emotional concepts, such as depression and pain, are effectively addressed by existing PRO instruments. However, the analysis also uncovered some concepts that may be important in addressing disease burden in AS patients but are not currently captured in existing PRO instruments. This study helps identify opportunities to refine existing PRO instruments.

SPEC-R Category	Top 3 Reported Sub-concepts	% of Total Reports	% within SPEC-R Category	ASAS-HI	ASQOL	BASDAI	BASFI	HAQ-S

The Importance of Outcome Measures in Ankylosing Spondylitis – Validity of the Routine Assessment of Patient Index Data 3 in a Real World Cohort

Sergio Schwartzman[1], Keith Knapp[2], Gary Craig[3] and Discus, [1]Rheumatology, Hospital for Special Surgery, New York, NY, [2]Arthritis Northwest PLLC., Spokane, WA, [3]Discus Analytics LLC., Spokane, WA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Outcome measures in AS are well established in clinical trial settings but infrequently used in real-world (RW) practice. These measures include the BASDAI, BASFI, and ASDAS. The RAPID3 is an established RA measure, but infrequently used in real world (RW) settings. It has been tested most recently in 75 patients with AS correlating RAPID3 scores with BASDAI and ASDAS-ESR[1]. The purpose is to compare RAPID3 to BASDAI, BASFI, ASDAS-(CRP, ESR), in a cross-sectional analysis of 456 AS patients enrolled in the JointMan® registry (JM), a real-world (RW) database capturing five AS outcome measures.

Methods: A retrospective review of data collected in the JM registry. These study measures were recorded in 456 patients at 1706

visits. Indices and individual measures were compared using Spearman's (ρ) and Cohen's Kappa (κ) correlations.

Results: BASDAI > 4, active AS, correlated with moderate/high RAPID3; Kappa of 0.486 (p = 0.001). ASDAS >1.3, high disease activity correlated with moderate/high RAPID3; Kappa correlation of 0.544 (p = 0.001).

Patient Characteristics	**Value**
Mean Age (SD)	52 (14.16)
Female	45.83%
White	90.57%
HLA-B27 (+)	61.90%

Spearman's correlation of RAPID3 for Specific Measures	**ρ**	**p-value**
BASDAI	0.85	< 0.0001
ASDAS-ESR	0.75	< 0.0001
ASDAS-CRP	0.81	< 0.0001
BASDAI Fatigue	0.54	< 0.0001
BASDAI Spinal Pain	0.75	< 0.0001
BASFI	0.81	< 0.0001
Acute-phase reactant ESR	0.16	< 0.0001
Acute-phase reactant CRP	0.09	< .0003
Cohen's Kappa correlation for Rapid3 (high, moderate, or low)	**κ**	**p-value**
ASDAS (High, moderate, or low)	0.455	0
BASDAI (Active)	0.235	0
Cohen's Kappa correlation for Rapid3 (High or moderate)		
ASDAS (High or moderate)	0.544	0
BASDAI (Active)	0.486	0

Conclusion: RAPID3 is the most common outcome measure utilized in RW settings for managing patients with RA. In clinical practice this outcome is frequently obtained in all patients seen in a rheumatology office at the time of registration prior to the rheumatologist's evaluation although it has only been validated in RA. In this cross sectional study of a large cohort of patients with AS, RAPID3 results had high correlations with BASDAI, BASFI, and ASDAS. This study supports the use of the RAPID3 in RW rheumatology practices for patients with AS.

Patient Attitudes Towards Being Prescribed Biosimilars in Inflammatory Autoimmune Diseases in Germany

James Piercy[1], John Waller[1], Emma Sullivan[1], Christopher Black[2] and **Sumesh Kachroo**[2], [1]Adelphi Real World, Manchester, United Kingdom, [2]CORE, Merck & Co., Inc., Kenilworth, NJ

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Our aim is to address the lack of understanding surrounding patient attitudes to being prescribed biosimilars in the real world for Rheumatoid Arthritis (RA), Axial Spondyloarthritis (AxSpA) and Psoriatic Arthritis (PsA).

Methods: The Adelphi Biosimilars Programme is a real-world, cross-sectional survey of patients receiving biosimilars or biologic originators in RA, AxSpA and PsA. Patients report their satisfaction, understanding and attitudes towards being prescribed biosimilars or bio-originators. Rheumatologists (n=50) reported matching data on patients who completed the survey.

Results: Data was collected from 174 biosimilar patients and 87 bio-originator patients. Less biosimilar patients, 78%, were satisfied that their current treatment was controlling their condition than bio-originator patients, 85%. Physician satisfaction reflected that of patients, with only 27% stating they were 'very satisfied' when prescribing a biosimilar compared to 43% a bio-originator (p=0.005). Biosimilar patients demonstrated lower understanding of their treatment, 39% felt they didn't know enough about the drug when it was initiated, vs. 28% for bio-originators. The lack of understanding of biosimilars was again observed as 42% of biosimilar patients were not aware that their treatment was based on an alternative original product. Biosimilar patients who had not previously received a bio-originator stated the most common reasons they accepted biosimilars was cost (30%) and doctor's recommendations (30%), whilst biosimilar patients who switched from a bio-originator accepted due to doctor's recommendations (73%) and cost or insurance reasons (43%).

Conclusion: These data demonstrate biosimilar patients show less satisfaction than bio-originator patients and their understanding of their treatment is lower. Whilst many patients seem unaware that biosimilars are based on existing bio-originators, they seem aware that cost is a factor behind their prescription. This may be indicative of the conversations that prescribers are having with both patients and payers when deciding on treatment options.

Patient-Reported Outcomes Measures and Economical Burden of Patients with Ankylosing Spondylitis in a Chinese Prospective Cohort with Smart Management System for Spondyloarthritis

Qiongfang Wen, Xiaojian Ji, Jinshui Yang, Jian Zhu, Jianglin Zhang and **Feng Huang**, Rheumatology, Chinese PLA General Hospital, Beijing, China

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing Spondylitis (AS) is characterized by relatively young onset age, easily causing spinal deformity and stiffness, and seriously influencing the health related Quality of Life (QoL) and engaging heavy economical burden for the patients, their families and even the whole society. There were adequate clinical studies about the Patient-reported Outcomes (PROs), which include Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) et al. This study was designed to assess the clinical value of various PROs in a prospective cohort study of AS patients, and to evaluate the medicine cost and other treatment-related cost of patients with AS in Chinese population, and to explore the global economical burden and the factors that may affect the cost.

Methods: 517 AS patients were collected from the Department of Rheumatology, Chinese PLA General Hospital. Data were obtained from Smart Management System (SMSP) for Spondyloarthritis collected online. The Quality of Life (QoL) were assessed by SF-36 questionnaire and compared with the general Chinese population. The correlation between QoL and clinical measures of AS, including BASDAI, BASFI et al, were analysed.Meanwhile, a retrospective study of 283 AS patients and multivariate logistic regression analysis

were performed to explore the global economical burden and influence factors.

Results: BASDAI and BASFI were significantly correlated with SF-36 scores($r>0.3$, $P<0.01$). Logistic multiple regression analysis showed that BASDAI, BASFI, BASMI and education had close correlation with the baseline global QoL, physical and mental health. BASDAI variation showed the most important influence on the change of global QoL, physical health and mental health (*OR*=0.235, 0.209, 0.125; *P*<0.01). The total average medicine cost in the past year was $2654.27 per patient，of which non-steroid anti-inflammatory drugs represented 4.2% percentages, conventional disease modifying anti-rheumatic drugs represented 11.7%, biological disease modifying anti-rheumatic drugs represented 81.9%, herbal drugs represented 2.2%. The mean value of other cost correlated with the treatment of AS were laboratory examination ($260.62/year), transportation ($323.26/y), accommodation ($177.16/y), other cost ($40.21/y). Peripheral articular involvement (*OR*=2.412, 95%*CI*: 1.006~4.562, *P*=0.048) and disease duration (*OR*=0.197, 95%*CI*: 0.056~0.693, *P*=0.011) showed the most important influence on the total medicine cost.

Conclusion: SF-36 can objectively reflected the QoL of Chinese patients with AS. PROs such as BASDAI and BASFI showed great application value in this prospective cohort study of AS patients. High medicine cost directly increased the economical burden of AS patients. Peripheral articular involvement and disease duration showed the most important influence on the total medicine cost. Other indirect cost related with the therapies also increased the economical burden of AS.

Adherence to the International Consensus Quality Indicators for Longitudinal Health Maintenance and Preventative Care in a Pediatric Rheumatology Clinic

Abigail Bosk, Barbara Edelheit, Lawrence Zemel and Heather Tory, Rheumatology, Connecticut Children's Medical Center, Hartford, CT

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile systemic lupus erythematosus (jSLE) is a chronic disease associated with significant morbidity. Variability in the health maintenance-related management of these patients can contribute to suboptimal outcomes. International consensus quality indicators (QIs) were developed to guide management in SLE, with a subset focused on health maintenance and preventative care. We performed a retrospective chart review to assess adherence to the health maintenance-related QIs for jSLE in our clinic, with the goal of using this data to drive a quality improvement initiative to improve adherence.

Methods: A retrospective chart review was performed on patients with an active diagnosis of SLE followed in the pediatric rheumatology clinic at our institution from December 1, 2014 to April 30, 2016. Patients were included if they had a current active diagnosis of jSLE and were seen within the study period. Patients were excluded if they were no longer followed in our clinic, or received alternative diagnoses. Data were abstracted in a standardized database for analysis. To assess adherence to the health maintenance-related QIs, we calculated the percentage of patients who had documentation of performance of each measure, including: (a) Receiving antimalarial therapy (hydroxychloroquine) unless contraindicated; (b) Vaccination against influenza and encapsulated organisms; (c) Bone mineral testing; (d) Prescription for calcium and vitamin D supplementation for patients exposed to any glucocorticoid dose for longer than 3 months; (e) Annual ophthalmology evaluation; and (f) Serum lipid levels every 2 years.

Results: Sixty-six patients were identified with jSLE on initial screening, with 15 excluded based on criteria. We reviewed charts of the remaining 51 patients with an active diagnosis of jSLE seen during the study period. Mean age was 17 years (range 10-25) and 42 (83%) were female. Forty-nine (96%) were taking hydroxychloroquine. The 2 patients not taking had contraindications of allergy to medication and inability to take due to anxiety. 29 (57%) had documentation of the need for an annual ophthalmologic exam. 47 patients (92%) were on chronic steroid therapy, but only 13 (28%) were prescribed calcium and vitamin D. 7 (12%) had documentation of the necessary vaccinations and 7 (12%) had serum lipids checked within the last two years. None (0%) had bone mineral testing.

Conclusion: Adherence to the international consensus QIs for SLE in our pediatric rheumatology clinic varied considerably. Adherence was greatest for anti-malarial medication treatment and ophthalmology examination screening, and lowest for health maintenance-related measures of documentation of vaccination status, serum lipid level screening and bone mineral testing. This may reflect dissociation between routine jSLE disease management and preventive health maintenance activities. Accordingly, a standardized, system-based process that incorporates health maintenance-related activities into standard daily work may be necessary for improved adherence to recognized evidence-based QIs.

Estimates of Global Status By Physicians and Patients Are More Likely to be Discordant in Osteoarthritis Than in Rheumatoid Arthritis

Isabel Castrejón[1], Joel Block[2] and Theodore Pincus[1], [1]Rheumatology, Rush University Medical Center, Chicago, IL, [2]Division of Rheumatology, Rush University Medical Center, Chicago, IL

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Concordant 0-10 estimates of global status by physicians (DOCGL) and patients (PATGL) are associated with greater expectations for improvement and better outcomes[1], and appear desirable in shared decisions concerning therapy. However, previous studies have shown that physicians and their patients with rheumatoid arthritis (RA) and other rheumatic conditions have discordant global estimates in about 50% of instances[2,3]. Although recent evidence suggests that disease burden RA is similar or lesser than in osteoarthritis OA, OA generally remains regarded as being less severe than RA. We analyzed discordance between PATGL and DOCGL in OA vs RA patients seen in routine care at an academic rheumatology setting.

Methods: All patients in this setting complete a multidimensional health assessment questionnaire / routine assessment of patient index data (MDHAQ/RAPID3) at each visit, which includes 0-10 scores for physical function, pain, and PATGL compiled into a 0-30 RAPID3, as well as fatigue VAS, 60 symptom checklist, RADAI self-report joint count, and demographic data. Rheumatologists complete a RheuMetric checklist, which includes a physician global (DOCGL). Mean differences between PATGL & DOCGL were calculated. Patients with primary OA or RA were classified into 3 categories: PATGL ≥ DOCGL by 2/10 units, PATGL = DOCGL, and DOCGL ≥ PATGL by 2 units, and compared with other measures using chi-square tests, ANOVA, and logistic regression.

Results: The study included 216 patients with RA and 243 with OA. Patients with OA were older and showed higher scores for PATGL, pain, fatigue, and number of symptoms (data not shown). A higher percentage of patients with OA showed discordance with PATGL>DOCGL in comparison with RA (34% vs 18%) while concordance and discordance with DOCGL > PATGL were higher in RA patients (67% vs 56% and 15% vs 10%) ($p<0.001$). In general, patients with PATGL>DOCGL had lower formal education levels ($p<0.05$ in RA but not OA), and had higher scores for pain, function, fatigue, number of symptoms ($p<0.05$ in OA but not RA), and self-report RADAI (Table). In logistic regressions, pain was the only significant predictor of discordance in both RA [odds ration (OR) 1.47, 95% confidence interval (CI) 1.12-1.93] and OA (OR 1.40, 95% CI 1.04-1.89), but not age, gender, race, education, function, symptom checklist or self-report RADAI.

Conclusion: Patients with OA are more likely to have their clinical status underestimated by rheumatologists than patients with RA, although the burden of disease was greater in OA than in RA. The data suggest that rheumatologists and the medical and general public might revise generally held views that OA is less severe than RA. **References: 1.** *Am J Public Health* 1981, **71**(2):127-131. **2.**Arthritis Care Res (Hoboken) 2014;66:934-42. 2. **3.**Arthritis Care Res (Hoboken) 2012;64:206-14.

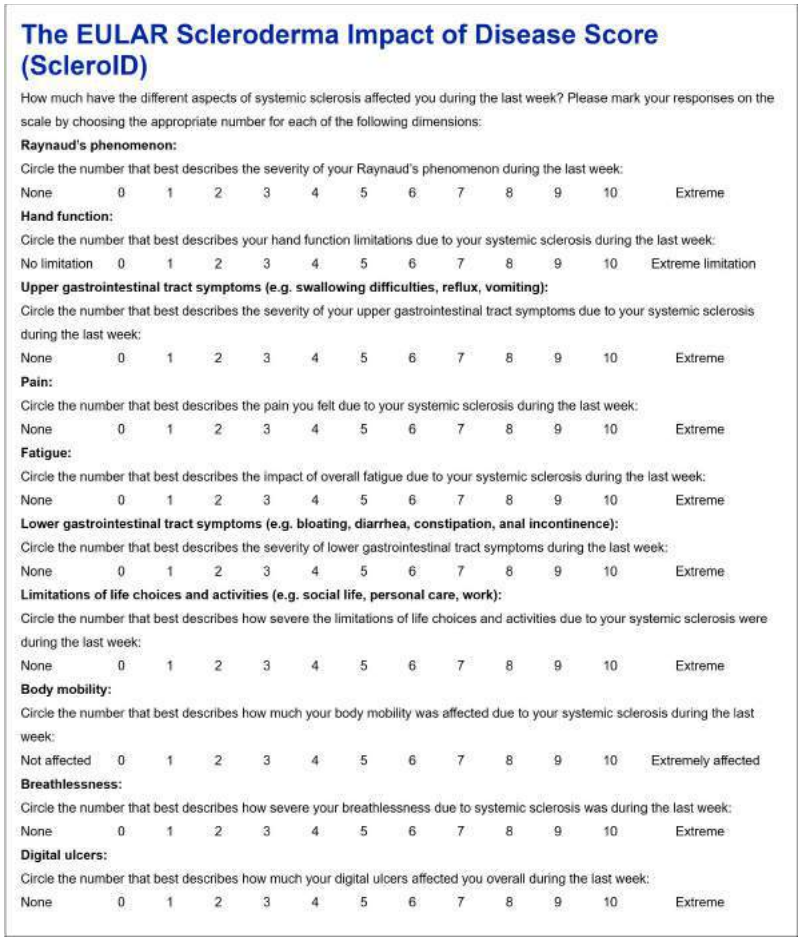
Session Title: Quality Measures and Quality of Care - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient reported outcome measures (PROM) are required as key outcomes in disease modifying therapeutic trials in systemic sclerosis (SSc). A PROM tool in SSc, covering the different features of this multi-organ autoimmune disease, is lacking. In this study, we aim to develop and validate a brief, disease-specific, patient-derived, composite disease impact score for scientific and clinical use in SSc.

Methods: This multi-center project endorsed by EULAR involves SSc patients and experts from 11 European countries. Firstly, using the nominal group technique, patients with SSc selected the health dimensions where the disease has the most significant impact. The dimensions were subsequently given numeric priority by an international group of SSc patients. Patients were asked to rank the dimensions in order of their importance by giving a rank from 1(most important) to 17 (least important). Each rank could only be used once. The dimensions with the top 10 median ranks, as ranked by the patients, were used to construct the ScleroID questionnaire using numeric rating scales. An observational study to weight the dimensions in order to calculate the ScleroID score and to validate the questionnaire is currently ongoing and aims to target a larger cohort of patients from all participating countries.

Results: 24 SSc patients selected 17 health dimensions in the nominal group exercise. The prioritization cohort included 108 SSc patients from 11 centers (female:male 82:25, limited: diffuse SSc subset 53:54). The top 10 health dimensions which were ranked most relevant by the patients were Raynaud's phenomenon, hand function, upper and lower gastrointestinal tract symptoms, pain, fatigue, limitation of life choices and activities, body mobility, breathlessness and digital ulcers. Based on this, the ScleroID questionnaire was constructed (Figure 1).

Conclusion: The EULAR ScleroID score is a novel, patient-derived, tool under development designed for use in clinical practice and clinical trials to display the disease impact of SSc. A large scale observational study for weighting of the dimensions and validation of this new instrument is ongoing. **Figure 1. The ScleroID questionnaire.**



The EULAR Scleroderma Impact of Disease Score (ScleroID)

How much have the different aspects of systemic sclerosis affected you during the last week? Please mark your responses on the scale by choosing the appropriate number for each of the following dimensions:

Raynaud's phenomenon:

Circle the number that best describes the severity of your Raynaud's phenomenon during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Hand function:

Circle the number that best describes your hand function limitations due to your systemic sclerosis during the last week:

No limitation 0 1 2 3 4 5 6 7 8 9 10 Extreme limitation

Upper gastrointestinal tract symptoms (e.g. swallowing difficulties, reflux, vomiting):

Circle the number that best describes the severity of your upper gastrointestinal tract symptoms due to your systemic sclerosis during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Pain:

Circle the number that best describes the pain you felt due to your systemic sclerosis during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Fatigue:

Circle the number that best describes the impact of overall fatigue due to your systemic sclerosis during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Lower gastrointestinal tract symptoms (e.g. bloating, diarrhea, constipation, anal incontinence):

Circle the number that best describes the severity of lower gastrointestinal tract symptoms during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Limitations of life choices and activities (e.g. social life, personal care, work):

Circle the number that best describes how severe the limitations of life choices and activities due to your systemic sclerosis were during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Body mobility:

Circle the number that best describes how much your body mobility was affected due to your systemic sclerosis during the last week:

Not affected 0 1 2 3 4 5 6 7 8 9 10 Extremely affected

Breathlessness:

Circle the number that best describes how severe your breathlessness due to systemic sclerosis was during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Digital ulcers:

Circle the number that best describes how much your digital ulcers affected you overall during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Session Title: Quality Measures and Quality of Care - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SS) involves multiple systems that affect the ability to move and function. When ability is lost the individuals living with this autoimmune disorder may experience changes in day-to-day abilities. If a decline in function occurs then independence and quality of life changes; therefore an assessment of function and quality of life in persons with SS was done.

Methods: Thirty individuals (22 African-American, 6 Caucasians, 2 other) with SS were given a health literacy test before administering self-report tests on quality of life; these included the Health Assessment Questionnaire Disability Index (HAQDI), ADLs, IADLs and the St. George Respiratory Questionnaire. Additionally medical records showed the 6 Minute Walk Test had been performed on 15 of the individuals. Health literacy was assessed prior to giving the paper and pencil reports using the Rapid Estimate of Adult Literacy in Medicine (REALM).

Results: The average age was 62.5 (range 55-82). Individuals reported impairment as follows: 33% with the HAQDI, 11% ADLs, 10% IADLs. The REALM score ranked an average of 7-8th grade level. The average duration of SS diagnosis was 9.4 years. Seventeen of the participants (15 African American, 1 male) had 6-M-W scores, walking an average of 334 meters (m) with a dyspnea level of 2.5 (out of 10); 6 out of 13 had Pulmonary Function Test of Forced Vital Capacity < 80%. Only 1 individual walked the normal distance for their age group a 76 year old woman walked 820 m (normal 471 m).

Conclusion: Most individuals scored a high ability with low impairment on ADLs and IADS, with average HAQDI score of 0.98 (out of 3.0). This indicates a low impact of the disease on daily function; however more than half of the participants reported difficulty with stair climbing, meaning individuals may struggle with more challenging movements. Individuals with SS perceived they were able to perform independently at relatively high levels, 66%-90% of function on the disability and self-care reports but when it came to actual performance these individuals were not able to walk at normal age-ranked levels when walking for 6 minutes. Perhaps these individuals adjusted to lower levels of function over time and did not see themselves as having much disability. A low number of respiratory symptoms were reported on the St. George Respiratory Questionnaire yet only one individual was able to walk the norm for her age group. Another possibility is that individuals could have had difficulty understanding the self-report tests, even when assistance and explanation was offered resulting in higher scores on those tests. The health literacy scores did score at a 7-8th grade level. It is vital that health care professionals understand that individuals who are living with SS may not always accurately report their ability to function; therefore it behooves the professional to have their patient perform the skill in question so that more accurate information can be obtained and optimal intervention can be sought. Villalba WO, Sampaio-Barros PD, Pereira MC, Cerqueira EMFP, Leme Jr CA, Marques-Neto JF, Paschoal IA. Six-Minute Walk Test for the Evaluation of Pulmonary Disease Severity in Scleroderma Patients *CHEST*. 2007;131:217–222.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients are at higher risk for insulin resistance (IR). The association between RA and IR, and its role on the different characteristics of the disease, such as duration and activity have not been well defined. In addition, there is a gap of knowledge regarding the link between systemic/local inflammation and insulin sensitivity and lipid metabolism in RA patients. **Objective:** To explore the effects of the systemic and local inflammation on the insulin sensitivity and lipid metabolism in RA patients and collagen induced arthritis (CIA) mouse model.

Methods: **Human study:** 120 RA patients and 40 healthy donors were included. IR was quantified using the homeostatic model assessment of IR (HOMA-IR) and was compared between RA patients and demographically matched non-RA controls. **Mouse model:** To investigate the mechanisms underlying the link between inflammation and insulin sensitivity and lipid metabolism in RA, a CIA mouse model was used. A total number of 20 mice were used; five mice were used as non diseased control group, and 15 were used in CIA modelling. Scoring for CIA was performed after injection of chicken collagen type II and arthritis index (AI) was calculated. Leukocytes, skeletal muscle and adipose tissue were collected for gene and protein profiling. mRNA expression of genes involved in lipid and glucose metabolism, insulin signalling and inflammation were evaluated (CD36, CPT1a, MCAD, PGC1b, PPARa, PPARg2, ACC, DGAT2, FADS1, FADS2, LPL, PLIN2, AOX, FAS, GLUT4, IRS1, IRS2, TNFa, MCP-1 and F4/80). Phosphorylation and expression of AKT and JNK as markers of insulin sensitivity and inflammation were analysed. Protein expression of IL-1b was also evaluated.

Results: Percentages of obesity, hypertension, atherogenic risk, metabolic syndrome and insulin resistance were significantly increased in the RA group. Although mean time of evolution was 8 years, no association between insulin resistance and the duration of the disease was found. Levels of HOMA-IR significantly correlated with number of swollen joints, DAS28 and C-reactive protein levels, suggesting that systemic and local inflammation might lead to the development of insulin resistance. In mice, the induction of arthritis promoted an alteration of the expression of genes involved in inflammation as well as lipid metabolism and insulin signalling in skeletal muscle, adipose tissue and leukocytes of diseased CIA mice vs. controls. Levels of phosphorylation of AKT and JNK and protein expression of IL1b were significantly increased in those tissues of the CIA mice group.

Conclusion: 1) Insulin resistance was closely associated with an increase in disease activity and systemic and local inflammation in RA patients. 2) Induction of arthritis in mice promoted an increase in inflammation markers in skeletal muscle, adipose tissue and leukocytes, and a reduction of genes involved in lipid uptake and storage, generating an insulin resistance state in those tissues. In sum, our results suggest that chronic inflammation associated with RA might directly impact relevant metabolic tissues, altering glucose and lipid homeostasis. Funded by CP15/00158 and PI2013/0191.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibroblast-like synoviocytes (FLS) develop a high degree of invasiveness during rheumatoid arthritis (RA), leading to joint degradation. There are currently no therapeutics that specifically target the pathogenic phenotype of FLS. We have previously found that FLS from RA patients and from rats with a model of RA express higher levels of the KCa1.1 potassium channel at

their plasma membrane than FLS from patients with osteoarthritis or from healthy rats. Selectively inhibiting KCa1.1 with the small molecule paxilline reduces the *in vitro* invasiveness of FLS and reduces disease severity in multiple rat models of RA. However, KCa1.1 is expressed in a variety of tissues and systemic KCa1.1 block induces side effects that preclude paxilline's use as a potential therapeutic in humans. Here, we investigated the efficacy of the peptide KCa1.1 inhibitor iberiotoxin (IbTX), which has a limited biodistribution, in reducing disease severity in an animal model of RA, assessed IbTX's side effects, and determined the mechanism by which KCa1.1 regulates FLS invasiveness.

Methods: Starting at disease onset, rats with the pristane-induced arthritis (PIA) model of RA were given either vehicle, paxilline, or IbTX. Disease severity was measured daily using a standard scoring system. After three weeks of treatment, X-rays and histology were completed on paws of rats from each treatment group. Side effects, including incontinence and tremors, were determined in healthy rats given a single treatment of either IbTX, paxilline, or vehicle. Flow cytometry and *ex vivo* functional assays were used to assess the effects of KCa1.1 inhibition on the expression and activation of signaling molecules involved with FLS invasion.

Results: Both paxilline and IbTX significantly reduced clinical signs of disease in PIA by approximately 55% ($p<0.001$) and 65% ($p<0.001$), respectively, as determined by a standard scoring system of paw inflammation. X-rays and histological analysis of joints from each treatment group indicated that the KCa1.1 blocker-treated rats had less bone and cartilage damage and reduced synovial hyperplasia, fibrosis, and immune infiltrates compared to vehicle-treated animals. Side effects, including tremors and incontinence, were significantly reduced in IbTX-treated rats compared to those treated with paxilline. *Ex vivo* analysis of RA-FLS demonstrated that KCa1.1 inhibition alters integrin expression and activation through modulation of calcium homeostasis and Akt phosphorylation, resulting in decreased invasiveness.

Conclusion: KCa1.1 is an attractive therapeutic target for the treatment of RA by inhibiting the invasive phenotype of FLS through modulating integrin expression. The use of the selective peptide KCa1.1 inhibitor IbTX provides for a novel targeted pharmacological approach to inhibit KCa1.1 expressed on FLS while minimizing side effects. Overall, these studies emphasize the efficacy of targeting FLS in reducing disease severity and suggest selective KCa1.1 inhibitors as potential therapeutics in the treatment of RA.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The family of Janus kinases (JAKs) plays important roles in signaling pathway mediated by various cytokine receptors. An aberrant activation of JAK-STAT signaling has been reported to be involved in the pathogenesis of autoimmune diseases.Non-selective JAK inhibitors have shown excellent efficacy in patient with rheumatoid arthritis (RA). However, their use is limited due to adverse effects and safety concerns by inhibiting JAK1/2 signaling. Selective inhibition of JAK3 might result in an improved safety profile while maintaining excellent efficacy. The objectives of this study were to identify pharmacological profiles of TAS8274, a novel JAK3 inhibitor with high selectivity, and to evaluate its therapeutic potential in rat adjuvant-induced arthritis (AIA).

Methods: In vitro biochemical assay was performed using available kinase assay panels. In cell-based assay, JAK3 activation was evaluated by interleukin (IL) -2-induced human peripheral blood mononuclear cells (PBMC) proliferation. IL-2–, IFN-α– and IL-3–induced phosphorylation of STAT proteins in PBMC were analyzed and quantified by a flow cytometry-based assay. Female Lewis rats were injected intradermally with adjuvant at the base of the tail. In order to evaluate the therapeutic efficacy of TAS8274 in rat AIA, treatment was initiated when the overt clinical signs of disease were observed. TAS8274 was administered orally twice daily for 2

weeks. Swelling in hind paws were measured using a plethysmometer. At the end of the experiment, the paws were removed to analyze the histopathological changes. The scoring of inflammation, pannus, cartilage and bone damage in two joints of the rat AIA was performed by a single blinded pathologist using a modified Mankin score system.

Results: TAS8274 strongly inhibited the enzymatic activity of JAK3, and showed more than 1000-fold selectivity against other JAK family members, JAK1, JAK2 and TYK2. TAS8274 inhibited the IL-2–induced proliferation of PBMC in a dose dependent manner (IC_{50} = 25.3 nM) and also potently suppressed IL-2–induced STAT5 phosphorylation (IC_{50} = 18.9 nM). On the other hand, TAS8274 showed 300-3000 fold less inhibitory effects against JAK3–independent IFN-α or IL-3–induced STAT phosphorylation than that of JAK3–dependent STAT phosphorylation. In an established rat AIA, the hind paw volume in TAS8274-treated rats was dose-dependently decreased after oral administration of TAS8274 (0.3 to 10 mg/kg). TAS8274 also significantly reduced paw histopathology scores compared with those in vehicle-treated rats.

Conclusion: Our results demonstrate that TAS8274 has the potential to elicit JAK3-mediated immunomodulatory effects without affecting the activities of JAK1, JAK2 and TYK2 and improves clinical signs of arthritis in the rat AIA. TAS8274 would be an attractive therapeutic agent for patients with autoimmune disorders such as RA, and reduce the side effects induced by inhibiting other JAK family members. TAS8274 was selected as a clinical candidate and is being evaluated for its safety profile to initiate Phase 1 study.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease that causes chronic inflammation and destruction of joints. Netrin-1, a laminin-like matrix protein that acts as a chemorepulsant, plays a pathogenic role during inflammation by preventing macrophage egress from inflamed sites, and it is required for osteoclast differentiation. We asked whether blockade of Netrin-1 or its receptors (Unc5b, DCC) may be useful therapeutic targets in the treatment of inflammatory arthritis.

Methods: 8wk-old-C57Bl/6 mice were ip-injected with 0.2ml K/BxN serum twice. Murine monoclonal antibodies against Netrin-1, Unc5b or DCC (10µg/mice) were ip-injected weekly for 4wk (n=10). Clinical signs (paw swelling and thickness) were observed daily. Animals were sacrificed 2-4wk after serum transfer, and paws were prepared for microCT and histology

Results: Serum transfer induced an increase in paw inflammation that was maximal 2wk after injection. Anti-Netrin-1 or anti-Unc5b, but not anti-DCC, antibodies significantly reduced paw inflammation (clinical score of 9.8±0.8, 10.4±0.9 and 13.5±0.5 respectively vs. 16±0 for control, $p<0.001$, n=10). Same results were observed for changes in paw thickness. microCT showed bony erosions in untreated or anti-DCC-treated-mice whereas there were no erosions in anti-Netrin-1/anti-Unc5b-treated-animals. TRAPstaining demonstrated a marked decrease in osteoclasts in anti-Netrin-1/anti-Unc5b-treated-animals but not in anti-DCC-treated-mice (4±1, 3±1 and 9±2cells/hpf respectively vs.12±1cells/hpf for control, $p<0.001$ and p=ns, n=5). Immunofluorescence staining revealed a decrease Cathepsin K and CD68-positive cells in anti-Netrin-1/anti-Unc5b, but not anti-DCC-treated-animals.

Conclusion: Blockade of Netrin-1/Unc5b by treatment with murine monoclonal antibodies prevents bone destruction and K/BxN serum transfer-induced arthritis. Netrin-1 may be a novel therapeutic target for inflammatory bone destruction.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with active rheumatoid arthritis (RA) have significantly increased cardiovascular (CV) morbidity and mortality, paradoxically in association with reduced circulating levels of total cholesterol (TC) and LDL-C. Tofacitinib (TOFA), an oral Janus Kinase inhibitor, improves systemic and joint inflammation in RA, increasing serum TC and LDL-C without affecting CV disease. Our aim was to study the effect of TOFA on the lipid profile of hyperlipidemic rabbits with chronic arthritis (CA) and to go deeper into the mechanisms associated to the regulation of reverse cholesterol transport (RCT) exerted by this treatment in chronic inflammation

Methods: Twenty-four male, New Zealand white rabbits fed with a high fat diet (HFD) were randomly assigned to two groups: control (n=6) and CA (n=18). CA was induced over six weeks via intra-dermal ovalbumin sensitization and four subsequent intra-articular injections. Nine CA rabbits were treated with TOFA (10mg/kg/day) for two weeks. Fully differentiated THP-1 cells were exposed to HFD rabbit serum or ox-LDL to become foam cells. Thereafter, cells were stimulated with IFNγ to reproduce the inflammatory milieu in the presence or absence of TOFA for 24 hours. Intracellular lipid accumulation was assessed by Oil Red-O staining and protein and RNA were isolated for molecular studies.

Results: CA rabbits showed lower levels of serum TC and LDL-C compared to controls (p=0.001 and p=0.012), while TC/HDL-C ratio was higher in CA+TOFA rabbits when compared with CA animals (150±15 vs. 230±17; p=0.004). Synovial inflammation and C-reactive protein (CRP) levels were increased in CA animals, and a significant reduction was shown in CA+TOFA rabbits in both parameters (p=0.015 and p=0.006). We observed an inverse correlation between serum TC and CRP (R=-0.454, p=0.029). An increased infiltration of lipid-loaded macrophages was found in the synovial membrane of CA and CA+TOFA rabbits. In vitro experiments confirmed that IFNγ further stimulates intracellular lipid accumulation in macrophages incubated with HFD rabbit serum or with oxLDL. INFγ inhibited the expression of the cellular ATP-binding cassette transporter (ABCA1) that mediates the first step of RCT. The impaired lipid accumulation was prevented in the presence of TOFA. Furthermore, TOFA restored the IFNγ-induced ABCA1 downregulation, both preventing STAT1 phosphorylation and increasing LXRα expression.

Conclusion: Our experimental model of CA perfectly replicated the lipid paradox observed in RA patients, and the increase in circulating lipids evoked by TOFA, together with an amelioration of joint and systemic inflammation. In vitro studies showed that TOFA prevented the inflammation-induced dysregulation of lipid transport in macrophages through a LXRα depending mechanism, counteracting the IFNg inhibition of RCT. Therefore, these results suggest that chronic inflammation would sequester lipids into macrophages -in the synovium and probably in other tissues- thus decreasing serum lipid levels. Taking together, our findings partially explain the effect of TOFA on the lipid profile in RA patients.

The EP4 Receptor Antagonist CR6086 Is More Effective Than Classical NSAID and DMARD Treatment in a Murine Model of Arthritis and in Human RA Synovial Explants

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: CR6086 is a novel small molecule acting as a potent and selective antagonist of the prostaglandin E2 (PGE2) receptor EP4 subtype (EP4 receptor). Recent studies have shown that PGE2-EP4 signaling acts directly on type 3 innate lymphoid cells (ILCs) and T cell differentiation, and may therefore play a key role in the altered immune response observed in autoimmune diseases such as rheumatoid arthritis (RA). The **objectives** of this study were: (1) to evaluate the efficacy and immunomodulatory effects of systemic treatment with CR6086 in comparison to classical NSAID or DMARD treatment on experimental arthritis in mice; (2) to confirm the efficacy of EP4 receptor targeting in a translational setting using human RA synovial tissue.

Methods: In female C57Bl/6 mice, antigen-induced arthritis (AIA) was elicited by two immunizations with methylated bovine serum albumin (mBSA) as an antigen in Freund's complete adjuvant, and subsequently by intra-articular injection with mBSA into the right knee joint. Treatment was started two hours after the onset of arthritis, in 6 treatment groups: CR6086 (20 or 60 mg/kg/day), Naproxen (60 mg/kg/day), Dexamethasone (5 mg/kg/day), Etanercept (10 mg/kg every other day) or vehicle control. The effects of treatment were studied in vivo by ^{99m}Technetium measurements to detect joint swelling in the arthritic knee joint. At day 7 of treatment, mice were sacrificed and joints were isolated for histological analysis of inflammation and destruction. Synovial tissue was collected at day 3 to assess local cytokine and chemokine production by Luminex, and synovial gene expression by RT-QPCR. Furthermore, synovial explants of RA patients were cultured ex vivo in the presence or absence of CR6086 (300nM), Etanercept (10 µg/mL), or Tofacitinib (300nM), and the effect on spontaneous cytokine and chemokine production was analyzed by Luminex.

Results: Treatment with the EP4 receptor antagonist CR6086 significantly and dose-dependently reduced antigen-induced arthritis, as scored by macroscopic and histological scoring. Interestingly, CR6086 at 60 mg/kg/day was more effective than Naproxen, a classical NSAID, in reducing clinical inflammation scores and histological joint pathology. Furthermore, CR6086 at this dose was as effective as Dexamethasone in reducing histological inflammation, and even more potent in protecting from severe bone erosions. Regarding the immunomodulatory actions of CR6086, our study showed that CR6086 treatment reduced cytokines like IL-1beta, IL-17A, and to a lesser extent IL-6 and IFNgamma. The ex vivo experiment with human synovial tissue showed a beneficial, inhibitory effect of CR6086 on spontaneous secretion of cytokines and chemokines by synovial explants in two RA donors. In these two "responders", a comparable inhibitory effect of Etanercept was observed, whereas Tofacitinib was clearly less effective than CR6086.

Conclusion: These findings provide support for the potential therapeutic effects of the EP4 receptor antagonist CR6086 in RA patients, and point to the PGE2-EP4 receptor pathway as a rational target for the development of novel DMARDs with immunomodulatory and anti-inflammatory properties.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-TNF-alpha therapy has been a successful treatment strategy for rheumatoid arthritis (RA), but is associated with reduced resistance to infection. In mice, TNF is essential to control infection. We have developed a murine vaccine against TNF (mTNF-K) which protects mice from collagen-induced arthritis (CIA) to same extent as etanercept. We aimed at modelizing the infectious risk/benefit ratio of TNF-alpha neutralization by a vaccination strategy. Here we evaluated the consequence of TNF blockade by the mTNF-K in *Listeria* and *Mycobacterium* infection models.

Methods: Arthritis models were collagen-induced arthritis (CIA) in mice and collagen-antibodies induced arthritis (CAIA). In *Listeria monocytogenes* infection model, 4 groups of 10 C57Bl/6 mice were used and compared with a murine TNF KO group (same background). Wild type mice were treated either by mTNF-K, etanercept, KLH or PBS. Vaccines were emulsified in CFA (day 0) or IFA (days 13, 27 and 40) before injections. All groups were infected at day 44 by 10^4 cfu of *Listeria monocytogenes* (LO28 strain). Mice groups were divided in two arms: one was euthanized 4 days post-infection, survival of the lasting mice was evaluated until day 11. In Mycobacterium infection model, the same protocol was applied with same groups before infection by 10^4 cfu of *Mycobacterium tuberculosis* (H37Rv strain). Mice groups were divided in two arms: one was euthanized 28 days post-infection, the lasting mice were euthanized 56 days post-infection. Bacterial burden was evaluated in the lung. Cellular infiltration was studied by immunohistological analysis.

Results: Our vaccine was efficient in improving clinical and histological signs of arthritis in CIA and CAIA. A sustained anti-TNF-alpha antibody production was obtained in mTNF-K vaccinated mice in all experiments. At day 4 post-infection by Listeria, mTNF-K and non-targeted-TNF treatments groups (KLH, PBS) presented lower bacterial burden in liver and spleen than TNF KO and etanercept groups. At day 11, all mice of PBS and mTNF-K groups survived to infection. Large lesions in livers were observed only within TNF KO and etanercept groups. At day 28 post-infection by Mycobacterium, bacterial burden, organ weights and cellular infiltrations (Neutrophils, B cells) were similar between mTNF-K and non-targeted-TNF treatments groups. On the contrary, etanercept group presented increased surface of liver granuloma and lower lung infiltration by iNOS+ cells than mTNF-K group. At day 56, etanercept group presented higher surface of lung granuloma than mTNF-K and KLH group.

Conclusion: Together, our results indicate that anti-TNF-alpha vaccine could protect mice from inflammatory arthritis without deeply altering host immunity against infection, suggesting the existence of two distinct pathophysiologic thresholds for TNF inhibition, one for arthritis improvement, the other for infection deregulation.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Animal Models - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor-transgenic (TNF-Tg) mice develop systemic inflammatory polyarthritis. DC-STAMP, a multi-pass transmembrane protein, was originally identified from a dendritic cell library and required for cell-cell fusion between osteoclast precursors (OCPs). To examine if DC-STAMP also regulates inflammatory responses in TNFα-mediated arthritis pathogenesis, we introduced a DC-STAMP null mutation into the TNF-Tg background and examined immune responses and inflammatory-erosive arthritis progression in the presence or absence of DC-STAMP.

Methods: Two TNF-Tg lines (TNF-Tg3647 & Taconic 1006) were crossed to DC-STAMP-/- mice to generate distinct DC-STAMP genotypes (+/+, +/-, and -/-) under TNF-Tg (+ or -) background. Arthritis progression was evaluated by grip strength monthly until mice reached 4 months of age. Immune responses were evaluated by flow cytometry on cells obtained from the ascites of 4-month old mice. ELISA was performed to assess endogenous mouse and transgenic human TNF levels in sera. Immunohistochemistry (IHC) were performed to identify DC-STAMP+ cells in lung, heart and intestine.

Results: We observed the following:(1) Synthetic lethality in Taconic 1006: no live DC-STAMP-/-TNF+ pups were detected; (2) In TNF-Tg3647 background: although the majority of DC-STAMP-/-TNF+ pups died within a week after birth, several DC-STAMP-/-TNF+ pups survived; (3) In contrast to their DC-STAMP+/-TNF+ & DC-STAMP+/+TNF+ littermates where widespread inflammation (ascites, heart & lung pathology) and arthritis progression were observed, DC-STAMP-/- TNF-Tg+ mice showed attenuated joint pathology and inflammation. The grip strength of DC-STAMP+/-TNF+ & DC-STAMP+/+TNF+ mice decreased dramatically between weeks 11 & 12 (0.6±0.2N), whereas DC-STAMP-/-TNF+ mice grip strength was relatively strong at week 12 (1.6±0.3N), p=0.05 between 2 groups; (4) The protective effect of DC-STAMP null mutation on TNFα-induced arthritis progression and inflammation was independent of TNFα serum levels. Intriguingly, a higher serum TNFα level was detected in arthritis-free DC-STAMP-/-TNF+ mice compared to DC-STAMP+/+ TNF+ littermates with severe arthritis; (5) 65% of cells collected from inflammatory ascites were DC-STAMP+CD11b+ cells; (6) the lung, heart and intestine of DC-STAMP-/-Tg+ mice showed significantly less inflammation (neutrophils & CD11b+ monocytes infiltration) and attenuated pathology than their DC-STAMP+/+Tg+ littermates.

Conclusion: The absence of DC-STAMP expression in the TNFα-overexpressing mouse arthritis model was associated with suppression of both systemic inflammation and arthritis progression. The presence of DC-STAMP+ cells in ascitic fluid coupled with attenuated arthritis and systemic inflammation in DC-STAMP -/- mice provides preliminary evidence that DC-STAMP is involved in the regulation of TNF-induced immune responses. Examination of the molecular mechanism underlying the altered immune system and anti-inflammatory responses in DC-STAMP-/-TNF+ mice will provide new insights into the interplay between DC-STAMP and TNFα. Collectively, our results suggest that blockade of DC-STAMP may serve as an effective therapy for arthritis medication.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone maintenance is a balance between the removal of old bone by osteoclasts (OCL) and the production of new bone by osteoblasts. In the arthritides, bone erosion by OCL occurs at normally protected sites in the joints where bone replacement does not occur. N-MeDCPA allows the regulated reduction of OCL activity, that is, control damage to joints without complete elimination of OCL activity. Thus, the balance of bone maintenance in joints can be restored. OCL maturation is suppressed when calcium-release activated calcium (CRAC) currents are blocked by targeting Orai1, the pore-forming unit of CRAC. We provide evidence that N-MeDCPA is a Orai1 antagonist that suppresses OCL maturation, without significantly affecting osteoblastogenesis or immune function.

Methods: The Orai1-blocking activity of N-MeDCPA was measured in Jurkat T cells using Fura-2. In vivo data was collected after the induction of CIA in DBA/1 mice. Animals were dosed with 0 or 21 mg/kg body weight per day N-MeDCPA via a subcutaneous 21-day continuous time-release pellet inserted at day 20 - dose equivalent to 350 mg qid as a human anti-inflammatory drug. A booster injection of collagen II was administered at day 21 and the Arthritis Index (AI) and paw swelling were measured for 20 d thereafter. Bone erosion was assessed using micro-computer tomography (m-CT). Serum anti-(mouse) collagen IgG was measured by ELISA and serum cytokine levels were measured using MSD V–PLEX panels.

Results: Orai1 activity was blocked by N-MeDCPA in a concentration-related manner. CIA measurements, by blinded observers, showed that N-MeDCPA suppressed the AI (severity) over 3 weeks. Bone and cartilage damage in sections of animal feet was reduced; overall swelling of joints was reduced by a similar amount. Effects on bone density by μ CT showed clear separation in N-MeDCPA-treated CIA animals from CIA without treatment, while differences between controls without CIA and CIA treated with N-MeDCPA differed by small amounts and in most cases were not statistically different. Response was not related to anti-collagen titers. There were no adverse effects in the treated group on animal weight or activity, consistent with low toxicity. The effect was maximal 12-17 days after collagen booster, during the rapid appearance of arthritis in untreated CIA. At 20 days after treatment (day 40), differences in arthritis score were reduced and TNF-α, IL-1, or IL-6 in the serum of the animals were similar in treated and untreated animals.

Conclusion: N-MeDCPA, a novel inhibitor of Orai1 channels, suppresses bone erosion associated with acute arthritis in mice and potentially represents a new treatment modality for acute arthritis.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease leading to inflammatory destruction of the peripheral joints. Although pro-inflammatory T helper 1 (Th1) and/or Th17 cell responses play a central role in the immunopathology of RA, current therapies do not provide efficient inhibition of these pro-inflammatory T cells or their signature cytokines. In this study, we demonstrate that the peptide conjugate DerG-PG70 (CEL-4000) is able to inhibit Th1 and Th17 responses and can act as a therapeutic vaccine in an autoimmune mouse model of RA.

Methods: Female BALB/c mice were immunized intraperitoneally (ip) with the recombinant G1 domain of human cartilage proteoglycan (PG) aggrecan in adjuvant. This G1-induced arthritis (GIA) model of RA can display Th1- or Th17-skewed cellular responses depending on the route of immunization (ip or id/sc, respectively). We elected to focus on the more aggressive ip-induced form with a Th1 signature phenotype (IFNg). Peptide conjugates composed of an immune cell binding motif (designated DerG or J) and the arthritogenic epitope of human PG (PG70) were constructed. DerG-PG70 (CEL-4000) or J-PG70 vaccine was administered with adjuvant twice (2 weeks apart) to the mice, beginning at the early phase of arthritis. Mice treated with adjuvant only served as controls. Disease severity was monitored by visual scoring of joint inflammation. Three weeks after the second vaccination limbs were processed for histopathology and serum was collected for measurement of pro- and anti-inflammatory cytokines. Spleen cell cultures were set up to examine binding of peptide conjugates to Th cells or antigen-presenting cells (APCs) and to determine Th cell cytokine profiles using flow cytometry and Millipore's MagPix multiple cytokine assays.

Results: The CEL-4000 vaccine significantly suppressed arthritis severity and limited joint damage in the ip-induced form of GIA. The other peptide conjugate (J-PG70) or single PG70 and DerG peptides were not therapeutically effective in the disease. Increased ratios of anti-inflammatory cytokines (IL-4 and IL-10) to pro-inflammatory IL-17 were found in the serum of mice vaccinated with CEL-4000 as compared to the other treatment groups. Spleen cells from mice with ip-induced GIA and vaccinated with either CEL-4000 or J-PG70 showed reduced production of Th1 and Th17 signature cytokines as well as other pro-inflammatory mediators in vitro as compared to controls. However, this inhibitory effect was found to be more potent in cell cultures of CEL-4000-treated than J-PG70 treated animals. In vitro cell binding experiments revealed preferential binding of the CEL-4000 peptide conjugate to Th cells whereas J-PG70 bound primarily to APCs.

Conclusion: Our results suggest that while both peptide vaccines have an influence on the immune system, CEL-4000 powerfully down-modulates pro-inflammatory T-cell responses probably via direct binding to Th cells whereas J-PG70 does it indirectly, and less effectively, via binding to APCs. Robust inhibition of Th1, Th17, and pro-inflammatory pathways, as seen in mice with ip-induced GIA after receiving CEL-4000 vaccine, appears to be necessary for arthritis suppression.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

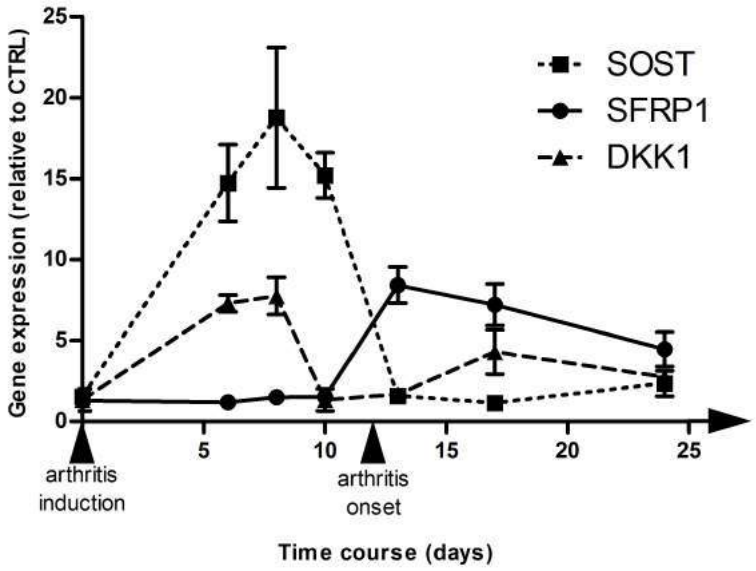
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Periarticular bone loss in rheumatoid arthritis is considered to be mainly related to synovial inflammation, leading to uncoupling between decreased bone formation and increased bone resorption. However, it has been recently demonstrated a paradoxical exacerbation of joint damage when blocking sclerostin in various arthritis models. Phase specific changes in Wnt pathway activity over the course of the disease could participate in the underlying mechanisms of these results. Thus, we proposed to determine kinetic expressions of Wnt inhibitors in a classic rodent model of arthritis, the rat adjuvant induced arthritis (AIA).

Methods: Arthritis was induced (AIA, n=35) or not (CTRL, n=35) at baseline. Inflammation and loss of articular function were monitored. Periarticular bone loss and joint damage were evaluated before, during and after arthritis onset in a 7 time-point follow-up, using micro-computed tomography (µ-CT) and histomorphometry. Gene expressions were assessed by quantitative RT-PCRs at each time point.

Results: AIA onset occurred at day 12 post-induction ($p<0.001$). Surprisingly, histomorphometry and µ-CT showed bone alterations as early as day 8. Indeed, cortical porosity increased and trabecular network was significantly impaired ($p<0.01$). Moreover, these early bone alterations before arthritis onset predicted arthritis severity outcome. As expected, gene expression confirmed an early upregulation of bone resorption markers like RANKL from day 8 to day 24 ($p<0.01$). More interestingly, expression of bone formation inhibitors followed a specific pattern with SOST upregulation only before arthritis onset ($p<0.01$) and return to normal expression afterwards. However, frizzled related protein 1 (SFRP1) expression only increased after arthritis onset ($p<0.01$). Furthermore, dickkopf related protein 1 (DKK1) expression increased before and after arthritis onset with a low expression during arthritis onset.
Figure: gene expression pattern of SOST, DKK1, and SFRP1.



Conclusion: Bone alterations before arthritis onset supports the hypothesis of an early involvement of bone compartment in arthritis. The specific pattern of sclerostin expression suggested that sclerostin might play dual effects depending on arthritis phases. In addition, SFRP1 later increased expression could play a strong role in bone formation alteration related to arthritis. Since DKK-1 was highly expressed before and after arthritis onset, its blockade was already described to be efficient in mice arthritic model. We infer from our results that better deciphering Wnt pathway changes during arthritis is required before using biologics targeting this pathway for preventing periarticular bone loss.

Session Time: 9:00AM-11:00AM

Background/Purpose: Immunomodulatory properties enable mesenchymal stem cells (MSCs) to be a promising alternative for the treatment of a wide range of immune-related diseases including rheumatoid arthritis (RA). However, underlying mechanisms with the perspective of systemic immune regulation are less verified. We sought to explore the therapeutic efficacy of human umbilical cord blood-derived MSCs (hUCB-MSCs) against murine collagen-induced arthritis (CIA) and to investigate distinct mechanisms mainly focused on macrophages.

Methods: CIA was induced in DBA1/J mice by the repeated immunization of bovine type II collagen with complete Freund's adjuvant. hUCB-MSCs were administered to CIA mice intraperitoneally each day for 5 days after the onset of disease, and clinical severity was assessed. Alternatively, CIA mice were given with a single intravenous injection of hUCB-MSCs at the same phase of disease progression. To verify the regulatory effects of hUCB-MSCs on macrophages, human and murine macrophages were co-cultured with hUCB-MSCs and the alteration of cytokine profile and marker expression was determined. These regulatory functions were confirmed using peripheral blood mononuclear cells (PBMCs) from patients with RA.

Results: The multiple intraperitoneal administration of hUCB-MSCs exerted significant therapeutic efficacy against CIA to a similar extent of etanercept, anti-TNF-α biologic agent. A single intravenous injection of hUCB-MSCs exerted sufficient therapeutic effect on CIA, and down-regulated the production of various pro-inflammatory cytokines concomitantly. hUCB-MSCs suppressed the classical M1 activation of macrophages, and simultaneously increased the anti-inflammatory M2 polarization. Concerted action of strengthened cyclooxygenase (COX-2) and tumor necrosis factor alpha stimulate gene 6 (TSG-6) signaling in response to TNF-α, a prominent inflammatory cytokine in RA, contributed to the regulation of macrophage plasticity by inducing M2 polarization. In addition, these immune-balancing effects of hUCB-MSCs were reproducible in PBMCs from patients with active RA.

Conclusion: The systemic application of hUCB-MSCs can effectively attenuate murine inflammatory arthritis through the regulation of macrophage plasticity. Upon TNF-α stimuli, COX-2 and TSG-6 signaling is enhanced, consequentially results in both inhibition of M1 activation and induction of M2 polarization. Therefore, our findings provide the clue that stem cell therapy using hUCB-MSCs can be an attractive candidate for the treatment of RA, especially who do not respond to current single-target biologic medications.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity is associated with many chronic diseases. However, evidence regarding obesity's impact on rheumatoid arthritis (RA) initiation and development remains controversial. Recent studies indicate that obesity could reduce the risk of men developing RA. Here, we examined the role of high fat diet (HFD)-induced obesity in antigen-induced arthritis in adult male mice.

Methods: Antigen-induced arthritis (AIA) was induced in normal diet (ND) or 8-week exposure HFD mice by immunizing with mBSA in complete Freund's adjuvant. Arthritis severity was assessed by knee swelling measurement and histological evaluation. Serum anti-mBSA antibody and cytokines were detected by ELISA or Multiplex bead assay at various time points. T cell subpopulations and B regulatory cell in spleen and lymph node were evaluated *in vivo,* and their function was also examined by measuring cytokines production after phorbol ester (PMA) and Ionomycin stimulations *in vitro*.

Results: When compared to ND-mice, HFD-mice displayed less knee swelling and delayed peak arthritis. Consistent with these observations, histological assessment showed reduced infiltration of inflammatory cell and bone erosion in obese mice joints. Despite no difference in TNF-a, IL-21, IL-22 and TGF-b1 level in sera, IL-21/23p40 and anti-mBSA IgG production was significantly lower in HFD mice. Interestingly, the anti-inflammatory cytokine IL-10 level was increased in sera from HFD mice. Surprisingly, Th1, Th2 and Th17 cell population did not differ in both spleen and lymph node. Consistently, levels of IFN-g, IL-4 and IL-17A were comparable in the splenocyte supernatant from ND and HFD mice. Interestingly, a significantly increased Treg population was detected in the spleen of HFD mice but not in the lymph node. $CD19^{+}IL\text{-}10^{+}$ (B10) cells in the spleen of HFD mice were also enhanced, accompanied by higher IL-10 level in the splenocyte supernatant *in vitro*.

Conclusion: In summary, these data suggest HFD-induced obesity alleviates AIA-induced arthritis in male mice. This might due to the enhanced Treg and B10 cell population in HFD mice, which leads to increased IL-10 in sera of obese mice. This study provides a novel mechanistic link of obesity and RA.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Mortality is increased in rheumatoid arthritis (RA), mainly due to cardiovascular disease (CVD). While molecular mechanisms underlining this clinical observation are unknown, systemic elevations in inflammatory cytokines such as interleukin (IL)-6 frequently correlate with increased cardiovascular risk. Importantly, IL-6 plays important roles in both immune homeostasis and driving chronic disease progression. Control of these processes is regulated by two modes of IL-6 signalling; classical IL-6 receptor signalling and IL-6 trans-signalling. Cellular responses controlled by IL-6 trans-signalling are mediated via soluble IL-6 receptor (sIL-6R) and is widely considered to promote deleterious pro-inflammatory outcomes. Importantly, a genetic polymorphism within IL6R enhances circulating sIL-6R levels and is associated with CVD incidence in the normal population. Biological drugs against IL-6 (e.g. olokizumab) or IL-6R (e.g. tocilizumab) block both classical and trans-signalling. However it is advocated that selective inhibition of IL-6 trans-signalling may reduce the incidence of clinical complications associated with a more global intervention strategy. Previously, murine collagen induced arthritis (mCIA) has been associated with vascular dysfunction, with reduced aortic constriction to 5-hydroxytryptamine (5-HT)[1]. Here, we found systemic alterations in vascular tone, as a response to mCIA, was attributable to the action of IL-6 trans-signalling.

-

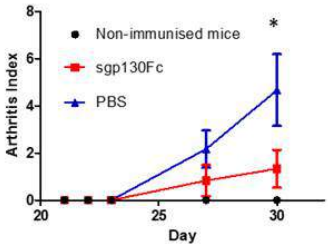
Methods:

-

Arthritis was induced in 8 week old male DBA/1 mice by type-II collagen, as previously described[2]. Animals were intravenously administered sgp130Fc (2.5mg/kg) or PBS weekly from day 21 after immunisation with type-II collagen. Arthritis severity was monitored daily from day 21 to 30. Vasoconstriction of isolated aortic rings in response to 5-HT was monitored as an index of vascular function using isometric tension myography.

Results are expressed as mean ± SEM (n=10).

Results:



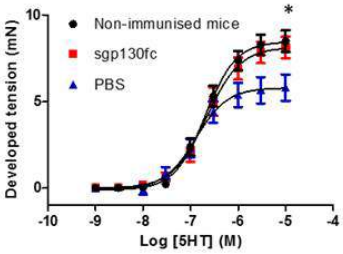


Figure 1 (A) Significant difference in Arthritis Index over time in mice administered spg130Fc compared with PBS. (B) Vasoconstriction concentration-response curves to 5-HT in aortic rings. N=10

When compared with PBS controls (Arthritis Index: 4.3±1.1), disease severity was significantly (P<0.05) reduced in sgp130Fc (1.5±0.6) treated mice (Figure1A). The induction of arthritis in PBS control animals was accompanied by reduced vasoconstriction (developed tension 8.5±0.6 mN for non-immunised mice, compared with 5.8±0.8 mN for mice with CIA; P<0.05). Significantly, improvement of disease activity observed for sgp130Fc treated animals was associated with normalisation of vascular function (developed tension 8.1±0.6 mN).

Conclusion:

Consistent with previous reports[2], sgp130Fc reduced arthritis in mCIA. Sgp130Fc also restored vascular function. Selective IL-6 trans-signaling blockade by sgp130Fc is a promising therapeutic strategy for both RA and its associated CVD. Further work is needed to elucidate the role of IL-6 trans-signalling in the pathogenesis of vascular dysfunction in both mCIA and RA.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic inflammatory autoimmune disease whose etiology is unclear. Recently, upregulated HDAC (histone deacetylase) activity has been reported in peripheral blood mononuclear cell (PBMC) from RA patient. In addition, it was reported that HDAC6 inhibitor (HDAC6i) improves cancers and inflammatory diseases by suppressing cell migration and proliferation and reducing pro-inflammatory cytokines such as TNF-α. Here, we investigated the therapeutic effects of a new HDAC6 inhibitor, CKD-M808 (M808), specifically targeting catalytic domain 1 of HDAC6 in RA.

Methods: We made adjuvant induced arthritis (AIA) model by injection of complete Freund's adjuvant (CFA) subcutaneously into the tail base of Lewis rat on the 1st day of experiment. Vehicle (n=9) and M808 (10, 30, 50 and 100 mg/kg, n=9, 9, 8 and 10, respectively) were administered orally every day. Clinical score was measured at 10th, 14th and 17th days after induction. PBMC from RA patients were treated with HDAC6i (Tubastatin A and M808) for 24 hours under lipopolysaccharide (LPS) stimulation. After incubation, cell viability and the levels of cytokines including TNF-α, IL-1ß, IL-6 and IL-10 in culture supernatant were measured using CCK-8 and multiplex ELISA assay, respectively. Fibroblast-like synoviocyte (FLS) from RA patients were treated with HDAC6i for 24 hours under IL-1ß stimulation. The levels of IL-6, MMP-1 and MMP-3 were measured in culture supernatant. Cortactin and acetylated cortactin in HDAC6i-treated RA-FLS were measured by Western blotting.

Results: Clinical score of AIA model were significantly decreased as the dose of M808 increased, indicating the therapeutic effect of M808. In RA-PBMC, M808 downregulated the level of TNF-α<span 'arial','sans-serif';"="'Arial','sans-serif';"" lang="EN-US"> and upregulated the level of IL-10 without any impact on cell viability. In RA-FLS, M808 decreased the production of MMP-1 and MMP-3. M808 increased acetylation of cortactin molecule in a dose-dependent manner.

Conclusion: M808 suppressed clinical arthritis in the AIA model. M808 decreased the production of TNF-α and increased IL-10 in PBMC of RA patients. M808 also decreased MMP-1 and MMP-3 in FLS of RA patients. The novel HDAC6i, M808, may provide a new therapeutic option in RA patients.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The regulation of Ca^{2+} entry by targeting a store-operated calcium release-activated channel (CRAC), known as *ORAI*, has shown benefits in the treatment of rheumatoid arthritis (RA). This study was undertaken to investigate the feasibility and efficiency of CRAC inhibitors in the treatment of RA.

Methods: Peripheral T cells and B cells were obtained from RA patients and health donors. We engrafted pannus tissue from synovia, articular cartilage, bone, and peripheral blood mononuclear cells from RA patients who underwent prosthetic replacement arthroplasty for therapeutic purposes into NOD/ShiJic-scid mice (SCID-HuRAg mice) and treated them with CRAC inhibitors, including YM-58483, a specific short hairpin RNA and a monoclonal neutralizing antibody.

Results: The treatment of CRAC inhibitors suppressed the Ca^{2+} entry and the activation in peripheral cells. CRAC inhibitors declined the production of human IgG2 and IgM in SCID-HuRAg mice. According to the results of histological evaluation, treatment of SCID-HuRAg mice with CRAC inhibitors markedly suppressed invasion of synovial tissue into cartilage. A decrease in mature osteoclast activity was also observed in CRAC inhibitor-treated SCID-HuRAg mice.

Conclusion: These results indicate that the regulation of Ca^{2+} entry through CRAC channel is beneficial in the treatment of RA.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the effects of umbilical cord-mesenchymal stem cell (UC-MSC) transplantation on joint damage and systemic osteoporosis in collagen induced arthritis (CIA) mice.

Methods: DBA/1 male mice were induced to CIA models by injecting type II Collagen (CII). Then CIA mice were divided into four groups, including CIA control group, UC-MSC transplantation group, anti-tumor necrosis factor alpha (anti-TNFα) treatment group and zoledronic acid (ZA) treatment group. The CIA mice were treated for 8 weeks. Arthritis score of CIA mice were evaluated every 3 days. Micro computed tomography (micro-CT) was used to analyze the bone morphology parameters. Bone marrow mesenchymal stem cells (BMMSCs) were isolated and cultured in the osteogenic medium. Osteogenic differentiation was determined by alkaline phosphatase (ALP) staining and ALP activity on day 7. The expression of the osteogenic markers ALP, Osterix and type I collagen (COL-I) were analyzed by RT-PCR and western bloton day 7 and day 14 respectively. Moreover, bone marrow monocytes (BMMs) were isolated and induced to osteoclast (OC) in the presence of macrophage colony-stimulating factor and receptor activator of nuclear factor-KB ligand. OC differentiation was determined by tartrate-resistant acid phosphatase (TRAP) staining and mRNA levels of nuclear factor of activated T cells (NFAT)2 and osteoprotegerin (OPG).

Results: The arthritis score was significantly reduced in UC-MSC transplantation and anti-TNFα treated CIA group compared with control mice. Micro-CT showed that the BMD, trabecular bone volume/total volume (BV/TV) and trabecular number (Tb.N) of the

femur were significantly decreased in CIA mice, compared with that in DBA/1 mice. H&E staining also showed a reduced Tb.N in CIA mice. Whereas these parameters were partially improved in UC-MSCs treated CIA mice compared with control mice. Impaired osteogenic differentiation functions were shown by decreased ALP activity, reduced gene and protein levels of osteogenic marker genes in CIA mice compared with DBA/1 mice. UC-MSCs treatment significantly upregulated the osteogenic differentiation ability in CIA mice. Moreover, TRAP staining and OC counting showed that OC number was increased in CIA mice compared to that in DBA/1 mice. The NFAT2 mRNA levels were elevated in CIA mice compared to that in DBA/1 mice, however the OPG mRNA levels were decreased in CIA mice. UC-MSC treatment downregulated the enhanced OC differentiation in CIA mice.

Conclusion: The present study demonstrated that CIA mice developed osteoporosis. UC-MSCs transplantation not only improved the joint damage significantly but also played a positive role in osteoporosis in CIA mice. The osteogenic differentiation ability of BMMSCs in CIA mice was impaired. The OC differentiation function of BMMs in CIA mice was enhanced. UC-MSCs transplantation could upregulate the osteogenic differentiation and downregulate the OC differentiation in CIA mice. Thus, we provide strong evidence that MSCs ameliorate inflammation-induced systemic bone loss in CIA mice by upregulating osteogenic differentiation and reducing OC differentiation.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Many signaling pathways activated under inflammatory and hypoxic conditions have profound effects on intracellular metabolism to support cell growth and survival. Cancer cells consume glucose and glutamine at a high rate compared to normal cells. Recent studies have identified cancer-specific metabolic changes that provide new therapeutic targets. The microenvironment in inflamed joints in RA is also characterized by hypoxia and low concentration of nutrients, and fibroblast-like synoviocytes from RA patients (RA-FLS) is known to have several tumor-like characteristics. However, little is known about how glucose or glutamine metabolism are involved in the aberrant proliferation of RA-FLS. We aimed to evaluate the role of these metabolisms in RA-FLS, and discover a metabolic characteristics of RA-FLS.

Methods: The expression of glycolysis- or glutaminolysis-related enzymes was evaluated by real-time PCR and Western blotting. The intracellular metabolites in FLS were analyzed by gas chromatography mass spectrometry (GC/MS) and capillary electrophoresis (CE)-MS. We used glucose- or glutamine-free medium for investigating the effects of glucose or glutamine on cell growth of RA-FLS. siRNA or compound 968 was used to inhibit glutaminase 1 (GLS1). Arthritis was induced in SKG mice by zymosan A injection. SKG mice were treated with compound 968 three days per week. Ki-67-positive cells were analyzed by immunohistochemistry.

Results: GLS1 expression was increased in RA-FLS and metabolome analyses suggested that glutamine metabolism was upregulated in RA-FLS. Cell proliferation of RA-FLS was significantly decreased under the glutamine-derived condition, but not under glucose-derived condition. Cell proliferation of RA-FLS was significantly suppressed by GLS1 inhibition. The levels of GLS1 mRNA was increased by treatment with IL-17 or PDGF in RA-FLS. Administration of GLS1 inhibitor, compound 968, ameliorated autoimmune

arthritis in SKG mice. Histologic score of arthritis in compound 968-treated mice were significantly lower than those in control mice. Furthermore, immunohistochemical analysis revealed that compound 968 treatment significantly downregulated the Ki-67-positive synovial cells. The number of Th17 cells and Treg cells in spleens from compound 968-treated and control mice were not changed by compound 968 treatment.

Conclusion: Glutamine metabolism was involved in the pathogenesis of RA. Glutamine deprivation or inhibition of GLS1 inhibited cell proliferation of RA-FLS. Administration of GLS1 inhibitor ameliorated the inflammatory arthritis in SKG mice by suppressing the proliferation of RA-FLS. GLS1 inhibition directly affected the cell cycle progression of RA-FLS and suppresses the aberrant cell proliferation. GLS1 may play an important role in regulating RA-FLS proliferation, and could be a novel therapeutic target in RA.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Collagen induced arthritis (CIA) mouse model is used for screening of new drugs for autoimmune arthritis. The conventional read outs of this model are clinical and histological scores. These read-outs have many limitations including (i) longitudinal studies in the same mouse cannot be performed (ii) clinical and histological scores are subjected to observer bias (iii) *in vivo* cellular events cannot be captured in its native environment. To meet these unmet needs here we have evaluated the utility of ^{18}F-FDG PET imaging in the CIA model.

Methods: Briefly, arthritis was induced using bovine type II collagen in 8-week old male DBA/1J mice (n=30), out of which 20 mice developed arthritis. The disease was allowed to progress till day 45 (pre-treatment time point- **Fig 1**), 5 mice were sacrificed for histological studies; 10 mice were treated with i.p anti-mouse TNF-α antibody (CNTO5048, Janssen Biotech, USA) every alternate day (300 ug/dose) for next 10 days, and 5 mice received sterile PBS (vehicle control). Mice were scored clinically and had ^{18}F-FDG PET scan on day 0, 28, 45 and 56. The maximum ^{18}F-FDG uptake (standardized uptake value normalized by body weight) was determined for each major joints to generate a comprehensive **PET score (PS).**

Results: All data represented as median with range. The median clinical score **(CS)** of the most affected limb in the vehicle treated and untreated gradually increased to 2 (range:1-2) at day 28 ($p<0.01$), 2 (range:2-3) at day 45 ($p<0.01$) and 3 (range:2-3) at day 56 ($p<0.01$) compared to day 0. The clinical observation was confirmed by histological scores **(HS).** Compared to day 0 (HS=0), the median HS on day 28 was 2 (range:1-3), day 45 was 4 (range:2-4) and day 56 was 4 (range:4-5). The PS on day 0 was 1.02 (range:0.85-1.05). PS increased to median values of 1.52 (range:1.14-2.01) on day 28 ($p<0.05$), 3.51 (range:1.23-4.76) on day 45 ($p<0.05$) and 1.76 (range:1.45-2.78) on day 56 ($p<0.05$). CNTO5048 treatment significantly reduced the median CS to 1 (range:0-2, $p<0.01$) and HS to 1 (range:1-2, $p<0.01$) compared to their respective pre-treatment levels (CS:2, HS:4). Similar to CS and HS, PS on day 56 was significantly low (median=0.97, range=0.62-2.12, $p<0.01$) compared to pre-treatment level (day 45) (median=3.51, range=1.23-4.76) (**Fig 1**).

Conclusion: Here we have validated in the CIA mouse model that ^{18}F-FDG PET is an *in vivo* preclinical drug screening tool for antiinflammatory therapies. The use of this imaging modality will allow longitudinal quantitative evaluation response in the same mouse.

Figure 1

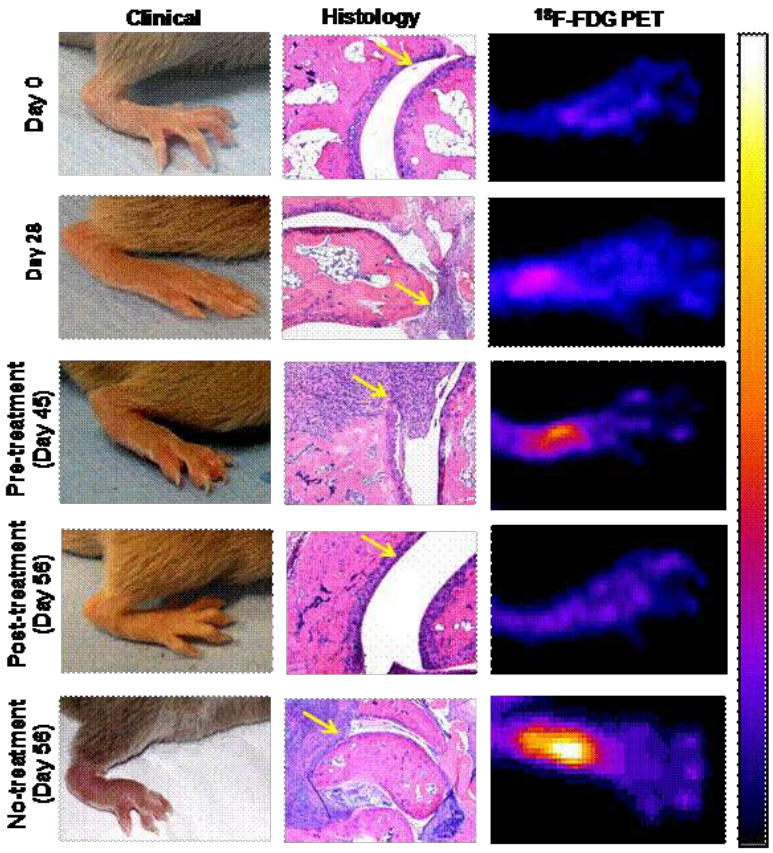

Figure 1: ^{18}F-FDG PET imaging, a quantative *in vivo* pre-clinical drug screening tool. 18F-FDG PET imaging effectively corelated with the both clinical and histopayhological (yellow arrows) therapuetic response of the anti-TNF-α (CNTO5048) antibody. The pseudo-color in PET indicates higher cellular metabolic activity, which resiprocates with the degree of inflammation.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients suffering from rheumatoid arthritis (RA) have an increased risk of lymphoma and disease activity is the main risk factor. The impact of treatment, and notably of anti- (TNF), is unclear. They might decrease the risk of lymphoma by controlling activity. But they also might alter anti-tumor immunosurveillance. Large epidemiologic studies have demonstrated that anti-TNF were not associated with an increased risk of lymphoma. However, some data support that this risk might vary according to the type or to the dose of anti-TNF. The aim of our study was to assess if the risk of lymphoma might differ according to the type of anti-TNF, comparing monoclonals to soluble receptor. For that, we used BAFF transgenic (Tg) mice as a model of autoimmunity-associated lymphomas. They develop lupus and Sjögren and 3% of them spontaneously developed lymphoma at 12-18 months.

Methods: Six months aged BAFF-Tg mice were treated with anti-TNF for 12 months: etanercept (ETA) (n=15, 8 mg/kgx3/week), monoclonal anti-mouse TNF (TN3 19.12, n=15, 20 mg/kg/week), adalimumab(ADA) (n=13, 20 mg/kg/week) or controls (n=22). Sera were assessed monthly to monitor drug trough level and anti-drug antibodies, auto-antibodies (antinuclear factor and rheumatoid factor) and immunoglobulins (Ig). Crude mortality was compared among the different groups (log rank test). Histologic examination of kidneys and of lymphoid tissue (spleen and lymph nodes) was performed at the end of the treatment period. The Fisher's exact test was used to compare the incidence of of lymphoma among the groups.

Results: Adjunction of low dose of methotrexate during the 3 first days of treatment with biologics prevented immunization in the 3 groups of treatment for life. Mean level of ETA, TN3 and ADA were 7 µg/ml, 69 µg/ml and 105 µg/ml, respectively. The level of auto-antibodies and serum Ig did not significantly differ among the groups. However, crude mortality was significantly higher in mice treated with monoclonals compared to controls (p=0.0001 for ADA and p=0.0003 for TN3) but not for mice treated with ETA (figure). Incidence of lymphoma was higher in mice treated with monoclonals: 5/15 (33%) with TN3 (p=0.03 / controls), 4/13 (31%) with ADA (p=0.054 / controls), 0/15 with ETA and 1/22 (5%) in controls.

Conclusion: Higher mortality and increased risk of lymphoma were observed in BAFF Tg mice treated with monoclonal anti-TNF compared to etanercept. This result may be linked either to the different mechanism of action between the soluble receptor and the monoclonals or to a difference of trough level observed in the different groups and new experiments with lower dose of monoclonals are ongoing. This study demonstrates the negative impact of a prolonged anti-TNF treatment on the risk of lymphoma in the context of BAFF increase. Negative impact on NK cells might explain this finding (accompanying abstract submitted). _

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Spleen Tyrosine Kinase (SYK) mediates signaling in hematopoietic cells important for the initiation and progression of rheumatoid arthritis (RA). GS-9876 is an oral, selective SYK inhibitor being developed in RA. Janus kinase (JAK) inhibitors, have demonstrated clinical efficacy in RA and exert their biological activity principally by blockade of proinflammatory cytokine signaling. Here we demonstrate that 1) the single agent activity of GS-9876 is efficacious in a late stage rat model of collagen-induced arthritis (CIA); 2) the combination of GS-9876 with a JAK inhibitor increases efficacy in this model; and 3) the effects of targeting SYK or JAK as single agents can be functionally differentiated.

Methods: The in vivo efficacy of GS-9876 and a JAK inhibitor were tested alone or in combination in a therapeutic rat CIA model. Dosing was initiated at the peak of disease (day 17-20) and continued into the chronic phase until day 34; making the test more indicative of late treatment effects in the highly destructive macrophage-mediated phase, rather than in the acute, early neutrophil mediated phase of t this model. Efficacy evaluations were based on animal body weights, daily ankle caliper measurements, ankle diameter (expressed as area under the curve), terminal hind paw weights, and histopathology of ankles and knees. Anti-type II collagen antibody levels in terminal serum were analyzed, and PK was collected to evaluate the relationship to efficacy. Joint tissue RNA and protein were analyzed for transcriptional and protein modulation.

Results: GS-9876 demonstrated dose-responsive efficacy in the rat CIA model. GS-9876 or a JAK inhibitor alone showed efficacy on clinical and histopathology parameters. Administration of the SYK or JAK inhibitor in combination showed significantly alleviated increases in terminal paw weights, ankle swelling, and ankle histopathology scores than either agent alone. Body weight loss was also significantly reduced in the combination therapy group, and weight was increased compared to the monotherapy arms. Knee ED-1 immunopositive osteoclast counts were significantly reduced in the animals treated with GS-9876, but not a JAK inhibitor, highlighting functionally distinct effects of SYK and JAK inhibition. PK analysis of GS-9876 showed serum exposure levels similar to those achieved in human studies.

Conclusion: GS-9876 is a novel SYK inhibitor which displays in vivo therapeutic efficacy in a chronic rat CIA model. Combining GS-9876 with JAK inhibition significantly improved clinical and histopathology scores, and reduced body weight loss in this model, at exposures similar to those achieved in healthy human volunteers. These data suggest that simultaneously targeting SYK and JAK can provide an efficacious therapy for inflammatory diseases.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor (TNF) is a critical effector of the autoimmune inflammation in rheumatoid arthritis (RA) and uveitis. TNF inhibitors are preferably used in the treatment of these autoimmune diseases. However, TNF inhibitors are not always effective in treating RA. Moreover, previous reports showed that some TNF inhibitors may even accelerate comorbid uveitis in RA patients. Therefore, it is very important to know the precise role of TNF signaling in RA and uveitis. TNF signals are mediated by two structurally related, but functionally distinct, receptors, p55 (TNFR1) and p75 (TNFR2). It has already been shown that genetic disruption of the TNF p55 receptor in mice can reduce the severity of collagen-induced arthritis (CIA) and experimental autoimmune uveitis (EAU), murine models of autoimmune arthritis and uveitis, respectively. However, it remains unclear whether mice lacking p75 or mice lacking both p55 and p75 are also resistant to CIA and EAU. In this study, we aimed to dissect the role of TNF signaling through the TNF p55 or p75 receptor in the development of EAU and CIA.

Methods: The p55-/-, p75-/-, and p55-/-p75-/- mice on a C57BL/6 background were generated by successive backcrossing to C57BL/6 for ten generations. EAU was initiated by immunization with interphotoreceptor retinoid binding protein (IRBP) in complete Freund's adjuvant (CFA) and administration of pertussis toxin. CIA was induced by immunizing these mice with type II collagen in CFA twice. Clinical examination was performed and severities of EAU and CIA were assessed using clinical scoring system.

Results: In EAU, the severity in p55-/- mice was reduced compared to that in control WT mice, as described previously. In contrast, EAU in p75-/- mice was similar to, or slightly more severe than that in WT mice. Mice lacking both p55 and p75 did not develop a typical acute disease but exhibited delayed-onset uveitis. In CIA, p55-/- mice were protected from arthritis. In contrast, the severity of CIA in p75-/- mice tended to be increased compared to that in control WT mice. Mice lacking both p55 and p75 developed less severe arthritis than WT mice.

Conclusion: Unlike p55-/- mice, p75-/- mice retained susceptibility to CIA and EAU. TNF signaling through p75 might contribute to limit inflammation in CIA and EAU. Antagonists selective to p55 may be advantageous for the treatment of autoimmune arthritis and uveitis.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Using the tumor necrosis factor transgenic (TNF-Tg) mouse model of rheumatoid arthritis (RA), we have shown that during progression of knee synovitis, popliteal lymph nodes (PLNs) initially expand and then collapse concomitant with arthritic flare in the ipsilateral knee. In these collapsed PLNs, there is an abundance of $B220^{+}/CD23^{+}/CD21^{hi}$ B cells in inflamed lymph nodes (Bin) clogging the lymph node sinuses. We have also recently shown that TNF-Tg mice have evidence of interstitial lung disease (ILD), with large numbers of B cells. To determine the relationship between these B cells and Bin, we performed histology to phenotype B-cells in PLN versus mediastinal lymph nodes (MLN) from WT and TNF-Tg mice.

Methods: MLNs and PLNs (n=3) were harvested from 12-month old male TNF-Tg mice (3647 line in C57B6 background) with established arthritis and ILD, and their WT littermates (MLN n=3, PLN n=6). Tissues were processed for immunohistochemistry with antibodies against B220, a pan B-cell marker, and DAPI and imaged at 10 and 20x magnifications. Fluorescent images were quantified by manually counting the number of high intensity areas in three 10x fields of view on each slide. Two slides per tissue type per animal were used, with six total images averaged for one count per tissue type per animal.

Results: PLNs from both WT and TNF-Tg animals showed a distinct pattern of increased high intensity staining compared to MLNs (4.74 vs 0 for WT, $p<0.05$ and 32.16 vs 0.36, $p<0.05$ for TNF-Tg). Furthermore, TNF-Tg PLNs showed increased high intensity staining compared to WT PLNs (32.16 vs 4.74, $p<0.05$) (Fig. 1).

Conclusion: This is the first description of a $B220^{hi}$ population in PLNs of aged mice with established arthritis and ILD. Interestingly, only PLNs display an increased $B220^{hi}$ population compared to MLNs, which drain the inflamed lung. The discordant expression in MLN versus PLN tissue suggests a continuous localized response of B cells in lymph nodes draining synovial tissue. Further specific characterization of this population at earlier timepoints during arthritis development is ongoing in order to determine if expression is altered in early disease, and if B220 expression pattern could help differentiate early inflammation from established disease. Figure 1: Representative $B220^{hi}$ images at 20x magnification of WT (A) and TNF-Tg (B) PLN

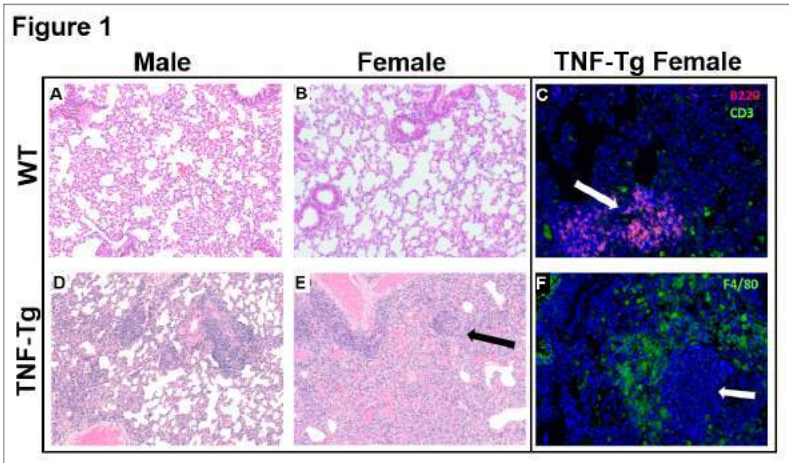
Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

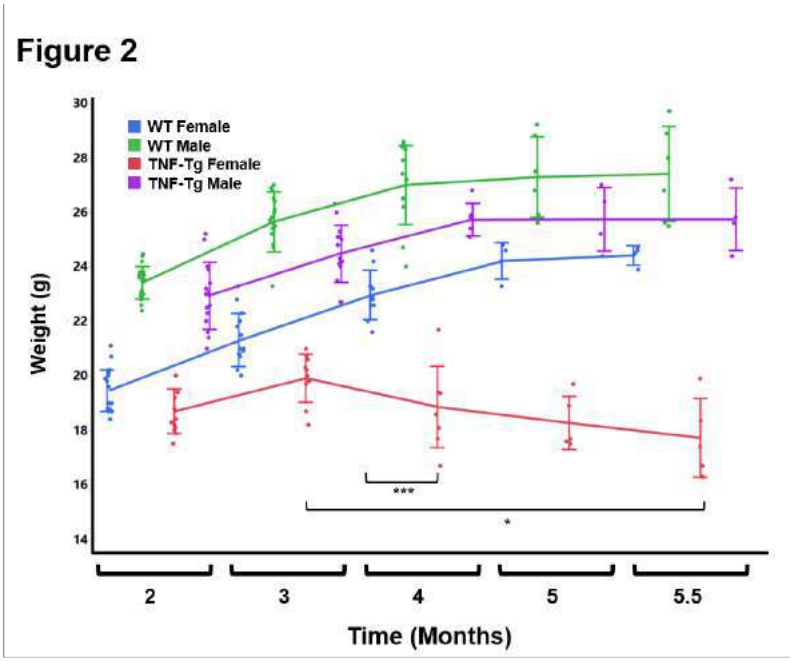
Session Time: 9:00AM-11:00AM



Background/Purpose: Although exacerbated morbidity and mortality in rheumatoid arthritis (RA) is frequently seen in women, the etiology of this sexual dimorphism remains unclear. Previously, we showed that the TNF-Tg mouse model of RA displays similar unexplored sex differences in the severity of inflammatory-erosive arthritis, interstitial lung disease (ILD) and early mortality from cardiopulmonary disease (female median life span = 165 vs. 226 days for males). Thus, the goal of this study was to elucidate the mechanisms that underlie these sex differences.

Methods: WT and TNF-Tg male and female mice in a C57BL/6 background (n = 3-12) were evaluated for weight and grip strength at 2, 3, 4, 5 and 5.5 months. At 5.5 months mice underwent in vivo micro-CT of the lung and a novel analysis technique was used to measure tissue (cells, fluid and ECM) volume within the lung. Mice were euthanized at 5.5 months for lung immunohistochemistry (CD3, B220 and F4/80), or flow cytometry (CD3, CD19, CD11b and CD11c).

Results: ILD lesions contained B-cells, T-cells, and macrophages, and showed signs of pulmonary arterial hypertension (Fig. 1). At 4 months, female TNF-Tg mice were significantly smaller vs. WT littermates (18.9 ± 1.5g vs. 23.0 ± 0.9g, $p<0.01$); and TNF-Tg females displayed significant weight loss from 3 to 5.5 months (19.9 ± 0.9g vs 17.7 ± 1.4g, $p<0.05$; Fig. 2). Female TNF-Tg grip strength was also significantly decreased starting at 2 months vs. WT females (1.9 ± 0.4N vs 2.2 ± 0.2N, $p<0.01$), while male WT and TNF-Tg mice did not differ until 3 months (2.0 ± 0.3N vs 2.7 ± 0.3N, $p<0.01$). Both female and male TNF-Tg mice had significantly greater tissue volume via µCT vs. WT animals (431 ± 52 vs 398 ± 75 vs 219 ± 9 vs 184 ± 28 mm^3; $p<0.05$; Fig. 3). Female and male TNF-Tg lungs also had significantly increased numbers of immune cells, in particular CD11b+/CD11c+ cells (105.5 ± 7.5, 345.0 ± 263.1 vs 8.6 ± 3.5, 4.5 ± 2.4 cells/lung x 10^3; $p<0.05$).



Conclusion: Here we describe a novel model of RA-associated ILD that recapitulates the sexual dimorphism known to occur in patients. While further work is necessary to elucidate the interactions of the comorbidities and their contributing factors, the significant weight loss observed in females may account for their early onset of arthritis and mortality.

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Animal Models - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA) and collagen-induced arthritis (CIA) the phenomenon of a relative insufficiency of adrenal glands to produce an adequate amount of anti-inflammatory glucocorticoids in later stages of the disease is well known (Spiess et al 2014, Wolff et al. 2015). At the same time, the presence and migration of macrophages and dendritic cells (DCs) in and into endocrine organs like the pituitary gland and the adrenal glands has been described (Glennon et al. 2015, Sato 1998, Engstrom et al. 2008). We hypothesized that resident and/or invading immune cells like DCs contribute to the inadequate secretion of endogenous glucocorticoids from adrenocortical cells during arthritis. The aim of this study is to elucidate first possible paracrine mechanisms between local DCs and adrenocortical cells and secondly to manipulate these pathways in order to prevent relative adrenocortical insufficiency in arthritis.

Methods: Cells from whole adrenal glands were harvested and cultured while DCs were differentiated from bone marrow, which was collected from healthy control and arthritic DA rats. Cytokine levels in supernatants from DCs and adrenal gland cells were analyzed by proteome profiler and ELISA. Corticosterone response upon stimulation with ACTH in a co-culture system of adrenal gland cells from control rats and DCs generated from control or arthritic rats was quantified with ELISA.

Results: Analysis of cytokine protein expression revealed a similar profile of the C-X-C ligand chemokines CINC-1, -2, -3 (Cytokine-induced neutrophil chemoattractant), LIX (LPS-induced CXC chemokine) and of the cytokine IL-1β in supernatants from DCs and adrenal gland cells. DCs generated from rats with CIA expressed significantly higher amounts of IL-1β, CINC-1, -2, -3, and LIX (all $p<0.001$) compared to DCs from control animals. Expression of IL-1β ($p<0.001$) and CINC-2 ($p=0.034$) in supernatants from arthritic adrenal gland cells was significantly higher than in supernatants from control cells. Co-culture experiments revealed an inhibitory effect of DCs from control and CIA rats on the corticosterone response of adrenal gland cells upon stimulation with ATCH.

Conclusion: DCs are present in the adrenal gland and seem to inhibit corticosterone production physiologically and during arthritis, possibly via expression of IL-1β and the CXC chemokines CINC-1,2,3 and LIX. Specific targeting of these cells and these chemokines might prevent progression of arthritis by inhibiting the relative adrenal gland insufficiency and, hence, could be a future therapy.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: IL-1 blockade is highly effective for systemic juvenile idiopathic arthritis (sJIA), but clinical observations raise the possibility that initiation of treatment in a "window of opportunity" before chronic arthritis develops may be more effective than in latyers disease. We have hypothesized that sJIA is a biphasic process in which an initial IL-1β-driven systemic phase gives rise to IL-17-driven chronic inflammatory arthritis. We sought to test this hypothesis in the IL-1ra$^{-/-}$model, a spontaneous T cell-mediated murine arthritis dependent upon both IL-1β and IL-17.

Methods: IL-1ra$^{-/-}$mice were treated with anti-mIL-1β or isotype-matched IgG (5mg/kg i.p. 2 times per week) for 2 weeks, beginning either 3 days after arthritis onset (early treatment) or 3 weeks after arthritis treatment (late treatment). Arthritis score (0-3/per paw, 0-12 total) and ankle and wrist thickening measured by caliper were followed for 54 days after arthritis onset. Synovial tissue was harvested at day 54 for flow cytometry to characterize lymphocyte surface phenotype and cytokine production.

Results: Clinical indices were reduced in both treatment groups compared with isotype control, without a difference between groups. However, joint thickening was reduced in early compared with late treatment, although worsening was again noted after anti-IL-1β was discontinued. Histological injury was minimized in the early treatment group, suggesting that early IL-1β antagonism was more efficient. In support of this possibility, early anti-IL-1β abrogated accumulation of lymphocytes expressing IFN-γ and IL-17A, while treatment of established disease resulted only in modest reduction of IL-17A-expressing cells. Consistent with published findings, γδT cells represented on average slightly more than half of all synovial CD3^{+}cells. The reduction in IL-17-expressing lymphocytes paralleled the lower abundance of this population after either early or late treatment, with an intriguing trend toward greater reduction in γδT cells in the early treatment group, corresponding to the reduction in synovial lymphocytes expressing IL-17.

Conclusion: In murine IL-1ra$^{-/-}$ synovitis, early IL-1β blockade more efficiently reduces tissue injury and lymphocyte accumulation than late blockade, although both are effective. Efficacy correlated with a reduction in IL-17-producting cells, and in particular with fewer IL-17-producing gdT cells. These findings support the hypothesis that early IL-1β blockade could represent an effective strategy to modulate the development of arthritogenic T cells in IL-1-driven arthritis, a result that may inform the understanding and treatment of sJIA.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Better understanding of lipid metabolism in active rheumatoid arthritis (RA) is needed to understand the cholesterol changes associated with active disease, as well as the increases in cholesterol which occur with common RA treatments involving specific cytokine and chemokine pathways. In the current work we used both short and long term K/BxN mouse models of RA to evaluate the relationship between active RA, lipid measures (cholesterol levels/HDL efflux and anti-oxidant function) and serum cytokine/chemokine levels.

Methods: 29 K/BxN mice were generated from cross of male KRN mice with NOD female mice expressing the MHC class II

molecule A^{g7} and arthritis was assessed regularly until sacrifice/serum collection at 21 weeks. 15/29 mice received an atherogenic diet at 11 weeks until sacrifice. 18 *C57BL/6* mice were injected intraperitoneally with either K/BxN serum (from 8 wk stock K/BxN mice) to induce inflammatory arthritis (n=9), or *C57BL/6* serum as controls (n=9), and sacrifice/serum collection occurred at 2 weeks. Serum cytokine and chemokine levels were assessed using Luminex-based 20-plex assays. HDL's cholesterol efflux and anti-oxidant functions were assessed as previously (*ARD* 2012; 71: 1157) and paraoxonase 1 (PON1) activity was assessed using both paraoxon and dihydrocumarin as substrates (*A&R* 2013; 65: 2765). Total and HDL cholesterol (HDL-C) were assessed by standard assays.

Results: At 21 weeks, male mice (n=17) had significantly worse arthritis activity compared to female mice (n=12) which was associated with significantly higher levels of GM-CSF, IFN-γ, IL-1β, IL-6, IL-12, and FGF-basic, and significantly lower levels of HDL and total cholesterol and PON1 activity (Table 1). Impairment in the cholesterol efflux capacity of HDL was associated with significantly higher levels of GM-CSF, IFN-γ, IL-17, and FGF-basic which also correlated significantly with suppression of cholesterol levels and impairment in PON1 activity (Table 2). An atherogenic diet was not associated with significant changes in lipid assessments or cytokine/chemokine panels compared to chow diet. Inflammatory arthritis of 2 weeks duration was not associated with a similar dyslipidemia or cytokine/chemokine changes.

Conclusion: Increases in GM-CSF, IFN-γ, IL-1β, and FGF-basic in K/BxN mice with inflammatory arthritis of 21 weeks duration are associated with impairment in the cholesterol efflux capacity of HDL and suppression of PON 1 activity, total and HDL-C levels. Further investigation of these pathways including the effects on accelerated atherosclerosis in RA is warranted. **Table 1. Comparison of Female and Male K/BxN Mice at 21 weeks**

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown that proteins modified with malondialdehyde-acetaldehyde (MAA) and/or citrulline (CIT) co-localize in rheumatoid arthritis (RA) synovial tissues, are pro-inflammatory, and promote robust antibody responses that correlate with disease severity in RA. The interaction of MAA and CIT modifications on proteins with respect to immune responses is not currently known. Thus, the purpose of this study was to first examine the feasibility of co-modifying protein with both MAA and CIT and secondly to evaluate the impact of these modifications on antibody responses.

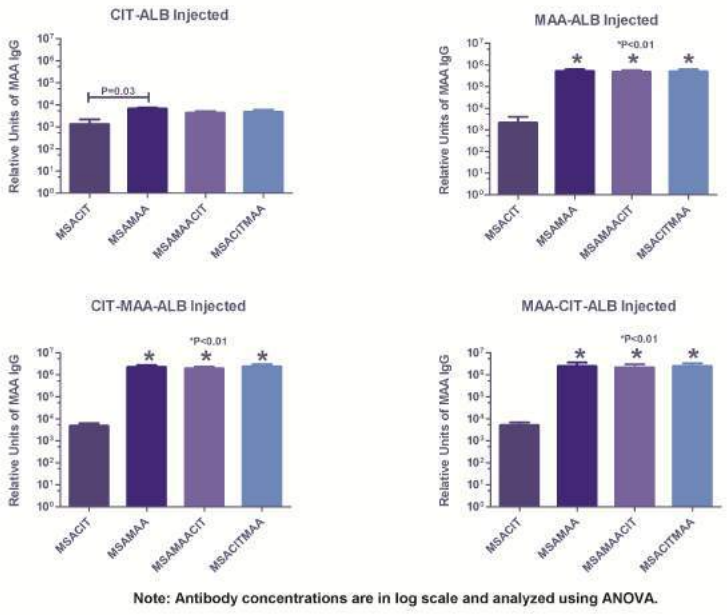
Methods: Human serum albumin (ALB) was modified with MAA (MAA-ALB), CIT (CIT-ALB), MAA then CIT (MAA-CIT-ALB), or CIT then MAA (CIT-MAA-ALB) in order to produce the unique antigens. Samples were analyzed for MAA adduction using fluorescence and CIT by Western blot. Protein concentrations were determined and separate groups of mice (n=10 per antigen) were immunized with 25 µg of MAA-ALB, CIT-ALB, MAA-CIT-ALB, or CIT-MAA-ALB weekly for 5 weeks. At week 6, serum was

tested for antibody reactivity to these modifications using ELISA with mouse serum albumin (MSA) used in place of ALB. This was done to eliminate background reactivity and to assess the reactivity specific to the MAA or CIT epitopes rather than ALB. Data is expressed in arbitrary units relative to a mouse IgG standard curve, and analyzed by one-way ANOVA.

Results: MAA levels (by fluorescence) and citrullination (by Western Blot) showed no differences with respect to the amount of modification between the different antigens, and all preparations remained soluble. Immunization with CIT-ALB produced a significant (P=0.03) antibody response to the MAA epitope with very little antibody to the CIT epitope. MAA-ALB, CIT-MAA-ALB, and MAA-CIT-ALB immunization significantly (P<0.01) increased the antibody responses to MSA-MAA, MSA-MAA-CIT, and MSA-CIT-MAA compared to immunization with CIT-ALB. Notably, immunization with CIT-MAA-ALB or MAA-CIT-ALB increased the antibody concentrations 4-fold over MAA immunization alone to all antigens except MSA-CIT.

Conclusion: Modification of protein with MAA in combination with CIT appears to form a stable protein adduct. The combination of these two modifications elicits a robust antibody response in mice to MAA or the MAA-CIT antigen regardless of which modification was performed first, but was highly dependent on the presence of the MAA modification to drive the immune response. These data provide a potential mechanism by which MAA-modification and citrullination of self-proteins conspire to promote the initiation or progression of RA. Future studies evaluating the T-cell response are under way to understand this unique immune response.

Figure 1.



Note: Antibody concentrations are in log scale and analyzed using ANOVA.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Given the effects of magnesium supplementation in suppressing components of the innate immunity in short-term studies, we examined the effect of dietary magnesium modifications in arthritis severity, a chronic model of autoimmune disease.

Methods: DBA1/J mice were placed on one of two short-term diets before (22-day) the induction of collagen-induced arthritis (CIA) or after disease onset (9-days): low-magnesium diet or normal diet. The diets were then discontinued and converted into a normal diet. CIA activity and arthritis severity was scored for 50 days. Spleens were used for qPCR and FACS, and synovial tissues and cells lines for qPCR.

Results: Mice on the low magnesium diets were significantly protected and had a >70% lower mean arthritis severity scores in the preventive arm. The group that started the low magnesium diet after the onset of disease also achieved a 50% reduction on their mean severity. The disease protective or ameliorating effects of the low magnesium diet persisted beyond the duration of the diet suggesting a permanent effect on a critical pathogenic pathway. The low magnesium diet mice preserved a normal joint histology without erosive changes. Mice on the low-magnesium diet had significantly reduced synovial tissue expression of IL-6, IL-17, CXCL10, RORA and RORC (genes required or implicated in the development of Th17 T cells), as well as reduced levels of MMP-2 and MMP-3, which are two key mediators of joint damage. Low magnesium concentrations also reduced synovial fibroblast expression of TNFa and IL-6. Spleens from low magnesium diet mice had reduced levels of Th17 T cells and increased numbers of FoxP3+ Treg cells and increased number of IL-10+ CD4+ T cells. *In vitro* studies demonstrated that low magnesium concentrations (0.1mM and 0.4mM) did not directly affect the differentiation of mouse naïve CD4+ T cells into Th17 T cells, nor affected the amount of IL-17 produced by these cells, suggesting an indirect effect mediated by another cell type.

Conclusion: This study revealed a novel role for magnesium in the regulation of autoimmune arthritis and opens new possibilities for the treatment of autoimmune diseases such as RA and psoriatic arthritis with short courses of dietary or drug-induced modulations of magnesium levels. We also describe a new effect of low magnesium in suppressing Th17-related genes and MMPs.

Session Title: Rheumatoid Arthritis – Animal Models - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: , Rheumatoid arthritis (RA) is a chronic auto inflammation of the joints, with a prevalence of about 1% in Western population. Treatment with lives helminths or helminths' secreted molecules in different autoimmune diseases. Recently, the critical involvement of the microbiome in the pathogenesis of autoimmune diseases has gained appreciation. In RA, there is a shift in microbial coupled with an inflammatory response which includes an alteration in the function of anti-inflammatory regulatory T cells (Treg) and susceptibility towards autoimmunity.

The aim of the current study addresses the correlation between TPC therapeutic efficacy and the microbiome composition in a mouse model of collagen-induced arthritis (CIA).

Methods: , Arthritis was induced in DBA mice by immunization with collagen type II. The mice were treated with TPC or PBS and compared to healthy mice. Stools from the mice were collected every 3 days. DNA was extracted then sequenced using Illumina Miseq

platform. Data analysis was performed using QIIME.

Results: Significantly lower arthritis score was illustrated in TPC treated mice in comparison to mice which received vehicle. We showed that the microbial composition changes with treatment and correlated to disease severity. At the order level, *Enterobacteriales* were significantly more abundant in the healthy mice while *Clostridiales* and *Deferribacterales* were more abundant in the PBS-CIA mice. CIA mice treated with TPC maintained a "healthy" microbiota, which was similar to mice in which RA was not induced.

Conclusion: Our results provide support for a microbial link in CIA and show the importance of the microbiome in the success of the treatment.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid Arthritis (RA) is associated with a greater cardiovascular mortality than the general population of the same age and gender. Cardiovascular events prediction scales, due to its significant dependence on age, underestimate absolute cardiovascular risk (CVR) in young people. Two methods exist to address this problem: a) Cardiovascular Relative Risk, which estimates the increased risk when compared to people of the same age without CVRF. B) Vascular age, defined as the lower age with the same absolute CVR but with no CVRF. OBJECTIVE: To evaluate the utility of the relative cardiovascular risk score scales and the vascular age predictors in patients with RA, younger than 50 years of age.

Methods: Transversal prospective study developed at the Rheumatology Services in two Spanish academic hospitals. Only patients under 50 years of age who fulfilled the EULAR/ACR 2010 criteria for RA were included. They were selected consecutively when they came on regular follow-up. We registered to calculate SCORE, REGICOR, Relative Cardiovascular Risk and Vascular Age (age, gender, tobacco habits, systolic blood pressure, total serum cholesterol concentration and HDL and diabetes Mellitus). According to the EULAR 2011 recommendations, a multiplying factor of 1,5 was applied to SCORE, REGICOR and Relative Cardiovascular Risk in patients who fitted in at least two of the following criteria: a) Duration of RA > 10 years, b) positive RF or CCP , c) Presence of extra-articular manifestations.

Results: 140 patients with RA under 50 years of age were included [120 (86%) women] with an mean age of 40 ± 7 years. 64% of patients had RF+ and 56% CCP+. Regarding to EULAR multiplying factors, 30% had RA duration > 10 years, 71% had CCP or RF+, 11% had extra-articular manifestations, and 26% had 2 or more factors. None of the patients had has a previous history of cardiovascular events. The modified (after the application of the multiplying fact) mean SCORE was 1,03 ± 0,52 and modified REGICOR 1,81 ± 1,37. Mean Cardiovascular relative risk was 2,05 ± 1,33 between 2x and 10x. 54% of the patients had a relative cardiovascular risk superior to 1, and 47% had cardiovascular relative risk between 2 and 3 times higher. Mean vascular Age's was of

44 ± 10 years, 4 years more than biological age. 41% of patients, vascular age was greater than biological age, from 3 to 20 years older. Relative Cardiovascular risk identifies more patients with CVR than Vascular Age. Patients with increased relative cardiovascular risk were older (41 ± 6 vs 38 ± 9 years; p < 0,01) and had been diagnosed with RA for over10 years (40% vs 7%, p < 0,001).

Conclusion: In young patients with Rheumatoid Arthritis, the estimates of Relative Cardiovascular Risk and the assessment of vascular age allow us to identify patients with an increased cardiovascular risk, who may be overlooked by SCORE event prediction charts.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid Arthritis (RA) is associated with a greater cardiovascular mortality than the general population of the same age and gender. Cardiovascular events prediction scales, due to its significant dependence on age, underestimate the absolute cardiovascular risk (CVR) in young people. Two methods exist to address this problem: a) Cardiovascular Relative Risk, which estimates the increased risk when compared to people of the same age without CVRF. B) Vascular age, defined as the lower age with the same absolute CVR but with no CVRF. **Objective**: to evaluate the presence of subclinical carotid atherosclerosis and the utility of the carotid ultrasound (US) in patients with AR under the age of 50 and compare it with relative CVR scores.

Methods: Transversal prospective study. Patients under 50 years of age who fulfilled the EULAR/ACR 2010 criteria for RA were included. They were selected consecutively when they came on regular follow-up. We registered to calculate SCORE, REGICOR, Relative Cardiovascular Risk and Vascular Age (age, gender, tobacco habits, systolic blood pressure, total serum cholesterol concentration and HDL and diabetes Mellitus) and history of previous CVR event. According to the EULAR 2011 recommendations, a multiplying factor of 1,5 was applied to SCORE, REGICOR and Relative Cardiovascular Risk in patients who fitted in at least two of the following criteria: a) Duration of RA > 10 years, b) positive RF or CCP , c) Presence of extra-articular manifestations. A carotid ultrasound was performed; Intimal medial thickness (IMT) was measured and the presence of atheromatous plaques was assessed. Database and analyzed using SPPSS-Windows 15. Sensitivity and specificity, positive and negative predictive values were calculated.

Results: 83 AR patients under the age of 50 years old were included (71 (85,5%) women) with a mean age of 39 ± 8 years. 61% had RF+ and 50% PCC+. 34% had bone erosion on X-ray and 3.6% presented rheumatoid nodules. About the CVRF: 45% were active smokers; 22% had high blood pressure; 8% were diabetics; 25 had a high LDL levels and 4% presented with hypertriglyceridemia.

Regarding to EULAR multiplying factors, 30% had RA duration > 10 years, 69% had CCP or RF+, 13% had extra-articular manifestations, and 27% had 2 or more factors. The prevalence of subclinical carotid pathology was 9.6%. The US results demonstrated that 9.6% (8 patients) had atheromatous plaque (6% unilateral and 4% bilateral). An IMT ≥0, 9 were observed in 1% (1 patient). None of the patients had had a previous history of cardiovascular events. Sensitivity and positive predictive value to identified carotid atheromatous plaques were very low for the modified SCORE and REGICOR, with the exception of the modified RCR, which presented a sensitivity of 87%. Superior specificity was observed with the modified SCORE and REGICOR than with the modified RCR. The negative predictive value was similar in the 3 scales (>90%).

Conclusion: The prevalence of subclinical atherosclerosis in RA patients under 50 years old is not small (10%). The RCR is the scale with more sensitivity and with an important negative predictive value that allow us to recognize and select the patients for a carotid ultrasound.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Persons with rheumatoid arthritis (RA) have increased morbidity and mortality attributable to atherosclerotic cardiovascular disease (ASCVD) events. It is unknown how presence of subclinical ASCVD, as measured by arterial health parameters, is affected by the current state of RA disease activity. The objective of this study was to determine the relationship between non-invasive arterial health measures and measures of both current and average disease activity over time in patients with established RA.

Methods: 50 patients with RA underwent non-invasive arterial health testing (measures of arterial stiffness: corrected aortic augmentation index; pulse wave velocity) and rheumatologic assessment of clinical disease activity (tender/swollen joint counts; the Clinical Disease Activity Index (CDAI); the Health Assessment Questionnaire (HAQ) disability index). Clinical measures of disease activity during 3 years prior to the study visit were averaged to obtain time-averaged measures. The AHA/ACC Pooled Cohort Equation (estimated 10-year CV risk %) was used to classify patients as low/intermediate/high risk. Spearman methods were used to determine the correlation between the rheumatologic disease activity scores and arterial health testing parameters.

Results: In the 50 patients (mean age: 57.5 years; 76% female, mean RA disease duration: 6.4 years), the disease activity was moderate, with mean (±SD) CDAI of 16.9 (15.3). At the study visit, the corrected aortic augmentation index correlated with the CDAI (r=0.37, p=0.009) and the HAQ (r=0.33, p=0.019). The corrected aortic augmentation index correlated with time-averaged measures of the tender joint count (r=0.37, p= 0.008); CDAI (r=0.36, p=0.01); HAQ (r=0.36, p=0.009); swollen joint count (r=0.36, p =0.01); patient global assessment (r=0.33, p=0.02); physician global assessment (r=0.35, p=0.014); and pain score (r=0.38, p=0.007). Marginally significant correlations emerged between the aortic pulse wave velocity and the time-averaged CDAI (r=0.26, p=0.07); tender joint count (r=0.26, p=0.07); and physician global assessment (r=0.28, p=0.05). Adjusted correlations between time-averaged CDAI and corrected aortic augmentation showed statistical significance (r=0.41, p=0.007) when adjusted for the pooled cohort CV risk

score, and marginal significance when adjusted for the pooled cohort CV risk score and use of prednisone, methotrexate and/or biologics (r=0.3, p=0.07).

Conclusion: The results demonstrate that measures of arterial stiffness, especially the corrected aortic augmentation index, correlate with the time-averaged burden of disease activity as well as current disease activity. The findings suggest that non-invasive arterial health testing provides a means to measure the effects of inflammatory disease burden on arterial function even after accounting for estimated CV risk scores.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Measures of arterial health may be useful in assessing the risk of atherosclerotic cardiovascular disease (ASCVD) in patients with rheumatoid arthritis (RA). The objective of this study was to determine if our innovative arterial health testing panel would identify early ASCVD that is not reflected in traditional CV risk scores in patients with RA. The AHA/ACC Pooled Cohort Equation (estimated 10-year CV risk %) is used to classify patients as low/intermediate/high risk. Our study evaluated early CV disease (plaque presence, carotid intima media thickness) using non-invasive arterial health testing in RA patients classified in the low/intermediate CV risk category.

Methods: 50 patients with RA underwent non-invasive arterial health testing (brachial artery reactivity testing, pulse wave velocity, and carotid intima media thickness [CIMT] and plaque presence) and calculation of the estimated 10 year CV risk (%) using the AHA/ACC Pooled Cohort Equation. Comparisons between non-invasive arterial health measures and the low/intermediate/high risk category as identified by the AHA/ACC Pooled Cohort Equation (10-year risk %) were performed using chi-square and rank sum tests. Descriptive statistics were examined to determine whether we could identify early CV disease (plaque presence) in patients typically classified as low or intermediate risk.

Results: In the 50 patients (mean age: 57.5 years; 76% female, mean RA disease duration: 6.4 years), the AHA/ACC Pooled Cohort Equation (10-year risk %, as measured as low <4%, intermediate 4-7.5%, and high >7.5%) was used to estimate CV risk. Carotid plaques were found in 7 of 21 (33%) patients with low AHA/ACC risk, 11 of 15 (73%) patients with intermediate AHA/ACC risk, and 2 of 8 (25%) patients with high AHA/ACC risk. Plaque in the intermediate AHA/ACC risk group was identified as mild in 9 (82%) and severe in 2 (18%) of the 11 patients with plaques. Brachial artery reactivity testing showed that hyperemic forearm flow was highest in the high risk category (median 712 compared to 510 in intermediate risk and 459 in low risk, p=0.048). No significant differences were identified with measures of arterial stiffness, such as pulse pressure, aortic pulse wave velocity, aortic augmentation index and corrected aortic augmentation index between low, intermediate, and high risk categories. The mean CIMT was highest in the high risk group (median 0.9 compared to 0.8 in intermediate and 0.7 in low risk, p=0.006), and maximal common carotid IMT highest in the high risk group as well (p=0.01).

Conclusion: Among patients with RA considered to have intermediate CV risk by the AHA/ACC Pooled Cohort Equation (4-7.5% AHA/ACC risk), non-invasive arterial health testing identified a high proportion of patients with both mild and severe carotid plaques. The presence of carotid plaques may identify early ASCVD that is not adequately predicted by standard CV risk scores calculators.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is chronic, systemic, inflammatory, multifactorial disease that mainly affects synovial joints. RA-patients have an increased risk of cardiovascular (CV) morbidity and mortality, being atherosclerotic CV disease the leading cause of death. Valvular heart disease (VHD) associated with RA has not been well characterized and its clinical predictors are undefined. Prevalence of VHD varies greatly in the published reports. Data in Mexican mestizo patients with RA is scarce.

Methods: A case-control study with 56 RA-patients aged 40 to 75 years that fulfilled the 2010 ACR/EULAR criteria and 28 matching control were included. Exclusion criteria included prior atherosclerotic cardiovascular disease and overlap syndromes. Patients were matched using age and sex. A standard transthoracic echocardiogram was performed according to the American Society of Echocardiography guidelines in our echocardiography lab using a 5 MHz linear transducer with a Vivid 9 (GE Healthcare, WI, USA), analyzing data in EchoPAC (GE Healthcare, WI, USA). Valvular regurgitation was classified as mild, moderate or severe according to the European Association of Echocardiography and American Society of Echocardiography recommendations.

Results: Clinical and demographic characteristics of both groups are shown in Table 1. Mean DAS28-CPR was 3.29 ± 1.56. As shown in table 2, VHD was reported in 45 (80.4%) RA-patients and 13 (46.4%) individuals in the control group ($p < 0.003$). Statistical difference was found in mitral and tricuspid regurgitation ($p < 0.001$ and $p < 0.003$, respectively) in RA-patients when compared with the control group. In the RA group, 5 (8.9%) showed mild aortic regurgitation; 28 had mild and 1 had moderate (50% and 1.8%, respectively) mitral regurgitation; 8 (14.3%) showed mild pulmonary regurgitation; 39 had mild and 4 had moderate (69.6% and 7.1%, respectively) tricuspid regurgitation. In the control group, 1 (3.6%) showed mild aortic regurgitation; 3 (10.7%) had mild mitral regurgitation; 1 (3.6%) showed mild pulmonary regurgitation; 12 (42.9%) had mild tricuspid regurgitation.

Conclusion: In our cohort, VHD was present in 80.4% of the RA-patients, with the tricuspid valve being the most affected (76.8%). Statistical difference was found between the RA and the control groups when comparing mitral and tricuspid valve. Prospective studies are needed to evaluate the role in morbidity and mortality of VHD in RA-patients.

Table 1. Clinical and Demographic characteristics			
	RA group (n = 56)	Control group (n = 28)	P value
Age, mean ± SD	56.01 ± 9.38	53.15 ± 6.27	0.922
Women, n (%)	54 (96.4)	27 (96.4)	0.845
BMI, mean ± SD	28.51 ± 4.61	28.49 ± 4.54	0.538

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Atherosclerotic cardiovascular disease is the leading cause of death in patients with rheumatoid arthritis (RA). Two dimensional speckle tracking echocardiography (TSE) assess local and global myocardial function by analyzing myocardial deformation (strain). In ischemic pathologies, early strain abnormalities are observed. We aimed to analyze if longitudinal strain abnormalities occur following vascular territories, and to compare our findings in RA-patients with matched controls.

Methods: Case-control study with 53 RA-patients aged 40 to 75 years that fulfilled with 2010 ACR/EULAR criteria and 27 matching control were included. Subject with prior atherosclerotic cardiovascular disease (myocardial infarction, stroke and peripheral arterial disease) and overlap syndromes were excluded. Patients were matched using age, sex and comorbidities. A standard transthoracic echocardiogram was performed according to the American Society of Echocardiography guidelines using 5 MHz linear transducer with

a Vivid 9 (GE Healthcare, WI, USA), and EchoPAC (GE Healthcare, WI, USA) was used to analyze the data. Affection of coronary territories was compared between groups using longitudinal strain by speckle tracking according to the European Society of Cardiology and the American Society of Echocardiography recommendations.

Results: Mean age of RA-patients was 55.54 ± 9.11 years, and 51 (96.2%) were women. Mean RA disease duration was 12.45 ± 6.72 years, with mean DAS28-CRP of 3.11 ± 1.46. No statistical difference was found in age, sex, body mass index, hypertension or diabetes between RA-patients and controls (Table 1). Global longitudinal strain showed no statistical difference between RA-patients and controls (20.86 ± 2.82 vs -21.19 ± 2.46, p=0.620). Comparison between longitudinal strain values of the three vascular territories evaluated between RA-patients and controls did not reach statistical difference.

Conclusion: Global longitudinal strain values were not different in the Mexican mestizo RA-patients evaluated when compared with controls, which is not consistent with previous published evidence. Larger studies are needed to determine the utility of strain abnormalities to detect subclinical cardiovascular disease in our population.

Table 1. Clinical and Demographic characteristics

	RA group (n = 53)	Control group (n = 27)	P value
Age, mean ± SD	55.54 ± 9.11	52.81 ± 6.61	0.172
Women, n (%)	51 (96.2)	26 (96.3)	0.988
Body mass index, mean ± SD	27.53 ± 5.85	28.05 ± 4.66	0.956
Hypertension, n (%)	18 (33.96)	5 (18.5)	0.149
Diabetes, n (%)	7 (13.2)	4 (14.8)	0.844

Table 2. Longitudinal strain characteristics

	RA group (n = 53)	RA group (n = 53)	P value
Anterior descendent territory, mean ± SD	-21.16 ± 3.13	-21.64 ± 2.91	0.510
Circumflex territory, mean ± SD	-20.12 ± 3.28	-21.09 ± 3.1	0.207
Right coronary territory, mean ± SD	-18.98 ± 2.38	-18.79 ± 2.37	0.735

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

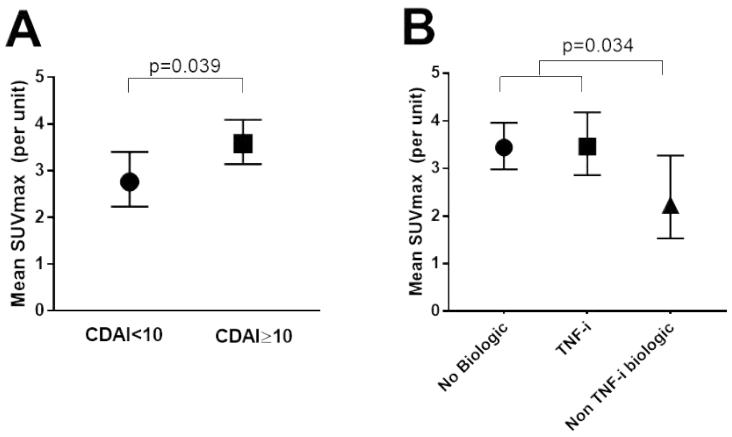
Background/Purpose: RA patients are at increased risk for developing heart failure (HF) even after controlling for coronary artery disease (CAD), indicating that factors other than flow-limiting CAD contribute to HF in RA. Chronic myocarditis may be one mechanism that contributes to HF in RA. We investigated the prevalence of myocardial inflammation in RA patients without known

cardiovascular disease (CVD) compared to non-RA controls, and evaluated its association in the RA group with disease characteristics.

Methods: RA patients without prior CVD events underwent a cardiac [18F-fluorodeoxyglucose (FDG)] positron emission-computed tomography (FDG PET-CT). A small sample of non-RA controls frequency matched on age and gender were also enrolled. Participants also underwent 3-D echocardiography to assess left ventricular (LV) mass, volumes, and systolic and diastolic function. The mean maximal standardized uptake value (SUVmax) for myocardial FDG uptake, was compared according to disease status. Generalized linear models were used to explore the associations of SUVmax with RA patient characteristics and measures of LV structure and function.

Results: A total of 118 RA patients [mean age=55 years, 81% Female, 37% non-Hispanic White, 44% Hispanic, mean BMI=28.5, median RA duration=7 years, 76% RF or anti-CCP positive, mean DAS28=3.78, CDAI was < 10 (low disease activity) in 28%] and 13 controls were scanned. Biologics were used in 45 (38%), primarily TNF inhibitors (TNFi; n=34 (29%)]. Median SUVmax was 12% higher in RA vs. controls (2.9 vs. 2.6 units; p=0.047). In univariate analyses, higher BMI and having a moderate/severe disease activity (CDAI>10) were positively associated with SUVmax in the RA group. After adjusting for BMI and RA treatment, mean SUVmax was 30% higher for those with moderate/severe disease activity (CDAI>10) compared with low disease activity (CDAI<10) (p=0.039; figure 1A). Treatment with a non-TNFi biologic was associated with a 35% lower mean SUVmax compared to patients not on biologics or on TNFi's (p=0.034; figure 1.B). SUVmax was not associated with age, gender, race, diabetes, level of CRP or IL-6, coronary flow reserve and coronary calcium score. There was no significant association between SUVmax and echocardiographically defined measures of left ventricular structure or function.

Conclusion: In patients with RA, moderate/high disease activity was associated with elevated levels of myocardial inflammation, while treatment with non-TNFi biologic DMARDs was associated with lower level. Longitudinal studies are needed to assess whether chronic myocarditis is a risk factor for HF in RA, and whether treatment of articular disease activity reduces myocardial inflammation and HF risk.



The mean of the global myocardial maximum Standardized Uptake Values (SUVmax) was not normally distributed and was log transformed for linear regression. Depicted are back-transformed means and 95% confidence intervals. Panel A was adjusted for RA treatments and BMI whereas Panel B was adjusted for BMI and RA disease group (low disease activity vs moderate/severe disease activity), all of which were the only relevant covariates retained in multivariable modeling. CDAI: Clinical Disease Activity Index, TNF-i: Tumor Necrosis Factor inhibitor.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

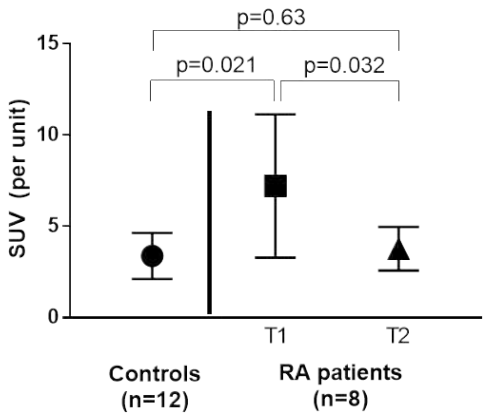
Background/Purpose: Symptomatic heart failure (HF) and HF-associated mortality rates are higher in RA compared with the non-RA population, even after controlling for coronary artery disease (CAD)[1], indicating that factors other than flow-limiting CAD contribute to HF in RA. Chronic myocarditis may be one mechanism that contributes to HF in RA. We hypothesized that RA patients without clinical cardiovascular disease (CVD) would have a higher prevalence of subclinical myocarditis compared with non-RA controls, and that it may improve with disease modifying therapy (DMARDs).

Methods : RA patients without prior CV events and with an inadequate response to methotrexate (MTX) underwent a baseline (T1) cardiac [^{18}F-fluorodeoxyglucose (FDG)] positron emission-computed tomography (FDG PET-CT) and a repeat scan six months later following initiation of step-up therapy (T2). Non-RA controls were recruited for a baseline scan only. Myocardial FDG uptake, a measure of myocardial inflammation, was assessed using INVIA Corridor 4DM software and calculated as the global maximum standardized uptake values (SUV max). Participants also underwent 3-D echocardiography to assess left ventricular (LV) mass, volumes, and systolic and diastolic function.

Results : 12 RA patients were enrolled but only 8 completed both scans. 25% received triple therapy and 75% anti-TNF therapy (with background MTX). 12 non-RA controls were enrolled and scanned. Characteristics of RA patients were: 87.5% female, mean age 61± 7.6 years; mean disease duration 5±7 months, 62% seropositive. Controls were younger (mean age 53±12.2) and with fewer women (75%). Mean DAS28-CRP decreased from 4.57±0.31 at T1 to 3.51± 0.41 at T2 (p=0.036. At T1, mean global myocardial SUV max was significantly higher in RA compared with controls (7.2 vs. 3.4 units, respectively; p=0.021). At T2, mean global myocardial SUV max decreased in the RA group, and was now not significantly different from controls at baseline (Figure). Measures of left ventricular (LV) Ejection Fraction (LVEF) and LV mass (LVM) were in normal ranges for both the RA patients and controls with no significant differences between groups. There were no significant changes in LVEF or LVM from T1 to T2 in RA patients.

Conclusion: Patients with active RA exhibited significantly higher myocardial ^{18}FDG-uptake when compared to controls. Improvements in disease activity were paralleled by improvement in myocardial FDG uptake. Larger long-term studies are necessary to determine whether myocardial inflammation is a major risk factor for myocardial dysfunction and HF. **Figure:**

Global Maximum Standard Uptake Values (SUV) of controls and RA patients before (T1) and after (T2) step up therapy.



Means and 95% confidence intervals are depicted. Controls had only one scan while Rheumatoid Arthritis (RA) patients had a scan before and 6 months after step-up therapy to either TNF-inhibitors or Triple therapy with Methotrexate/Hydroxychloroquine/sulfasalazine. T-test were used to compare global maximum myocardial Standard Uptake Values (SUV max) between T1 or T2 and Controls. In RA patients paired t-test were used to compare the RA characteristics and myocardial SUV max between T1 and T2.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Carotid plaque (CP) detected by ultrasonography and carotid intima-media thickness (cIMT) are useful surrogate markers for subclinical atherosclerosis and good predictors of cardiovascular disease in the general population and rheumatoid arthritis (RA). Our aim was to determine if cIMT may predict the presence of carotid plaques.

Methods: We evaluated 670 RA patients from Northern Spain without previous history cardiovascular events. Carotid

ultrasonography was performed by a MyLab 70 scanner (Esaote; Genoa, Italy), equipped with 7-12 MHz linear transducer and the *automated software guided technique radiofrequency-Quality Intima Media Thickness* in *real-time* (*QIMT*, *Esaote*, *Maastricht*, *Holland*). The cIMT was determined as the average of three measurements in each common carotid artery. The final cIMT was the largest average cIMT (left or right). Carotid plaque was defined according to the Manheim Consensus Conference criteria. Based on studies reported in non-rheumatic patients, a cIMT was considered as associated with high cardiovascular risk if it was ≥ 0.90 mm.

Results: Unilateral and bilateral carotid plaque frequency and cIMT values are summarized in the **TABLE**. cIMT values were 0.619±0.105 mm in patients without plaques and 0.774±0.161 mm in those with plaques ($p<0.001$). Using 0.90 mm as the cIMT cut-off value for high cardiovascular risk, the sensitivity to detect carotid plaques was 21.2% and the specificity 99%. A ROC curve comparing the presence of carotid plaque and cIMT was performed, being the area under the curve 0.795. The best cIMT cut-off point to determine the presence of plaques was considered as the one with the highest sensitivity and specificity. According to that, 0.670 mm was found to be the best cut-off point, being sensitivity and specificity for plaque detection 71.9% and 74% respectively. Positive predictive value for a cIMT ≥0.670 mm was 78.3% in our population, being 66.8% the negative predictive value. Regarding bilateral plaques, a cIMT cut-off value of 0.90 mm had sensitivity of 0.277 and specificity of 0.966. The ROC curve showed that the best cut-off point for bilateral plaque detection was also 0.670 mm with sensitivity 79.1% and specificity 64.2%.

Conclusion: In Spanish RA patients cIMT ≥0.670 mm is a good predictor of carotid plaques. Our study suggests the possibility of considering a cIMT greater than 0.67 mm as a predictor of high cardiovascular risk in RA. **TABLE**

Variable	
Carotid plaque, n (%)	379 (56.8)
Unilateral plaque, n (%)	128 (19.2)
Bilateral plaque, n (%)	251 (37.6)
cIMT (mean ±SD) mm	0.71± 0.16

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Vitamin D has an important role in the immune system, and has been linked to inflammation, rheumatoid arthritis (RA) and coronary artery disease (CAD)[1, 2]. However, the exact mechanisms how vitamin D is involved in these processes are still unclear. Therefore, the aim of this study was to compare the expression of vitamin D receptor (VDR) associated genes in the aortic

adventitia of CAD patients with and without RA.

Methods: RNA was isolated, and Affymetrix microarray was used to determine the gene expression profile in specimens from the ascending aorta in 8 patients with CAD and 8 patients with CAD and RA from the Feiring Heart Biopsy Study. Partek Genomics Suite software was used to identify differentially expressed genes by one-way ANOVA (p<0.05; FC>1.1), and differences in expression of VDR associated genes were determined by Ingenuity Pathway Analysis.

Results: Among the 15586 transcripts that were identified, pathway analysis determined two genes within the VDR signaling pathway, Growth arrest and DNA-damage-inducible protein 45 alpha (GADD45A) (p=0.006; FC=1.474) and Nuclear Receptor Corepressor 1 (NCOR1) (p=0.005; FC=1,210), that where both up-regulated in RA patients.

Conclusion: GADD45A induces cell cycle arrest, DNA repair and apoptosis in response to various environmental stresses [3], and NCOR1 has an important role as a gene-specific integrator of positive and negative signals that control inflammation [4]. In theory, the accelerated atherosclerosis in RA might be related to the up-regulation of GADD45A and NCOR1 through the VDR signaling pathway.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with various inflammatory rheumatic diseases (IRD) have increased cardiovascular morbidity caused by atherosclerosis. The aetiology of the accelerated atherosclerosis in IRD is still unclear, but both traditional cardiovascular risk factors and inflammation seem to play a role. There has been increasing attention to Lipoprotein (a) (LP(a)) as a risk factor for atherosclerotic cardiovascular disease (CVD). LP(a) exhibits homology to plasminogen, and thereby interfere with fibrinolysis.

Moreover, through binding to macrophages it may promote foam cell formation and cholesterol deposition in atherosclerotic plaques. The aim of this study was to compare levels of Lp(a) in patients with CVD with and without IRD, and in healthy controls (HC).

Methods: We examined the plasma level of LP(a) and other plasma lipids in patients included in the Feiring Heart Biopsy Study, comprising patients referred to coronary artery bypass grafting (CABG): 69 patients with IRDs and 53 sex and age matched patients without IRDs called CVD. We also examined blood samples from a group of 30 HC, matched for sex and with the same age range as the CVD-IRD group. All measurements were done by standard laboratory methods.

Results: Patients with CVD and IRD had increased plasma levels of LP(a) compared to HC (631.4 vs 335.7 mg/l, p=0.0018), while they had reduced levels of the classical atherogenic lipids, i.e. total cholesterol (TC) (4.9 vs 6.1 mmol/l, p<0.0005) and Low Density Lipoprotein cholesterol (LDL) (3.1 vs 3.9 mmol/l, p=0.002) compared to HC potentially reflecting the use of statins as most CVD patients (78 %) are on statins at the time of CABG. The levels of Lp(a) were not significantly different between IRD and non-IRD CVD patients (631.4 vs 592.5 mg/l).

Conclusion: Despite reduced levels of TC and LDL, patients with CVD regardless of IRD have higher levels of LP(a) than HC. It is likely that the reduced levels of TC and LDL are result of statin treatment which seems to not normalize Lp(a) levels. This unmask a plausible role of Lp(a) in CVD and evokes a hypothesis that there might be a need for a better control of Lp(a), e.g. by TNF inhibition, to protect from CVD at least in the IRD population.[1]

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Topical NSAIDs (tNSAIDs) have less systemic absorption than oral NSAIDs (oNSAIDs). Thus, tNSAIDs may be associated with a reduced cardiovascular disease (CVD) risk compared with oNSAIDs. We examined risk of incident CV events associated with tNSAIDs versus oNSAIDs among Rheumatoid Arthritis (RA) patients in Taiwan.

Methods: We conducted a retrospective cohort which included incident RA patients who newly started non-selective tNSAIDs or oNSAIDs. We used the Taiwan National Health Insurance Research Database (NHIRD). The first date patients received NSAIDs was defined as the index date, and the 6 month baseline period before the index date was used to define covariates. Patients were excluded if they had NSAIDs exposures, cancer, HIV, psoriatic arthritis or ankylosing spondylitis claims during the baseline period. Treatment episodes continued until there was a treatment gap more than 30 days. Follow-up was censored at the first of any of the following: 30-days after treatment was discontinued, switch/addition of other NSAIDs category, CV outcome, death, or the end of study. Patients without any NSAID use for at least 180 days could contribute a second treatment episode. The main outcome was a CV event, including myocardial infarction, unstable angina, heart failure, stroke or revascularization. Inverse probability of treatment weight (IPTW) weighted Cox regression model was used to compare the risk of CV events between tNSAIDs and oNSAIDs, with oNSAIDs as the reference group. Sensitivity analyses included varying the length of treatment gap and subgroups.

Results: There were 10,758 and 78,056 treatment episodes for topical and oral NSAIDs indentified from our cohort. The mean age was 55.1±15.4 years in tNSAIDs users and 51.7±15.1 years in oNSAIDs users. tNSAIDs users were also more prevalent in female (82.3% vs. 76.0%), CVD risk factors and co-medications than oNSAIDs users. After weighting by IPTW, the cohorts were well balanced. 34 CV events were found during 1,854.6 person-year follow-up in tNSAIDs users, and 433 CV events in 20,205.3 person-year in oNSAIDs users. The crude CV event rate was 1.87 and 2.14 per 100 person-year in topical and oral NSAIDs groups. Results of IPTW weighted Cox regression found tNSAIDs groups had 36% lower risk for CV events as compared with oNSAID group (**table**, HR: 0.64; 95%CI: 0.43-0.95). Consistent results were found in sensitivity analyses (**figure**).

Conclusion: We found tNSAIDs users experienced a reduced risk of CV events compared with oNSAID users. If future studies with larger sample size and longer follow-up confirm these results, NSAID prescribing might change accordingly. **Table. Incidence and risk of composite CV events in topical and oral NSAIDs recipients**

	Follow-up person-year	Event (N)	Crude incidence per 100 person-year	Propensity score adjusted HR* (95%CI)
Topical NSAIDs (N=10,758)	1,855	34	1.83	0.64 (0.43-0.95)
Oral NSAIDS (N=78,056)	20,205	433	2.14	REF

* Adjusted by Inverse probability of treatment weight (IPTW), conditioning on patient demographic information (age, gender, income levels), comorbid conditions and co-medications that correlated with CVDs and traditional and biologic DMARDs patients.

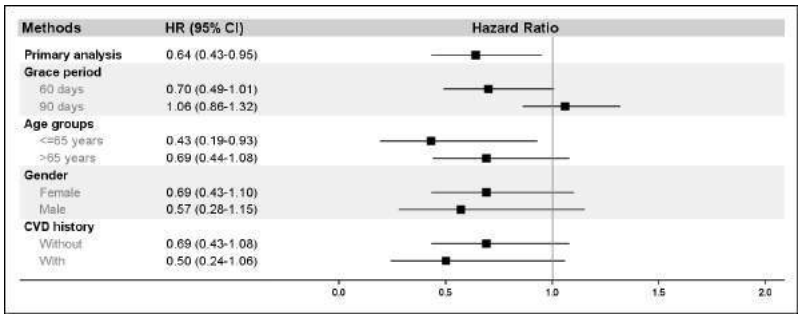

Figure. CV event risk comparing topical NSAIDs versus oral NSAIDs users in the primary analysis and in subgroups.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The impairment of left ventricular (LV) relaxation and passive filling, known as diastolic dysfunction, undergirds the development of heart failure in patients with rheumatoid arthritis (RA). Little is known about factors that contribute to the progression of diastolic dysfunction over time in these patients. The objective of this study was to identify predictors of progression of LV diastolic dysfunction over five years in patients with RA.

Methods: A prospective longitudinal study of a population-based cohort of patients with RA was performed. Patients participated in research study visits at baseline and 5 years later. Clinical evaluation included the Rapid Assessment of Patient Index Data-3 (RAPID-3), Health Assessment Questionnaire (HAQ) disability index, use of disease-modifying antirheumatic drugs (DMARDs), biologics and prednisone, and measurement of C-reactive protein (CRP), rheumatoid factor (RF), and anti-cyclic citrullinated peptide antibodies (anti-CCP). At baseline and 5 years, participants underwent pulse-wave and tissue Doppler echocardiography, according to a standardized research protocol. Spearman methods were used to determine the age- and sex-adjusted correlations between the 5-year changes in echocardiographic parameters and baseline clinical variables.

Results: A total of 160 patients with RA were included in this study. The mean age at baseline was 58.5 years, and 76.3% were female. The mean (SD) values of the RAPID-3, HAQ and CRP were 6.4 (5.8), 0.47 (0.55) and 4.2 (6.3) mg/L, respectively. Previous analyses demonstrated that RA is associated with increasing mitral A velocity and decreasing E/A ratio over 5 years. The present analysis demonstrated statistically significant correlations between the 5-year increases in the mitral A velocity and higher baseline values of the RAPID-3 ($r = 0.24$, $p = 0.003$), the HAQ disability index ($r = 0.21$, $p = 0.011$), CRP ($r = 0.21$, $p = 0.011$), and baseline prednisone use ($r = 0.17$, $p = 0.039$). Similarly, 5-year decreases in the E/A ratio correlated with higher baseline values of RAPID-3 ($r = -0.17$, $p = 0.041$), HAQ disability index ($r = -0.19$, $p = 0.019$), and CRP ($r = -0.16$, $p = 0.047$). Increases in the e' velocity correlated only with higher values of CRP ($r = 0.19$, $p = 0.021$) while increases in the E/e' ratio correlated with higher values of RAPID-3 ($r = 0.19$, $p = 0.018$). There was no evidence of any significant correlations between echocardiographic parameters and RF, anti-CCP or DMARD/biologic use.

Conclusion: Higher disease activity and severity at baseline are predictive of progressive changes over time in key parameters of LV diastolic function among patients with RA. The findings suggest that disease activity is a determinant of future myocardial disease in patients with RA. Echocardiographic monitoring of LV diastolic function should be considered as an outcome measure in future clinical trials of treat-to-target strategies for RA.

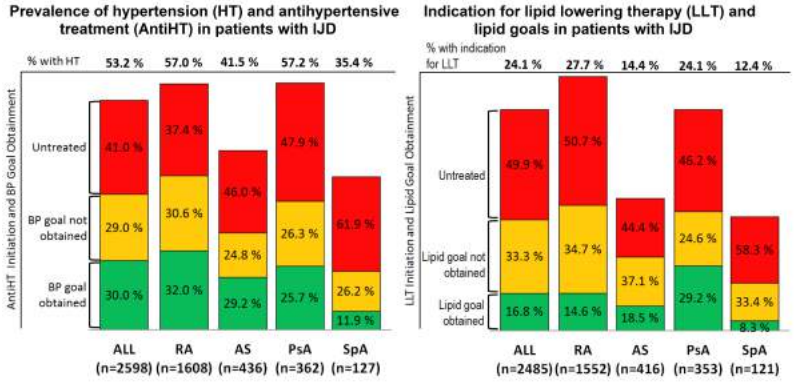
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Antihypertensives (antiHT) and lipid lowering therapies (LLT) prevent cardiovascular disease (CVD)

effectively. It has been reported that patients with rheumatoid arthritis (RA) receive suboptimal CVD-prevention. Whether other inflammatory joint diseases (IJD), such as ankylosing spondylitis (AS), psoriatic arthritis (PsA) and other spondyloarthropathies (SpA), also receive inadequate CVD management remains unknown. In a large IJD cohort we aimed to evaluate 1) Rate of indications for antiHT and/or LLT, 2) rate of antiHT and/or LLT initiation, and 3) blood pressure (BP) and low-density lipoprotein cholesterol (LDL) goal attainment in patients treated with antiHT or LLT, respectively.

Methods: The present IJD cohort is derived from the Norwegian COllaboration on Cardiovascular disease in patients with Rheumatic joint diseases (NOCAR). In NOCAR, CVD risk factors are collected in daily rheumatology practice. Need for antiHT was defined as BP ≥140/90mmHg or self-reported hypertension (HT). BP levels <140/90 mmHg were recognized as BP goal attainment. Ten year risk of a fatal CVD event was estimated by the Systematic COronary Risk Evaluation (SCORE). According to guidelines, patients with diabetes, hyperlipidemia or SCORE ≥5% are at high CVD risk and should receive LLT (LDL target <2.6 mmol/L); whereas established CVD or SCORE ≥10% imply a very high CVD risk (LDL target <1.8 mmol/L). Rates were calculated for the whole cohort and compared across IJD entities using logistic regression, age and sex adjusted.

Results: Of the 2647 patients (RA: n=1696, AS: n=445, PsA: n=376, SpA: n=130), 53.2% had indication for antiHT, and this was significantly higher in RA (57.0%) and PsA (57.2%). Among patients for whom antiHT was indicated, 59.0% received treatment and half of the patients on antiHT had obtained BP goal. There was indication for LLT in 24.1%, which was comparable across the IJD entities except for AS (14.4%) (p<0.0001). In the group with indication for LLT, 55.6% had high CVD risk which was most frequently seen in PsA (p=0.02), whereas 43.7% had very high CVD risk, which was more common in AS patients (p=0.02). Half of the patients with indication for LLT received this therapy, and treatment rates were higher for patients with very high CVD risk compared to those with high CVD risk (p<0.001). In total, 16.8% had achieved LDL treatment targets; LDL goal attainment was particularly high in PsA patients (p<0.01), and higher in patients with high CVD risk than in those with very high CVD risk (p<0.001).



Conclusion: CVD-preventive medication is often indicated, but infrequently initiated in IJD patients. Moreover, when antiHT and LLT are started, quite few patients obtain treatment goals. There is a need for improving CVD risk assessment, initiation of proper CVD-prevention and careful monitoring of target achievements to successfully reduce the excess CVD risk in IJD patients.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In the general population individuals with coronary artery disease (CAD) have a significantly increased frequency of particular susceptibility single nucleotide polymorphisms (SNPs). Since CAD is increased in rheumatoid arthritis (RA), we sought to determine whether RA patients with CAD will have an increased frequency of these SNPs compared to those without CAD, implying that RA enhances the risk for CAD by acting on established genetic pathways predisposing to CAD, or alternatively, whether RA acts to increase CAD by mechanisms independent of these genetic pathways.

Methods: CAD was assessed by coronary artery calcification (CAC) using computed-tomography in 561 patients with RA. 100 SNPs associated with CAD in the general population were genotyped or imputed and their relation to CAC established through multiple regression analysis for individual SNPs and a genetic risk score (GRS) representing their cumulative effect.

Results: Ninety-one CAD SNPs were genotyped successfully; these were not significantly associated with CAC (Agatston units) or different CAC categorizations, either individually or collectively in the GRS. Only rs6544713 (ABCG8), rs3869109 (HCG27), rs1332844 (PHACTR1), rs579459 (ABO), rs4773144 (COL4A2), rs2075650 (TOMM40) and rs9982601 (KCNE2) expressed any positive relation with CAC in one or more of the analyses. Notably, none of the group of the 12 SNPs mapping in the 53 kb region of chromosome 9p21 that are among the strongest predictors of CAD in the general population exhibited any association with CAD. Moreover, rs1333040 (CDKN2B-AS1), which in the general population is positively associated with CAD risk, showed a significant inverse association between genotype and CAC. Only rs579459 (ABO) exhibited a consistent positive association between genotype and CAC score, with a significant increase of the effect allele frequency in both homozygous or heterozygous genotype distributions. When the association of the CAD related SNPS with CAC was studied through the non weighted and weighted set of SNPs, no significant association was found. In particular, an increase in the number of homozygous cardiovascular disease related SNPs was not significantly associated with an increase in *log*CAC Agatston units. GRS was not associated with CAC both in the univariate, and in the multivariate analysis adjusted for age and sex and for traditional cardiovascular factors. Additionally, when CAD related SNPs were weighted by their effect sizes, the resulting GRS was not significantly associated with CAC. Besides, trend analysis showed no relation between GRS and log CAC Agatson units (p=0.93). Interestingly, the positive association found between DAS28 and CAC after adjusting for traditional cardiovascular risk factors was not modified by correcting for the CAD related SNPs GRS.

Conclusion: The increased risk for CAC in RA does not appear to primarily operate through established genetically regulated atherogenic mechanisms that are preponderant in the general population.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have a higher risk of cardiovascular disease (CVD) and premature mortality, compared to the general population. Inflammatory burden and conventional cardiovascular (CV) risk factors contribute to the development of carotid atherosclerosis in patients with RA. We evaluated the effects of RA on the occurrence of CVD and mortality in a prospective study of an Asian population.

Methods: A total of 369 patients with RA and 160 healthy controls were followed up for 5 years or until deaths in a prospective KARRA cohort study (412 patients and 221 controls at baseline). To detect the presence and progression of carotid atherosclerosis, we performed carotid ultrasound at baseline and 5-year. We analyzed the incidence of CVD, conventional CV risk factors, RA disease activity and severity markers, medication histories, mortality rate, and causes of death.

Results: During 5-year follow-up period, the mortality rate was 5.8% (24/412) in RA patients and 0% in healthy controls ($p<0.001$), while the incidence of CVD were 6.1% (25/412) in RA patients and 0.5% (1/221) in healthy controls ($p<0.001$). Among CVD in RA patients, cerebrovascular accident (CVA) and cardiovascular event (CVE) were 8 (32%) and 17 (68%) events, respectively. Major causes of death included infection (11/24, 45.8%), CVD (6/24, 25%), and others (7/24, 29.2%). The mean age, presence and number of carotid plaques, functional class, modified Korean version of the HAQ (mKHAQ), tender joint count (TJC), swollen joint count (SJC), ESR and CRP, and conventional CV risk factors at baseline were significantly associated with mortality among RA patients. Multivariate logistic regression analysis showed that the presence of carotid plaque (OR 5.32 [95% CI 1.09-25.99; P = 0.039]), mKHAQ (OR 1.07 [95% CI 1.02-1.13; P = 0.007]), and ESR (OR 1.04 [95% CI 1.02-1.06; P < 0.001]) at baseline were independent risk factor for mortality of RA patients. In contrast, factors associated with new-onset CVD included the mean age, presence and number of carotid plaques, peak CRP, and conventional CV risk factors at baseline. Carotid plaque (OR 7.86 [95% CI 2.14-28.83; P = 0.002]) and two or more CV risk factors (OR 4.77 [95% CI 1.07-21.23; P = 0.040]) at baseline were independent predictive factors for new-onset CVD of RA patients in a multivariate logistic regression analysis.

Conclusion: This prospective study shows that a common risk factor for CVD and mortality is carotid plaque which is determined by disease activity and CV risk factors. While disease activity of RA is a critical determinant for the mortality, the development of CVD depends on conventional CV risk factors.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased cardiovascular morbidity and mortality. This cardiovascular risk is mainly determined by the lipid profile, which may change during the course of the disease(1). For a proper cardiovascular risk assessment stable lipid values should be used and in cardiovascular risk prediction models mostly lipid ratios are applied. As the increased cardiovascular risk is already present at the time of diagnosis, it is important to initiate cardiovascular risk management as early as possible in the disease(2). However, first it is necessary to know if measurement of the lipid profile is adequate (i.e. stable lipid values) early in the disease. The aim of this study was to 1) investigate the change in lipid profile during the first 4

weeks of RA treatment 2) analyse the association between the alteration in the lipid profile and the change in ESR.

Methods: In 66 consecutive DMARD-naive early RA patients lipid profile and disease activity were measured. This was repeated after four weeks of treatment with methotrexate (3 weeks 10 mg, 4th week 17.5 mg) and prednisolone (30 mg tapered to 10 mg). Lipid profile assessment comprised TC, HDL-C, LDL-C, triglycerides and apolipoprotein A and B (Apo A and Apo B). Disease activity was assessed by the disease activity score of 44 joints (DAS44), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Patients on statins were excluded. The change in lipid profile (week 4 minus week 0) versus change in ESR was analysed in 2 patient groups: a group with high (median -31.0 mm/h) and a group with low (median -3.0 mm/h) improvement in ESR.

Results: Three patients on statins were excluded, analyses were thus performed on 63 early RA patients. All components of the lipid profile increased significantly during treatment, except for Apo B. In addition, ratios of lipid values, particularly the TC/HDL cholesterol ratio improved significantly (table 1). The group with high ESR versus the group with low ESR improvement had a significantly higher increase in TC, HDL-C, LDL-C and Apo A levels. This was 2.7% in the group with less improvement in ESR and 23.1% in the most improvement group. The spearman rho test showed a correlation between delta ESR and delta TC, HDL, LDL and Apo A of r=0.456, r=0.313, r=0.507 and r=0.281, respectively (all $p<0.05$).

Conclusion: Lipid levels increased significantly after four weeks of methotrexate and prednisolone treatment after RA diagnosis and this change is associated with the improvement in ESR. In both groups ratios of lipid values improved substantially. Hence, cardiovascular risk management in early arthritis should be postponed until low disease activity has been obtained, as assessment during active disease leads to an inappropriately high cardiovascular risk estimation. **References:** 1) Nat Rev Rheumatol 2013 Sep;9(9):513-23. 2) Arthritis Res Ther 2010;12(4):R158.

Table 1.

	Baseline samples	Week 4 samples	P-value
Total cholesterol, mmol/l (mean, SD)	4.9 (1.1)	5.6 (1.3)	P=0.000
Triglycerides, mmol/l (mean, SD)	1.3 (0.6)	1.4 (0.8)	P=0.023
HDL, mmol/l (mean, SD)	1.3 (0.4)	1.9 (0.6)	P=0.000
LDL, mmol/l (mean, SD)	3.1 (0.9)	3.3 (1.1)	P=0.020
Apo A, g/l (mean, SD)	1.4 (0.3)	1.8 (0.3)	P=0.000
Apo B, g/l (median, IQR)	0.9 (0.8-1.1)	0.9 (0.8-1.1)	P=0.740
TC/HDL ratio (mean, SD)	4.0 (1.4)	3.2 (1.1)	P=0.000
Apo B/ Apo A ratio (mean, SD)	0.7 (0.2)	0.6 (0.2)	P=0.007

Values are reported as mean (SD) or median (IQR); mmol/l: millimole per liter, HDL: High-density lipoprotein, LDL: Low-density lipoprotein, Apo: apolipoprotein, g/l: gram per liter, TC: Total cholesterol

Success Rate of Blood Pressure Goal Achievement in Patients with Inflammatory Joint Diseases

Silvia Rollefstad, Pia Norheim, Eirik Ikdahl and Anne Grete Semb, Preventive Cardio-Rheuma clinic, Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

<>

Background/Purpose: The excess risk of cardiovascular disease (CVD) in patients with inflammatory joint diseases (IJD) is attributable to several risk factors, including a high prevalence of hypertension. However, there is limited knowledge on the effect of antihypertensive treatment (a-HTT) in these patients. Our objective was to initiate a-HTT when indicated and treat to guideline recommended blood pressure (BP) goal in IJD patients. We also aimed to evaluate the effect of a-HTT in this patient population, and which factors were associated with BP goal attainment.

Methods: Patients with IJD (n=765) were referred from a rheumatology outpatient clinic or general practitioners to a preventive cardio-rheuma clinic. All patients underwent a CVD risk evaluation, including BP measurements (performed using and Omron M7 apparatus). Antihypertensive treatment was initiated in accordance with guidelines, and the BP treatment goal was <140/90 mmHg.

Results: Of the 765 IJD patients referred (rheumatoid arthritis n= 450, ankylosing spondylitis n=210 and psoriatic arthritis n=105), 104 (13.6%) had an indication for BP lowering, while 224 (29.3%) were already using a-HTT at the first consultation. For those where a-HTT was initiated at baseline (n=104), there was a highly significant change in BP from first to final consultation (Fig 1a). BP goal was achieved in 84 (80.8%) patients (Fig 1b), using mean±SD 3.1±1.7 consultations. Dose adjustments was done in 38 (36.5%) of the patients with median (IQR) a-HTT dose adjustments of 1 (1, 1.25). In 9 (8.7%) patients the a-HTT was changed. Systolic BP (p <0.0001), but not use of anti-rheumatic medication or inflammatory biomarkers at baseline, was significantly associated with BP goal attainment in age- and sex adjusted logistic regression analyses. Patients with the lowest systolic BP were more likely to achieve BP goals. For patients already on a-HTT (n=224), only 52.7% had a BP <140/90 mmHg at baseline. After up titration or change of a-HTT, the percentage of patients achieving BP goal in this group increased to 82.6%.

Conclusion: This is to our knowledge the first prospective report on success rate of BP goal achievement in patients with IJD. Approximately 80% reached BP target, which is even a higher proportion than what is shown in the general population. Treatment to BP goal is feasible in patients with IJD, and is not complicated by inflammation or use of anti-rheumatic medication.

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is the leading cause of mortality in rheumatoid arthritis (RA), underscoring the importance of CVD prevention. The rates of screening and intervention for modifiable traditional and RA-specific CVD risk factors are low among RA patients. The primary objective of this study was to design and test a web-based educational intervention (EI) for RA patients.

Methods: A 28-minute educational web-based video presentation was designed, recorded on CVD risk specifically for RA patients and pretested. Thirty-eight consecutive consenting RA patients completed onsite EI offered on web. Participants also completed web-based surveys assessing heart disease knowledge, unique heart disease risk factors specific to RA patients, and illness perceptions for CVD as RA patients (HDKQ; HDFQ-RA; IPQ-R) before and after EI. HDKQ and HDFQ-RA were scored using correct response ratios

(CRR). Smoking status and sedentary lifestyle were assessed by self-report, whereas chart review was used to ascertain hypertension, diabetes, dyslipidemia, weight, RA control, medication use. General linear model analyses for repeated measures were used to compare within-person changes in CVD risk knowledge post EI.

Results: The participants were 57±13 years old; 77% were women. Cardiac risks were: 21% current smokers, 44% hypertension, 21% diabetes, 63% dyslipidemia, 47% overweight, 45% sedentary, 49% poor RA control; of which 51% reported steroid and/or nonsteroidal anti-inflammatory medication (NSAIDS) use for >15 days within the past 3 months. At study initiation, patients had poor perception of increased CVD risk in context of RA. CRR was ≤ 50% on 8/30 HDKQ domains relating to recognition of CVD symptoms, role of stress, diet and exercise and treatment in CVD. Post EI, significant improvements (Table 1) were evident in 5/8 of these domains ($p<0.01$). CRR was ≤70% on 3/13 domains on HDFQ-RA, with CRR of 34% and 53% in two domains specifically related to CVD in RA (Table 1). Significant improvements after EI were noted across all three HDFQ-RA domains ($p<0.05$).

Conclusion: RA patients have poor perception and knowledge of CVD risk associated specifically with RA and RA-related medications. This brief web-based EI increased their awareness about RA-related CVD risk. This may be a step towards mitigating RA related CVD morbidity. Longitudinal study is ongoing. Table 1.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritits (RA) patients have an increased risk of mortality from cardiovascular (CV) disease. Proposed adaptation of CV risk score models in RA patients include criteria such as anti-cyclic citrullinated peptide antibodies (ACPA) positivity. The existing literature on the association between ACPA positivity and CV risk is not definitive.[1-3]

Methods: This is a retrospective chart review of patients over 18 years of age with ACPA testing between 2007 and 2013 at a single academic center. Patients with non-RA autoimmune disease were excluded. Information about RA diagnosis and treatment, CV risk factors and CV events was collected. Statistical methods included chi-square tests, t-tests, Wilcoxon Rank Sum tests, Fisher's exact tests, simple logistic regression and multivariable logistic regression.

Results: 2,030 records were reviewed. 309 patients with non-RA autoimmune disease were excluded. The mean RA duration was 12.1 years. RA and non-RA groups were similar in gender, tobacco status, hyperlipidemia, statin use, chronic kidney disease, and diabetes; significant differences included race, BMI, and systolic blood pressure. Primary outcomes included coronary artery disease (CAD, defined as acute coronary syndrome or intervention), stroke (CVA, defined as clinical or radiographic stroke or transient ischemic attack), and a combined outcome (CAD or CVA). The combined outcome occurred in 173 patients. There was a significant association between an increasing prevalence of the combined outcome and ACPA quartile in all patients (p=0.002) and in RA patients (p=0.05). A similar trend was seen in non-RA patients but did not reach statistical significance. There was an increased odds ratio of the combined outcome with each increasing ACPA quartile in all patients (p=0.002) (Figure 1). Subgroup analyses of the RA and non-RA groups did not reach statistical significance, though the trend was preserved.

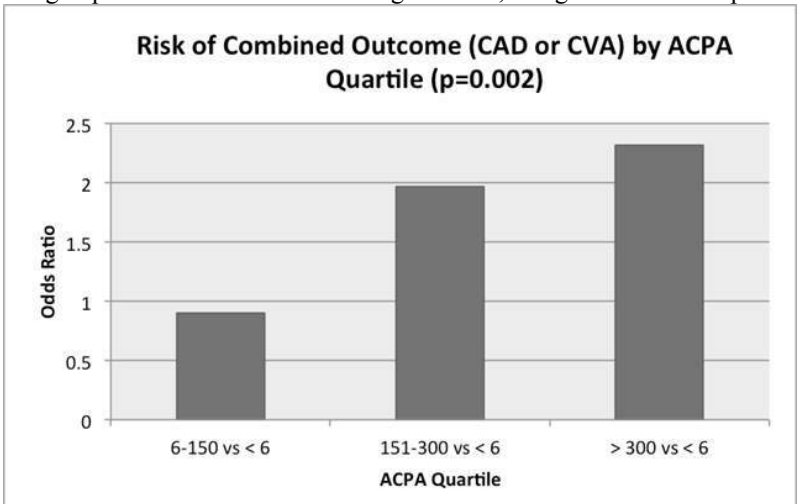

Fig 1. Odds ratio for combined outcome of CAD or CVA in all patients

Conclusion: Increased ACPA is associated with increased risk of the combined outcome of CVA or CAD. To the authors' knowledge, this is the first study to demonstrate progressively increased risk of CV disease with extent of ACPA elevation. Although statistical significance was not reached in non-RA patients, the observed trends warrant larger studies to evaluate this population. **References:**

Exploring the Link Between RA Disease Activity, Lipid Levels, and Cardiovascular Disease in an Early Inflammatory Arthritis Cohort

Saurash Reddy, Xiaobo Meng and Carol Hitchon, University of Manitoba, Winnipeg, MB, Canada
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) has been established as a risk factor for cardiovascular disease (CVD), with systemic inflammation being linked with atherosclerosis. Traditional CVD risk indices like the Framingham Risk Score (FRS) underestimate CVD risk in RA. RA patients that develop CVD often have more inflammation yet lower levels of atherogenic cholesterol in what is labelled “the lipid paradox”. Additionally, evidence suggests RA disease activity may modify the cardioprotective function (versus the absolute value) of cardioprotective high density lipoprotein (HDL). We explore the link between CVD, disease activity, lipid levels, and apoA1 (an atheroprotective HDL subcomponent) in an early inflammatory arthritis (EIA) cohort.

Methods: Data was obtained from subjects followed in a single centre EIA cohort with systematic collection of disease activity measures, comorbidities and serum lipids. FRS scores were calculated for each patient, and new CVD (myocardial infarction, unstable angina, stroke) confirmed by chart review. Annual lipid profiles (total cholesterol (TChol), triglycerides (TG), low density lipoprotein (LDL) and HDL) were correlated with disease activity (DASESR283variable) using Spearman’s rho (first profile obtained after median (IQR) of 25 (0, 40) months follow-up). ApoA1 was measured by ELISA in serial samples from 22 patients matched for age and DAS28ER3variable (5 with new CVD) and differences in apoA1, lipid levels, and DAS28ESR-3variable over time in both non-CVD and CVD patients compared using non-parametric tests and logistic regression.

Results: 278 patients with EIA (<12months symptoms at baseline) and no prior CVD history (mean(SD) age 49(15) years, 75% female, 67% RA) were followed for a median (IQR) of 67 (25, 102) months. Considering all visits, there was modest negative correlation between DAS28ESR-3variable and HDL levels (r=-0.12, p<0.001), a trend for negative correlation with TChol level (r=-0.07 p=0.03), but no correlation for LDL and TG. CRP correlated with TChol (r=-0.12 p<0.0001), TG (r=0.14 p<0.0001), and HDL (r=-0.31 p<0.0001). A good or moderate EULAR treatment response was achieved by 70% of the cohort at last visit and there was greater increase in LDL levels in these individuals than those with no response (mean(SD) +0.24(0.7) vs +0.01(0.6), p=0.02). Five subjects developed CVD after a median (IQR) of 64(42, 104) months. FRS increased from baseline to last visit (median (IQR) 4.4(1.2, 9.1) vs 5.1(2.1,10.8) p<0.0001) however there was no difference in FRS at baseline, last visit or change in FRS between those with or without CVD. Baseline high FRS (FRS in fourth quartile) was not significant in cox-proportional hazards modelling of CVD-free survival. ApoA1 levels modestly fluctuated over time, but did not correlate with HDL or other lipids nor associate with CVD.

Conclusion: In EIA, high disease activity is associated with lower levels of pathogenic lipids, supporting the lipid paradox. Neither Framingham risk scores nor apoA1 levels adequately associate with CVD risk in these EIA patients. Alternate measures of lipid metabolism may be more predictive of CVD.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic and systemic inflammatory disease. The incidence of cardiovascular (CV) disease is increased in patients with RA compared with the general population, which is related to the fact that atherosclerosis has an inflammatory etiology. We previously have shown that synergistic interaction between inflammatory burden and conventional CV risk factors in the development of carotid atherosclerosis. In the present study, we investigated the risk factors for the progression of the carotid atherosclerosis in RA patients in the Kyungpook National University Hospital Atherosclerosis Risk in Rheumatoid Arthritis (KARRA) cohort study.

Methods: After a baseline evaluation for KARRA enrollment, all RA patients and healthy controls were prospectively followed up for 5 years or until deaths. We analyzed the demographic findings, conventional risk factors and RA disease activity. Carotid ultrasound at baseline and year 5 was performed to evaluation of the intima-medial thickness (IMT) and presence and progression of carotid plaque.

Results: A total of 417 patients with RA and 221 age- and sex- matched healthy controls were included in the baseline KARRA cohort, and 314 patients with RA and 160 healthy controls were followed for the 5 year period. Mean age and female frequency of RA patients were not different compared with those of healthy controls at year 5. At year 5, the mean carotid intima-medial thickness (IMT) of RA patients was higher than that of controls [0.85mm (S.D 0.15) vs 0.89 (S.D 0.18), p=0.032]. However, frequency and number of carotid plaque were similar in both groups, which reflects steeper increase of plaque number during 5-year follow-up in healthy controls. Factors associated with plaques at year 5 included IMT, mean blood pressure, and total and LDL cholesterols at baseline. New development of carotid plaques at year 5 in RA patients (n=90) was predicted by IMT and total and LDL cholesterols at baseline, while it was associated with IMT and DAS28-CRP at year 5. Multivariate logistic regression analysis revealed that baseline IMT (OR 36.48 [95% CI 1.66-803.62; P = 0.023]) and DAS28-CRP at year 5 (OR 1.56 [95% CI 1.06-2.30; P = 0.024]) were independent risk factors for new plaque formation in 5-year followed period.

Conclusion: This study shows that carotid plaque at year 5 is predicted by IMT and dyslipidemia at baseline, whereas formation of new plaques after long-term follow-up depends on the preexisting carotid atherosclerosis that is aggravated by suboptimal disease control.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk for myocardial infarction (MI), which is often silent. Heart rate adjusted ST segment (ST/HR index) is a novel method for assessing myocardial ischemic changes during exercise testing. This index has been related to MI risk and has been shown to have greater sensitivity in detecting ischemic changes than conventional ST segment depression, which relies on reaching maximal workload intensity during exercise tolerance test (ETT). ST/HR index takes heart rate responses to exercise into account, which means that it is not necessary for study participants to reach maximal workload. This is particularly important for patients with RA, who might have limited exercise ability due to joint problems. Reduced heart rate variability (HRV) at rest is an indicator of reduced parasympathetic activity and poorer cardiac autonomic balance, and it has been suggested to contribute to the risk of developing MI. Both ST/HR index and HRV are related to MI, but little is known about their associations. Thus, this study is aimed to explore the association between resting HRV indices and ST/HR index in patients with RA.

Methods: Two minutes beat to beat R-R interval data from ECG were recorded in 96 RA patients (54.4±12.6 years, 68% women). ST/HR index was measured as the difference between ST-segment depression at rest and maximum ST-segment depression during ETT, divided by the absolute change from resting heart rate (HR) to the HR at maximum ST depression during the ETT. Low frequency (LF; 0.04-0.15 Hz) and high frequency (HF; 0.15-0.40 Hz) spectral powers, LF/HF ratio, and the normalised units (nu) of LF and HF were used as HRV indices to measure cardiac autonomic control.

Results: Mean ST/HR index was 2.6 ± 1.7v μV/beats/min. Mean or median values for HRV indices were LF (nu) [60.4 (41.7-76.1)], HF (nu) (43.0 ± 24.4), LF/HF ratio [1.5 (0.7-3.1)]. Pearson moment correlation (controlling for gender) revealed that LF/HF ratio (r (81) = .28, p= .01) and LF (r (81) = .23, p= .03) were positively and HF (r (81) = -.27, p= .01) was negatively associated with ST/HR index.

Conclusion: This is the first study to report an association between ST/HR index, parasympathetic activity and autonomic balance in patient with RA. Measuring ST/HR index during ETT could be a particularly relevant indicator for p with RA who might not be able to exercise to their maximal HR due to joint problems. Thus, the use of ST/HR index during exercise testing may help in early detection of risk for MI in people with RA. Further research is needed to explore the associations between ST/HR index and clinical cardiac endpoints.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Intima media thickness (IMT) and coronary artery calcification (CAC) quantification using multidetector computed tomography (MDCT) scanner are useful in detecting subclinical atherosclerosis and are good surrogate markers of cardiovascular morbidity and mortality in general population and in rheumatoid arthritis (RA). A good correlation between these methods has been reported in RA, being CAC a slightly more sensitive technique **(ref. 1).** Our aim is to determine the value of IMT that better predicts the presence of coronary atherosclerosis, using CAC as reference and assuming CAC value of 100 as the cut-off point indicating high cardiovascular risk.

Methods: We evaluated 127 RA patients without previous cardiovascular events. Carotid ultrasonography was performed by a MyLab 70 scanner (Esaote; Genoa, Italy), equipped with 7-12 MHz linear transducer and the *automated software guided technique radiofrequency-Quality Intima Media Thickness* in *real-time* (*QIMT*, *Esaote*, *Maastricht*, *Holland*). According to data from non-rheumatic patients and also from RA patients, an IMT≥ 0.90 mm is a good predictor of high cardiovascular risk. To determine CAC score, a CT Imaging of coronary arteries using a 32-slice MDCT scanner (Lightspeed, Pro 32, GE Healthcare, USA) was performed.

Results: Patients with IMT below 0.90 mm had CAC values of 88±210 whereas patients with IMT≥0.90 mm had mean CAC values of 190 ± 272 (p=0.066). We found a positive correlation between IMT and CAC (correlation coefficient 0,303; p=0.001). The IMT cut-off value ≥ 0.90 mm had a sensitivity of 32% for detecting CAC ≥100. ROC curve analysis showed and area under the curve of 0.664. The IMT cut-off value of 0.80 mm had a sensitivity of 40% and a specificity of 71.3%. Lowering the IMT cut-off point to 0.70, we reached a sensitivity of 76% and a specificity of 51.5% for CAC ≥100 detection. The positive predictive value for the IMT cut-off point of 0.70 mm was 76% in our population, being the negative predictive value 49.5%

Conclusion: IMT values ≥0.70 mm predict coronary artery calcification score above 100 with a sensitivity of 76%. According to that, the IMT value considered as predictor of high cardiovascular risk would be 0.70 mm instead of 0.90 mm. **TABLE:**

Variable	
Age (mean ± SD)	58. 57 ±9.7
Female sex, n (%)	92 (72.,4)
IMT ≥ 0,9 mm, n (%)	19 (15)
IMT ≥ 0.7 mm, n (%)	71 (56)
CAC score (mean ± SD)	103.4 ±222.6
CAC score ≥ 100, n (%)	26 (20.5)

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Carotid ultrasonography (CU) and coronary artery calcification score (CAC) evaluated by multidetector computed tomography (MDCT) scanner are useful in detecting subclinical atherosclerosis in the general population and in rheumatoid arthritis (RA) patients. A good correlation between both diagnostic tools was demonstrated in RA, being CU more sensitive for detecting subclinical atherosclerosis **(ref. 1).** Using the presence of carotid plaque as a reference, we aimed to determine the cut-off value of CAC score that better predicts subclinical carotid atherosclerosis.

Methods: We evaluated 127 RA patients without previous cardiovascular events. Carotid ultrasonography was performed by a MyLab 70 scanner (Esaote; Genoa, Italy), equipped with 7-12 MHz linear transducer and the *automated software guided technique radiofrequency-Quality Intima Media Thickness* in *real-time* (*QIMT*, *Esaote*, *Maastricht*, *Holland*). Carotid plaque was defined according to the Manheim Conference Consensus criteria. To determine CAC score, a CT Imaging of coronary arteries using a 32-slice MDCT scanner (Lightspeed, Pro 32, GE Healthcare, USA) was performed. A CAC score ≥100 was considered as a surrogate marker of very high cardiovascular risk.

Results: Unilateral and bilateral carotid plaque frequency and the mean CAC score in the different groups are summarized in the **TABLE**. Patients without carotid plaques had a mean CAC value of 23±49 [range 0-250] whereas it was 50±116 [0-569] in patients with unilateral plaque and 192±302 [0-1205] in patients with bilateral plaques, being these differences statistically significant ($p<0.001$). The sensitivity to detect unilateral carotid plaques using a CAC score ≥100 as a marker of very high cardiovascular risk was very low (28%). A ROC curve comparing the presence of carotid plaque and CAC quantification was performed, being the area under the curve 0.692. The sensitivity and specificity for the presence of unilateral carotid plaques increased (69.3% and 64.1%, respectively) when we used a CAC score value ≥1 as the cut-off value to predict high cardiovascular risk. Positive predictive value using CAC ≥1 was 81.3% in our population, being 48.1% the negative predictive value.

Regarding bilateral carotid plaques, the CAC score ≥100 had a sensitivity of 40%. ROC curve showed an area under the curve of 0.712. Using a CAC score value ≥ 1 as the cut-off value to predict high cardiovascular risk, the sensitivity to determine the presence of bilateral carotid plaques increased to 76.4% but the specificity decreased to 54.2%.

Conclusion: A CAC score value score ≥1 is a good predictor of carotid plaques, showing sensitivity close to 70%. Our data support the use of a CAC score value score ≥1 instead of a CAC score ≥100 as the cut-off value to predict high cardiovascular risk in patients with RA. **TABLE**

Variable	
Age (mean ± SD)	58.57±9.7
Female, n (%)	92 (72.4)
Plaque: no, n (%)	39 (30.7)
Plaque: yes, n (%)	88 (69.3)
Unilateral plaque, n (%)	33 (26.0)
Bilateral plaque, n (%)	55 (43.3)
CAC (media±DE)	103.4±222.6
CAC ≥1, n (%)	75 (59.0)
CAC ≥100, n (%)	26 (20.5)

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased incidence of cardiovascular disease. Hypertension is a major cardiovascular risk factor and it is one of the most common comorbid conditions in RA patients. The incidence and associated factors of hypertension occurring during the course of RA have not been extensively studied. Thus, we determined the demographic features, clinical manifestations, and pharmacologic profile associated with incident hypertension in a cohort of Hispanics with RA.

Methods: Hispanics from Puerto Rico with RA (per 1987 American College of Rheumatology classification criteria) were studied. Hypertension was defined as a blood pressure ≥140/90 mmHg on 2 or more subsequent visits. Incident hypertension was defined as that occurring after the onset of RA, whereas prevalent hypertension was defined as that occurring at or before the onset of RA symptoms. Demographic features, health-related behaviors, clinical manifestations, comorbidities, disease activity (per Disease Activity Score 28), functional status (per Health Assessment Questionnaire), patient's and physician's global disease assessments by visual analog scales, and pharmacologic treatment were determined. Differences between patients with incident hypertension and those without hypertension were examined by bivariable (chi-square and Student t tests) and multivariable (logistic regression) analyses.

Results: The entire cohort consisted of 405 RA patients. Prevalent hypertension was present in 83 (20.5%), incident hypertension in 140 (34.6%), and 182 (44.9%) patients did not have hypertension. The mean age of the study population was 54.4 years; 88.2% were women. The mean disease duration was 16.8 years. In the multivariable analysis adjusted for age, gender, disease duration, body mass index, dyslipidemia, and type 2 diabetes mellitus, incident hypertension was associated with joint replacement (OR 3.16, 95% CI 1.46-6.85, p=0.003), presence of fibromyalgia (OR 5.99, 95% CI 1.98-18.16, p=0.002), and corticosteroid use (OR 2.70, 95% CI 1.34-5.46, p=0.006). Conversely, exercise was negatively associated with incident hypertension (OR 0.41, 95% CI 0.19-0.88, p=0.023). No associations were observed for smoking, alcohol use, joint deformities, extra-articular manifestations, disease activity, functional status, patient's or physician's global disease assessments, early therapy (within 6 months of disease onset), or exposure to nonsteroidal anti-inflammatory drugs, disease-modifying anti-rheumatic drugs, or biologic agents.

Conclusion: In this population of patients, nearly 35% developed hypertension during the course of RA. Several features including joint replacement, presence of fibromyalgia, and corticosteroid use were associated with incident hypertension, whereas exercise was associated with decreased risk. Clinicians should be aware of these associations to provide appropriate management and counseling to RA patients, especially those related to modifiable factors such as exercise and steroid use.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is the leading cause of mortality in rheumatoid arthritis (RA) patients. Hydroxychloroquine (HCQ) has been shown to improve major outcomes like survival rates in other inflammatory diseases, like systemic lupus. The aim of our study was to assess currently available literature on the cardio-vascular impact of hydroxychloroquine (HCQ) in patients with RA.

Methods: We systematically searched literature (via Pubmed, Embase and abstracts from recent ACR and EULAR congresses) for studies evaluating the effects of HCQ, wether in monotherapy or in combination with other conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) on cardio-vascular outcomes or known risk factors for CVD in RA patients (lipid profiles, diabetes incidence, insulin resistance and incidence of CVD). A meta-analysis was performed with Review Manager Software, with random-effects models, whenever methodologically possible and relevant. Data were extracted by one investigator and independently checked by another.

Results: The literature search revealed 213 articles and abstracts of potential interest, and further examination resulted in 13 studies fulfilling required criteria for preplanned analyses regarding the cardio-vascular impact of HCQ in RA. For lipid profiles, the mean difference (mg/dL) between HCQ users versus non-users was -9,82 (95% confidence interval [95% CI] -14.03; -5.60) for total-cholesterol (figure 1), -10.61 [-14.17;-7.04] for low-density-lipoprotein, +4.13 [2.22;6.04] for high-density-lipoprotein, and -19.15 [-27.20; -11.10] for triglycerides (figure 2); with respectively a decrease (mg/dL) of -13.15 [-20.96; -5.34], -12.35 [-20.14; -4.36], 1.67 [-0.96, 4.31] and -12.54 [-28.94; 3.86] after HCQ initiation. Diabetes incidence was reduced in “HCQ ever users” versus “patients who never used HCQ” with a hazard-ratio of 0.59 [0.49; 0.70] (figure 3). In addition, HCQ seems to decrease insulin resistance and incidence of cardio-vascular events but data were too scarce for meta-analysis.

Conclusion: Beside its limited efficacy on disease activity, this study supports the benefit of HCQ on metabolic profile and to a lesser extent on cardio-vascular events of patients with RA, suggesting its usefulness in combination with other csDMARD.

Figure 1 – Forest plot for the mean difference (mg/dL) of total-cholesterol between HCQ users and HCQ non users

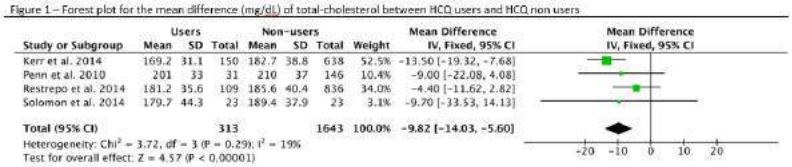

Figure 2 – Forest plot for the mean difference (mg/dL) of triglycerides between HCQ users and HCQ non users

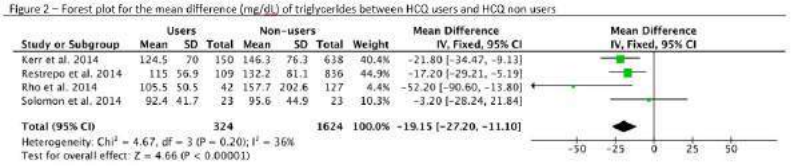

Figure 3 – Forest plot for the hazard ratios of diabetes incidence between HCQ ever users versus patients who never used HCQ

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The aim was to investigate M-ficolin and Map44, proteins from the lectin pathway, as prognostic markers of subclinical cardiovascular disease in untreated early rheumatoid arthritis (RA) patients. We evaluated the associations between M-ficolin, MAp44 and disease activity (DAS28, CRP and HAQ-score), the degree of coronary artery calcification and myocardial deformation of left ventricle in an inception cohort.

Methods: 79 DMARD-naïve RA patients with a disease duration < 6 months were included from an inception cohort. Clinical variables, plasma- and serum-M-ficolin and MAp44 levels, myocardial deformation analysis and coronary calcification were measured at baseline and after two years. M-ficolin and Map44 were measured with an in-house time-resolved flourometric immunoassay. Coronary calcification was evaluated by Agatston calcium-score using cardiac computer tomography. Left ventricle deformation imaging was determined by speckle tracking echocardiography. Level of statistical dependence and significance were determined with Spearman rank correlation test.

Results: Baseline serum M-ficolin was associated to CRP (r=0.26, p=0.02) and DAS28 (r=0.24, p=0.04). Further, baseline Map44 was associated to CRP in serum (r=0.25, p=0.03) and plasma (r=0.29, p=0.01). At the two-year follow-up patient's global assessment, assessment of pain, fatigue and HAQ score were associated to serum MAp44 (range p=0.002; 0.04), (range r=-0.36; -0.25). We found associations between baseline fasting insulin and M-ficolin and MAp44 (range p=0.001; 0.02). No associations were found between Agatston calcium score and MAp44 or M-ficolin. Only baseline plasma MAp44 showed association to global longitudinal strain (GLS) (r=0.27, p=0.03).

Conclusion: M-ficolin and MAp44 were associated with disease activity markers and plasma insulin at baseline and at two-year follow-up. GLS and MAp44 were positively associated at baseline.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Serious infection events (SIE) and myocardial infarction (MI) are among the most concerning adverse events that occur in rheumatoid arthritis (RA) patients. The role of RA disease activity and associated systematic inflammation has been examined only in a limited fashion as it relates to these outcomes.

Methods: Multi-biomarker disease activity (MBDA) test scores (n=77,641) were linked to Medicare claims at a patient-level for individuals with RA who had at least 12 months of Medicare coverage from 2011-2014, excluding patients with other autoimmune diseases. The 4 outcomes studied were pneumonia or sepsis as the primary reason for hospitalization (SIE-primary); any pneumonia or sepsis during hospitalization (SIE-secondary); MI; and a composite CHD outcome (MI, PCI or CABG), using previously-validated definitions defined by ICD9 and HCPCS codes. Patients were excluded from the MI/CHD analysis for prior MI. The MBDA score was analyzed in a time-varying fashion, updated with each new test result, and analyzed according to its established disease activity cutpoints and in quartiles. MBDA scores were lagged by 1 week (MI/CHD) or 2 weeks (SIE). Tests were excluded (n=10,996) for vaccination, antibiotic use, or hospitalization within the prior 21 days. Patient baseline characteristics were measured at the time of the first usable MBDA test and in the previous 12 months. Cox proportional hazards models evaluated the association between MBDA score and SIE, MI, and CHD events, controlling for age, sex, and race.

Results: A total of 17,333 patients were eligible for the SIE, and 16,796 for the MI/CHD analyses. Baseline characteristics were mean (SD) age 69 (10) years, 79% women, 80% white, and 37% disabled. RA therapies included biologics (20%), MTX (55%), other non-biologic DMARDs (40%), and oral glucocorticoids (51%). In up to 16,424 person-years of follow-up, there were 452 SIE-primary, 653 SIE-secondary, 132 MI, and 181 CHD events. The crude rates of all outcomes were associated with increasing MBDA score in a dose-response fashion (Table), using either established cutpoints or quartiles. After adjustment for age, sex, and race, higher MBDA score was associated with all outcomes of interest. Sensitivity analyses that examined the MBDA score without CRP, and separately adjusted for CRP, yielded similar findings to the main results.

Conclusion: Higher MBDA scores were associated with increased risk for hospitalized infection, MI, and CHD events in a large U.S. RA population predominantly consisting of older individuals. Use of the MBDA score to risk-stratify patients for these serious adverse events may help clinicians identify those at highest risk.

Table: Incidence Rates and Adjusted Risk of Serious Infection Events and MI/CHD Outcomes Associated with MBDA Score								
	SIE-primary		SIE-secondary		MI		CHD

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Coronary heart disease (CHD) is increased among patients with rheumatoid arthritis (RA). Limited data suggest that there is a screening gap for hyperlipidemia, a risk factor for CHD, among RA patients. To evaluate the pattern of lipid testing among RA patients based on whether patients are receive care from a primary care physician (PCP), a rheumatologist, or both.

Methods: We used a dataset that linked commercial and public health plan claims data together over 2006 to 2010. Eligible participants were required to 1) have at least 12 months of continuous medical and pharmacy coverage (baseline), and 2) have 2+ physician diagnosis plus relevant DMARD/biologic medications to categorize them as having RA; 3) 2 years of follow-up. Patients with prevalent myocardial infarction (MI), stroke or CHD during baseline were excluded as well as patients who had baseline diagnosis of hyperlipidemia and/or were already using hyperlipidemia medications The patterns of care at baseline were characterized into 3 categories: 1) visited ONLY PCP; 2) visited ONLY Rheumatologist; 3) visited both rheumatologist AND PCP. We used logistic regression to determine the likelihood of been screened for hyperlipidemia during 2 years of follow-up based on whether RA patients received care from a PCP (only), a rheumatologist (only) or both.

Results: There were 13,319 patients with RA. Overall, 83% were women. The overall age distribution was: 26% 41-60 and 74% >65 years old. There were 18 % of the RA patients who did not see a PCP the 12-month baseline. The proportion of patients that were screened for hyperlipidemia , stratified by physician specialty pattern were: 1) care from a PCP only = 42%; 2) care from a Rheumatologist only = 40%; 3) care from both a rheumatologist AND PCP = 47% . After controlling for multiple potential confounders, there was a 32% increase in the likelihood of being screened for hyperlipidemia if RA patients received combined care between PCPs and rheumatologist (Table).

Conclusion: Screening for hyperlipidemia may not be part of the factors that rheumatologist considered as part of the care of RA patients. Improvement in coordination of care between PCP and rheumatologist s,as well as establishing which physician should be responsible for hyperlipidemia management, may increase appropriate cardiovascular risk factor screening. Table: Likelihood of RA patients being tested for hyperlipidemia in regards to visiting either a rheumatologist or primary care physician

Characteristic	% tested for hyperlipidemia	Unadjusted (95% CI)	Adjusted* (95% CI)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of heart failure is increased 2-fold in RA; this is not explained by ischemic heart disease or other risk factors for heart failure. We have previously shown that N-terminal pro-brain natriuretic peptide and high-sensitivity cardiac troponin-I are elevated in RA, suggesting subtle myocardial dysfunction or chronic myocyte injury. We hypothesized that in patients with RA without known heart disease, cardiac magnetic resonance imaging (CMR) would detect altered cardiac structure, function, and

fibrosis.

Methods: We performed 1.5-T CMR in 59 patients with RA and 56 controls frequency-matched for age, race, and sex. CMR indices of structure, function, and fibrosis (late gadolinium enhancement (LGE), T1 values, extracellular volume fraction (ECV)) were compared between RA and control subjects using Mann-Whitney U tests and linear regression adjusting for age, race, and sex. Measurements were performed by CMR expert cardiologists blinded to disease or control status.

Results: Patients with RA had low to moderate disease activity (DAS28-CRP median [interquartile range] =3.16 [2.03, 4.05]. Indexed left ventricular (LV) mass, indexed LV end diastolic and systolic volumes, and left atrial size were not altered in RA. LV ejection fraction was also not significantly altered in RA. LGE was found in 2 patients with RA and 1 control subject; T1 mapping and ECV (measures of diffuse fibrosis) did not differ significantly between RA and control subjects (Table).

Conclusion: Contrary to a prior report, CMR measures of cardiac structure, function, and fibrosis were not significantly different in patients with well-controlled RA compared to a matched control group in the largest study to date.

Table. CMR findings

	Control (N=56)	RA (N=59)	Adjusted P
LVEDV indexed to BSA, ml/m2	61.1 [55.0, 66.3]	59.3 [46.9, 66.9]	0.13
LVESV indexed to BSA, ml/m2	20.9 [16.0, 26.3]	18.0 [11.7, 24.5]	0.05
LVEF, %	66.7 [60.1, 70.3]	67.9 [62.4, 74.4]	0.07
LV mass indexed to BSA, g/m2	42.2 [36.4, 48.5]	43.8 [40.0, 49.5]	0.21
LA size, mm	29 [26, 32]	29 [24, 32]	0.19
Presence of LGE, n (%)	1 (1.8)	2 (3.4)	-
Native myocardial T1, msec	978 [928, 996]	973 [945, 1001]	0.92
Post-contrast T1, msec	453 [427, 476]	457 [424, 486]	0.15
ECV, %	26.6 [24.7, 28.5]	27.5 [25.4, 30.4]	0.06

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Plasma concentrations of lipoprotein (a) [Lp(a)], a lipoprotein with proatherogenic and thrombogenic properties, have a strong genetic basis, although high concentrations of Lp(a) have also been reported in the context of inflammation, as rheumatoid arthritis (RA) (1). There are few studies that evaluate the impact of biologic therapies on Lp(a) in RA (2), taking into account that with these new therapies a better control of inflammation is achieved.This study evaluate the plasma concentrations of Lp(a) in Spanish RA patients on biological therapies attending rheumatology outpatient clinics.

Methods: Baseline analysis of the CARMA project (CARdiovascular in rheuMAtology), a 10-year prospective study evaluating the risk of cardiovascular events in RA patients and other forms of inflammatory arthritis who attended rheumatology outpatient clinics at 67 hospitals in Spain. RA patients were classified into four categories: no biologic therapy, undergoing anti-TNF therapy, receiving anti-IL-6 receptor tocilizumab (TCZ), and other biologic therapies (rituximab or abatacept). A model of linear multivariate regression was built in which the dependent variable was Lp(a) concentration and the explanatory variable was biologic therapy. The model was adjusted for confounding factors.

Results: Seven hundred and seventy-five RA patients were analyzed. Total cholesterol and triglycerides concentrations were significantly higher in TCZ-treated patients. Nevertheless, no significant difference in the atherogenic index (TC/HDL-c) between TCZ-treated patients and patients without biological therapy was found. After adjusting for confounding factors, patients treated with biologic therapy had lower plasma concentrations of Lp(a) than those not undergoing biologic therapy. However, only TCZ-treated patients achieved statistically significant differences when compared with those not undergoing biologic therapy (β-coefficient: -0.303, 95% confidence interval: -0.558 to -0.047; p=0.02).

Conclusion: RA patients treated with tocilizumab, an inhibitor of interleukin 6 receptor, show lower plasma concentrations of Lp (a) compared to patients without biological therapy.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) associated interstitial lung disease (ILD) carries a risk for serious infection due to lung disease, immunosuppressive therapy, and RA disease itself.

Methods: All patients with RA-ILD (ACR 1987 criteria for RA) seen at a single center from 1998-2014 were identified and manually screened for study inclusion. Follow-up data were abstracted until death or December 31, 2015, including immunosuppressive

medications at and after ILD diagnosis. Serious infection was defined as an infectious process requiring both antimicrobial therapy and hospitalization. Risk of infection was analyzed by person-year (py) methods using a 30-day washout period after discontinuation of individual medications.

Results: Of the 181 included patients, 87 (48%) were female and 96% were Caucasian. The mean age at ILD diagnosis was 67.4 (±9.9) years with a median time of 4.9 (range: -10.9 to 48.1) years from RA to ILD diagnosis. Median follow-up time was 3.1 (range: 0.01 to 14.8) years. Sixty-seven (37%) were never smokers. Ninety-eight (54%) had usual interstitial pneumonia (UIP), 73 (40%) had non-specific interstitial pneumonia (NSIP), and 10 (6%) had RA-related organizing pneumonia (OP). A total of 54 serious infections were identified of which pneumonia was the most common with (3.9 per 100 py) followed by opportunistic infections (1.5 per 100 py) and septicemia (1.0 per 100 py). Overall infection risk was higher in OP (27.1 per 100 py) than UIP (7.7 per 100 py) or NSIP (5.5 per 100 py) (P<0.001), and did not differ in UIP and NSIP (p=0.24). Pneumonia and septicemia were also significantly more common among OP patients (although number with OP was small) than in UIP and NSIP (p=0.002 and p=0.007, respectively), but there were no differences between groups in opportunistic infections (p=0.63). Immunosuppressive regimens were summarized into distinct groups (see table), of which tumor necrosis factor inhibitors with or without disease modifying anti-rheumatic drug (DMARD) or glucocorticoids was the most common (163.0 py). Sulfasalazine and/or hydroxychloroquine (SSZ/HCQ) were used as the referent group for comparisons and had an infection rate of 2.9 per 100 py. The highest infection rate observed was with a daily prednisone use > 10mg per day with or without additional DMARDs with a rate of 15.4 per 100 py. There were no significant differences observed between baseline and no immunosuppression, methotrexate/leflunomide (MTX/LEF), tumor necrosis factor inhibitor (TNFi) or other DMARD combination. Prednisone > 10mg (RR: 4.40; 95%CI: 1.38, 27.7) and non-TNFi biologic (RR: 3.87; 95%CI: 1.22, 24.3) had the highest risk.

Conclusion: Patients with RA-ILD are at high risk of serious infection. Prednisone use at >10 mg per day was associated with higher rates of infection, and lowest risk was in patients on SSZ/HCQ and TNFi. Channeling bias cannot be excluded.

Table 1. Risk of Serious Infection by Medication in 181 Patients with Rheumatoid Arthritis Associated Interstitial Lung Disease

Medication Category	Number of Patients	Number of Patients with Infections	Number of Infections	Number of Person Years (PY)	Infection Rate per 100 PY
Overall	181	38	54	726.2	7.4
SSZ/HCQ alone*	36	2	2	68.3	2.9
MTX/LEF alone	54	5	8	107.4	7.4
TNFi (with any**)	59	3	3	163.0	1.8
non-TNFi biologic (with any)	38	7	11	81.2	13.5
Prednisone ≤ 10 mg per day alone*	54	4	6	54.4	11.0
Prednisone > 10 mg per day (with any**)	86	11	11	71.5	15.4
Other DMARD or combination	80	8	9	119.6	7.5
No therapy	48	4	4	60.7	6.6

*Alone: without other antirheumatic drug or glucocorticoid **with any: any other antirheumatic drug in combination.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is associated with substantial morbidity in rheumatoid arthritis (RA), but virtually nothing is known about the long-term of progression of pulmonary disease.

Methods: All patients with RA-ILD (ACR 1987 criteria for RA) seen at a single center from 1998-2014 with at least 4 weeks follow-up and at least 1 pulmonary function test (PFT) were identified and manually screened for study inclusion. Follow-up data were abstracted until death, 10 years follow-up or December 31, 2015, including all PFTs within 12 months of initial diagnosis and first PFT for each subsequent follow-up year. Progression was defined as a diffusing capacity for carbon monoxide (DLCO) < 40% predicted/ too ill to perform DLCO or a forced vital capacity (FVC) < 50% predicted. Time to progression was analyzed using Kaplan-Meier methods and Cox models adjusted for age and sex.

Results: Of the 167 included patients, 81 (49%) female, 97% Caucasian, mean age was 67 years (±10) at ILD diagnosis. 62 (37%) were never smokers. Median follow-up time from ILD diagnosis was 3.3 (range 0.01-14.8) years. Eighty-nine (53%) had usual interstitial pneumonia (UIP), 70 (42%) had non-specific interstitial pneumonia (NSIP), and 8 (5%) had RA-related organizing pneumonia (OP). A total of 564 PFTs were abstracted. Baseline PFTs at time of ILD diagnosis (± 6 months) included mean percent predicted FVC of 72% ± 20, forced expiratory volume (FEV1) of 72% ±21, total lung capacity (TLC) of 73% ± 16 and DLCO of 55% ±18. Mean percent predicted DLCO for UIP was 51% ±16, for NSIP 58% ±20, and for OP 74% ±13 (P=0.006). During follow-up, DLCO declined to <40% predicted or were too ill to perform the test in 57 patients, and 29 patients developed an FVC < 50%. By 5 years after ILD diagnosis, 33.2% of patients reached DLCO<40% predicted or were too ill to perform the test and 16.3% of patients reached FVC<50% predicted. Risk factors for progression to DLCO < 40% were UIP (vs NSIP) (hazard ratio [HR]: 2.22; 95% confidence interval [CI]: 1.26, 3.92) and male sex (HR: 1.63; 95% CI: 0.96, 2.75). C-reactive protein at ILD diagnosis was associated with progression to FVC<50% (HR: 1.16 per 10 mg/L increase; 95% CI: 0.97, 1.38). Higher percent predicted DLCO and FVC at baseline reduced the risk for progression to a DLCO < 40% (HR: 0.48 per 10 unit increase; 95% CI: 0.40, 0.58; HR: 0.70 per 10 unit increase; 95% CI: 0.60, 0.82; respectively) and an FVC < 50% (HR: 0.64 per 10 unit increase; 95% CI: 0.48, 0.84; HR: 0.38 per 10 unit increase; 95% CI: 0.29, 0.50; respectively). Estimated rate of change in the first 6 months for FVC was a median increase of 1.0% predicted (interquartile range: -5.0, 7.0) and for DLCO was a median loss of 1.0% (interquartile range: -6.0, 5.0). There was a significant association between the DLCO 6-month rate of change progression to DLCO < 40% (HR: 1.55 per 10-unit decrease; 95% CI: 1.10, 2.18) and between the FVC 6-month rate of change and progression to FVC<50% (HR: 2.44; 95% CI: 1.44, 4.13).

Conclusion: Progressive loss of pulmonary function is common in RA-ILD and is typically worse in patients with UIP than NSIP. A higher baseline DLCO and FVC reduced the risk of progression, but higher rates of change in the first 6 months increased the risk of severe pulmonary impairment.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To characterize a cohort of patients with rheumatoid arthritis (RA) who have interstitial lung disease (ILD) and to assess the utility of the GAP (gender, age, pulmonary function) and ILD-GAP staging system for mortality risk prediction in patients with RA-ILD.

Methods: All patients with RA and ILD seen at a single center from 1998-2014 were identified and manually screened for study inclusion and followed until death or December 31, 2015. All cases fulfilled the 1987 ACR criteria for RA. Pulmonary function test (PFT) results closest to ILD diagnosis were recorded. The GAP and ILD-GAP scores were calculated using age, sex, and lung physiology variables (forced vital capacity [FVC], diffusing capacity for carbon monoxide [DLCO]) at ILD diagnosis. Survival rates were calculated using the Kaplan-Meier method. Cox models were used to examine associations between baseline characteristics and mortality. The accuracy of risk predictions was assessed using standardized incidence ratios and c-statistics.

Results: Of the 181 included patients, 87 (48%) were female and 96% were Caucasian. The mean age at ILD diagnosis was 67.4 (±9.9) years with a median time of 4.9 (range: -10.9 to 48.1) years from RA to ILD diagnosis. Median follow-up time was 3.1 (range: 0.01 to 14.8) years. Sixty-seven were never smokers (37%) and 44 (24%) had erosive disease. Ninety-eight (54%) had usual interstitial pneumonia (UIP), 73 (40%) had non-specific interstitial pneumonia (NSIP), and 10 (6%) had RA-related organizing pneumonia (OP). Anti-citrullinated protein antibodies were present in 77% of 136 tested and rheumatoid factor in 82% of 176 tested. The baseline PFTs at time of ILD diagnosis included mean percent predicted FVC of 72% ± 20 and DLCO of 56% ±20. At last follow-up 72 had died. Pulmonary disease accounting for 21 (29%) of deaths. The five-year survival rate was 59.7% (95% confidence interval [CI] 51.5-69.2). Survival did not differ between ILD types (p=0.42). Baseline risk factors significantly associated with mortality were age at ILD diagnosis (hazard ratio [HR]: 1.34 per 10 year increase; 95% CI: 1.11-1.63) and RA disease duration at ILD diagnosis (age and sex adjusted HR 1.71 per 10 year increase; 95% CI: 1.22-2.39). Lower baseline percent predicted DLCO and FVC were associated with significantly higher mortality (HR: 2.48; 95% CI: 1.55-3.95 and HR: 1.20; 95% CI: 1.04-1.41, per 10% predicted decrease, respectively). GAP and ILD-GAP scores were calculated for 159 patients with PFTs within 6 months of diagnosis. 30 patients died within 3 years of diagnosis. The GAP model predicted 31.0 deaths and demonstrated good calibration (standardized incidence ratio [SIR]: 0.97; 95% CI: 0.68, 1.38) and discrimination (c-statistic: 0.71). The ILD-GAP score reduced the predicted mortality risk, so only 18.3 deaths were predicted within 3 years of ILD diagnosis, this demonstrated poor calibration (SIR 1.64; 95%CI 1.15, 2.35).

Conclusion: In this large single-center cohort of patients with RA-ILD, most patients were seropositive and had a history of smoking. RA-ILD is associated with decreased survival, similar for NSIP and UIP. The GAP model may be useful in informing prognosis and patient management.

Anti-Cyclic Citrullinated Peptide Antibodies and Severity of Interstitial Lung Disease with Rheumatoid Arthritis

Masaomi Yamasaki, Rheumatology, Shin-Yokohama Arthritis and Rheumatology Clinic, Yokohama, Japan
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Serum anti-cyclic citrullinated peptide antibodies (anti-CCP2) positivity was associated with presence of interstitial lung disease and airway disease in rheumatoid arthritis (RA). This study analyze whether high resolutional CT (HRCT) and anti-CCP2 can predict the outcome of ILD in RA.

Methods: 472(Male74/Female398, age 58.9+/-14.0) cases were analyzed in this study. Participants met 2010 ACR/EULAR classification criteria of RA were followed up at least one year as newly onset RA. All patients were also performed chest radiological

examinations at the initial presentation. ILD extension Score was determined based on the presence and extent of ILD features (i.e., ground glass opacification (GGO), reticulation and honeycombing (HC) using a semiquantitative scale at the each of the three zones of each lung with a maximum total score possible of 6. HRCT parameters which include ILD extension Score and titer of anti-CCP2 at the initial presentation were retrospectively analyzed.

Results: 231 out of 472 patients (48.9%) had abnormal chest radiological findings which included bronchiectasis, bronchitis and ILD. 101 out of 472 patients (21.4%) showed ILD at initial presentation. The titer of anti-CCP2 showed statistical difference between RA only vs. RA-ILD patients(Ave. 47.8 and 164.3 U/ml, respectively, $p<0.001$). 6 out of 101 RA-ILD patients showed rapidly progressive ILD. These 6 patients had widely spread honeycombing compared to asymptomatic RA-ILD patients ($p=0.0012$). In 101 RA-ILD patients, higher anti-CCP2 levels were associated with more severe RA-ILD. Average titer of anti-CCP2 in ILD extension Score 1, 2, 3, 4, 6 showed 20.3+/-28.4, 155.0+/-49.6, 290.9+/-26.3, 693.7+/-308.9 and 1582.5+/-120.9 U/ml respectively. Higher extension score of each ILD features GGO ($p=0.0052$), reticulation ($p=0.0047$) and honeycombing ($p=0.0025$) also showed association with higher anti-CCP2.

Conclusion: Anti-CCP2 antibodies are marker of severity and extent of RA-ILD in HRCT. HRCT findings focused on ILD extension Score at the initial presentation is a useful predictor of the outcome of ILD in RA. Anti-CCP2 is one of the related factor of ILD extension Score.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A few cases of the concomitant development of interstitial pneumonia associated with dermatomyositis (DM-IP) and rheumatoid arthritis (RA) have been reported mainly in Asia, but the details are still unclear. The possible induction of dermatomyositis (DM) and polymyositis by TNF inhibitor has been pointed out, but no conclusion has been reached. We investigated the clinical features of DM-IP which concomitantly developed during the treatment of RA.

Methods: The subjects were 14 consecutive patients with DM-IP complicating RA treated at our department between November 2005 and October 2015, and the clinical features, such as patient background, clinical symptoms, examinations, treatment, and outcome, were retrospectively investigated. RA was diagnosed using the 1987 Revised ACR classification criteria and 2010 ACR/EULAR classification criteria, and DM was diagnosed using the criteria of Bohan and Peter. For the classification of clinically amyopathic dermatomyositis (CADM), the criteria of Sontheimer and Gerami were used. IP was diagnosed using chest HRCT, and the pattern was classified following the 2013 Update of the International Multidisciplinary Classification of the Idiopathic Interstitial Pneumonias.

Results: The median (IQR) onset age of DM-IP was 62.5 years old (54-68.5). All patients were female, and 4 were smokers (29%). The duration of RA illness until the development of DM-IP was 1,095 days (577-1,580). DM-IP newly developed during RA treatment in 5 patients at our department and the incidence was 0.57%. Nine patients were transferred for IP treatment from other hospitals. ACPA was >100, 15-100, and <15 U/mL at the time of RA diagnosis in 7 (54%), 3 (23%), and 3 (23%), respectively, RF was 58 IU/mL (33-149), and radiologic damage was noted in 11 (79%). RA was treated with MTX in 6 (42.9%), PSL in 6 (42.9%), BUC in 2 (14.3%), TAC in one (7.1%), biologics in 4 (28.6%) (ETN in 3 and GLM in 1), and others in 4 (28.6%). IP exacerbated within one month in 3 (21.4%) and 1-3 months in 4 (28.6%), and a slow course taking 3 months or longer was observed in 7 (50%). At the onset

time of DM-IP (at the time of diagnosis), KL-6 was 769 U/mL (368-1,215), aldolase was 7.2 U/L (5.8-11.2), CK was 83 U/L (40-331), and ferritin was 119 (91-253) ng/mL. On chest HRCT, the NSIP and OP patterns were noted in 7 each (50%), and no honeycomb lung was seen. In all patients, dorsal lower lung field-dominant shadows newly appeared. On imaging before the development, the NSIP pattern was observed in 4 (28.6%), but no existing feature of IP was noted in 10 (71.4%). DM-IP was treated with PSL in all patients, and IVCY, CsA, and TAC were administered to 3, 9, and 3 patients, respectively. Cyclosporin was administered at 4 mg/kg in all treated cases, and cyclophosphamide was concomitantly administered to severe cases. Regarding the outcome, remission was achieved in all patients without recurrence.

Conclusion: DM-IP frequently developed concomitantly with RA in females with a high ACPA titer. Various DMARDs were used in previous RA treatment, but TNF inhibitor was used as a biological product in all cases. When NSIP and OP appear dominantly in the lower lung field during RA treatment, the concomitant development of DM-IP should be suspected.

The Incidence of Interstial Lung Disease and Malignancies in Veterans with Rheumatoid Arthritis

Katherine Larson[1], Faizah Siddique[2] and Samya Mohammad[1], [1]Virginia Commonwealth University, Richmond, VA, [2]Department of Veterans Affairs, Richmond, VA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic disease with a known association with lymphoma and interstitial lung disease (ILD). ILD is a frequent extraarticular manifestation of RA with a prevalence as low as 4% and as high as up to 68%. Additionally, patients with RA also have been documented to have an increased risk of lymphoma. It is unclear if the increased incidence of lymphoma or ILD is correlated to the disease itself or the treatment. In particular, new attention is being drawn to biologic agents being used to treat severe rheumatoid arthritis and whether these agents in particular, through immune-mediated actions, may specifically pose an increased risk of either ILD or lymphoma. This study aims to examine the incidence for ILD and malignancies in patients at the McGuire Veteran's Medical Center with a diagnosis of RA as well as to examine the whether this incidence is affected by treatment.

Methods: Patients with an ICD-9 code of RA who have received care from a rheumatologist at the McGuire VA Medical Center are included in this study. Diagnosis of malignancy and ILD was determined by ICD-9 codes as well. As of now, 275 patients have met our inclusion criteria. Baseline demographic data, data regarding diagnosis and treatment of rheumatoid arthritis, and diagnosis of cancer and/or ILD were collected.

Results: Based on our current data, compared to the general population, the incidence of malignancy in our veteran population is 49% ($p < 0.0001$). This is higher than the general population. Patients with RA diagnosed at age 65 or above have a higher chance of being diagnosed with cancer (HR 1.089). The incidence of ILD is 9%; however, this is not significant compared to general population ($p = 0.08$). Interestingly, there appears to be a protective effect of treatment with a biologic in patients diagnosed with cancer (HR 0.54).

Conclusion: This is currently an ongoing study to examine the incidence of ILD/malignancy and correlation with biologic agents in the veteran population. The data collected shows an increased risk of malignancy. This appears to be rather notable when RA is diagnosed at an older age (>65). This could imply that later onset RA needs more aggressive treatment, and the potential protective effect of biologics on development of cancer imply that late onset RA may need more aggressive treatment with biologics. More studies need to be done to determine the significance of the protective effect of biologics. Our study is ongoing and sample size should be increased for more robust data. Additionally, study duration should be increased in order to follow younger patients that have been newly diagnosed with RA.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Rheumatoid Arthritis (RA) are at increased risk of infections, especially serious respiratory infections. Immunization is a recommended to reduce these complications. Our aim was to assess the incidence of hospitalizations due to serious respiratory infections before and after the onset a program of systematic vaccination.

Methods: Prospective study of a cohort of 294 patients diagnosed with RA who were invited to participate in a vaccination program. It included seasonal flu vaccination (from October to April), pneumococcal (combined regimen 13-valent and 23-valent vaccines) and haemophilus influenzae type B vaccine. Only 7 patients (2.94%) refused vaccination. The follow-up time of this cohort was from October 1, 2011 (starting date) to June 30, 2015. Information on serious respiratory infection episodes before and after being immunized was conducted using the hospital information system by reviewing hospital records.

Results: 287 RA patients (225 women /62 men), average age 58.1±12.7 years, were vaccinated. The main features at the time of vaccination were: Disease duration (93±95.9 months; Rheumatoid Factor positive in 154 (53.65%), erosive arthritis in 97 (33.8%), and pulmonary fibrosis in 7 cases. Also, at the timwe of vaccination 245 (85.45%) were taking disease modifying drugs, including methotrexate in 98 (34.1%) and/or anti-TNF-alpha therapy in 98 patients (34.1%). In most of the remaining patients vaccination was performed at the time of disease diagnosis. Twenty (7%) patients had required hospital admissions by serious respiratory infections, before being included in the vaccination program. After the onset of the vaccination program only 6 of the 287 patients (2.1%) required admission because of serious respiratory infections **(TABLE).** The reduction achieved from 7% to 2.1% was statistically significant ($p = 0.0017$).

Conclusion: A program that includes systematic vaccination of RA patients seems to be an effective procedure to prevent hospitalizations caused by serious respiratory infections. **TABLE**

Patterns and Factors Associated with Immunization Among Adult Patients with Rheumatic Diseases in the US

Huifeng Yun[1], Shuo Yang[2], Sofia Pedro[3], Jeffrey Curtis[4] and Kaleb Michaud[5], [1]Epidemiology, University of Alabama at Birmingham School of Public Health, Birmingham, AL, [2]Division of Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [3]National Data Bank for Rheumatic Diseases, Wichita, KS, [4]Division Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [5]University of Nebraska Medical Center, Omaha, NE

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rates of adult vaccination are low in patients with autoimmune disease despite broad recommendations for many years. In the U.S., pneumococcal vaccination is recommended for people age 65 or older or with a risk factor (e.g. immunosuppression); herpes zoster (HZ) vaccination is recommended for adults aged 60 years and older, and influenza vaccination has been recommended for all persons aged ≥ 6 months. Despite many studies showing patients with rheumatic diseases or treated with immunosuppressive medications are at an increased risk of infections, but factors associated with receive recommended immunizations

are not well known. We evaluated the pattern of pneumococcal, HZ, and seasonal influenza vaccination and factors associated with receiving these vaccinations among patients participating in a national US. registry.

Methods: We examined patient self-reported survey responses among participants in the National Data Bank for Rheumatic Diseases (NDB) from 2006-2015. After excluding patients who never answered vaccine questions, all adult patients in the registry with a rheumatologist-diagnosed rheumatic disease were eligible for analysis. Patients <60 years old or who enrolled after 2007 were excluded from the analysis of the HZ vaccine use due to incomplete vaccine history. Vaccine administrations and potential confounders were time-varying and updated at the time of each 6 month survey. For pneumococcal and HZ vaccine, follow-up started at the first survey that all required criteria were met and ended at the earlier date of either vaccination, death, or exited the registry. For influenza, patients were allowed to have multiple vaccinations. A generalized estimating equation model with repeated measures was used to evaluate the factors associated with receipt of each vaccine.

Results: Among 21,522 patients (72.8% with RA, 16.9% with OA, 10.1% with Fibromyalgia, 7% with SLE, patients were allowed to have multiple conditions) who were eligible for pneumococcal and influenza vaccination analysis, we identified 9,162 and 84,991 vaccinations, respectively. Of the cohort, 74.7% had at least one influenza vaccination during the 10 years of study period.The proportion of patients receiving the influenza vaccine in each year is on the average of 60%.). 9,867(45.8%) patients never had pneumococcal vaccination and 5,438 (25.2%) patients never had influenza vaccination. Of 11,947 eligible patients for HZ vaccine analysis, 1,724 (14.4%) received the HZ vaccine over a median (IQR: 6 years) of 4.5 years of follow-up. After multivariable adjustment, older age, African American race, biologic use, cardiovascular disease, and prior hospitalization were significantly associated with all three vaccinations. Factors associated with each vaccine vary (see Table).

Conclusion: Overall rates of pneumococcal, HZ, and influenza vaccinations were low among patients with rheumatic diseases. For each type of vaccination, more efforts on different associated factors are needed to improve the vaccination rate. Table: Multivariable factors associated with vaccination among patients with rheumatic diseases in the NDB

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is a chronic autoimmune disease that requires chronic immunosuppressive treatment. Urinary tract infections (UTI) are common among patients with RA. It has been suggested that hydroxichloroquine (HCQ), a drug used in the treatment of RA, may have antimicrobial activity and induce selective resistance to fluoroquinolones in bacterial species. However, this has not been well established.

To evaluate the association between use of HCQ and development of fluoroquinolone resistance in *Escherichia coli* among patients with RA and UTI.

Methods:

Retrospective case-control study. We evaluated 225 patients with RA and UTI. Cases were defined as patients receiving HCQ, and controls as those receiving a different treatment. Demographics and clinical features were assessed, and laboratory data was obtained from urine cultures and antibiotic susceptibility tests. Univariate and multivariate analyses were performed.

Results:

There were 112 subjects in the HCQ group and 113 controls. The mean±SD age in the HCQ group and controls was 51 ± 15.66, and 60 ± 15.35 years, respectively. Duration of RA was 12± 8.67 and 17± 9.48 years in the HCQ and control groups, respectively. Overall, 61% of patients received methotrexate, 50% HCQ, and 29% prednisone. Class I/II functional status was observed in 63% of patients, and class III/IV in 37%. Resistance to ciprofloxacin was found in 102 (45%) patients overall, and it was less common among the HCQ group compared with controls, although the difference was not statistically significant (43% vs. 48%, *p*-value = 0.458). The factors associated with resistance to ciprofloxacin in univariate analysis were: UTI within the last six months, previous antibiotic use, diabetes mellitus, and RA functional status. In logistic regression analysis, RA functional status class and previous antibiotic use were the only significant independent predictors of fluoroquinolone resistance.

Conclusion:

Resistance to ciprofloxacin is common among patients with RA and UTI. We found no evidence that the use of HCQ is associated with fluoroquinolone resistance in patients with RA and *Escherichia coli* UTI. RA functional status class III/IV was a significant independent predictor of fluoroquinolone resistance.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: With the increasing uptake of RA treatments that confer infection risk, an increase in the rates of infection hospitalizations among RA patients is expected, but limited data exists. Additionally, some studies show a doubling of sepsis in the general population in recent years, possibly due in part to changes in coding practices. We sought to investigate the national trends in hospitalization for infections in US patients with rheumatoid arthritis (RA).

Methods: We conducted serial cross-sectional analyses of 1993-2013 data from the National Inpatient Sample, a nationally representative sample of all community hospitals in the US. We identified hospitalized adults with RA using an *ICD-9* codes in any secondary diagnosis field. We evaluated 5 infections as the primary diagnosis: pneumonia, sepsis, urinary tract infection (UTI), skin and soft tissue infections (SSTI), and opportunistic infections (OI). The primary outcome was the proportion of hospitalizations for each infection, among all hospitalizations with a secondary diagnosis of RA. We considered the proportion of myocardial infarction (MI) hospitalizations among RA as a control condition, since reports indicate decreased incidence. We also calculated the incidence of each infection among RA patients by year, using an estimate of the national adult RA population as 1% of the adult US census population. The Cochran-Armitage Trend Test was used to examine trends.

Results: From 1993 to 2013 there were 792,921 hospitalizations for infection with a secondary diagnosis of RA. Hospitalizations with any secondary RA code increased from 60 to 160 per 100,000 persons (US general population). Among RA patients, the proportion of hospitalizations decreased for pneumonia (5.4 to 4.6%, $p<0.001$), UTI (0.42 to 0.38%, $p=0.04$), and OI (0.44 to 0.26% ($p<0.001$). The rate for SSTI increased slightly (2.3 to 2.5%, $p<0.001$), while the proportion of hospitalizations for sepsis more than tripled (1.9 to 6.4%, $p<0.001$). Consistent with previous reports, MI hospitalizations decreased from 2.2 to 1.8%. Using the theoretical national RA population as the denominator, without accounting for the increased RA coding over the study period, there appeared to be an increase in the rates of all infections: pneumonia (0.48 to 0.96%), UTI (0.37 to 0.79%), SSTI (0.20 to 0.52%), OI (0.039 to 0.055%) and sepsis (0.17 to 1.32%); all p values <0.001.

Conclusion: Between 1993 and 2013, the proportion of hospitalizations for infections among RA patients declined for pneumonia, UTI, and OI, with a small increase in the proportion for SSTI and a marked increase in sepsis. The sepsis results are consistent with previous reports that the sensitivity of sepsis coding has increased, but still warrant confirmation in other data sets such as RA cohorts. There has been a doubling of coding for RA in hospital discharges, which should be investigated further and acknowledged in studies using hospitalization data.

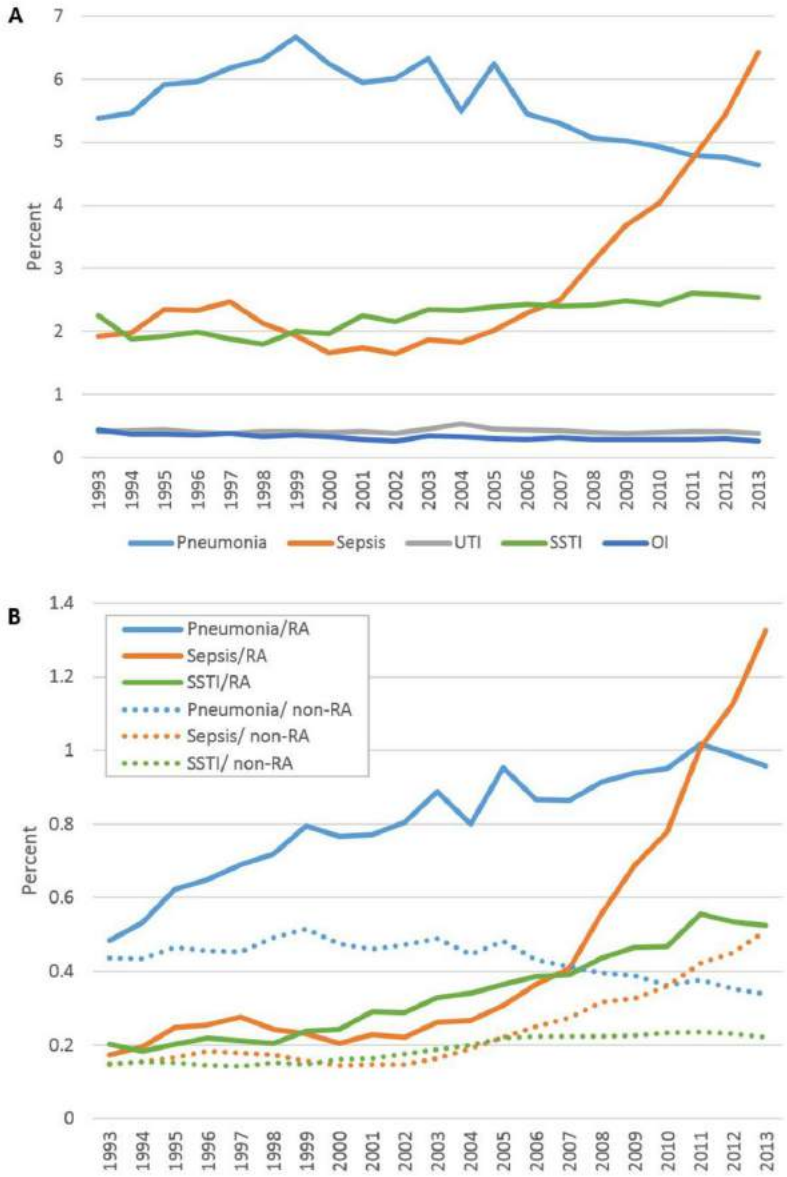

Figure. A. Proportion of all US RA hospitalizations for infection, stratified by infection type; **B.** Incidence of hospitalized infection for pneumonia, sepsis and SSTI among RA (solid lines) and non-RA (dashed lines), from 1993-2013 National Inpatient Sample.
RA: rheumatoid arthritis, UTI: urinary tract infection, SSTI: skin and soft tissue infections, OI: opportunistic infections

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Influenza and pneumococcal vaccinations are recommended in all patients with RA. However, it is well known that a gap exists between recommendations and their implementation in real life. As EULAR recommendations for vaccinations are now widely disseminated, we took the opportunity of assessing vaccination rates of the patients who participated in the COMEDRA study [1], both at study entry and 3 years after the trial ended, to assess the progression of vaccination rate in this long-standing RA population undergoing a nurse-led program.

Methods: This was an open long term (3 years) extension of the COMEDRA 6 month randomized controlled trial in which patients with definite, stable RA were visiting a nurse for comorbidity counselling. Vaccination status was assessed during the RCT and nurses provided advice on vaccinations, and again 3 years later, during a face-to-face interview with a nurse. Agreement with the vaccination recommendations was defined as (a) influenza vaccination performed within the last 12 months and (b) pneumococcal vaccination performed within the last 5 years. The proportion of patients in accordance with the recommendations was compared between baseline and 3-year assessment using a McNemar test for paired data. The probability to be in accordance with recommendations was assessed by logistic mixed models including in the model the patient as random effect and as fixed effects: age, gender, disease duration, DAS28, educational level, work status, any biologic at baseline, and trial group and centre.

Results: Of the 970 recruited patients, 776 (80%) were followed up at 2-4 years and 759 (78%) had available data regarding both influenza and pneumococcal vaccination status: mean (±sd) age 58 (±11) years, mean disease duration 14 (±10) years; 607 (80%) were women and 538 (70%) were receiving a biologic. The mean baseline and 3-year DAS28 scores were respectively 2.99±1.30 and 2.83±1.34. At baseline, 337 (44.4%), 459 (60.5%) and 252 (33.2%) patients were in agreement with recommendations for influenza, pneumococcal and both vaccinations, respectively. After 3 years, this agreement increased for both vaccinations, to 420 (55.3%), 499 (65.7%) and 317 (41.8%) respectively. (Table 1) Having ever received a biologic (odds ratio, OR= 4.73 [95% CI: 2.62 - 8.52]), centre size (OR=2.8 [1.04-1.7]) , university education (OR=1.79 [1.11 - 2.89]) and higher age (OR=1.07 [1.04 - 1.10]), were independently associated with being in accordance with both vaccinations recommendations .

Conclusion: the agreement with the EULAR vaccination recommendations is moderate but has increased in patients who had participated in a nurse-led program aiming at checking systematically for vaccination status.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: According to the report by WHO, Japan is still in moderately-prevailing countries of TB. The annual incidence of TB in Japan is approximately 15/100,000, which is 4 – 5 times higher than those in western countries. The incidence of TB in patients with RA is reported to be 2 – 3 times higher than that of general population. Moreover the TB incidence increases 4 – 5 times when bDMARDS are used for the treatment. Therefore, the TB incidence becomes approximately 10 times higher than that of general population when prevention of TB is not done properly. We, in this study, aimed to show the effectiveness of our strategy of TB prevention in patients with rheumatic diseases under the treatment with bDMARDS.

Methods: Subjects were 235 patients with rheumatic diseases who were introduced with bDMARDS, most of them were RA. The mean age was 62 with the range of 18 – 90 years. The duration of administration of bDMARD was 0.25 – 11.8 years, including 2nd bDMARDS and thereafter, with the mean duration of 3.0 years, and the total duration of administration was 818 years. TB prevention by isoniazid (INH) was applied to patients who fit more than 1 of the following 5 items (risk factors). They are; 1. more than 70 years of age, 2. moderate or strong positive tuberculin skin test (STS), 3. positive or intermediate QuantiFerron (QFT) result (intermediate result was established by Japan Society for TB), 4. findings suggestive of old TB on chest CT, and 5. history of treatment of TB. In addition, there were patients who chose to had prevention after consulting attending physicians. The duration of INH administration was 9 months. The reasons why patients of more than 70 years of age was indicated for TB prevention are as follows; 1. more than 50 % of TB patients in Japan are more than 70 years of age, 2. TB incidence of more than 70 years of age is very high (approximately 50/100,000), and 3. compatible with the BTS guideline of TB prevention.

Results: Tb prevention was done for 166 patients (70 %). The number of patients who had 0, 1, 2, 3, 4, 5 risk factors listed above were 30, 91, 31, 6, 7, 1, respectively. Thirty patients took INH despite they did not have risk factors. In patients with one risk factor, the most risk factor was advanced age, followed by positive STS, chest CT findings, and positive QFT. Five patients did not take INH despite

that they had risk factors. Predictive value of TB development was calculated from the annual incidence stratified by age and the duration of bDMARDS administration. It was estimated to be 2.2, but no TB developed actually.

Conclusion: Our strategy of preventing TB by INH is so far working well.

Title: Prevalence and Clinical Characteristics of Rheumatoid Arthritis in Sickle Cell Patients

Background/Purpose: Rheumatoid arthritis (RA) has been rarely reported in association with sickle cell disease (SCD). It was hypothesized that sickle cell-associated vasculopathy impairs angiogenesis; a key step in the formation and maintenance of the panus in RA, thus preventing the development of RA. However, there is no substantial data available on the prevalence and clinical characteristics of RA in SCD patients. We performed a cross-sectional analysis to estimate the prevalence of RA in SCD population and to describe the clinical characteristics of RA associated with SCD.

Methods: Retrospective chart review of SCD and RA patients followed at 2 large urban hospitals. Seven RA/SCD patients were identified and compared to age and sex matched cohort of SCD only and of RA only group. All patients were black.

Results: Of the 658 SCD cases, 7 (1.0%) met ACR criteria for RA (SCD-RA), 411cases were RA only group. Mean age = (41.1±2.21 (±SEM) vs 34.55± 0.13), vs.60.7±16.3 P<0.01. Compared to age and sex matched groups of RA and of SCD, RA/SCD group tended to have more frequent hospitalization and increased LOS, as well as lower hemoglobin / hematocrit values. Other clinical and biochemical characteristics were similar for the 3 groups (table1). There were also no significant differences in rheumatologic parameters between SCD/RA and RA only groups, except for increase in periarticular osteopenia and difficulty in ADL among SCD/RA cohort (table2). **Table 1 Comparison** of the Clinical and Biochemical Characteristics of SCD, SCD and RA, and RA patients.

Measurements	SCD (n=7)	SCD+RA (n=7)	RA (n=7)	P-Value
Age	41.7 ± 3.9	41.7 ± 3.9	39.8 ± 4.1	0.93
Body Mass Index	23.5 ± 0.86	20.8 ± 1.9	25.6 ± 2.1	0.17
Systolic BP	119 ± 4.7	118 ± 5.0	128 ± 4.9	0.3
Diastolic BP	70 ± 1.8	68 ± 4.3	79 ± 5.8	0.19
Hemoglobin	8.3 ± 0.6	7.4 ± 0.49	11.0 ± 0.59	**<0.01**
Hematocrit	25.7 ± 1.7	23.1 ± 1.5	34.6 ± 1.5	**<0.01**
CRP	38.6 ± 23.3	12.2 ± 5.6	38.1 ± 13.8	0.47
ESR	63.0 ± 15.4	71.6 ± 20.2	37.0 ± 10.0	0.23
Lymphocyte Count	3.0 ± 1.9	3.9 ± 2.2	1.7 ± 1.0	**0.023**
Creatinine	0.57 ± 0.057	0.72 ± 0.097	0.8 ± 0.087	0.09
Reticulocyte Count	9.5 ± 2.4	13.2 ± 2.3	-----	0.28
# of Hospitalizations	8.7 ± 3.2	9.1 ± 4.9	1.8 ± 0.14	0.26
Total length of stay in hospital	52.1 ± 24.6	88.2 ± 40.7	6.4 ± 2.2	0.13
# ED visits	30.7 ± 22.0	12.8 ± 5.4	4.5 ± 0.86	0.37
# Blood transfusions	6.2 ± 3.8	6.5 ± 3.7	0.71 ± 0.47	0.34
Acute Chest Syndrome	71.4% (5/7)	71.4% (5/7)	-----	1.0

Table 2 Comparison of Clinical Characteristics and Radiographic Profiles in patients with SCD and RA, and RA alone.

Measurements	SCD + RA (n=7)	RA (n=7)	P- Value
Rheumatoid Factor	86% (6/7)	71% (5/7)	0.46
Anti-citrullinated protein antibody	83% (5/6)	60% (3/5)	0.54
Antinuclear antibody	40% (2/5)	50% (3/6)	1.0
Prednisone	71.4% (5/7)	71.4% (5/7)	1.0
Methotrexate	42.9% (3/7)	71.4% (5/7)	0.59
Hydroxychloroquine	14.3% (1/7)	14.3% (1/7)	0.26
Biologics	14.3% (1/7)	14.3% (1/7)	1.0
Leflunomide	42.9% (3/7)	42.9% (3/7)	1.0
Duration of Morning Stiffness	127.5±18.8	55.3±34.7	0.10
Peri-articular Osteopenia	100% (5/5)	0% (0/5)	**0.01**
Erosive arthritis	50% (3/6)	17% (1/6)	0.54
Difficulty with ADLs	57 % (4/7)	0% (0/7)	**0.01**

Conclusion: The prevalence of RA among SCD patients is similar to that of the general population and is associated with increased hospitalizations and length of stay as well as difficulty in activities of daily living. This is contrary to previous reports from 1980-1990s indicating rare occurrence of RA in SCD patients. Given the increase prevalence of RA with age, our findings are likely a reflection of increased longevity among SCD patients with hydroxyurea and other modern interventions.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporotic fractures represent one of the serious extra-articular manifestations of rheumatoid arthritis (RA). The aim of this study was to investigate whether fracture incidence differs between patients with early RA diagnosed in the 1990s and the 2000s, and compared to the general population.

Methods: The RA-patients were recruited from the BARFOT (Better Anti-Rheumatic FarmacO Therapy) cohort, which is a Swedish multicentre observational study of patients with early RA. All patients fulfilled the 1987 American College of Rheumatology classification criteria and were included between 1992 and 2006. For each patient four reference subjects matched for sex, age and residential area were randomly selected from the general population using data from the Swedish Central Statistics Office. Cases with new osteoporotic fractures were identified through the Swedish National Inpatients Register, the Swedish Outpatients Register and the Swedish Cause of Death Register until December 2013. Analysis were performed for the total study population and also stratified by inclusion period; 1992-1999 and 2000-2006.

Results: During a mean (SD) follow-up period of 14 (3.9) years 617 of 2751 (16.8%) patients with RA and 1901 of 11004 (13.6%) of controls had an osteoporotic fracture ($p < 0.001$). 18.2% of RA-patients included 1992-1999 (n=314) experienced a fracture (controls 14.8%; p=0,001) and 15.9% of RA-patients included 2000-2006 (n=303) experienced a fracture (controls 12.4%; p=0.002). Compared to the controls the risk HR (95%CI) of sustaining any clinical fracture in the whole RA-group was 1.33 (1.18, 1.50) ($p<0.001$). The risk was increased for both inclusion periods; 1990s 1.28 (1.09, 1.52) (p=0.003) and 2000s 1.41 (1.17, 1.70) ($p<0.001$), although the patients included later more often started treatment with DMARDs at the first visits, inclusion; 88% vs 65% ($p<0.001$) and at 3 months follow-up; 90% vs 72% ($p<0.001$).

Conclusion: Our study showed an increased risk of osteoporotic fractures in patients with early RA compared with population based reference subjects matched for sex and age and residential area. This was also shown when stratified by the 1990s and the 2000s.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Along with increased proportions of patients using methotrexate (MTX) and biological agents (from 34.2% and 0.0% in 2000 to 77.3% and 18.8% in 2013, respectively), the proportions with DAS28 remission and low disease activity increased from 8.4% and 13.8% in 2000 to 54.7% and 20.8% in 2013, respectively, based on our observational cohort of Japanese patients with RA, the Institute of Rheumatology, Rheumatoid Arthritis (IORRA). Trends for malignancies in patients with RA have not been examined comprehensively in a specific cohort. The aim of this study is to investigate the trends in the occurrence of overall and site-specific malignancies in Japanese patients with RA over a long period.

Methods: Among Japanese patients with RA enrolled in the IORRA, all malignancies occurring from April 2000 to September 2013 were extracted from self-reported information and confirmed by medical records. Malignancies occurring in patients who dropped out

of the IORRA study during the subsequent 3 months were also collected by follow-up mailings and medical information from affiliated hospitals. For malignancies overall and at frequently involved sites (breast, malignant lymphoma, stomach, lung, colorectal), the standardized incidence ratios (SIRs) and 95% confidence intervals (CIs) during 3 periods (pre-biologics, 2000-2003; early biologics, 2004-2007; and late biologics, 2008-2011) were calculated based on data from the general Japanese population.

Results: Among 11,106 Japanese patients with RA (68,483 person-years), 507 malignancies (72 breast cancers, 68 malignant lymphomas, 65 stomach cancers, 60 lung cancers, 54 colorectal cancers) were confirmed. The incidence of overall malignancies decreased gradually, with SIRs (95% CIs) of 0.96 (0.80-1.14) in pre-biologics, 0.95 (0.80-1.11) in early biologics and 0.91 (0.79-1.05) in late biologics, respectively (*P* for trend = 0.43 by Poisson regression). The lung cancer incidence decreased to a level comparable to that of the general Japanese population, with SIRs (95% CIs) of 1.68 (1.07-2.53), 0.60 (0.29-1.10) and 0.97 (0.60-1.48), respectively. The incidence of malignant lymphoma was markedly increased, with SIRs (95% CIs) of 4.53 (2.59-7.35), 4.06 (2.36-6.50) and 4.59 (3.00-6.72), respectively.

Conclusion: Trends in the occurrence of overall and site-specific malignancies in Japanese patients with RA did not increase with the expanding use of MTX and biological agents in this decade.

Malignancy	Pre-biologics (2000-2003) (Male, 3,376 pys; Female, 16,171 pys)	Early biologics (2004-2007) (Male, 3,482 pys; Female, 17,682 pys)	Late biologics (2008-2011) (Male, 3,502 pys; Female, 19,015 pys)
	SIR (95% CI)	SIR (95% CI)	SIR (95% CI)
Total	0.96 (0.80-1.14)	0.95 (0.80-1.11)	0.91 (0.79-1.05)
Breast	0.61 (0.30-1.09)	1.37 (0.95-1.92)	0.64 (0.40-0.97)
Malignant lymphoma	4.53 (2.59-7.35)	4.06 (2.36-6.50)	4.59 (3.00-6.72)
Stomach	0.95 (0.57-1.48)	0.90 (0.55-1.38)	0.81 (0.50-1.25)
Lung	1.68 (1.07-2.53)	0.60 (0.29-1.10)	0.97 (0.60-1.48)
Colorectal	0.44 (0.21-0.81)	0.66 (0.39-1.04)	0.68 (0.43-1.02)

pys: person-years; SIR: standardized incidence ratio; CI: confidence interval

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and depression is closely associated with each other. The serum level of neurotrophic factors are related with the major depressive disorder (MDD). However, the impacts of disease activity, pro-inflammatory cytokines and neurotrophic factors on depression in RA patients have not well studied. The aims of this study were to determine the risk factors for depression and to examine the effect of disease activity, pro-inflammatory cytokines and neurotrophic factors on depression in patients with RA.

Methods: This cross sectional study was conducted from Jan, 2014 to Jan, 2015 from 3 university hospitals. Demographic and laboratory data were examined and routine assessment of patient index data 3 (RAPID 3) questionnaire and 28 joints disease activity score (DAS28-CRP) were assessed for disease activity. Depression was measured by Korean version of the Beck Depression Inventory second edition (K-BDI II). Serum level of pro-inflammatory cytokines and neurotrophic factors such as BDNF, VEGF, GDNF, and IGF-1 were assessed by ELISA.

Results: A total of 507 RA patients were recruited. The prevalence of depression was 33.1% (n=168). RAPID 3 score (OR 1.2, 95% CI 1.1-1.4, P=0.006) and severity of fatigue (OR 1.19, 95%CI 1.07-1.32, P=0.001) showed significant associations with depression in multivariate analysis. The RA patients with DAS 28-CRP $\geq$3.2 (n=126) had more risk for depression than those with DAS 28-CRP<3.2 (n=279) in multivariate analysis (OR 2.02 95% CI 1.34-3.06, p=0.006). When patients was followed up for a year after strict treatment, as DAS28-CRP decreased, BDI score also decreased (ΔDAS28-CRP: -1.4±1.6, and ΔK-BDI II: -5.4±10.1, P<0.001). There were no relationships between pro-inflammatory cytokines and depression (IL-1β: r=0.057, IL-6: r=0.169, TNF-α: r=-0.078). In the case of neurotrophic factors, only the level of BDNF showed weakly correlation with K-BDI II score (r=-0.233, P<0.001).

Conclusion: This study suggests strict control of fatigue and disease activity is important in regulating depressive symptoms in patients with RA. To evaluate psychological manifestation of RA patients, using both RAPID 3 score and DAS28 might be helpful. Larger studies of the possible role of BDNF should be conducted.

Bone Structural Deficits in Rheumatoid Arthritis: Impact of Muscle Mass and Density

Joshua Baker[1], Jin Long[2], Babette S. Zemel[3], Janet E. Dinnella[4], Prerna Sharma[5], Said Ibrahim[6] and Mary B. Leonard[7], [1]Medicine/Rheumatology, University of Pennsylvania, Philadelphia, PA, [2]Stanford University, Palo Alto, CA, [3]Pediatrics, The Children's Hospital of Philadelphia and the Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [4]Arthritis/Immun Center, U Penn & VA Med Ctr, Philadelphia, PA, [5]University of Pennsylvania, Philadelphia, PA, [6]Medicine, University of Pennsylvania, Philadelphia, PA, [7]Pediatrics, Division of Nephrology, Stanford School of Medicine, Stanford University, Palo Alto, CA

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with muscle loss, obesity, and osteoporotic fractures. Body composition and muscle quality are important regulators of bone strength among healthy adults. This study determined if patients with RA have deficits in cortical bone thickness (CBT; a structural measure highly correlated with fracture load) and trabecular bone density (TBD; a measure of volumetric bone mineral density) relative to their body mass. The study also assessed the degree to which these deficits are related to deficits in skeletal muscle.

Methods: Participants with RA, ages 18-75 years, were recruited from academic practices (2012-2016) and compared to a reference sample of healthy controls (ages 21 to 80). Participants underwent peripheral quantitative CT (pQCT) of the tibia to measure CBT and TBD as well as muscle cross-sectional area and density and fat area. Whole-body DXA measured appendicular lean mass index (ALMI), and fat mass index (FMI). BMI and body composition measures were converted to age-, sex, and race-specific Z-Scores. Multivariable linear regression models evaluated independent associations between body composition exposures and bone outcomes in RA and controls with assessment for altered associations in RA.

Results: The study consisted of 102 RA patients (50 men) and 416 controls (192 men). Patients with RA had greater BMI (p=0.004), greater total fat mass (p=0.02) and lower adiposity-adjusted ALMI Z-Scores (p=0.004), and low muscle density Z-Scores (p<0.0001). TBD and CBT Z-Scores were similar in RA and controls. However, RA patients had lower Z-Scores for bone outcomes compared to controls with similar BMI Z-Score (**Figure**). Sequential adjustment for ALMI, FMI, and muscle density Z-Scores in linear regression models attenuated these associations. Results were similar in analyses incorporating pQCT muscle and fat cross-sectional area Z-Scores. Relationships between body composition and bone outcomes were similar in RA and controls (no interaction) (**Table**). Men with RA had lower TBD Z-Scores than women with RA (p=0.005). Disease duration >10 years was associated with lower TBD (p=0.07) and CBT (p=0.04) independent of sex, ALMI, and FMI.

Conclusion: Patients with RA have bone structure and density that is maladapted to their weight. Muscle deficits in RA likely contribute to bone deficits through a loss of mechanical loading. Deficits in muscle mass and quality are, therefore, under-recognized risk factors for maladapted bone structure in RA; potentially impacting the long-term risk of fracture.

Figure: Estimation of bone deficits (by standard deviation score) between RA and controls in sequential linear regression models.

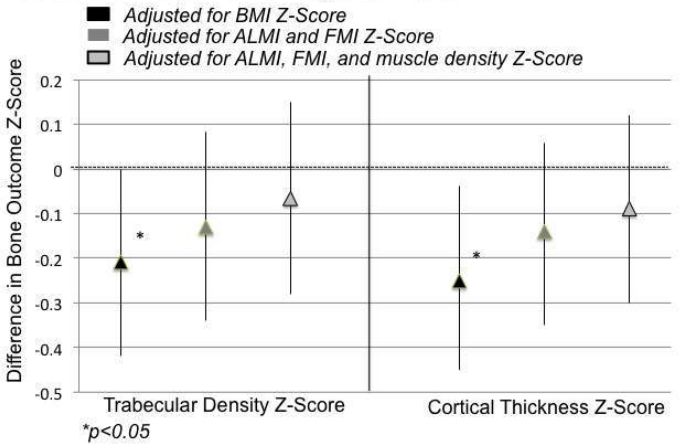

Table: Beta-coefficients representing associations between body composition and bone structure outcomes in patients with RA and controls. RA has similar relationships (no significant disease interaction) between body composition, muscle quality and bone outcomes.

	Rheumatoid Arthritis (N=102)		Controls (N=416)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis is a well-known complication in patients with rheumatoid arthritis (RA). The FRAX tool is an online computer-based algorithm developed by WHO to evaluate the 10-year risk of an osteoporotic hip fracture and major fracture (hip, clinical spine, proximal humerus or forearm fracture). Clinical risk factors include age, height and weight and dichotomized risk factors comprising prior fragility fracture, parental history of hip fracture, current tobacco smoking, ever use of long-term oral glucocorticoids, RA, other causes of secondary osteoporosis and alcohol consumption. Bone mineral density (BMD, g/cm2) of the femoral neck can be optionally included as a risk factor but FRAX does not provide recommendations on which side to measure BMD.

The usability of fracture risk assessment without BMD has been evaluated on group level, but the agreement between fracture risks assessed with and without BMD in individual patients has not met much attention. The objective of this study was to investigate the intra-individual agreement between 10-year fracture risk calculated with and without BMD in patients with RA.

Methods: Data from 50 RA patients registered in the Danish registry for biological treatment in rheumatology (DANBIO) were used for analysis. BMD of the left and right femoral neck had been measured using a Lunar iDXA-scanner (GE, Lunar) by experienced laboratory technicians. The intra-individual agreement between fracture risk assessed with and without BMDs was examined using the Bland-Altman method. 95 % lower and upper limits of agreement (LLoA and ULoA) were estimated as the mean difference (bias) in percent points (pp) between paired measurements ± 1.96SD (2.5 % - 97.5 % range for side comparison due to screwed distribution). Student's t-test was used for comparison on the group level.

Results: Mean age was 63.6 ± 11.7 (range 40-50) years, mean disease activity score (DAS28-CRP) 3.3 ± 3.5 and the mean femoral neck T-score -1.4 ± 1.2. 64 % of the patients were on oral steroids, 50 % on DMARDs and 46 % on biological treatment (±DMARD). The mean 10-year risk of a major fracture and a hip fracture calculated with BMD was 22.9 ± 15.8 % and 8.5 ± 10.8 %, respectively. The LLoA and ULoA [bias] for major fracture risk calculated with BMD (side with lowest value) and without BMD were -14.5 pp and 20.4 pp [2.93 pp, $p < 0.05$]. For hip fracture risk, LLoA and ULoA were -14 pp and 23.2 pp [4.6 pp, ($p < 0.001$)]. When calculating fracture risk based on the side with lowest versus the highest BMD-value, the LLoA and ULoA for hip fracture were 0 pp and 6.8 pp [0.8 pp, $p < 0.001$] and for major fracture 0 pp and 7.3 pp [1.0 pp, $p < 0.001$]. There was an overall trend of a greater bias, the higher the FRAX fracture risk but the bias was lower and LoA more narrow in osteopenic and osteoporotic patients compared to patients with normal BMD.

Conclusion: The FRAX 10-year fracture risk estimated with and without BMD may disagree to a substantial degree in individual RA patients and should therefore not be considered inter-changeable in the daily clinic. Choice of measurement side may also impact the fracture risk assessment, especially in the individual patient.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Depression and anxiety disorders are common in RA patients, with the most recent prevalence estimates indicating that 16.8% of RA patients have a diagnosis of depression and 25.1% of RA outpatients have screened positive for anxiety (1,2). In RA patients, depression and anxiety have been shown to be associated with increased pain, fatigue, reduced quality of life, and increased healthcare utilization use. Our aim was to examine the longitudinal impact of depression and anxiety on RA disease activity and functional status in a cohort of RA patients with established disease.

Methods: Data from a prospective longitudinal RA cohort study were analyzed and included joint exams, serological analyses, and patient reported measures. The Mental Health Index-5 (MHI-5), a validated scale that screens for depression and anxiety, was collected annually for two years. At baseline, univariate analyses were performed using MHI-5 as a dichotomous variable (scale 0-100, ≤65 positive for mood/anxiety disorder) to study the association between depression/anxiety with age, gender, ethnicity, seropositivity,

education, social support (Berkman Social Network Index), disease duration, disease activity measures (DAS28-CRP3, RADAI, CRP), and functional disability (MHAQ). To examine the association between MHI-5 and outcomes of disease activity and functional disability, linear repeated mixed model analyses were performed where the predictor variable, MHI-5 mood/anxiety disorder, was lagged by one year in relation to the outcomes.

Results: Of 992 participants analyzed, the average age was 57 (±13.6) years, most were female (82.6%), with an average disease duration of 13.8 (±11.9) years. Univariate analyses showed that MHI-5 scores were associated with DAS28-CRP3 ($p<0.0001$), MHAQ ($p<0.0001$), education ($p=0.04$), and social support ($p=0.0006$). The linear repeated mixed model analyses indicated that MHI-5 mood/anxiety disorder predicted worse DAS28-CRP3 ($p=0.0002$), worse RADAI scores ($p<0.0001$), and worse MHAQ scores ($p<0.0001$) one year later. MHI-5 score did not predict worse CRP levels overtime ($p=0.48$) (Table 1). Lower education also predicted worse DAS28-CRP3 ($p=0.03$), RADAI ($p=0.0007$), and MHAQ ($p=0.0002$) scores.

Conclusion: Symptoms of depression and anxiety defined by the MHI-5 score, predict worse disease activity and functional disability in RA patients. Ongoing monitoring and treatment of a patient's mental health is important and may impact long-term RA outcomes.

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Periodontitis and rheumatoid arthritis (RA) are chronic destructive inflammatory diseases with significant worldwide prevalence. They are characterized by inflammatory lesions adjacent to bone destruction involving connective tissue and bone. Dickkopf-1 (DKK-1) is a major regulator of bone mass; however, their involvement in local bone resorption is largely unknown. The aim of this study was to assess the utility of DKK-1 levels in gingival crevicular fluid (GCF) and serum as a potential predictor of bone loss in periodontal disease and/or early RA

Methods: Cross-sectional study. Samples of serum and GCF (including 240 interproximal periodontal sites) were obtained from 24 patients with early RA. Adult patients were classified according to the 2010 ACR-EULAR criteria. The periodontal diagnosis was stablished according to the American Association of Periodontology and the Center for Disease Control and Prevention. Radiographs from hands and feet were taken and evaluated using the Sharp-van der Heijde score (SvH) as well as dental cone-beam computed tomography (CBCT) to evaluated interproximal sites. Serum DKK1 levels were determined by ELISA. An association analysis was made to evaluate the relationship between Dkk1 levels and periodontal, rheumatologic or radiographic scores using X2 test, and a multinomial or basic logistic regression model was performed to confirm this associations. The comparisons for Dkk1 levels and bone loss by tomography according to rheumatic scores were made by Kruskal Wallis and U Mann-Whitney tests. This study was approved by the Ethics Committee of the Institution

Results: Mean age 50±12.0 years, Bone Mass Index 25.3±3.6, C-reactive protein 4.6±20.7, ESR 15±21.7, DAS28-ESR 4.04±1.4, SDAI 17.5±22.28, HAQ 1.3±2.4, APCA IgG/IgA 130.5±7.8, RF 33.2±54.6, SvH 50.4% without the presence of erosion or decreased joint space, 66.6% periodontal diagnosis with moderate severity of 33.3% with 59.6% bone loss in interproximal sites (CBCT). GCF DKK1 levels showed a relationship with periodontal bone loss (p = 0.011). DKK1 levels were associated with both periodontal diagnosis and periodontal severity (p = 0.07 and 0.011 respectively). That condition was maintained for periodontal severity (OR: 2.58 $IC_{95\%}$ 2.28 – 7.28 p= 0.001). 47.5% of GCF DKK1 high levels had also increased DKK1 serum levels (p = 0.022 by X2; OR: 2,41 $IC_{95\%}$ 1.14 – 5.09 p= 0.021). It was observed associations between GCF-DKK1 levels and the activity score DAS28ESR (p = 0.000), HAQ (p = 0.000; RRR: 1,96 $IC_{95\%}$ 1.04 – 4.21 p= 0.035), RAPID 3 (p = 0.000) and presence of painful joints (p = 0.04). Despite that, It was not observed associations between GCF-DKK1 levels and SvH. However, feet bone erosion evaluated by SvH and juxta-articular osteopenia were associated with high levels of serum DKK-1 (p=0.009 and 0.001 respectively), showing serum levels up to 7 folds increased. Serum DKK1 levels also showed associations with SDAI (p=0.006; RRR: 2,38 $IC_{95\%}$1.03 – 5.52 p= 0.043), RAPID (p=0.000) and RF (0.018).

Conclusion: The DKK1 can be considered as a potential biomarker for bone resorption in joint and periodontal disease in patients with early rheumatoid arthritis. Seror R et al. Sci Rep. 2016; 20:18421

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In primary Sjögren's syndrome (pSS), labial minor salivary gland epithelial cells (LMSGEC) inappropriately express various molecules, including B7, HLA-DR, ICAM, as assessed previously by in-situ and in-vitro studies, indicating an epithelial cell activation. Sicca symptomatology is encountered in around 30% of rheumatoid arthritis patients (RA-sicca). We previously showed that RA-sicca labial minor salivary gland (LMSG) lesions differ from those observed in pSS, primarily by displaying higher frequency of antigen presenting cells (APCs) [1]. Also, in a subgroup of RA-sicca patients, LMSGECs were found to express the B7 molecule. Interestingly patients exhibiting B7-positive LMSGECs had distinct histopathological and clinicoserological characteristics resembling those observed in pSS. We sought to further investigate if there is, indeed, evidence of a pSS-like epithelial activation in this subgroup of RA-sicca patients.

Methods: Serial sections of LMSGs from 32 RA patients (2010 ACR criteria) with sicca symptoms were evaluated with immunohistochemistry for the presence of total T cells, helper and cytotoxic T cell subpopulations, B cells, macrophages (MΦ), interdigitating (iDC) and follicular dendritic cells (fDC) and for the expression of B7, HLA-DR and ICAM molecules. Stained cells and total mononuclear cells (MNC) were counted in the entire section. Counts were expressed as cell frequency (% of cell type/total infiltrating MNC numbers) and staining for activation markers was assessed on an arbitrary scale (0-1). Correlations between epithelial cell activation status and cell frequencies or clinicoserological features were performed.

Results: LMSGECs in 16/32 patients were triple (B7.1, HLA-DR, ICAM) positive while the rest were either single, double or triple negative. Triple positive patients versus the remaining ones had more severe LMSG lesions (focus score; Mann Whitney, $p=0.05$) and exhibited lower frequencies of MΦ, iDCs and fDCs (Table 1). No differences on clinicoserological features were observed among groups. Expression of the aforementioned molecules by primary cultured LMSGECs of the same patients will be confirmed by flow cytometry.

Conclusion: A distinct subgroup was identified within the RA-sicca patients. This is characterized by expression of activation markers by their LMSGECs and also by an immunohistopathological pattern resembling pSS rather than RA-sicca. In vitro studies of primary LMSGEC cultures will confirm if these cells are indeed activated in such patients. 1. GE Fragoulis, et al. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease activity is considered to improve in approximately 75% of patients with rheumatoid arthritis (RA) during pregnancy. This figure, however, is derived from historical data from mostly retrospective studies, which lack standardised and objective measures of disease activity. More recently, prospective studies have been carried out in patients with various forms of inflammatory arthritis using validated disease activity scores, which have shown a more modest improvement in disease activity during pregnancy. We carried out this systematic review of prospective studies to examine whether inflammatory arthritis truly does improve during pregnancy.

Methods: A systematic review of PubMed, EMBASE/Medline, Cochrane and LactMed databases was performed using the terms 'pregnan*', 'lactat*', 'breastfeeding', 'breast feeding', 'rheumat*', 'inflammatory arth*', 'arthritis', 'psoria*', 'spondyloarthropath*' and 'ankylosing spondylitis'. Exclusion criteria included: retrospective, <5 subjects, no validated disease activity scores and abstracts. Two reviewers independently assessed each study for quality and extracted data using a predesigned proforma. A chi-square test for heterogeneity was performed to determine whether findings were consistent between studies, and random effects meta-analysis was used to account for the heterogeneity observed. A 95% confidence interval was calculated for final data analysis.

Results: Of 762 articles screened, 86 were selected for full length review and 14 eligible for the final analysis, including 965 pregnancies (939 with RA, 6 with juvenile idiopathic arthritis (JIA), 20 with ankylosing spondylitis (AS)). A significant amount of heterogeneity between studies was noted (I^2= 76.3%). All studies utilised the DAS(3)28 (for RA), RADAI (for RA and JIA) or BASDAI (for AS) to measure disease activity. Overall, disease activity improved in 523 pregnancies (54.3% (95% CI 51.0-57.6%)); this total comprised 510 patients with RA (54.3% (95% CI 51.0-57.7%)), 5 patients with JIA (83.3% (95% CI 36.5 - 99.1%)) and 8 patients with AS (40.0% (95% CI 21.5-58.5%)). Post-partum disease activity was recorded in 808 pregnancies and flares were noted in 48.57% of pregnancies (95% CI 45.02 – 52.02%) overall, of which 47.97% (95% CI 44.4 – 51.46%) were in patients with RA (793 pregnancies), 66.6% (95% CI 24.11 – 94.0%) were in patients with JIA (6 pregnancies) and 89.9% (95% CI 50.67 – 99.42%) occurred in patients with AS (9 pregnancies). Pregnancy outcomes were only reported in 2 studies (of 303 pregnancies) with no increase in adverse events.

Conclusion: We found that half of all patients with RA had an objective improvement in disease activity during pregnancy and a similar proportion relapsed post-partum. In contrast, patients with JIA were more likely to improve during pregnancy and relapse post-partum whilst patients with AS in pregnancy were less likely to improve and far more likely to relapse post-partum. This information is vital when counselling patients with inflammatory arthritis pre-partum and considering alterations in therapy to ensure maintenance of disease control with medications that are compatible with pregnancy.

Immunoglobulin Binding Protein (BiP), an Antigen for CCP Sero-Positive Rheumatoid Arthritis Patients, Can Result in a False Positive Quantiferon-Gold Tuberculosis Test

JoAnn Ball[1], Kelsy Greenwald[1], Atul A. Deodhar[2] and Kevin L. Winthrop[3], [1]Rheumatology, Desert Medical Advances, Palm Desert, CA, [2]Division of Arthritis & Rheumatic Diseases OP09, Oregon Health & Science University, Portland, OR, [3]Oregon Health and Sciences University, Portland, OR

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Citrullinated BiP is a newly described target for cyclic citrullinated peptide(CCP). BiP in both serum and synovial fluid is over-expressed in RA patients and correlates with CCP[1]. Serum BiP causes T cell expansion and increases interferon during incubation of the QuantiFERON-Gold tuberculosis in-tube test (QFT-G TB) which can result in a false positive TB test. The QFT-G TB has never been validated where interferon is increased, as for example RA.

Methods: Positive CCP RA patients (n=126) were tested prior to initiating biologic therapy with QFT-G TB (Cellestis). TB evaluation at baseline and annually for two years included history, physical, standard blood tests, chest radiograph, PPD and control skin testing. RA patients had CCP, RF, Wesr, CRP, DAS, wrist temperature, tender and swollen joint counts at baseline (table 1). Three healthy middle-aged female controls with no arthritis were tested with QFT-G TB. Their serum was later tested with BiP added, with 2 ug/ml, 5ug/ml, 10ug/ml, and 20ug/ml, levels seen in RA. (Sourced BiP Novus Biologicals.)

Results: Of 126 CCP+ patients, 16 tested positive for TB (13%) by QFT-G TB, despite no known risk factors for TB (no travel, low endemic rural area, no exposure history), negative chest radiograph, negative PPD with positive candida control, normal blood testing, no symptoms or signs of TB. The CDC established local TB rate is 0.0007%. All 16 had high levels of CCP and active inflammation (mean DAS-esr 6.17). With consultation of an Infectious Disease specialist, all 16 patients received biologic therapy with no INH prophylaxis. In follow up after 24 months, none developed TB and QFT-G TB reverted to negative in 5 patients, correlating with the RA control on biologic therapy. (The other 11 did not have repeat QFT-G.) Mean QFT-G interferon levels in test tubes were 1.57 IU for TB, 0.18 IU for nil, and >10 IU for the mitogen tube. Positive TB defined by the lab kit was > 0.35 IU. False TB interferon levels correlated with CCP level ($p<0.02$). Three healthy women with no arthritis or TB exposure had negative QFT-G TB. These three subjects tested positive every time for TB correlating to the dose of BiP added, at concentrations of 2 ug/ml, 5 ug/ml, 10 ug/ml, and 20 ug/ml (fig 1).

Conclusion: BiP is naturally found in the majority of CCP+RA patients and presence of BiP in serum can result in a false positive QFT-G TB. Patients with the highest CCP had the highest QFT-G TB interferon levels. Subsequent undertreatment of RA, if biologic therapy is withheld, and overtreatment of presumed latent TB may harm patients.

How Much, and When, Does Autoimmune Thyroid Disease Increase the Risk of RA, and Does RA-Onset Impact the Risk of Autoimmune Thyroid Disease?

Kristin Waldenlind[1], Saedis Saevarsdottir[1], Camilla Bengtsson[2] and Johan Askling[1], [1]Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Environmental medicine, Karolinska Institutet, Stockholm, Sweden

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmune thyroid disease (AITD) is one of the most common autoimmune diseases, and occurs more often than expected in patients with Rheumatoid Arthritis (RA). The nature (shared susceptibility or risk factors, AITD triggering RA, or vice versa) and the pattern of risks in relation to RA onset remain unknown. We therefore aimed at assessing risks and relative risks of AITD as a function of time before and after, respectively, RA onset, overall and by age and sex.

Methods: In the Swedish Rheumatology Quality Register, we identified a large cohort of patients with incident RA (symptom duration at diagnosis < 1 year) 2006 through 2013 (n=8090). For each RA-patient 10 general population controls were individually matched. (n=80 856). Incident AITD was defined as a first ever prescription of thyroxin, based linkage to the Swedish Prescribed Drug register (excluding participants with prescriptions for iodine-containing drugs and thyroid cancer. We used a case-control approach to assess relative risks (odds ratios) for AITD before RA, and a cohort approach to assess relative risks (hazard ratios) of AITD after RA.

Results: By the time of RA diagnosis, 259 (3.2%) RA patients vs. 1613 (2.0%) of the general population controls had a history of AITD (OR=1.6, 95%CI 1.4-1.9). We noted increased risks for AITD up to five years before RA onset (OR=1.4, 95%CI 1.2-1.8), with the highest relative risks 3 months or less between the onset of AITD and the RA-diagnosis (OR=5.1, 95% CI 3.6-7.2). Separate analyses revealed higher relative risk among younger and seropositive patients. Following diagnosis of RA, AITD occurred among 121 (1.7%) RA-patients and 1384 (1.9%) controls, overall HR=0.9, 95% CI 0.7-1.1. The risk of AITD was increased during the first three months following RA diagnosis (HR= 2.1, 95% CI 1.2-3.7), but decreased over time into a decreased risk two or more years after RA diagnosis (HR=0.7, 95%CI 0.5-0.99).

Conclusion: This study confirms the increased risk of incident RA among patients with AITD, and extends this observation by demonstrating that the risk of incident AITD varies with time before/after RA, and that the increased risk before RA onset is replaced

by a decrease in risk in patients with established RA. This temporal pattern of risk is compatible both with a critical link between AITD and RA onset, and with increased diagnostic intensity around the time-point of RA diagnosis. Whether the decrease in risk with increasing RA duration is a reciprocating decline after a transient increase in diagnostic intensity, or is a true protective effect e.g., via anti-rheumatic therapies, remains to be investigated.

Table 1. Relative risk of AITD before the diagnosis of RA in 8090 patients with RA compared with 80856 matched controls

	No of thyroxintreatment in RA cases/controls	OR (95% CI)	P-value

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Post-op flares are frequent for RA patients after total hip (THA) and total knee arthroplasty (TKA), when medications are discontinued to mitigate infection risk. The association of flares and patient-reported outcomes (PROs) at 1 year after THA and TKA is unknown. We aimed to describe the relationship of post-op flares with 1 year THA/TKA outcomes.

Methods : Post-op flares were identified in patients with RA undergoing TKA/THA by self-report. Patients completed a questionnaire comprised of a subset of questions from the RA Flare Questionnaire, administered weekly for 6 weeks after arthroplasty. Flare was defined by concordance between patient report ("Are you in a flare? Yes/No"), plus MD assessment of patient-reported survey data including patient reported swollen and tender joints and Rapid III. Pain and function scores (HOOS/KOOS) and disease characteristics were collected at baseline before surgery and after one year. Baseline characteristics and HOOS/KOOS scores were compared using t-tests and chi-square.

Results: One-year outcome scores were available for 20 THA and 14 TKA patients, predominantly women with established RA (Table 1). Baseline DAS-28 and CDAI were higher in TKA flarers, but not THA flarers. 20 (59%) were using biologic medications that were stopped for surgery, and 21 (61%) were flaring before or within six weeks of surgery. MTX use was similar in all groups. Despite this, flarers and non-flarers both had excellent pain and function outcomes at 1 year. There was no statistically or clinically significant difference between flarers and non-flarers, despite poorer pre-operative KOOS scores and higher disease activity for TKA flarers.

Conclusion: Although post-op flares were frequent in RA patients undergoing THA/TKA, pain and function outcomes were similar at 1 year in those who reported flare or not. While these preliminary data are reassuring that perioperative flares do not appear to affect long term functional outcomes, further validation in a larger sample of patients is needed, as well as more study in different settings to increase confidence in these findings. This study was supported by the Clinical Translational Science Center (CTSC) (UL1-TR000457-06)

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) treatment may differ according to hepatitis B state and consequently bring about different outcome of arthritis. Only a small number of studies have addressed the differences in disease characteristics and treatment patterns of RA in relation to hepatitis B state. However, it has not yet been elucidated whether hepatitis B affects treatment outcome such as disease activity. We investigated possible differences in change of arthritis activity between RA patients according to concomitant hepatitis B virus (HBV) infection.

Methods: We conducted an age-matched, sex-matched and entry-time-matched cohort study using single center data, from 1 January 2000 to 31 March 2015. Up to three hepatitis B surface antigen (HBsAg)-negative rheumatoid arthritis (RA) patients were matched to each patient with HBsAg-positive RA by age, sex and year of cohort entry. The longitudinal relationship between HBsAg-positivity and RA activity was analyzed using generalized estimating equations in linear regression models. Similar analysis was performed for RA medication use within each group.

Results: One hundred fifty-two patients were included in the study; 40 were HBsAg-positive. Baseline characteristics did not differ significantly between groups. In regression analysis, RA activity showed time-dependent improvement. The reductions of swollen joint count over time were significantly larger in HBsAg-negative group (b-coefficient 7.91 [95% confidence interval (95% CI) 1.41, 14.41], P = 0.017). However, changes of disease activity score in 28 joints with 3 variables (DAS28-3), tender joint count, erythrocyte sedimentation rate and C-reactive protein level did not differ between groups. There was no difference in alanine aminotransferase level. Over all visits, HBsAg-positive patients were less likely to receive methotrexate (OR 0.09 [95% CI 0.04-0.19], P < 0.0001) and more likely to receive sulfasalazine (OR 3.67 [95% CI 1.94-6.95], P < 0.0001).

Conclusion: RA medication use was different according to HBsAg-positivity. However, the improvement of RA activity was not significantly affected by concomitant hepatitis B state.

Disease Burden in Rheumatoid Arthritis (RA) Patients Who Have Secondary Osteoarthritis (OA) Is Lower Than in OA but Higher Than in RA with No Secondary OA

Isabel Castrejón[1], Anne-Marie Malfait[2], Joel Block[3] and Theodore Pincus[1], [1]Rheumatology, Rush University Medical Center, Chicago, IL, [2]Biochemistry & Rheumatology, Rush University Medical Center, Chicago, IL, [3]Division of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Recent data indicate that the disease burden experienced by patients with osteoarthritis (OA) is similar to or greater than in rheumatoid arthritis (RA) (EULAR meeting, 2015)(1). Many patients with RA may have secondary (2°) OA, which may affect disease burden and clinical management. We compared disease burden in patients with RA, RA with 2° OA, and OA, according to scores on a multi-dimensional health assessment questionnaire (MDHAQ) and physician RheuMetric checklist.

Methods: At one academic rheumatology center, all patients with all diagnoses complete an MDHAQ. The MDHAQ includes 0-10 scores for physical function (FN), pain (PN), and patient global estimate (PATGL), compiled into a 0-30 composite routine assessment of patient index data (RAPID3), and a 0-48 RA disease activity index (RADAI) self-report joint count. Rheumatologists complete a RheuMetric checklist, which includes four 0-10 visual analog scales (VAS) for overall physician global estimate (DOCGL), inflammation or reversible findings (DOCINF), damage or irreversible findings (DOCDAM), and patient distress unexplained by DOCINF or DOCDAM (e.g. fibromyalgia, depression) (DOCSTR). Patients were classified as RA, RA with 2° OA, and OA, according to medical record diagnoses. Measures were compared in the 3 groups by MANOVA, adjusted for age.

Results: 669 patients seen in routine care between September 2014 and June 2015 were studied, including 248 with RA, 47 with RA and 2° OA (16% of all RA), and 374 with OA. Patients with OA were significantly older, but no differences were seen in formal education level or gender. MDHAQ scores indicated substantial disease burden in all 3 diagnosis groups, although least in RA patients with no 2° OA, intermediate in RA patients with 2° OA, and greatest in patients with primary OA, e.g., RAPID3 was 11.0±7.7, 12.3±6.7, and 15.1±6.3 in the 3 groups, respectively (Table) ($p<0.001$ adjusted for age). Among RheuMetric checklist scores, DOCGL did not differ significantly in the 3 groups; DOCDAM was higher than DOCINF in all 3 groups, but differed by 0.7 /10 units in RA vs 1.6 units in RA with secondary OA and 3.2 units in patients with primary OA (Table).

Conclusion: Patients with OA appear to have a greater disease burden than those with RA; the disease burden is intermediate in RA patients who have 2° OA. The higher DOCDAM scores vs DOCINF relative in RA patients may help explain why RA remission rates are below 50%, even though inflammation appears to be effectively controlled (2). Patient MDHAQ and physician RheuMetric are useful and feasible to assess and monitor rheumatic diseases in busy clinical settings. **References: 1.** C. El-Haddad, I. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The disease activity score (DAS) is a method used to monitor disease activity in Rheumatoid Arthritis (RA). Diseases that cause chronic pain or mood disorders have been previously studied to assess their effect on the activity of RA. The aim of the study was to assess clinic, activity, and function characteristics on the DAS28-ESR in RA patients.

Methods:

This is an observational, descriptive cross-sectional study fron march 2013 to march 2014. We included patients with RA according to 2010 ACR/EULAR classification criteria. We analyzed the effect of Fibromyalgia, Knee Osteoarthritis knee, presence of Tendinopathy (any) on the status of RA activity. Evaluation of Health Assessment Questionnaire (HAQ) and Patient Global Visual Analogue Scale (PG-VAS) were included. We considered a VAS> 40 with clinical significance. All patients underwent joint count and ESR.

Results:

We analyzed 395 patients, 360 (91.1%) women , with mean age of 51.1 (SD 12.7). Table 1 shows the clinical and activity characteristics of the patients. We found in the bivariate analysis that the presence of a PG-VAS >40 was associated with a DAS28-ESR greater than 2.6 (OR: 12.47, 5.2-29 95% CI, p = 0.001). Fibromyalgia was a predictor of PG-VAS >40 (OR 3.49, 1.72-7.08 95% CI, p = 0.0001). The rest of the variables analyzed did not influence.

Conclusion:

We observed a negative effect of Fibromyalgia in the PG-VAS and therefore in the DAS28-ESR in patients with RA. The effect size of diagnostic Fibromyalgia on the DAS28 was 27%. We propose to adjust the DAS28, when the PG-VAS is above 40, by multiplying by 0.73, to consider the effect of Fibromyalgia in the evaluation.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmune thyroid disease often coexists with RA and has been associated with an elevated cardiovascular (CV) risk, especially in hypothyroid patients. However, the existing studies show conflicting results and long term follow up studies are scarce. Therefore, we have investigated whether RA patients with thyroid dysfunction have an increased incidence of CV disease (CVD) compared to euthyroid RA patients.

Methods: Thyroid-stimulating hormone (TSH) and serum free thyroxine (FT4) were assessed in 348 RA patients participating in an ongoing prospective cohort study designed to assess CV risk factors, morbidity and mortality. Cox proportional hazard models were

used to calculate hazard rates (HR) for incident CVD.

Results: The participants were predominantly females (66.1%) with a mean age of 63 ± 8 years and a mean disease duration of 7 ± 4 years. At baseline 4.6% was hypothyroid (n=16, TSH >4.0 mU/L, FT4 <10 pmol/L), 4.0% was hyperthyroid (n=14, TSH <0.3, FT4 >24 pmol/L), 2.6% had subclinical hyperthyroidism (n=9, TSH<0.3 and normal FT4), 2.9% had subclinical hypothyroidism (n=10, TSH>4.0 and normal FT4) and 85.9% (n=299) was euthyroid. 99 patients (28%) developed CVD during 15 years of follow up. 50% of the subclinical hypothyroid, 25% of the hypothyroid, 44.4% of the subclinical hyperthyroid, 21.4% of the hyperthyroid and 27.4% of the euthyroid RA patients developed CVD. Compared to the euthyroid persons, age and gender adjusted HR were 0.77 (95%CI 0.24 – 2.47; P=0.65) for hyperthyroid patients, 0.75 (95% CI 0.27 – 2.09; P=0.58) for hypothyroid patients, 1.26 (95%CI 0.46 – 3.44; P=0.67) for subclinical hyperthyroidism and 2.54 (95%CI 1.03-6.30; P=0.04) for subclinical hypothyroidism. Only subclinical hypothyroidism was associated with incident CVD compared to euthyroid patients in all models, with a HR of 2.94 (95% CI 1.05 – 8.19; P=0.04) in the final model after adjustment for prevalent CV disease, metabolic syndrome, RA duration, disease activity and creatinine.

Conclusion: Coexistence of subclinical hypothyroidism with RA is associated with an increased incidence of CVD. If external validation can confirm this amplified CV risk, thyroxine supplementation and CV risk management may be warranted in this subgroup of patients.

Pain, Physical Function, and Worry (But Not Depression and Poor Sleep) Lead to Greater Fatigue in RA

Susan J. Bartlett[1], Michelle Jones[2] and Clifton Bingham III[3], [1]Department of Medicine, Division of ClinEpi, Rheumatology, Respirology, McGill University, Montreal, QC, Canada, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Some view fatigue as resulting from disease activity, while others see it as a natural consequence of the pain, disability, and the emotional burden of living with RA. We explored how RA symptoms and impacts contribute to fatigue.

Methods: Participants had MD-diagnosed RA, were receiving care at an academic arthritis clinic, and were enrolled in an observational study. All completed PROMIS measures of fatigue, mood (depression, anxiety), and symptoms/impacts (physical function [PF], sleep disturbance, pain interference, and participation in social roles and activities). Clinical RA indicators and self reports of exercise frequency we also obtained. Pearson correlation and multiple regression models were used to evaluate associations among variables.

Results: Data are from the baseline visit of 177 RA patients who were mostly female (82%) and white (83%) with a mean (SD) age of 56 (13) years; 24% had ≤ high school, 29% had RA ≤ 5 years with 13% ≤ 2 years, and 22% were disabled. Mean CDAI was 7.9 (7.8). Most were in CDAI remission (n=56; 32%) or LDA (n=67; 38%); 39 (22%) were in MDA, and 14 (8%) in HDA. As compared to the general US population, patients with active RA had higher disability, fatigue, and pain; only those with HDA had elevated mood, sleep disturbance and impaired participation (Table 1). Fatigue was moderately-strongly and directly associated with pain, sleep, depression, and anxiety (r's .45-.67), inversely to PF and participation (r=-.61 and -.64, respectively), weakly and directly with swollen joints (r=.27) and weakly and inversely with regular exercise (r=-.24)(p's <.001). Age and RA duration were not associated with fatigue (p's .967 and .677, respectively). VIF estimates among remaining variable ranged from 1.1–3.3. In multiple regression, pain, physical function, and anxiety were significant predictors of fatigue [F (7,157) = 28.60, p<.001, r^2=.54](Table 2).

Conclusion: In RA, fatigue is common and increases with disease activity. Pain, disability, and anxiety contributed to fatigue, whereas depression and sleep disturbance did not. Overall, anxiety was within the normal range for most (72%) except those with the high disease activity. Our data suggest that beyond pain and disability, in 28% of people with RA, anxiety may also contribute to fatigue. Stress management coaching may offer opportunities to help reduce fatigue in people whose RA is otherwise well controlled. PCORI IP2-PI0000737 and SC14-1402-10818.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Overweight and obesity are comorbidities that may increase the risk of cardiovascular disease in rheumatoid arthritis. Increase in in body fat is observed in a high proportion of patients and increase of risk for cardiovascular diseases. Several biomarkers have been tested to be associated with cardiovascular risk. Neuropéptido-Y(NPY) is a neuroendocrine protein of anabolic signaling involved in the pathogenesis of increased body mass index and body fat mass, cardiovascular regulation and pro-inflammatory modulation. Currently, there is a lack of information regarding the clinical association of serum NPY levels in established RA.
Objective: To evaluate the association between NPY levels with disease activity, body fat mass and risk factors for the development of cardiovascular disease in RA.

Methods: In this cross-sectional study, we evaluated 110 women with diagnosis of RA according to 1987 ACR criteria. We assessed disease activity by DAS-28. Percentage of fat mass was measured by dual X-ray absorptiometry (DXA) and cardiovascular risk factors using the Framingham index. Serum levels of NPY were measured by ELISA. Pearson's test was used for the correlation between NPY with the variables of interest and multiple regression analysis in order to control for confounders

Results: The mean age was 58.5±11.2, mean disease duration 13.8±10.2, 97% of RA patients had high percentage of fat mass, and 62.7% had activity of their disease. In the correlation analysis we observed a negative correlation between NPY and body fat mass (r= -0.20, p=0.04) and a negative correlation with atherogenic index (r= -0.23, p=0.02); whereas, a positive correlation was observed between NPY with the TNF-alpha levels (r=0.52, p=0.005) and high-density lipoproteins (HDL-C) (r = 0.25, p <0.001); whereas, no correlation was observed between NPY and DAS-28, HAQ-DI or other variables. In the adjusted analysis after controlling by age, disease duration, fat mass, and other variables; the serum NPY levels were associated with increased in serum TNF-alpha levels

(p=0.006); Glucocorticoids doses or use of biologic agents were not significant as confounders in the final model.

Conclusion: Serum levels of NPY are associated with lower percentage of body fat mass, lower score of atherogenic index and greater concentrations of TNF-alpha on RA. These interesting results encourage future longitudinal studies evaluating if changes of NPY levels during the disease may be associated with a modification of important outcomes mainly the development of future cardiovascular diseases in these patients.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There has been growing interest in anxiety sensitivity, defined as the fear of behaviors or sensations associated with the experience of anxiety, in chronic pain research. However, few studies have investigated anxiety sensitivity in the context of inflammatory arthritis. The current study aimed to understand the relationship between anxiety sensitivity and indicators of severity in inflammatory arthritis.

Methods: Data included 148 subjects (mean age = 57.7, 72% female) drawn from a prospective longitudinal Early Arthritis Cohort (symptom less than 12 months at baseline) from 2012 to 2015. Anxiety sensitivity (AS) was assessed using the validated Anxiety Sensitivity Index (ASI). Three factors were investigated: physical AS (fear of autonomic arousal and physical symptoms), cognitive AS (fear of the cognitive aspects of anxiety), and social concerns AS (fear of social consequences of anxiety). Patients completed the ASI on their annual visits. Arthritis activity indicators included patient reported visual analogue scales for pain, fatigue, and functional status (modified health assessment questionnaire; mHAQ), physician assessed global disease activity, swollen 28 joint count, tender 28 joint count, Lansbury weighted joint count, erythrocyte sedimentation rate (ESR), c-reactive protein (CRP), and composite indices (DAS28ESR-3variable, Clinical Disease Activity Index (CDAI)). Bivariate correlations first examined the cross-sectional relationship between AS factors and indicators of disease severity. Adjusted linear and logistic regressions controlling for number of visits examined the longitudinal relationship between change in AS factors on indicators of severity. Only results significant at the 0.01 level are reported to adjust for multiple comparisons.

Results: Total summed mean scores significantly differed for social AS (M = 6.96, SD = 8.43), cognitive AS (M = 2.80, SD = 4.07), and physical AS (M = 3.56, SD = 4.19). The three AS factors were significantly associated with worse pain levels (r range = 0.250-0.293), fatigue (r range = 0.312-0.403), mHAQ (r range = 0.284-0.340) and CDAI (r range = 0.200-0.272). The strongest correlations were consistently indicated for the social AS. Only social (r = 0.211) and physical AS (r = 0.250) were significantly associated with physician assessed global functioning and social AS was the only factor associated with the Lansbury Index (r = 0.197). There was no significant relationship between changes in AS on disease severity; however, only higher physical AS scores at baseline significantly predicted persistence indicated by DAS28ESR > 2.6 (adjusted odds ratio = 1.150, 95%CI = 1.036-1.269, p< 0.01).

Conclusion: Anxiety sensitivity is associated with several indicators of severity among those with inflammatory arthritis; unique

findings emerged across factors and the social AS factor has a particularly strong association with arthritis severity indicators.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Incretins hormones have been found to be a function of glucose tolerance in normal subjects, individuals with impaired glucose tolerance and patients with type 2 diabetes. Similarly, chronic inflammation, and rheumatoid arthritis (RA), is associated with an insulin resistance (IR) phenomenon, a well-known risk factor for cardiovascular diseases. The aim of the present study was to examine whether incretins hormones are disrupted in RA patients and if they are related with the insulin resistance (IR) that these patients express.

Methods: Cross-sectional study that encompassed 361 non-diabetes individuals; 151 patients with RA and 210 age- and sex-matched controls. IR by homeostatic model assessment (HOMA2), insulin, C-peptide, amylin, glucagon-like peptide-1 (GLP-1), gastric inhibitory polypeptide (GIP), and dipeptidyl peptidase 4 (DPP-4) soluble form and lipoproteins serum concentrations, were assessed in patients and controls. A multivariable regression analysis, adjusted for IR related factors, was performed to evaluate the differences between patients and controls in incretins hormones and how these were related to inflammation and IR in patients and controls.

Results: RA patients, compared to controls, disclosed higher levels of HOMA-IR (2.49 ± 2.35 vs. 1.13 ± 0.58 vs, p=0.00), insulin (13.0 ± 13.4 vs. 9.8 ± 6.5 U/ml, p=0.04) and C-peptide (3.37 ± 2.94 vs. 1.53 ± 0.77 ng/ml, p=0.00). These differences remained significant after adjustment for age, sex, waist circumference, dyslipidemia, statins, antihypertensive treatment and cholesterol levels. Similarly, amylin showed superior serum levels in RA patients in the univariate analysis, however, after adjusting for confounders this relation was lost. Incretins, GIP (0.37 ± 0.40 vs. 1.78 ± 0.51 ng/ml, p=0.00) and GLP-1 (0.49 ± 1.28 vs. 0.71 ± 0.22 ng/ml, p=0.00), were higher in RA patients after multivariable analysis. Contrary, DPP4 was found to be down regulated in RA patients after adjusting for IR related factors (811 ± 459 vs. 696 ± 301 ng/ml, p=0.02). While DDP-4 was correlated with disease activity through DAS28 (r=0.18, p=0.03), DAS28-PCR (r=0.5, p=0.08) and CDAI (r=0.20, p=0.01), neither insulin, C-peptide, incretins (GLP-1 and GIP) nor amylin were found to be associated with disease activity. DPP4 serum levels were significant and negatively associated with HOMA-IR-C-peptide index (beta coef -0.03 [-0.05--0.01 ng/ml], p=0.01) in the entire sample. Interestingly, the addition of RA as an interaction term in this relation disclosed a significant association (interaction p=0.04). Patients and controls in the higher HOMA-IR-C-peptide quartile (#4) disclosed different levels of GLP-1 (mean difference 0.4 [0.3-0.5] ng/ml, p=0.00), GIP (1.7 [1.4-2.0] ng/ml, p=0.00) and DPP-4 (-220 [38-402] ng/ml); showing, therefore, a different relation of IR indexes with these molecules between patients and controls.

Conclusion: Incretin axis is disrupted in non-diabetic RA patients. These defects may participate to the development of IR in RA or arise as a consequence of IR and/or other metabolic manifestations of RA itself.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) exert a wide variety of therapeutic responses to disease controlling anti-rheumatic drugs (DMARDs). P-glycoprotein (P-Gp) is involved in treatment resistance in some chronic diseases. Although, to date there is lack information to identify if high levels of P-gp are associated with low therapeutic response to s-DMARDs. The aim of the present study is analyze the association between serum P-Gp levels with the severity of disease activity despite treatment with DMARDs in RA.

Methods: We included in this cross-sectional study eighty-one patients with RA treated for at least six months with DMARD. Patients were assessed for disease activity (DAS-28), type of DMARD, as well as other drugs currently used for the treatment of their disease and other clinical characteristics. Serum P-Gp levels were measured by ELISA.

Results: The patients had a mean age of 57±10, the frequency of synthetic DMARDs received by the patients were methotrexate 59%, sulfasalazine 38%, leflunomide 30%, azathioprine 14%, chloroquine 14%, d-penicillamine 3%; whereas anti-TNF agents were received by 11% (etanercept 9%, adalimumab 1%, infliximab 1%) and rituximab 4%. Overall, patients with RA had higher serum P-Gp levels compared with controls 153 ± 187 versus 31 ± 29 ng/mL; respectively, $p<0.0001$). Patients with moderate or severe disease activity had higher serum P-Gp levels compared with patients with low-disease activity or remission (201 ± 207 versus 109 ± 156 ng/mL; respectively, $p=0.028$). Serum P-Gp levels were correlated with DAS-28 (r=0.26, $p=0.018$). There were no differences observed between patients with biologic agents vs patients with synthetic DMARDs in the serum P-Gp levels (228 ± 200 vs. 140 ± 183 ng/mL; $p=0.14$). P-Gp levels were independent of methotrexate utilization ($p=0.5$). After adjusting for age, disease duration and biologic agents' utilization, the serum P-Gp levels remain associated with moderate or severe disease activity in the logistic regression analysis ($p=0.021$, using forward conditional method)

Conclusion: Higher serum P-Gp levels are associated with the severity of disease activity despite treatment with DMARDs in RA. These serum levels can be used as biomarkers in patients with a non-therapeutic response. Further longitudinal studies should

demonstrate if these levels can be predictive of failure to therapeutic response.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : To analyze the temporal trend of incidence rate (IR) of hip and/or knee total joint replacement in a cohort of rheumatoid arthritis (RA) patients

Methods : We performed a retrospective longitudinal study, including patients diagnosed of RA between 1994 and 2009, according to the 1986 ACR diagnostic criteria, attending the rheumatology outpatient clinic of the Hospital Clínico San Carlos (Madrid, Spain). Clinical records were reviewed in order to collect demographic and clinical information. Our main outcome was total hip or knee replacement surgery, considering only the first replacement per joint (multiple event variable). In order to ensure a similar maximum follow-up time for all included patients, regardless the moment when they were included, time of observation comprised only the first 5 year after RA diagnosis (from such date until both knees and hips were replaced, lost of follow-up or 5 years had elapsed). Total joint replacement (TJR) IR was expressed per 1000 patients-year. Kaplan Meier curves were set to account for all TJRs. Cox bivariate and multivariate regression models were constructed to assess the effect of calendar time, demographic and clinical-related variables in the IR. Three time intervals were considered, defined by the year of RA diagnosis: 1994-1999, 200-2004, and 2005-2009. Statistical analyses were performed using STATA v12.

Results : We included 1812 patients, 74% women, with a median (interquartile range) age at RA diagnosis of 60.4 (47.6-71.8) years, 85% Spaniards, 65% with rheumatoid factor (FR), and 48% with anti-citrullinated peptides antibodies (ACPA). 526 patients had been diagnosed between 1994-1999, 551 between 2000-2004 and 735 between 2005-2009. 69 total joints (25 hips and 44 knees) were replaced during a follow-up time of 7522.0 patients-years, resulting in an IR of 9.2 [7.2 to 11.6] per 1000 patients-year. We observed an incidence rate for the time periods 1994-99, 2000-04, and 2005-09 of 10.8 [7.3 to 16.2], 10.5 [7.4 to 15.7], and 6.9 [4.5 to 10.6], respectively (**Figure 1**). In the bivariate analysis, only age at RA diagnosis showed a significant association with a higher risk of TJR ($p=1.0x10^{-4}$). In the multivariate analysis (adjusted by sex, age at RA diagnosis, country of birth, presence of ACPA and FR), year of RA diagnosis was not associated with the rate of TJR (2000-2004 vs. 1994-1999: HR 0.97 [95%CI: 0.55 to 1.71], p=0.91; 2005-2009 vs. 1994-1999: HR 0.67 [95%CI: 0.37 to 1.21], p=0.18).

Conclusion : Although we observed that patient diagnosed with RA more recently had a smaller rate of TJR in our RA cohort, differences were not statistically significant. **Table 1**: Baseline demographic and clinical characteristics of the RA patients included in this study.

Variables	n = 1812
Women, n (%)	1337 (73.8)
Age of RA diagnosis, median (IQR)	60.4 (47.6 to 71.8)
Elapsed time from RA symptoms onset to diagnosis in years, median (IQR)	1.0 (0.3 to 4.6)
Follow-up time in years, median (IQR)	5 (4.1 to 5)
Presence of Rheumatoid Factor, n/N (%)	1152/1780 (64.7)
Presence of ACPA, n/N (%)	482/1002 (48.1)
Spaniard, n (%):	1534 (84.7)
Year of RA diagnosis, n (%):	
1994 - 1999	526 (29.0)
2000 - 2004	551 (30.4)
2005 - 2009	735 (40.6)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Digital X-ray radiogrammetry (DXR) is a method to calculate peripheral bone mineral density (BMD) which calculates BMD of the hands (DXR-BMD). The aim of this study was to evaluate whether hand bone loss (HBL) during the initial three months after diagnosis predicts radiographic joint damage after 12 and 24 months in patients with rheumatoid arthritis (RA).

Methods: Patients with early RA (<12 months since symptom onset) were consecutively included from three Swedish rheumatology departments (and treated according to the Swedish guidelines). Radiographs of hands and feet were taken at baseline, 3 months (hands only), 12 and 24 months. The baseline, 12 and 24 months radiographs were evaluated according to the Larsen score by one reader at each centre. The smallest detectable change (SDC) was established for each reader individually. DXR-BMD was performed on radiographs of the hands taken at baseline and after 3 months. Changes in BMD were evaluated in metacarpals 2, 3 and 4. HBL was defined either as a moderate change in DXR-BMD (≥0,25 but <2,5 mg/cm^2 per month) or a severe change (≥2,5 mg/cm^2 per month), as defined by the device manufacturer Sectra AB, Sweden. Radiographic progression was defined as a difference in Larsen score above the SDC [of the corresponding reader]. Statistical calculations were performed using SPSS 23 software. After testing different variables in a simple regression with change in Larsen score as dependent variable, all variables with the lowest p-value ($p<0.2$) were extracted to perform univariate analysis of variance. ESR and anti-CCP were measured at baseline and DAS28 was evaluated at each visit.

Results: One hundred and sixty seven patients (64% women) with a mean disease duration of 6 months (SD 3.7) and mean age 58

years (SD 14.5) were included. 63% tested positive regarding serum anti-CCP antibodies. HBL occurred in 58.7% of the patients (44.3% moderate and 14.4% severe HBL). Thirty two patients (19.2%) had radiographic progression at 12 months and 45 (34.9%) at 24 months. Greater HBL within 3 months associated significantly (p= 0.033) with greater increase in Larsen score between baseline and 12 months, adjusted for sex and baseline values of ESR, DAS28, Larsen score and anti-CCP status. No significant association was observed between early bone loss and radiological damage at 24 months (p=0.626).

Conclusion: HBL during the initial three months is an independent predictor of radiologic joint damage at 12 months in patients with early RA, but does not predict the 24 months outcome. Thus, DXR-BMD examinations after three months may be useful to detect ongoing joint damage, but the long-term predictive ability seems to be limited.

Sleep Hygiene Practices and Associations with Patient-Reported Outcomes in Rheumatoid Arthritis

Sapna Sangani[1] and Joshua F. Baker[1,2], [1]Rheumatology, University of Pennsylvania, Philadelphia, PA, [2]Medicine/Rheumatology, University of Pennsylvania and Philadelphia VAMC, Philadelphia, PA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies showed a high prevalence of sleep disturbances in Rheumatoid Arthritis (RA). Poor sleep has been associated with patient-reported outcomes (PROs) for measuring disease activity in RA. Sleep hygiene is a variety of behavioral practices important for normal, quality nighttime sleep. The relationship between sleep hygiene behaviors themselves and PROs has not been described. We evaluated associations between sleep hygiene, sleep quality, and PROs in veterans with RA.

Methods: This is a cross-sectional study of patients with RA attending a single VA rheumatology clinic. Participants were administered 3 questionnaires by telephone survey: 1) Sleep Hygiene Index (SHI), 2) Pittsburgh Sleep Quality Index (PSQI), and 3) RAPID3 (comprising the Multi-dimensional Health Assessment Questionnaire [MD-HAQ], pain and, patient global scores [0-10]). Furthermore, information about demographics, BMI, inflammatory markers within the past 6 months, RA serologies, medications, and comorbid diagnoses were collected by chart review. Correlations between sleep hygiene, sleep quality, and PRO's were performed using Spearman's correlations and linear regression analyses.

Results: The cohort consisted of 51 subjects (86% male, mean age of 63 (range 27-77), mean BMI of 28.7, 84% seropositive). The mean SHI score was 17 (6.3) and mean PSQI score was 9.23 (4.0). Only 11/51 (22%) patients had normal sleep quality (PSQI <5 units). The SHI was strongly associated with PSQI (Rho: 0.40, p = 0.004). Both SHI and PSQI were strongly correlated with all RA PROs (Table, Figure). Question 8 from the SHI, "I go to bed feeling stressed, angry, upset, or nervous" was particularly associated with PROs. Specific domains of the PSQI associated with the PROs included subjective sleep quality, habitual sleep efficiency, sleep disturbances, and daytime dysfunction. PSQI total score and SHI total score were significantly higher among those with comorbid depression, but similar among those with osteoarthritis (p>0.78). RAPID3 correlated with SHI and PSQI, but was not associated with ESR. In multivariable models adjusting for age, gender, and depression SHI was independently associated with RAPID3.

Conclusion: Sleep hygiene behaviors and sleep quality play an important role in a patient's experience of their RA and correlate with self-report of function, pain, and well-being. Sleep hygiene questions that assessed patient distress at night were most strongly associated with these PROs. This study emphasizes how sleep and sleep behavior might impact the patient reporting of disease activity.

Pregnancy Outcomes in Women with Rheumatoid Arthritis : A Systematic Review

and Meta-Analyses

Anne-Lise Gaillard[1], Thomas Barnetche[2] and Thierry Schaeverbeke[3], [1]Rhumatologie, CHU Bordeaux Pellegrin, Bordeaux, France, [2]Rheumatology Department, Pellegrin University Hospital, BORDEAUX, France, [3]Rheumatology Department, Bordeaux Hospital, Bordeaux, France

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Actually better control of rheumatoid arthritis (RA) activity leads to new interrogations and daily questions about pregnancy. Only few studies have studied pregnancy outcomes in women with RA, and results have shown some discrepancies. The objective is to determine the effect of Rheumatoid Arthritis on pregnancy outcomes, specially hypertension and preeclampsia, low birth weight, preterm birth, perinatal mortality, congenital malformation and cesarean section in women with Rheumatoid Arthritis

Methods: A litterature search was performed from Medline and Cochrane databases for articles published in english from 1955 to May 2016. Studies were eligible if they presented prevalence study, including national birth registry. Population were women with Rheumatoid Arthritis and keys terms related to pregnancy outcomes. Meta-analysis were performed to assess odds-ratios (OR) for each studied group using the inverse variance approach to estimate pooled OR with their 95% confidence interval (95% IC). Heterogeneity was assessed according to Cochran's Q-test and I2 values. Calculations were made with the Cochrane RevMan 5.3 software. P-values less than 0.05 were considered as significant.

Results: Expanded literature searche identified 1002 papers, of which 68 were eligible. Meta-analysis calculations showed a significant increased risk of prematurity with an OR of 1,42 (95% CI 1,29 to 1,56), low birth weight with an OR of 1,53(95% CI 1,35 to 1,75), small size at birth with an OR of 1,22 (95% IC : 1,00 to 1,48), perinatal mortality with an OR of 1,84(95% IC 1,25 to 2,72), preeclampsia with an ORof 1,46 (95% IC 1,06 to 1,85) , cesarean with an OR of 1,52 (95%IC 1,25 to 1,85). We did not find a higher risk of congenital malformation , hypertension or instrumental delivery. A higher risk of pregnancy outcomes seems to be showed before the disease onset. Furthermore, disease activity and drug treatment such as NSAIDs and corticosteroids should decrease fertility and increase pregnancy outcomes and specially prematurity and miscarriage.

Conclusion: A significative higher risk of several pregnancy outcomes in women with Rheumatoid Arthritis . Rheumatologist should be advised of these risks to refer women in apropriate obstectrics department.

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Lower extremity arthritis, proprioceptive dysfunction related to foot deformities, muscle weakness, joint restrictions, biomechanical disoerders, fatigue, sleep disorders, depression, and pain are frequently seen in patients with romatoid arthritis and may affect the balance. The aim of this study to evaluate the static and dynamic balances of the patients diagnosed with rheumatoid arthritis (RA) and also to disclose the relationship between these parameters and clinical, functional and radiological findings.

Methods: Patients diagnosed with RA according to ACR 2010 diagnostic criteria were compared with *age and gender matched* healthy controls. The age, sex and body mass index (BMI) data of the cases were recorded. DAS-28 score was calculated for determining the disease activity and the detailed rheumatologic and musculoskeletal examination was performed. Radiographic assessments of feet were done to evaluate the presence of pes planus, hallux valgus, metatarsus primus varus and splaying foot deformities. 'Foot and Ankle Outcome Score' (FAOS) was applied for foot function assessment. The level of fatigue, depression and sleep disorders of all patients were determined with 'Multidimentional Assessment of Fatigue', 'Beck Depression Inventory' and 'Pittsburgh Sleep Quality Index', respectively. The state of balance of the patients was evaluated by means of 'Berg Balance Scale' (BBS) and also 3 static (Modified Clinical Test of Sensory Interaction and Balance, Unilateral Stance , Weight Bearing Squat) and 4 dynamic (Step Up/Over, Sit to Stand, Tandem Walk, Limits of Stability) balance tests with 30 parameters were assessed via the '*Neurocom Balance Master*' device available in our clinic. Statistical analyses were performed with SPSS version 22 and p values less than 0.05 were considered statistically significant.

Results: This study included 165 cases that consist of 81 RA group (66 female, 15 male) and 84 healthy control group (70 female, 14 male). The mean age of patients and controls were 48.90±10.36 and 45.89±12.07 years, respectively. Age, sex and BMI data of both groups were similar between ($p>0.05$). The mean score of DAS28 of patients were 3,69±1,17. There were significant differences in the results of Modified Clinical Test of Sensory Interaction and Balance, Unilateral Stance, Tandem Walk, Limits of Stability, Step Up/Over tests between the patient and the control groups ($p<0.05$). Sit to Stand and Weight Bearing Squat test results were similar ($p>0.05$). It was deduced that 66.7% of patients have depression, 64.2% sleep disorders and 93.8% fatigue according to surveys; however there was no correlation between these symptoms and presence of balance disorders. Although 61% of patients were established with hallux valgus, 52% metatarsus primus varus, 33% pes planus, 26% splaying foot, these deformities were not correlated with FAOS and balance disorders. The presence of the swollen joint was determined as the most relevant factor about the balance disorders of RA patients.

Conclusion: Patients diagnosed with RA may have balance disorders as an important finding independently from other findings and symptoms during the course of the disease.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Depression is an important comorbidity in patients with rheumatoid arthritis (RA). Its incidence is variable (10-25%), being more frequent in women[1]. Wolfe et al. determined that pain, HAQ-DI and disease activity predict depression[2]. The main objective is to determine depression in patients with RA by the PHQ-9 questionnaire and evaluate its relationship with disease activity.

Methods: A cross-sectional study was conducted in patients with established diagnosis of RA according to the criteria of the ACR-1988, from the Luis Vernaza Hospital and a private rheumatology center. The database included demographic data, pain visual analog scale (VAS), activity index DAS-28, HAQ-DI disability index and the PHQ-9 questionnaire. Data was loaded and analyzed in the statistical program SPSS V. 22. Statistical significance used was 0.01, with a 99% reliability.

Results: 184 patients with a mean age of 51 years (20-90) were included, 90.8% women and 9.2% men. The mean age of onset of the disease was 40 years (18-49) with a delay of visit to the specialist of 26 months (1-432). 94.6% were mestizos, 3.8%, whites and 1.6% afroecuadorians, 50% were married, 16.3%, cohabiting 16.3% divorced, 9.2% single, and 8.2% widowed. The mean patient VAS was 3.4 (0-10) and physician VAS 2.8 (0-10). The mean DAS28-CRP was 3.11 (0.7-7.6), with 44% (81) in remission, 16.8% (31) low activity, 32.1% (59) moderate activity and 7.1% (13) high activity. 21.7% (40) patients had HAQ-DI disability and 1.6% (3) severe disability. The mean PHQ-9 was 5.39 points (0-24). According to this questionnaire, depression was found in 42.9% (79), 24.5% (45) mild depression, 9.8% (18) moderate, 7.1% (13) moderate-severe and 1.6% (3) severe. Of these, 89.9% (71) were women and 10.1% (8) men. Depression related to disease activity with DAS-28. 66.7% (20) of patients in remission had mild depression while 70% (7) patients with high activity had moderate to severe depression ($p = 0.009$). Mean DAS-28 for patients with moderate to severe depression was higher than those with mild depression (4.0 vs. 2.9, $p = 0.004$) Disability also related to depression levels as 40.7% (11) patients with functional disability had moderate to severe depression, compared with 35.1% (13) patients without disability ($p = 0.009$). Likewise, the average HAQ of patients with major depression was higher ($p = 0.000$). The average patient VAS in people with mild depression was 3.7, while in moderate to severe depression was 5.4 ($p = 0.000$). In the physician VAS, it was 3.1 for mild depression, and 4.6 for moderate to severe depression ($p = 0.000$). The number of tender and swollen joints was higher in patients with major depression than in those with mild depression ($p = 0.000$).

Conclusion: The presence of depression was common in our population, women were the most affected. Depression was related with disability and disease activity. The presence of depression in ecuadorian patients with RA was similar to that of other populations. This is the first study of depression in patients with RA in Ecuador.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sleep disturbance is common in patients with rheumatoid arthritis (RA). Poor sleep can result in increased psychological distress, depression, fatigue, inability to work, socioeconomic burden and consequently significantly decreased health-related quality of life. Achievement and maintenance of tight disease control using disease-modifying anti-rheumatic drugs (DMARDs) including biologic DMARDs (bDMARDs) is associated with significant improvement in the outcome of RA as these strategies have the potential to control synovitis and to slow disease progression. The aim of this study was to assess the relationship between sleep disturbance and disease activity, pain, fatigue, health-related quality of life and treatment.

Methods: A total of 172 participants diagnosed with RA meeting the 2010 ACR/EULAR criteria were enrolled in this study, including 137 females (79.7 %) with a mean age of 44.37 ± 12.90 years. Among all the patients, 110 were treated with conventional DMARDs (cDMARDs), while 62 treated with bDMARDs (47 with tumor necrosis factor inhibitors and 15 with tocilizumab). Participants

completed the following questionnaires: Pittsburgh Sleeping Quality Index (PSQI), Health Assessment Questionnaire (HAQ), Hospital Anxiety and Depression Scale (HADS), and Fatigue Severity Scale (FSS). RA disease activity was assessed using the 28 joint disease activity score (DAS28), erythrocyte sedimentation rate, serum C-reactive protein and pain visual analog scale (VAS). Data were analyzed using SPSS v.17.0 software by descriptive statistics such as frequency, mean (SD) and inferential statistics including Wilcoxon rank sum test, Chi-square, and logistic regression.

Results were considered statistically significant when p value was less than 0.05. Results: PSQI was used to assess the quality of sleep in RA patients. Sleep disturbance was considered if PSQI score was greater than 6. Sleep disturbance was present in 46.5% (80/172) of RA patients and was associated with disease activity. Compared with RA patients without sleep disturbance, RA patients with sleep disturbance had increased pain levels, poor health-related quality of life, depression and fatigue as assessed by VAS ($p<0.01$), HAQ ($p<0.05$), HADS ($p<0.05$) and FSS ($p<0.01$) respectively. Better disease control could improve the quality of sleep in RA patients. In addition, patients treated with bDMARDs had significantly lower scores of DAS28 ($p<0.01$), PSQI ($p<0.01$) and VAS ($p<0.05$) compared to those treated with cDMARDs (Table 1).

Conclusion: High prevalence of sleep disturbance in patients with RA was observed. Sleep disturbance was associated with several measurements of health-related quality of life. Control of disease activity improved sleep disturbance. Treatment with bMARDs not only had better disease control, but also improved functional status by improving quality of sleep and pain.

Table1. Association of sleep disturbance with disease activity and other measurements of health-related quality of life in RA patients.

Variable	DAS28	VAS	HAQ	FSS	HADS	bMARDS (number of patients)	cDMARDS (number of patients)

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis also commonly report other chronic conditions ("multimorbidity") with higher counts of conditions associated with reduced response to treatment and persistent disease activity. However little is known about which specific conditions have stronger associations with RA outcomes. The objective of the present study was to estimate the prevalence and impact of chronic inflammatory multimorbidity on the trajectory of disease activity in the first year in patients with early rheumatoid arthritis (ERA).

Methods: We analyzed data from ERA patients (<1-year symptom duration) enrolled in a large prospective multi-center cohort study who completed a standardized clinical assessment and self-report questionnaire every 3-months in the first year of follow-up, who met 1987 or 2010 ACR/EULAR RA criteria, and had at least two DAS28 measures available in the first year. Information on physician-diagnosed chronic inflammatory conditions including cardiovascular disease (CVD), pulmonary disease, bowel disease, diabetes, cancer, obesity, psoriasis and other rheumatologic conditions was obtained by patient self-report and information on depressive symptoms from SF-12 responses (using a depressive symptom cut-off of 42). Prevalence of each condition, as well as chronic inflammatory multimorbidity counts were estimated with standard descriptive statistics. Linear growth models were used to examine individual and cumulative effects of each chronic inflammatory condition on trajectory of DAS28 disease activity in the first year adjusting for age, sex, education, race, smoking, symptom duration, and treatment.

Results: The sample included 1595 patients with a mean(sd) age of 54(15) years, symptom duration of 6(3) months, 1153 (72%) were female and 1316 (83%) were white. At baseline 1434 (92%) were treated with a conventional DMARD (majority with methotrexate (76%)) and 33 (2%) with a biologic. Multimorbid inflammatory conditions were common: 1138 (72%) reported at least 1 condition, 541 (34%) reported at least 2 conditions and 166 (10%) reported 3 or more conditions. Depressive symptoms reported in 589 (40%), obesity in 355 (32%), pulmonary disease in 220 (14%), CVD in 191 (12%) and other rheumatic conditions in 197 (12%) were most prevalent, followed by diabetes 127 (8%) and cancer 109 (7%). Bowel disease in 61 (4%) and psoriasis in 60 (4%) were least prevalent. Results of multivariable growth models showed that depressive symptoms were associated with higher baseline disease activity and both depressive symptoms and obesity were associated with less change in DAS28 over time ($p<0.05$).

Conclusion: Results of the present study showed that multimorbidity with other chronic inflammatory conditions is common in ERA patients. Integrated treatment approaches to address multimorbid rather than single inflammatory conditions may yield better outcomes.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the influence of age on the components of the 28-joint Disease Activity Score (DAS28)-C-reactive protein (CRP) in patients with rheumatoid arthritis (RA) and whether DAS28-CRP can be equally interpreted in all age groups.

Methods: For RA subjects enrolled in the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER), a cross-sectional analysis was performed. The share was expressed as a proportion and calculated by dividing the formula the DAS28 by the entire DAS28 (CRP share = [0.36 x ln(CRP +1] / DAS28, Relative of the contribution of the patient reported measures (tender joint count [TJC] and patient global assessment [PtGA] in DAS28-CRP [DAS-P] = [0.56 x sqrt (TJC) + 0.014 x PtGA] / DAS28-CRP). Share of CRP and patient reported components of the DAS28 (DAS-P) were analyzed and compared between 2 age groups (younger RA <60, older RA ¡Ã 60) using Mann-Whitney U test. Inflammatory disease burden in the joint was calculated by modified DAS28 (MDAS28 = 0.49 x ln(C-reactive protein (CRP)) + 0.15 x swollen joint count 28 (SJC) + 0.22 x physician global assessment (PhGA) +1). Multivariate analyses were used to design models best predicting the effect of age on CRP, the share of CRP, inflammation level calculated by MDAS28, DAS-P, and pain levels.

Results: CRP and the share of CRP in DAS28-CRP were not influenced by age. MDAS28 did not increase significantly with age but was associated with disease duration and anti-tumor necrosis factor (TNF) therapy. Female gender had significantly higher DAS-P, while age was associated with lower DAS-P. Pain level had significant negative association with age (Table 1). In subjects with moderate inflammation (defined by MDAS28 score above 50 percentile, N=370), older RA subjects (age >= 60, N=189) had lower pain level, tender joint count (TJC), patient and physician global assessment, DAS28-CRP than younger subjects (age < 60, n=157) (Table 2).

Conclusion: CRP, CRP share, and MDAS28 were not associated with age. However, age played a role in how subjective components of DAS28-CRP and pain level are assessed and rated in patients with RA. Disease activity could be underestimated by DAS28-CRP in older RA patients with moderate to high grade inflammation from RA.

Table 1 Multiple regression analysis of influence of age on modified disease activity score 28 (MDAS28), subjective components of DAS28 relative to the total DAS28 (DAS-P), pain level (visual analog scale, VAS) (β denotes the standardized regression coefficient, SE denotes the standard error)

Physician-Reported and Patient-Reported Anxiety and Depression in Rheumatoid Arthritis

Nan Li[1], Emma Sullivan[2], Stuart Blackburn[2], Danuta Kielar[1] and Steve Peterson[1], [1]Janssen Research & Development, LLC, Spring House, PA, [2]Adelphi Real World, Manchester, United Kingdom

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: As many as 40% of people with rheumatoid arthritis (RA) experience significant symptoms of mood disorders. In addition to the pain, fatigue, and disability associated with RA, inflammatory mediators such as IL-1, TNF and IL-6 are thought to play a role in the aetiology of mood disorders. This study examined comorbid anxiety/depression in RA (both physician- and patient-reported), and its association with work and activity impairment.

Methods: Data were drawn from the 2014 Adelphi RA Disease Specific Programme, a cross-sectional survey in the US and 5 European countries (France, Germany, Italy, Spain, UK). Physician-reported anxiety or depression was documented as a comorbid condition for each patient. In addition, patient-reported anxiety/depression was collected using the EQ-5D health status questionnaire: anxiety and depression were rated as "none," "moderate," or "extreme." These 2 distinct markers for anxiety/depression in RA patients within the Adelphi survey were analyzed separately in univariate/multivariate analyses. Univariate analysis was initially used to identify any association between physician- and patient-rated anxiety/depression with patient-reported work productivity and activity impairment (WPAI) questionnaire scores. Controlling for patient age, gender, region, body mass index, physician-reported disease severity, number of flares (past 12 months), and physician-reported global health, multivariate regression analyses further examined the relationships between these markers and outcomes of interest.

Results: Of the total 3,379 patients, 15.3% had physician-reported anxiety/depression as a comorbid condition. 38.4% of those who completed the EQ-5D question on anxiety and depression (n=1015) had self-reported anxiety/depression of at least moderate severity at the time of the survey. Multivariate analyses demonstrated that patient-reported anxiety/depression was significantly associated with overall work impairment (among employed patients) (coefficient [95% CI], 11.04 [4.23, 17.84]; P=0.002) and activity impairment (among all patients) (14.11 [10.69, 17.54]; P<0.001). Separate multivariate analysis demonstrate that physician-reported

anxiety/depression was also borderline significantly associated with overall work impairment (6.80 [-0.01, 13.62]; *P*=0.050) and significantly associated with activity impairment (6.80 [2.89, 10.72]; *P*=0.001), respectively.

Conclusion: Both physician-reported comorbid anxiety/depression, and patient-reported anxiety/depression during EQ-5D administration were independently and significantly associated with overall work impairment as well as activity impairment. Further research on optimal management of mood disorders in RA is warranted.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite advances in the RA treatment, substantial humanistic and economic burdens remain. This study of patients with RA, with moderate to severe disease activity and on active treatment, explored unmet treatment needs and the resultant impact on physical functioning and activities of daily living.

Methods: Semi-structured interviews were conducted with 46 patients with RA from Germany (n=15), France (n=15), UK (n=11), and Spain (n=5). Eligible patients had been diagnosed for 2-5 years, had a current disease activity score in 28 joints (DAS28) >3.2, and were receiving ongoing treatment. Initial questions were open-ended, followed by more focused questions to probe unmet need. Patients completed the HAQ-Disability Index and EuroQol 5 dimensions questionnaires. Interviews were conducted with 10 rheumatologists across countries, to explore their understanding of unmet need in RA.

Results: Patients had a DAS28 mean score of 4.23 (SD=1.0) and either, were eligible for but had not yet received biologic DMARDs (bDMARDs) (23/46; 50.0%), were receiving bDMARDs (12/46; 26.1%), had received >1 anti-TNF treatment previously and were now receiving a treatment with a different mode of action (3/46; 6.5%), or were receiving another treatment regimen (8/46; 17.4%). The majority of patients (44/46; 95.7%) experienced pain due to RA (Table). A high proportion of patients (37/46; 80.4%) specifically identified pain as an unmet need and experienced pain despite advances in treatments. Joint stiffness and swelling, and fatigue were experienced by 87.0% (40/46), 84.8% (39/46), and 91.3% (42/46) patients, respectively. Over half reported each symptom spontaneously, suggesting they are relevant to the symptom experience of RA. All 10 clinicians reported that patients experience each of the above mentioned symptoms. In almost all patients (45/46; 97.8%), RA had impacted their physical functioning, including walking (35/46; 76.1%), sleep (26/46; 56.5%), gripping (22/46; 47.8%), lifting/carrying (28/46; 60.9%), mobility/flexibility (34/46; 73.9%), and speed/agility (15/46; 32.6%). All patients (46/46; 100%) reported an impact on activities of daily living; 40/46 (88.9%), emotional well-being; 37/46 (80.4%), family and social relationships; and 26/46 (57.0%) experienced a financial impact.

Conclusion: Although pain, joint stiffness and swelling, and fatigue are well-known symptoms associated with RA, they persist in most patients who are eligible for, or who are receiving, bDMARDs. Pain severity showed relationships to the wider scope of impact on patients' lives. Despite the high standards of care available for patients in the countries in which this study was conducted, the level of unmet need described from both patients and clinicians is compelling.

Table: Patient experiences and clinician perceptions of pain due to RA, n (%)

	Total	Spontaneous	Probed	Not experienced	Individual experiences and perceptions of pain
Patients

Frailty Is Associated with Decreased Physical Function in Adults with Rheumatoid Arthritis

James Andrews[1], Ken Covinsky[2], Catherine Hough[1], Laura Trupin[3], Edward H. Yelin[3] and Patricia P. Katz[3], [1]Medicine, University of Washington, Seattle, WA, [2]Medicine, University of California San Francisco, San Francisco, CA, [3]Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Reduced physical function and health-related quality of life remain common in Rheumatoid Arthritis (RA), and further studies are needed that examine potential, novel determinates of reduced physical function in RA. Frailty is a state of excess vulnerability to stressors, with reduced ability to maintain or regain homeostasis after a destabilizing event. Frailty is associated with increased risk of poor health outcomes including death. The present study examines whether frailty is associated with differences in self-reported physical function among adults with RA.

Methods: Adults (n=124) from a longitudinal RA cohort participated in the study. All measures were collected during in-person research visits. Using an established definition of frailty[1], individuals with 3 or more of the following physical deficits were classified as frail: 1) body mass index ≤ 18.5, 2) low grip strength (adjusted for sex and BMI, measured by handheld dynamometer), 3) severe fatigue (measured by the Fatigue Severity Inventory), 4) slow 4-meter walking speed (adjusted for sex and height), 5) low physical activity (measured by the International Physical Activity Questionnaire). Individuals with 1 or 2 deficits were classified as "pre-frail", and those with no deficits as "robust[1]." Self-reported physical function was assessed by the Health Assessment Questionnaire (HAQ) and the Valued Life Activities Difficulty scale (VLA), (HAQ and VLA scored 0-3). Regression analyses modeled associations of frailty category with HAQ and VLA Difficulty scores with and without controlling for age, sex, disease duration, hsCRP, use of oral steroids, and pain. Secondary analyses tested whether associations of frailty category and physical function scores were robust to using knee strength rather than grip strength in assigning frailty category and relationships between pain, frailty category, and physical function.

Results: Among adults with RA, being frail compared to being robust was associated with a 0.54 worse HAQ score (p<0.01) and a

0.63 worse VLA score (p<0.001) when the effects of all covariates are held constant (Table 1). The association of frailty category with HAQ and VLA Difficulty scores persisted when knee strength was used to assign frailty category (Table 2).

Conclusion: Frailty is common among individuals with RA. Being frail, compared to being robust, is associated with significantly worse self-reported physical function among adults with RA. Future studies should continue to advance understanding of frailty as a potential source of reduced physical function in RA.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: rheumatoid arthritis (RA) has been stablished as an independent risk factor for cardiovascular diseases. Metabolic syndrome (MS) may provide additional link between accelarated atherosclerosis and inflammation in RA. Objective: to estimate the prevalence of MS and modifiable and non-modifiable risk factors for cardiovascular disease among patients with RA, correlating them to disease activity markers.

Methods: a cross-sectional study in patients with established RA (according to the ACR classification criteria) from three Brazilian university hospitals. Demographic and clinical data, and the presence of cardiovascular risk factors were collected. Blood pressure, weight, height and waist circumference were determined in the assessment visit and laboratory data were assessed from medical records. Disease activity was evaluated by the Disease Activity Score in 28 joints (DAS28), and patients were classified in remission <2.6; low disease activity (LDA) 2.6 to ≤3.2; moderate disease activity (MDA) >3.2 to ≤5.1; or high disease activity (HDA) >5.1. The diagnosis of MS was done according to the National Cholesterol Education Program (NCEP ATPIII 2005) and to the International Diabetes Foundation (IDF 2005). Remission was correlated to LDA, MDA and HDA in the analysis. Multiple logistic binary response analysis with Huber/White standard errors that accounted for clustering on hospitals was performed. Variables were sequentially deleted when not reaching significance equal to or less than 5%.

Results: 791 patients were included, 86.9% women, mean age 54.7 (±12) years, 59.9% Caucasian, mean disease duration of 12.8 (±8.9) years. Rheumatoid factor was positive in 75% of the patients, mean body mass index (BMI) was 27.1 (±4.9) kg/m^{2}and mean waist circumference was 93.5 (±12.5) cm. Methotrexate were used by 67.7% and prednisone in 37.4% of the patients. Dyslipidemia, DM, HBP and family history of premature cardiovascular disease occurred in 34.3%, 15%, 49.2% and 16.5% of the patients, respectively. MS prevalence was 36.4% (NCEP) and 30.7% (IDF), with 91.5% of agreement. Age, dyslipidemia, HBP, DM and body mass index were associated with MS by NCEP and IDF definitions. MS (IDF) was associated to CRP levels (OR=1.30; p<0.001), to LDA (OR=1.62; p=0.001) and to MDA (OR=1.47; p<0.001). MS (IDF) and HAD association was fairly significant (OR=1.79; p=0.093). MS (NCEP) was associated to CRP levels (OR=1.32; p<0.001) and to HDA (OR=1.52; p=0.004). Dyslipidemia was positively correlated to LDA (OR=1.71; p=0.002), MDA (OR=1.51; p=0.001) and HDA (OR=1.77; p<0.001). HBP was positively correlated to LDA (OR=1.24; p<0.001). DM was positivily correlated to MDA (OR=1.83; p<0.001) and HDA (OR=3.18; p<0.001) and BMI was positivily correlated to MDA (OR=1.69; p= p<0.039) and HDA (OR=1.36; p=0.010).

Conclusion: our results depicted the association of MS to CRP levels and to DAS28, emphasizing the relevance of inflammation control in RA. Lipid, hypertension, diabetes and weight control are relevant metabolic aspect and should be valued and point to the more comprehensive medical approach. Disclosure of Interest:none declared

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: An association between obesity and RA activity has been proposed in the literature. Kuwait has the highest obesity rate in The Middle East and is ranked among the top 10 most obese countries in the world. We describe obese patients with RA and study the influence of body mass index (BMI) on RA activity and severity.

Methods: Adult patients from The Kuwait Registry for Rheumatic Diseases (KRRD) who satisfied the ACR classification criteria for RA from four major hospitals were studied from February 2013 through December 2015. Patients were classified using WHO criteria to underweight (<18.5), normal (18.5-24.99), pre-obese (25-29.99) and obese (>30). Their demographic, clinical and serological features were compared. Statistical tests were applied where appropriate.

Results: A total of 425 RA patients with1615 hospital visits and available BMI were identified, 351 (82.6%) were females. The mean age was 52.6 years (18-86) and disease duration 6.7+7.2 years (0.1-46). Among them, 156 (36.7%) were obese, 177 (41.6%) were pre-obese, 89 (21%) were normal and 3 (0.7%) were underweight. Based on DAS28 scores, 257 (60.5%) were in remission or had low disease activity, 146 (34.4%) had a moderate disease activity and 22 (5.1%) had a severe disease activity. Patients with a higher BMI were diagnosed at an older age (p=0.02). BMI was positively correlated to DAS28 (p=0.03), CDAI (p=0.006), ESR (p<0.001), CRP (p=0.02), tender joint count (p=0.022), swollen joint count (p=0.012), positive rheumatoid factor (RF) (p=0.014), positive anti-citrullinated protein antibodies (ACPA) (p=0.029) and a combination of positive RF and ACPA (p<0.001). Increased BMI was associated with a lower VAS pain (p=0.022), a lower patient's global assessment of disease activity (p=0.027) and less deformities (p<0.001). There was no significant association with gender, HAQ score, sicca symptoms, rheumatoid nodules or other extra-articular features. Biologic therapy was more prescribed to patients with a higher BMI score (p=0.005).

Conclusion: The distribution of BMI among RA patients in Kuwait was similar to the general population with the majority being overweight. Patients with a higher BMI had a more seropositive and a more active RA but less deformities. We recommend that BMI is measured and approached in all RA patients and that overweight patients are aggressively managed to control disease activity.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Metabolic syndrome (MS) is a common comorbidity in patients with rheumatoid arthritis (RA). Several adipokines have been implied in the pathogenesis of MS on general population and rheumatic inflamatory disorders. Omentin-1 is an adipokine implied in reducing insulin resistance, and improving hypertension and dyslipidemia among general population. Nevertheless, the role of this adipokine in MS is not conclusive and there is no information about the association between serum levels of omentin-1 and the components of MS in RA. In order to test the hypothesis that serum omentin-1 levels are biomarkers of protection for MS the aim of the present study was to evaluate if serum omentin-1 levels are associated with the MS components in patients with RA.

Methods: In this cross-sectional study we included adult women with established RA (according to 1987 ACR criteria). Exclusion criteria were active infections, cancer, chronic renal failure, hepatic failure or pulmonary fibrosis. Thirty women with RA and MS (RA+MS) according to the NCEP-ATP III criteria were compared with 30 women with RA without MS (RA-MS) matched by range of age. Clinical and epidemiological characteristics were evaluated, as well as disease activity measured by DAS-28 index. Serum omentin-1 levels were determined by ELISA.

Results: Patients with RA+MS had higher body mass index compared with RA-MS (28.1 vs 24.4 kg/m^2, $p< 0.001$). Serum omentin-1 levels were similar in patients with RA+MS compared with RA-MS (794 vs 941 ng/mL, respectively, $p = 0.15$). In the correlation between specific components of MS, serum omentin-1 levels correlated with higher diastolic blood pressure (rho= 0.22, p= 0.03) and higher HDL-cholesterol levels (rho= 0.20, p=0.05). After adjusting by age and disease duration, BMI was the major risk factor for MS in this patients (OR= 1.46, 95% CI= 1.06-1.99, p= 0.02), and serum omentin-1 levels did not achieve statistical significance.

Conclusion: No significant difference in omentin-1 levels in RA patients with and without MS was observed. However serum omentin-1 positively correlated with HDL-cholesterol and diastolic blood pressure. This implies the assumption that this adipokine influences some cardiovascular risk factors and should be evaluated in future studies.

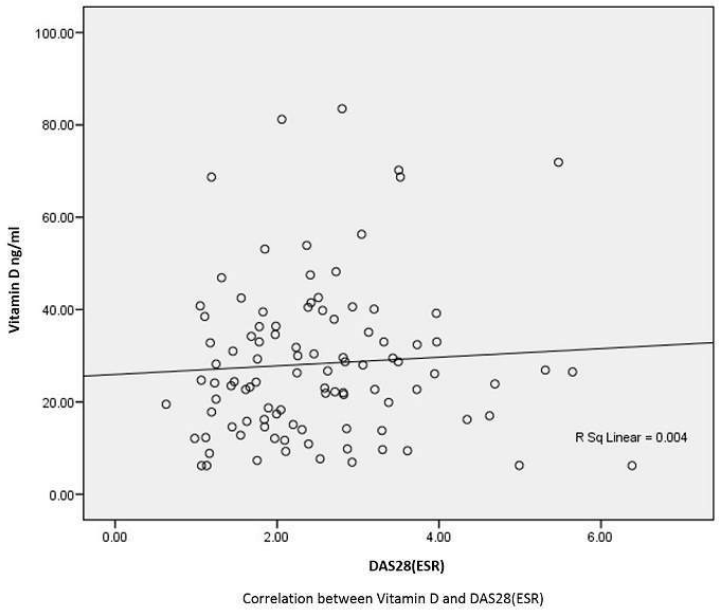
SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Lower serum vitamin D levels have been shown to be associated with various autoimmune disorders including Rheumatoid Arthritis (RA). We undertook this study to evaluate vitamin D status and assess the relationship if any between vitamin D levels and disease activity and disability in patients with RA.

Methods: A total of 100 adult patients (82 females, 18 males) of RA (ACR/EULAR-2010 criteria) presenting to Rheumatology department and 50 healthy controls drawn from hospital staff matched for age and gender (42 female, 8 male) were enrolled. Exclusion criteria comprised severe hepatic, and/or renal disease, uncontrolled diabetes, granulomatous disease. Disease activity and disability was evaluated by DAS28(ESR) and Indian HAQ disability index (HAQ-DI) respectively. Serum total 25(OH)D_3 levels were measured by electrochemiluminescence assay. Vitamin D insufficiency was defined as <30 ng/ml. Unpaired t-tests, chi square, ANOVA, Kruskal Wallis, Pearson and multivariate regression were applied as appropriate.

Results: The mean 25(OH)D_3 levels in cases and controls were 28.29±16.67 and 15.59±10.58 ng/ml respectively (p-value=0.000). As many as 62% of the patients and 88% (44/50) of the controls had vitamin D insufficiency (p-value<0.001). Mean serum vitamin D levels were significantly higher in patients who were on high dose (oral 60,000 IU/week or injection within last 6 months) of vitamin D supplementation (40%) (39.55±17.00 ng/ml) (p-value<0.001) compared to that of those who had received either none (23%), 250 IU/day (23%) or 500 IU/day (14%). Vitamin D levels were not significantly different in patients who were in remission, low, moderate and high disease activity (27.05±15.05, 32.44±18.52, 27.49±17.30 and 32.88±27.75 ng/ml respectively, p-value=0.709). No significant correlation was seen between mean vitamin D levels and age, BMI, SJC, TJC, ESR, General Health (GH), DAS28(ESR), HAQ-DI and serum PTH. Only duration of illness was positively correlated with vitamin D level (r=0.212, p-value=0.035). Vitamin D levels were also not different with regard to gender, menopause, deformity, hypothyroidism, RF, anti CCP status and current glucocorticoid use. On multivariate analysis, vitamin D levels were not related to various disease activity and disability variables [SJC, TJC, ESR, GH, DAS28(ESR) and HAQ-DI].



Correlation between Vitamin D and DAS28(ESR)

Conclusion: Vitamin D insufficiency was widespread both in patients with RA (62%) and in hospital staff without any disease (88%). No correlation was found between mean 25(OH)D_3 levels and disease activity, disability and other variables. Longer disease duration of RA was associated with higher vitamin D levels. This could be because of greater use of vitamin D supplements by patients with long standing disease. The healthy hospital staff had low vitamin D possibly due to greater time spent indoors.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is intrinsically associated with an increased incidence of lymphoproliferative disorders (LPDs). Although treatment with immunosuppressive agents, such as methotrexate, tacrolimus, or biological disease-modifying antirheumatic drugs (b*DMARDs*) is highly efficient, development of immunodeficiency-associated LPDs is becoming a more important issue. However, previous reports have come mainly from university or flagship hospitals, where the patient populations might differ from average RA patients. Furthermore, those studies have focused on the pathological features and regression of LPDs after withdrawal of methotrexate (MTX), and information that could allow earlier diagnosis of LPDs has been scant. Here we surveyed the clinical course of RA patients who developed LPDs seen at our hospital, focusing especially on the clinical features at LPD onset.

Methods: RA patients who had been treated at Niigata Rheumatic Center between October 2006 and April 2016 were analyzed. The patients' data were obtained retrospectively from their medical records. Data indicated are median ($IQR_{1/4-3/4}$) values.

Results: Among 2,986 RA patients, 26 patients with pathologically identified LPDs were analysed. The median patient age at the time of LPD diagnosis was 71 (62.5-78.3) years, and the duration of RA was 181 (106.5-238.3) month. Twenty-two patients were treated with MTX, 8 with bDMARDs (infliximab in 6 cases, etanercept in 1 case and golimumab switched from infliximab in 1 case), and 8 with tacrolimus. Ten patients were diagnosed as having diffuse large B cell lymphoma, 7 as having Hodgkin lymphoma, and 3 as having T cell lymphoma. The primary site of LPDs was extranodal in 11 (42.3%), and only 7 patients complained of lymph node swelling. Furthermore, even computed tomography image could not detect lymph node swelling in 6 cases. Although the C-reactive protein level (CRP) significantly rose from 0.2 (0.1 - 0.4) mg/dL at 6 months before LPD diagnosis to 2.1 (1.4 – 5.2) mg/dL after LPD diagnosis ($p<0.001$, Wilcoxon signed-rank test), neither the number of tender and swollen joints nor the matrix metalloproteinase-3 level showed any significant change (0.0 (0.0 – 0.5) vs 0.0 (0.0 – 1.3), $p=0.389$, 1.0 (0.0 – 2.0) vs 0.0 (0.0 – 2.0), $p=0.309$, and 64.2 (54.7- 108.1) to 90.3 (55.8 -125.2) ng/mL, $p=0.482$, respectively). Lactate dehydrogenase (LDH) level and total lymphocyte count changed significantly from 198.0 (184.0 – 230) to 270.5 (209.3 – 384.8) IU/L, $p=0.005$, and 1365.0 (1101.8 – 1758.0) to 1008.5 (692.8 – 1628.0) /mm^3, $p=0.032$, respectively. By June 2016, 9 patients had died, and the median survival period was 27.0 (9.0 – 45.5) months. Among the 9 patients who died, 7 had diagnosed as LPDs with poor performance status (i.e. 3 to 4).

Conclusion: Twenty-two out of 26 patients who developed LPDs were receiving MTX. MTX users might have a higher incidence of LPDs in our hospital. Patients with poor performance status had poor prognosis, and over the half of patients develops LPDs without subjective symptoms of lymph node swelling. CRP elevation that is disproportionate to RA activity, LDH elevation, and decrease of lymphocyte count might be the signs of underlying LPDs.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibodies targeting carbamylated proteins (Anti-CarP) have been recently described in Rheumatoid Arthritis (RA) and are reported to be associated with increased disease activity and with more severe joint damage. The specificity of the antibodies has been debated due to the fact that they are present in other rheumatic conditions. The aim of this study was to assess the presence of anti-CarP in RA patients from the CAP48 early arthritis Belgian cohort, as well as established RA patients regularly followed in our department, compare them to healthy subjects and controls from other rheumatic diseases and evaluate the specificity, sensitivity and diagnostic values of the Anti-CarP antibodies.

Methods: We tested sera from a total of 103 RA patients (38 early RA and 65 established RA), classified using the ACR/EULAR 2010 criteria for RA, healthy controls (n=56) as well as 142 patients with different rheumatic conditions (Juvenile Idiopathic Arthritis (n=80), Ankylosing Spondylitis (n=25) and Sjögren's Syndrome (n=37)). Sera were obtained from the CAP48 Early Arthritis cohort and from the biobank of the Rheumatology department of Erasme Hospital. An in-house ELISA technique, as described previously by Shi et al, was used to determine the presence of IgG class antibodies against carbamylated Fetal Calf Serum. A cut off for positive response was established as the mean plus two SD of the anti-CarP reactivity of the healthy controls.

Results: In our RA patients, Anti-CarP were detected in 38 patients (37%), while 66 patients (66%) were positive for Rheumatoid Factor and 68 (68%) patients were positive for ACPA. Anti-CarP were also found in 4 patients (4%) seronegative for both RF and ACPA. In the control population, 5 healthy controls were positive, along with 12 JIA patients, 5 SA patients and 11 Sjögren Syndrome Patients. (figure 1) The sensitivity of the anti-CarP antibodies at the cut-off chosen was at 35% and the specificity at 92,8%. Overall, the Positive Predictive value of the antibodies was estimated at 88,4%, whereas the Negative Predictive value was 44%.

Conclusion: Anti-CarP antibodies were detected in the sera of RA patients in a Belgian cohort, including a subgroup of patients seronegative for ACPA and RF. The anti-CarP are not exclusive to RA, our study confirms their presence in other rheumatic diseases (JIA, Sjogren's, Ankylosing Spondylitis). Whether this reactivity can be attributed to other interfering antibodies present in the sera of the controls or whether it is predictive of a particular articular phenotype remains to be elucidated.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is a frequently mentioned symptom by people living with rheumatoid arthritis (RA). However, little research has explored the associations between fatigue and other indicators of health and well-being in this population, such as cardiovascular disease (CVD) and quality of life. Therefore, the current study aimed to examine the relationships between fatigue and disease activity, CVD risk, as well as psychological well-being.

Methods: 98 RA patients (66 female, 54 (12) years) completed the Multidimensional Assessment of Fatigue Scale, as well as questionnaires measuring depression, anxiety, subjective vitality, quality of life, and functional ability. CVD risk was assessed with blood pressure, body mass index, cardiorespiratory fitness, as well as serological measures (e.g., lipids, insulin resistance) and Qrisk was used to measure global CVD risk. Disease activity was measured by DAS28 and inflammatory markers. Participants were divided into tertiles based on levels of low (mean [SD] fatigue = 15.5 [4.7]), moderate (mean [SD] fatigue = 27.8 [3.3]) and high (mean [SD] fatigue = 39.9 [4.2]) levels of fatigue. Group differences were analysed by one-way Analyses of Variance, corrections were made for multiple comparisons.

Results: The fatigue groups did not differ with regards to age and sex. Clinical disease activity (p=.03), but not serological markers of inflammation, was different between the three fatigue groups. Those with greater levels of fatigue had lower functional ability, quality of life and subjective vitality, and higher anxiety and depression (p's<.01). Measures of insulin resistance (p's<.02), HDL cholesterol (=.03) and cardiorespiratory fitness (p=.03) were poorer in those with high fatigue (p's<.02), but no other markers of CVD risk (e.g., BMI, lipids, blood pressure) differed between the groups.

Conclusion: These results showed that RA patients with lower levels of fatigue also reported better psychological well-being, functional ability and DAS28 and some CVD risk indicators, but no differences were observed for levels of inflammation. These cross-sectional associations between fatigue and well-being suggest that improving psychological wellbeing, functional ability and cardiorespiratory fitness could also induce improvements in fatigue. However, this will need to be confirmed in longitudinal and intervention studies in which associations between improvements in psychological wellbeing and fatigue can be determined.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We evaluated the periodontal involvement of rheumatoid arthritis (RA) patients, and we correlated with various laboratory biomarkers including lipids, autoantibodies, serum vitamin D levels, markers of bone metabolism in relation with the periodontal condition and cariological indices; and also correlated them with salivary citrulline and anti citrullinated protein autoantibody levels with the above mentioned clinical and blood test findings.

Methods: Twenty-three RA patients were recruited for the study. Saliva samples were taken following whole scale periodontal and cariological examination. Protein concentration, peptidyl-citrulline and anti-cyclic citrullinated protein (anti-CCP) levels were measured from saliva samples. Blood test results were provided by rheumatologists. Citrullinated enolase protein-1 (CEP-1) level from serum was also measured.

Results: Periodontal diagnoses (scores) seem to have a positive dependency on LDL (R=0.722, p=0.008), PTH1 (R=0.586, p=0.022), D_3 vitamin level (R=0.586, 0.022), the sum of D3/D2 (R=0.634, p=0.011) respectively, in these patients. Anti-CEP-1 positive patients had significantly higher periodontal scores (2.71±0.11 vs 2.50±0.09, $p<0.05$) compared to anti-CEP-1 negative subjects. Interestingly, anti-CEP-1 positive patients had significantly higher triglyceride levels compared to seronegative ones (1.81±0.17 vs 1.42±0.05 mmol/l; $p<0.05$). Salivary citrulline and salivary anti-CCP, (p=0.007, R: 0.583) level has a correlation with the maximum of clinical probing depth.

Conclusion: Our results may add further pieces to the mosaic of RA-periodontitis connection. The possible role of antimicrobial immunity, as well as the possible role of lipids and bone metabolism have also been delineated. Future therapies should aim the disruption of this framework.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the prevalence of comorbidities in patients with rheumatoid arthritis (RA) compared with non-RA population.

Methods: The 2010-2012 Korea National Health and Nutrition Examination Survey (KNHANES), which assesses the general health status of populations in South Korea using interviews and basic health assessment, was analyzed retrospectively. Weighted prevalence and odds ratio (OR) of comorbidities were analyzed in patients with RA compared with non-RA population.

Results: The overall weighted (n = 37,453,158) prevalence RA was 1.5%. Patients with RA were older and more female predominant than subjects without RA. The prevalence of living in urban area, collage graduation, drinking and smoking was lower in patients with RA than non-RA. Patients with RA had more comorbidities including hypertension, dyslipidemia, myocardial infarction (MI) or angina, stoke, osteoarthritis, lung cancer, colon cancer, pulmonary tuberculosis, asthma, diabetes, depression, thyroid disease and chronic kidney disease. After adjusting socioeconomic and lifestyle characteristics, RA was associated with the increased the prevalence of MI or angina (OR 1.86, 95% CI 1.17-2.96, p = 0.009), pulmonary Tb (OR 1.95, 95% CI 1.24 to 3.09, p = 0.004), asthma (OR 1.97, 95% CI 1.05 to 3.71, p = 0.036), thyroid disease (OR 1.71, 95% CI 1.05 to 2.77), depression (OR 2.38, 95% CI 1.47 to 3.85, p < 0.001) and hepatitis B (OR 2.34, 95% CI 1.15 to 4.80, p = 0.020) compared with non-RA population. Prevalence of solid cancer was not significantly associated with RA after adjustment.

Conclusion: RA was associated with increased risk of cardiovascular disease, pulmonary Tb, asthma, thyroid disease, depression and hepatitis B.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: This study aimed to evaluate the association between rheumatoid arthritis (RA) and hearing impairment in the Korean adult population.

Methods: Audiometric and laboratory test data from the 2010–2012 Korean National Health and Nutrition Examination Survey (KNHANES) were used for analysis. The relationship between RA and hearing impairment was analyzed, adjusting various known risk factors associated with hearing impairment. We defined hearing impairment for 2 categories of frequency (low/mid, high): Low/mid frequency, average of 0.5, 1.0, and 2.0 kHz, and high frequency, average of 3.0, 4.0, and 6.0 kHz.

Results: A total of 15,598 subjects completed the audiometric tests. The overall weighted (n = 32,898,665) prevalence of RA was 1.5%. Frequency of hearing impairment was higher in subjects with RA than in those without RA in both low/mid and high frequency (22.0% vs 7.8%, $p < 0.001$ and 43.3% vs. 26.4%, $p < 0.001$, respectively). In multivariable logistic analysis, RA (odds ratios (OR) 1.54, 95% CI 1.07 to 2.22, $p = 0.021$) was an independent risk factor for low/mid frequency hearing impairment along with age (OR 1.12, 95% CI 1.11 to1.13, $p < 0.001$), college graduation (OR 0.51, 95% CI 0.38 to 0.69, $p < 0.001$), and occupational exposure (OR 1.46, 95% CI 1.19 to 1.81, $p < 0.001$). In the multivariable analysis of high-frequency hearing impairment, RA did not show any association with hearing impairment.

Conclusion: This study first demonstrated that RA is associated with low-/mid-frequency hearing impairment after adjustment of various known risk factors.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The mechanisms of fatigue in rheumatoid arthritis (RA) are still unclear and the effect of antirheumatic drugs on fatigue not fully established. Objectives: To analyse in a large cohort of RA the factors associated with fatigue focusing on social aspects, comorbidities and treatment intake.

Methods: Cross sectional analyses were performed on RA patients from the French cohort study of comorbidities COMEDRA (1). Fatigue was assessed as a quantitative variable (RAID3 0-10 numeric scale) or by class (acceptable <3; moderate 3-4; severe ≥5 out of 10). Relationship with demographic, social, disease characteristics, treatments, comorbidities, physical activity, quality of life was investigated in univariate analyses (Table) and multivariate polynomial regression (Figure).

Results: 962 patients were analysed (age 57.7 ± 11.1 years, disease duration 11.1 years [6.2-19.1], mean DAS28 3.1 ± 1.3), 763 (79 %) were female. The mean fatigue score was 3.8± 2.7. Severe fatigue was more frequent in women, in patients not working, with less physical activity and more obesity. Fatigue was correlated with disease duration ($p=0.05$), all disease activity index ($p<0.001$), pain ($p<0.001$), mHAQ ($p<0.001$), sleep ($p<0.001$) and emotional well-being ($p<0.001$). Among comorbidities, hypertension, chronic obstructive pulmonary disease (COPD), fracture history and RA-related surgery were associated with fatigue. Multimorbidity assessed

by the weighted multimorbidity index (MMI.weight) (2) was independently associated with severe fatigue as well as current treatment with NSAID or biotherapy. Methotrexate use and the type of biologic did not impact fatigue score.

Conclusion: Beyond the expected association of fatigue with female gender and disease activity, less physical activity, comorbidities and multimorbidity, treatments could contribute to the persistent fatigue noted in RA. Fatigue was associated with steroids, NSAIDs, biotherapies but not with methotrexate and did not depend of the type of biotherapy. 1. Dougados M et al. Ann Rheum Dis. 2015;74(9):1725-33 2. Declining Flare Rates in the First Five Years of RA Disease, but Not after

Shafay Raheel[1], Cynthia S. Crowson[2], Eric L. Matteson[1] and Elena Myasoedova[1], [1]Rheumatology, Mayo Clinic, Rochester, MN, [2]Health Sciences Research, Mayo Clinic, Rochester, MN

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Flare or episodic worsening of disease activity is an important aspect of the disease experience for patients with rheumatoid arthritis (RA). Improving trends towards lower RA disease activity have been suggested in recent years. However, long-term data on flare rates in RA are lacking. This study aimed to assess trends in the occurrence of flares in RA over disease duration.

Methods: A population-based cohort of patients with RA (age≥18 years; 1987 ACR criteria met in 1988-2007), was used to perform this retrospective medical records review of each clinical visit to estimate flare status. RA flare was defined as any worsening of RA activity leading to initiation/change/increase of therapy (OMERACT 9). All subjects were followed until death, migration or July 1, 2012. Flare rates were calculated as the percentage of visits in flare. Binomial regression models with random effects to account for multiple visits per subject were used to assess the associations between patient characteristics and flare rate. Smoothing splines were used to allow for non-linear effects. Two way interactions between RA disease duration and other patient characteristics were examined.

Results: The study included 650 RA patients (mean age 55.8 years; 69% female) with mean follow up of 10.3 years. Flare status was collected for a total of 17,323 clinical visits. Patients were flaring in 2887 (17%) visits. Figure 1 shows trends in flare rates after RA onset by calendar year of RA diagnosis. There was a statistically significant decline in the RA flare rate across disease duration ($p<0.001$), predominantly in the first 5 years after diagnosis of RA. Patients diagnosed with RA in more recent years experienced fewer flares during the first few years of RA ($p<0.001$). Women tended to have marginally higher flare rates as compared to men, but this did not reach statistical significance ($p=0.16$). There were no differences between the sexes in trends of flare rates over time (interaction $p=0.42$). Flare rates were similar for all ages in the first few years after RA diagnosis, but in subsequent years patients diagnosed with RA at younger ages had higher flare rates than those diagnosed at older ages. Patients with positive rheumatoid factor (RF) had higher flare rates than negative RF ($p<0.001$), and flare rates declined more over disease duration in patients with negative RF than those with positive RF (interaction $p=0.047$; Figure 2).

Conclusion: Patients diagnosed more recently have lower rates of flares than those diagnosed in prior decades. Flare rates declined fastest in the first 5 years of disease and tended to be stable thereafter. These patterns likely reflect improved control of RA activity and possibly milder RA disease course in the recent years. However, flares continue to occur persistently at a constant rate after the five years of RA, reflecting the need for improved long term disease management.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Residual disease activity impacts functional status and quality of life (QoL) in patients with early rheumatoid arthritis (ERA). Large weight bearing joints are more likely to impact function such as walking than small non-weight bearing joints although the effect may be task dependent. The Lansbury Articular Index (LAI) weights large joints more than small joints thus may give a better estimate of overall disease burden with respect to large joint function. The Health Assessment Questionnaire (HAQ) seems to weigh upper extremity tasks more than lower extremity or weight bearing tasks. In a large multicenter cohort of ERA patients, we therefore sought to determine associations of LAI with HAQ, QoL and baseline disability status and whether changes in the LAI trajectory more closely reflected the evolution of the HAQ trajectory than the standard joint count measures.

Methods: We used data from subjects with ERA (less than 1 year symptom duration at first visit) followed in a multicentre Early Arthritis Cohort. Arthritis activity measures (DAS28, tender 28 joint count (tjc28), swollen 28 joint count (sjc28), function (Health Assessment questionnaire; HAQ) QoL (SF12 physical (PCS) and mental (MCS) indices) and work status were captured per study protocol. The LAI based on 28 joints was calculated separately for swollen (LS28) and tender (LT28) joint counts. The impact of LS28, LT28 on baseline disability status was modeled using logistic regression. Individuals' trajectories for each measure (HAQ, DAS28, TJC28, SJC28, LT28,LS28) were visualized with LOESS plots and marginal trajectories by variable plotted. Each measure's longitudinal trajectory was fitted using the best fitting fractional polynomials. Each individual disease activity trajectory was then jointly modelled with the HAQ longitudinally (joint modelling). Correlations between each pair of joint trajectories (HAQ with TJC28 or SJC28 or LT28 or LS28) were calculated.

Results: ERA subjects (n=2133, 73% female; baseline mean (SD) Age 53(15) years, DAS 5.1(1.4)) were followed for median (IQR) 24(10,48) months. At last visit 44 % were in remission (DAS28<2.6). Combining all visits, the LS28 strongly correlated with SJC28 (r= 0.9 p<0.0001), PCS (r=-0.4 p<0.0001) and HAQ (r= 0.4 p<0.0001). The LT28 correlated with the TJC28 (0.9 p<0.001), PCS (r=-0.5 p<0.0001) and HAQ (0.5 p<0.0001). Correlations were even stronger with the full LAI (42 joints). Disability or sick leave at baseline (6% of cohort) was associated with higher LT28 (OR 1.003 p=0.001) and higher TJC28 (OR 1.071 p<0.0001) in separate logistic regression models that included age. The HAQ trajectory was highly correlated with the trajectories for DAS28 (r=0.83), LT28 (r=0.83), and TJC28 (r=0.85) and less strongly with trajectories for LS28(r= 0.59) and SJC28 (r=0.61).

Conclusion: The trajectories of function (HAQ) and both Lansbury and standard joint counts are highly correlated over time in ERA. The LAI performed similarly to standard joint counts which are easier to determine. Although type of occupation was not addressed and likely influences the impact of lower extremity involvement, both LT28 and TJ28 associated with baseline work disability.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: 1. to assess the validity of an electronically comorbidity assessment strategy to identify comorbid conditions among RA and PsA patients in standard practice. 2. To evaluate the impact of e-comorbidity assessment on the patients' care and adherence to therapy.

Methods: A cohort of 448 RA and 437 PsA subjects with varying disease duration met the following inclusion criteria: RA diagnosed according to ACR/EULAR criteria and PsA according to CASPAR criteria, started a DMARD/biologic agent, continued therapy >6 months, and followed longitudinally from baseline to follow-up (mean time 24months). Electronic patients reported comorbidities questionnaire according to a RACI [1] and PsACI [2] was implemented as part of electronic patient reported outcome measures tool. The sensitivity, specificity, positive and negative predictive values of the electronic data entry and calculated comorbidity risk were compared to ICD-10 medical record (reference standard) and rheumatology clinic visits outcomes. A control group of 241 RA patients and 252 PsA patients managed according to standard protocols were also assessed and monitored for 2 years. Primary end point: no inferiority of outcomes of the electronic and standard formats. Secondary end point: the patients' adherence to their medications and actions taken to assess and manage the comorbidity risk.

Results: The sensitivity for identifying comorbidities using the electronic approach ranged from a minimum of 94% for atlanto-axial sublaxation to a maximum of 100% for cardiovascular risk (median, 99.2%; interquartile range [IQR]: 96%-100%). Sensitivities for extracting comorbidities using ICD-10 codes ranged from a minimum of 8% for Anxiety to 100% for tumors (median, 66%; IQR: 50%-74%); whereas, sensitivities for extracting comorbidities using clinic outcomes data ranged from a minimum of 4% for falls risk to 100% for diabetes and tumors (median, 38%; IQR: 32%-54%). The median PPV and NPV were 97.7% (IQR: 96-100%) and 99.6% (IQR: 99-100%) for the e-comorbidity tool Vs 61.8% (IQR: 41%-76%) and 97.4% (IQR: 91%-98%) for the ICD-10 codes, respectively. The patients' adherence to anti-rheumatic therapy was significantly ($p<0.1$) higher in the studied group whereas stopping DMARDs for intolerability was significantly ($p<0.01$) higher in the control group. Number of procedure/ screening tests for comorbidity risk assessment was significantly higher in the e-comorbidity group ($P< 0.001$).

Conclusion: e-comorbidity assessment offered a specific and dynamic approach tailored to the patient's needs over the 2-years study period, which is applicable in standard practice. Patient reported e-comorbidity outperformed the standard medical recording systems and can have a role in healthcare management and research. Reclassifying RA patients according to their comorbidity risk would have a positive impact on their adherence to therapy, early assessment of comorbidities with subsequent preventive or treatment decisions.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster II: Co-morbidities and Complications

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is associated with a high prevalence of comorbidities, negatively affecting outcomes like disease activity and physical function. However, not all comorbid conditions have the same impact on the outcomes of interest. The Rheumatic Diseases Comorbidity Index (RDCI) was validated to measure more accurately the burden and prognostic impact of overall comorbidity, based on a weighted preselection of comorbid conditions. We aimed to quantify the total burden of comorbidities, its association with disease outcomes, demographics and Serious Adverse Events (SAE) in early RA.

Methods: The presence of comorbidities was recorded on screening, before treatment initiation in 379 patients with recently diagnosed RA (<1 year) participating in the Care in early RA (CareRA) trial. The RDCI (0-9) was calculated by scoring 11 weighted comorbid conditions. Demographics including gender, age, smoking status, alcohol use and BMI were registered on screening. Disease activity (DAS28-ESR/CRP) was measured at baseline and after 1 year treatment using a treat-to-target approach. All SAE were registered during a 2-year follow-up. The association of RDCI with disease activity, functional disability (HAQ-DI), demographics and SAE was explored by assessing Spearman correlations. Correlations ≤0.29 were considered small, 0.30-0.49 moderate and ≥0.50 strong. Additionally, a multivariate linear regression analysis was performed to control for confounders.

Results: Out of 379 patients, slightly more than half (55.9%) had a RDCI equal to zero. The mean score was 0.8 and the maximum 6. RDCI scores of 1, 2 or ≥3 were obtained in 65 (17.2%), 70 (18.5%) and 32 (8.4%) participants respectively. The most frequent comorbidities were hypertension (22.4%), cardiovascular events (myocardial infarction/stroke or other) (16.6%) and lung diseases (8.4%). A moderately positive correlation was found between RDCI and age ($r = 0.39$, $p<0.001$). RDCI also correlated with disease activity (DAS28-CRP and DAS28-ESR) ($r = 0.19$-0.21, $p<0.001$) and with physical functioning (HAQ-DI) ($r = 0.13$, $p=0.009$) at baseline. After 1 year no more statistically significant correlation was found between the RDCI and DAS28-CRP, DAS28-ESR or HAQ-DI scores. In addition, RDCI correlated positively with the amount of SAE per patient, occurring during this 2-year study ($r = 0.24$, $p<0.001$). Multivariate linear regression confirmed these findings. RDCI was significantly associated with DAS28-CRP at baseline ($\beta=0.127$, $p=0.034$), and amount of SAE per patient ($\beta=0.109$, $p=0.001$) when controlled for gender, age, smoking status, alcohol use, BMI and treatment strategy.

Conclusion: At disease onset, almost half of RA patients in our study population had at least one clinically important comorbidity, as assessed by the RDCI. Scores of this co-morbidity index were positively correlated with age, disease activity and functional ability at baseline, but this correlation disappeared after one year treatment with intensive remission induction strategies. The incidence of SAE was associated with RDCI, reflecting an important impact of comorbidities on patients' overall health evolution.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tissue resident memory T (T_{RM}) cells survive indefinitely in barrier tissues and mediate swift immunologic memory responses at sites of microbe entry. T_{RM} cells have been implicated in recurrent site-specific inflammation in skin, intestine, and lung, but little is known about T_{RM} cells in synovium. We employed a highly efficient 3-dimensional (3-D) explant culture technique, developed to recover T_{RM} from skin, to investigate synovial infiltrating T cells.

Methods: Subjects with rheumatoid arthritis (RA) were identified by International Classification of Disease (ICD) codes, supported by medical record review by a board-certified rheumatologist. Synovial tissue samples were obtained from RA patients undergoing medically necessary joint surgery. Collagenase digestion and/or 3-D explant culture was used to isolate synovial T cells. In the 3-D explant culture system, 2mm x 2mm pieces of synovial tissue were placed on Cellfoam matrices, and cultured in T cell media enriched with IL-2 and IL-15 for 3 weeks. Multidimensional analysis of surface markers and cytokine production upon stimulation was performed by mass cytometry (CyTOF).

Results: Synovial samples were obtained from 13 women and 2 men with established RA. Treatment regimens varied (methotrexate, n=9; tumor necrosis factor inhibitors, n=6; prednisone, n=5; non-steroidal anti-inflammatory drugs, n=5). 3-D explant culture of RA synovium samples yielded 5-fold more mononuclear cells, on average, than collagenase digestion (mean number mononuclear cells per mg tissue ± SEM: 25,000 ± 17,000 vs. 5,600 ± 4,700). Approximately, 80% of cells collected by the 3-D explant culture method were $CD3^+$ T cells, with the majority being $CD4^+$ T cells (~80%). The ratio of $CD4^+$ to $CD8^+$ cells was not significantly different between the recovery methods. Multidimensional mass cytometry analyses demonstrated dramatic differences in phenotype between synovial and blood $CD4^+$ memory T cells, with significantly increased CD49d and MHCII and decreased CD27 on synovial T cells. A Th1 phenotype predominated in synovial T cells isolated by explant cultures, with ~35% of $CD4^+$ memory T cells expressing IFNγ and Tbet upon stimulation. Notably, memory $CD4^+$ T cells with a phenotype consistent with T_{RM} cells ($CD62L^-$, $CCR7^-$, $CD69^+$) were identified in all tested synovial samples. While CD69 expression may be induced by recent activation, many of these potential T_{RM} ($CD62L^-$, $CCR7^-$, $CD69^+$) cells did not express two other markers of recent activation, CD25 and MHCII.

Conclusion: 3-D explant culture is a novel tool that can be employed to study lymphocytes that are resident in synovium. Memory T

cells with T_{RM} features were identified in synovial samples from RA patients, supporting the hypothesis that this T cell subset may contribute to the persistence and recurrence of inflammatory arthritis. Further study will be needed to define the functional characteristics and pathophysiologic role of these cells.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Emerging evidence indicates that long noncoding RNAs (lncRNAs) play critical regulatory roles in various human diseases, especially in cancers and inflammatory disorders. However, the role of lncRNAs in the pathogenesis of rheumatoid arthritis (RA) remains largely unknown.

Methods: Fibroblast-like synoviocytes (FLSs) were separated and cultured from synovial tissues of healthy control (HC) and RA patients. Differentially expressed lncRNAs between HC and RA FLSs were identified by microarray. Expression level and subcellular localization of RNA was validated by quantitative real-time PCR (qRT-PCR) and in situ hybridization (ISH). Transcriptional initiation and termination sites of NR_122076 were identified by rapid amplification of cDNA ends (RACE) analysis. Lentivirus mediated overexpression of NR_122076 were adopted to investigate the function of NR_122076. Proliferation rate was assessed by EdU assay. Migration and invasion of FLSs *in vitro* were measured by the Boyden chamber assay. Cytoskeleton was visualized by immunofluorescence.

Results: We used microarray to establish lncRNA expression profiles in FLSs from HC and RA patients. We found that 94 lncRNAs were upregulated and 195 lncRNAs downregulated by more than 2-fold in RA FLSs compared with HC FLSs. Further qRT-PCR confirmed that, among them, only NR_122076 expression was significantly decreased in the synovial tissues and FLSs from RA patients. Stimulation with PDGF-BB decreased the expression of NR_122076, whereas treatments of methotrexate or dexamethasone increased NR_122076 expression. RNA fluorescent in situ hybridization (FISH) and qRT-PCR of nuclear and cytoplasmic fractions suggested that NR_122076 was mainly located in the cytoplasm. Overexpression of NR_122076 significantly inhibited cell proliferation, migration and invasion in RA FLSs. Furthermore, overexpression of NR_122076 impaired PDGF-BB induced formation of lamillipodia and filopodia.

Conclusion: Decreased expression of NR_122076 contributes to excessive proliferation and aberrant aggressive behaviors of RA FLSs. Our findings suggest NR_122076 might be a possible new therapeutic target against RA.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is one of the leading causes of mortality for rheumatoid arthritis (RA) patients. Despite its high prevalence and mortality, little is known about the pathogenesis of RA–associated ILD (RA-ILD). Given that idiopathic pulmonary fibrosis (IPF) and RA–ILD share the usual interstitial pneumonia pattern and common environmental risk factors such as tobacco smoking, we hypothesized that the two diseases may share additional risk factors including familial pulmonary fibrosis (FPF) susceptibility genes.

Methods: We used whole-exome sequencing (WES) followed by restricted analysis of a discrete number of FPF-linked genes to compare mutations among consecutive RA–ILD patients collected by a French network of pulmonologists and rheumatologists. A burden test was used to assess the excess number of mutations in RA–ILD patients.

Results: Among the 101 RA–ILD patients included, 12 (11.9%) had 13 WES-identified heterozygous mutations in the *TERT*, *RTEL1*, *PARN* or *SFTPC* coding regions. The burden test, based on 81 RA–ILD patients and 1010 controls of European ancestry, revealed an excess of *TERT*, *RTEL1*, *PARN* or *SFTPC* mutations for RA–ILD patients compared to controls ($p=9.45 \times 10^{-4}$, odds ratio [OR] 3.17 95% CI 1.53–6.12). Telomeres were shorter for RA-ILD patients with a *TERT*, *RTEL1* or *PARN* mutation than controls ($p=2.87 \times 10^{-2}$).

Conclusion: Our results support the contribution of FPF-linked genes to RA–ILD susceptibility, linking RA–ILD and IPF pathogeneses. Recent therapeutic advances in IPF may open new avenues for treatment of ILD, the most severe RA manifestation for which effective drugs are lacking.

A Unique Immune Signature in Patients with Active Rheumatoid Arthritis but Normal C-Reactive Protein Levels: Potential for New Therapeutic Targets?

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Using musculoskeletal ultrasound (US) to assess joint erosions and disease activity in patients with seropositive rheumatoid arthritis (RA) an atypical subgroup was identified with active disease demonstrated by significant Power Doppler, but normal C-reactive protein (CRP) and erythrocyte sedimentation rate levels. We questioned whether this presentation was associated with delayed diagnosis or relative under treatment, risking worse disease outcome and/or disability. We hypothesized that understanding the underlying immune pathology in this atypical subset could directly influence therapeutic targeting in patients whose needs are not currently met. We aim to stratify patients based on their immune signature to identify new treatment algorithms and therapeutic targets.

Methods: 44 RA patients with active synovitis were recruited, defined by ≥1 joint with Power Doppler detected by US, 29 had normal (n)CRP (≤5mg/L) and 15 had high (h)CRP (>5mg/L) levels. Peripheral blood mononuclear cells (PBMCs), serum and detailed clinical data were collected. 18 age and sex matched healthy donors were also analyzed. Multiple 14-colour flow cytometry panels were used to perform in-depth PBMC immunophenotyping. Serum and intracellular cytokines were assessed using Cytometric Bead Array and flow cytometry. Plasma was subjected to SOMAscan™ (Slow Off-rate Modified Aptamer) Proteomic Assay. Data was analyzed using cluster analysis (partitioning and hierarchical agglomerative algorithms) and correlation analysis (using a shrinkage estimator of the partial correlation matrix).

Results: nCRP patients had increased erosion accrual rate compared to hCRP patients (p=0.022) reflecting more disease-associated joint damage, while other clinical and laboratory parameters were identical. However, nCRP patients were able to mount a CRP response to infection. Serum IL-6 and IL-1β, pro-inflammatory cytokines known to trigger CRP production and support T-cell activation, were significantly elevated in both patient groups compared to healthy donors (p=<0.001) suggesting either defects in downstream IL-6 signaling or the disease mechanism may be IL-6-independent in nCRP patients. In support of this, nCRP patients had an anti-inflammatory phenotype characterized by significantly increased regulatory T-cells (Tregs) (p=0.014) with increased CD161 expression, known to be inversely correlated with CRP levels and associated with increased Treg suppressive capacity. Alternatively, hCRP patients had the expected activated T-cell phenotype including increased central memory T-cells (p=0.024) and Th17 populations. Preliminary proteomic analysis identified significant increases in complement components, serum amyloid P (SAP) and CRP in the hCRP compared to nCRP patients. Strikingly, serum amyloid A, an acute phase protein that has different ligands to CRP and SAP was significantly increased in both patient groups.

Conclusion: This study stratifies distinct patient subgroups using detailed immunophenotyping and proteomic signatures. We have identified altered immunopathological mechanisms in nCRP patients which could translate to improved patient-specific therapies.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose : Numerous genetic susceptibility loci have been identified in RA. The HLA-DRB1 shared epitope (SE) sequence is most strongly associated, though there has been increasing interest in amino acids outside the SE region. Recently, investigators have identified 16 HLA haplotypes defined by amino acids at positions 11, 71, and 74. Valine at position 11, particularly the VKA haplotype, has been associated with radiographic progression, mortality, and poor RA treatment response. In this study we examined HLA haplotypes and associations with mortality, presence of subcutaneous nodules, radiographic damage, and RA-associated autoantibodies.

Methods: The study included 1443 U.S veteran participants. Clinical characteristics were recorded at enrolment. Mortality was ascertained via linkage to the National Death Index. DNA was obtained at enrollment and 4-digit HLA-DRB1 genotyping was completed. Amino acids at positions 11, 71, and 74 were determined, and haplotypes assigned based on three amino acid combinations. RF and aCCP were measured from banked serum. Haplotype associations with mortality were examined using age- and sex-adjusted Cox proportional hazards regression, while associations with other disease characteristics were examined using Chi square or Student's t-tests comparing subjects with at least one copy of a given haplotype to those with no copies.

Results: The most frequent haplotype was VKA with 34% of subjects possessing at least one copy. Eight haplotypes were present in frequencies >10% (VKA, VRA, LRA, PAA, GRQ, SRA, SKR, SEA). We found an increased risk of all-cause mortality with SKA (HR 1.38 [95% CI 1.13-1.69]) but not with SE status or other haplotypes, including those with valine at position 11. Radiographic damage was more common in patients with VKA (60% vs 51%, p = 0.002) or VRE (70% vs 53%, p = 0.032) but less common with SRA (44% vs 55%, p = 0.005) and SEA (46% vs 57%, p = 0.023). There were no haplotype associations with subcutaneous nodules. We identified associations between several haplotypes and autoantibody concentration (Table). The VKA haplotype was associated with higher RF and aCCP concentrations. SE positivity based on dual autoantibody status was: RF+/aCCP+ = 77%; RF-/aCCP+ = 79%; RF+/aCCP- = 53%; and RF-/aCCP- = 56%. A similar pattern was observed for VKA haplotype positivity: RF+/aCCP+ = 39%; RF-/aCCP+ = 37%; RF+/aCCP- = 18%; and RF-/aCCP- = 18%.

Conclusion: In contrast to recent reports, we observed little association between HLA haplotype and all cause mortality. However, there were associations of both VKA and VRE haplotypes with presence of radiographic damage and robust associations of VKA with higher RF and aCCP values. Our observations also suggest that associations of both SE and VKA status with seropositivity are driven by associations with aCCP status independent of RF.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Traditional and non-traditional cardiovascular (CV) risk factors underlie CV disease occurrence in rheumatoid arthritis (RA). Recently, a functional impairment of HDL antioxidant capacity has been observed. Although the actual players are unknown, anti-HDL antibodies have been associated with altered lipid profile, decreased paraoxonase 1 (PON1) activity and CV disease in RA patients. Therefore, we aimed to evaluate whether the presence of antibodies against PON1 may be involved in this scenario.

Methods: IgG anti-PON1 antibodies were quantified by ELISA in serum samples from 175 healthy controls (HC), 54 subjects with traditional CV risk factors and 212 RA patients (all fulfilling 2010 ACR/EULAR classification criteria, 56.1% RF+, 57.0% ACPA+, DAS28 median (IQR) 3.73 (2.24)). A subgroup of 13 RA patients was prospectively followed upon TNFa-blockade for 3 months. PON1 activity and total antioxidant capacity (TAC) were measured in serum. IFNg, IL-8, MCP-1, VEGF, sICAM and TNFa serum levels were assessed by immunoassays. PON1 rs662 (Q>R) status was studied by RT-PCR.

Results: IgG anti-PON1 antibodies are increased in RA patients compared to HC ($p<0.0001$) and CVR groups ($p<0.001$), even after correcting for total IgG levels. Although no associations with lipid profile were found, a positive correlation with HAQ was observed ($r= 0.215$, $p=0.004$). An ANCOVA analysis confirmed an independent effect of both rs662 status ($p<0.0001$) and anti-PON1 levels ($p=0.015$) on PON1 activity, these associations remain after adjusting for disease parameters. Anti-PON1 antibodies were negatively associated with PON1 activity and TAC, a rs662-mediated gene-dosage effect being found. The association between anti-PON1 and TAC mirrored that of found between PON1 and TAC (Table 1) after stratifying by rs662 variants. Similarly, anti-PON1 antibodies were correlated to sICAM serum levels in univariate ($r= 0.226$, $p=0.010$) and multivariate models (B[95% CI], p: 0.159 [0.065, 0.2253], <0.001). Finally, anti-PON1 serum level and TAC were not affected by TNFa-blockade.

Conclusion: Anti-PON1 antibodies can be responsible of PON1 impairment in RA patients, with a potential impact on biomarkers of oxidative status and endothelial activation. A gene-environment interaction of rs662 variants is supported. Overall, anti-PON1 may be the missing link between autoimmunity, oxidative stress and CV disease in RA.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by hyperplasia of synovial lining cells, consisting of macrophage-like type A synoviocytes and fibroblast-like type B synoviocytes. It has been appreciated that type A synoviocytes, which are also called intimal macrophages, are derived from monocyte precursors in the bone marrow (BM). Previous studies showed the accelerated generation of monocyte-lineage cells from BM progenitor cells in RA. Of note, recent studies have demonstrated that response gene to complement 32 (RGC32) is a novel membrane regulator for macrophage phagocytosis. It has been well appreciated that synovial macrophages as well as peripheral blood monocytes have enhanced capacities of phagocytosis. It is thus possible that abnormal expression of RGC32 genes in the BM might be involved in the enhanced phagocytosis of monocytes and macrophages. The current study therefore examined the mRNA expression of RGC32 in BM CD34+ cells from RA patients.

Methods: BM samples were obtained from 48 patients with RA (6 males and 42 females: mean age 58.6 years) and 31 patients with OA (3 males and 28 females: mean age 71.1 years), who gave informed consent, during joint operations via aspiration from iliac crest. CD34+ cells were purified from the BM mononuclear cells by positive selection with magnetic beads. The expression of mRNA for RGC32 was examined by quantitative reverse transcription PCR. The results are shown as the ratio of the copy numbers to those of b-actin mRNA.

Results: The expression of mRNA for RGC32 was significantly higher in RA BM CD34+ cells than OA BM CD34+ cells (Figure). The mRNA expression levels of RGC32 were not correlated with serum C-reactive protein. There were no significant differences in RGC32 mRNA expression between RA patients with MTX and those without MTX (*p=0.4788*) or between RA patients with oral steroids and those without oral steroids (*p=0.0607*). RGC32 mRNA expression was significantly correlated with nuclear factor-kappa B1 (NFkB1) (*p<0.0001,* r=0.5550) gene expression in RA BM CD34+ cells.

Conclusion: These results indicate that the enhanced expression of RGC32 mRNA in BM CD34+ cells plays a pivotal role in the pathogenesis of RA through upregulation of phagocytosis capacities of peripheral blood monocytes and synovial macrophages. Moreover, the data also suggest that the enhanced RGC32 mRNA expression might be closely associated with mRNA expression of NFkB1.

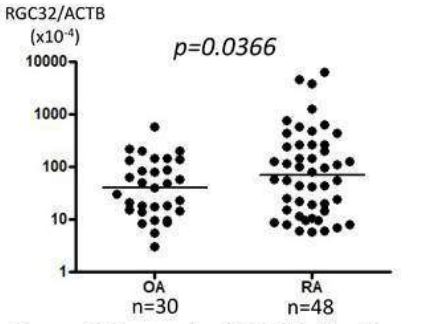

Figure: mRNA expression of RGC32 in Bone Marrow CD34+ cells from OA patients and RA patients

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Fibroblast-like synoviocyte (FLS) is expected to be a novel therapeutic target for rheumatoid arthritis (RA) because of their contribution to pathogenesis. FLS expresses matrix metalloproteinases, chemokines and cytokines in a response to various cytokines in affected joints, which leads bone and cartridge destruction, inflammatory cell recruitment and angiogenesis in pannus. The objective of this study is to investigate the transcriptional organization of stimuli responses and to clarify a character of RA-FLS.

Methods: Synovium were obtained from RA (n = 21) and osteoarthritis (OA) patients (n = 23) who underwent joint replacement surgery with informed consent. Minced synovium were treated with collagenase and cultured in Dulbecco modified Eagle's medium supplemented with 10% fetal bovine serum. At passage 2, FLS were isolated with removal of contaminating CD14 positive cells by magnetic-activated cell sorting. Purified FLS were stimulated with cytokines (TNF-α, IL-1β, IL-6/sIL-6R, IL-17A, IL-18, IFN-γ, IFN-α, TGF-β1 and combination of all 8 cytokines which simulated the mixture of stimuli in the joint) for 10 and 24 hours. Total RNA was extracted and libraries for RNA-sequence were prepared using TruSeq Stranded mRNA Library Prep kit (Illumina), and paired-end sequencing was performed using HiSeq 2500 (Illumina).

Results: The overview of transcriptomes with multi-dimensional scaling plot revealed that there were conserved transcriptome differences between RA and OA-FLS for each stimulatory condition, although the fluctuation vector with each stimuli were similar between RA and OA-FLS. Through the pathway analysis, 12 transcriptional regulators and those downstream genes were supposed to be significantly upregulated in RA-FLS compared to OA-FLS. In particular, E2F transcription factor 6 (E2F6), heat shock factor protein 1 (HSF1), Lysine (K)-specific demethylase 5B (KDM5B), nuclear protein 1 (NUPR1), tumor protein P53 (TP53) were expected to affect the downstream gene expression in stimulatory conditions compared with non-stimulatory condition. Among 1468 downstream genes of these 5 transcriptional regulators, 26 genes related to RA genome-wide association study (GWAS) were detected. Notably, colony stimulating factor 2 (CSF2), cyclin-dependent kinase 2 (CDK2) and flap structure-specific endonuclease 1 (FEN1) were significantly differentially expressed gene not only in RA-FLS compared with OA-FLS, but also in cytokine-stimulated FLS compared with non-stimulatory condition. Furthermore, through the correlation analysis, CSF2 expression which was induced by certain cytokines (IL-1β, TNF-α, all cytokine mixture) was highly correlated with particular transcription factors (i.e. JUN, FOX, JUND).

Conclusion: CSF2 was specifically expressed in RA-FLS and significantly expressed in the presence of stimulation. Although CSF2 locus was raised in RA GWAS, the expression quantitative trait loci (eQTL) effect for CSF2 gene has yet to be determined. Through comprehensive analysis, the mechanism for CSF2 expression and the pathway of RA-FLS specific transcription is expected to be elucidated.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Although there are several reports of transcriptome analysis of peripheral blood mononuclear cells (PBMC) in RA, analysis of detailed $CD4^+$ subset and the effect of abatacept on their expression has not been reported so far. We analyzed the transcriptome of detailed $CD4^+$ T cell subsets including them after abatacept treatment, and examined the difference among $CD4^+$T cell subsets and identified gene sets that are closely associated disease activity and abatacept treatment.

Methods: PBMC were taken from RA patients (n = 10) fulfilling 2010 ACR/EULAR criteria, and healthy control (HC) (n = 10). Samples were repeatedly taken from three RA patients 6 months after abatacept treatment. Seven $CD4^+$ T cell subsets (Naive, $CD25^+$ regulatory T cell, follicular helper T cell, helper T cell subsets (Th1, Th17, Th17.1, Th2)) were sorted and total RNA was extracted. Libraries for RNA-sequence were prepared using TruSeq Stranded mRNA Library Prep kit (Illumina), and paired-end sequencing was performed using HiSeq 2500 (Illumina). 149 samples except for 12 outliers were analyzed (4 outliers because of different FACS gating strategy, 8 outliers detected with robust PCA). R version 3.2.3 was used for analysis. Knowledge-based pathway analysis were performed using Ingenuity Pathway Analysis (QIAGEN).

Results: Overview of expression using principal component analysis (PCA) revealed that the samples form RA and HC form distinct groups. Moreover, administration of abatacept exert a large shift toward the expression pattern of HC. Most of differentially expressed gene (DEG) upregulated in RA (n = 1,776) were downregulated with abatacept treatment (n = 1,349). Inversely, most of DEG downregulated in RA (n = 1,860) were upregulated with abatacept treatment (n = 1,294). Knowledge-based network analysis revealed canonical pathway and upstream analysis associated with RA $CD4^+$ subsets and administration of abatacept. While the difference among $CD4^+$ T cell subsets was not remarkable, abatacept treatment largely changed the direction of network including canonical pathway and upstream analysis. Weighted gene co-expression network analysis (WGCNA) revealed the association between gene set (module) and clinical traits. One module was detected that consist of 227 genes and highly correlated with DAS28-CRP (Spearman's rho=0.46, $p=4x10^{-9}$) and abatacept administration (Spearman's rho=-0.91, $p=5x10^{-57}$). Expression of this module differentiate the sample before abatacept treatment and after treatment. Abatacept treatment suppress this module expression and JAK3 and ZAP70 were included in top 30 gene of this module. Pathway analysis of this module revealed that abatacept treatment suppress the network under the TCR signal pathway.

Conclusion: Administration of abatacept exerts a great change on gene expression of general $CD4^+$ subsets. WGCNA identified a gene module that is closely associated with disease activity and abatacept treatment, and the network under the TCR signal pathway was supposed to be suppressed with abatacept administration.

Histone Lysine Methylation and STAT3 Differentially Regulate Constitutive and IL-6-Induced MMPs Gene Activation in Rheumatoid Arthritis Synovial Fibroblasts

Yasuto Araki[1,2], Takuma Tsuzuki Wada[2,3], Yoshimi Aizaki[1,2], Kazuhiro Yokota[1], Hiroshi Kajiyama[1], Yu Funakubo Asanuma[1], Kojiro Sato[1], Hiromi Oda[4] and Toshihide Mimura[1,2], [1]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan, [2]Project Research Division, Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan, [3]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Iruma, Japan, [4]Orthopedic Surgery, Faculty of Medicine, Saitama Medical Univeristy, Morohongo Moroyama, Japan

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that causes progressive joint destruction. In spite of the modern medications, including biologic reagents, it is still hard to cure RA completely. A line of evidence suggests that synovial fibroblasts (SFs) play an important role in the pathogenesis of RA. RASFs produce matrix metalloproteinases (MMPs) that degrade articular cartilage. Although interleukin-6 (IL-6) is proved to be involved in the pathogenesis of RA, it is unknown whether IL-6 affects MMPs gene transcription in RASFs. Furthermore, recent advances have revealed that epigenetic mechanisms, including histone modifications, are important regulators in gene transcription. Trimethylation of lysine 4 at histone H3 (H3K4me3) is an active histone marker whereas trimethylation of lysine 27 at histone H3 (H3K27me3) is a repressive histone marker. We have hypothesized that epigenetic dysregulation might induce RASF activation. The purpose of this study is to clarify whether histone modifications are associated with MMPs gene activation in RASFs and whether IL-6 regulates MMPs expression in RASFs.

Methods: We compared MMPs gene expression by quantitative RT-PCR and histone lysine methylation in the MMP promoters by chromatin immunoprecipitation (ChIP) assay after stimulation with IL-6 and/or soluble IL-6 receptor α (sIL-6Rα) in RASFs and osteoarthritis (OA) SFs as a control. Chromatin structures in the MMP promoters were evaluated by micrococcal nuclease (MNase) assay in RASFs and OASFs. We investigated the change in the MMPs gene expression after silencing of WDR5 that is required for generating H3K4me3. IL-6 signal induces Signal Transducer and Activator of Transcription 3 (STAT3) activation. To elucidate the mechanisms of IL-6-induced MMPs gene activation in RASFs, we investigated cell surface expression of the IL-6 receptor (gp130 and membrane-bound IL-6Rα) by flow cytometry, phosphorylation of STAT3 by immunoblotting, and binding of STAT3 to the MMP promoters after IL-6 stimulation by ChIP assay in RASFs and OASFs.

Results: MMP-1, 3, 9 and 13 genes were actively transcribed in RASFs. The profiles of histone lysine methylation (H3K4me3 and H3K27me3) and the result of MNase assay indicated that chromatin structures were open in the MMP-1, 3, 9 and 13 promoters in RASFs. The depletion of WDR5 reduced the levels of H3K4me3 as well as the MMP-1, 3, 9 and 13 gene expression. Interestingly, IL-6 and sIL-6Rα significantly increased the expression of MMP-1, 3 and 13, but not MMP-9, in RASFs. Although the expression levels of gp130 as well as IL-6Rα were comparable and STAT3 was similarly phosphorylated after IL-6 stimulation in RASFs and OASFs, STAT3 bound to the MMP-1, 3 and 13 promoters, but not the MMP-9 promoter, after stimulation with IL-6 and sIL-6Rα only in RASFs. It was suggested that binding of STAT3 to the promoters resulted in MMP-1, 3 and 13 gene activation after IL-6 stimulation in RASFs.

Conclusion: Altered profiles of histone lysine methylation and binding of STAT3 to the promoters differentially regulate constitutive and IL-6-induced MMPs gene activation in RASFs and possibly arthritogenic properties of RASFs.

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), genome-wide association studies have identified over 100 risk alleles. A major challenge is identifying causal genes in RA risk loci. As RA risk loci are enriched with many genes expressed in $CD4^+$ memory T cells, our objective was to determine which risk-associated genes regulate T cell cytokine expression and dissect relevant biologic pathways important in RA development.

Methods: A lentiviral small hairpin RNA (shRNA) library targeting ~40 RA risk genes was generated. Each RA risk gene was targeted by 5-8 shRNA clones. The shRNA was used to disrupt expression of RA risk genes in primary human $CD4^+$ memory T cells, which were negatively isolated from healthy donor peripheral blood mononuclear cells. Primary human $CD4^+$ memory T cells underwent infection, selection and then T cell receptor activation to promote cytokine expression. Enzyme-linked immunosorbent assay (ELISA) was used to measure expression of IL-10, IL-13, IL-17A and IFN- γ in culture media. Generation of relative cytokine level per cell number, line of best fit and additional analysis was performed using SAS v9.3. Rank order system was generated to identify genes that modulated cytokine expression in comparison to control shRNA. Genes identified in the primary screen were reassessed in a secondary screen and then further validated.

Results: *DDX6*, a member of the DEAD-box helicase and post-transcriptional regulator family, was identified in our screen as a negative regulator of IL-10, IL-13, IL-17A and IFN-γ expression in activated $CD4^+$ T cells. *DDX6* silencing in $CD4^+$ T cells increased cytokine expression, validating the screen findings. In addition, *DDX6* mRNA levels were elevated in resting $CD4^+$ T cells but decreased when $CD4^+$T cells are functionally activated. Loss of expression inversely correlated with cytokine expression. We then demonstrated that DDX6 (p54/Rck) physically interacts with cytokine mRNA during transcriptionally quiescent states using RNA immunopreciptation.

Conclusion: Our experimental approach provides a systematic strategy to functionally differentiate candidate RA susceptibility genes based on relevant biological pathways. Specifically, we identified *DDX6* as an important regulator of effector function of primary human $CD4^+$ T cells.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF-α is a major cytokine implicated in rheumatoid arthritis (RA) and its expression has shown to be regulated at transcriptional and posttranscriptional levels. However, the impact of changes in microRNA (miRNA) expression on posttranslational processes involved in TNF-α signaling networks is not well-defined in RA. Here we evaluated the effect of miR-17 on TNF-α signaling pathway in human RA synovial fibroblasts (RASFs).

Methods: MiR-17 expression was correlated in SFs/synovial tissue (ST) and serum from RA, osteoarthritis (OA), or healthy (NL) donors using qRT-PCR. Expression of miR-17 was also validated in the rat adjuvant-induced arthritis (AIA) model of RA. RNA sequencing was performed in RASFs transfected with pre-miR-17 or NC-pre-miR using an Ion Proton™ System. Effect of miR-17 on the expression of TNF-α signaling proteins (TRAF2, cIAP1, cIAP2, USP2, and PSMD13) at the basal level and in TNF-α (20ng/ml) stimulated RASFs was determined using Western immunoblotting. Immunoprecipitation (IP) and Western immunoblotting methods were used to determine the effect of miR-17 on the ubiquitination processes in RASFs. Culture supernatants from miR-17 overexpressing and TNF-α-stimulated RASFs were used to study the effect of miR-17 on IL-6, IL-8, production using cytokine array (Ray Biotech). Effect of miR-17 on the nuclear translocation of p-c-Jun and p-STAT3 was studied in TNF-α-stimulated RASFs. Statistical value of $P<0.05$ was considered significant.

Results: We demonstrate that miR-17 expression was significantly low in the serum, SFs, and STs from RA patients as well as in the serum and joints of AIA rats. RNA sequencing analysis showed modulation of 664 genes by pre-miR-17 in human RASFs. Ingenuity pathway analysis of RNA sequencing data identified the ubiquitin proteasome system (UPS) in TNF-α signaling pathway as a primary target of miR-17. Western blot analysis confirmed the reduction of TRAF2, cIAP1, cIAP2, USP2, and PSMD13 expression by miR-17 in TNF-α-stimulated RASFs. IP assays showed that miR-17 restoration increased the K48-linked polyubiquitination of TRAF2, cIAP1, and cIAP2 in TNF-α-stimulated RASFs. Thus, destabilization of TRAF2 by miR-17 reduced the ability of TRAF2 to associate with cIAP2, thereby resulting in the downregulation of TNF-α-induced nuclear translocation of NF-κBp65, p-c-Jun, and p-STAT3 and the production of IL-6, IL-8, MMP-1, and MMP-13 in human RASFs.

Conclusion: This study provides a novel evidence for the role of miR-17 as a negative regulator of TNF-α signaling by modulating the protein ubiquitin processes in human RASFs.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Three different subsets of monocytes, $CD14^{bright}CD16-$ (classical), $CD14^{bright}CD16+$ (intermediate), and $CD14^{dim}CD16+$ (nonclassical) have been recently identified. It has been reported that $CD14^{bright}CD16+$ monocytes are increased in rheumatoid arthritis (RA). However, the role of each monocyte subset in the pathogenesis of RA is still unclear. The purpose of this study was to investigate the association of $CD14^{bright}CD16+$ monocytes with RA.

Methods: The study enrolled 35 untreated RA patients and 14 healthy volunteers. DAS28-ESR was evaluated and peripheral blood samples were obtained at baseline and following 12 weeks after methotrexate treatment. The three subsets of peripheral blood monocytes were analyzed by flow cytometry. Serum levels of cytokines were measured at baseline of the patients. $CD14^{bright}CD16-$

monocytes were isolated and cultured in vitro with indicated cytokines for 14 hours and assessed in CD16 induction.

Results: The proportion of $CD14^{bright}CD16+$ monocytes and serum levels of interleukin-6 (IL-6), IL-8, and IL-10 were increased in RA patients at baseline compared to healthy controls. The degree of disease activity of RA positively correlated with the proportion of $CD14^{bright}CD16+$ monocytes, while proportion of $CD14^{bright}CD16-$ monocytes had negative correlation. When isolated $CD14^{bright}CD16-$ monocytes were stimulated with IL-6, IL-8, and IL-10, IL-10 was the only cytokine that remarkably induced CD16 expression on the cells. Moreover, addition of anti-IL-10 receptor blocking antibody significantly suppressed CD16 expression on $CD14^{bright}CD16-$ monocytes compared with that of control antibody.

Conclusion: The proportion of $CD14^{bright}CD16+$ monocytes positively correlated with RA disease activity and $CD14^{bright}CD16+$ monocytes were induced from $CD14^{bright}CD16-$ monocytes by IL-10 but not by other cytokines upregulated in the sera from RA patients. Our results suggest that $CD14^{bright}CD16+$ monocytes are possibly involved in the pathogenesis of RA and IL-10 may be a key cytokine that regulates $CD14^{bright}CD16+$ monocytes.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate whether working in cold environment is associated with an increased risk of developing rheumatoid arthritis (RA) (overall), anti-citrullinated protein antibody (ACPA)-positive RA and ACPA-negative RA.

Methods: Data from the Swedish population-based case-control study (Epidemiological Investigation of Rheumatoid Arthritis (EIRA)) involving 3650 incident cases and 5838 controls were analyzed. Study participants were asked through questionnaires whether they had ever worked in cold indoor or cold outdoor environment. Individuals who were exposed to working in cold environment were also asked to report their exposure duration and frequency. Only exposure up to the year when the first disease symptom appeared was considered. Exposed subjects were compared with unexposed subjects by calculating odds ratios with 95% confidence interval (CI) using logistic regression.

Results: When compared with subjects who had never worked in cold environment, the odds of developing RA (overall), ACPA-positive RA and ACPA-negative RA among those who had ever worked in cold environment were 1.5 (95%CI, 1.4-1.7) ,1.6(95%CI,1.4-1.8) and 1.4(95%CI,1.2-1.6) respectively. These results did not change substantially after adjusting for age, sex, residential area, cigarette smoking, educational level, body mass index, alcohol consumption, occupational class and occupational physical workload. The risk of developing RA increased with increasing cumulative dose of working in cold indoor environment (P for Trend <0.0001) but not working in cold outdoor environment.

Conclusion: Working in cold environment is observed to be associated with increased risk of developing both ACPA-positive and ACPA-negative RA. A dose-response relationship is found between working in cold indoor environment and risk of developing RA.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic joint disease, characterised by synovial inflammation and destruction of articular cartilage/bone. The Janus-Kinase and Signal Transducer and Activator of Transcription (JAK-STAT) signalling pathway is implicated in the pathogenesis of RA. The objective of our research was to examine the effect of tofacitinib, a selective JAK inhibitor, on metabolic activity, mitochondrial function and pro-inflammatory mechanisms in RA.

Methods: Primary RA synovial fibroblasts and *ex-vivo* RA synovial explants were cultured with tofacitinib (1μM). Expression of active phosphoSTAT3 (pSTAT3) was quantified by Western blot. The effect of tofacitinib on RA pro-inflammatory mediators, including cytokines, growth factors and matrix metalloproteinases (MMP) was quantified by ELISA and MSD multiplex assays and on RASFC invasion by Biocoat^{TM} assays. RASFC metabolism was assessed by the XF24-Flux-analyser and RASFC mitochondrial mutagenesis was quantified using a mitochondrial random mutation capture assay (RMCA). Mitochondrial function was assessed for reactive oxygen species (ROS), mitochondrial membrane potential (MMpot) and mitochondrial mass (MM) using the specific cell fluorescent probes and differential gene expression by mitochondrial gene arrays. Mitochondrial morphological structure was assessed by TEM. Lipid peroxidation (4HNE) and serum amyloid A were quantified by ELISA.

Results: IL-6, OSM and IL-17 induce pSTAT3 expression in RASFC. Tofacitinib inhibited basal, OSM- and IL-17-induced secretion of IL-6 and MCP-1 from RASFC ($p<0.05$) with no effect observed for basal and IL-17-induced IL-8 and Rantes. OSM inhibited Rantes secretion from RASFC, an effect that was reversed by Tofacitinib. In RASFC, tofacitinib significantly inhibited ROS ($p<0.05$), MM ($p<0.05$), MMpot ($p<0.05$) and induced glycolytic activity with concomitant attenuation of mitochondrial respiration. This was coupled with altered mitochondrial structural morphology in RASFC and differential regulation of mitochondrial genes, specifically inhibiting BCL2L1, TOMM24, PMAIP1, and inducing UCP-1 and SCS25A ($p<0.05$). This was also associated with changes in hypoxia response genes including HIF1a and PHD2. In RA whole tissue synovial explants, which maintain the architecture and cell-cell contact of the joint thus closely reflecting the *in-vivo* environment, tofacitinib significantly inhibited spontaneous secretion of IL-6, IL-8, IL-1b, ICAM-1, VEGF, Tie2 and MMP1 (all $p<0.05$). While tofacitinib also inhibited TNFa, IFNg and IL-12, this did not reach significance, with no effect on VCAM-1, PIGF, bFGF, 4HNE or A-SAA. Finally conditioned media from tofacitinib treated RA synovial explants inhibited RASFC invasion.

Conclusion: This study further supports JAK-STAT inhibition as a therapeutic target for the treatment of RA

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is one of the chronic autoimmune diseases, with genetic and environmental predisposition, and synovial angiogenesis is considered to be a notable stage in its pathogenesis. Angiogenesis or vascular proliferation has been suggested to be a pivotal mechanism involved both inflammation/immune activation and joint invasion and destruction. RA may be considered an „angiogenic| disease" because it is associated with active tissue neovascularization. Vascular endothelial growth factor receptor 2 (VEGFR2; KDR) is the earliest marker for endothelial cell development, it is considered a crucial signal transducer in angiogenesis. And therefore is involved in the development of inflammation. VEGFA is the one of most potent proangiogenic molecule promoting the angiogenic phenotype of RA and is upregulated in RA. The aim of the study was to identify functional KDR variants and their possible association with KDR expression, susceptibility to and severity of RA.

Methods: 641 RA patients and of 340 healthy individuals were examined for +1416A/T KDR gene polymorphisms by PCR-RFLP method and for +889G/A and -604 T/C KDR gene polymorphisms by TaqMan SNP genotyping assay. Serum KDR levels in RA patients and controls were measured by ELISA.

Results: The +1416A/T KDR gene polymorphism under the codominant and recessive (AA+AT vs TT) models were associated with RA (p=0.02; p=0.019, respectively). The +889 G/A KDR gene polymorphism under the dominant (GG vs GA+AA) model was associated with RA (p=0.005). Furthermore, KDR -604 T/C revealed differences in the case-control distribution in codominant and dominant models (all p<0.0001). The genotype-phenotype analysis showed significant association between the KDR+889G/A and Larsen score (p=0.03), VAS score (p=p<000.1), DAS-28 score (p=p<0.0001), HAQ sore (p=0.02), number of swollen joints (p<0.0001), mean value of ESR (p=0.006), mean value of CRP (p<0.0001), and mean value of creatinine (p=0.02). Additionally the number of women with the polymorphic allele +889 A was higher than the number of women with wild type allele -+889 G (p<0.0001). Serum KDR levels were significantly higher in RA patients than in control groups (p=0.002).

Conclusion: Present findings indicated that KDR genetic polymorphism may be associated with the susceptibility to and severity of RA in the Polish population.

Major Histocompatibility Antigen HLA-DQ6.1 (DQA1*0103/DQB1*0601) Increases Rheumatoid Arthritis Risk Independent of Shared Epitope Among Indians

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The association of HLA-DRB1 shared epitope (SE) with rheumatoid arthritis (RA) does not completely explain MHC association. The HLA-DRB1 alleles are classified into high risk (S2, S3P), low risk (S1, S3D) and neutral (Sx) alleles which increase, decrease or do not affect RA risk respectively. Unlike HLA-DR antigens, HLA-DQ is polymorphic at both alpha and beta chains. DQA1*0103 and DQB1*0601 that form the DQ6.1 heterodimer are autoimmune prone and are associated with achalasia cardia, HashimotoÕs thyroiditis and autoimmune hepatitis). They are common in Japan and India but rare outside Asia. DQ6.3(DQA1*0103/DQB1*0603) was reported to be protective in Finland population. We studied the association of HLA-DQ6 isoforms with RA after controlling for shared epitope.

Methods: 181 patients with RA fulfilling ACR 1987 criteria were recruited from a tertiary referral center in North India along with 250 healthy controls from the same ethnic and regional background. Molecular typing of HLA-DRB1, HLA-DQA1 and HLA-DQB1 alleles were done using PCR and SSOP (sequence specific oligo probe). Subjects were classified into risk strata based on HLA-DRB1 shared epitope genotype. Logistic regression was used to study association. Subjects were risk stratified based on the shared epitope genotype to study the interaction between SE alleles and DQ6.1

Results: The mean age of patients were 37.2(±10.2) years at onset and 74% were female. 76.1% were RF positive and 16.5% had extra-articular manifestations. 43(23.8%) of RA patients had DQ6.1 against 33(13.3%) controls (Odds ratio 2.01, P=0.007). DQ6.3(DQA1*0103/DQB1*0603) was present in 3(1.7%) patients against 16(6.4%) controls (OR 0.37, P=0.037). High risk SE alleles S2 or S3P were present in 84/179 (47%) patients and 73/249 (29%) controls (OR 2.1, P<0.001). Low risk SE alleles S1 or S3P were present in 104/179(58%) of rheumatoid and 178/250 (81%) of controls (OR 0.70, P=0.016). On multivariate analysis, the OR for DQ6.1 increased to 2.76 (P<0.001) while high risk SE alleles S2/S3P had OR 1.99 (P=0.001). After adjustment for SE genotype by stratification and meta-analysis (Fig 1), OR for DQ6.1 further increased to 4.3(1.7-10.7 P=0.002). Both DQ6.1 and DQ6.3 (Fig 2) were in linkage with low risk SE alleles but not high risk alleles.

Conclusion: HLA-DQ6.1 (DQA1*0103/DQB1*0601) is an independent genetic risk factor for Rheumatoid Arthritis in North Indians especially those negative for high risk DRB1 shared epitope alleles. Protective effect of HLA-DQ6.3 (DQA1*0103/DQB1*0603) requires further study.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: T cells abnormality is an essential part in the pathogenesis of rheumatoid arthritis (RA), which includes a signature of premature immune aging, and restricted proliferative potential of naïve T cells. Shelterin complex is critical for maintaining Telomeres, which are important regulators of aging. We hypothesized that shelterin deficiency may play a key role in the senescence of RA T cells.

Methods: Naïve CD4 T cells were isolated from **29** Newly-onset treatment-naive RA patients and 38 gender-and age- matched healthy controls (HC) . The expression of six shelterin subunits was assessed in naïve and activated CD4 T cells. Critical DNA damage responses and the role of TRF2 in cell apoptosis were tested as well.

Results: The mRNA levels of subunits TRF1, TRF2, Rap1 and TPP1, except POT1 and TIN2, were significantly lower in RA naïve CD4 T cells compare with those from HC. TCR stimulation significantly up-regulated all subunit expression in both group in a time-dependent manner, but the level of healthy controls remained higher than RA patients. Additionally, the deficiency of shelterin subunits were independent of disease activity (measured by DAS28), disease duration or treatment. Consistently, DNA lesions related to apoptosis triggers, including ATM, CHK2, H2AX histone, p53, p21 and GADD45, were up-regulated in RA naïve CD4 T cells compared with HC. Finally, by TRF2-silencing, we showed loss of telomere protection by shelterin ultimately resulted in ATM-p53-dependent DNA damage response in naïve CD4 T cells, which was correlated with caspase-3 activation.

Conclusion: Shelterin deficiency of naïve CD4 T cells in RA patient may be involed in the perturbed T cell homeostasis, and restore T cell competence may be a potential therapeutic target.

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Circulating multipotential stromal cells (MSCs) also termed mesenchymal stem cells have previously been implicated in fibroblast mediated polyarticular joint destruction in rheumatoid arthritis (RA). We hypothesized that skeletal trauma (a biophysical process) rather than a biological basis related to RA may account for any MSC circulation.

Methods: Deep (femoral) and matched peripheral (antecubital) vein blood was collected from 36 patients undergoing lower limb orthopaedic procedures. Peripheral blood was also taken from 15 early and 11 established RA patients as well as 12 healthy controls. Colony-forming unit-fibroblast (CFU-F) assays and cytometric phenotyping of cells were performed. Molecular characterisation of genes related to MSC function was undertaken in comparison to MSCs from iliac crest and femoral marrows, bone, periosteum, adipose tissue and dermal fibroblasts.

Results: 17/36 femoral vein samples contained CFU-Fs, but only 7/74 peripheral vein samples almost exclusively from the orthopaedic cases with only a single peripheral blood colony from one established RA patient. The MSC nature of CFU-Fs was confirmed by expansion and phenotype: CD105/CD73/CD90 positivity and CD19/CD31/CD33/CD34/CD45/CD61 negativity. Their molecular profiles were typical of MSCs with 39/80 genes showing similarity across multiple MSC tissue controls; including osteogenesis-related *ALPL, COL1A1, SPARC,* adipogenic *LPL,* chondrogenic *COL2A1, COL10A1, SOX9* and immature *POU5F, NANOG*, but not fibroblasts.

Conclusion: There is no evidence that MSCs circulate in RA or health. Deep vein MSC numbers may relate to biophysical micro-damage to the trabecular vascular architecture caused by skeletal manipulation. Their numbers are so low that a biological role seems unlikely in early RA or other autoimmune diseases.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The histopathologic features of synovial tissue vary widely among patients with rheumatoid arthritis (RA) undergoing arthroplasty and the clinical significance of this variability is unknown. Improved methods for assessing synovial histopathology could help characterize subtypes of RA and predict clinical outcomes.

Methods: 149 RA patients undergoing total hip or knee arthroplasty were enrolled. 130 synovial tissue samples were stained with hematoxylin and eosin and assessed for 20 histologic features such as lymphocytic infiltrates, neutrophils, mucoid change, vascularity, synovial lining hyperplasia, detritus, fibrin, plasma cell inflammation, binucleate plasma cells, germinal centers, Russell bodies, mast cells, giant cells and synovial giant cells. 19 of the synovial samples were disaggregated and their synovicoytes analyzed by RNA sequencing. We used a standard unsupervised hierarchical clustering approach to group samples and genes with similar expression

profiles. Using the resultant RNAseq sample clusters, we applied a machine learning algorithm (standard Support Vector Machine) using binarized histology features and a leave-one-out cross-validation approach. The model was able to accurately predict which RNAseq cluster a given sample would most likely belong to, suggesting good harmony between the genomic data and the histology. We then used our histology SVM model derived on the 19 samples to cast cluster predictions on the broader set of 130 synovial samples, for which we had complete histology data but no RNAseq.

Results: Unsupervised hierarchical clustering of 19 synoviocyte samples based on genome-wide RNA expression levels identified 2 well-separated subtypes of synovial tissue composition that distinguished samples based on the level of inflammatory cell presence, and a third subgroup within the low-inflammatory cell subset that suggests further subclassification of RA synovial tissue based on non-immune cell types. Confirming the validity of this approach, histology scoring of lymphocytic infiltrates correlated significantly with the RNAseq clusters containing the highest level of hematopoietic lineage transcripts. Furthermore, clinical features such as ESR and obesity correlated with the subsets defined by the RNAseq analyses. Gene set enrichment analysis of differentially expressed genes between the clusters showed variable levels of immune and stromal cell subsets, noting particular differences in IFNg responses. Application of the histology SVM models to the remaining ~100 samples generated predictions of RA synovial gene expression subtypes, which together with ongoing studies connecting clinical parameters to this model suggest an approach to subclassify the disease with greater specificity.

Conclusion: Gene expression clusters derived from RNAseq were used to train a histology scoring system to distinguish between inflammatory and noninflammatory RA synovial tissue. SVM weights indicate that lymphocytic infiltrates, plasma cells, fibrin and synovial lining hyperplasia are predicted to be associated with inflammatory gene expression, while mast cells, vascularity, detritus and mucoid changes are predicted to associate with non-inflammatory samples.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Translocator protein (TSPO) is a mitochondrial cholesterol transporter, utilised in diseases as a Positron Emission Tomography (PET) imaging marker of macrophage infiltration. Recent observations support its utility as a PET marker in rheumatoid arthritis (RA), predictive of persistent synovitis and response to treatment. Here, we use synovial tissue taken from areas of known increased TSPO PET tracer uptake *in vivo*, to profile the expression of TSPO within cellular components found within synovium. We further investigated the potential of TSPO as a peripheral blood biomarker of disease activity in RA.

Methods: 10 patients with RA and clinical evidence of knee synovitis were included. Each patient underwent PET-CT of knees with PBR28, a PET tracer targeted to TSPO followed by synovial biopsy within 7 days. Formalin fixed paraffin embedded tissue sections were generated, and stained for macrophage markers CD68, CD163 and the fibroblast activation marker gp38. Peripheral blood mononuclear cells were collected just prior to PET, and lysed for RNA and protein. From surgically obtained synovium in patients with active RA, Fibroblast-like synoviocytes (FLS), monocytes and lymphocytes, were isolated and lysed for RNA and protein analysis. Macrophages were generated by stimulation of synovial monocytes with M-CSF for 7 days. FLS and monocyte-derived macrophages were further stimulated with TNF alpha before being harvested for RNA and protein analysis. Cells from synovium, as well as

monocyte derived macrophages, were also incubated with PBR28 tracer to assess tracer uptake in each cell type.

Results: A positive correlation between PBR28 tracer uptake, clinical synovitis, and semi-quantitative staining scores for TSPO, CD68, CD163, and gp38 was observed (see table). At both RNA and protein level, TSPO was expressed most highly in monocyte derived macrophages, and FLS treated with TNF for 24 hours, being negligible in synovial derived lymphocytes, monocytes and unstimulated FLS; findings that were mirrored by PBR28 uptake radioassay of these cell groups. There was an average 3 fold increase in TSPO expression at mRNA level in peripheral blood mononuclear cells of treatment naïve arthritis patients with clinically active disease, independent of CRP, compared with healthy controls, with TSPO expression correlating with tender and swollen joint count.

Conclusion: Our work demonstrates that TSPO imaging is likely to reflect FLS activation in the synovium as much as it is macrophage infiltration. For treatment-naïve patients, there appears to be a statistically significant, higher expression of TSPO in peripheral blood compared to healthy controls, at both RNA and protein level. Further studies are needed to profile TSPO cell expression in inflammation and ascertain whether TSPO may be a sensitive peripheral blood marker in patients with rheumatoid arthritis.

Table 1: semi-quantitative staining scores of knee synovial biopsy tissue for TSPO, CD68, CD163 and gp38, in relation to clinical synovitis scoring, and PBR28 tracer standardised uptake values (SUV).

Clinical synovitis severity score	PBR28 tracer uptake (SUV) from same knee compartment as biopsy site	TSPO staining score	CD68 staining score	CD163 staining score	gp38 staining score
3 (severe synovitis)	1.3±0.2	3.5±0.4	3.1±0.3	2.5±0.4	2.7±0.3
2 (moderate synovitis)	0.7±0.2	1.7±0.9	1.8±0.5	1.5±0.3	1.6±0.5
1 (minimal synovitis)	0.3±0.1	0.5±0.4	0.4±0.2	0.2±0.1	0.5±0.1

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial fibroblasts play crucial roles in the pathogenesis of rheumatoid arthritis (RA). They secrete proteinases and proinflammatory cytokines to damage the synovial tissues in the RA joints. Their functions are regulated by a number of molecules including microRNAs (miRNAs). MiRNAs are endogenous small noncoding RNAs, and suppress expression of target genes

by binding to 3'- untranslated region (UTR) of the corresponding messenger RNAs. The present study was conducted to identify miRNAs to regulate expression of matrix metalloproteinase-3 (MMP-3) and interleukin-6 (IL-6), which are crucial in the pathogenesis of RA.

Methods: Nine hundred and twenty-four inhibitors of human miRNAs were transfected individually into synovial fibroblast cell lines developed from the RA synovial tissues. The transfected cells were cultured in the presence or absence of 1 ng/ml TNF-α for 24-72 hours. The expression levels of MMP-3 and IL-6 were quantified with enzyme-linked immunosorbent assay. The expression level of ets variant 6 (ETV6) was determined with Western blotting and quantitative polymerase chain reaction analysis. MiRNA array analysis was conducted for evaluation of the miRNA expression levels in the synovial fibroblasts with or without the TNF-α stimulation.

Results: Functional screening of 924 miRNAs using miRNA inhibitor library identified 14 miRNAs to regulate expression of MMP-3 in synovial fibroblasts. Out of these miRNAs, miR-103, miR-129-5p, miR-135a and miR-193b have seed sequence that match with 3' UTR of ETV6, which is a transcriptional repressor of MMP-3. The effects of the four miRNA inhibitors on MMP-3 expression were validated with independent experiments. Inhibitors of miR-103 and miR-129-5p suppressed the expression level of IL-6. The four miRNA inhibitors increased the protein expression of ETV6 without upregulating the mRNA level. MiRNA array analysis revealed that the expression levels of miR-103, miR-129-5p and miR-135a in synovial fibroblasts were increased when they were stimulated with TNF-α.

Conclusion: Functional screening of miRNAs using the inhibitor library identified miR-103, miR-129-5p, miR-135a and miR-193b, which target ETV6, as regulators of MMP-3 and IL-6 expression in RA synovial fibroblasts. These miRNAs could be novel drug targets in RA.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: MicroRNAs (miRNAs) are ~22-nt RNAs that post-transcriptionally regulate gene expression and serve as biomarkers of many disease states. Most previous plasma miRNA studies in inflammatory autoimmune diseases have relied on PCR or microarray for candidate miRNAs based on limited information about miRNA function; however, unbiased small RNA sequencing (sRNAseq) could reveal new miRNA disease biomarkers. We hypothesized that plasma miRNAs are altered in inflammatory autoimmune diseases (RA and SLE) compared to control subjects and are differentially altered in RA and in SLE.

Methods: This cross-sectional study included patients with RA, SLE, and age, race and sex matched control subjects (N=12, each). Sequencing was done by Illumina HiSeq3000. High quality reads were mapped to the human genome using Bowtie1. MiRBase21.0 was used to quantify miRNAs. All samples had ≥1 million miRNA reads, and miRNAs having ≥10 reads per sample were analyzed. Reads per mapped read were compared between RA, SLE and control subjects. Significantly altered miRNAs with ≥1.5 fold difference were examined. Putative miRNA targets were generated using TargetScanHuman 7.1 and compared to disease-related pathway genes using the KEGG database.

Results: Significantly elevated plasma miRNAs in patients with RA and SLE compared to control subjects (Table 1) were miR-24-3p and miR-345-5p, which are predicted to target mRNAs encoding interferon gamma or its receptor and HLA-DOA, HLA-DPB1, HLA-

DRB1, and HLA-DRB5. Significantly altered plasma miRNAs in SLE compared to RA and control subjects (Table 2) included miR-194-5p, miR-424-3p, let-7d-5p, miR-652-3p, miR-548o-3p, miR-335-5p, let-7a-3p, miR-369-3p, miR-204-5p, and miR-98-3p, some of which are predicted to target histone and complement proteins, IL10, SSA, and NMDA receptors. Significantly increased plasma miRNAs in RA compared to SLE and control subjects (Table 3) included miR-501-3p, miR-450b-5p and miR-22-3p, some of which are predicted to target TGF beta or its receptor, TLR4, IL6 and IL17.

Conclusion: Several miRNAs in plasma measured by sRNAseq are differentially altered in patients with RA and SLE. Many of the altered miRNAs have predicted targets in disease-related pathways. Further validation is necessary to confirm these findings.

Table 1. Altered miRNAs in both SLE and RA compared to control subjects

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) experience diminished quality of life and increased disability. Patient-reported outcomes (PROs) are important measures of response to therapy in patients with RA. The objective of this study was to examine the impact of rituximab on PROs in a US observational cohort of patients with RA.

Methods: Between March 1, 2006, and September 1, 2015, patients with RA who had prior exposure to ≥ 1 tumor necrosis factor inhibitor (TNFi) and newly initiated rituximab while not in remission (Clinical Disease Activity Index [CDAI] > 2.8) with a follow-up visit at 1 year (± 3 months) were identified. Changes in PROs, assessed 1 year from baseline and stratified by prior TNFi use, included patient global assessment (PtGA) of disease, pain and fatigue (visual analog score; 0-100); morning stiffness (hours); modified Health Assessment Questionnaire (mHAQ; 0-3) and Euro QoL 5 dimensions questionnaire (EQ-5D). Improvement in EQ-5D domains was defined as patients reporting improvement or resolution of impairment among those who reported impairment at baseline. Outcomes between the 1 and ≥ 2 prior TNFi groups were compared using χ^2 or *t*-tests, as appropriate; only statistically significant differences were noted.

Results: Of the > 40,000 patients in the Corrona RA registry, 667 patients met the study inclusion criteria; 284 (43%) had received 1 prior TNFi and 383 (57%) had received ≥ 2 prior TNFis. Overall, 79% of patients persisted on rituximab through 1 year, 80% of whom received retreatment. The median (IQR) age was 59 (50-66) years; 79% were female. Baseline mean (SD) CDAI was 25.6 (13.9; high disease activity = CDAI > 22). At baseline, patients were substantially impaired by their disease: patients reported median (IQR) PtGA, pain, fatigue and mHAQ scores of 50 (35-73), 60 (31-75), 65 (40-80) and 1 (0.6-1.6), respectively, and a median (IQR) of 1 (0.5-2) hour of morning stiffness. Baseline PROs were mostly similar between the 1 and ≥ 2 prior TNFi groups, although patients with 1 prior TNFi tended to have longer duration of morning stiffness and higher fatigue scores. At 1 year, improvements were reported in all PROs with no significant difference between patients with 1 or ≥ 2 prior TNFis. Overall median (IQR) improvements (baseline value minus the 1-year value) in PtGA, pain and fatigue were 7 (−10 to 25), 7 (−5 to 25) and 9 (−5 to 20), respectively. Improvement in EQ-5D categories is shown (**Figure**). 51.7% of patients reported no improvement in morning stiffness, 28.5% reported improvement of 1-60 minutes and 19.8% reported improvement of > 60 minutes.

Conclusion: Real-world data showed that quality of life in this cohort of patients with long-standing, refractory RA and prior TNFi exposure was substantially impacted by the disease. One year after initiation of rituximab, improvements were reported in all PROs, such as self-care and usual activities, and were similar between patients with exposure to 1 or ≥ 2 prior TNFis.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Several predictors of response to tocilizumab have been described. They include a low HAQ, high baseline CRP or NK levels and certain IL-6R polymorphisms. IL-6 and sIL-6R levels have also been considered as response predictors, but with contradictory results. However, the combination of them has not been studied.

Methods: Heparinized peripheral blood was obtained from 10 healthy donors and 63 RA patients meeting the ACR criteria. In all patients, RA was refractory to treatment with DMARDs, including methotrexate. Tocilizumab treatment was begun following European and Spanish guidelines. Plasma was collected prior to first infusion(baseline), at 4 and at 12w. Laboratory analysis included an haemogram, ESR, CRP, Igs, RF, ACPAs, IL-6 and sIL-6R concentrations. Clinical data collected was DAS28, SDAI, CDAI and EULAR response criteria. *K*-means clustering (SPSSv.18) analysis was applied to identify groups of patients based on IL-6 and sIL-6R concentrations.

Results: Three statistical significant clusters of RA patients were defined by IL-6 and sIL-6R concentrations at baseline: Group 1 with the highest levels of IL-6 and low levels of sIL-6R; Group 2 with low levels of IL-6 and sIL-6R; and Group 3 with the highest levels of sIL-6R (fig. 1). Baseline clinical data of RA patients in each group are presented in Table 1. DAS28 was markedly reduced after 24 weeks of treatment in all groups of patients (group 1: 6.09±0.24 to 3.55±0.46 at t=24w, p=0.001; group 2: 4.68±0.32 to 2.66±0.22 at t=24w, p=0.001;group 3: 6.04±0.30 to 2.89±0.34 at t=24w, p=0.0001). Patients in group 1 achieved the highest rate of remission (60% vs.27% in group 2 and 18% in group 3,p <0.04) and the highest rate of good EULAR response (83,3% vs. 44% and 30.8% in group 3) (fig.2). IL-6 levels, that correlated with RF and IL-15 levels, SDAI and CDAI, did not substantially change after 12w of tocilizumab. On the other hand, sIL-6R levels increased significantly in most patients(93.6%) after 4w of tocilizumab. After 12w, sIL6R levels in all patients of group 1 were still high, and they decreased in 50% of patients of group 3. sIL-6R levels inversely correlated with leukocyte counts/mL and with VSG, PCR and DAS28.

Conclusion: Combination of biomarkers IL-6 and sIL6R is more useful to discriminate those patients with the best response outcome to tocilizumab than both of them separately.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Aberrant CD40-CD154 pathway signaling has been linked to pathology in autoimmune disease. Blocking the CD40-CD154 pathway prevents T cell-dependent antibody responses, germinal center formation and prolongs renal allograft survival in non-human primates. CFZ533 is a novel, fully human, non-agonistic Fc-silent, anti-CD40 monoclonal antibody being developed for treatment of autoimmune diseases and prevention of rejection in solid-organ transplantation. The objective of present study was to assess the safety, pharmacokinetics (PK) and pharmacodynamics activity (PD) of CFZ533 in humans

Methods: A double-blind, placebo controlled, ascending, single-dose study was conducted in 48 healthy volunteers (HVs) receiving 0.03, 0.1, 0.3, 1.0, 3.0 mg/kg i.v., 3.0 mg/kg s.c. CFZ533 or matching placebo (3:1) as well as in 12 rheumatoid arthritis (RA) patients receiving 10.0 mg/kg i.v. CFZ533 or placebo (1:1). HVs were immunized with a single intramuscular dose of a T-cell dependent neo-antigen, Keyhole Limpet Hemocyanin (KLH) with alum adjuvant on Day 3 and again between Day 29-85 depending on predicted loss of CD40 receptor occupancy (RO) as a function of CFZ533 dose. Blood samples for PK, CD40 RO and anti-KLH IgG and IgM profiling were collected at multiple time points during the study. Anti-KLH antibodies were assessed using a validated human ELISA system with an LOQ of 0.7 (IgG) and 2.1 (IgM) µg/mL. RA patients were evaluated for safety, PK and RO

Results: All doses of CFZ533 and KLH were safe and well tolerated. CFZ533 PK concentrations were quantifiable at all dose levels tested. Complete (≥90%) peripheral CD40 RO by 3.0 mg/kg i.v. CFZ533 in HVs was maintained for 28 days. During this period of full RO, full suppression of the primary humoral response to KLH was evident in all treated subjects (KLH administered 2 days after CFZ533 dosing). After complete CFZ533 washout in 3.0 mg/kg cohort, all subjects mounted a robust anti-KLH response following a re-challenge on Day 85. Full RO in RA patients who received 10.0 mg/kg i.v. CFZ533 was maintained for at least 6 weeks and up to 10 weeks

Conclusion: The favorable safety and tolerability profile of CFZ533 coupled with a predictable concentration-CD40 receptor occupancy relationship and suppression of a primary T cell-dependent antibody response supports future clinical trials of CFZ533 in select autoimmune diseases and transplantation

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: High BMI is associated with reduced remission rates with anti-TNF agents in RA.[1,2] In ACQUIRE (NCT00559585), SC and IV abatacept (ABA) achieved similar ACR20 responses at 6 months (M)[3] and therapeutic trough concentrations[4] across body weight groups in patients (pts) with RA. This *post hoc* analysis explored clinical outcomes reflecting disease status and pharmacokinetics with SC (fixed dose) or IV (weight-tiered) ABA by BMI.

Methods: In ACQUIRE, pts with RA and MTX inadequate response were randomized (1:1) to SC (125 mg/week) or IV (~10 mg/kg/M) ABA plus MTX. Disease status over 6 M was assessed by DAS28 (CRP) (<2.6), SDAI (≤3.3) and CDAI (≤2.8) remission, mean change in Pt Global Assessment, TJC and SJC, and high-sensitivity CRP (hsCRP). Trough (C_{min}) serum ABA concentrations were measured at 3 and 6 M. Data were analyzed by baseline BMI (underweight/normal, <25 kg/m^2; overweight, 25–<30 kg/m^2; obese, ≥30 kg/m^2) and ABA administration route.

Results: 526 pts (SC 265, IV 261) were underweight/normal; 497 (SC 249, IV 248) overweight; 433 (SC 221, IV 212) obese. Baseline characteristics did not differ by administration route, and for the pooled SC/IV group were similar by BMI (Table 1). Clinical outcomes by BMI at 6 M were similar for SC and IV groups measured by the % of pts in DAS28 (Figure 1), SDAI (underweight/normal, 9.1 vs 10.6%; overweight, 12.0 vs 11.8%; obese, 11.9 vs 9.8%) and CDAI (underweight/normal, 9.0 vs 11.8%; overweight, 13.1 vs 13.7%; obese, 14.3 vs 11.8%) remission; 95% CIs overlapped at all time points. There were no differences in the other outcomes by BMI, except for hsCRP, but this had no impact on remission rates. Results were consistent for the pooled SC/IV group. Although SC ABA C_{min} concentrations decreased with BMI increase, >90% of pts had concentrations >10 µg/mL (efficacy threshold) across BMI groups at 3 and 6 M for both SC and IV ABA (Figure 2).

Conclusion: The clinical efficacy of SC and IV abatacept was independent of BMI, even when stringent remission criteria were used. Across BMI groups, >90% pts achieved therapeutic trough concentrations, irrespective of SC or IV administration. 1. Gremese E, et al. *Arthritis Care Res* 2013;**65**:94–100. 2. Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib is an oral selective inhibitor of Janus kinases 1/2 and has demonstrated dose-dependent efficacy in moderate-to-severe RA patients who were DMARD-naïve or with inadequate response to previous conventional or biological disease-modifying anti-rheumatic drugs (cDMARD/bDMARD-IR), in multiple phase 2 and 3 studies. The objective was to characterize the exposure-efficacy relationships and time course of 20, 50, and 70% improvement in the American College of Rheumatology criteria (ACR 20, 50, and 70, respectively) and disease activity score based on 28 joints and high sensitivity C-reactive protein (DAS28-hsCRP), in a combined phase 2/3 analysis.

Methods: The database comprised 7 baricitinib phase 2 and 3 studies in RA patients receiving placebo, 1, 2, 4, 7, 8 and 10 mg QD or 2-mg BID up to 24 weeks. The corresponding pharmacokinetics (PK), ACR 20/50/70 and DAS28-hsCRP response rates were analyzed by both quartile analysis and population pharmacokinetics/pharmacodynamics (PK/PD) modeling. For the quartile analysis, average steady-state concentrations from patients receiving 2- and 4-mg in 4 phase 3 studies were grouped into quartiles and correlated with the percentage of patients achieving ACR 20/50/70 and DAS28-hsCRP $\leq$3.2 and <2.6, at Week 12 and 16. Exposure-response models were also developed to describe the time-course and the exposure-response relationships of ACR 20/50/70 and DAS28-hsCRP following administration of baricitinib or placebo. Patient specific factors affecting the ACR 20/50/70 and DAS28-hsCRP response rates were explored.

Results: Plasma baricitinib concentrations were best characterized by a 2-compartment model with clearance partitioned between renal and non-renal components. Quartile exposure response analysis indicated that clinically relevant higher rates of ACR20/50/70 and DAS28-hsCRP responses were observed in the 3 upper quartiles compared to the lowest quartile. The PK/PD models adequately characterized the time course and exposure-responses of ACR20/50/70 and DAS28-hsCRP. Both baricitinib and placebo exhibited an indirect inhibitory effect on disease progression of ACR and DAS28-hsCRP. The model-estimated maximum response rates for ACR 20, 50, and 70 were 87%, 64%, and 39%, respectively, and 59% and 43% for DAS28-hsCRP $\leq$3.2 and <2.6, respectively. Model-estimated exposure response curves demonstrated that exposures from the 4-mg dose resided on the plateau of the response curves and exposures from 2-mg were lower and closer to the ascending portion of the curves for both ACR responses and DAS28-hsCRP states.

Conclusion: The final models successfully described and predicted the time-dependent changes in ACR20/50/70 and DAS28-hsCRP across the range of doses tested. A 4 mg QD dose was predicted to achieve close to maximal response.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (BARI), an oral JAK1/JAK2 inhibitor, is in development for patients (pts) with moderate to severe RA.[1,2] The purpose of this post hoc analysis of 2 completed Phase 3 studies was to determine if previous failure of cDMARDs altered the response to BARI in RA pts and to evaluate the effect of concomitant steroid use and prognostically unfavorable factors on the efficacy of BARI.

Methods: Pts with ≥6 swollen and tender joints and no prior biologic DMARD use were eligible for study inclusion. In RA-BUILD, cDMARD-inadequate responder (IR) pts with hsCRP ≥3.6 mg/L were randomized to placebo (PBO) or BARI (2 or 4 mg) once daily (QD).[1] In RA-BEAM, MTX-IR pts with X-ray erosions and hsCRP ≥6.0 mg/L were randomized to PBO QD, BARI 4 mg QD, or adalimumab 40 mg biweekly.[2] Patients continued background cDMARD (including MTX) therapy. The primary endpoint in both trials was ACR20 at Week 12 for BARI 4 mg vs. PBO.[1,2] This post hoc analysis included the PBO (N=716) and BARI 4 mg (N=714) pts and assessed the number of previous cDMARDS, concurrent corticosteroid use, and effect of poor prognostic factors (high disease activity by Simplified Disease Activity Index [SDAI]>26), RF/ACPA positive, and radiographic erosions).

Results: In PBO pts, 40%, 34%, and 23% previously used MTX alone, MTX + 1 cDMARD, and MTX + ≥2 cDMARDs, respectively; in BARI 4 mg pts the rates were 46%, 29%, and 23%. Oral corticosteroids were used in 56% of PBO and 55% of BARI pts at baseline; pts continued use throughout the studies. Regardless of treatment assignment, the majority of pts had 2 or 3 of the prognostically unfavorable factors (95% in PBO; 96% in BARI pts). The primary objectives were met for both studies.[1,2] The clinical efficacy of BARI 4 mg over PBO at 12 weeks (Table 1) and the percentage of pts with van der Heijde modified Total Sharp Score (mTSS) change from baseline ≤0 at 24 weeks (Table 2) each was similar regardless of the number of cDMARDs previously used, the concomitant use of corticosteroids, or the presence of prognostically unfavorable factors. The rates of serious adverse events and discontinuation due to adverse events were comparable regardless of the number of cDMARDs used, corticosteroid use, or the number of risk factors.

Conclusion: Baricitinib has demonstrated clinical efficacy in a wide range of patients with varying exposure to cDMARDs, concomitant use of corticosteroids, serologic status, and baseline disease activity. **References:** [1]Dougados M et al. *Ann Rheum Dis* 2015;74(S2):79. Efficacy and Safety of Baricitinib in Patients with Rheumatoid Arthritis and an Inadequate Response to Conventional Disease-Modifying Antirheumatic Drugs: A United States Subpopulation Analysis from Two Phase 3 Trials

Alvin F. Wells[1], Maria Greenwald[2], John D. Bradley[3], Jahangir Alam[3], Vipin K. Arora[3] and Cynthia E. Kartman[3], [1]Rheumatology & Immunotherapy Center, Franklin, WI, [2]Desert Medical Advances, Palm Desert, CA, [3]Eli Lilly and Company, Indianapolis, IN

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (bari), an oral selective JAK1 and JAK2 inhibitor, has been shown to be safe and efficacious compared to placebo (PBO) in two Phase 3 trials in patients (pts) with moderate to severe RA and an inadequate response (IR) to conventional DMARDs (cDMARDs).[1,2] The objective of this analysis was to evaluate efficacy and safety of bari 4 mg vs. PBO in the United States (US) vs. the "rest of world" (ROW) subpopulations of these two studies.

Methods: Eligibility requirements included ≥6 swollen and tender joints and no prior biologic DMARD use. In RA-BUILD, cDMARD-IR pts with hsCRP≥3.6 mg/L were randomized to PBO or bari (2 or 4 mg) once daily (QD).[1] In RA-BEAM, MTX-IR pts with x-ray erosions and hsCRP≥6.0 mg/L were randomized to PBO QD, bari 4 mg QD, or adalimumab 40 mg biweekly.[2] Primary endpoint in both trials was ACR20 at Wk 12 for bari 4 mg vs. PBO. This post-hoc analysis combined data from both trials providing overall samples for bari 4 mg (N=714) and PBO (N=716). The geographically-defined subpopulations were US/Puerto Rico [US/PR] and ROW. Descriptive statistics were utilized for efficacy and safety analyses.

Results: There were 188 US/PR and 1,242 ROW pts in this analysis. The proportions of pts who were White or Black/African-American were higher in US/PR; Asians were more represented in ROW. US/PR pts were slightly older, with fewer years of RA, and a lower percentage were RF/ACPA positive or used corticosteroids. More US/PR pts had previously used 1 cDMARD and more ROW had previously used ≥3cDMARDs (Table 1). Bari 4 mg demonstrated better responses vs. PBO across US/PR and ROW for multiple

efficacy outcomes, including ACR20/50/70, LDA, remission, DAS28-CRP, and HAQ-DI (Table 2). Comparing US/PR and ROW efficacy, no systematic differences were observed. No significant safety differences were identified for US/PR or ROW pts at Wk 12 for bari 4 mg vs. PBO in the incidence of ≥1 adverse event (AE), serious AE, or discontinuation due to AE or death (Table 3). There was 1 death in PBO in each subpopulation.

Conclusion: In this post-hoc, pooled analysis from two Phase 3 trials in cDMARD-IR patients, bari 4 mg demonstrated efficacy compared to PBO in US/PR patients. **References:** [1]Dougados M et al. *Ann Rheum Dis* 2015;74(S2):79; [2]Taylor P et al. *Arthritis Rheumatol* 2015;67(suppl 10):3928.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: CC-292 is a small molecule inhibitor of Bruton's tyrosine kinase (Btk), which is a component of the B cell receptor signaling complex found in B lymphocytes and myeloid cells. Btk plays a crucial role in B cell development, maturation, and function. CC-292 inhibits Btk activity by irreversible covalent binding with high affinity to the adenosine triphosphate (ATP) binding site of Btk. Inhibition of Btk could regulate inflammation in RA by two different mechanisms; by blocking B cell receptor–dependent B cell proliferation and the reduction of autoantibody levels, and by inhibiting Fc gamma receptor (FcγR)-induced TNFα, IL-1β and IL-6 production in macrophages. CC-292 was evaluated over a 4 week treatment period in female subjects with active RA on background methotrexate (MTX) (NCT01975610).

Methods: 47 adult female RA subjects were randomized 1:1 CC-292 375 mg PO daily or placebo (PBO). Subjects were required to have a diagnosis of sero-positive RA for at least 6 months, meeting the 2010 ACR/EULAR Classification Criteria for RA. The RA must have been active despite at least 3 months of treatment with MTX and on a stable dose (7.5 to 25 mg/week oral or parenteral) for at least 4 weeks prior to randomization. Permitted concomitant RA medications included sulfasalazine, antimalarials, and low dose corticosteroids (prednisone or equivalent ≤ 10 mg/day).

Results: CC-292 showed ACR20 (primary endpoint) improvement in 10 (42%) of 24 RA subjects vs. 5 (22%) of 23 RA subjects on placebo. ACR20 improvement separated from placebo as early as week 1, and progressed through week 4. This positive trend was not considered statistically significant (p=0.25). The magnitude of ACR20 difference of 20% between treatment groups at 4 weeks, although not statistically significant, is on par with the effect seen in RA with other DMARDs. There were numerical trends for ACR50 and ACR70 favoring CC-292. No trends for improvement were observed for the exploratory endpoints of DAS28, HAQ-DI, or swollen and tender joint counts. Pharmacodynamic measurement of Btk occupancy showed no free Btk in the peripheral blood mononuclear cells as early as week 1. CC-292 reduced osteoclast activity, reduced B-cell lymph node trafficking, reduced class switched and activated memory B-cell, and increased mature naive B-cells. Treatment emergent adverse events (TEAEs) were comparable across both treatment arms. The most frequently reported TEAEs (≥ 5% subjects) in the CC-292 arm were nausea, back pain, diarrhea, cough, and migraine. There were no deaths in the study. There were no serious TEAEs and one severe TEAE of stomatitis.

Conclusion: The study did not meet its primary endpoint of improvement in ACR20 at 4 weeks, nor the secondary endpoints of ACR50 and ACR70 at 4 weeks, although there were numerical trends combined with a responder sub-group analysis suggest potential efficacy of CC-292 in this female subject RA population. In this study, CC-292 was well tolerated and had a favorable safety profile over 4 weeks of treatment. CC292 BTK inhibition impacts RA with a different MOA and profile than current therapies.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Costimulation through the CD40–CD40L axis is implicated in the pathogenesis of RA including T cell-mediated responses, B cell-driven autoantibodies, adhesion molecule expression, synovial hyperplasia and pannus formation, in addition to secretion of proinflammatory cytokines and MMPs. Circulating sCD40L levels are elevated in RA patients versus healthy controls. Studies have shown a significant association between the CD40 rs4810485 T allele and RA. BI 655064 is a humanized antagonistic anti-CD40 monoclonal antibody that blocks the CD40–CD40L interaction in *in vitro* CD40L-induced B cell and APC activation assays with IC50 of <1 nM. In healthy volunteers, BI 655064 was well tolerated in doses up to 240 mg q1w s.c. for 4 wks. Doses ≥120 mg resulted in persistent >90% CD40 receptor occupancy and >90% inhibition of CD40L-induced CD54 upregulation.

Methods: In this double-blind randomized trial (NCT01751776), RA patients (n=67) received either 120 mg BI 655064 or placebo q1w for 12 wks as add-on to MTX. Inclusion criteria were ≥6 swollen and ≥6 tender joints, CRP ≥8 mg/L or ESR ≥28 mm/1h. The primary efficacy endpoint was ACR20 response at wk 12. Select biomarkers were assessed in whole blood and serum pre- and post-treatment with BI 655064. Rs4810485 was genotyped in a subset of patients (25 BI 655064, 18 placebo) by an allelic discrimination assay based on TaqMan PCR. For statistical analysis, patients were grouped into T allele carriers (TT/GT) and non-T allele carriers (GG).

Results: Higher ACR20/50 response rates were observed with BI 655064 (68.2%, 36.4%) vs placebo (45.5%, 18.2%) at wk 12. Baseline variables for the two groups were comparable except mean CRP (BI 655064 9.8 mg/L, placebo 23.6 mg/L; p<0.02). BI 655064 had minimal effects on the median %CD19+ B cell population but larger median decreases in select %CD95+ activated B cell subsets, specifically class switched (CD19+IgD-CD27+CD95+), pre-switched (CD19+IgD+CD27+CD95+) and double-negative (CD19+IgD-CD27-CD95+) cells (p=0.0097) at wk 12. Reductions in median IgG and IgA rheumatoid factor (RF, p=0.0018, p=0.005) and total IgG and IgM levels (p=0.0082, p=0.0002) were observed with BI 655064 vs placebo at 12 wks. Median decreases in IL-6 levels (B cell and monocyte differentiation) and select bone resorption biomarkers (MMP-3 and RANKL p=0.0041) were also observed with BI 655064 vs placebo at 12 wks. In patients who carried at least one T allele, a trend towards better ACR20 responses [72% (TT/GT) vs 50% (GG)] was observed with BI 655064 but not placebo. Two SAEs were reported in each group, but were not considered drug related. The most frequently reported AEs were nasopharyngitis (BI 655064 13.6%, placebo 21.7%) and headache (BI 655064 6.8%, placebo 13.0%).

Conclusion: Treatment of MTX-IR RA patients with BI 655064 resulted in moderate efficacy, which was potentially impacted by the relatively high placebo response rate and the imbalance in baseline CRP, and did not indicate any safety concerns. Treatment with BI 655064 decreased selected activated B cell subsets, inhibited RF production, and reduced levels of select circulating inflammatory and bone resorption biomarkers through 12 wks in RA patients.

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with RA, obesity may impair clinical response to anti-TNF agents.[1,2] In contrast, BMI does not appear to impact treatment retention or clinical response to abatacept (ABA);[3] however, data on the effects of BMI are limited for patients with poor prognostic factors (radiographic erosion or RF/anti-citrullinated peptide antibody [ACPA] double seropositivity). Previously, poor prognostic factors were found to positively impact ABA retention, independently of treatment line.[4] The current analysis tested the impact of BMI on ABA retention in biologic-naïve patients with RA who had poor prognostic factors at baseline.

Methods: ACTION is a 2-year, international, observational study of patients with RA who initiated IV ABA in routine clinical practice. Time to ABA discontinuation in biologic-naïve patients was estimated using Kaplan–Meier survival analysis. Clinically relevant variables, known risk factors, and potential predictive factors with significance in univariate models ($p \leq 0.20$) and no collinearity, were entered into multivariate Cox proportional hazards regression models. Prognostic factors of ABA retention were assessed in subgroups of patients with and without radiographic erosion at baseline. As comorbid obesity has previously been linked to a decreased likelihood of joint damage progression in patients with RA who are ACPA positive,[2] BMI status was forced into the multivariate model after stratification for RF/ACPA double-seropositive versus double-seronegative status.

Results: Here we report 1-year results for 677 biologic-naïve patients with ≥1 prior conventional synthetic DMARD failure who enrolled into the ACTION study in two cohorts: 122 from Europe and Canada between May 2008 and December 2010; 555 from across Europe between September 2010 and December 2013. Data from the two enrollment cohorts were pooled owing to similar baseline characteristics. The 12-month ABA crude retention rate (95% CI) in biologic-naïve patients was 78.14% (74.72, 81.16). When forced into the multivariate model, BMI did not significantly impact ABA retention in the subgroups of patients who were RF/ACPA double seropositive (p=0.142) or double seronegative (p=0.518) at baseline (Figure).

Conclusion: Real-world evidence shows that RF/ACPA double seropositivity is predictive of abatacept retention in biologic-naïve patients.[4] BMI does not significantly impact abatacept retention, even in subgroups of patients with poor prognostic factors such as RF/ACPA double seropositivity. 1. SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (bari), an oral JAK1 and JAK2 inhibitor, is in development for patients (pts) with moderate to severe RA. Drug-related problems are common in the elderly; therapies may be less effective and adverse effects more common. The purpose of this post hoc analysis was to evaluate the safety and efficacy of bari in the elderly subpopulation of 2 pooled phase 3 studies.

Methods: Patients with ≥6 swollen and tender joints and no prior biologic DMARD use were eligible for study inclusion. In the RA-BUILD study, csDMARD-IR pts with hsCRP ≥3.6 mg/L were randomized to placebo (PBO) or bari (2 or 4 mg) once daily (QD).[1] In RA-BEAM, methotrexate (MTX)-IR pts with X-ray erosions and hsCRP ≥6.0 mg/L were randomized to PBO QD, bari 4 mg QD, or adalimumab (ADA) 40 mg biweekly.[2] Patients continued background csDMARD (including MTX) therapy. The primary endpoint in both trials was ACR20 at Week (Wk) 12 for bari 4 mg vs. PBO. This post hoc analysis combined data from both trials providing overall samples for PBO (N=716) and bari 4 mg (N=714). Elderly pts were defined as those ≥65 years of age. Summary statistics are presented for demographic, efficacy, and safety data for pts aged <65 and ≥65 years.

Results: In these 2 studies, 249 patients ≥65 years old were randomized and initially treated with PBO (n=113) and bari 4 mg (n=136) (Table 1). The primary endpoints were met for both studies; bari showed significant differences vs. PBO for ACR20 at Wk 12; all key secondary endpoints were also met including mean change in DAS28, SDAI, and HAQ-DI.[1,2] Efficacy measures were similarly improved in pts <65 and ≥65 years of age (Table 1). Adverse events (AEs) occurred more frequently in the elderly population compared to pts aged <65 years; however, the prevalence of serious adverse events (SAEs) and discontinuations due to AEs was not different from PBO (Table 2). At 12 wks there were 2 deaths (both in PBO group <65) and cardiac events were rare, as were serious infections (Table 2); there were 2 herpes zoster events (both in bari 4 mg ≥65). There was 1 SAE of hospitalization due to thrombophlebitis (bari 4 mg <65) and 3 due to fractures, all related to falls (PBO <65, n=1; bari 4 mg <65, n=1; bari 4 mg ≥65, n=1); none of these pts discontinued the study and all events resolved.

Conclusion: In 2 phase 3 studies of bari in RA pts, age did not affect efficacy, but as expected there were more AEs in the elderly in both treatment arms. **References:** [1]Dougados M et al. *Ann Rheum Dis* 2015;74(S2):79. [2]Taylor PC et al. *Arthritis Rheumatol* 2015;67(S10):3927-3928.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (bari) is an oral JAK1/JAK2 inhibitor under investigation for the treatment of patients (pts) with moderate to severe RA.[1-2] In the 52-week Phase 3 RA-BEAM study, bari 4 mg once daily (QD) showed clinical improvements compared to placebo (PBO) and to adalimumab (ADA) in MTX-inadequate-responder (IR) pts.[2] The objective of this analysis was to evaluate efficacy and safety in pts from RA-BEAM who changed treatment from ADA to bari either after rescue in RA-BEAM or switch after entering a long-term extension (LTE) study (RA-BEYOND).

Methods: In RA-BEAM (completed September 2015), 1305 pts were randomized 3:3:2 to PBO, bari 4 mg QD, or ADA 40 mg every 2 weeks (wks). At Wk 16 or subsequent visits, IRs (lack of ≥20% reduction in tender and swollen joint count) were rescued to open-label bari 4 mg. At Wk 52, pts could enter the LTE, where all pts received bari 4 mg and remained blinded to their randomized treatment in RA-BEAM. No ADA washout period was applied for rescue or switch from ADA to bari. Efficacy analyses evaluated both rescued and not rescued RA-BEAM pts who entered the LTE ≥24 wks before the present data cutoff. Safety analyses included pts not rescued in RA-BEAM who entered the LTE.

Results: A total of 51 pts were rescued from ADA to bari 4 mg in RA-BEAM; at Wk 52, 67%, 49%, and 24% achieved ACR20, ACR50, and ACR70, respectively. Among pts who completed RA-BEAM without rescue, 381/394 (97%) bari, and 238/241 (99%) ADA pts entered the LTE. Of these, 185 (continued bari) and 108 ADA (switched to bari) pts reached the 24 wk time point and were included in the LTE efficacy analysis and 340 (continued bari) and 211 ADA (switched to bari) pts were included in the LTE safety analysis. Patients who switched from ADA to bari showed improvements in disease control through 12 wks post-switch in the LTE, without evidence of worsening through the following 12 wks (Table 1). Exposure-adjusted incidence rates for total treatment-emergent adverse events (TEAEs) and infections, including serious events, were similar for pts who switched from ADA to bari and those who continued on bari (Table 2).

Conclusion: Switching from ADA to bari without ADA washout was associated with improvements in disease control during the initial 12 wks post-switch, without an increase in overall TEAEs or serious AEs or infections, and without subsequent evidence of worsening. **References**: [1]Dougados M et al. *Ann Rheum Dis* 2015;74(S2):79. [2]Taylor PC et al. *Arthritis Rheumatol* 2015;67(S10):3927-3928.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The non-inferiority of subcutaneous tocilizumab (TCZ-SC) monotherapy every 2 weeks (q2w) to intravenous TCZ monotherapy every 4 weeks was demonstrated in Japanese patients with rheumatoid arthritis (RA).[1] During the open-label period, patients with an inadequate response to TCZ-SC q2w could shorten the dosing interval to receive TCZ-SC weekly (qw), which resulted in improved efficacy.[2] To confirm this preliminary result, the objective of this study was to determine the efficacy and safety of TCZ-SC qw vs TCZ-SC q2w in patients with RA who had an inadequate response to TCZ-SC q2w.

Methods: Adult RA patients with Disease Activity Index 28-joints based on erythrocyte sedimentation rate (DAS28-ESR) > 3.2, tender joint count (TJC) using 66 joints and swollen joint count (SJC) using 68 joints ≥ 4 each, and C-reactive protein (CRP) ≥ 0.3 mg/dL within 2 weeks of their last TCZ-SC dose, despite ≥ 8 weeks of TCZ-SC q2w therapy, were included. Patients were randomized 1:1 to receive either TCZ-SC 162 mg qw as monotherapy or TCZ-SC 162 mg q2w as monotherapy (double-blind period). After 12 weeks, all patients received TCZ-SC qw for 40 weeks (open-label period). The primary endpoint was the change from baseline in DAS28-ESR at week 12 using analysis of covariance (ANCOVA), adjusted by DAS28-ESR at randomization. The aim of this study was to demonstrate the superiority of TCZ-SC qw to TCZ-SC q2w. Additional efficacy, safety and pharmacokinetic parameters were assessed.

Results: Of the 43 patients enrolled, 21 received TCZ-SC qw and 21 received TCZ-SC q2w. TCZ-SC qw was superior to TCZ-SC q2w for adjusted mean change in DAS28-ESR from baseline to week 12 (−2.10 vs −0.89; $P = 0.0108$ [Table]). The adjusted mean change in Clinical Disease Activity Index from baseline to week 12 was −16.0 in the TCZ-SC qw group and −8.7 in the TCZ-SC q2w group ($P = 0.0979$; as per hierarchical testing). The proportions of patients who achieved DAS28-ESR remission or low disease activity were 42.9% and 25.0% for the TCZ-SC qw and TCZ-SC q2w groups, respectively. Improvements in TJC, SJC, CRP and ESR, and the proportion of patients achieving ACR20/50, were greater in the TCZ-SC qw group than the TCZ-SC q2w group. The proportions of patients who experienced adverse events (AE) were 71.4% and 66.7% in the TCZ-SC qw and TCZ-SC q2w groups, respectively. One patient in each group experienced ≥ 1 serious AE. There was 1 death in the TCZ-SC qw group.

Conclusion: In patients with an inadequate response to TCZ-SC q2w, TCZ-SC qw was superior to TCZ-SC q2w for improving DAS28-ESR at 12 weeks. The safety profile was comparable between patients who received TCZ-SC qw or TCZ-SC q2w, and was consistent with the safety profile of TCZ from previous studies. This study suggests that in patients with an inadequate response to TCZ-

SC q2w, shortening the dosing interval to TCZ-SC qw is an effective treatment option.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib is a small molecule inhibitor of the Janus kinase (JAK) pathways that reduce and modulate the production of inflammatory mediators and cytokines. We conducted a systematic review to evaluate the efficacy and safety of baricitinib for the treatment of patients with rheumatoid arthritis.

Methods: A comprehensive search of the literature was conducted in the following electronic databases: Cochrane Library, MEDLINE, EMBASE and Web of Science through April 2016. Also, we searched clinicaltrials.gov. Any randomized controlled trial (RCT) comparing baricitinib alone or in combination with any DMARD versus placebo or other traditional or biologic DMARDs for the treatment of patients with rheumatoid arthritis were included. Two independent reviewers performed study selection, data collection and risk of bias assessment using Covidence.org. Our primary outcome was the percent of patients achieving an American College of Rheumatology (ACR) 50% response. Secondary outcomes included: clinical remission (Disease Activity Score (DAS<2.6)), minimum clinical important difference (MCID) ≥0.22 in the Health Assessment Questionnaire (HAQ), total withdrawals and serious adverse events (SAEs).

Results: Out of 171 citations, 7 RCTs met our inclusion criteria. Most studies were published in abstract format and risk of bias assessment was judged unclear in most domains. Five studies compared more than two doses of baricitinib, however, we only report here results for the dose of 4 mg once daily. Four comparisons were included: i) baricitinib plus methotrexate (MTX) vs MTX, ii) baricitinib alone vs MTX, iii) baricitinib plus MTX vs adalimumab (ADA) plus MTX, and iv) baricitinib plus MTX vs baricitinib alone. For the combination of baricitinib plus MTX, more patients in the baricitinib group achieved an ACR 50 response and clinical remission compared to patients in the MTX group at 12 and 24 weeks (at 12 weeks patients in the control group were re-assigned to baricitinib). The combination group reported lower withdrawal rates at 24 weeks (RR 0.61, (95% CI 0.47-0.81) and similar SAEs at 24 weeks compared to control. For baricitinib alone vs MTX, improvement rates were higher in the baricitinib group at 12 weeks (RR 1.7, 95% CI 1.3-2.1; 1.8, 95% CI 1.2-2.6; 1.3, 95% CI 1.2-1.4; for ACR50, clinical remission, and MCID HAQ rates, respectively). No differences were found in total withdrawals or SAEs. When baricitinib was compared to ADA, greater rates of ACR50 response were observed in the baricitinib group at 12 weeks (RR 1.3; 95% CI 1.1, 1.5); but also higher rates of SAEs compared to the ADA group at 24 weeks were reported (RR 2.5; 95% CI 1.0, 6.1). No significant differences were observed between baricitinib plus MTX compared with baricitinib alone.

Conclusion: Baricitinib alone or combined with MTX had better efficacy responses compared to MTX alone at 12-24 weeks. Total withdrawal rates were lower in the baricitinib combined group when compared to MTX. Baricitinib had similar effects compared to adalimumab, but higher rates of SAEs. Baricitinib can be considered an additional therapeutic option to treat patients with moderate to severe disease who have an inadequate response to other treatment agents.

First-in-Human Pharmacokinetics and Safety of Escalating Single- and Multiple-Doses of GS-9876, a Novel, Oral SYK Inhibitor, in Healthy Subjects

Michael Dolton[1], Franziska Matzkies[2], Kevin Currie[3], Julie Di Paolo[4], Lu Wang[3], Hao Zheng[3], Srini Ramanathan[3] and Jeffrey Silverman[3], [1]Clinical Pharmacology, Gilead Sciences, Inc, Foster City, CA, [2]Gilead Sciences, Inc, Foster City, CO, [3]Gilead Sciences, Inc, Foster City, CA, [4]Biology, Gilead Sciences, Foster City, CA
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Spleen Tyrosine Kinase (SYK) mediates immunoreceptor signaling in a range of hematopoietic cells important

for the initiation and progression of inflammatory diseases such as rheumatoid arthritis (RA) and other autoimmune diseases including B lymphocytes, monocytes, macrophages, dendritic cells, and osteoclasts. Cellular data and multiple animal models of disease provide strong preclinical validation for SYK as a therapeutic target in RA. GS-9876 has been identified as a novel, potent and selective SYK inhibitor. Preclinical characterization of GS-9876 utilized in vitro biochemical and cellular assays to assess on-target and off-target pharmacology, and the rat collagen-induced arthritis model to establish in vivo efficacy. Here we describe first-in-human studies of GS-9876 which characterize the pharmacokinetic (PK) profile, safety and tolerability of escalating single- and multiple-doses of GS-9876, as well as the impact of food and acid-reducing agents on GS-9876 PK in healthy subjects.

Methods: Healthy subjects were administered escalating single (2 mg to 50 mg) or multiple (15 mg once daily to 50 mg once daily for 7 days) doses of GS-9876 in the fasted state. PK, safety and tolerability were assessed throughout the study, and reviewed following each dose level, prior to initiation of successive dose escalation cohorts. The impact of food (high-fat breakfast) and a representative acid-reducing agent (omeprazole 20 mg) on GS-9876 PK were assessed using a crossover study design.

Results: Sixty-two subjects received at least one dose of GS-9876. GS-9876 exhibited slightly greater than dose proportional increases in C_{max} but not area under the curve extrapolated to infinity (AUC_{inf}) following single doses (2 mg, 5 mg, 15 mg, 30 mg and 50 mg); dose proportional PK was observed following multiple doses (15 mg and 30 mg once daily). The median terminal elimination half-life was consistent following single or multiple doses and ranged from approximately 21 to 28 hours. Accordingly, GS-9876 exposure accumulated approximately 1.9-fold following multiple once daily doses. Administration of GS-9876 with a high-fat meal slightly reduced GS-9876 C_{max} (13%), but did not affect AUC_{inf}; administration with omeprazole did not affect GS-9876 C_{max} or AUC_{inf}. Intersubject variability in GS-9876 C_{max} and AUC following multiple doses was <25% (coefficient of variation). No clinically significant changes in vital signs, ECGs and safety laboratory tests were observed. No clinically relevant changes in bleeding time were observed. Mild vomiting in one subject was reported as related to GS-9876. All reported AEs were generally mild and self-limiting. No serious AE or discontinuations were reported.

Conclusion: GS-9876 was safe and well tolerated following single doses up to 50 mg and multiple doses up to 30 mg once daily for 7 days. The long terminal elimination half-life of GS-9876 supports a once daily dosing regimen, and GS-9876 may be administered without regard to food or acid-reducing agents. These data support the ongoing development of GS-9876 in inflammatory diseases.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. ORAL Solo[1] and ORAL Sync[2] are two Phase 3 index studies that demonstrated the efficacy of tofacitinib in adult patients (pts) with RA who were DMARD inadequate

responders (DMARD-IR). Early onset of effect is a clinically meaningful endpoint. This post-hoc analysis examined the magnitude and durability of early response to tofacitinib in ORAL Solo and ORAL Sync.

Methods: ORAL Solo and ORAL Sync were double-blind, placebo (PBO)-controlled, parallel-group studies in pts with active RA and an inadequate response to ≥1 conventional synthetic (cs) or biologic (b) DMARD.[1,2] Pts were randomized to tofacitinib 5 mg BID, tofacitinib 10 mg BID, PBO advanced to tofacitinib 5 mg BID, or PBO advanced to tofacitinib 10 mg BID, either as monotherapy in ORAL Solo or with background csDMARD in ORAL Sync. In ORAL Solo, pts randomized to PBO were advanced to tofacitinib at Month 3; in ORAL Sync, pts randomized to PBO were advanced to tofacitinib at Month 3 (non-responders) or Month 6 (all other pts). In this post-hoc analysis, the following clinical efficacy data for pts on tofacitinib or PBO (prior to advancement to tofacitinib) ± csDMARD, were evaluated at Week 2, Month 3, and Month 6 (ORAL Sync only; no Month 6 PBO comparison in ORAL Solo): change from baseline in Clinical Disease Activity Index (CDAI) >12,[3] HAQ-DI change from baseline ≥0.22, CDAI ≥50% improvement from baseline, CDAI ≥70% improvement from baseline, CDAI ≥85% improvement from baseline, Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) score improvement from baseline ≥4, Pain visual analog scale (VAS) score change from baseline ≥10. This analysis is post hoc and multiplicity adjustment was done.

Results: Clinical efficacy endpoint data are summarized in Table 1. At Week 2, more patients receiving tofacitinib 5 or 10 mg BID ± csDMARDs (compared to PBO ± csDMARDs) achieved a CDAI change from baseline >12, HAQ-DI improvement from baseline ≥0.22, CDAI ≥50% improvement from baseline and pain VAS change from baseline ≥10. By Month 3, more pts receiving tofacitinib 5 or 10 mg BID ± csDMARDs (compared to PBO ± csDMARDs) achieved the efficacy outcomes measured including improvements from baseline in FACIT-F scores ≥4, CDAI ≥50%, CDAI ≥70%, and CDAI ≥85% improvement from baseline. Responses attained at Month

*p<0.05 vs placebo. [a]Included all randomized subjects who took ≥1 dose of study medication. [b]Patients who withdrew for any reason before Month 6, or subjects who were advanced to tofacitinib after Month 3 (only for ORAL Sync) have their values on or after withdrawing or advancing set to Non-Response in this analysis. N = total number in each treatment group, number of subjects available for the analysis may vary for individual endpoints. PBO group included only those patients who had not yet advanced to tofacitinib. Comparisons for tofacitinib vs PBO at Month 6 not available for ORAL Solo as all PBO patients advanced to tofacitinib at this time point.

BID, twice daily; CDAI, Clinical Disease Activity Index; csDMARD, conventional synthetic DMARD; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; FAS, full analysis set; NA, not available; NRI, non responder imputation; PBO, placebo; Pts, patients; VAS, visual analog scale.

3 were maintained or increased at Month 6.

Conclusion: DMARD-IR pts with active RA receiving tofacitinib ± csDMARDs appeared to show greater improvements compared to PBO in clinical disease activity, HAQ-DI, and pain as early as Week 2 (first post-baseline assessment), and improvements in fatigue by Month 3. Responses were maintained or improved through Month 3 (monotherapy) or Month 6 (with background DMARD).

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical studies have demonstrated the superior efficacy of tocilizumab monotherapy (TCZ mono) to tumor necrosis factor inhibitor (TNFi) monotherapy and the comparable efficacy of TCZ mono with TCZ in combination with methotrexate (MTX). The objective of this study was to compare the effectiveness of TCZ mono vs TNFi in combination with ≤ 10 mg/week MTX (demonstrated effective dose with TNFi[1]) in patients with active rheumatoid arthritis (RA) and prior exposure to TNFis in routine clinical practice.

Methods: Eligible participants were TCZ-naive patients from the Corrona registry who had prior exposure to ≥ 1 TNFi, initiated TCZ mono or a TNFi + ≤ 10 mg MTX between 2010 and 2016 and had a 6-month follow-up visit. The primary outcome was mean change in Clinical Disease Activity Index (CDAI) from baseline at 6 months. Secondary outcomes included change in modified Health Assessment Questionnaire (mHAQ) score, achievement of low disease activity (LDA) or remission (CDAI ≤ 10) and achievement of modified American College of Rheumatology (mACR) 20/50/70 responses at 6 months. The main cohort was a trimmed population excluding patients who fell outside the propensity score (PS) distribution overlap. The PS included age, race, body mass index, smoking status, work status, disease duration, concomitant prednisone use/dose, prior biologic/TNFi use and a baseline disease assessment including ACR functional class, mHAQ, CDAI and patient pain. As a sensitivity analysis, a stratified-matched population was created (stratified by 1 vs ≥ 2 biologics, then matched on PS). Linear and logistic regression models were estimated in the trimmed population adjusting for the same covariates as in the PS.

Results: A total of 312 patients initiated TCZ mono and 119 initiated TNFi + ≤ 10 mg MTX (mean [SD] dose, 8.1 [2.6] mg). Using the PS, there were 416 patients in the trimmed population (TCZ mono, n = 304; TNFi + ≤ 10 mg MTX, n = 112). Both groups included middle-aged patients (mean age, TCZ mono, 59 years; TNFi + ≤ 10 mg MTX, 58 years) with established disease (mean disease duration, TCZ mono, 13 years; TNFi + ≤ 10 mg MTX, 12 years). Those initiating TCZ mono had more severe disease based on mean CDAI (28 vs 25; $P = 0.029$), mean reported pain (61 vs 55, $P = 0.033$) and prior use of ≥ 2 biologics (81% vs 58%; $P < 0.001$) compared with those initiating TNFi + ≤ 10 mg MTX. Both groups had improvement in CDAI and mHAQ and ≈ one-third of patients achieved LDA and a mACR20 response at 6 months. In adjusted models, improvement in disease activity was similar between the treatment groups (**Table**). Similar results were observed in the PS-matched cohort.

Conclusion: Treatment with TCZ mono or TNFi + ≤ 10 mg MTX in patients with prior TNFi exposure was associated with clinical improvement. TCZ mono appears to have similar efficacy as TNFi + MTX and warrants further study in a larger population.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Olokizumab (OKZ) is an anti-interleukin-6 (IL-6) monoclonal antibody in development for the treatment of rheumatoid arthritis (RA). In phase 2 studies, treatment with OKZ+methotrexate (MTX) resulted in significant improvements in disease activity compared to placebo (PBO)+MTX.[1,2] Here, we use dose-response modeling based on phase 2 efficacy and safety data to determine the optimal OKZ doses for phase 3 development. This modeling approach utilizes all available data to reach a scientifically-based decision.

Methods: The nonparametric Jonkheere-Terpstra (JT) test was fitted to DAS28(CRP) data from two phase 2, double-blind, randomized, dose-ranging (60 to 480 mg 4-week [wk] cumulative dose [cd]) studies (RA0056 [NCT01242488] and RA0083 [NCT01463059]) to test for a monotonic dose-response curve with no assumptions on curve shape. The JT test indicated that a dose-response model was statistically significant, allowing the Hill parametric model to be used, with study as a categorical covariate that affected both the ED_{50} and E_{max} parameters. Mean and 95% confidence intervals for response were calculated. The Hill model fitted the data adequately, allowing estimation of the response curves using all available information. To select an appropriate dose, a balance between both safety and efficacy must be achieved. Thus a dose-response model for the incidence of adverse events (AEs) was also required. A logistic regression model was fitted to the 17 most commonly observed preferred terms across pooled phase 2 data.

Results: The JT test indicated a statistically significant monotonic dose-response relationship: $p<0.005$ for all dosing regimens (every 2 wks [Q2W] and every 4 wks [Q4W]) in each study, and across pooled data from the two studies. Categorical DAS28(CRP) endpoints also indicated a monotonic dose-response relationship (Table). A parametric dose-response curve fitted using a Hill model[3] to combined data from the studies (Figure) adequately described the data, with an inflection point of 120 mg 4-wk cd. This is the smallest

dose that attains a response near the maximum. Dosing frequency had a small, non-statistically significant effect on categorical DAS28(CRP) response. Logistic regression analysis of AEs did not indicate a dose-related increase in AEs vs PBO+MTX, with the exception of injection site reaction.

Conclusion: Efficacy increased with dose without an increase in safety events, and plateaued at approximately 120 mg 4-wk cd. Modeling data were robust, with comparable results for individual studies vs pooled data, and continuous vs categorical responses. Thus a dose at the inflection point (128 mg 4-wk cd, given as 64 mg Q2W) and a dose below the inflection point (64 mg 4-wk cd) were selected for inclusion in the phase 3 program. **References:** 1. Genovese M. Ann Rheum Dis 2014;73(9):1607–15; 2. Takeuchi T. Mod Rheum 2016;26(1):15–23; 3. Reeve R. 2013. J Biopharm Stat 2013;23(3):648–61

Table: Probability of a monotonic dose-response relationship based on the Jonkheere-Terpstra test

Categorical endpoint	Dosing frequency	JT p value
DAS28(CRP) <2.6	Q4W	0.0001
DAS28(CRP) <2.6	Q2W	0.0003
DAS28(CRP) <3.2	Q4W	<0.0001
DAS28(CRP) <3.2	Q2W	0.0020

Figure: Model for proportion of patients with DAS28(CRP) <3.2 at Week 12 as a function of 4-week cumulative dose, based on the Hill model

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) has a high patient (pt) burden with significant impact on health-related quality of life. We report the effect of treatment with olokizumab (OKZ), an interleukin-6 (IL-6)-targeting monoclonal antibody, on pt-reported outcomes (PROs) in both Western and Asian pts with moderate to severe RA who have previously failed anti-TNF therapy.

Methods: Data are reported from two multicenter, double-blind RCTs, RA0056 (NCT01242488) and RA0083 (NCT01463059), and their corresponding open-label extension (OLE) studies, RA0057 (NCT01296711) and RA0089 (NCT01533714). In the RCTs, pts with RA receiving MTX who had previously failed anti-TNF therapy were recruited from Belgium, the US and the UK (RA0056),[1] and Japan, Korea and Taiwan (RA0083).[2] Pts received placebo (PBO), subcutaneous (sc) OKZ 60/120/240 mg every 2 weeks (wks; Q2W) or 4 wks (Q4W) (240 mg Q2W in RA0056 only), or (in RA0056 only) intravenous tocilizumab (TCZ) 8 mg/kg Q4W. Completers were eligible for the OLEs, in which all pts received sc OKZ 120 mg Q2W + MTX (RA0057: 12.5–25.0 mg/wk with dose reductions permitted after Wk 12; RA0089: 6.0–16.0 mg/wk in Japan, 7.5–20.0 mg/wk in Korea and Taiwan). Pts with ongoing serious adverse events were excluded from the OLEs. Clinical efficacy and safety data have been reported previously.[1,2] PROs assessed included health assessment questionnaire-disability index (HAQ-DI), pt's global assessment of disease activity (PtGADA), pt's assessment of arthritis pain (PtAAP), Bristol Rheumatoid Arthritis Fatigue-Multi-Dimensional Questionnaire (BRAF-MDQ) and EuroQol 5-Dimensions Questionnaire (EQ-5D). Data are reported for the OL full analysis set (all pts who received ≥1 dose of OKZ with ≥1 efficacy measurement in the OLE). Observed data are reported for Wk 12 of the RCTs and the last time point at which ≥50% of pts reported data in the OLEs; Wk 48 in RA0057 and Wk 40 in RA0089.

Results: 198 pts completed RA0056; 190 (114 OKZ, 40 PBO, 36 TCZ) enrolled in RA0057. 105 pts completed RA0083; 103 (79 OKZ, 24 PBO) enrolled in RA0089. At Wk 12 of the RCTs, both Western (Table A) and Asian (Table B) OKZ-treated pts reported greater improvements in PROs compared to PBO-treated pts, similar to TCZ pts. As expected, PBO-treated pts reported rapid improvements in PROs following switch to OKZ. These changes were maintained to Wk 40/48 of the OLE both in pts receiving OKZ throughout (OKZ→OKZ) and in TCZ-pts switching to OKZ at OLE entry (TCZ→OKZ). Improvements were comparable in magnitude in Western and Asian patients.

Conclusion: OKZ treatment of both Western and Asian pts with moderate to severe RA resulted in sustained improvements across a range of PROs, both in the RCT and OLE, with similar levels of improvement seen in both populations. Changes were maintained to the last time point examined: Wk 40 in Asian pts and Wk 48 in Western pts. **References:** 1. Genovese M. Ann Rheum Dis 2014;73(9):1607–15; 2. Takeuchi T. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (bari), an oral Janus kinase (JAK) 1/JAK2 selective inhibitor, has demonstrated clinical efficacy with a satisfactory safety profile when administered once daily in 4 completed Phase 3 studies in patients with RA[1,2,3,4]. In 2 studies, RA-BEAM (52-week study in patients with inadequate response (IR) to MTX) and RA-BUILD (24-week study in patients with IR to conventional synthetic [cs] DMARDs), patients recorded their worst joint pain, duration and severity of morning joint stiffness (MJS), and worst tiredness each day for 12 weeks using electronic diaries. In previous analyses based on weekly averages of daily scores[3], bari produced significant improvements in patient-reported outcomes (PROs) compared to placebo (pbo) as early as Week 1 and compared to adalimumab (ada) as early as Weeks 2 4. The aim of these analyses was to explore the kinetics of response using daily diary scores without weekly averaging.

Methods: PRO data were analyzed by study day after randomization (Day 1) - Day 28 for all treated patients. Mixed models for repeated measures analysis were applied (with MJS duration by nonparametric methods).

Results: Consistent with the original weekly-averaged data[3], daily diary scores showed significant improvement in patients receiving bari compared to pbo and ada. Improvements relative to pbo were apparent as early as the 3rd day of treatment for MJS severity, worst tiredness, and worst joint pain, and by Day 5 for MJS duration (Figure and Table). Improvements relative to ada were apparent as early as Day 19 for MJS severity, Day 21 for worst tiredness, and Day 17 for worst joint pain. The greatest rapidity and magnitude of benefit was seen with the bari 4-mg daily dose.

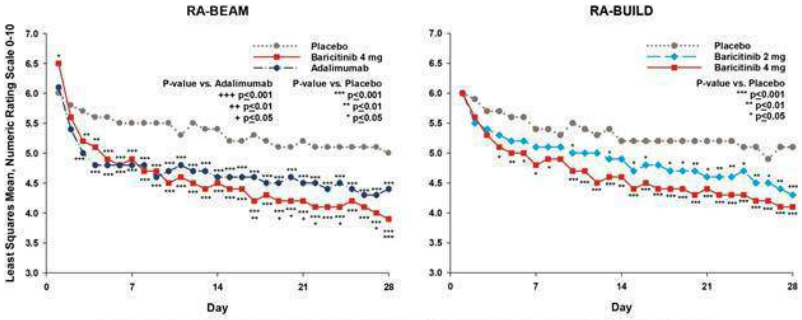

Figure. Worst Joint Pain during the initial 28 days of treatment in Studies RA-BEAM and RA-BUILD.

Table. Patient-Reported Outcomes Collected by Daily Patient Electronic Diaries: First Study Day at which Improvement relative to Placebo or Adalimumab was Observed‡

	RA-BEAM (MTX-IR)			RA-BUILD (csDMARD-IR)	
	Bari 4 mg (N=487) vs Placebo (N=488)	Ada 40 mg (N=330) vs Placebo (N=488)	Bari 4 mg (N=487) vs Ada 40 mg (N=330)	Bari 2 mg (N=229) vs Placebo (N=228)	Bari 4 mg (N=227) vs Placebo (N=228)
MJS Duration	Day 5	Day 3	NS	Day 26	Day 10
MJS Severity NRS	Day 3	Day 2	Day 19	Day 25	Day 4
Worst Tiredness NRS	Day 3	Day 3	Day 21	NS	Day 3
Worst Joint Pain NRS	Day 3	Day 3	Day 17	Day 10	Day 4

‡ First study day demonstrating statistically significant differences in the noted comparisons.
Ada=adalimumab; Bari=baricitinib; csDMARD-IR=inadequate response to conventional synthetic DMARDs; MJS=morning joint stiffness; MTX-IR=inadequate response to methotrexate; NRS=numeric rating scale; NS=no significant differences observed through the first 28 days; RA-BEAM=Study I4V-MC-JADV; RA-BUILD=Study I4V-MC-JADX.

Conclusion: In this post hoc analysis from Phase 3 studies of patients with RA with inadequate response to MTX or other csDMARDs, treatment with bari produced rapid improvements in PROs compared to pbo and ada, with significant differences appearing within the initial days of treatment. **References:** [1]Dougados et al. *Ann Rheum Dis* 2015;74(S2):79; [2]Fleischmann et al. *Arthritis Rheumatol* 2015;67(S10):1360-1361; [3]Taylor et al. presented at ACR 2015; [4]Genovese et al. *N Engl J Med* 2016;374(13):1243-1252.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. The treatment target for RA is remission or low disease activity (LDA). Routine assessment of patient index data 3 (RAPID3) consists of 3 patient-reported ACR RA core data set measures: function, pain, and patient global estimate of status. Here, we use RAPID3 to evaluate disease activity in RA patients treated with tofacitinib in 6 Phase 3 (P3) studies.

Methods: Data were analyzed from 6 P3 studies in which MTX-naïve patients or patients with inadequate response (IR) to MTX, biologic/conventional synthetic DMARDs, or TNF inhibitors (TNFi) received tofacitinib as monotherapy, or with MTX or other csDMARDs. ORAL Standard also included an adalimumab arm. All patients were required to meet the ACR classification criteria for the diagnosis of RA. To calculate RAPID3 scores, each of the 3 individual measures (HAQ-DI, pain visual analog scale [VAS], and patient global assessment VAS) was scored from 0–10 (HAQ-DI was scored from 0–3 × 3.33) for a total of 30, and divided by 3 to give an adjusted 0–10 score. Remission was defined as RAPID3 ≤1 and LDA was defined as RAPID3 ≤2. RAPID3 scores were calculated at the time of the primary endpoint of the index study (either 3 or 6 months) and at the end of each study (either 6, 12, or 24 months). Non-responder imputation was used for all comparisons between treatment and control groups. This analysis was post-hoc. No multiple comparison adjustment was done.

Results: Of the 4,218 patients included in the P3 studies, 3,162 (75.0%) patients were treated with tofacitinib. Across studies, baseline demographics and disease characteristics were similar with the exception of shorter and longer disease duration in ORAL Start and ORAL Step, respectively. Mean RAPID3 score (0–10) at baseline ranged from 5.1 to 6.1 and the proportion of patients with RAPID3 LDA at baseline ranged from 2.8% to 6.3%. At the time of the primary endpoint, significantly ($p<0.05$) higher rates of RAPID3 remission and LDA were observed with tofacitinib 5 mg or 10 mg twice daily (BID) vs the control groups (placebo/MTX) in ORAL Standard, Start and Solo. Adalimumab was not significant vs placebo in ORAL Standard. In ORAL Scan (MTX-IR), ORAL Step (TNFi-IR) and ORAL Sync (DMARD-IR), higher rates of RAPID3 remission and LDA were observed vs placebo, respectively, however these were not consistently significant. At the end of each P3 study, the rates of RAPID3 remission and LDA were sustained or slightly increased vs at the time of the primary endpoint. Higher rates were seen in patients receiving tofacitinib 10 mg BID vs 5 mg BID (Table).

Conclusion: This analysis of the tofacitinib P3 studies demonstrated that patients receiving tofacitinib had improvements in the 3 patient-reported ACR RA core data set measures, and can achieve RAPID3-defined remission and LDA.

Table. RAPID3 rates of remission and LDA in each of the tofacitinib P3 studies

n/N (% response)	Time of primary endpoint[a]		End of study[b]	
	RAPID3 remission (≤1)	RAPID3 LDA (≤2)	RAPID3 remission (≤1)	RAPID3 LDA (≤2)
ORAL Standard (MTX-IR)				
Tofacitinib 5 mg BID	32/193 (16.6)*	65/193 (33.7)*	38/193 (19.7)	75/193 (38.9)

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Aim of this study was to evaluate the feasibility of maintenance therapy with reduced dose of abatacept (ABT) to 250mg/body after achieving low disease activity (LDA).

Methods: RA patients treated with ABT at 13 sites were enrolled to this prospective, interventional study during the period between March 2013 and March 2015. This study was approved by the ethical committee of Hokkaido University or by each clinical center (UMIN-ID：UMIN000010286). Inclusion criteria were as follows: 1) ages at 20 years or older, 2) under treatment with intravenous ABT at approved doses based on weight range, 3) in LDA (DAS28-CRP < 3.2) at least for 6 months, 4) agreed to join this trial with written informed consent, 5) body weight under 125 kg. Recruited patients were maintained with intravenous monthly ABT at a dose of 250 mg/body (MATADOR protocol). The primary end point was the proportion of the patients continued with MATADOR protocol at 1-year. Secondary endpoints included disease activity measured by DAS28CRP, safety and tolerability. Therapy with reduced dose was discontinued when physicians decided upon disease flare or other reasons, when patients requested, or when severe adverse event(s) occurred.

Results: A total of 57 patients were enrolled fulfilling above criteria and received ABT with MATADOR protocol. Data at 1-year was collected from 53 patients. Age of the patients was 60 ± 11 year (mean, SD) and disease duration was 10.5 ± 9.1 years (mean, SD). Methotrexate was used in 60% (32/53) of the patients at dose of 9.0 ± 3.3 mg/wk (mean, SD). MATADOR protocol was continued for 1-year in 81% (43/53) of the evaluated patients. In 5 patients, ABT was re-increased to the original dose. Resting patients discontinued because of severe adverse events in 2, switching to other bDMARDs in 2, and one dropout. DAS28CRP and remission rate (DAS28CRP < 2.6) was 1.59 ± 0.48 (mean, SD) and 88% (46/53) at the beginning of MATADOR protocol and 1.74 ± 0.70 (mean, SD) and 81% (43/53) at 1-year.

Conclusion: In the early phase II study conducted in Japan, placebo or monthly intravenous ABT at 2mg/kg or 10mg/kg was given for active RA patients despite methotrexate treatment. ACR20 response was significantly better both in the 2mg/kg and 10mg/kg group compared with the placebo (Takeuchi T et al, *Mod Rheumatol* 2013). Therefore, it would be

understandable that 250mg/body of ABT exerts its therapeutic effect in patients once reached remission or LDA with approved doses of ABT. Reducing dose of monthly intravenous ABT (250mg/body) is a realistic choice of maintenance therapy for patients with RA after achievement of remission or LDA with approved doses of ABT.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral JAK inhibitor for the treatment of RA. Open-label, long-term extension (LTE) studies enrolled tofacitinib-treated patients (pts) to evaluate safety and efficacy over time. The time on treatment is considered a composite measure of efficacy and safety, as discontinuation (D/C) is often due to lack of efficacy (LOE) and/or adverse events (AEs) for DMARDs. This analysis estimated drug survival of tofacitinib up to 96 months (mo; 8 years) in LTE studies and describes reasons for D/C.

Methods: Data were pooled from 2 LTE studies (NCT00413699 [ongoing; database unlocked at March 2015 data-cut] and NCT00661661) of pts with RA who had participated in Phase (P) 1/2/3 tofacitinib studies. Of the 6570 pts from P1/2/3 studies, 4867 pts (74.1%) received treatment in LTE studies. Pts received tofacitinib 5 or 10 mg BID as monotherapy or with background DMARDs. Assignment to tofacitinib dose group in this analysis was based on the average daily dose in LTE. Kaplan-Meier analyses estimated drug survival in pts who withdrew for any reason, due to LOE or due to AEs in the LTE, including pts who had previously responded to and tolerated treatment in P1/2/3 studies. Ongoing pts were censored as of March 2015, while pts completing the trial(s) were censored at their completion date. Data are included over 96 mo. Retention data were analyzed by dose, mono vs combination therapy, and baseline characteristics.

Results: 4867 pts were treated for a mean (maximum) duration of 3.0 (7.9) years (yrs) in the LTE. Overall, the median survival for all tofacitinib-treated pts in the LTE was 5.0 yrs [95% CI 4.7, 5.2]; for pts receiving tofacitinib with background DMARDs was 4.9 [4.5, 5.2] yrs and as monotherapy was 5.1 [4.6, 5.9] yrs. Similar survival was observed between doses: median survival was 5.2 [4.8, 5.7] and 4.8 [4.5, 5.2] yrs for 5 and 10 mg BID, respectively. The D/C rate due to LOE was considerably lower than due to AEs (LOE: 3.1%, 3.5%, 3.0%; AEs: 21.6%, 25.2%, 20.0% for all tofacitinib, 5 or 10 mg BID, respectively). The most commonly reported reasons for D/C due to AEs by system organ class were infections/infestations (8.8%, 8.5%, 8.9%), investigations (4.2%, 5.6%, 3.5%) and neoplasms (benign, malignant,

unspecified) (3.2%, 4.4%, 2.8%) for all tofacitinib, 5 or 10 mg BID, respectively. Overall, median survival was generally similar for pts receiving all tofacitinib, 5 and 10 mg BID across selected baseline characteristics (tofacitinib 5 mg BID, Table; tofacitinib all and 10 mg BID, data not shown).

Conclusion: Drug survival in LTE studies provides important information on the long-term safety, efficacy, and tolerability of a therapy. Median survival of tofacitinib was ~5 yrs, with D/C more commonly associated with AEs than LOE. Similar survival was observed for the 5 and 10 mg BID dose groups, for mono vs combination therapy, and across selected baseline characteristics. These data support the use of tofacitinib for long-term RA management.

Table. Median survival by selected baseline characteristics[a] for patients who received tofacitinib 5 mg BID[b]

Baseline characteristic	Total patients	Patients with event (%)[c]	Censored patients (%)[c]	Median survival, yrs (95% CI)
All patients	1,471	48.7	51.3	5.2 (4.8, 5.7)
RF+	930	48.5	51.5	5.5 (5.0, 6.0)
RF-	291	56.7	43.3	4.4 (3.5, 5.2)
Anti-CCP+	333	38.7	61.3	4.4 (3.9, NE)
Anti-CCP-	84	50.0	50.0	3.3 (2.7, NE)
Disease duration				
<1 yr	129	46.5	53.5	4.9 (3.3, NE)
≥1 yr	1,342	48.9	51.1	5.2 (4.8, 5.7)
DAS Q1[d]	289	42.2	57.8	4.9 (4.2, NE)
DAS Q2[d]	271	42.4	57.6	5.0 (4.5, NE)
DAS Q3[d]	240	43.3	56.7	5.5 (4.6, NE)
DAS Q4[d]	213	50.7	49.3	4.2 (3.5, 6.0)

[a]Baseline values were taken from the P1/2/3 index studies
[b]Tofacitinib dose group was based on the average TDD for each patient: TDD <15 mg was considered 5 mg BID; TDD ≥15 mg was considered 10 mg BID
[c]Percentages are based on the total number of patients with available data for each baseline characteristic
[d]DAS quartiles were based on all tofacitinib-treated patients
BID, twice daily; CI, confidence interval; CCP, citric citrullinated peptide; DAS, disease activity score; NE, not evaluable; Q, quartile; RF, rheumatoid factor; TDD, total daily dose; yrs, years

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Clinical Responses to Tocilizumab Analyzed by Serologic Status in Rheumatoid Arthritis

Background/Purpose: Biologic medications have improved outcomes for patients with rheumatoid arthritis (RA), but little is known about factors that predict individual response to therapy. One potential factor is the presence or absence of rheumatoid factor (RF) or anti-cyclic citrullinated peptide antibodies (CCP). Rituximab and some csDMARDs show greater efficacy in patients with RF or CCP than in seronegative patients. Recent studies have shown increased expression of genes and activation of IL-6/STAT3 pathways and transcription factors in seronegative RA patients compared with seropositive patients. Tocilizumab (TCZ), a monoclonal antibody to the IL-6 receptor, targets this pathway. We evaluated whether seronegative RA patients differed in their response to TCZ as compared to seropositive patients.

Methods: Data from the US Corrona RA registry were analyzed. Patients with RA starting on TCZ with a follow up visit 4-8 months following initiation of therapy were included. Serological status was analyzed by three methods: seropositivity was defined as RF positive, CCP positive, and either RF or CCP positive. Univariate tests of change scores for measures of disease activity between baseline and follow-up were made for each definition of seropositivity. General linear models were used to adjust for disease duration and baseline disease activity level.

Results: 482 patients initiating TCZ with information on CCP and/or RF status were included. CCP or RF positive patients were less likely to be white and had longer disease duration than seronegative patients; other demographic and clinical features were similar. Univariate analysis showed significant decrease in most measures of clinical disease activity and ESR and CRP with TCZ treatment in both seropositive and seronegative groups (table 1), but no significant differences in responses between groups were observed. Adjusted analyses accounting for disease duration and baseline activity also showed no difference in improvement by serostatus.

Conclusion: In this cohort of patients with RA, the presence of RF or CCP did not influence initial response to TCZ for most measures of disease activity. Both groups had statistically significant improvements in clinical disease activity measures and inflammatory markers. **Table 1:** Differences in disease activity from time of Tocilizumab initiation to follow up, by serologic status at baseline, N=482

a First-in-Human Study of CR6086, a New Potent EP4 Prostanoid Receptor Antagonist, Demonstrates Good Safety and Tolerability at Therapeutically Relevant Exposures

Stefano Persiani[1], Carla Manzotti[1], Cristina Vitalini[1], Giampaolo Giacovelli[2], Federica Girolami[1], Massimo D'Amato[1], Gianfranco Caselli[1] and **Lucio C. Rovati**[2,3], [1]Rottapharm Biotech, Monza, Italy, [2]Clinical Research Department, Rottapharm Biotech, Monza, Italy, [3]University of Milano Bicocca, Milano, Italy

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: CR6086 is a potent and selective antagonist of the prostaglandin EP4 receptor. EP4 receptors have a role in T-cell differentiation and expansion, and thus in the altered immune response in autoimmune diseases such as rheumatoid arthritis. EP4 receptors are then a rational target for novel DMARDs/immunomodulators with added anti-inflammatory properties. Indeed, when oral CR6086 was tested in a series of widely accepted models of arthritis in rodents, it was at least as effective as biological DMARDs in all parameters examined, including edema, clinical arthritis score, and histology. The present first-in-human study evaluated the safety, tolerability, and pharmacokinetics of CR6086 in single ascending doses.

Methods: Oral doses of CR6086 ranging from 5 to 300 mg were administered to healthy men in a randomized, double blind, placebo-controlled fashion. Each of the nine cohorts comprised 6 volunteers on active and 2 on placebo. Food interaction was assessed at 150 mg.

Results: CR6086 was well tolerated up to 300 mg, and the maximum tolerated dose was not reached.The few observed adverse events where mild or moderate in severity, all resolved spontaneously, and their incidence was not dose-related. The pharmacokinetics of CR6086 were dose-independent, with mean peak plasma concentrations (C_{max}) ranging from 90 to 8151 ng/mL and occurring between 1 and 1.75 h after administration. The extent of bioavailability (AUC) ranged from 602 to 68200 ng.h/mL and a high fat meal did not affect CR6086 bioavailability. Plasma protein binding was around 95% (unbound fraction; $f_u = 0.0564$) and CR6086 did not invert into its antipode. CR6086 elimination half-life averaged 13 h and urinary excretion of the unchanged drug was a minor elimination route. Mean peak plasma concentrations of CR6086 (Figure) were above the K_i for the human EP4 receptor (adjusted for plasma protein binding) already at a dose of 15 mg. From the 100 mg dose, the plasma concentrations of CR6086 were higher than the adjusted K_i for a 24-hour period. A comparison with the exposure in rodents indicated that from the single dose of 30 mg, the exposure is pharmacologically relevant in humans.

Conclusion: CR6086 was safe up to the maximum tested dose of 300 mg. The compound is characterized by dose-independent pharmacokinetics producing therapeutically relevant concentrations at well tolerated doses in support for further clinical development as a novel DMARD.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarilumab is a human mAb blocking the IL-6Rα. Sarilumab (150 or 200 mg every 2 weeks [q2w] subcutaneously) + MTX demonstrated efficacy vs placebo in patients with RA and inadequate response to MTX (MOBILITY; NCT01061736),[1] and sarilumab (150 or 200 mg q2w) + conventional synthetic DMARDs demonstrated efficacy vs placebo in patients with RA and inadequate response to or intolerance of TNF inhibitors (TARGET; NCT01709578).[2] In both studies, the most common treatment-emergent adverse events (TEAEs) included infections, neutropenia, injection site reactions, and increased transaminases.[1,2] In this pooled exploratory analysis, safety and efficacy of sarilumab were examined in patients <65 and ≥65 years of age from MOBILITY and TARGET.

Methods: Safety and efficacy endpoints (Table) were analyzed in subgroups of patients <65 and ≥65 years. A logistic regression model was used to analyze ACR20 and DAS28-CRP <2.6 responses, and a mixed-effect model for repeated

measures was used for HAQ-Disability Index (HAQ-DI), DAS28-CRP, and clinical disease activity index (CDAI).

Results: In both subgroups, most patients were female (80%-82%). In patients ≥65 years, mean RA duration was longer (13.2 vs 9.5 years) and a higher proportion had prior biologic use (63% vs 48%) vs those <65 years. In both subgroups, incidence of TEAEs and serious AEs (SAEs) was greater in sarilumab-treated patients vs placebo. Infections were the most common TEAEs with sarilumab in both age groups. Incidence of SAEs, including serious infections, was higher in patients ≥65 years vs patients <65 years. In both subgroups, both sarilumab doses vs placebo led to numerically higher ACR20 and DAS28-CRP <2.6 response rates at week 24, improvement from baseline in HAQ-DI at week 12, and improvement from baseline in DAS28-CRP and CDAI at week 24 (Table). In general, efficacy of sarilumab 150 and 200 mg q2w was comparable between patients ≥65 years and <65 years. There was some variability in the proportion of patients >65 years who achieved ACR20 and DAS28-CRP <2.6 responses due to the small number of patients in this subgroup; however, the age-by-treatment interaction was not significant for any of the efficacy endpoints (P>0.2).

Conclusion: Adverse events in both age groups were consistent with the known safety profile of sarilumab. SAEs occurred more frequently in patients ≥65 years compared with patients <65 years, consistent with other studies of biologic agents in the elderly.[3] Both sarilumab doses were superior to placebo in ACR20 and DAS28-CRP <2.6 responses, DAS28-CRP, and CDAI at week 24 and in change from baseline in HAQ-DI at week 12 in both subgroups defined by age. **References:** 1. Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is the most commonly used DMARD in rheumatoid arthritis (RA) patients. Since the first reports of the efficacy of low-dose MTX in RA, several studies have established its central role in the treatment of RA. Activated T CD4+ lymphocytes play a pivotal role secreting cytokines initiating and perpetuating the chronic inflammation characteristic for this disease. The role of circulating $CD4^+$T lymphocytes in early RA is under discussion and is not well understood. The objective is evaluate the number of IFNγ, IL-4, IL-9 and IL-17 producing $CD4^+$ T lymphocytes and in their $CD4^+$ naïve T cells (T_N), central memory (T_{CM}), non-terminated effector memory (T_{NTEM}) and terminated effector memory (T_{TEM}) T cells activation/differentiation subsets in a population of recently diagnosed DMARD naïve RA patients along the first 6 months of methotrexate (MTX) treatment.

Methods: The number of IFNγ, IL-4, IL-9 and IL-17 producing CD4+ T lymphocytes, and in their T_N, T_{CM}, T_{NTEM} and T_{TEM}subsets in forty untreated patients with RA before MTX treatment and at 3 and 6 months of treatment were assayed using a multiparametric flow cytometry. We have obtained peripheral blood mononuclear cells (PBMC) from AR patients. PBMC were stimulated during six hour with phorbol-myristate-acetate and ionomycin. To study the intracellular cytokine production of CD4+ T lymphocytes we used the next surface antigens: CD3, CD4, CD45RA, CD27, cells were fixed and permed, and simultaneously stained with the next intracellular cytokines: IFNγ, IL-4, IL-9 and IL-17. We acquired in a FacsAria-II flow cytometer and analyzed in Diva and Flow-Jo software. We also studied twenty-five age and sex-matched

healthy subjects as controls.

Results: MTX treatment provoke a significant decrease of the IFNγ CM, NTEM and TEM effector producing T CD4 lymphocytes but not in naïve T CD4+ cells at 3 and 6 months of MTX treatment. However, the IL-17 naïve producing T CD4 lymphocytes were significant expanded along the 6 months of MTX treatment. In other hand, IL-17 CM and NTEM producing T CD4 lymphocytes were significant decreased at 6 months of MTX treatment. The intracellular expression of IL-4 and IL-9 do not shown alterations in RA naïve patients along the MTX treatment.

Conclusion: MTX treatment show immunomodulatory effects on circulating IFNγ and IL-17 producing T CD4 lymphocytes activation/differentiation stage subsets along the first 6 months of MTX treatment. Therefore, MTX are able to reduce the inflammation produce by Th1 effector T CD4 lymphocytes at 6 months. However, MTX are able to reduce Th17 in central memory but not in naive T CD4 lymphocytes, that appear increased, at 6 months of treatment.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While interleukin-6 (IL-6) blockade with monoclonal antibodies is an established, clinically validated mechanism for the treatment of rheumatoid arthritis (RA), the need for significant quantities of protein due to the potency and half-life of available agents with resultant high cost has limited patient access to these medications. We have developed gerilimzumab, a highly potent anti-IL6 cytokine antibody with a long half-life, to address this problem. Gerilimzumab is a humanized llama antibody with femtomolar potency and a Fc region mutation engineered to prolong half-life. A 20-24-day half-life in cynomolgus monkeys was observed. We now evaluate the safety of gerilimzumab in healthy volunteers and whether the long half-life seen in monkeys translates to a long half-life in human subjects.

Methods: The primary objective of our multi-ascending dose study was to assess the safety and tolerability of gerilimzumab when administered as three SC doses at 4-weekly intervals to healthy adult participants. Two cohorts were included in the study: a gerilimzumab 5 mg and 20 mg cohort. Each cohort included 6 subjects treated with active drug and 3 subjects treated with placebo.

Results: No SAEs or deaths were observed during the study. All adverse events were mild or moderate in severity. One participant was withdrawn due to a mild urticarial rash. Only injection-site erythema occurred in a dose dependent manner. No laboratory, vital signs or ECG findings of clinical significance were assessed by the investigator. All participants in the placebo and gerilimzumab groups recorded negative ADA test results at all time points. While steady state was not achieved in this study, the estimated half-life of gerilimzumab was approximately 50 days for the 20 mg cohort and

exposure was dose-proportional. No anti-drug antibodies were detected over the course of the study. A numeric decrease from baseline in C-reactive protein, a pharmacodynamic marker of an anti-IL6 effect, was observed in the gerilimzumab groups.

Conclusion: Overall, gerilimzumab (within the dose range 5 mg to 20 mg) appeared safe and well tolerated when administered as three SC injections with an inter-dosing interval of 28 days to healthy volunteers. Gerilimzumab's long half-life and expected potency (based upon preclinical data) differentiate it from other anti-IL6 monoclonal antibodies and provides the potential for a very low cost and conveniently dosed biologic therapy for RA.

Lack of Early Change in Disease Activity Score Predicts the Likelihood of Achieving Low Disease Activity at Month 6: Tofacitinib Monotherapy Versus Methotrexate in Methotrexate-Naive Patients with Rheumatoid Arthritis

Edward Keystone[1], Ronald F van Vollenhoven[2], Bethanie Wilkinson[3], Lara Fallon[4], Lie-Ju Hwang[5], Douglass Chapman[5], Ryan DeMasi[5] and Eun Bong Lee[6], [1]Mount Sinai Hospital, Toronto, ON, Canada, [2]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands, [3]Pfizer Inc, Groton, CT, [4]Pfizer Canada, Montreal, QC, Canada, [5]Pfizer Inc, New York, NY, [6]Seoul National University, Seoul, Korea, Republic of

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). Treatment guidelines recommend targeting remission or low disease activity (LDA), herein defined as Disease Activity Scores ≤3.2 based on 28 joint counts (DAS28≤3.2) and adjusting therapy after 3–6 months[1] (Mos). Predicting the likelihood of clinical response may help inform early treatment decisions. The aim of this study was to understand the relationship between timing and magnitude of early changes in DAS28, erythrocyte sedimentation rate (DAS28-4[ESR]) and the likelihood of achieving LDA at Mo 6 in RA patients (pts) naïve to methotrexate (MTX).

Methods: In a Phase 3 study (ORAL Start; NCT01039688), MTX-naïve RA pts were randomized 2:2:1 to the following monotherapies: tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID or MTX. Conditional probabilities of pts achieving LDA at Mo 6 were calculated, given failure to achieve DAS28-4(ESR) improvement from baseline (range ≥0.3 to 1.8) at Mo 1 or 3. One-year data with non-responder imputation for missing values was used.

Results: 948 pts received treatment; tofacitinib 5 mg BID (n=370), tofacitinib 10 mg BID (n=394) or MTX (n=184); results previously reported.[2] In this post-hoc analysis, of those patients who failed to achieve DAS28-4(ESR) improvement from baseline ≥1.2 at Mo 3, 6.8% for tofacitinib 5 mg BID, 11.3% for tofacitinib 10 mg BID, and 6.2% for MTX achieved LDA at Mo 6 (Table). A minority of pts (74/353 [20.9%]) receiving tofacitinib 5 mg BID failed to achieve DAS28-4(ESR) improvement ≥1.2 from baseline at Mo 3, while a greater proportion failed for MTX (65/171 [38.0%]). Failure to achieve DAS28-4(ESR) improvement from baseline at Mo 3 (range ≥0.30–1.8) for tofacitinib 5 mg BID and MTX was associated

with a low probability (≤10%) of achieving LDA at Mo 6. For tofacitinib 5 mg BID, failure to achieve lower thresholds of DAS28-4(ESR) improvement (range ≥0.3 to 0.9) at Mo 1 was associated with lower probability of LDA at Mo 6 than higher DAS28-4(ESR) thresholds (≥1.2–1.8) (Table).

Conclusion: Failure to achieve DAS28-4(ESR) improvement ≥1.2 from baseline at Mo 3 was associated with a low probability of achieving LDA at Mo 6 (≤6.8%) for tofacitinib 5 mg BID and MTX. For the minority of MTX-naïve RA pts treated with tofacitinib 5 mg BID or MTX who failed to achieve a minimal clinical response (DAS28-4[ESR] improvement ≥1.2) by Mo 3, another treatment option can be considered at Mo 3, as there is a low probability of reaching LDA at Mo 6.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. This post-hoc analysis of data from Phase 3 studies investigated the efficacy of tofacitinib in patients (pts) according to RA duration (early vs late).

Methods: Pts from 5 placebo-controlled Phase 3 studies (ORAL Step [NCT00960440]; ORAL Scan [NCT00847613]; ORAL Solo [NCT00814307], ORAL Sync [NCT00856544]; ORAL Standard [NCT00853385]) of tofacitinib as monotherapy or with background DMARDs were included. This analysis included pts who were inadequate responders (IR) to ≥1 DMARDs randomized to tofacitinib 5 mg or 10 mg BID, placebo or adalimumab (ORAL Standard); results for tofacitinib 5 mg BID are presented. Pts were evaluated according to RA duration at baseline (years [yr]): ≤1 vs >1; ≤2 vs >2; ≤3 vs >3. For each subset pair, at Month 3 and Month 6 we evaluated proportions of pts achieving ACR20/50/70 response, Disease Activity Score (ESR) (DAS 28-4[ESR]) <2.6 (remission), DAS28-4(ESR) ≤3.2 (low disease activity), HAQ-DI minimal clinically important difference (MCID) ≥0.22, 0.30, 0.50, and 0.80, and mean changes from baseline in DAS28-4(ESR) and HAQ-DI scores. Odds ratios (ORs [for rates]) and mean differences (for change from baseline) were calculated with corresponding 95% CIs, and 2-sided p values (‘>’ category as reference). Non-responder imputation (NRI) was applied for rates. Pts meeting criteria for rescue (failed to achieve ≥20% improvement from baseline at Month 3 in applicable studies) had NRI applied or were excluded from mean change analyses at Month 6.

Results: At Month 3, significantly greater OR for ACR20, ACR50, HAQ-DI MCID ≥0.22, and ≥0.30 were shown for ≤1 vs >1 yr and ≤2 vs >2 yr subsets (Figure). HAQ-DI MCID ≥0.50 and ≥0.80 were significantly greater for ≤1 vs >1 yr, ≤2 vs >2 yr, and ≤3 vs >3 yr subsets. For all other efficacy outcomes, ORs were not statistically significant between subsets at Month 3. Mean changes from baseline in DAS28-4(ESR) were significantly greater for ≤1 vs >1 yr and ≤2 vs >2 yr subsets at Month 3 (Table). Mean changes from baseline in HAQ-DI at Month 3 was significantly greater for ≤1 vs >1 yr, ≤2 vs >2 yr, and ≤3 vs >3 yr subsets. In general, higher responses were seen at Month 3 in pts with early vs late RA disease duration.

Conclusion: In this analysis, a trend was observed indicating that DMARD-IR pts with earlier disease duration at treatment initiation respond better to tofacitinib 5 mg BID than pts with late disease duration. Results suggest that initiating tofacitinib earlier in the disease may yield greater treatment response and thereby reduce the time pts experience active disease.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The CD40L/CD40 co-stimulatory pathway is important for T-cell-dependent antibody production. Previous clinical programs with intact monoclonal antibodies against CD40L have been discontinued due to thromboembolic events (TE) despite preliminary evidence of clinical efficacy in autoimmune diseases such as systemic lupus erythematosus and idiopathic thrombocytopenic purpura. MEDI4920 is an engineered Fc-deficient CD40L antagonist that is being developed for treatment of numerous autoimmune diseases.

Methods: A Phase 1, randomized, double-blinded, placebo-controlled study was conducted to evaluate the safety and tolerability of single-ascending intravenous doses of MEDI4920 in healthy subjects. Secondary endpoints were T-cell–dependent antibody response (TDAR) inhibition, pharmacokinetic (PK) parameters, and anti-drug antibodies (ADAs) to MEDI4920. To assess TDAR, titers of IgG and IgM antibodies to neoantigen keyhole limpet hemocyanin (KLH) were quantified at Day 43 post-dose. A dose-response model was generated for TDAR inhibition. Fifty-six healthy adult male subjects were randomized and treated in this study: 3 subjects each in a 2:1 ratio in Cohorts 1 and 2 (3 and 10 mg of MEDI4920, respectively, or placebo) and 10 subjects each in a 4:1 ratio in Cohorts 3 through 7 (30, 100, 300, 1,000, and 3,000 mg of MEDI4920, respectively, or placebo).

Results: There were no deaths, no TE events or clinically significant coagulation or platelet function abnormalities, no severe or serious hypersensitivity reactions, no severe or serious infection events, and no infusion-related reactions. Only 1 serious adverse event of fractured tibia was reported in the placebo arm. No safety signals were identified overall. TDAR dose-response analysis at Day 43 demonstrated a statistically significant E_{max} dose response ($P < 0.001$; $ED_{50} = 491$ mg) with the 3,000 mg dose showing 86% inhibition of the TDAR IgG response compared to placebo (95% CI: 68%, 94%; Figure 1). PK parameters (C_{max} and AUC) increased dose proportionally. Most subjects in the lower dose cohorts (3, 10, 30, and 100 mg) developed ADAs to MEDI4920, whereas a decreasing trend was observed for the higher doses (300, 1,000, and 3,000 mg).

Conclusion: MEDI4920 demonstrated an acceptable safety and tolerability profile while showing significant dose-dependent inhibition of TDAR. These encouraging results support further exploration of the safety and efficacy of repeat administration of MEDI4920 in an autoimmune disease in which the CD40/CD40L pathway activation plays a significant role.

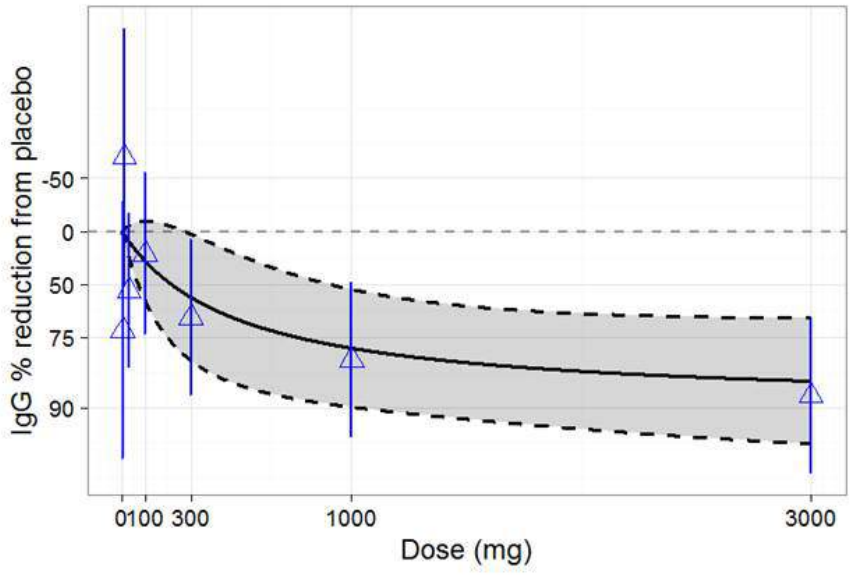

Figure 1: Plot of dose-response model for TDAR inhibition (anti-KLH IgG at Day 43).

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IL-6 plays a central pathogenic role in rheumatoid arthritis (RA). IL-6 signals through a complex of transmembrane IL-6R or soluble IL-6R (sIL-6R) with gp130 to mediate classic or *trans*-signaling, respectively. Sirukumab (CNTO 136) is a human IgG1 k monoclonal antibody (mAb) specific for human IL-6 cytokine and is currently in clinical trials for the treatment of adults with moderately to severely active RA and other diseases. A human primary cell-based phenotypic screening systems (BioMAP®) was used to investigate the effects of sirukumab and to identify discriminating biological activities compared to tocilizumab, an anti-IL-6R mAb. Comparisons were also made with a reference database that includes profiles of drugs used to treat RA.

Methods: BioMAP® systems model disease biology in primary human cells. Sirukumab was profiled across a panel of 12 BioMAP® systems, relevant to inflammatory diseases, at different concentrations in the presence or absence of sIL-6R (50ng/ml). Sirukumab profiles were directly compared to those of tocilizumab and indirectly to compounds already profiled in the BioMAP® reference database including adalimumab, tofacinitib, methotrexate and prednisolone in the presence or absence of sIL-6R. Serum samples from the RA phase 3 sirukumab studies (SIRROUND-M, D, T, & H) were also analyzed at baseline and week 4 post-treatment using the SomaLogic SOMAscan™.

Results: Sirukumab significantly inhibited expression of biomarkers linked to inflammation (P-selectin), immunomodulation (CD69, M-CSF) and tissue remodeling (MMP-9, aSMA, Collagen IV) in the BioMAP® systems. Addition of sIL-6R induced further biomarkers that sirukumab completely blocked. A direct comparison of sirukumab to tocilizumab showed that whilst there was a similar impact on multiple mediators, there were significant differences across all systems assessed. Sirukumab significantly decreased 5 (CD40, Collagen III & IV, TF, PAI-I) and increased 8 (IL-8, ICAM-1, IL-1a, IP-10, IL-2, EGFR, MIG, IL-10) biomarkers under sIL-6R *trans*-signaling; these mediators were not affected by tocilizumab. Conversely, tocilizumab significantly decreased 9 (P-selectin, uPAP, IL-18, MMP3, EGFR, IP-10, MCP-1, MIP-1a E-selectin) and increased 1 (VCAM-1) biomarkers which were not affected by sirukumab. Of note, the serum analysis of RA patients treated with sirukumab confirmed some of the changes seen in the BioMAP® systems, including reduction of PAI-I, increase in IP-10, and lack of decrease in MMP3, MCP-1, MIP-1a, and E-selectin levels. Indirect comparisons of sirukumab to adalimumab, tofacinitib, methotrexate and prednisolone using the BioMAP® algorithm showed that overall the drugs were not similar, reflecting different mechanisms of action.

Conclusion: Sirukumab has a unique BioMAP® phenotypic signature that is further separated from tocilizumab (as well as other reference profiles) with addition of sIL-6R. This signature was confirmed in sera from RA patients treated with sirukumab supporting the hypothesis that the impact of sirukumab on IL-6R signaling is distinct from tocilizumab. The clinical significance of these data requires further experimental exploration.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In the pathogenesis of rheumatoid arthritis (RA), T cells can differentiate into functionally distinct subsets, leading to the persistent inflammation and immune abnormality associated with the interactive activation between B cells, monocytes and dendritic cells. However, little is known about pathological immune cell subsets targeted by biologic DMARDs (bDMARD) therapy. The aim of this study was to assess the therapeutic effects of bDMARDs on the diversity of immune cell phenotypes in peripheral blood of patients with RA.

Methods: Peripheral immune cell phenotypes were determined in 108 patients with bio-naïve RA who showed inadequate response to DMARDs and 26 healthy control (HC) subjects by comprehensive 8-color flow cytometric analysis for human immune system termed “the Human Immunology Project” by NIH and FOCIS. We also examined the correlation between the phenotypes and clinical course and assessed the effects of 24-week treatment with bDMARDs.

Results: The proportions of $CD3^+CD4^+CD45RA^-CCR7^-$ effector memory, $CD3^+CD4^+CD45RA^+CCR7^-$ effector T helper cells and $CD4^+CXCR5^+ICOS^+$ T follicular helper cells (Tfh) were higher in patients with active RA than in HC. The

percentages of memory T cells, $CD3^+CD4^+CXCR3^-CCR6^+$ Th17 cells and Tfh cells correlated with serum levels of autoantibodies, whereas that of $CD19^+CD20^-CD27^+CD38^+$ plasmablasts correlated with disease activity scores. All of bDMARDs markedly improved the disease activity scores after 24 week treatment. Treatment with TNF inhibitors reduced the proportion of $CD3^-CD19^-CD14^-CD20^-HLA\text{-}DR^+CD123^+$ plasmacytoid dendritic cells, while tocilizumab reduced the proportion of $CD19^+CD20^+IgD^-CD27^-$ double-negative B cells but increased $CD4^+CCR4^+CD25^+CD127^{low}$Treg cells. Abatacept treatment resulted in marked decrease in the proportion of activated Tfh and the absolute number of Tfh, but slightly reduced Th17 and Treg cells. The proportion of Tfh cells was an independent and significant predictor of the response to abatacept therapy.

Conclusion: These results indicated that the abnormal T cell differentiation correlated with autoantibody production while plasmablast did with disease activity of RA. Molecular targeted therapies induced different changes in different immune cell phenotypes. Among the phenotypes, Tfh cells seem a potential target for abatacept. Immunophenotypic analysis is useful for evaluation of the pathogenesis and prediction of the response to bDMARDs.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The non-interventional study ICHIBAN was set up in 2010 to evaluate the effectiveness and safety of intravenously administered Tocilizumab (TCZ IV) in patients (pts) with moderate to severe RA in Germany. Clinical data were collected during routine medical consultations including concomitant therapies, co-morbidities, therapeutic responses and adverse events. This interim analysis assessed the effectiveness and safety of long-term TCZ IV treatment

with respect to patients' age.

Methods: The present interim analysis included pts with complete baseline (BL) data before 03rd December 2015 (total; n=2999). 902 pts have completed the maximal 104 week observation period (W104). Subgroups according to age have been defined as <50 years, 50-65 years, >65 years.

Results: At BL the age distribution showed the following proportions: <50 years 28.9%, 50-65 years 48.6%, and >65 years 22.5%. The mean TCZ IV treatment duration was 1.7, 1.8, and 1.7 years, respectively, for the three groups. In comparison to younger pts, the elderly (>65 years) showed longer disease duration, higher inflammatory parameters, higher disease activity, and higher co-morbidity rates at BL. Nevertheless, TCZ IV showed comparable effectiveness in all age groups. At last visit, DAS28 BSG remission (< 2.6) was reached by 55.2%, 51.6%, and 48.8% of pts aged <50, 50-65, and >65 years, respectively. The mean reduction from BL in DAS28-BSG was 2.6, 2.7, and 2.8, respectively. Regarding co-medication, the mean glucocorticosteroid (GC) dose was reduced from 7.1 (BL) to 4.6 mg/d (last visit) and was similar in all subgroups. About 12% of pts stopped GC therapy completely, again similar in all subgroups. At baseline, the rate of TCZ monotherapy (without concomitant sDMARD) was highest in the elderly (53.2%) while combination therapy is more common in younger pts (47.1%). Despite slightly higher incidence rates of adverse events (AE) and serious adverse events (SAE) for the elderly, the rates of infections (27.2; 19.8; 19.2 per 100 patient years [PY]) and serious infections (2.9; 2.9; 3.1 per 100 PY) as well as TCZ discontinuation rates due to an AE (2.9; 2.7; 3.1 per 100 PY) did not increase with age. Gastrointestinal perforation was rarely observed (Figure 1).

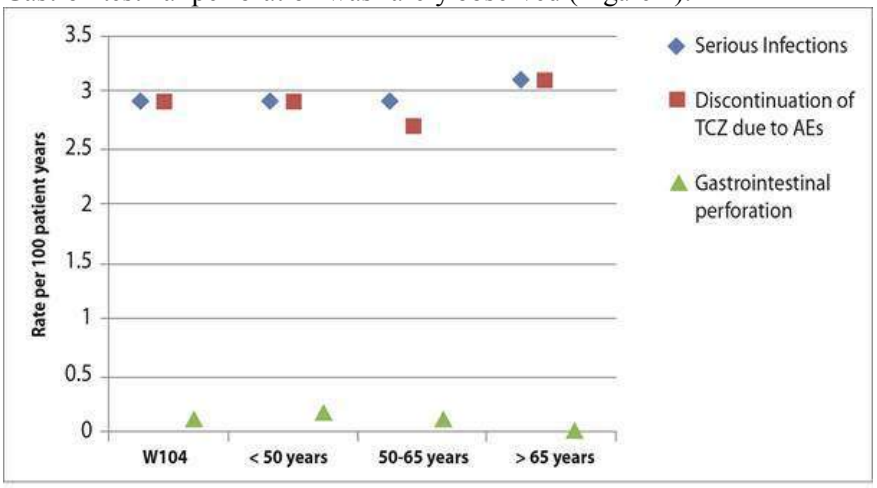

Figure 1

Serious Infections: All SAEs with a MedDRA Preferred Term indicating an infection.

5 patients of the subgroup > 65 years were older than 80 years. No serious infection, no gastrointestinal perforation nor a TCZ discontinuation due to an AE was observed within those 5 patients.

For the two patients with gastrointestinal perforation no history of gastrointestinal disease was documented.

Conclusion: 902 pts were observed for 2 years. TCZ IV treatment resulted in improvements of all disease activity parameters and a reduction in concomitant GC dosing was observed. Despite higher disease burden at baseline, elderly RA pts (> 65 years) benefited to the same extent as younger pts, without increased risk of infections. Considering natural age related risks, the low infection and gastrointestinal perforation rates of elderly pts seem to be attributable to the steroid sparing effect of TCZ therapy. Safety concerns should be no reason to argue against anti IL 6 therapy in elderly pts.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Data are very limited concerning the association between cotreatment with a conventional synthetic DMARD (csDMARD) and long term retention of abatacept (ABA), rituximab (RTX) and tocilizumab (TCZ) in real life.

Methods: This was a pre-specified sub-group analysis of a multicenter open-label observational study of patients with RA according to 1987 ACR criteria who initiated RTX, ABA, or TCZ and were enrolled in 3 French Society of Rheumatology prospective registries (AIR for rituximab, ORA for abatacept, and REGATE for tocilizumab). We used a propensity-score approach to adjust for differences in observed factors that might affect both treatment assignment and outcome.

Results: Data on concomitant treatment were available in 4469 out of 4498 patients (99.6%). 34.9, 34.3 and 40.2% of patients respectively treated with ABA, RTX and TCZ, initiated their biologic in monotherapy. 79.5% of patients with a csDMARD received methotrexate. 3507 patients had a follow-up at 24 months for a total follow-up of 18898 patient-years (RTX: 10545; ABA: 4912; TCZ: 3441). - Effect of concomitant csDMARD on the effectiveness of each drug Drug retention without failure of RTX at 2 years was 67.8[65.2; 70.4]% in patients treated in combination with a csDMARD and 65.1 [61.5;68.8]% in monotherapy, HR of discontinuation 0.89 [0.76;1.05], p= 0.21. Drug retention without failure of RTX at 5 years was 50.1[47.4; 53.0]% in combination and 45.3 [41.5;49.4]% in monotherapy, HR of discontinuation of 0.88 [0.77;1.0], p= 0.08. Drug retention without failure of ABA at 2 years was 42.6[38.9; 46.7]% in patients treated in combination and 36.7 [31.9;42.2]% in monotherapy, HR of discontinuation 0.86 [0.73;1.01], p= 0.08. Drug retention without failure of ABA at 5 years was 22.8[19.7; 26.4]% in combination and 18.7 [15;23.5]% in monotherapy, HR of discontinuation of 0.87 [0.75;1.01], p= 0.07. Drug retention without failure of TCZ at 2 years was 66.1 [62.9; 69.6]% in patients treated in combination and 60.9 [56.8;65.4]% in monotherapy, HR of discontinuation 0.82 [0.66;1.02], p= 0.09. - Effect of concomitant csDMARD on the comparative effectiveness between ABA, RTX and TCZ At 2 years, drug retention without failure among patients treated in combination with a csDMARD was significantly greater with RTX and TCZ than ABA (hazard ratio 1.85 [95% CI: 1.52;2.26], and 1.83 [95% CI: 1.39;2·42], respectively), with no difference between

RTX and TCZ. At 2 years, drug retention without failure among patients treated in monotherapy was significantly greater with RTX and TCZ than ABA (HR 2.29 [95% CI: 1.62;3.25], and 1.84 [95% CI: 1.15;2·96], respectively), with no difference between RTX and TCZ. At 5 years, drug retention without failure among patients treated in combination was significantly greater with RTX than ABA (HR 1.94 [95% CI: 1.64;2·29], and it was the same for patients treated in monotherapy (HR 2.31 [95% CI: 1.22;2·42]).

Conclusion: In real life patients, monotherapy with abatacept, rituximab or tocilizumab is not associated with a lower long term retention than combination with synthetic DMARD.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Improvement in physical function and morning stiffness are key goals of rheumatoid arthritis (RA) treatment. Sirukumab, a selective human anti–IL6 monoclonal antibody, has recently been evaluated in the SIRROUND-T global, Phase 3 study for the treatment of RA in patients (pts) with active disease who were intolerant or refractory to therapies targeting tumor necrosis factor (TNF). This study evaluated the impact of sirukumab on physical function and morning stiffness in pts with active RA despite anti-TNF therapy.

Methods : Eligible pts with active RA who were intolerant or refractory to anti-TNF therapy were randomized (1:1:1) to sirukumab SC 50 mg q4w, sirukumab SC 100 mg q2w, or placebo SC q2w. A significant proportion of pts were also exposed to other non-anti-TNF therapies. At Wk 18, pts in the placebo group were re-randomized to 1 of the 2 sirukumab doses if they had insufficient (<20%) improvement in tender/swollen joints, and at Wk 24, all pts remaining in the placebo group crossed over to 1 of the 2 sirukumab doses. To assess physical function, pts completed the Health Assessment Questionnaire-Disability Index (HAQ-DI) at baseline (BL) and from Wk 2 to 52. A clinically meaningful improvement in

HAQ-DI from BL was defined as a change (reduction) of 0.22 in HAQ-DI, and a normal HAQ-DI score was defined as ≤0.5. The average duration of daily morning stiffness during the previous week in minutes (0–1440 minutes) was evaluated at the same visits as HAQ-DI.

Results: Mean improvement from BL in HAQ-DI score was significantly greater for both sirukumab 50 mg q4w and sirukumab 100 mg q2w compared with placebo at Wk 24 (both P <0.001; **Table**). Improvements from BL were maintained for both sirukumab doses through Wk 52. Improvements from BL in the HAQ-DI score were clinically meaningful (change of −0.22) for a significantly greater proportion of pts with both doses of sirukumab compared with placebo at Wk 24 (both P <0.001); differences between sirukumab and placebo in the proportion of pts achieving a clinically meaningful improvement in HAQ-DI scores were observed as early as Wk 4. A significantly greater proportion of pts receiving sirukumab 100 mg q2w (numerically greater with 50 mg q4w) achieved a HAQ-DI score of ≤0.5 at Wk 24 compared with placebo (P = 0.029). Additionally, there was a significantly greater reduction from BL in the duration of morning stiffness with sirukumab 50 mg q4w (P = 0.011) and a numerically greater reduction from BL with sirukumab 100 mg q2w compared with placebo at Wk 24; for both sirukumab dose groups, these reductions were observed as early as Wk 2 and maintained through Wk 52.

Conclusion: Sirukumab treatment was associated with early, sustained, and clinically meaningful improvements in both physical function and morning stiffness in pts with active RA who were intolerant or refractory to anti-TNF therapy.

Table. HAQ-DI and Morning Stiffness Outcomes at Week 24[a]

		Sirukumab	
Outcome	Placebo (n=294)	50mg q4w (n=292)	100mg q4w (n=292)
HAQ-DI, mean (SD) change from BL	−0.12 (0.49)	−0.31 (0.54)[b]	−0.33 (0.53)[b]
Proportion of pts with clinically meaningful improvement from BL in HAQ-DI, %[c]	37.4	52.2[b]	54.8[b]
HAQ-DI ≤0.5, %	12.6	15.1	19.2[d]
Change from BL in duration of daily morning stiffness (min), mean (SD)	−28.9 (219)	−87.0 (333)[e]	−71.2 (253)

[a]n values are based on initial treatment assignment.
[b]P <0.001 vs placebo.
[c]Minimum clinically meaningful improvement, change of −0.22 from BL.
[d]P = 0.029 vs placebo.
[e]P = 0.011 vs placebo.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Inhibition of GM–CSFR-α is a novel approach to treat RA. Mavrilimumab, an investigational human monoclonal antibody targeting GM–CSFR-α, has demonstrated efficacy and an acceptable safety profile in prior 12- and 24 week studies. Here, the long-term (LT) efficacy and safety of mavrilimumab 100 mg every other week (eow) is evaluated for up to 158 (median = 122) weeks treatment in patients (pts) with moderate to severe RA.

Methods: Adult pts were enrolled into this open-label extension (OLE) study (NCT01712399) after completing either EARTH EXPLORER 1 or 2 (NCT01706926; NCT01715896), or transferred from Week 12 onwards because of inadequate response. Pts received subcutaneous mavrilimumab 100 mg eow, consistent with the highest dosage in the Phase IIa study. The LT risk:benefit ratio of mavrilimumab was assessed via evaluation of treatment-emergent adverse events (TEAEs), serious TEAEs (TESAEs), and pulmonary events. Exploratory LT efficacy was measured using clinical (DAS28–CRP and ACR responses) and patient-reported outcomes [PROs: HAQ-DI; Short Form Health Survey (SF)-36; Functional Assessment of Chronic Illness Therapy (FACIT) fatigue]; efficacy duration was assessed via evaluation of major clinical response (maintenance of ACR70 for 24 weeks) and maintenance of DAS28–CRP <2.6. Radiographic progression (modified total Sharp score [mTSS]) was assessed in pts initially enrolled in EARTH EXPLORER 1.

Results: 397 pts were included in the OLE study. Between the Phase IIb and OLE studies, 442 pts received mavrilimumab, with a cumulative safety exposure of approximately 900 pt-years (yrs). Across all time points, the most frequently reported TEAEs for all pts (n [rate/100 pt-yrs]) were nasopharyngitis (69 [7.68]), bronchitis (51 [5.68]), RA (44 [4.90]), urinary tract infection (38 [4.23]), and hypertension (38 [4.23]); the serious infection rate was 1.56/100 pt-yrs. Treatment with mavrilimumab was not associated with substantial effects on pulmonary safety, including function; monocytopenia was not reported and shifts in laboratory values were not clinically significant. At Week 122, ACR20/50/70 responses were achieved in approximately 80%, 50%, and 30% of pts, respectively; 65% of pts achieved DAS28−CRP <3.2 and 41% of pts achieved DAS28−CRP <2.6. In addition, efficacy was demonstrated across PRO endpoints; mean FACIT fatigue and SF-36 components showed improvements from baseline, which were maintained through 122 weeks (Table).

Conclusion: Mavrilimumab demonstrated sustained efficacy and an acceptable safety profile for up to 158 (median = 122) weeks in pts with moderate to severe RA. Mavrilimumab 100 mg eow is suboptimal compared with 150 mg eow in DMARD-IR pts; however, efficacy results remain comparable with previous studies, validating the use of mavrilimumab to

Table. Long-term safety and efficacy data in the as-treated population

Baseline characteristics	**Mavrilimumab eow**			
Mean (SD) age, yrs (N=397)	51.1 (11.2)

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients (pts) with rheumatoid arthritis (RA) often experience both substantial fatigue and a decline in their health-related physical and emotional well-being. Sirukumab is a human anti-IL-6 monoclonal antibody that selectively binds to the cytokine with high affinity, and is under development for RA and a number of other diseases. The effects of sirukumab on health-related physical and emotional well-being and fatigue were evaluated in 2 separate randomized, double-blind, placebo-controlled, multicenter global phase 3 studies in pts with RA refractory to conventional DMARDs (SIRROUND-D) or refractory or intolerant to anti-TNF therapy (SIRROUND-T). Pts may have been taking other biologics prior to both studies.

Methods: In both studies, eligible pts were randomized (1:1:1) to treatment with SC sirukumab 50 mg q4w, 100 mg q2w, or placebo q2w. The placebo-controlled portions of SIRROUND-D and -T were 52 and 24 wks, respectively; thus, results from both studies were examined at Wk 24 and are presented here. The primary objective of both studies was to evaluate

the efficacy of sirukumab in the study-specific RA pt populations. Health-related physical and emotional well-being were evaluated as secondary endpoints using the SF-36 health survey, and fatigue evaluated using the FACIT-Fatigue scale. For SF-36 physical and mental component summary (PCS and MCS) scores, clinically meaningful improvement was defined as a ≥5-point increase from baseline (BL); for FACIT-Fatigue, clinically meaningful improvement was defined as a ≥4-point increase from BL.

Results: A total of 1,670 and 878 pts in SIRROUND-D and -T, respectively, had evaluable data. In both studies, increases (improvements) from BL at Wk 24 in mean SF-36 PCS and MCS scores and all 8 SF-36 domain scores were significantly greater with either sirukumab dose level (50 mg q4w or 100 mg q2w) versus placebo (all $P<0.02$; **Table**). Similarly across both studies, significantly greater mean increases (improvements) from BL at Wk 24 were observed in the FACIT-Fatigue score with sirukumab (either dose) versus placebo (all $P<0.001$ [not adjusted for multiplicity]; **Table**). Improvements in SF-36 and FACIT-Fatigue scores with both sirukumab doses versus placebo were observed at Wk 8 through all time points to Wk 24 in both studies. In addition, across studies, the percentages of pts who achieved clinically meaningful improvements from BL at Wk 24 in SF-36 PCS and MCS scores, and in FACIT-Fatigue score were significantly higher with sirukumab (either dose) versus placebo (all $P<0.02$).

Conclusion: Treatment with sirukumab was associated with significant and clinically meaningful improvements from BL in health-related physical and emotional well-being and fatigue for pts with active RA who had not responded adequately to prior treatment, regardless of whether prior treatment was with conventional DMARDs or TNF inhibitors.

Table. SF-36 and FACIT-Fatigue Outcomes at Week 24[a]

	Placebo		Sirukumab 50 mg q4w		Sirukumab 100 mg q2w	
Outcome	DMARD-refractory (n = 556)	TNF-refractory (n = 294)	DMARD-refractory (n = 557)	TNF-refractory (n = 292)	DMARD-refractory (n = 557)	TNF-refractory (n = 292)
Mean (SD) change from baseline						
SF-36 PCS	2.29 (6.28)	1.68 (6.65)	5.36 (7.33)[b]	4.85 (7.09)[b]	5.85 (7.07)[b]	5.06 (6.88)[b]

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The combination of methotrexate (MTX), sulfasalazine (SSZ) and hydroxychloroquine (HCQ) (triple therapy) is a highly effective and well-tolerated treatment in rheumatoid arthritis (RA). While MTX is the cornerstone of most successful combination therapies, not all patients are candidates for, or tolerate, MTX. Leflunomide, a disease-modifying anti-rheumatic drug (DMARD) that inhibits DNA synthesis, is a common alternative to MTX. Whether leflunomide can be used as an alternative for MTX in combination with SSZ and HCQ has not previously been studied.

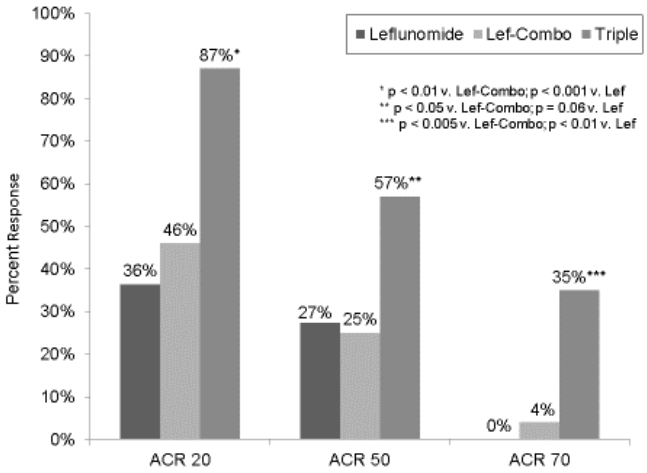
Methods: We performed a 48-week, double-blind, randomized three-armed trial to compare: conventional triple therapy (Triple); the combination of leflunomide, SSZ and HCQ (Lef-Combo); and leflunomide alone (Lef) in RA. Patients were enrolled between 2002 and 2007 and were eligible if they had not previously used leflunomide or combination DMARDs, met 1987 ACR classification criteria for RA, had active disease (≥6 swollen and ≥6 tender joints), and were on stable doses of prednisone ≤ 10 mg/day for at least 4 weeks prior to entry into the study. Patients with intra-articular injections within 4 weeks of entry, functional class IV RA, serum creatinine > 2.0 mg/dL, radiographic evidence of rheumatoid lung disease, significant liver, renal, hematologic, pulmonary, cardiovascular, retinal, or active peptic ulcer disease were excluded from the study. The primary outcome was an ACR-20 response at 48 weeks. Secondary outcomes included ACR-50 and ACR-70 responses. The study was designed to enroll 180 patients in order to achieve a power of 80% for detecting significant differences in the primary outcome.

Results: The study included 69 patients with mean ages ranging from 50-54 years across the three study arms, 77% of whom were RF positive, with median disease duration ranging from 10-24 months, and mean DAS28-ESR scores ranging from 5.7-6.0. Women comprised more of the Lef group (83%) than Triple (52%) ($p<0.05$). In an intent-to-treat analysis, conventional therapy was superior to both Lef-Combo and Lef in the achievement of ACR-20, -50, and -70 responses (Figure 1). The study was terminated prematurely due to the frequency of gastrointestinal (GI) toxicity in the Lef-Combo group (29.2%), which included dyspepsia/nausea and diarrhea in 5 and 2 patients, respectively, all of whom withdrew from

the study. Lef-Combo was efficacious in those that were able to tolerate it with 73% achieving an ACR-20 response.

Conclusion: Although efficacious as combination DMARD therapy in RA, Lef-Combo is poorly tolerated due to GI complications in almost one-third of patients. The loading dose of leflunomide used at enrollment could have contributed to GI toxicity. Providers who employ this combination need to be aware of the potential for GI toxicity and educate patients

Figure 1: ACR Responses by Treatment



accordingly.

EARTH EXPLORER 2, a Phase IIb Exploratory Study Evaluating Efficacy and Safety of Mavrilimumab, a Fully Human Granulocyte-Macrophage Colony-Stimulating Factor Receptor-Alpha Monoclonal Antibody, and the Tumor Necrosis Factor Antagonist Golimumab in Rheumatoid Arthritis

Michael Weinblatt[1], IB McInnes[2], JM Kremer[3], P Miranda[4], J Vencovský[5], A Godwood[6], M Albulescu[6], D Close^[6] and GR Burmester^[7], [1]Brigham and Women's Hospital, Boston, MA, [2]University of Glasgow, Glasgow, United Kingdom, [3]The Albany Medical College, Albany, NY, [4]Centro De Estudios Reumatológicos, Santiago, Chile, [5]Charles University, Prague, Czech Republic, [6]MedImmune, Cambridge, United Kingdom, [7]Charité – University Medicine Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mavrilimumab, a fully human monoclonal antibody targeting the granulocyte-macrophage colony-stimulating factor receptor-α, has demonstrated efficacy and safety in disease-modifying antirheumatic drug (DMARD)-inadequate responder (IR) patients (pts) with rheumatoid arthritis (RA).[1] Few head-to-head studies in tumor necrosis factor antagonist (aTNF)-IR assess alternative aTNFs vs. other agents; this Phase IIb exploratory study (NCT01715896) evaluates the efficacy and safety of mavrilimumab and golimumab in aTNF-IR and DMARD-IR pts.

Methods: This 24-week study enrolled pts with active RA (28-joint Disease Activity Score [DAS28]–C-reactive protein [CRP]/erythrocyte sedimentation rate [ESR] ≥3.2); ≥4 swollen joints; inadequate response to ≥1 DMARDs and/or 1–2 aTNFs receiving concomitant methotrexate (MTX; 7.5–25.0 mg/week). Pts received subcutaneous mavrilimumab 100 mg every other week (eow), based on data from the Phase IIa study,[2] or golimumab 50 mg alternating with placebo eow. Key endpoints were ACR20/50/70 responses, DAS28–CRP <3.2 and <2.6, Health Assessment Questionnaire Disability Index improvement >0.22 at Week 24 and safety/tolerability. Treatment estimates for mavrilimumab and golimumab are presented with standard errors.

Results: Pts were randomized to mavrilimumab or golimumab (1:1) (Table). Data for pts receiving mavrilimumab 100 mg eow and golimumab 50 mg at Week 24 are shown for the aTNF-IR, DMARD-IR and overall strata (Table). The most common treatment-emergent adverse events (TEAEs) for mavrilimumab 100 mg and golimumab 50 mg were nasopharyngitis (5.7%, 1.5%), headache (4.3%, 2.9%), upper respiratory tract infection (4.3%, 2.9%), viral upper respiratory tract infection (4.3%, 2.9%), and hepatic enzyme increase (4.3%, 2.9%), respectively. Related serious TEAEs were pneumocystis pneumonia (n=1) and lung disorder (n=1) [both in golimumab-treated pts]. No deaths were reported and no significant pulmonary safety signals were identified.

Conclusion: In this exploratory study, mavrilimumab 100 mg eow and golimumab 50 mg demonstrated efficacy and an acceptable safety profile in DMARD-IR and aTNF-IR pts. The study was not powered to demonstrate statistical significance between mavrilimumab and golimumab. As mavrilimumab 100 mg eow has previously been shown to have suboptimal efficacy compared with 150 mg eow in DMARD-IR pts (EARTH EXPLORER 1),[1] additional studies are needed to establish the benefit of a higher dose in pts with moderate to severe RA and inadequate response to aTNF agents.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: MEDI4920 is a CD40 ligand (CD40L) antagonist under development for the treatment of autoimmune diseases. It is an engineered protein lacking a fragment crystallizable (Fc) moiety to avoid potential thromboembolic events associated with the Fc domain. The safety and tolerability of single ascending intravenous (IV) doses of MEDI4920 in healthy adults were studied in a Phase 1, randomized, blinded, placebo-controlled study. In addition, the pharmacokinetics (PK), immunogenicity, and PK/pharmacodynamic (PD) relationship were assessed and characterized in the study.

Methods: Fifty-six healthy adult male subjects were randomized in the study at a single site and administered either placebo or MEDI4920 (3, 10, 30, 100, 300, 1000, 3000 mg). Blood samples were collected to evaluate the PK, anti-drug antibody (ADA), and PD profiles. MEDI4920 and total soluble CD40L (sCD40L) concentrations were determined using a validated immunoassay and a qualified enzyme-linked immunosorbent assay (ELISA) method, respectively. The presence of ADA to MEDI4920 was determined using a validated ELISA method. PK parameters were obtained using non-compartmental analysis, and a mechanism-based PK/PD model was developed to describe the relationship between MEDI4920 and total sCD40L accumulation in healthy subjects.

Results: Following IV administration, MEDI4920 exposure increased in a dose-proportional manner. The clearance and terminal half-life ranged from 453 to 668 mL/day and 4.41 to 9.68 days, respectively, across the dose cohorts. Administration of MEDI4920 produced a dose-dependent increase in total sCD40L levels that reached a plateau at doses of 1000 mg and higher. A high incidence of ADA was observed in the lower dose cohorts (3, 10, 30, and 100 mg); ADA incidence and titers decreased with increasing dose. In subjects with high ADA titers, MEDI4920 was cleared faster from the circulation at concentrations lower than 1 µg/mL. A rapid decrease in total sCD40L accumulation was observed in subjects with high ADA titers. No association of ADA with clinical adverse events was established.

Conclusion: The PK of MEDI4920 was linear and showed a dose-dependent increase in total sCD40L, consistent with target engagement. The decrease in ADA incidence and titers observed with increasing dose is consistent with the MEDI4920 immunosuppressive mechanism of action. Overall, MEDI4920 demonstrated safety and tolerability in a single ascending dose study in healthy subjects. These data support further investigation of MEDI4920 as a therapy for patients with rheumatoid arthritis. The mechanism-based PK/PD model can be used to explore the effects of various MEDI4920 doses and regimens on target engagement.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Spleen Tyrosine Kinase (SYK) plays a pivotal role in the regulation of downstream signals in immune receptors, including B cell receptors (BCRs), which play a key role in autoimmune diseases such as rheumatoid arthritis (RA). This abstract reports the results of the first-in-humans study of HMPL 523, a highly selective, potent, and orally available inhibitor of SYK.

Methods: We conducted a 3-part study to investigate the safety, tolerability, and pharmacokinetics (PK) of HMPL-523 as well as its pharmacodynamics (PD) measured by $CD63^+$ as the biomarker, and the effect of food on PK in healthy adult male subjects. The study design is summarized in the table below.

Table Study Design

Endpoints	Part A (Single Ascending Dose) PK							Part B (Multiple Ascending Dose) PK/PD								Part C Effect of Food on PK
general design	A randomized, double- blind, placebo-controlled design															Cross over
Dose	Single dose							Once daily for 14 days								Once on Day 1 and Day 8, respectively
Meal condition	Fasted							Fed					Fed			Fasted on Day 1; wash-out for 7 days; after the consumption of a high-calorie meal on Day 8
Dosage (mg)	5 (N=6)	20 (N=6)	50 (N=6)	100 (N=6)	200 (N=6)	300 (N=6)	Placebo (N=12)	300 (N=6)	400 (N=6)	600 (N=6)	800 (N=6)	Placebo (N=8)	200 (N=12)	300 (N=6)	400 (N=6)	Placebo (N=8)	100 (N=6)

Results: A total of 118 adult male healthy subjects were enrolled at baseline. 114 (96.6%) Subjects completed the study. A total of 83 treatment emergent adverse events (TEAEs) were reported as the following: 38.9% in the HMPL-523 groups, and 32.1% in the placebo groups, respectively. The majority of TEAEs were mild (63/83 or 75.9%) with 18/83 (21.7%) moderate events. Two serious adverse events (SAEs) were reported due to elevated lipase (HMPL-523 200mg) and febrile illness (HMPL-523 400mg) in Part B (multiple ascending doses [MAD]). As a result, HMPL-523 was discontinued in the two subjects. All of the TEAEs and SAEs were resolved. Part A (single ascending dose [SAD]) PK results revealed that HMPL-523 was rapidly absorbed with median time to maximum plasma concentration (T_{max}) between 3 and 6 hours under both fasted and fed conditions. The maximum plasma concentration (C_{max}) and area under the plasma concentration-time curve (AUC) of HMPL-523 increased proportionally with dose increase up to 800 mg. The terminal half-life ($t_{1/2}$) ranged between 9.808 hours and 13.488 hours across HMPL-523 doses of 100 to 800 mg. Part B (MAD) PK results showed that steady state was achieved within 48 hours of daily administration and accumulation of 1.3 to 1.5 folds was observed over 14 days of dosing. In an *ex vivo* human whole blood PD assay, HMPL-523 inhibited anti-IgE-induced basophil ($CD63^+$) in a concentration-dependent manner with an estimated half maximal effective concentration (EC_{50}) of 47.70 ng/mL. The human PK exposures at 200 mg once daily and above can be expected to provide the target coverage required for clinical efficacy based on the preclinical PK/PD analysis. In Part C, systemic exposure of HMPL-523 was increased up to 1.5 folds when administered in the fed condition compared to the fasted condition, indicating that food consumption increases the relative bioavailability of HMPL-523.

Conclusion: Overall, the safety and laboratory data suggests that the single and multiple doses of HPML-523 were generally well tolerated. A multiple-dose regimen of 300 mg or less of HMPL-523, administered once daily, is

recommended for future Phase II clinical trials for autoimmune diseases.

Safety and Efficacy of Iguratimod in Patients with Active Rheumatoid Arthritis: A Multicenter, Single-Arm, Open-Label, Real World Study

Rong Mu, Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the safety and efficacy of iguratimod, a novel DMARD, in active rheumatoid arthritis patients.

Methods: Patients with active rheumatoid arthritis received iguratimod treatment for 24 weeks. During the study, eligible patients could continue to use their anti-rheumatic drugs which were taken in stable dose for at least 3 months before the trial. The investigator could adjust the regimen according to disease activity after 12 weeks treatment. The efficacy and safety of iguratimod were assessed at week 2、4、8、16 and 24. The primary endpoints of efficacy were ACR 20/50/70 response rates at the end of 12^{th} and 24^{th} week; the secondary endpoint of efficacy included changes of DAS28-ESR, HAQ and emotion score from baseline, clinical remission rates at the end of 12^{th} and 24^{th}week. AEs, laboratory/physical examination, and vital signs were investigated to analyze the safety.

Results: The trial was conducted in 48 centers in China. 1759 patients were enrolled in this study, among them 1751 were included in safety analysis, and 1597 patients were evaluated for efficacy. At the end of the 12^{th} week, ACR 20/50/70 response rates were 62.2% (994/1597), 29.5% (471/1597) and 11.0% (176/1597) respectively. At the end of 24^{th} week, ACR20/50/70 response rates were 71.9% (1148/1597), 47.4% (757/1597) and 24.0% (384/1597). DAS28-ESR score was significantly reduced since Week 4 compared to baseline($P<0.001$). The proportions of patients who obtained clinical remission or low disease activity were 22.6% and 34.5% at the end of 12^{th} and 24^{th} week,according to DAS28-ESR score. The disease remission rate by the 2011 ACR/EULAR remissin criteria was 5.7% (79/1379) at the end of 12^{th} week, and 13.3% (187/1403) at the end of 24^{th}week. 38.5% (674/1751) of the patients experienced at least one ADR.Increased ALT 10.8% (189/1751) and AST 9.8% (171/1751), abdominal discomfort 6.3% (111/1751), abdominal pain 4.5% (78/1751), leukopenia 3.9% (69/1751), nausea 2.7% (47/1751), bloating 2.6% (45/1751), dizziness 2.3% (41/1751), diarrhea 2.1% (37/1751).

Conclusion: Iguratimod was effective and well tolerated in active RA patients in this large sample phase IV clinical trial. No unexpected adverse drug reaction was found.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The selective Janus kinase (JAK) inhibitor tofacitinib inhibits progression of structural damage in rheumatoid arthritis (RA). These results suggest the possibility that tofacitinib improves osteoclastic bone destruction of RA. However, the detailed mechanism of tofacitinib for bone metabolism in RA is poorly understood. The purpose of this study is to clarify the effect of tofacitinib on bone metabolism, especially osteoclast regulating factor in RA.

Methods: Fourteen patients with active RA who inadequate response to DMARDs (mean age: 54.6 years, mean disease duration: 4.1 years, mean simplified disease activity index: 26.9, ACPA positive: 86%, oral steroid use: 29%, mean oral steroid dose: 10mg/day, MTX use: 93%, mean MTX dose:10.9mg/week, biologic DMARDs naïve: 57%) were started on treatment with tofacitinib 5mg twice daily (BID). Disease activity was assessed using the simplified disease activity index (SDAI). Next, the following soluble biomarkers of bone remodeling were measured by ELISA at the baseline and after 2, 4 and 12 weeks. (i) bone formation marker: osteocalcin (IRMA SRL, corp.); (ii) bone resorption maker: type I collagen cross-linked N-telopeptides (NTx) (ELISA , SLR corp.); (iii) osteoclat regulator: soluble receptor activator of nuclear factor kappa B ligand (sRANKL) (human RANKL ELISA kit, Biomedica) and osteoprotegerin (OPG) (human osteoprotegerin ELISA kit, Biomedica)

Results: After treatment of tofacitinib, SDAI score among all fourteen patients decreased significantly from 26.9±12.4 (mean±SD) at the base line to 14.7±9.9 at week 4 (p<0.0001), to 8.3±6.1 at week 12 (p<0.0001). Average of osteocalcin levels increased significantly from 6.9±4.3 ng/mL at the baseline to 8.8±6.1 at week 12 (p=0.0142), whereas average of NTx levels tend to decrease from 18.2±5.9 nmol BCE/L at the baseline to 16.7±5.8 at week 12. At the baseline, sRANKL levels were significantly correlated with CRP levels (Spearman r^2=0.488, P=0.0054). Average of sRANKL levels decreased significantly from 0.15±0.11 pmol/L at the baseline to 0.09±0.05 at week 2 (p=0.0097), to 0.11±0.10 at week 4 (p=0.0311), to 0.08±0.05 at week 12 (p=0.0014). On the other hand, statistically significant changes in OPG levels were not observed during 12 weeks. Consequently, average of sRANKL/OPG ratio decreased significantly from 4.81±4.82 at the baseline to 2.62±1.84 at week 2 (p=0.0186), to 3.11±2.81 at week 4 (p=0.0191), to 2.11±1.72 at week 12 (p=0.0052). Interestingly, decreasing effects of sRANKL level or sRANKL/OPG ratio were greater in patient with the high sRANKL level (>0.14 pmol/L: mean value of 70 RA patients in previous our study) at the base line.

Conclusion: Here, we show for the first time that tofacitinib has improved inflammatory bone metabolism immediately through the regulation of sRANKL levels and sRANKL/OPG balance in patients with RA. It had been reported that tofacitinib regulated synovitis through inhibition of IL-17 production by CD4+ T cells and IL-6 production by synovial

fibroblasts in RA (Maeshima K. et al. Arthritis Rheum.64:1790-8.2012). Thus, tofacitinib might control of RANKL induction via inhibition of IL-17 and IL-6 production in RA synovium.

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) patients have a higher risk of post-operative complications compared with the general population, especially considering the risk of infection. It remains unclear whether use of biological DMARDs, including Tocilizumab (TCZ), is an independent risk factor for post-operative complications. The aim of this study was to evaluate safety and predictive factors of complications after surgery in rheumatoid arthritis patients receiving Tocilizumab in routine care.

Methods: Patients treated with TCZ for RA included in the French REGATE registry were included if they underwent surgery. When TCZ was interrupted more than 12 weeks prior to surgery, patients were excluded. Post-operative complications were defined as an adverse event occurring in the 12 weeks after surgery. Frequency of post-surgery complications was collected and compared in patients with and without complications in order to identify factors associated with complications. A second analyze was achieved in patients with post-operative infection (local or general). Qualitative variables were compared by Fisher's test and quantitative variables were compared by the Mann-Whitney test.

Results: Out of 1499 patients from the REGATE registry, a total of 167 patients underwent 175 surgical procedures. These patients were mainly women (84%), the mean age was 58.11 +/- 12.83 years, and the disease duration of 14.96+/- 11.29 years. The mean delay between surgery and the last TCZ infusion was 4.94+/-1.74 weeks (median 4 weeks). Fifteen patients experienced 15 complications (8.9%) with 10 severe infections, 1 intestinal obstruction, 1 RA flare, 1 delayed wound healing, 1 thromboembolic disorder and 1 hemorrhagic complication. Postoperative complications occurred after 7.8% of orthopedic surgeries (8 of 103). The 10 severe infections occurred mostly after orthopedic surgery (7/10). There was 7 surgical site infections (46.7%) and 3 general infections. In 5 patients, TCZ treatment was definitely stopped. On univariate analysis, no risk factor was significantly associated with post-operative complications. However, corticosteroids (p=0.096), previous biological treatment (p=0.096) and previous RTX treatment (p=0.074) almost reached statistically significancy.In multivariate analysis, only previous RTX treatment was close to be significant in multivariate

analysis (OR: 3.27, IC95% 0.92-11.49, p=0.052). Concerning infectious complications, no risk factor was found statistically associated with post-operative complications on univariate analysis. Only diabetes mellitus (p=0.091), foot surgery (p=0.095) and number of TCZ infusions before surgery (p=0.084), were almost statistically significant. In multivariate analysis, only foot surgery (OR: 3.17, IC95% 0.82-12.21 p=0.078) and diabetes mellitus (OR: 3.73, IC95% 0.88-15.79, p=0.057) tended to be associated with infectious post-operative complications.

Conclusion:

In routine practice, the postoperative period in TCZ treated patients seem to be safe when TCZ is stopped 1 month before surgery. Diabetes was significantly associated with an increased risk of post-operative infection in RA patients treated with TCZ.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sirukumab is a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, and is under development for rheumatoid arthritis (RA) and other diseases. Efficacy and safety of sirukumab have recently been evaluated in a global Phase 3 study (SIRROUND-D) in patients (pts) with active RA refractory to conventional, synthetic, disease-modifying antirheumatic drugs (DMARDs). This analysis aimed to compare the efficacy of sirukumab across various subgroups based on demographics, baseline characteristics, and prior/baseline medication use.

Methods: Eligible pts were randomized (1:1:1) to treatment with sirukumab subcutaneous (SC) 50 mg q4w, sirukumab SC 100 mg q2w, or placebo SC q2w. The 2 co-primary efficacy endpoints were ACR20 response at Wk 16 and change from baseline in the modified Sharp/van der Heijde (SHS) radiographic damage score at Wk 52. The first prespecified analysis compared the consistency of ACR20 response at Wk 16 across subgroups, including geographic region, age, weight, rheumatoid factor (RF) positivity, anti-cyclic citrullinated peptide (CCP) positivity, Health Assessment Questionnaire–Disability Index (HAQ-DI), C-reactive protein (CRP) level, disease duration, prior/baseline DMARD use, and baseline

methotrexate (MTX) use. Post-hoc analyses examined ACR50 and DAS (CRP) remission at Wk 24.

Results: Sirukumab 50 mg q4w and 100 mg q2w led to higher rates of ACR20 response at Wk 16 compared with placebo across all parameters analyzed and regardless of disease duration, use of baseline DMARDs, number of prior DMARDs, or baseline MTX dose (**Table**). For most parameters, including age, weight, anti-CCP positivity, combined RF and anti-CCP positivity, and HAQ-DI, sirukumab efficacy, as assessed by rate of ACR20 response at Wk 16 vs placebo, was not significantly associated with a particular subgroup (with the exception of geographic region [$P = 0.032$], RF positivity [$P = 0.012$], and CRP level [$P = 0.005$] when comparing sirukumab 100 mg q2w vs placebo). In all cases, the odds ratios favored sirukumab, but Asia Pacific region, RF-positive status, and CRP level ≥15 mg/dL were associated with the greatest differences in ACR20 response rate at Wk 16 for sirukumab 100 mg q2w vs placebo. In post-hoc analyses of Wk 24 ACR50 and DAS (CRP) remission, greater efficacy was consistently demonstrated with sirukumab compared with placebo across all parameters analyzed, with a few significant associations between sirukumab efficacy and particular subgroups.

Conclusion: Both doses of sirukumab demonstrated greater efficacy than placebo, based on ACR20 response at Wk 16, as well as ACR50 and DAS (CRP) remission at Wk 24, across all subgroups analyzed. These results confirm the consistency of sirukumab efficacy in pts with active RA, regardless of disease duration and prior medication use.

Table. Odds Ratios Comparing ACR20 Response Rates at Wk 16 by Subgroups

	Odds ratio (95% CI) for ACR20 at Wk 16	
Baseline characteristic	**Sirukumab 50 mg q4w, placebo**	**Sirukumab 100 mg q2w, placebo**
Disease duration		
<1 yr	4.154 (1.7, 10.0)	3.846 (1.6, 9.3)
≥1 yr to <3 yrs	3.078 (1.7, 5.7)	3.567 (1.9, 6.6)
≥3 yrs	3.364 (2.5, 4.5)	3.071 (2.3, 4.1)

In Real Life Rheumatoid Arthritis Patients, Leflunomide Has Limited

Impact As a Second Line DMARD after Methotrexate

Gundula Weigt, Anne Erler and **Martin Aringer**, Medicine III, University Medical Center and Faculty of Medicine at the TU Dresden, Dresden, Germany

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with rheumatoid arthritis (RA), in whom methotrexate (MTX) is not inducing remission or at least low disease activity, or is not tolerated, leflunomide is one conventional synthetic DMARD option that is still commonly used in some countries. We thus investigated whether real life patients with RA benefit from instituting leflunomide after methotrexate.

Methods: The clinical data of all RA patients who had at least once received leflunomide, and who agreed to the pseudonymized analysis of their data (approved by the local ethics committee), were analyzed from the time of leflunomide initiation on to the time of stopping leflunomide or the last visit in 2015, which ever came first.

Results: 144 RA patients treated with leflunomide were identified. Of these, 86 received leflunomide after MTX had failed as a first line DMARD, and 8 received leflunomide as a first line DMARD. 50 patients had another first line therapy. Of the first line leflunomide patients 3 (38%) were still on leflunomide at the last visit, as compared to 6 of the 43 patients (14%) who were switched from MTX to leflunomide, and 0 of the 27 patients in whom leflunomide was added to MTX ($p<0.01$ vs 1^{st} line leflunomide). For leflunomide monotherapy, 29% and 19% were still on the drug after 24 and 48 months, respectively, as compared to 14 and 0% under the combination with MTX. Of all patients who started leflunomide, remission (at least low disease activity) as per CDAI (≤ 2.8 (≤ 10)) was reached by 23% (57%) 3 months, 20% (40%) 6 months, and 16% (34%) one year after initiating leflunomide monotherapy, with corresponding percentages of patients of 39% switched to other approaches at six months and of 60% switched at one year. Under the combination of leflunomide and MTX, remission (at least low disease activity) was seen in 18% (53%) at 3 months, 20% (37%) at 6 months, and 8% (20%) at one year, and 55% and 71% had switched to other modes of action at six months and one year, respectively. Gastrointestinal and mucocutaneous adverse events and hypertension were common, and 4 our patients experienced serious bacterial infections.

Conclusion: While leflunomide may be a longer term option for a subgroup of RA patients with contraindications to MTX or after MTX failure, only a third of patients had acceptable disease control after one year under leflunomide monotherapy, and one in five under leflunomide combined with MTX. These results are supportive of the EULAR recommendations that patients should be switched to a second conventional DMARD in the absence of predictors of bad outcome only. If leflunomide is initiated, the patients need to be followed closely for potential secondary loss of efficacy.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Sirukumab is a human anti-interleukin-6 cytokine monoclonal antibody evaluated for the treatment of moderate to severe active rheumatoid arthritis (RA) and other diseases. Our aim is to update previous network meta-analyses (NMAs) comparing biologic (b) disease modifying anti-rheumatic drugs (DMARDs) and targeted synthetic (ts) DMARDs with conventional (c) DMARDs with the inclusion of sirukumab data from the SIRROUND-D trial, a phase 3 pivotal randomized clinical trial in this patient population.

Methods: Bayesian NMA were conducted using randomized controlled trials identified from a systematic literature review. The analysis included only trials assessing a treatment combined with one cDMARD. Studies reporting ACR20 response and change from baseline in disease activity score 28 (DAS28) based on the C-reactive protein (CRP) at 24±4 weeks were included. A Bayesian network meta-regression adjusted for baseline risk (ie, the estimated baseline effect of the common comparator arm in each trial) was conducted for the ACR20 analysis. The baseline risk is used as a proxy to adjust for differences in patients' characteristics that lead to variations across common comparator arms. Evidence networks included treatment and dose-specific nodes except for cDMARDs. Non-informative prior distributions were used. Selection of fixed versus random effects was based on the Deviance Information Criterion (DIC).

Results: The review identified 24 studies reporting results at 24 weeks for abatacept, adalimumab, baricitinib, certolizumab pegol, etanercept, golimumab, rituximab, sarilumab, tocilizumab and tofacitinib, all combined with a cDMARD. ACR20 response rates in the cDMARD arms varied greatly across trials (9% to 46%). The meta-regression adjusting for baseline risk suggested a strong interaction between baseline risk and treatment effect. Based on the DIC, a random effects model was selected for the ACR20 analysis. All bDMARDs (including sirukumab) and tsDMARDS achieved better ACR20 response compared with cDMARDs (**Figure 1a**). Most biologics' credible intervals show significant overlap, suggesting a similar level of efficacy in achieving ACR20. For DAS 28, a fixed effect model was used, and with a small network of available studies. The 4 biologics included in this evidence network performed better than cDMARDs. Sirukumab and abatacept appear to demonstrate improvement over the other agents in the network on this measure (**Figure 1b**).

Conclusion: The NMA suggests that sirukumab has similar ACR20 response, and similar or slightly higher DAS28-CRP improvement, compared with most bDMARDs and tsDMARDs.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Baseline differences in rheumatoid arthritis (RA) disease characteristics and molecular profile

across populations may be a reflection of genetic variations and environmental factors such as regional differences in treatment paradigm, access to biologics, diet and lifestyle. These differences may influence response to treatment. The objective of this study was to compare baseline and post treatment molecular profiles of RA patients across geographic regions that were inadequate responders (IR) to conventional DMARDs and anti-TNFs and were treated with sirukumab, a monoclonal antibody that binds IL6.

Methods: Serum samples were taken at baseline, Week 4, and Week 24 in two phase 3 studies of sirukumab in RA: SIRROUND-D (DMARD-IR), and SIRROUND -T (anti-TNF-IR).

Results are reported (from SIRROUND -D|-T) for patients from Asia-Pacific (AP), Europe (EU), and North America(NA), respectively, in the following dose groups: sirukumab 100mg q2w (n=49|33, 98|36, 24|67) and sirukumab 50mg q4w (n=40|21, 103|40, 25|67). Serum was analyzed using the SomaLogic SOMAscan^{TM} platform (376 analytes). Analytes significantly and differentially expressed in baseline RA samples versus independently collected demographically-matched healthy control serum samples were used to derive a serum composite score for each sample set via a log2-transformation of the median of normalized values for the analytes. mRNA from whole blood samples was isolated and profiled using the Affymetrix HT HG-U133+ PM Array. Gene set variation analysis was used to evaluate enrichment of an in vitro derived IL-6 gene signature in each sample and compared across geographic regions. Results: The following analytes, elevated in baseline serum samples from RA patients versus healthy controls, formed the basis of the serum composite score: annexin I, BLC/CXCL13, BPI, CRP, IL6, IP-10/CXCL10, LEAP1/hepcidin, MMP1, MMP3, PBEF, PHI, SAA, SP-D, TIMP-3. At baseline, the serum composite score, as well as individual RA-associated analytes, such as CXCL13, MMP3, and SP-D, were significantly elevated in patients from AP compared with EU or NA. Patients from AP also showed higher enrichment for the in vitro-derived IL-6 gene expression signature at baseline. After 4 and 24 weeks of treatment, the serum composite score and IL-6 gene signature was significantly decreased in all patients from both sirukumab treatment arms compared with placebo. However, stronger pharmacodynamic effects and significantly greater down regulation of both the serum composite score and IL-6 gene signature were observed in AP patients at both 4 and 24 weeks post treatment. These molecular changes were associated with higher baseline RA disease severity and CRP levels observed in patients from the AP region.

Conclusion: RA-related inflammatory proteins and the IL-6 gene signature are significantly elevated at baseline and more extensively down-regulated post sirukumab treatment in both DMARD-IR and TNFi-IR patients from the AP region compared with the rest of world. These differences and their implications with respect to RA disease activity and clinical treatment options will be explored in subsequent analyses.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: ABT-494 is a selective Janus Kinase 1 inhibitor. In two Phase 2b studies in subjects with rheumatoid arthritis, 6 mg and 12 mg twice-daily (BID) doses of ABT-494 immediate-release formulation achieved optimal benefit-risk profiles. To enhance patients' compliance, an extended-release formulation was developed targeting to achieve comparable exposures with the 6 mg and 12 mg BID of the immediate-release formulation with once-daily (QD) administration. This work characterized the pharmacokinetics of ABT-494 with the extended-release formulation that is currently being utilized in Phase 3.

Methods:

Comparison of ABT-494 pharmacokinetics from the immediate-release and extended-release formulations was conducted following multiple-dose administration in healthy subjects. Two cohorts of subjects were evaluated. In the first cohort, healthy subjects (N = 12) received multiple 15 mg QD doses of the extended-release tablet formulation and multiple 6 mg BID doses of the immediate-release capsule formulation for 7 days. In the second cohort, healthy subjects (N = 12) received multiple 30 mg QD doses of the extended-release tablet formulation and multiple 12 mg BID doses of the immediate-release capsule formulation for 7 days. Both evaluations were conducted following an open-label, randomized, 2-period, 2-sequence, crossover design under fasting conditions. ABT-494 plasma concentrations were measured and pharmacokinetic parameters were calculated using non-compartmental analyses.

Results: At steady-state, ABT-494 AUC_{0-24} ratio [and 90% confidence interval] was 0.94 [0.84 – 1.05], C_{max} ratio was 0.91 [0.74 – 1.12] and C_{min} ratio was 1.09 [0.85 – 1.40] for the 15 mg QD regimen of the extended-release formulation relative to the 6 mg BID regimen of the immediate-release formulation. Similarly, ABT-494 mean AUC_{0-24} ratio was 0.97 [0.87 – 1.09], C_{max} ratio was 0.90 [0.73 – 1.11] and C_{min} ratio was 0.87 [0.75 – 1.02] for the 30 mg QD regimen of the extended-release formulation relative to the 12 mg BID regimen. All evaluated regimens were well-tolerated by healthy subjects.

Conclusion: ABT-494 regimens of 15 mg QD and 30 mg QD of the extended-release formulation, currently being utilized in Phase 3 RA studies, provide similar exposures to 6 mg BID and 12 mg BID, respectively of the immediate-release capsule formulation previously shown to provide optimal benefit-risk profiles in RA Phase 2 trials.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The efficacy of sirukumab, an anti-IL-6 cytokine antibody, was evaluated in multiple phase 3 studies in patients with rheumatoid arthritis (RA) (SIRROUND -M, -D, -T, and -H) including the following populations: methotrexate (MTX) inadequate responders (IR), conventional DMARD-IR, and TNF inhibitor (TNFi)-IR. Treatment with sirukumab was hypothesized to normalize expression levels of serum analytes dysregulated at baseline in RA, with a dose response association.

Methods: Serum samples from the 4 studies were analyzed at baseline and Week 4 post-treatment using SomaLogic SOMAscan^{TM} (376 analytes) and validated antibody-based (Meso Scale Discovery, Luminex, and ELISA; 33 analytes) platforms. For the SIRROUND -M, -D, -T, and -H studies, respectively, results are reported for patients given sirukumab 100mg q2w (n=61, 205, 136, 106), sirukumab 50mg q4w (n=61, 203, 128, 115), or placebo (n=0, 122, 56, 0) and demographically-matched healthy controls samples (0, 50, 35, 145). Differences between groups were evaluated by comparing within-subject $\log_2$ ratio of Week 4 over baseline values between treatment groups (adjusted for MTX dose; SIRROUND -D, -T) or versus 0-change (SIRROUND -M, -H), with FDR <0.05 and |fold/reference geometric means|>1.5 considered significant.

Results: At baseline, 24 analytes were significantly elevated and 6 were suppressed in RA patients compared to healthy controls (**Table 1**). Among the elevated analytes, 8 were suppressed by treatment with sirukumab 50mg q4w and 100 mg q2w across all 4 studies, consisting of acute phase proteins, S100A12, MMP-1, and surfactant protein D. Sixteen of the analytes elevated at baseline were not decreased by sirukumab, notably MMP-3 and lymphocyte chemoattractants CXCL10 and CXCL13, the latter 3 known to be decreased by TNF inhibitors. Among analytes suppressed at baseline, none were increased by sirukumab. Among analytes not significantly dysregulated in RA at baseline, 14 were significantly decreased by sirukumab, including complement components, acute phase proteins and neutrophil-associated proteins. Changes in analyte levels were not significantly different between 100mg q2w and 50mg q4w sirukumab dose groups, with the exception of CRP, where decreases were significantly greater with the higher dose only in TNFi-IR patients .

Conclusion: Sirukumab consistently decreased 8 inflammatory proteins which were elevated at baseline across multiple RA populations, with no consistent dose response observed. In addition to expected reductions in acute phase proteins with sirukumab, these included MMP-1 and SP-D. Several markers were not affected, including some lymphocyte chemoattractants that are known to be decreased by TNF inhibitors. The clinical implications of RA-associated analytes not normalized by sirukumab, as well as those decreased below normal levels, remain to be understood.

Table 1. Pharmacodynamic Effects of Sirukumab 50mg q4w on Serum Analytes*

Disease-association	Elevated at baseline			Suppressed at baseline		Not dysregulated at baseline

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarilumab is a human mAb blocking the IL-6Rα. In the phase 3 MOBILITY (NCT01061736) and TARGET (NCT01709578) studies, sarilumab (150 or 200 mg subcutaneously every 2 weeks [q2w]) demonstrated efficacy in adults with active, moderate-to-severe RA.[1,2] In both studies, infections, neutropenia, injection site reactions, and increased transaminases were among the most common treatment-emergent adverse events. Laboratory changes were consistent with IL-6 signaling blockade. This analysis examined laboratory changes and treatment continuation after sarilumab dose reduction observed through January 2016 in EXTEND (NCT01146652), an open-label, follow-up study evaluating long-term safety and efficacy of sarilumab with or without concomitant conventional synthetic DMARDs.

Methods: Adults with RA who previously participated in sarilumab studies were eligible. Patients who entered into EXTEND initially received sarilumab 150 mg weekly. After dose selection for phase 3 studies, patients were switched to or initiated on sarilumab 200 mg q2w. Per protocol, investigators could reduce the sarilumab dose from 200 mg q2w to 150 mg q2w for absolute neutrophil count (ANC) ≥0.5 to 1.0 Giga/L, platelet count ≥50 to 100 Giga/L, or alanine aminotransferase (ALT) ≥3 to 5 × upper limit of normal. Dose reductions were also performed at the investigator's discretion. Efficacy data from EXTEND were analyzed before and 24 weeks after dose reduction for MOBILITY (n=148) and TARGET (n=47) patients.

Results: As of the January 2016 interim analysis (N=1652), dose reduction from sarilumab 200 mg q2w to 150 mg q2w had occurred in 17.7% of patients (n=292). The most common reasons for dose reduction were decreased ANC (11.3%; n=187) and increased ALT (3.9%; n=65) levels. The most common non-laboratory reason for dose reduction was infection (0.4%; n=7). At the time of analysis, 76.9% of patients (n=247) whose dose was reduced were continuing treatment, with a median treatment duration of 2.3 years after dose reduction. Improvements in ANC and ALT levels were observed over the 6 months after dose reduction (Table). Sarilumab efficacy was maintained in MOBILITY and TARGET patients 24 weeks after dose reduction as assessed by ACR20 response rates (83.1% and 85.1%, respectively) and improvements in HAQ–Disability Index scores (-0.68 and -0.82, respectively).

Conclusion: In patients whose sarilumab dose was reduced from 200 mg q2w to 150 mg q2w, there was an improvement in laboratory abnormalities and continuation of treatment for the majority of patients. Improvements in signs and symptoms of RA and physical function were maintained after dose reduction. **References: 1.** Genovese et al. *Arthritis Rheumatol*. 2015;67:1424-1437. **2.** Fleischmann et al. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarilumab is a human mAb blocking the IL-6Rα. Efficacy of sarilumab + MTX was demonstrated in patients with RA and inadequate response to MTX (MOBILITY; NCT01061736).[1] Sarilumab + conventional synthetic DMARDs demonstrated efficacy in patients with RA and inadequate response or intolerance to TNF inhibitors (TARGET; NCT01709578).[2] Efficacy and safety of sarilumab across prespecified subpopulations were assessed in a pooled analysis of patients from MOBILITY and TARGET.

Methods: Adult patients from MOBILITY and TARGET were included in this analysis (N=1743). Incidence of ACR20 response at week 24, change from baseline in HAQ–Disability Index (HAQ-DI) at week 12, and change from baseline in DAS28-CRP at week 24 were evaluated for placebo (n=579), sarilumab 150 mg every 2 weeks (q2w) (n=581), and sarilumab 200 mg q2w (n=583) in prespecified subpopulations. Post hoc analysis of clinical disease activity index (CDAI) at week 24 was performed. Treatment-by-subgroup interactions were assessed by a logistic regression model (ACR20: week 24) or mixed-effect model for repeated measures (HAQ-DI: week 12; DAS28-CRP, CDAI: week 24).

Results: Superiority of both sarilumab doses vs placebo was observed across all subgroups except baseline RF status, anti-CCP autoantibody status, and weight (Table; Figure). A smaller treatment effect for sarilumab 150 mg q2w was observed in RF and anti-CCP seronegative patients and those weighing ≥100 kg for ACR20 and DAS28-CRP (Table). Treatment-emergent AEs and serious AEs were more frequent with sarilumab vs placebo. Infections, neutropenia, injection site reactions, and increased transaminases were among the most common TEAEs and occurred more frequently with sarilumab. As previously reported in the individual trials, no serious infections were associated with neutrophil reductions.

Conclusion: Superiority of sarilumab vs placebo, measured by ACR20 response and changes in HAQ-DI, DAS28-CRP, and CDAI, was generally consistent across patient subgroups. The magnitude of the treatment effect was smaller, particularly for sarilumab 150 mg q2w, in patients with baseline seronegativity for RF or anti-CCP autoantibody or with baseline weight ≥100 kg, although there were few patients in these subgroups.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarilumab is a human mAb blocking the IL-6Rα. Sarilumab + MTX demonstrated significant improvements in RA signs and symptoms, physical function, and inhibition of radiographic progression in the 1-year phase 3 MOBILITY study (NCT01061736). This analysis examined 3-year clinical and radiographic outcomes and safety in patients who completed MOBILITY and entered the open-label extension (OLE) study EXTEND (NCT01146652).

Methods: Patients in MOBILITY were initially randomized to placebo or sarilumab 150 or 200 mg every 2 weeks (q2w) subcutaneously for up to 1 year. Early rescue with open-label sarilumab 200 mg q2w was allowed for insufficient response after week 16. After completion of MOBILITY, patients were eligible for enrollment in EXTEND, in which all patients received active treatment (sarilumab 200 mg q2w after final dose selection) + MTX. DAS28-CRP and clinical disease activity index (CDAI) assessed clinical efficacy. Radiographs from patients at baseline and subsequent second and third years were centrally read by 2 readers independently. Linear extrapolation was applied at year 3 for patients who had data at year 2 and from an unscheduled visit between years 2 and 3 but not at year 3. Statistical analysis at year 3 was performed on the basis of patients' original randomized treatment assignment, regardless of whether they were rescued during the double-blind period (MOBILITY).

Results: Of the 1197 randomized patients in MOBILITY, 901 participated in EXTEND (Table). At year 3, after all patients had received open-label sarilumab for 2 years, percentages of patients achieving DAS28-CRP <2.6 or CDAI ≤2.8 were similar in patients originally treated with either dose of sarilumab or placebo, though the initial sarilumab 200 mg group exhibited the most favorable outcomes (Table). Improvements were maintained within each group from year 2 to year 3. Three-year radiographic data were available for 755 patients; linear extrapolation was used in 29. Modified total Sharp scores at year 3 in the initial placebo and sarilumab 150 and 200 mg groups were only slightly increased since year 2 (Table). Treatment-emergent adverse events (TEAEs) occurred in 89.7% of patients over 3 years. The most common TEAEs (≥10%) were neutropenia (19.4%), increased alanine aminotransferase (13.0%), and upper respiratory tract infections (12.7%). Infections were the most frequently reported serious AE (4.2/100 patient-years).

Conclusion: Active treatment with sarilumab 200 mg q2w resulted in durable clinical response and stabilization of radiographic progression at 3 years irrespective of prior treatment, though the initial sarilumab 200 mg group showed the most favorable outcomes. Adverse events were consistent with the anticipated effects of IL-6 inhibition and the known safety profile of sarilumab.

Table. Clinical and Radiographic Data at Baseline, Year 1, Year 2, and Year 3 for Patients With RA Enrolled in the EXTEND Study, in Which All Patients Received Active Treatment (Sarilumab 200 mg q2w After Final Dose Selection) + MTX

Population[a]		**Placebo + MTX -> sarilumab 200 mg q2w + MTX**	**Sarilumab 150 mg q2w + MTX-> sarilumab 200 mg q2w + MTX**	**Sarilumab 200 mg q2w + MTX**

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Pharmacokinetics and Safety of Three Formulations of Rituximab (CT-P10, US-sourced Innovator Rituximab and EU-sourced Innovator Rituximab) in Patients with Rheumatoid Arthritis: Result from Phase 3 Randomized Controlled Trial over 24 Weeks

Background/Purpose : CT-P10 is a proposed biosimilar candidate of rituximab, and it has been concluded to be highly similar to the reference product in terms of analytical and functional characteristics and equivalent to EU-sourced innovator rituximab (EU-RTX) in pharmacokinetics (PK) in the patients with RA through phase 1 study.[1] The similarity in terms of PK was tested among CT-P10 and two innovator rituximabs from the different manufacturing sources in RA patients.

Methods : A total of 189 RA patients in PK analysis part from a randomized controlled phase 3 study (NCT02149121) was randomly assigned in 1:1:1 ratio to receive 2 infusions of 1,000 mg CT-P10, US-sourced innovator rituximab (US-RTX) or EU-RTX with a 2-week interval. The following PK parameters were coprimary endpoints: area under the serum concentration-time curve from time zero to the last measurable concentration ($AUC_{0\text{-last}}$), AUC from time zero extrapolated to infinity ($AUC_{0\text{-inf}}$) and maximum concentration after the second infusion (C_{max}) of CT-P10, US-RTX or EU-RTX. Pharmacokinetic similarity is concluded if the 90% confidence interval (CI) for the ratio of geometric means in $AUC_{0\text{-last}}$, $AUC_{0\text{-inf}}$, and C_{max} are entirely contained within the bounds of 80% and 125% for the following comparisons: CT-P10 vs US-RTX, CT-P10 vs EU-RTX, and US RTX vs EU-RTX.

Results : The PK parameters among 3 treatment groups were highly similar (Table 1). The 90% CIs for the ratio of geometric means for coprimary endpoints fell within the PK equivalence margin of 80-125% indicating that drug exposures from CT-P10 are similar to those from both US-RTX and EU-RTX and also from US-RTX to those of EU-RTX (Table 2). The safety profiles among 3 treatment groups were generally similar. Adverse events (AEs) due to infusion related reaction were reported for 6 (9.4%), 4 (6.2%) and 12 (20.0%) patients in CT P10, US-RTX and EU-RTX, respectively. All these events were mild to moderate (grade 1 or 2) in intensity. Six patients were discontinued due to an AE (2 [3.1%], 3 [4.6%] and 1 [1.7%] patients in CT-P10, US-RTX and EU-RTX, respectively). No malignancy, progressive multifocal leukoencephalopathy, serious infection or death occurred in any of the treatment groups.

Table 1. Pharmacokinetic Secondary Endpoints (Mean ± SD)

Parameter	CT-P10 N=62	US-RTX N=63	EU-RTX N=59
$AUC_{0\text{-last}}$ (h•μg/mL)	188400.03 ± 65341.092	184121.66 ± 65532.728	199754.50 ± 68057.989
$AUC_{0\text{-}\infty}$ (h•μg/mL)	184478.20 ± 56373.724	187138.88 ± 63794.582	206484.59 ± 64727.223
C_{max} (μg/mL)	425.05 ± 95.491	423.07 ± 124.053	474.19 ± 100.494
C_{min} (μg/mL)	0.36 ± 0.583	0.45 ± 0.708	0.47 ± 0.756
$T_{1/2}$ (day)	15.04 ± 3.006	15.19 ± 3.591	15.65 ± 3.198

EU-RTX (T) vs US-RTX (R)	$AUC_{0\text{-last}}$ (h*µg/mL)	T	59	172450.97	103.07	(93.32, 113.85)
		R	60	167309.07		
	$AUC_{0\text{-}\infty}$ (h*µg/mL)	T	56	180637.81	106.58	(97.03, 117.08)
		R	60	169480.80		
	C_{max} (µg/mL)	T	59	412.40	106.66	(100.56, 113.13)
		R	59	386.65		

T, test; R, reference

Conclusion : Pharmacokinetic equivalence was demonstrated in terms of $AUC_{0\text{-last}}$, $AUC_{0\text{-inf}}$ and C_{max} in the comparisons of CT-P10 to US-RTX, CT-P10 to EU-RTX, and US-RTX to EU-RTX in RA patients. In addition, comparable safety profiles were observed among the 3 treatment groups. Reference 1. Yoo DH, et al. Arthritis Rheum 2013;65(Suppl 10): S736

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Efficacy and Safety of CT-P10, Rituximab Biosimilar Candidate, and Innovator Rituximab in Patients with Rheumatoid Arthritis: Result from Phase 3 Randomized Controlled Trial over 24 Weeks

Background/Purpose: Pharmacokinetic (PK) equivalence was demonstrated, and similar safety profiles of CT-P10 to EU-sourced innovator rituximab (EU-RTX) were shown in the phase 1 studies up to 2 years in RA patients including switching to CT-P10 from EU-RTX.[1,2] The purpose of this study was to demonstrate efficacy equivalence and compare safety profiles of CT-P10 to reference products (combined EU and US-sourced RTX) in RA patients up to 24 weeks.

Methods: In this randomized, controlled phase 3 study, RA patients were randomized to receive CT-P10 or reference products (NCT02149121). The primary efficacy endpoint, change of DAS28-CRP from baseline to week 24, was evaluated and analyzed by using an analysis of covariance (ANCOVA). Therapeutic equivalence is to be concluded if the 95% confidence interval (CI) for the treatment difference in the change of DAS28-CRP from baseline to Week 24 is entirely within the pre-specified equivalence margin of +/-0.60. Additional efficacy, pharmacodynamics (PD) and safety were also evaluated.

Results: A total of 372 RA patients (161 patients and 211 patients in CT-P10 and reference products groups, respectively) were enrolled. Overall efficacy, PD and safety profiles were similar between CT-P10 and reference products groups. The adjusted mean change of DAS28-CRP/ESR from baseline to week 24 was similar between the groups. The 95% CI for the estimate of treatment difference in DAS28-CRP/ESR was entirely within the equivalence margin which indicated therapeutic equivalence between the treatment groups (Table 1). Additional efficacy including ACR and EULAR responses was also shown to be comparable between 2 groups (Table 2). Rapid and complete depletion of B-cell counts were observed immediately after the first infusion, and B-cell kinetics over 24 weeks were similar between the groups. Adverse events (AEs) related to study drug were reported with a similar proportion in each treatment group; 49 (30.4%) and 59 (28.0%) patients in CT-P10 and reference products groups, respectively. Infection related to study drug was reported in 13 (8.1%) and 22 (10.4%) patients in CT-P10 and reference products groups, respectively. No malignancy, progressive multifocal leukoencephalopathy, and serious infusion-related reaction were reported.

Table 1 Improvement of DAS28-CRP and DAS28-ESR

Parameter Treatment	n	Adjusted Mean Change (SE)	Estimate of Treatment Difference	95% CI of Treatment Difference
DAS28-CRP				
CT-P10	139	-2.14 (0.177)	-0.05	(-0.29, 0.20)
Reference products	196	-2.09 (0.176)		
DAS28-ESR				
CT-P10	140	-2.41 (0.182)	-0.06	(-0.31, 0.19)
Reference products	196	-2.35 (0.182)		

Note: Adjusted least squares means and standard error, estimate of treatment difference [CT-P10 – reference products] and 2-sided 95% confidence interval calculated from the ANCOVA model.

Table 2 Proportions of Patients Achieving ACR and EULAR Responses at Week 24

	CT-P10 (N=155)	Reference products (N=203)
Parameter*	**Number (%) of patients**	
ACR20	114 (73.5)	154 (75.9)
ACR50	74 (47.7)	102 (50.2)
ACR70	43 (27.7)	62 (30.5)
EULAR-CRP	129 (83.2)	170 (83.7)
EULAR-ESR	127 (81.9)	170 (83.7)

* For EULAR-CRP/ESR, patients with moderate or good responder were included.

Conclusion: CT-P10 showed highly similar efficacy, PD and safety profiles to reference products up to 24 weeks.

Decrease of Tocilizumab in Rheumatoid Arthritis in Remission : A Multicenter Study

Renaud DESBARBIEUX, 59037, CHRU de Lille, Lille, France

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The advent of biological therapies in rheumatoid arthritis has significantly reduced the activity of rheumatoid arthritis, leading to obtaining a remission in a significant proportion of patients. However, few data are available to determine the feasibility of decrease of a biological DMARD and define the strategy once remission is achieved.

Methods: This retrospective multicenter study have included patients with rheumatoid arthritis treated with tocilizumab (8mg/kg every 4 weeks) for at least 6 months and who have been a decrease dose for reasons of efficacity. Data were collected in major hospitals in the region Hauts-de-France, 3 months, 6 months and 12 months after reducing tocilizumab (study conducted between 1 January 2010 and 31 December 2015).

Results: 337 patients were included in the analysis. 48 patients had a decrease because of efficacity. All of them were in DAS remission (DAS28 < 2.6) with a mean DAS28 CRP 1.55. 42 patients had a dose reduction to 4mg/kg, when 6 patients had a spacing of the infusions every 6 weeks. At 12 months, the median ΔDAS was 0.49 (p = 0.0002). DAS28 CRP usual dose group was higher than in the Efficacy group (2.99 vs 2.12, p <0.0001). 30 patients (70%) were able to maintain remission (61%) or low dose activity (9%). 4 patients have a DAS28 CRP higher than 3.2 at 12 months. 7 patients (16%) resumed tocilizumab 8mg/kg every 4 weeks before the end of the follow. In case of resumption of tocilizumab in usual dose, there was no significant difference between the initial DAS28 and DAS28 at 3 months (p = 0.1563 and 0.2197) and 6 months of recovery (p = 0.8125 and 0.8984). There was no significant increase of methotrexate or corticosteroids (p <0.0001). The initial weight, a long period of remission before decrease, a low DAS28 CRP appeared predictive of favorable response at 12 months (p = 0.016, 0.012 and 0.0032).

Conclusion: Our study demonstrates the feasibility, safety and efficacy of tocilizumab decrease dose (from 8 to 4mg/kg), to maintain remission or low activity in a majority of patients without concomitant increase in corticosteroids or conventional DMARD.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The oral Janus kinase inhibitor Tofacitinib (Tofa) has been licensed in Switzerland 2013 for the treatment of patients with moderate to severe rheumatoid arthritis (RA), who have failed methotrexate. Besides Tofa, rheumatologists in Switzerland can choose from 5 TNF inhibitors (TNF) and 3 non-TNF-bDMARD (nonTNF) licensed in

the same indication. We aimed at characterizing the patient population starting treatment with Tofa for the first time and at gaining insight into the factors determining the prescription of Tofa vs bMARDs in routine care.

Methods: This is an observational cohort study within the Swiss Clinical Quality Management (SCQM) registry. All therapies with Tofa, TNF, and non-TNF initiated in adult RA patients naïve to Tofa between August 1, 2013 and May 1, 2016 were considered. Exposure of interest was the initiated treatment (Tofa, TNF, non-TNF). Baseline characteristics were described and compared between treatments. Odds for the prescription of Tofa vs TNF and vs non-TNF were assessed with logistic regression after multiple imputation (MI) of missing covariate data assuming a missing at random mechanism. The following covariates at baseline of treatment were included in the model: sex, age, smoking status, seropositivity (rheumatoid factor or ACPA), disease duration, number of previous bDMARDs, BMI, HAQ, and DAS28. A sensitivity analysis with a complete case analysis revealed no concerns with respect to the chosen MI approach.

Results: A total of 1805 therapies were initiated during the study period (328 Tofa, 772 TNF, 705 non-TNF). Tofa therapy was initiated in 25% as second line therapy after conventional DMARDs, in 20% after one bDMARD and in 55% after two or more bDMARDs. Significant differences between Tofa, TNF, and non-TNF were observed for some patient, disease, and treatment characteristics, as well as comorbidities and quality of life measures (Table 1). Tofa as well as non-TNF were used more often as monotherapy than TNF. The multiple regression analysis revealed significantly increased odds for prescribing Tofa as opposed to TNF in patients with two or more previous bDMARDs and with higher age, BMI, and HAQ. Compared to non-TNF, the odds for prescribing Tofa were also significantly higher for patients who had two or more previous bDMARDs and who were seronegative. Of the observed associations, the most relevant was with number of previous bDMARDs.

Conclusion: Taken together our data suggest that in real-life, since being licensed 2013, Tofa was used predominantly as a third+ line therapy.

Table 1 : Baseline characteristics for which significant differences (α = 0.05) between Tofa, TNF, and non-TNF were observed based on univariate tests of available cases (*) using chi-square tests for categorical and Kruskal-Wallis tests for continuous variables or on one of the multiple logistic regression analyses of imputed data (last two columns). Where not indicated otherwise, the sample sizes correspond to the n provided in the first three column headers.

Antibody Mediated Immunity Drives Response to Methotrexate Treatment in Rheumatoid Arthritis Patients

Boel Brynedal[1], Helga Westerlind[2], Lasse Folkersen[3,4], Leonid Padyukov[5], Nancy Vivar[5], Anca I Catrina[6], Lars Klareskog[5] and Louise Berg[5], [1]Section of Epidemiology, Institute of Environmental Medicine, Karolinska Institutet, Karolinska, Sweden, [2]Section of Epidemiology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Department of Systems Biology, Technical

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is the first line treatment for Rheumatoid Arthritis (RA) in Sweden, but one third of patients do not experience satisfying treatment response. Delay in effective treatment cause increased inflammation, handicap and decreased quality of life. The prescription of the most appropriate treatment, in a stratified manner, is thus crucial to provide better and more cost effective health care. MTX is an inhibitor of protein and nucleic acid synthesis that is known to inhibit immune cells. The exact mechanism of MTX is unknown. Here we aimed to:

- Detect the cellular processes elicited by MTX treatment and/or connected to treatment response.
- Predict MTX treatment response using data collected prior to treatment initiation.

Methods: We modeled treatment response based on gene expression and flow cytometry data in a well-characterized routine clinical care cohort. The 57 RA patients underwent clinical evaluation by rheumatologist at the Karolinska Hospital at baseline as well as three months into their treatment. Both times patients contributed blood samples in which broad panels of cell type and activation markers were assayed using flow cytometry and RNA was extracted and sequenced.

Results: We first detected genes whose expression changed upon treatment and/or in connection with a better EULAR treatment response. Treatment had a large effect on gene expression where 132 genes were regulated with a false discovery rate (FDR) < 5%. The gene expression changes that were associated to treatment response (25 genes with FDR < 5%) overlap with the genes regulated by treatment, but in patients that respond well the induced changes were larger. Thus, if MTX is able to elicit stronger effects the patient is more likely to respond well to treatment. Pathway analysis revealed that MTX treatment down-regulated the antibody-driven immune response ($p:1x10^{-26}$). The proportion of plasma cells in peripheral blood was indeed decreased by MTX treatment (p: 0.008). Next we detected genes whose expression in treatment-naïve patients is associated to a later good or moderate EULAR response. We adjusted our analysis for potential confounding factors: percentage of B-cells, ancestry, age, sex and anti-CCP. Our analysis was restricted to genes that we detected as modulated by treatment (50% FDR, 1.3k genes). We observe an enrichment of small p-values, indicating the presence of true associations. Two immunoglobulin genes had a higher expression in those who later respond to treatment (IGLV8-61, IGLV7-46, FDR: 5.4%). Patients who later respond well to treatment indeed had a larger proportion of plasma cells in their peripheral blood (p:0.007). CXCL9 had a lower expression among patients that later respond to treatment ($p: 2x10^{-5}$, FDR: 2.1%). CXCL9 was in fact up-regulated by treatment (p: 0.007), and this up-regulation was stronger in patients who respond well (p: 0.001).

Conclusion: We have detected that MTX treatment is effective in patients with a larger proportion of plasma cells, and that the presence of these cells is significantly diminished by MTX treatment. Patients who respond well express less CXCL9 at baseline, but up-regulates this gene strongly during treatment.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Development of biosimilar monoclonal antibodies should not be limited by evaluation of quality, efficacy and safety in comparison with innovator biological product. Interchangeability assessment may have a major impact on biosimilar use in routine practice.

Methods: 160 adults (18-80 y. o.) with active seropositive rheumatoid arthritis (RA) diagnosed by ACR 1987 criteria who did not respond to 1 or more TNF-inhibitors were included in Russia, Ukraine, Belarus and India. After the screening, patients were randomized (1:1) into 2 arms: in the main arm BCD-020 (rituximab biosimilar, JSC BIOCAD, Russia) was dosed at 1000 mg IV on day 1 and 15; in the reference arm innovator rituximab (F.Hoffmann-La Roche, Ltd., Switzerland) was administered using the same regimen. After 6 months patients with active RA were treated repeatedly with partial crossover: half of patients from the main arm received BCD-020, whereas the second half was treated with innovator rituximab (arms BB and BR, respectively). The same was done in patients with active RA from the reference arm (arms RR and RB, respectively). Both periods of treatment (0-24 weeks, 24-48 weeks) were conducted in double-blind manner.

Results: efficacy after the first course of treatment in both arms was equal: at 24 weeks of the treatment ACR20 was reached in 84.14% of patients from the main arm and in 87.01% of patients in the reference arm (95% CI [-13.95%; 8.74%], p=0.773). There were no significant differences after partial crossover at 48 weeks: ACR20 was obtained in 77.78% and 92.31% of patients in RB and RR arms (p=0.250), and in 96.00% and 89.29% in BB and BR arms (p=0.613). Similar data were observed when other efficacy endpoints were compared (remission by DAS28, low activity by DAS28, ACR/EULAR2011 remission etc.). In all arms high rate of ACR70 at week 48 was reached: 40.0% of patients in BB arm, 34,62% in RR arm, 40.74% in RB arm and 39.29% in BR arm. In total, during the first 6 months of treatment AEs were registered in 59.34% and 54.12% of patients in the main and reference arms, respectively, with 2 SAEs in reference arm (myocardial infarction and lung thromboembolism, possibly related). There were no differences in rates of AEs in the switched arms: 44.44% in BB arm, 38.46% in RR arm, 57,14% in RB arm and 62.50% in BR arm, with 1 SAE in BB arm (death due to car accident, unrelated). Incidence of binding antibodies to rituximab was 3.57% and 8.75% in the main and reference arms, respectively (0-24 weeks), and 3.85% in BB arm (24-48 weeks; no binding antibodies in other groups).

Conclusion: BCD-020 is highly similar to innovator rituximab in terms of efficacy, safety and immunogenicity. 1-year data show that switching between products does not affect treatment outcomes.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : The efficacy of some rheumatoid arthritis (RA) therapies is reduced among patients with high BMI. This analysis assessed the effects of baseline BMI on the response to baricitinib treatment in patients with RA and incomplete responses to conventional disease-modifying antirheumatic drugs (cDMARDs).

Methods: This post hoc analysis used pooled data from two phase 3, double-blind, randomized, controlled trials of 6-12 months' duration in patients with RA and an incomplete response to cDMARDs. Efficacy outcomes (e.g., ACR responses, and changes in DAS28-hsCRP, HAQ-DI, SDAI, and CDAI scores) were analyzed by baseline patient BMI tertile (calculated from height and weight measurements at screening).

Results: In all BMI tertiles, patients who received baricitinib 4-mg (n=714) achieved improved clinical outcomes compared to those who received placebo (n=716) in efficacy measures including ACR20, ACR50 and ACR70, mean change in DAS28, SDAI, and CDAI, as well as the proportions of patients who reached low disease activity or remission (Table). No clear pattern emerged to suggest that baseline BMI tertile had a consistent effect on baricitinib efficacy. For some outcomes (e.g., ACR responses), a numeric trend toward reduced efficacy was observed among patients with greater BMI who received baricitinib 4-mg (Table).

Conclusion: Post hoc analysis of these pooled RA trial data suggests that baricitinib therapy is associated with improved clinical outcomes compared to placebo, regardless of baseline patient BMI tertile. As has been shown for other DMARDs, baricitinib treatment effect for patients with higher BMI was numerically smaller than for patients with lower BMI.

Outcome	Lowest BMI Tertile (<22.9)	Middle BMI Tertile (22.9-30.7)	Highest BMI Tertile (>30.7)
ACR20 NRI response, n (%)			
Placebo (N=716)	90 (36.1%)	92 (40.4%)	104 (43.5%)
Baricitinib 4 mg (N=714)	160 (68.4%)	166 (68.0%)	152 (64.7%)
ACR50 NRI response, n (%)			
Placebo (N=716)	36 (14.5%)	38 (16.7%)	37 (15.5%)
Baricitinib 4 mg (N=714)	103 (44.0%)	110 (45.1%)	81 (34.5%)
ACR70 NRI response, n (%)			
Placebo (N=716)	7 (2.8%)	10 (4.4%)	13 (5.4%)
Baricitinib 4 mg (N=714)	44 (18.8%)	51 (20.9%)	37 (15.7%)
DAS28-hsCRP, mLOCF LSM change from baseline (SE)			
Placebo (N=716)	-1.2 (0.12)	-0.9 (0.11)	-1.2 (0.10)
Baricitinib 4 mg (N=714)	-2.5 (0.13)	-2.2 (0.11)	-2.0 (0.10)
HAQ-DI, mLOCF LSM change from baseline (SE)			
Placebo (N=716)	-0.4 (0.06)	-0.3 (0.05)	-0.4 (0.04)
Baricitinib 4 mg (N=714)	-0.7 (0.06)	-0.6 (0.05)	-0.6 (0.04)
CDAI, mLOCF LSM change from baseline (SE)			
Placebo (N=716)	-14.4 (1.25)	-12.2 (1.12)	-15.0 (1.00)
Baricitinib 4 mg (N=714)	-24.0 (1.27)	-21.6 (1.13)	-21.1 (0.99)
SDAI, mLOCF LSM change from baseline (SE)			
Placebo (N=716)	-14.6 (1.29)	-12.2 (1.16)	-14.9 (1.03)
Baricitinib 4 mg (N=714)	-25.6 (1.32)	-22.7 (1.17)	-22.2 (1.02)
mTSS change ≤0 LE (no progression of structural damage), n (%)			
Placebo (N=716)	137 (60.4%)	155 (74.9%)	176 (83.8%)
Baricitinib 4 mg (N=714)	180 (81.1%)	180 (80.0%)	188 (85.5%)

All outcomes are at week 12 except mTSS is at week 24 with data up to rescue.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: After more than twenty years using Disease Modifying Drugs (DMARDs) is widely known their efficacy in the treatment of Rheumatoid Arthritis (RA) but it is necessary to increase our knowledge on how they work in the long-term in clinical practice. The purpose of this study is to assess the long-term survival of DMARDs (synthetic and biological) and the causes of discontinuation in patients with recent onset of Rheumatoid Arthritis (RA).

Methods: Observational longitudinal study was conducted. Recent onset RA patients diagnosed between April 15th 2007 and 31st December 2010 followed in out-patient clinic at Hospital Clinico San Carlos until December 31st 2015, which used any DMARD treatment were included. Primary outcome: DMARDs discontinuation due to: adverse drug reaction (ADR: moderate or severe), inefficacy, patient decision, improvement, and other causes. Incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI].

Results: We included 293 courses of DMARDs treatment in 97 patients (815 patient-years). Of these, 78% were women with a mean age at diagnosis of 55.6 ± 15 years. The median time to the start of the first DMARD was 0[0-41] days. 11.5% were taking biological DMARDs, 60.75% were using combined therapy and 86% were taking corticoids. We found 171 discontinuations with an IR of 21 [18-24.4] mainly due to ADR (IR: 13.5[11.2-16.2]) followed by inefficacy (IR: 2.6 [1.6-3.9]). The median survival was 2.6[1.9 to 4] years. The IR of discontinuation related to synthetic and biological DMARDs was 20.4 [17.4-23.9] and 27.2 [17.2-42.3] respectively. The crude IR of discontinuation was higher for Gold (IR: 36.5[22-59]) and Leflunomide (IR: 32.0[21.2-48.1]) being 11.1 [8.2-15] for Methotrexate. Regarding types of regimens, monotherapy had an IR of 17.94[13.9-23.1] whereas combined therapy had an IR of 23.1 [19.2-27.8].

Conclusion: The discontinuation rate is estimated in 21 per 100 patients-year, being ADR the most common cause. Synthetic DMARDs seem to have more survival than biological, being Methotrexate the drug with lowest crude IR of discontinuation rate. Monotherapy seems to have more survival rate than combined therapy. This study contributes to increasing knowledge of the long-term survival of these drugs in real life.

Pharmacokinetic-Pharmacodynamic Analysis of GS-4059-Mediated Bruton's Tyrosine Kinase Inhibition

Justin D. Lutz[1], Cara Nelson[2], Helen Yu[2], Albert Liclican[2], Joy Feng[2], Andrew Billin[2], Brian E. Schultz[2], Mark Bresnik[2] and Anita Mathias[2], [1]Department of Clinical Pharmacology, Gilead Sciences, Foster City, CA, [2]Gilead Sciences, Foster City, CA

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: GS-4059 is a covalent inhibitor of Bruton's Tyrosine Kinase (BTK) under development for the treatment of rheumatoid arthritis (RA) and oncology. This work aimed at characterizing the in vitro and in vivo binding kinetics of GS-4059 and, using pharmacokinetic-pharmacodynamic modeling, to explore the relationship between dose and BTK occupancy to provide a framework for dose selection in clinical studies.

Methods: In vitro, BTK inactivation kinetics of GS-4059 and two other irreversible BTK inhibitors, CC-292 (Cellgene) and ACP-196 (Acerta), was characterized using the Omnia Kinase assay, a highly sensitive fluorescence-based assay that allows for continuous monitoring of BTK activity. Ex vivo BTK binding by GS-4059 was investigated in samples from healthy volunteers who received a single 100 mg or multiple once daily 20 mg oral doses of GS-4059. Free and total (free + drug bound) BTK in peripheral blood mononuclear cells (PBMCs) was measured. A pharmacokinetic-pharmacodynamic (PKPD) model (NONMEM v.7.3) incorporating both BTK inactivation and turnover in PBMCs was developed. BTK occupancy in both PBMCs and splenocytes after multiple ascending daily doses (1.25 - 160 mg) were simulated based on model derived BTK binding kinetics to predict the optimal dose(s) to explore in future studies.

Results: All three compounds exhibited efficient BTK inactivation in vitro with comparable time-dependent inactivation rates over affinity constant ratios (k_{inact}/K_I: 86 - 133 $\mu M^{-1}*h^{-1}$). Significant BTK occupancy was observed after single 100 mg and multiple once daily 20 mg GS-4059 dosing and this occupancy persisted following GS-4059 washout. The PKPD model estimated in vivo population k_{inact}/K_I (69 $\mu M^{-1}*h^{-1}$) was in agreement with the in vitro data. The BTK degradation half-life in PBMCs was estimated to be 64 h (k_{deg} value of 0.011 h^{-1}) providing an explanation for the significant persistence of BTK occupancy following drug washout. Simulations conducted to explore dose (range of 1.25 - 160 mg) suggested that once daily 10 mg GS-4059 provides >80% BTK occupancy in PBMCs over a 24 h period at steady-state; higher doses may be needed to obtain comparable occupancy in the splenocytes.

Conclusion: This analysis provides a mechanistic understanding of in vivo time- and concentration-dependent BTK inactivation and presents a valuable tool in guiding GS-4059 dose selection for RA and oncology patients. The results in this abstract are planned to be presented in part at the American Conference on Pharmacometrics in Bellevue, WA, October 23rd to October 26th, 2016, and published in the conference proceedings (abstract number T.B.D.)

SESSION INFORMATION
Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. This study examined response to treatment with tofacitinib 5 mg or 10 mg twice daily (BID) in seropositive (anti-cyclic citrullinated peptide [CCP]+ and/or RF+) versus seronegative (anti-CCP- and RF-) groups of patients with moderately to severely active RA and an inadequate response to disease-modifying antirheumatic drugs.

Methods: 'Serotype' subgroups were defined at baseline as: anti-CCP+/RF+ (Sero-1); anti-CCP+/RF- (Sero-2); anti-CCP-/RF+ (Sero-3); anti-CCP-/RF- (Sero-4). Subgroup data were pooled from one monotherapy (ORAL Solo) and four combination therapy (ORAL Sync, Standard, Scan, and Step) Phase 3 studies. The proportions of patients achieving ACR20/50/70, disease activity score in 28 joints (4-variable) using erythrocyte sedimentation rate (DAS28-4[ESR])-associated remission and low disease activity, change from baseline in Health Assessment Questionnaire-Disability Index (HAQ-DI), Short Form (36) (SF-36) physical functioning, and functional assessment of chronic illness therapy (FACIT) were evaluated after 12 weeks. Incidence of adverse events (AEs), discontinuation due to AEs, and serious AEs (SAEs) were compared among subgroups.

Results: In this exploratory analysis, baseline demographics and characteristics were similar between Sero-subgroups 1–4 (n=1551, n=249, n=142, n=449, respectively) for tofacitinib and placebo (PBO; n=670). After 12 weeks of treatment, all Sero-subgroups showed significantly improved ACR20/50/70 response rates with tofacitinib versus PBO (range: $p<0.0001$–$p<0.05$). The same range of significance was obtained for Sero-1 and Sero-2 versus PBO in achieving DAS28-4(ESR)<2.6; the lower treatment differences observed in Sero-3 and Sero-4 subgroups were not significant versus PBO. Tofacitinib showed significant (same range) changes in HAQ-DI and FACIT versus PBO for all Sero-subgroups, and SF-36 physical functioning with the exception of Sero-4 subgroup patients receiving tofacitinib 5 mg BID. Frequencies of AEs and SAEs were similar across all treatment groups and Sero subgroups. Tofacitinib-treated patients showed similar discontinuation incidence rates (per 100 patient-years) due to AEs in all Sero-subgroups (7.7–13.3 versus PBO: 8.6–19.7).

Conclusion: Tofacitinib treatment significantly reduced the signs and symptoms of RA, irrespective of anti-CCP or RF status. In this analysis, DAS28 remission rates and SF-36 physical functioning appeared to be lower in anti-CCP patients. Similar safety endpoints for tofacitinib treatment were observed across all Sero-subgroups.

Dose Selection of Filgotinib, a Selective JAK1 Inhibitor, for Rheumatoid Arthritis Phase 3 Studies: Exposure-DAS28 and ACR Modeling Approach

Namour Florence[1], Paul Diderichsen[2], Eugène Cox[2], Shringi Sharma[3] and Chantal Tasset[4], [1]Galapagos SASU, Romainville, France, [2]Quantitative Solutions-Certara, Breda, Netherlands, [3]Gilead Sciences, Foster City, CA, [4]Galapagos NV, Mechelen, Belgium

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Filgotinib is an oral, selective Janus kinase 1 (JAK1) inhibitor showing good efficacy and safety in Phase 2B studies in rheumatoid arthritis (RA) patients. The exposure-response modeling and simulation to support the filgotinib dose selection for Phase 3 studies in RA is presented here.

Methods: Population predicted and individual responses to treatment were investigated on the basis of simulated exposures to filgotinib and its active metabolite. Non-linear mixed-effects E-R models using either direct response regression (DAS28) or logistic regression (ACR 20/50/70) models were built to describe improvement in clinical response from baseline in RA patients treated for 24 weeks. The drug effect was modeled using linear or E_{max} model and a composite effective exposure (AUC_{Eff}) defined as sum of individual-predicted exposure for filgotinib and its metabolite taking into account an estimated 10-fold relative potency for filgotinib versus the metabolite. The observed DAS28 change from baseline and ACR responder rates were described as a sum of individual placebo and drug effects. Continuous covariates were evaluated in the models as power functions while binary covariates were tested as factors. The analysis was performed pooling all Phase 2 data available over the doses of 30 to 300 mg as twice or once daily regimen. Simulations of clinical responses (DAS28, ACR and Low Disease Activity [LDA]) were investigated over the 50 to 200 mg daily dose range.

Results: The PK of filgotinib and its metabolite were described by two independent population PK models. Renal function (CLcr) and race were included as statistically significant covariates on the metabolite clearance while no significant covariates were identified in the PK model for filgotinib. Based on the distribution of random effects, filgotinib and its metabolite follow dose-linear PK across the studied dose range. Region was identified as the only significant covariate on the placebo response; placebo effect was predicted to be higher in Western Europe, USA and South America than in the other countries, and included in the exposure-response model for both endpoints. Clinical response at week 12 and week 24 (DAS28 change from baseline and ACR responder rate) increased with dose. A rapid onset in clinical response was also observed during the first 12 weeks followed by continued increase in effect until week 24. Time to reach a given response was shorter at higher doses. Dosing frequency (once or twice daily) did not influence PK of filgotinib and its metabolite as well as clinical response. Simulated clinical response at week 24 following 50 to 200 mg daily dose is reported as mean (95%CI) in the table below:

Parameter (95%CI)	Placebo	50 mg/day	100 mg/day	200 mg/day
Mean DAS28 response	-1.32 (-1.54, -1.10)	-2.19 (-2.33, -2.06)	-2.56 (-2.66, -2.46)	-2.92 (-3.03, -2.80)
LDA (DAS28<3.2)	0.142 (0.109, 0.182)	0.320 (0.287, 0.354)	0.416 (0.387, 0.444)	0.513 (0.482, 0.548)
ACR20 responder rate	0.472 (0.394, 0.533)	0.678 (0.631, 0.720)	0.755 (0.726, 0.785)	0.819 (0.790, 0.848)
ACR50 responder rate	0.204 (0.152, 0.252)	0.385 (0.343, 0.435)	0.476 (0.439, 0.508)	0.563 (0.517, 0.606)
ACR70 responder rate	0.0854 (0.0564, 0.116)	0.201 (0.169, 0.235)	0.273 (0.240, 0.306)	0.353 (0.306, 0.397)

Conclusion: Modeling and simulation on the basis of Phase 2 clinical data show a dose-related response with a maximum efficacy achieved at a daily dose of 200 mg filgotinib, the maximum dose currently being tested in the Phase 3 program.

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: ASP5094 is a recombinant humanized anti-alpha-9 integrin IgG1 monoclonal antibody (mAb) under development for the treatment of rheumatoid arthritis. This first-in-human placebo controlled single ascending dose study was designed to evaluate the safety, tolerability, PK and PD of a single 30 minute intravenous (IV) infusion of ASP5094 at doses ranging from 0.002 to 10 mg/kg in healthy adult subjects.

Methods: 7 sequential cohorts consisting of any race (cohorts A to D) and non-Asian (cohorts E to G) received single increasing doses of IV administered ASP5094 or placebo. Serial Cohorts A and B consisted of 6 subjects each (4 active and 2 placebo) while cohorts C to G consisted of 8 subjects each (6 active and 2 placebo). Serial blood samples were collected for PK (ASP5094 and anti-ASP5094) and PD (alpha-9- integrin receptor occupancy (RO)).

Results: Following a 30-minute infusion of ASP5094 at doses <0.25 mg/kg most serum ASP5094 concentrations fell below the limit of detection (10 ng/mL). At doses that ranged from 0.25-10 mg/kg, mean maximum ASP5094 serum concentrations (C_{max}) increased nonlinearly with dose and ranged from 4742 to 277365 ng/mL. Similarly, mean ASP5094 $AUC_{0\text{-}inf}$ also increased nonlinearly from 165,455 to 77,829,650 ng*h/mL with ASP5094 doses ranging from 0.25 to 10 mg/kg. ASP5094 PK exhibited nonlinear target-mediated drug disposition. Alpha-9 receptor occupancy (RO) on neutrophils remained at 100% for periods of 1, 2, 4 and 8 weeks following a single IV administration at doses of 0.25, 1, 3 and 10 mg/kg ASP5094 respectively. A direct response relationship was observed between serum ASP5094 exposure and RO. One subject dosed at 0.25 mg/kg with ASP5094 tested positive for anti-drug antibodies (ADA) on Day 90 and remained positive throughout study. The last study visit was Day 360. Drug-related adverse events (AE) were reported in 16.7% of the 0.25 mg/kg dose cohort; 33.3% of the 1 mg/kg cohort; 50% of the 3 mg/kg cohort; and 16.7% of the 10 mg/kg cohort, with no dose-dependency. There were no clinically significant abnormal ECG findings in this study.

Conclusion: Single doses of ASP5094 (≤ 10 mg/kg IV) were safe and well tolerated in healthy subjects (any race and non-Asian). ASP5094 PK exhibited nonlinear target-mediated drug disposition. Based on these results, an additional study to explore the PK, PD and safety of multiple doses of ASP5094 in stable RA patients has been initiated.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. In a post-hoc analysis of the tofacitinib RA long-term extension (LTE) studies, we evaluated the effect of discontinuation of MTX or glucocorticoids (GC) on the maintenance of clinical efficacy of tofacitinib.

Methods: Data were analyzed from 2 open-label studies (NCT00413699 [ongoing; March 2015 data-cut] and NCT00661661) of patients (pts) with RA who completed randomized Phase 1/2/3 tofacitinib studies and 3 years of the LTE studies (LTE baseline to Year 3). Pts in this analysis received tofacitinib 5 or 10 mg twice daily (BID) and utilized MTX or GC at LTE baseline. Discontinuation of MTX or GC was defined as no MTX/GC use within the last 30 days prior to the Year 3 visit. Clinical efficacy was evaluated at Year 3 utilizing the Clinical Disease Activity Index (CDAI); further assessment stratified patients by clinical response 3 months after entrance into the LTE studies and was performed for maintenance of response out to Year 3.

Results: Overall, 186/1,608 pts that received MTX at LTE baseline (11.6%; tofacitinib 5 mg BID: n=49; tofacitinib 10 mg BID: n=137) discontinued MTX and 319/1,434 pts that received GC at LTE baseline (22.2%; tofacitinib 5 mg BID: n=114; tofacitinib 10 mg BID: n=205) discontinued GC out to Year 3. Baseline demographics and disease characteristics for pts receiving tofacitinib 5 and 10 mg BID were generally similar irrespective of whether pts discontinued/continued MTX or GC. Most pts who discontinued MTX or discontinued GC achieved CDAI remission (≤2.8) or low disease activity (>2.8–≤10) vs CDAI incomplete response (>10) at Year 3 (Table 1). Mean (standard deviation) time off MTX and GC prior to Year 3, respectively, was 532 (347) and 523 (324) days for tofacitinib 5 mg BID and 593 (338) and 592 (337) days for tofacitinib 10 mg BID. Most pts maintained their 3-month response at Year 3 after the discontinuation of MTX or GC, and response rates were comparable with pts who did not discontinue MTX or GC after Month 3 (Table 2). Furthermore, of those not receiving MTX (1,044 pts) or GC (1,218 pts) at LTE baseline, 65 pts (6.2%; tofacitinib 5 mg BID: n=22; tofacitinib 10 mg BID: n=43) initiated MTX, and 306 pts (25.1%; tofacitinib 5 mg BID: n=82; tofacitinib 10 mg BID: n=224) initiated GC prior to Year 3.

Conclusion: Pts who achieve a high level response with tofacitinib may be able to discontinue MTX or GC and maintain their response. Additional analysis is warranted to understand the reasoning behind why pts initiated MTX or GC in the LTE studies.

Table 1. CDAI response at Year 3 for patients receiving tofacitinib 5 or 10 mg BID stratified by whether patients discontinued MTX or GC

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. The objective of this analysis was to report tofacitinib safety and tolerability and clinical efficacy in long-term extension (LTE) studies over 96 months (Mo).

Methods: Data were pooled from 2 open-label studies (NCT00413699 [ongoing; database unlocked at January 2016 data-cut] and NCT00661661) of patients (pts) with RA who had participated in Phase 1/2/3 tofacitinib studies. Pts received tofacitinib 5 or 10 mg twice daily (BID) as monotherapy or with background DMARDs. Primary endpoints: adverse events (AEs) and confirmed laboratory safety data. Secondary endpoints included clinical efficacy measures (ACR20/50/70

response rates, DAS28-4[ESR], HAQ-DI, and clinical disease activity index). Safety data were included up to Mo 105 and efficacy data up to Mo 90 (n≤100 at Mo 96).

Results: 4,967 pts were treated (mean [max] duration: 1,215 [3,182] days). Total tofacitinib exposure was 16,711 pt-years (py); 77.4% of pts maintained initial dose. In total, 2,370 pts (47.7%) discontinued (AEs: 1,131 [22.8%]; insufficient clinical response: 175 [3.5%]). Most common AE classes: infections and infestations (68.9%) and musculoskeletal/connective tissue disorders (39.0%). Most common AEs: nasopharyngitis (18.7%), upper respiratory tract infection (17.2%), bronchitis and urinary tract infection (12.2% each). Serious AEs occurred in 28.6% of pts, and serious infections (SIEs) in 8.8% of pts. Malignancies, excluding non-melanoma skin cancer, were reported in 3.0% of pts. Incidence rates (IR; pts with events per 100 py) for AEs of interest, with 95% confidence intervals (CIs), are provided in Table 1. IRs for SIEs and malignancies through Mo 105 did not increase vs reported data through Mo 96.[1] Confirmed laboratory data are provided in Table 1. No new safety risks were identified. Clinical responses were sustained from Mo 1 to Mo 90 (Table 2).

Conclusion: In patients with RA who remained in LTEs, tofacitinib (5 or 10 mg BID) with or without background DMARDs was associated with consistent safety through Mo 105, and sustained clinical efficacy through Mo 90.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. RAPID3 (Routine Assessment of Patient [Pt] Index Data 3) is a pooled index of the three RA core data set pt-reported outcomes (PROs): function, pain, and pt global assessment of disease activity. We compared clinical outcomes, radiographic progression, and PROs at Month 24 in pts achieving remission, low, moderate, and high disease activity (REM, LDA, MDA, and HDA) based on RAPID3 at Month 6.

Methods: ORAL Start (NCT01039688) was a 2-year, Phase 3 randomized controlled trial in which MTX-naïve pts with RA received tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or MTX titrated to 20 mg/week over 8 weeks. RAPID3 scores were calculated at Months 6 and 24 for pts with radiographs at both time points. To calculate RAPID3 scores, each of the 3 individual measures (PtGA visual analog scale [VAS], pain [VAS] and HAQ DI were scored from 0–10 for a total of 30, and divided by 3 to give an adjusted 0–10 score. Outcomes assessed at Month 24 included REM (defined as ≤1), LDA (>1–≤2), MDA (>2–≤4), and HDA (>4) rates based on RAPID3; change from baseline (CFB) in RAPID3, CDAI, and modified Total Sharp Score (mTSS); and proportion of pts with no radiographic progression based on CFB in mTSS ≤0 and HAQ-DI <0.5 (defined as normative).

Results: Pts with RAPID3 HDA at Month 6 had higher baseline RAPID3 scores than those achieving REM/LDA (Table). At Month 6, 24.6%, 32.5%, and 14.1% of pts receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID, and MTX achieved REM, respectively; 19.3%, 20.9%, and 17.9% LDA; 33.2%, 26.2%, and 36.5% MDA; and 22.8%, 20.4%, and 31.4% HDA. A higher proportion of patients were in RAPID3 REM and LDA with tofacitinib vs MTX. Regardless of treatment group, the majority of pts who achieved a specific response at Month 6 maintained or improved their responses at Month 24. CFB in RAPID3 and CDAI at Month 24 was greatest for pts who were in RAPID3 REM/LDA at Month 6. In each treatment group, patients in REM/LDA at Month 6 were more likely to achieve mTSS ≤0 at Month 24 than those with RAPID3 HDA at Month 6. Overall, regardless of RAPID3 category, a higher proportion of pts receiving tofacitinib than MTX had mTSS ≤0. Furthermore, CFB in mTSS at Month 24 with tofacitinib was generally similar across RAPID3 categories; with MTX, it was higher for patients with RAPID3 MDA and HDA. The proportion of pts with normative HAQ-DI scores at Month 24 was highest for pts achieving RAPID3 REM at Month 6, and lowest for those in RAPID3 HDA at Month 6, for each treatment group.

Conclusion: The majority of pts who attained a RAPID3 response at 6 months maintained that response at 24 months. More pts achieving RAPID3 REM or LDA at Month 6 were radiographic non-progressors or had normative HAQ-DI scores at Month 24, compared with those in RAPID3 MDA or HDA.

SESSION INFORMATION
Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of early RA treatment is remission. Intensive treatment with MTX and treat-to-target approach achieve remission in 30-50% patients. Modifiable risk factors, as cigarette smoking and alcohol, coffee and tea intake, may affect response to MTX. The objective of this research was to study the influence of tobacco, alcohol, coffee and tea on the response to MTX in RA patients early DMARD-naive

Methods: We conducted a case-control study from 2010 to 2015, where cases were patients who achieved a sustained remission (DAS28PCR<2,6) or low activity (DAS28PCR<3,2) and controls were patients who not reached it. We collected information from a cohort of 182 Caucasian patients with early RA, aged 18-77 years, treated with MTX monotherapy from 1990 to 2015, evaluated quarterly in a specialized unit early RA. Clinical evaluations included DAS28CRP, HAQ, comorbiditIes, cardiovascular risk factors and pharmacovigilance data. All the patients underwent a structured interview about their smoking history and others habits. A descriptive study, comparison of means, univariate and multivariate correlations, logistic regression and survival analysis with SPSS statistics 21 was performed.

Results: Of the 182 patients achieved sutained remission 68 (37,4%) and low activity 99 (54,4%). Almost all patients (95 %) received MTX in rapid escalation (7,5-25mg) in the first 24 months of the onset of symptoms. Younger patients and current smokers responded worse to monotherapy and required higher doses of MTX. The univariate and multivariate analysis of the baseline patient characteristics and relationship of their smoking history with age, RF, ACPA and outcome of MTX monotherapy are shown in table 1 and 2, respectively. The median survival of MTX monotherapy (measure of efficacy, safety and tolerability) was 170 months for non-smokers and 30 months for current smokers (Log Rank 20,21, p 0,000) (see graphic).

Conclusion: The treatment of early RA with MTX alone achieved high rates of remission and low activity, especially in non-smokers. Smoking cessation could significantly improve the response to MTX and therefore should be an integral part of the treatment of early RA patients.

Tabla 1. Analysis of association between baseline characteristics and clinical remission with MTX monotherapy in early RA

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: B cells are pivotal to the pathogenesis of many autoimmune diseases including rheumatoid arthritis (RA). Tofacitinib, a JAK inhibitor, is effective and safe in the treatment of RA. Tofacitinib interferes with signal transduction via cytokine receptors using the common γ-chain.Despite of extensive data on T lymphocytes, the impact of tofacitinib on B lymphocytes is poorly understood. In this study we assess the effect of tofacitinib on the differentiation of naive B-lymphocytes and their function.

Methods: Sorted human B cells from cord blood or buffy coat were stimulated in the presence of increasing doses of tofacitinib. B cell phenotypes were determined by flow cytometry. Immunoglobulin concentrations were measured by ELISA. The expression of B cell fate determining genes PRDM1, IRF4, XBP1, and AICDA was analyzed by quantitative RT-PCR.

Results: Tofacitinib treatment strongly impaired plasmablast development, immunoglobulin secretion and induction of PRDM1, IRF-4, and XBP-1 from naive B cells. Interestingly, class switch and AICDA induction from activated naive B cells was only slightly reduced. B cells purified from buffy coats, including naive and memory B cells, stimulated in the presence of tofacitinib, showed only a moderate reduction in plasmablast formation, immunoglobulin secretion and proliferation.

Conclusion: We demonstrated that tofacitinib has a direct impact on human naive B-lymphocytes, independently from its effect on T lymphocytes, by impairing their development into plasmablasts and immunoglobulin secretion. Tofacitinib predominantly affects naive B lymphocytes, while its effect on total peripheral B cells containing naive and memory B cells is less pronounced. Our data are of clinical importance as they suggest that vaccinations should be performed prior to tofacitinib treatment. Furthermore, impairement of B cell function by tofacitimib may directly contribute to its therapeutic effects. This fact has implications for the potential use of tofacitinib in B cell-mediated diseases.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although there have been significant advances in the treatment of rheumatoid arthritis (RA) and psoriatic arthritis (PsA). patients can experience a lack of or loss of efficacy over time, requiring additions/switching among drugs. Tofacitinib is a highly targeted DMARD but it is not approved for use with biologics. and there has been concern about using tofacitinib in combination with biologics, particularly regarding the toxicity of these combinations. In this small case series, we report 6 patients on tofacitinib and various biologics as an initial documentation of the use tofacitinib and biologics in combination.

Methods: Clinical data of five RA patients and one PsA patient was extracted retrospectively from time prior to starting tofacitinib/biologic combination therapy until completion of 6-28 months of combination treatment. Data extracted included patient demographics, disease characteristics, significant comorbidities, previous and concomitant medications, adverse events (AEs) and serious adverse events (SAEs), laboratory data and clinical disease activity index (CDAI). Data was compared pre and post initiation of combo therapy. Relationship of AEs and SAEs to the combo was assessed based on known potential side effects of tofacitinib and the biologics.

Results: All RA patients fulfilled the 1987 American College of Rheumatology (ACR) classification and the PsA patient fulfilled the ClASsification criteria for Psoriatic ARthritis (CASPAR) All had moderate to severe disease(Table) 3 RA patients on tofacitinib in combination with tocilizumab, 1 with rituximab and 1 with etanercept, and 1 PsA patient on tofacitinib plus tocilizumab experienced no serious AEs and no deaths over 6-28 months (mean: 14 months) infections (67%), GI (67%), and hyperlipidemia (33%) occurred. 2 pts stopped tofacitinib secondary to AE's (table). CDAI at the last report was essentially unchanged (20.9 vs 22.8 table)

Conclusion: In a small case series, there were no deaths nor serious AEs observed when patients used tofacitinib in combination with a biologic for a 6-28 months. This preliminary data indicates that further investigation of such combinations may be justified. Table 1

Session Date: Monday, November 14, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with neovascularization of the synovial membrane and increased risk of cardiovascular disease, consequent to vascular and endothelial dysfunction, which leads to remodeling, and degradation of the basement membrane proteins, such as type IV collagen. The purpose of the study was to investigate the association between basement membrane turnover and disease activity, as well as structural progression in RA.

Methods: Serum samples from patients giving informed consent of the LITHE (n=740) and RADIATE (n=217) studies (two phase III double-blinded placebo controlled studies testing 4- and 8-mg/kg tocilizumab (TCZ) in combination with methotrexate) were included. Basement membrane turnover was measured by the blood-based biomarker C4M reflecting MMP-degraded type IV collagen degradation at baseline, week 4, 16, 24 and 52, and at baseline and week 16 in the LITHE and the RADIATE study. Associations between basement membrane turnovers, treatment response and clinical parameters.

Results: Basement membrane turnover was associated with clinical scores including visual analog scale for pain ($p<0.0001$) and DAS28 DAS28 ($p=<0.0001$) in both studies (table). It was dose-dependently reduced by TCZ (11-40%, figure) and baseline levels were significantly correlated with change in radiographic scores (joint space narrowing ($p=0.001$) and sharp score ($p=0.0002$)).

Conclusion: Basement membrane remodeling was associated with disease activity and radiographic progression at baseline, and was dose-dependently inhibited by TCZ, suggesting a continuous clinical benefit extending past the joint tissue. These data suggest that active RA and disease progression is associated with increased remodeling of basement membrane collagen.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - ARHP Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis is associated with an excess cardiovascular disease (CVD) burden. Fewer CVD events associated with specific DMARD therapies have been reported; however, causal effects on atherosclerosis have never been evaluated rigorously in a randomized trial. Radiolabeled fluorodeoxyglucose (FDG) is taken up by macrophages in atherosclerotic plaques, is detectable with positron emission tomography (PET), and is a surrogate for atherosclerosis. We designed a multi-center randomized controlled clinical trial to: 1) Compare the change (over 24 weeks) in FDG uptake in the aorta and carotid arteries among methotrexate (MTX) inadequate responders who will be

randomized to adding either a TNF inhibitor (i.e. step-up MTX + TNFi) or sulfasalazine + hydroxychloroquine (i.e. step-up triple therapy), and 2) assess whether achieving low RA disease activity or remission (LDAR) is associated with a parallel reduction in arterial FDG uptake. Correlations of change in arterial FDG uptake with change in circulating biomarkers will also be performed.

Methods: The primary hypothesis of the Treatments Against Rheumatoid Arthritis and Effects on FDG-PET (TARGET) Trial is that TNFi +MTX will reduce vascular inflammation to a greater extent than triple therapy after 24 weeks. Secondarily, RA patients with LDAR at 24 weeks will have less vascular inflammation than those with persistent moderate/high disease activity. The primary outcome measure will be the maximal aortic FDG uptake of the most diseased segment (MDSmax) standardized to the blood pool in the superior vena cava [i.e. the target to background ratio (TBR)]. Sample size projections are based on estimates of change in aortic FDG uptake from preliminary sources, 0-15% dropout, 0-15% unintended crossover into the TNFi arm, a conservative 30% LDAR achieved, at least 90% power for the primary and secondary analyses, a two-tailed alpha=0.05, and equal allocation to the treatment arms.

Results: From a published study of 17 RA patients, the mean ± SD baseline aortic MDSmax TBR was 2.51±0.33 units. In the same study, there was a 0.46 unit reduction in this measure after 8 weeks of TNFi. We calculated that the trial would require a pooled sample size of n=170 (n=85 per arm) to detect an absolute difference in the 6-month MDSmax TBR of 0.17 units between the treatment groups with 90% power should the highest projected crossover occur. This same sample size would also have 90% power to detect a 0.19 unit difference in MDSmax TBR between those achieving LDAR vs. moderate or high disease activity, using the same assumptions. The magnitude of these differences is consistent with studies comparing low vs. high dose statin use. Conservatively assuming a 15% drop-out, 100 patients per arm will be enrolled beginning in July 2016.

Conclusion: The TARGET trial, the first to explore the effect of immunomodulation on vascular inflammation in any rheumatic disease, is powered to detect meaningful differences in vascular inflammation between treatments. Further, the minimal detectable difference in arterial inflammation between those achieving LDAR compared with those not responding as may be small, yet clinically meaningful.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease with diverse clinical and radiographic manifestations. A number of human leukocyte antigen (HLA) alleles have been found to be associated with PsA.[1] HLA-C*06:02 is associated with severe skin disease and a late onset, milder musculoskeletal phenotype; HLA-B*27:05 with entheseal-based disease, severe musculoskeletal disease, enthesitis, symmetric sacroiliitis (SI) and mild psoriasis; HLA-B*08:01 with synovial-based disease, asymmetric SI, joint deformity, joint fusion and dactylitis while HLA-B*38:01/39:01 is associated with more axial involvement and joint damage progression.[2] Our hypothesis is that in each of these distinct genetic groups and perhaps as a consequence of the inflammatory events that occur following MHC-peptide interaction, a different pattern of inflammation involving diverse systemic molecules and mediators may be unleashed which in turn determines clinical phenotype and possibly therapeutic response. Our objective is to identify whether there are differences in serum protein expression between groups of patients with specific combinations of HLA genotypes and clinical features.

Methods: Patients with a diagnosis of PsA, fulfilling the CASPAR criteria, aged >18 years were clinically assessed, 10 patients from each of the 4 defined HLA groups. We included a fifth distinct clinical group, Arthritis Mutilans, which as yet has no defined genotype. Serum samples were obtained from all patients. *Proteomics Strategy*: Serum samples from patients in each of the 5 groups were pooled. Serum pools were depleted of high-abundant proteins. The protein concentration of the remaining low abundant protein fractions was measured and subsequently, protein was digested. Finally, samples were purified prior to liquid chromatography-mass spectrometry LC-MS/MS analysis. Data was imported into MaxQuant and Perseus for quantitative and statistical analysis.

Results: Replicate LC-MS/MS analysis of each the 5 pools (n=3) revealed that a total of 437 proteins could be identified. Of these proteins, 219 were found to be significantly differentially expressed between the different groups (False Discovery Rate: 0.01, $p \leq 0.05$). Table 1 describes the number of proteins differentially expressed when comparing one PsA subgroup to the other 4 combined groups.

Comparison	Univariate Analysis (p value ≤0.05)
Arthritis Mutilans vs. Other Genotypes	43 proteins
B*27 vs. Other Genotypes	28 proteins
B*08 vs. Other Genotypes	91 proteins
B*38/39 vs. Other Genotypes	37 proteins
C*06 vs. Other Genotypes	20 proteins

Table1 shows the discovery data analysis summary

Conclusion: In this study, it was possible to identify proteins that were significantly differentially expressed across the 5 PsA phenotypes. Validation strategies are in progress to measure all differentially expressed proteins in individual patient samples using a targeted proteomics approach. This work is an important first step toward the development of a protein biomarker panel that can be used to distinguish between different PsA subgroups. References: 1. Winchester R, et al. SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: MicroRNAs (miRNAs) are a group of single-stranded non-coding RNAs of 20-25 nucleotides in length that can potentially regulate every aspect of cellular function. Recent studies have demonstrated that miRNAs can be detected in the circulation and serve as potential biomarkers of various diseases. Our aim was to evaluate whether AS pathogenesis is related to the aberrant expression of plasma miRNAs.

Methods: The expression profile of 800 miRNAs was determined in pooled RNA samples from plasma of AS patients and healthy donors (HDs) (n=3 each) using a nCounter miRNA assay. Next, candidate miRNAs were validated by real time RT-PCR in a validation cohort of 26 AS patients and 26 HDs. To evaluate their relevance in the AS pathogenesis, an analysis was carried out by using the web-based bioinformatics tool IPA. Association studies with the clinical status of the AS patients were also performed. AS activity was defined as BASDAI ≥ 4, CRP > 8 mg/L and ESR > 20 mm/h. Structural damage was evaluated by mSASSS.

Results: In discovery phase, nine miRNAs were differentially expressed (fold change ≥ 2) in the plasma of AS patients *vs.* HDs. After validation, seven of the nine miRNAs clearly distinguished AS plasma samples with high confidence level ($P < 0.05$). Specifically, the circulating levels of miR-146a-5p, miR-125a-5p, and miR22-3p were upregulated, whereas those of miR-320e, miR-151-3p, miR150-5p and miR-451a were downregulated in AS patients *vs.* HDs. The ROC curve analyses of these miRNAs exhibited a moderate distinguishing efficiency, with the AUCs for these miRNA ranging from 0.674 to 0.746. In addition, target gene prediction by IPA analysis showed that these altered miRNAs were involved in affecting various aspect of AS, such as signaling pathways related to inflammatory response and bone turnover. Association studies showed that plasma miR-146a-5p expression was significantly increased in active AS patients as compared with non-active AS patients ($P = 0.037$). In addition, we observed that AS patients with higher structural damage exhibited significantly lower miR-151-3p expression than those with less radiographic severity ($P = 0.045$); the ROC curve analyses showed that relative expression of this miRNA could distinguish AS patients with radiographic severity, with a power AUC of 0.761 ($P= 0.05$).

Conclusion: This study has identified a set of circulating miRNAs which could be attractive candidates as noninvasive biomarkers for the diagnosis of AS patients and may help elucidate the pathogenesis of AS. Funded by PI-0314-2012, SER

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Bone marrow (BM) is not only the place where osteoclast precursors (OCPs) are derived from, but also the major reservoirs of OCPs. Current data suggested that the local inflammatory conditions caused by arthritis progression will induce the proliferation of BM-residing OCPs to further mature into multinucleated mature OC with bone erosion activity, which subsequently expedite arthritis progression. No direct evidence is available to support this notion due to the absence of reliable OCP biomarkers and OCP enumeration with high accuracy. It also remains unclear whether the differentiation of OCPs within BM could be affected solely by skin (psoriasis, Ps) but not bone condition (psoriatic arthritis, PsA). We have previously shown that DC-STAMP, a master regulator in osteoclast differentiation, is elevated in patients with psoriatic arthritis (PsA). In addition, we also showed that DC-STAMP has the potential to serve as a diagnostic biomarker to predict the susceptibility of patients with psoriasis to PsA transition. Given that changes in the BM microenvironment might occur at the early stage of Ps to PsA transition, in this study, we investigate whether Ps pathogenesis could affect the microenvironment of bone marrow for OCP differentiation by comparing DC-STAMP expression level and DC-STAMP+ cell frequency in BM and periphery at healthy and disease status.

Methods:

Bone marrow aspirates (BMA) and blood were collected from 13 Ps patients (PASI score between 35-60) and 5 healthy controls (HC). Total cells or enriched CD14+ monocyte were isolated from BMA and blood, analyzed by 12-color flow cytometry *ex vivo*, and enumerated OC by TRAP staining after 8-day *in vitro* culture in OC-promoting media.

Results:

		(a) OC (total)	(b) OC (monocytes)	(c) DC-STAMP MFI	(d) DC-STAMP %	(e) CD14+CD16+ %
HC	blood	21 +/- 22	565 +/- 624	2063 +/-892	10 +/- 12	1.1 +/- 0
	BM	724 +/- 914	1651 +/- 1101	2010 +/-510	22 +/- 8	0.1 +/- 0
Ps	blood	56 +/- 134	992 +/- 813	2478 +/- 591	17 +/- 6	0 +/- 0
	BM	438+/- 625	1800 +/- 1620	1740 +/- 359	27 +/- 12	2.1+/- 0

There are 5 major results: (1) More OCPs were found in BM than blood, which is common for both HC and Ps patients (column b); (2) Ps patients have a slightly higher OCPs in BM than HC (1800 +/- 1620 vs. 1651 +/- 1101); (3) Mean Fluorescence Intensity (MFI) of DCSTAMP: This measure the expression level of DC-STAMP. Comparable MFI were found between blood and BM in HC, whereas DC-STAMP MFI is reduced, although not significant, in BM in Ps patients (column C); (4) OCP (purified monocytes) in Ps's BM is higher than HC (1800 +/- 1620 vs. 1651 +/- 1101, column b). However, the total OCP readouts are lower if monocytes were co-cultured with T & B cells (column a); (5) the inflammatory CD14+CD16+ monocyte subset was elevated in the BM of Ps patients.

Conclusion: (1) Ps pathogenesis induces changes in the BM microenvironment which subsequently affects OCgenesis and OCP frequency within the BM; (2) unidentified cellular factors, such as cell subset & chemokine/cytokines, are present in human bone marrow to suppress OC differentiation (Column A, Ps BM) and DC-STAMP expression (Column C, Ps BM); (3) 3 potential Ps-specific biomarkers are (i) % of CD14+CD16+ cells in BM, (ii) difference between DC-STAMP% in BM and blood (Δ(BM-blood) of DC-STAMP%), and (iii) difference between DC-STAMP MFI in BM and blood (Δ(BM-blood) of DC-STAMP MFI).

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: It is often difficult to differentiate psoriatic arthritis (PsA) from osteoarthritis (OA) in clinical practice. To aid clinical diagnosis, we aimed to identify soluble biomarkers that differentiate PsA from OA.

Methods: Serum samples from 201 patients with OA (mean age 65 years, 43.3% males, no history of inflammatory disease), 77 patients with PsA satisfying CASPAR criteria (mean age 45 years, 54.5 % males) and 76 healthy controls (mean age 37 years, 50% males) were obtained from the respective biobanks of the Arthritis Program. Samples were obtained at the time of joint replacement surgery (OA) or at the time of clinical assessment (PsA, healthy controls), and stored at -80°C until laboratory assays were conducted. Soluble markers of cartilage metabolism (COMP, hyaluronan), metabolic syndrome (adiponectin, adipsin, resistin, HGF, insulin, leptin) and inflammation/immune response (CRP, IL-1b, -6, -8, TNF-α, MCP-1, NGF) were assayed in the samples using Luminex multiplex assay. Marker levels in serum were compared across the 3 groups using the Kruskal-Wallis test. Pair-wise comparisons were made with Wilcoxon rank sum test. To identify markers that differentiate PsA from OA, multivariate logistic regression analyses with backward elimination, adjusted for age and sex, were constructed using markers determined to be significant at a $p \leq 0.1$ from univariate analyses. Discriminative ability was assessed by way of receiver operating characteristic (ROC) curves based on findings from multivariate models. The final model was further validated in an independent set of 73 PsA and 75 OA samples using predicted probabilities estimated using coefficients from the model developed on the training set.

Results: Univariate analyses revealed the following markers significantly differed across groups ($p<0.001$): COMP, hyaluronan; resistin, HGF, insulin, leptin; CRP, IL -6, -8, TNF-α, MCP-1, NGF. When comparing PsA to OA controlling for age and sex, the following markers significantly differed ($p<0.001$): COMP ; resistin, HGF, insulin; IL-6, -8, TNF-α, MCP-1, NGF; and Adipsin ($p<0.03$). Multivariate analysis demonstrated that COMP (OR 1.24, 95% CI 1.06, 1.46), resistin (OR 1.26, 95% CI 1.07, 1.48), MCP-1 (OR 1.28, 95% CI 1.01, 1.48) and NGF (OR <0.001, 95% CI <0.001, 0.25) were independently associated with PsA vs. OA. The area under the ROC curve (AUROC) for this model was 0.99. Internal cross-validation of the model consistently identified MCP-1 as a PsA marker. Further validation of the model including COMP, resistin, MCP-1 and NGF in an independent sample set showed an AUROC of 0.98 (Figure).

Conclusion: A panel of 4 biomarkers (COMP, resistin, MCP-1, NGF) may distinguish PsA from OA. Clinical utility of these markers will need to be determined in prospective studies.

Figure 1. ROC curve on the validation set (PsA=73 OA=75), with predicted probabilities calculated with coefficients of age, sex, COMP, MCP1, NGF, Resistin from the model developed on the training set.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Earlier we have reported that synovial tissues of psoriatic arthritis (PsA) and rheumatoid arthritis (RA) are enriched with the Th9 cells along with its key cytokine IL-9 (1). Here we are reporting new functions of IL-9; its

regulatory role on (i) FLS (fibroblast like synoviocyte) biology and (ii) pannus formation in PsA and RA.

Methods : FLS were isolated from synovial tissue biopsies of PsA, RA and OA (n=5, for each) and cultured (1). IL-9R expression was determined by immunobloting and RT-PCR studies. MTT assay and apoptosis assay (Annexin-V) were performed to determine the pro-growth/survival effect of rIL-9 on FLS. In the cultured FLS IL-6, IL-8, MMP-3 were measured by ELISA.

Results: RT-PCR and immunoblot studies demonstrated presence of IL9-R in FLS of PsA, RA and OA (Fig 1). rIL-9 induced proliferation of FLS and inhibited TNF-a induced apoptosis (Fig 2). rIL-9 induced IL-6 and MMP-3 expression in FLS (Fig 3).

Conclusion: Here we observed that FLS survival/prolifeartion, inflammatory cytokine expression and upregulation of MMP 3 the major components of the inflammatory proliferative cascades for pannus formation are regulated by IL-9. This is the first report to identify the presence of IL-9R on FLS and the functional significance of the IL-9/IL-9R system on FLS biology in PsA and RA. **Figure 1. IL-9R is expressed in FLS -** IL-9R gene was expressed in FLS of PsA and RA patients. Compared to the unactivated T lymphocytes the relative gene expression of IL-9R in FLS of PsA and RA patients was 3.5±0.67, 2.4±0.5, respectively (p<.01, Fig 1). IL-9R expression was confirmed by immunoblotting. The relative intensity (R.I) of IL-9R in FLS of PsA, RA and OA patients was 0.3 ± 0.02, 0.37 ± 0.05, 0.28 ± 0.08 respectively.

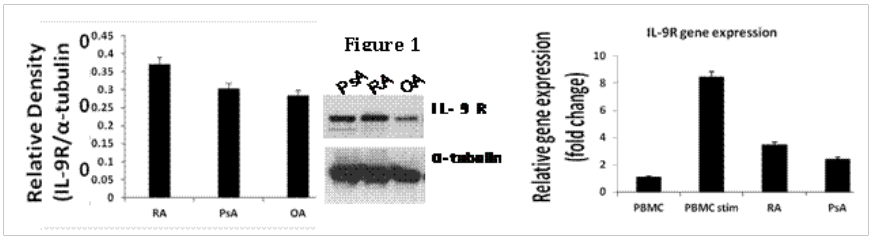

Figure 2. Human rIL-9 promoted survival of FLS- To test the functional significance of the IL9R we investigated whether rIL-9 can promote FLS survival. FLS of PsA, RA and OA were treated with rIL-9 (25 ng/ml) for 48hrs then TNFα (20 ng/ml) for 24 hours to induce apoptosis (1). In the FLS of PsA, TNFα + rIL-9 induced 11.41±3.61% apoptosis compared to 35±5.53% induced apoptosis seen in TNFα alone (p<.01). Similar results were seen in RA and OA FLS.

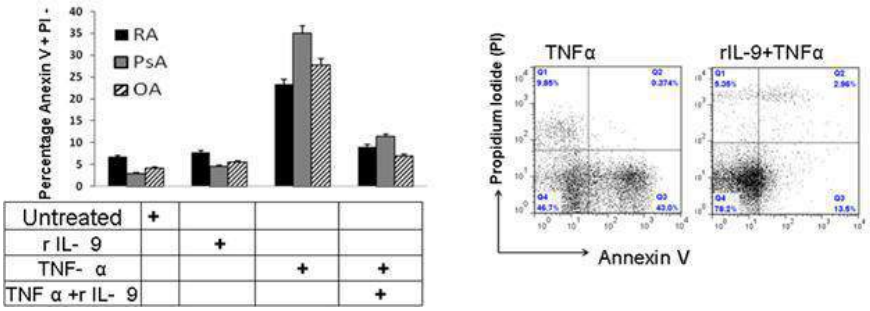

Figure 3. Compared to the untreated FLS, rIL-9 (100 ng/ml) induced upregulation of IL-6 and MMP- 3 (p<.01).

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing Spondylitis (AS) is a chronic inflammatory disease associated with the development of atherosclerosis. Our aims were: 1) To evaluate the involvement of immune system cells and NETosis in the atherosclerosis process in AS patients. 2) To analyze *in vitro* the role of leukocyte subsets in the endothelial function.

Methods: Thirty four AS patients and 34 healthy donors (HDs) were included in the study. Endothelial function was determined by the post occlusive hyperaemia test using Laser-Doppler. The expression of 84 genes related to atherosclerosis was determined in pooled RNA samples from peripheral blood mononuclear cells (PBMCs) of patients and HDs (n=3 each) by PCR array. Validation of several differentially expressed genes in PBMCs and the expression of various markers of oxidative stress and inflammation was quantified in leukocyte subsets. In neutrophils, NETosis markers and cell death by Sytox staining were also analyzed. Plasma DNA was quantified by fluorimetry. *In vitro* co-cultures of endothelial cells (HUVEC) with PBMCs or neutrophils from AS patients were performed.

Results: AS patients showed a prominent endothelial dysfunction, along with a significant alteration (fold change ≥ 2) in the expression of 50 genes related to atherosclerosis in PBMCs. Validation and expression studies showed that lymphocytes of AS patients exhibited an increase of inflammatory markers (STAT3, TNFα, IL1α, IL1β, IL6, IL23, IL2, ERAP1, IL10, IL5 mRNA), nitric oxide synthase (NOS) enzymes (NOS3 mRNA), and genes involved in adhesion (SELL, CDH5, THBS4 mRNA). In turn, monocytes displayed an augmented expression of inflammatory markers (STAT3, IFNγ, IL5, SPP1) and adhesion molecules (VCAM1, SELL), as well as a decrease in mRNA for IL6 and adhesive glycoprotein trombospondin 4 (THBS4). Neutrophils from AS patients showed a significant increase in NETosis and extruded plasma DNA levels, the latter associated with endothelial dysfunction present in AS. In addition, an increase of inflammatory markers (STAT3,

TNFα, IL1β, IL1α, IL5 mRNA), adhesion molecules (ICAM1, SELL mRNA) and NOS3 mRNA was also found in this cell type. Oxidative status-related analyses demonstrated that leukocyte subsets from AS patients displayed an increase in oxidative stress and mitochondrial membrane potential, along with an alteration of TAC and NO at plasma levels. *In vitro* treatment of HUVECs with PBMCs or neutrophils from AS patients promoted an altered activity of the endothelial cells, which displayed altered expression of adhesion molecules, oxidative stress markers, cytokines and NOS enzymes, all of them associated to the pro-atherogenic profile of these patients.

Conclusion: 1) Leukocyte subsets from AS patients display an altered expression profile of key genes involved in the development of atherosclerosis. 2) NETosis is a cellular death mechanism occurring in AS, whose induction may act a key mediator of endothelial dysfunction in these patients. 3) That highly inflammatory PBMCs and neutrophils are responsible, at least partially, for the endothelial alteration displayed by AS patients. Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The pathogenesis of spondyloarthritis (SpA) involves activation of the innate immune system, inflammation and new bone formation. The innate immune system is activated through pattern recognition receptors including Toll like receptor 4 (TLR4). Inflammation is a result of increased production of pro-inflammatory cytokines and chemokines including tumor necrosis factor alpha (TNFα) and monocyte chemoattractant protein 1 (MCP-1). New bone formation by osteoblasts is determined by a balance between the inhibitory effect of Dickkopf-1 (DKK1) and the stimulatory effect of bone morphogenetic proteins (BMPs). The two cytokines IL-20 and IL-24 have been shown to link innate immune activation and tissue homeostasis.(1) Previously, we have found increased plasma levels of IL-20 and IL-24 in SpA patients. We hypothesized that IL-20 and IL-24 are secreted as part of activation of the innate immune system and affect bone homeostasis. The aim was to describe associations of IL-20 and IL-24 and disease activity and magnetic resonance imaging (MRI) scores and to identify the sources and targets of the two cytokines in SpA.

Methods: Patients with axial SpA (n=83) were included in the study of associations between cytokine levels and disease activity and MRI scores. Patients with peripheral SpA (n=16) were included for studying sources and targets of IL-20 and IL-24 among synovial fluid mononuclear cells (SFMCs), peripheral blood mononuclear cells (PBMCs), and fibroblast-like

synoviocytes (FLSs) using lipopolysaccharide (LPS) and TNFα as positive controls. Healthy human osteoblasts were used for studying the effect of the two cytokines on mineralization using BMP2 as a positive control. The secretion of IL-20, IL-24, MCP-1 and DKK1 were measured by enzyme linked immunosorbant assays and flow cytometry, and mineralization was measured by hydroxyapatite deposition.

Results: The plasma IL-20 and IL-24 levels were increased in SpA patients compared with healthy controls (HCs) by 57% and 83%, respectively (both $p<0.0001$) and there was a trend towards associations with both future switch to biologic therapy ($p=0.031$ and $p=0.11$, respectively), and spine MRI chronicity score ($p=0.10$ and $p=0.15$, respectively). The production of IL-20 and IL-24 was increased by LPS, and this TLR4 induced secretion was greater in SpA PBMCs compared with HC PBMCs. IL-20 and IL-24 increased the production of MCP-1 by SpA SFMCs (but not by SpA FLSs), decreased the production of DKK1 by SpA FLSs (but not by SpA SFMCs) and increased mineralization by human osteoblasts (see Figure). The IL-20 and IL-24 induced production of MCP-1 among the SFMCs was found in activated synovial monocytes only.

Conclusion: Taken together, our findings indicate that IL-20 and IL-24 could be novel links between activation of the innate immune system and new bone formation in SpA. References: 1. Rutz S et al. The IL-20 subfamily of cytokines - from host defence to tissue homeostasis. Nat Rev Immunol. 2014.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The association between inflammation and spinal damage in Ankylosing Spondylitis (AS) remains unclear. Tumor necrosis factor-α (TNF- α) plays pivotal role in inflammatory process of AS. However current cytokine inhibitor strategies in AS fail to halt new bone formation. This condition propounds that the structural damage of AS patients might be affected by noninflammatory processes or non-TNF- α inflammatory pathways. The aim of this study is to investigate the effects of some markers with possible contributions to structural damage in AS and their relationship with radiographic progression.

Methods: The study included 238 AS patients and age and sex-matched 150 healthy controls. All AS patients met Modified New York criteria or ASAS axial spondyloarthritis criteria. When patients applied for their routine follow ups, demographic data (age, gender, disease duration, mediacations), ESR, CRP, and total blood count were recorded. Along with the radiographic evaluation (*mSASSS*), serum levels of DKK-1, BMP-2, BMP-4, Sclerostin (SOST), IL-17, and IL-23 were analyzed.

Results: DKK, SOST, IL17, and IL23 were significantly higher in AS group while bm2 level was significantly lower among AS patients ($p<0.001$). (table-1) When the association between biomarker levels and disease activity parameters was investigated, bm2 concentration was significantly higher and bm4 concentration was lower among patients with higher BASDAI scores (>4) (p:0.046, p:0.033 respectively). No statistically significant difference was found between antiTNF and NSAID groups in terms of marker levels ($p>0.05$). Variance analyses showed that none of the factors solely affected the *mSASSS*. However, if bm2, bm4, and IL 17 levels were greater than median values, the *mSASSS* was affected by 3.3% ($p=0.017$). DKK, SOST, bmp2 and IL17 affected *mSASSS* by 2.6% if they exceeded median values ($p=0.029$). (table-2). These correlations were significant but weak.

Conclusion: The mechanism of new bone formation in AS seem to be complicated and a consequence of inextricable processes. As a manifestation of this confusion, DKK-1 and SOST, with inhibitory effect on bone formation were found to be higher, and BMP-2, a bone formation marker was found to be lower among AS patients. These results propound the importance of local factors (enthesis sites) and possible disease-specific effects of biomarkers.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Calprotectin is a protein involved in several cellular processes including immunomodulation[1]. Elevated levels of this protein have been observed in inflammatory diseases, since it is secreted into inflamed tissues during monocyte infiltration[2]. Osteoprotegerin (OPG), a member of the tumor necrosis factor receptor superfamily, has been associated with increased risk and severity of atherosclerotic disease[3]. Both molecules have been proposed as potential biomarkers of atherosclerosis[4,5]. In contrast to ankylosing spondylitis (AS), non radiographic axial spondyloarthritis (nr-axSpA) patients do not seem to develop early atherosclerotic disease[6]. Due to this, we aimed to compare calprotectin and OPG levels in AS and nr-axSpA and to assess the potential involvement of both molecules as biomarkers of subclinical atherosclerosis in both types of SpA.

Methods: Serum calprotectin and OPG levels were measured by ELISA in 202 Spanish patients diagnosed with axSpA recruited from Hospital Universitario Marqués de Valdecilla and Hospital de Laredo (Spain). axSpA patients fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria[7]. Of them, 53 fulfilled the definitions for nr-axSpA[7], while 149 also fulfilled definitions for AS according to the 1984 modified New York criteria[8]. Patients with previous history of cardiovascular (CV) disease were excluded. All the patients underwent a carotid ultrasound study to assess the presence of abnormal carotid intima-media thickness (cIMT) and presence of plaques (both surrogate markers of CV disease), as previously described[9]. Differences in calprotectin and OPG levels among the study groups were assessed by Mann-Whitney test. Correlations of these molecules with surrogate markers of CV disease were studied. The association with cIMT values was assessed by linear regression, while the association with plaques was tested by logistic regression. All the results were adjusted by potential confounder factors. Statistical analysis was performed using STATA® v. 11.1.

Results: nr-axSpA and AS patients displayed similar levels of serum calprotectin and OPG. When the potential association between calprotectin and OPG levels and cIMT values or presence of plaques was assessed, no statistically significant results were obtained, neither in the axSpA cohort nor in the two subgroups of AS and nr-axSpA patients ($p>0.05$ for all comparisons).

Conclusion: Our results do not confirm an association between calprotectin and OPG levels with subclinical atherosclerosis in our cohort of Spanish axSpA patients. SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To study the specific biomarkers by surface-enhanced laser desorption ionization/time of flight mass spectrometry (SELDI-TOF-MS) and protein chip in serum of patients with ankylosing spondylitis (AS).

Methods: The serum samples of 69 AS patients and 12 healthy individuals were detected by SELDI-TOF-MS and weak cation exchange (WCX-2) chip. To find the specific proteins and to set up the diagnostic models by using Biomarker Wizard and Biomarker Pattern software. Then 69 AS patients were divided into several types such as the condition of illness was active or not, HLA-B27 was positive or negative, with or without hip involvement. To study the possible roles of differentially expressed proteins in the pathogenesis of AS.

Results: The first diagnostic model (8085, 2640 and 2932)could be used to diagnose AS in early stage. The sensitivity and specificity were 94.23% and 100% respectively. The second diagnostic model (3677, 3880, 2539, 3159 and 3242) could be used to determine the disease activity of AS. The sensitivity and specificity were 98.11% and 100% respectively. The third diagnostic model (4700, 8687 and 18538) could be used to predict AS whether involve peripheral arthritis or not. The sensitivity and specificity were 80.00% and 82.35% respectively. The serum protein expression were not statistically difference between in the HLA-B27 positive group and HLA-B27 negative group.

Conclusion: The serum protein fingerprinting by SELDI-TOF-MS could identify new biomarkers in AS. The biomarkers may play an important role in pathogenesis of AS. We could diagnose AS in early stage, determine disease activity and predict disease progression by these biomarkers.

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Heritable epigenetic phenomena may play a role in the parent-of-origin effect observed in psoriasis and psoriatic arthritis (PsA). A previous epigenome-wide association study (EWAS) identified differentially methylated regions (DMRs) in sperm cells of PsA and psoriasis patients without PsA (PsC) compared to controls. This study aimed to assess differential methylation and expression of these regions in somatic tissues.

Methods: Genomic DNA was extracted from whole blood of PsC patients (n=24), PsA patients satisfying the CASPAR criteria (n=13), and controls (n=19). All subjects were males whose semen was previously analyzed by EWAS. DNA was bisulfite converted and the most biologically interesting and statistically significant EWAS hits (oxysterol binding protein like 5 [*OSBPL5*], myelin basic protein [*MBP*], imprinted maternally expressed transcript *H19,* small nucleolar RNA C/D box 115 [*SNORD115*], E74 like ETS transcription factor 5 [*ELF5*], interleukin 22 [*IL22*], protein tyrosine phosphatase receptor type N [*PTPRN2*], junctional adhesion molecule 3 [*JAM3*], and cysteinyl-tRNA synthetase 2 [*CARS2*]) were analyzed by pyrosequencing. Group-wise methylation differences were compared by Student's t test or Wilcoxon rank sum test. Multivariable logistic regression was also performed to adjust for age and psoriasis area and severity index (PASI). Whole blood RNA was collected in Tempus and Paxgene tubes and extracted with their respective kits. Differential expression was analyzed by qRT-PCR using the ΔΔCt method with normalization to glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*).

Results: In whole blood, CpG sites within *JAM3, MBP,* and *PTPRN2* were differentially methylated in PsA vs. controls. *JAM3* and *ELF5* were differentially methylated in PsA vs. PsC. *MBP* was differentially methylated in PsC vs. controls ($p<0.05$). After adjustment for age, *MBP* (OR=0.1, 95% CI 0.1-0.75, p=0.03) and *PTPRN2* (two CpG sites: OR=2.1, 95% CI 1.0-4.3, p=0.04 and OR=2.2, 95% CI 1.0-4.9, p=0.049) remained significantly associated with PsA vs. controls. After adjustment for age and PASI, *JAM3* (OR=26.7, 95% CI 2.6-276, p=0.006) and *ELF5* (OR=31.5, 95% CI 1.6-628, p=0.02) remained significantly associated with PsA vs PsC. No CpG sites were differentially methylated in PsC vs. controls in age-adjusted analyses. All genes except for *ELF5, PTPRN2,* and *IL22* were expressed at detectable levels in whole blood. Preliminary qRT-PCR results showed significantly higher expression of *CARS2* mRNA transcripts in PsA (fold change=1.18, p=0.02) and PsC patients (fold change=1.24, p=0.046) compared to controls, but no significant differences in the levels of *JAM3* and *MBP* between groups.

Conclusion: Several germ line DMRs associated with PsC and PsA were differentially methylated in whole blood. The presence of these DMRs in both the germ line and whole blood suggests they may be heritable epigenetic phenomena associated with PsC and PsA. Investigation of these sites in additional somatic tissues, and in extended patient populations is necessary to strengthen the evidence that they are true heritable epigenetic variations.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The role of miRNAs in immune and inflammatory diseases is increasing exponentially. miRNAs are present in the human plasma in stable form. We proposed to test the hypothesis that patients with ankylosing spondylitis (AS) have an altered miRNA expression profile compared to controls.

Methods: pared to controls. **Methods**: Sixtytwo patients ≥18 years of age with AS based on the modified New York classification criteria (grade 3 and 4 sacroiliitis) and 34 healthy (age, race and sex matched) controls were prospectively recruited. Subjects with active malignancy in last 5 years, rheumatoid arthritis, systemic lupus erythematosus and evidence of HIV or chronic hepatitis B or C infection were excluded. Patients and controls were screened, consented and peripheral blood samples (5 ml) were obtained. The samples were centrifuged at 400 g for seven minutes; plasma transferred to nuclease free tubes and stored at -20°C until analyses. ESR and CRP were measured using routine laboratory methods. Various validated Questionnaires to assess disease, functional activity and patient reported outcomes in AS were administered to the patients. Sixty-eight circulating miRNAs in the plasma of the study subjects were profiled by Firefly Multiplex Circulating miRNA Assay (Abcam, Cambridge, MA) using the Immunology Panel. The assay beads were scanned on BD Accuri C6 flow cytometer (BD Biosciences, San Jose, CA). Data were analyzed using Firefly Analyis Workbench (Abcam). Expression of ten selected miRNAs that were differentially expressed based on the multiplex assay was further validated by qPCR using TaqMan Advanced miRNA assay (ThermoFisher Scientific) following the manufacturer's instructions. Briefly, Total RNA (including miRNA) was isolated from 100 µl of plasma from all the study subjects using the MagMAX mirVana Total RNA Isolation kit. cDNA was generated using 2 µl of purified total RNA with the TaqMan Advanced miRNA cDNA Synthesis kit. qPCR was then performed for each sample using 1 µL of diluted cDNA, TaqMan Advanced miRNA Assays, and Applied Biosystems TaqMan™ Fast Advanced Master Mix under fast cycling conditions. Reactions were run on StepOne Plus real-time PCR system. Data were analyzed on DataAssist v3.01 (ThermoFisher Scientific). Descriptive analyses included continuous variables (the mean ± SD) and the categorical variables(percentage).

Results: Demographics, clinical characteristics and disease activity of the patients are in Table 1. Our data revealed that miR-30b-5p (p=0.005), miR-34a-5p (p=0.007), and miR-431-3p (p=0.014) were highly abundant in the plasma of AS patients compared to the levels prevalent in controls.

Table-1

Patient Demographics

Mean Age in Years ± SD	48.8 ± 12.3
% African American	31.6
% Females	34.4
% HLA B27 Positive	77.4
% TNF-I use	50
BASDAI	5.1 ± 2.5

Conclusion: This study demonstrates that specific miRNAs are differentially expressed between AS patients and healthy subjects and thus can be developed as potential biomarkers. This work was supported in part by USPHS/NIH grants (RO1 AT007373, RO1 AT005520, RO1 AR067056, R21 AR064890) and funds from North East Ohio Medical University to TMH.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is still frequently diagnosed late and its pathogenesis is still unclear. Although a strong genetic association of axSpA with HLA-B27 is known, the gene prevalence varies among different world regions, and its value for the identification of patients with axSpA has been questioned. IgG and IgA antibodies against CD74 have shown good sensitivity and specificity and higher positive likelihood ratio (LR+) for axSpA as compared to HLA-B27. In this prospective study, we tested the performance of IgG and IgA anti-CD74 as early diagnostic marker for axSpA as compared to HLA-B27 in Lebanon, which is known as one of the countries with the lowest HLA-B27 prevalence ever reported.

Methods: Sera of axSpA patients and healthy blood donors (HBD) were analyzed for HLA-B27 genes by PCR and for IgG and IgA anti-CD74 by ELISA. The laboratory workers were blinded for clinical data during the analyses. Patients and HBD were recruited after an advertising program among rheumatologists and primary care physicians across Lebanon. Clinical assessment and sera sample collection were performed at a center specialized in axSpA (University center, Hotel-Dieu de France, Beirut). Inclusion criteria were age 18-45 years, Lebanese nationality, symptom duration <3 years, classification to axSpA (ASAS criteria, imaging arm), no prior exposure to biologics. Interpretation of the radiographic images for inclusion in the study was performed centrally and independent of the recruiting rheumatologist. Clinical and laboratory assessments were performed in all axSpA patients. Comparison between groups was performed with the Mann-Whitney U test. For the diagnostic properties of HLA-B27 and anti-CD74 IgGs, ROC curves were calculated.

Results: Sera of 26 axSpA patients and 69 HBD were collected prospectively. AxSpA patients were slightly older than HBD (31.6 and 27.3 years, respectively, p=0.04) with no other demographic differences. Mean symptom duration was 36.4 months (SD 16.5), mean BASDAI 4.2 (SD 2.0) and mean ASDAS 3.2 (SD 1.2). A total of 14 patients (54%) were classified as nr-axSpA. HLA-B27 status was positive in 9/26 axSpA patients (34.6%) but in no HBD (Sensitivity 34.6%, Specificity 100%). In the ROC analysis, IgG4 anti-CD74 showed the best diagnostic value for axSpA (AUC 0.939, cut-off value 0.55). Using this cut-off, positive values of IgG anti-CD74 were found in 24/36 axSpA patients (66.7%) and 5/69 HBD (7.2%) (Sensitivity and Specificity 92.3%, positive predictive value 82.7%, negative predictive value 96.8%, LR+ 12.0, LR- 0.08).

Conclusion: In this first study in a population with low HLA-B27 prevalence, IgG anti-CD74 antibodies showed higher diagnostic value than HLA-B27 for AxSpA. This is of special interest in populations with low HLA-B27 prevalence, especially on the background of diagnosing axSpA when using the clinical arm of the ASAS classification criteria.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor-α (TNF) activates two receptors globally, TNFR1 and TNFR2. Neutralizing antibodies or soluble TNF receptors can inactivate TNF, blocking activity of both receptors, and have been successful in treating psoriasis (PsO) and psoriatic arthritis (PsA). However, continued use of anti-TNF therapy has been associated with an increase in serious infections, such as reactivation of tuberculosis and malignancies. These side effects are related to TNFR1 blockade. Using mouse models, we showed that activity of both TNFR1 and TNFR2 is critical for TNF-mediated inflammatory responses.[1] Recently, we identified that activation of PRMT5 (protein arginine methyltransferase 5), an enzyme critical for TNF-mediated inflammatory responses, is downstream of TNFR2 but not TNFR1 signaling. This makes PRMT5 a target for treating TNF-dependent inflammatory diseases. Our goal is to demonstrate that selective inactivation of TNFR2 via PRMT5 is effective in treating psoriatic diseases. Our objective is to determine the relative contributions of TNFR1 and TNFR2 to the development of PsO, and to test whether inhibition of PRMT5 activity will alleviate PsO and PsA in animal models.

Methods: To identify the role of TNF receptors in psoriasis we used the imiquimod (IMQ) mouse model. We applied IMQ (4 mg/day/mouse for 4 days) to 10-12 week old wild type (WT), TNFR1-null, TNFR2-null and TNFR1 & 2 double-null mice. To determine the role of PRMT5, we treated a specific PRMT5 small molecule inhibitor EPZ015666 topically 4 hours prior to IMQ application once a day for 4 days. Erythema, scaling and thickness of the IMQ or vehicle treated area was assessed by PASI (Psoriasis Area and Severity Index). Epidermal thickness was measured using ImagePro software on H&E stained skin sections. Immunohistochemistry was used to determine PRMT5 expression. Protein-incorporated SDMA (Symmetrical Dimethyl Arginine), which is the catalytic product of PRMT5 and works as a functional representation of PRMT5 activity, was measured in psoriatic skin using mass spectrometry. Further, we are currently testing whether EPZ015666 can inhibit PsA-like joint disease using a TNF overexpressing mouse strain (ihTNFtg mice[2]).

Results: In WT mice, erythema, scaling, and thickness peaked at day 8 (PASI ~ 8.0). TNFR2-null or double-null mice skin inflammation was undetectable. TNFR1-null mice showed a PASI score of 1 - 2.5. H&E revealed significant keratinocyte hyperplasia and leukocyte infiltration in WT treated with IMQ, which were inhibited in TNFR2-null, TNFR1-null or double-null mice. Further, IMQ-treated mouse skin showed elevated PRMT5 expression. There was a ~ 2-fold increase of SDMA in mouse psoriatic skin compared to the adjacent normal skin. Importantly, topical application of PRMT5 inhibitor, EPZ015666, diminished the IMQ-induced PsO pathogenesis in WT mice (~ 75%).

Conclusion: IMQ-induced psoriasis is critically dependent on TNFR2. An increase in the abundance of PRMT5 was also found in mouse psoriatic skin and the specific PRMT5 inhibitor that can block TNFR2 ameliorates psoriasis in mice.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

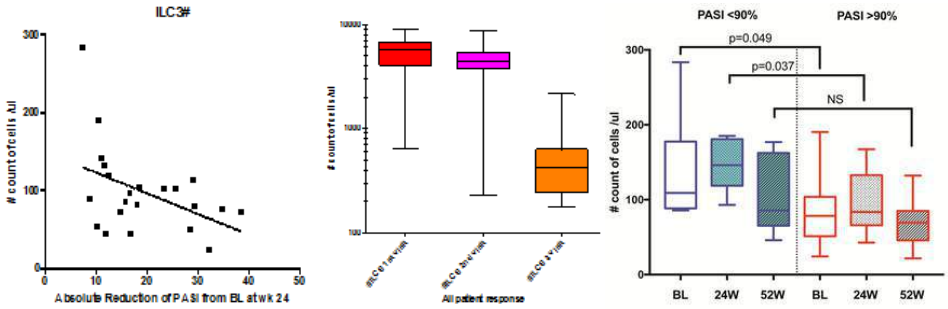
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ustekinumab[1] targets the common p40 sub-unit of interleukin-12 (IL-12/interleukin-23 (IL-23). In patients treated with Ustekinumab for psoriasis where patients were selected on the basis of subclinical imaging enthesopathy, we have noted an improvement in subclinical imaging enthesopathy (Savage et al. submitted), raising the possibility that it may be possible to find a biomarker for predicting response to therapy in psoriatic disease. Innate lymphoid cells may be centrally involved in the pathogenesis of psoriatic skin and joints disease[2], since they express IL-23R receptor and are associated with IL-17/IL-22 production. This work tested the hypothesis that peripheral blood ILC perturbations may be useful in defining response in psoriasis cases with imaging confirmed subclinical enthesopathy.

Methods: Peripheral blood collected at baseline (before therapy, 24weeks, 54 weeks) from patients in the MUSTEK trial (Ustekinumab in psoriasis cases who had ultrasound imaging confirmed subclinical enthesopathy) (n=23). Cellular immunophenotyping was performed density gradient separated PBMCs. Innate lymphoid cells were identified as lineage negative (CD3- TCRγδ- TCRαβ- CD19- CD14- CD11c- CD1a- CD303- FcεRI- CD34- CD123-) with positive expression of CD45, CD127. ILC2 cells were identified as Lineage- CD127+ and CRTH2 positive, while ILC3 were identified as Lineage- CD127+, CRTH2 – and CD117 (c-Kit) positive and further subdivided of NKp44+ and NKp44-. ILC1 were identified as lineage- CD127+ CD117-and CRTH2-. For data analysis we separated cases into PASI>90% or PASI <90% responders. The subclinical enthesopathy scores also fell significantly under therapy (Savage et al. submitted)

Results: No correlation was found with total ILCs absolute numbers (ILC1, 2, AND 3) (R= 0.104, p=321, Spearman R) and therapy response.



The absolute numbers of baseline ILC3s was inversely correlated in with the reduction in the PASI score (R= -0.404, p=0308, Spearman R). The ILC3s also fell progressively under therapy. All the patients respond with reduction of PASI score mean 92.6% (range 65.8-100%), Interestingly, those patients with reduction below 90% of PASI score has a significantly higher absolute numbers of ILC3+ cells in peripheral blood at the baseline than PASI (n=6/23) than super-responder group (n=17/23).

Conclusion: Only peripheral blood ILC3s, but not other ILCs changes, correlate with the PASI score (disease activity), Furthermore, excellent responders (PASI reduction > 90%) showed strong correlated with higher ILC3 population at the baseline. This may help to use ILC3 enumeration as predictive parameter for ustekinamab clinical therapeutic response and may be relevant to assessing novel biomarkers for subclincal arthropathy in psoriasis.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease with diverse clinical and radiographic manifestations. A number of human leukocyte antigen (HLA) alleles have been found to be associated with PsA.[1] HLA-C*06:02 is associated with severe skin disease and a late onset, milder musculoskeletal phenotype; HLA-B*27:05 with entheseal-based disease, severe musculoskeletal disease, enthesitis, symmetric sacroiliitis (SI) and mild psoriasis; HLA-

B*08:01 with synovial-based disease, asymmetric SI, joint deformity, joint fusion and dactylitis while HLA-B*38:01/39:01 is associated with more axial involvement and joint damage progression.[2] Our hypothesis is that in each of these distinct genetic groups and perhaps as a consequence of the inflammatory events that occur following MHC-peptide interaction, a different pattern of inflammation involving diverse systemic molecules and mediators may be unleashed which in turn determines clinical phenotype and possibly therapeutic response. Our objective is to identify whether there are differences in cytokine expression between groups of patients with specific combinations of HLA genotypes and clinical features.

Methods: Patients with a diagnosis of PsA, fulfilling the CASPAR criteria, aged >18 years were clinically assessed, 10 patients from each of the 4 defined HLA groups. We included a fifth distinct clinical group, Arthritis Mutilans (AM), which as yet has no defined genotype. Serum samples were obtained. *Cytokine Strategy*: 50 individual patient samples (10 per group) and 5 reference pools (each pool consists of 50 samples) were subjected to in-house developed and validated multiplexed immunoassays to measure 47 cytokines using the Luminex xMAP. Analysis was performed in the Laboratory for Translational Immunology, UMC, Utrecht, The Netherlands. Data were analysed by 5-parametric curve fitting using BIO-Plex Manager software version 6.1.1.

Results: Forty-seven cytokines were analysed in each individual sample (n=50). Four samples were excluded because of cross reaction. Fourteen cytokines were excluded because they were out of reference range (either above or below). Twelve cytokines were excluded as their coefficient of variation (CV) was > 20%. On analysis of the remaining 21, only 1 cytokines (IL18) was differentially expressed among the 5 groups, Figure1. IL18 was elevated in the HLA-B*27 group, with statistically significant difference between B*27 and AM (P<0.256, CI 135.6 to 9.982) and between B*27 and B*38/39 (P<0.0320, CI 129.3 to 6.524).

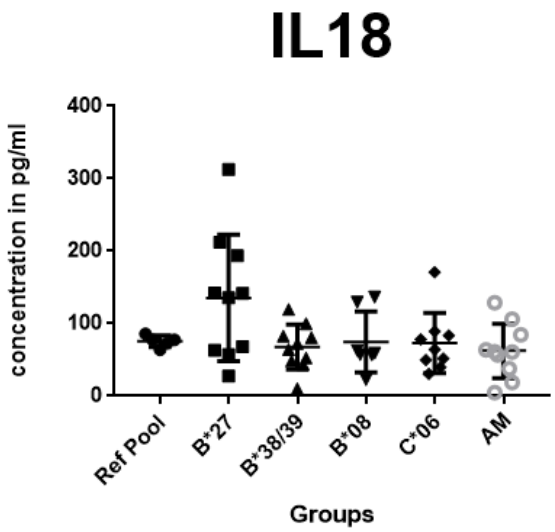

Figure 1 showing result IL18 cytokine in different group

Conclusion: IL18 was found to be elevated in HLA B*27 group. IL18 was significantly different between HLA B*27 group and AM and HLA B*38/39 group. Further analysis with a larger cohort is needed. **References:** 1. Winchester R, et al. A&R64:1134-44, 2012 2. Haroon M, et al. ARD75:155-162, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The pathogenesis of spondyloarthritis (SpA) involves both inflammation and new bone formation in the spine. In line with this, the disease has been characterized as both inflammatory and fibrotic. Current treatment including inhibitors of tumour necrosis factor alpha (TNFα) seems to dampen inflammation while new bone formation can progress. Therefore, there is an unmet therapeutic need for the treatment of new bone formation in SpA. Fibrosis is mediated by myofibroblasts and new bone formation is the result of increased osteoblast mineralization and decreased osteoclast bone degradation. Here, we evaluate the potential effect of the newly approved anti-fibrotic agent pirfenidone (Esbriet, Pirespa) on fibrosis and new bone formation in cell culture models of SpA. We hypothesized that pirfenidone inhibits SpA myofibroblast formation and activity and osteoblast mineralization.

Methods: Synovial fluid mononuclear cells from patients with SpA (n=6) were included for culturing fibroblast-like synovial cells (FLSs) while osteoblasts were purchased. The cells were cultured with pirfenidone in increasing concentrations (0.25, 0.5, and 1.0 mg/ml) with or without stimulation with tumor necrosis factor alpha (TNFα), transforming growth factor beta (TGFβ), or interferon gamma (INFγ). The proliferation of FLSs was analyzed with light microscopy and flow cytometry using the marker Ki67. The differentiation and activation of FLSs was assessed with flow cytometry, a proteome profiler assay and enzyme-linked immunosorbant assays. The mineralization capacity of the osteoblasts was measured as deposition of hydroxyapatite.

Results: Pirfenidone reduced the Ki67 expression 7.1-fold in untreated FLSs (p=0.001) and 11.0-fold in FLSs stimulated with TGFβ, TNFα, and INFγ (p=0.022). Pirfenidone further inhibited TGFβ induced upregulation of αSMA (Figure 2A) and INFγ induced upregulation of HLA-DR (Figure 2C) in all cultures. There was no difference between the percentage of ICAM-1 positive FLSs in cultures treated with or without pirfenidone. In supernatants from FLSs stimulated with TGFβ, TNFα, and INFγ a total of 12 cytokines or chemokines had values above the detection limit in the membrane-based antibody array. Pirfenidone decreased the secretion of 3 of these 12 cytokines or chemokines more than 2-fold. The changes in secretion of monocyte chemoattractant protein 1 (MCP-1) and chitinase-3-like protein 1 (CHI3L1, also known as YKL-40) were validated with ELISA. Further, pirfenidone decreased the secretion of both DKK1 (p=0.006) and OPG (p=0.02) by SpA FLSs stimulated with TGFβ, TNFα, and INFγ, while the concentration of RANKL was below the detection limit of the ELISA assay in all cultures. Finally, pirfenidone inhibited the deposition of hydroxyapatite by osteoblasts in a dose-dependent manner (p=0.0001). This inhibition was partly reversible when removing pirfenidone after the first week of the mineralization assay.

Conclusion: Taken together, pirfenidone inhibited SpA myofibroblast formation and activity and osteoblast mineralization. This encourages further research in using anti-fibrotics as treatment of new bone formation in SpA.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Aberrant regulation of the Wnt pathway is a key element in the pathogenesis of Ankylosing spondylitis (AS). We previously found that miR-29a was significantly upregulated in AS patients.

Methods: We enrolled 45 AS patients and 48 healthy controls. ESR, CRP and HLA-B27 were performed. BASDAI, BASFI, ASDAS and mSASSS were calculated. The levels of miR-29a and mRNA of DKK-1, GSK-3¦Â, ¦Â-catenin, ALP and OC from PBMCs were determined by real-time qPCR. Corresponding protein levels were measured by ELISA. Independent t-test was used to test for the differences between two groups. Correlation analysis was conducted using Spearman¡¯s correlation test. P <0.05 was considered statistically significant. The target prediction of miR-29a was performed. The luciferase activity levels were measured using Promega dual-luciferase reporter assay system. The miR-29a mimic or inhibitor or NC was co-transfected with constructed wt or mut-3¡¯UTR luciferase reporter into HEK293T cells. The miR-29a mimics (50 nmol/L) or inhibitor or NC was co-transfected to hFOB1.19 and MC3T3-E1 cells. The mRNA and protein level of DKK-1, GSK-3¦Â, ¦Â-catenin, OC, ALP, collegen X, Wnt-3a and Runx2 was detected at 48 and 72 hours.

Results: The levels of DKK-1 was significantly higher in AS patients than that in healthy controls, with no correlation with any clinical parameter. No significant difference was observed for other markers.The levels of miR-29a, Dickkopf (DKK)-1, ¦Â-catenin and Runx2 mRNA were significantly higher in AS patients than those in controls ($p<0.05$). In contrast, the levels of Gsk-3¦ÂmRNA was significantly lower in AS patients than that in healthy controls ($p<0.05$). Gsk-3¦ÂmRNA was positively correlated with¦Â-catenin mRNA expression ($p<0.05$) and no other correlation was observed between any other markers ($p>0.05$). Only DKK-1 mRNA expression was negatively correlated with disease course ($p<0.05$) and no other correlation was observed between markers and clinical measurements ($p>0.05$). The luciferase reporter analysis showed that LRP6 was a target of miR-29a. miR29a suppressed LRP6, GSK-3¦Â, DKK-1 expression and facilitated ¦Â-catenin, Wnt-3a, Runx2, OC, ALP, collegen X expression. (Figure 1)

Conclusion: Alteration of bone turnover markers in canonical Wnt pathway was observed in AS which partially explain the complicated mechanism of bone formation. Bioinformatics and ex vivo studies proved that LRP6 is a target gene of miR-29a in AS.

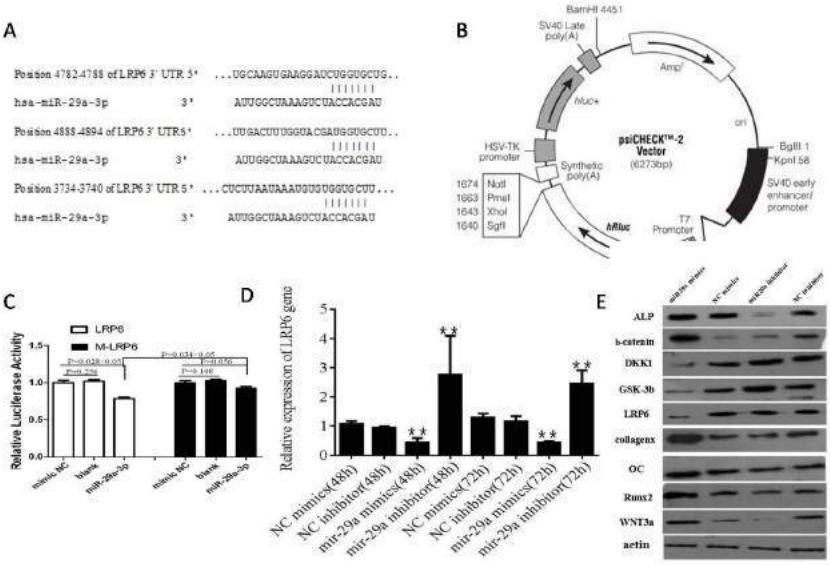

Figure legend: A. The has-miR-29a-3p conserved putative sites of LRP6 3¡¯UTR predicted by TargetScan and miRDB. B. XhoI and Not¢ñ restriction sites of PsicheckTM-2 Vector dual-luciferase miRNA target vector. C. Luciferase reporter result of miR29a mimics or inhibitor transfection to wildtype and mutated LRP6. D. Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Biological DMARDs (bDMARDs) such as adalimumab (ADA), infliximab (IFX), ustekinumab (UST) and secukinumab (SEC) become available and efficacious in patients with psoriatic arthritis (PsA). However, it remains unclear how we can differentially use these bDMARDs to individual patients. We assessed peripheral immune cell

phenotypes in PsA patients treated with bDMARDs and tried to subdivide patients by the lymphocyte phenotypic difference.

Methods: 44 PsA patients with inadequate response to conventional therapy were treated with bDMARDs (IFX 15, ADA 17, certolizumab pegol 1, UST 7, SEC 4 cases) and PASI score, SDAI, DAS28(ESR) were evaluated. Peripheral immune cell phenotypes were assessed by 8-color flow cytometric analysis for human immune system termed by NIH and FOCIS in 20 patients with PsA who showed.

Results: Baseline characteristics of patients with PsA were; mean age 47.7 years, the male/female 27/17, mean disease duration 139.2 months, respectively. All of patients had already been treated with topical therapy, corticosteroid, DMARDs and/or immunosuppressant. Following treatment with bDMARDs, the PASI score, SDAI, DAS28(ESR) were significantly decreased from 8.8/17.7/4.38 at baseline to 3.3/8.6/2.28 at 6 months, respectively, and 29.5 % of patients achieved both SDAI remission and PASI clear at 6 months. No statistical difference in clinical efficacy among bDMARDs was observed. Among $CD4^+$ T cells, although expression of differentiation markers such as CCR7/CD45RA and proportion of Th1 cells were comparable between PsA and HC, activated Th17 cells were significantly higher in patients with PsA than in HC. Contrarily, the proportion of naïve $CD8^+$ T cells were lower, that of central memory $CD8^+$ T cells, effector memory $CD8^+$ T cells, activated $CD8^+$ T cells were significantly higher in patients with PsA than in HC, and the proportion of activated $CD8^+$ T cells correlated with PASI score. In addition, 20 patients with PsA were categorized to 4 different subgroups according to phenotypic difference in $CD4^+CD45RA^-$ T helper subsets: $CXCR3^+CCR6^-CD38^+HLA\text{-}DR^+$ activated Th1 dominant (3 cases), $CXCR3^-CCR6^+$ activated-Th17 dominant (6), $CXCR3^+CCR6^+$ activated-Th1/Th17 high (4), and $CXCR3^-CCR6^-$ activated-Th1/Th17 low (7). After the 6 month-treatment, the proportions of central memory $CD8^+$ T cells, effector memory $CD8^+$ T cells, activated $CD8^+$ T cells, activated Th1 cells and activated Th17 cells were remarkably decreased in patients who showed clinical improvement.

Conclusion: Our study proved that peripheral activated $CD4^+$ helper T cells could divided to 4 patterns; Th1-high, Th17-high, both-high and both-low in patients with PsA. Furthermore, the proportion of activated $CD8^+$ memory T cells and activated Th17 cells was characteristically high, but it was decreased by the treatment with bDMARD, indicating these subsets may contribute to the pathogenesis in PsA. Immunophenotypic analysis is, therefore, useful for evaluation of the therapeutic target and prediction of the response to bDMARDs in patients with PsA.

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory arthritis affecting the sacroiliac (SI) joints and spine causing structural changes seen on clinical radiography. Studies have suggested that NSAID and TNF inhibitor (TNFi) use slow down new bone formation. We evaluated the impact of TNFi treatment on the evolution of radiographic changes in the SI joints in a large and well-characterized long term follow-up cohort and to determine whether TNFi use, over an extended period of time, can have an effect on radiographic change in the SI joints.

Methods: All AS patients satisfying the modified New York criteria prospectively followed, with multiple sets of pelvic radiographs multiple years apart spanning >2 up to >10 years were investigated. Radiographic change and TNFi use in patients with AS and sacroiliitis were assessed. Anteroposterior radiographs of the right and left SI joints were scored by a board certified musculoskeletal radiologist according to the Bath Ankylosing Spondylitis Radiology Index for the spine (BASRI-s). We selected a grade-2 BASRI score change to eliminate concerns associated with reliability for reading a grade-1 score change.

Results: 630 AS patients who met the New York criteria and had at least 2 sets of radiographic SI joint severity data were reviewed. There were 283 patients who initially started with bilateral grade-4 sacroiliitis. Ultimately, 180 patients who initially started either as grade 2 bilaterally or grade-3 on at least 1 side and who could meet these criteria were included in analysis (median follow-up year=3). We conducted multivariable logistic regression model using progression as a dichotomous outcome variable (progressor or non-progressor) to evaluate multivariable associations between TNF-inhibitor use (defined as those who used TNFi for more than 50% of their follow-up period) and SI joint progression after controlling for other factors (including follow-up period, baseline SI joint scores, baseline TNFi use, NSAID index over follow-up period, study sites and clinical/demographic variables such as disease duration, sex, education level, race, current smoking status, subjective disease activity (BASDAI), CRP and comorbidity). Our findings indicate that TNFi use was related to less SI joint progression in AS patients (AOR=0.06, 95% CI 0.004 to 0.99; p=0.0494). In addition, high and low NSAID use, sex, CRP were significantly associated with lesser SI joint progression and could be potential confounders. No significant interaction was found between NSAID and TNFi use.

Conclusion: TNFi use was associated with less radiographic progression utilizing the BASRI scoring system in a large cohort of AS patients who fulfilled NY criteria at entry and were followed, in many cases, for up to and greater than 10 years.

Variable	Adjusted Odds Ratio (AOR) (95% CI)	P

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Th17 plays important role in pathogenesis of AS inflammation, and its main effector, IL-17, was the critical effector on mediating it. Activated of Th17 and IL-17 are both depending on JAK/STAT signal pathway. A cluster of recent papers identify Thunder God Vine as a powerful drug in AS treatment in China, in which Triptolide was demonstrated as the key ingredient in anti-inflammatory. This research aims to explore the role of Triptolide played in Th17 differentiation and AS inflammation by interfering the JAK/STAT.

Methods: 30 AS patients (18-50years) in active stage and 15 healthy controls (18-50years) participated in the experiments. All patients were met with the modified New York criteria(Bath Disease Activity Score>4). PBMCs generated from patients were cultivate with different concentrations of Triptolide for 24 hours (High: 50ng/ml; Medium: 25ng/ml; Low: 12.5ng/ml). The supernate level of IL-17 was detected by ELISA, the protein levels of JAK2/STAT3 signal pathway were detected by Western blotting, and the mRNA level of RORc was detected by quantitative PCR (qPCR).

Results: Compared with controls, the protein expression level of pJak2,pSata3,RORc was higher in AS groups than in normal ones(**p<0.001£©. After the intervention of the triptolide, protein expression level of pJak2,pSata3,RORc was lower than in AS groups.(#p<0.05). (Figure1)

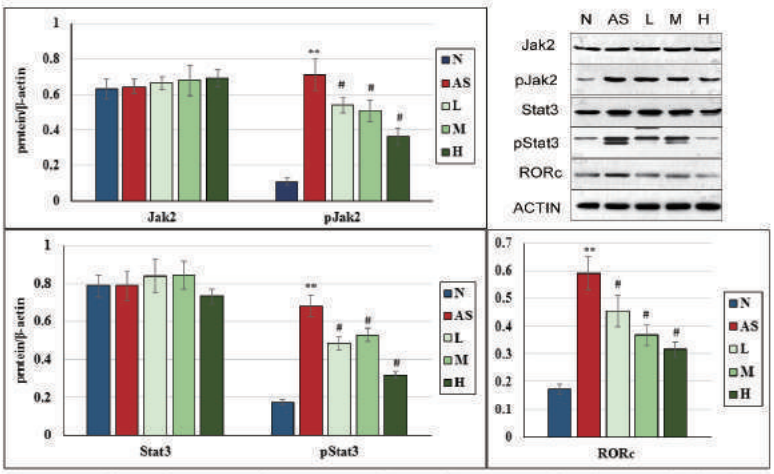

Figure1 Effect of the level of Jak2,pJak2,Stat3,pStat3 and RORc in PBMC of active AS patients after taking triptolide

It showed that protein expression level and phosphorylation level of pJak2,pSata3,RORc was higher in AS groups than in normal ones(**p<0.001). After the intervention of the triptolide,protein expression level and phosphorylation level of pJak2,pSata3,RORc was lower than in AS groups.(#p<0.05).

The transcriptional level of RORc mRNA was higher in AS groups than normal (**p<0.001£©.After the intervention of the triptolide, the transcriptional level of RORc mRNA was lower than in AS groups.(#p<0.05) (Figure2).

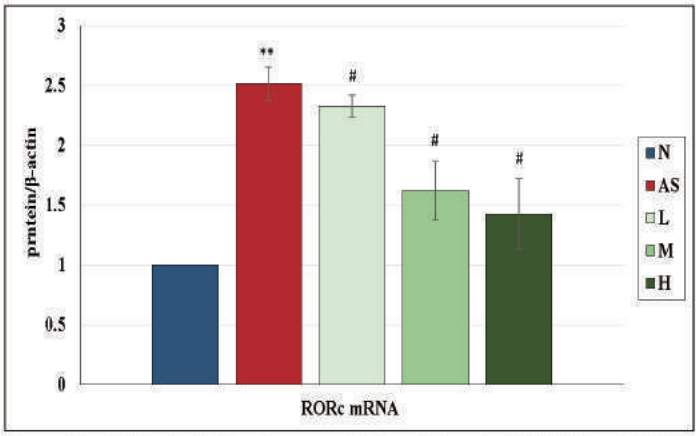

Figure2 Effect of the transcriptional level of RORc mRNA in PBMC of active AS patients after taking triptolide

It showed that the transcriptional level of RORc mRNA was higher in AS groups than in normal ones(**p＜0.001）.After the intervention of the triptolide,the transcriptional level of RORc mRNA was lower than in AS groups.(#p＜0.05).

The level of IL-17 in active AS patients was higher than normal; (**p<0.001);after the intervention of the triptolide,the levels of IL-17 was lower than AS groups .

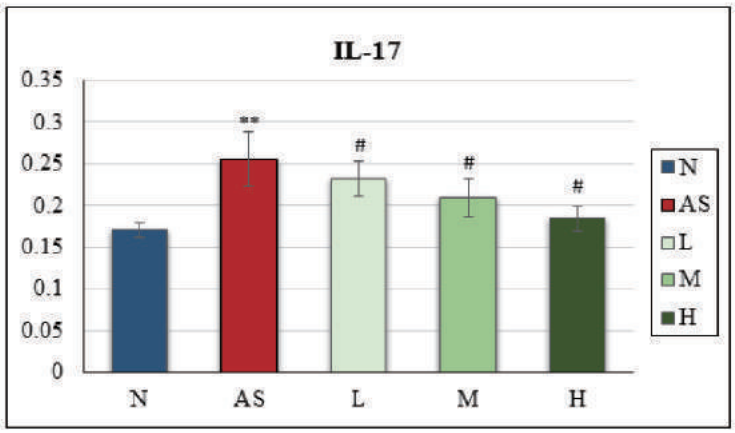

Figure3 Effect of the level of IL-17 in active AS patients after taking triptolide

It showed that the level of IL-17 was higher in AS groups than in normal ones(**p＜0.001）.After the intervention of the triptolide,the level of IL-17 was lower than in AS groups.(#p＜0.05).

(#p<0.05) (Figure3).

Conclusion: Our findings showed the suppression of activated JAK2/STAT3 signal pathway and the depression of pJAK2 and pSTAT3 expression by Triptolide. It might be one of the inhibitive factor modulate RORc transcription on one hand, and could be an depressor in IL-17 secretion directly on another. Which suggesting Triptolide may probably regulates Th17 differentiation through JAK2/STAT3 signal pathway. That¡¯s one of molecular mechanism which it plays in relieving AS inflammation. These exciting findings have broad implications for the inhibitor of JAK/STAT signal pathway in AS targeted therapy.

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory rheumatic diseases (IRDs) are associated with accelerated atherosclerosis, which progression is related to inflammation (1). One of the first stages in atherogenesis is endothelial dysfunction (ED). Therefore, we aimed to examine the effects of methotrexate (MTX) and anti-tumor necrosis factor (anti-TNF) treatment (with or without MTX co-medication) on endothelial function (EF) in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS).

Methods: From the data registry from PSARA (2) (an observational study), we evaluated patients with RA (n=64), PsA (n=30) and AS (n=20) who completed a 6 month follow-up after initiation of anti-rheumatic therapy due to active disease. Only patients with clinical indication of either MTX monotherapy or anti-TNF with or without MTX co-medication (anti-TNF±MTX) were included. Among patients with peripheral arthritis (i.e., all RA and PsA patients), all patients starting on anti-TNF therapy had been previously unsuccessfully treated with MTX, while in patients with axial affection only (i.e., all AS), anti-TNF could be used as the first as well as later disease modifying anti-rheumatic treatment. EF was assessed by finger plethysmography (RH-PAT): Reactive hyperemia index (RHI) <1.67 was considered as ED. In patients with ED at baseline (n=39), we searched for change in EF after 6 weeks and 6 months of anti-rheumatic therapy.

Results: In all IRD patients with ED, RHI improved from baseline to 6 weeks (mean change=0.56, $p<0.005$) and 6 months (mean change=0.46, $p<0.005$). RHI improved at 6 weeks and 6 months in all three diagnoses, but the differences were statistically significant only for RA at 6 weeks and 6 months, and for PsA at 6weeks, with the greatest improvements in RA. The effect of MTX and anti-TNF±MTX at 6 weeks was similar. However, at 6 months, RHI improved more in the MTX group than in the anti-TNF±MTX group (mean change 0.74 vs. 0.24; $p=0.010$), and this difference remained statistically significant after adjustments for potential confounders including traditional cardiovascular risk factors and markers of disease activity.

Conclusion: Treatment with MTX and anti-TNF±MTX appears to relatively fast improve EF in IRD patients with ED, independently of improvement in disease activity. After 6 months, the EF improvement was more pronounced in the MTX users than in the anti TNF±MTX users. Among other factors, this might be due to a better effect of MTX on the vasculature,

or due to different patient populations. For example, RA and SpA patients starting with anti-TNF were more likely to have a longer and therapy resistant disease than patients starting with MTX.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory arthritis that occurs in a subgroup of patients suffering from psoriasis. Assessment of PsA disease activity currently mainly rely on clinical examination of the patient, global scales of pain and activity, and the health assessment questionnaire. However, as in other inflammatory arthritides, there is a scarcity of biomarkers for disease activity, with erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) being relatively unspecific and within normal limits in many occasions. Serum complement C3 component has recently been suggested as a potential biomarker for disease activity in PsA. **Objective:** To explore the association of complement C3 component with disease activity in PsA.

Methods: We included 36 outpatients fulfilling the CASPAR classification criteria for PsA in our study. Patients were examined at baseline (n = 36), at week 12 (n = 22), and at week 24 (n = 13). Additionally to routine medical examinations, each patient received a full workup including patients and physicians global assessment (VAS), amount of pain (VAS), 66/68 joint count, skin involvement (% of body surface area), enthesitis assessment (Leeds Enthesitis Index), dactylitis count, the SF-36 questionnaire and a blood examination (white blood count, CRP, ESR, Complement C3c, Complement C4). As a surrogate marker for disease activity measurement we calculated the Psoriatic ArthritiS Disease Activity Score (PASDAS). C3c and C4 complement were measured by nephelometry out of heparin-plasma samples of the patient. We performed correlation analysis of the C3c and C4 components with individual markers of disease activity (see above) and then performed unvariable and adjusted regression analysis on the PASDAS. The statistical analysis was conducted using SPSS statistics.

Results: Pearson's correlation showed a significant linear correlation of C3c ($p = 0.001$, $r = 0.372$) and C4 ($p = 0.048$, $r = 0.236$) with the patients PASDAS (see table for individual associations of PsA manifestations). In regression analysis, after correction for age, BMI and duration of disease, the correlation of C3c and PASDAS remained significant ($p = 0.004$, R squared = 0.155), while there was no statistical significance in the correlation of C4 and PASDAS.

Conclusion: In this pilot study in patients with PSA, we observed a significant and independent association of serum C3c with overall disease activity (PASDAS). Looking at individual measures of PsA manifestations, associations for serum C3c were seen for patient global assessment, physicians global assessment, swollen joint count, skin involvement, ESR, CRP and SF-36 physical component score. These findings warrant further investigation of the usefulness of C3c complement component in disease activity monitoring of PsA.

JAK STAT Kinase Cascade Regulates the IL-23/IL-17 Cytokine Axis in Psoriatic Arthritis

Siba P. Raychaudhuri[1] and Smriti K. Raychaudhuri[2], [1]Davis, CA, [2]Rheumatology/Immunology, VA Sacramento Medical Center, Davis, CA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Aberrant activation of IL-23/IL-17 cytokine axis is a dominant pathology in the psoriatic disease. IL-23 regulates expansion/maintenance/functional maturation of Th17 cells. Th17 cells along with their signature cytokines IL-17 and IL-22 is now believed to play a critical role in the pathogenesis of psoriatic arthritis (PsA). Because Tyk2 and JAK2 is recruited to IL-23 receptor it is expected that JAK-STAT mediated signaling system is important in PsA. We hypothesized- (i) JAK STAT signaling system regulates the Th17 cells in PsA and (ii) that Tofacitinib an inhibitor of Jak-1,

Jak-2 and Jak-3 targets the Th17 cells by inhibiting the IL-23 induced JAK STAT signaling system.

Methods: • PBMC and synovial mononuclear cells (SFMC) from PSA patients (n=15) and PBMC from age/sex matched normal individuals (n=15) were collected • All patients had an active disease and were not on DMARDS or biologics • rIL-23 induced activated IL-17+ T cells were generated and evaluated as per our earlier reports (Raychaudhuri SP, et al. Mol Cell Biochem. 2012 ;359:419-29). • Cells were cultured with and without Tofacitinib (50nM) • Western blot studies were done to indentify Jak2/p-Jak2, Tyk2/p-Tyk2, stat3/p-stat3, stat4/p-stat4 in the sorted activated CD3+ T cells. • Hi-D FACS studies were done to identify the activated memory CD4+ CD11a+CD45RO+IL-17+ T cells and CD8+CD11a+CD45RO+IL-17+ T cells in SFMC/PBMC of PsA and PBMC of normal individuals.

Results: In both PsA and controls sorted activated CD3+ T cells in presence of IL-23 demonstrated activation of the following JAK-STAT signaling molecules: Jak2, Tyk2, and stat3 but stat4 activation was substantially weaker. Further we noticed Tofacitinib markedly inhibited phosphorylation of Jak2 and STAT-3 the signaling proteins induced by IL-23. HiD-FACS analysis of the activated CD3+T cells in PsA patients demonstrated that IL-23 induced marked upregulation of IL-17 in the memory T cells (CD11a+CD45RO+) (Fig 1). We noticed that SFMC and PBMC treated with rIL-23 in PsA patients had 30±4.5% and 18±3.8% activated memory CD4+IL-17+ T cells respectively compared to 5± 0.7% in healthy persons ($p<0.001\%$). Further we noticed that CD4+ CD11a+CD45RO+IL-17+ T cells were 5±2% ($p<0.001\%$) (Fig 1) in cells treated with Tofacitinib. Tofacitinib significantly inhibited proliferation of these CD4+CD11a+CD45RO+IL-17+ T cells ($p<0.01\%$) (Fig 1).

Conclusion: · In PsA the key immune response that is the generation of the pathologic CD4+ CD11a+CD45RO+IL-17+ T cells and their proliferation is regulated by the JAK-STAT signaling system. · JAK STAT signaling regulates the Th17 cells in PsA and this may be one of the mechanisms of action of Tofacitinib. These observations provide new insight about the disease process of PsA and its management.

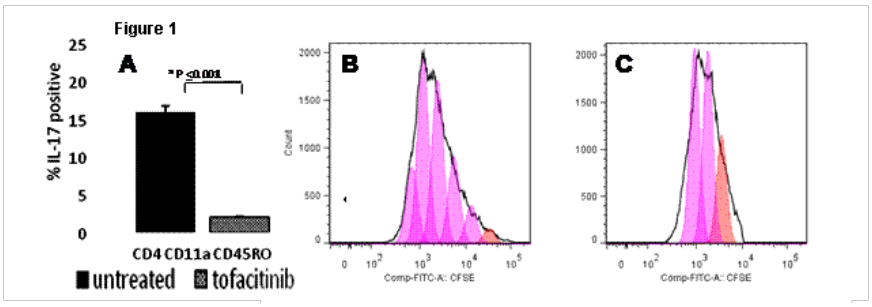

Figure 1. **A.** HiD FACS studies of the PBMC from active ankylosing spondylitis patients demonstrated that- (i) rIL-23 induced marked upregulation of IL-17 in the memory T cells (CD11a+CD45RO+) and that (ii) **rIL-23 induced IL-17 expression could be markedly inhibited by** Tofacitinib ($p<0.001$). **B and C.** CFSE dilution study demonstrated less number of generations and less numbers of CD4+ CD11a+CD45RO+IL-17+ T cells on day 5 in PBMC cultured with tofacitinib (C) compared to cells cultured without Tofacitinib (B).

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Little is known about factors associated with persistency of TNFi use among biologic-naïve and biologic-experienced Psoriatic Arthritis (PsA) patients in routine clinical practice in the US. The purpose of this analysis/study is to identify predictors of persistence with TNFi in biologic naïve (bio-naïve) and biologic experienced (bio-experienced) TNFi initiators in the US Corrona registry.

Methods: We identified all PsA patients initiating a TNFi with at least 1 follow-up rheumatology visit from October 2002 to March 2013. Patients were followed until the earliest of: discontinuation of the TNFi, initiation of another biologic/small molecule therapy or last follow-up visit; such that patients who remained on original TNFi were defined as persistent and patients that discontinued or switched TNFi were defined as non-persistent. Patient demographic and clinical characteristics at index date (TNFi initiation) were evaluated. Kaplan-Meier curves evaluated time to discontinuation/switch of TNFi, with censoring for all patients with ≥ 1year gap between visits. The log rank test assessed differences in persistency between bio-naïve versus bio-experienced patients. Cox proportional hazards models (allowing for factors to vary over time [time varying]) were performed to identify predictors of persistency, controlling for potential confounders; models were completed, separately, for the bio-naïve and bio-experienced subgroups.

Results: A total of 1241 patients initiated a TNFi during the study period (at initiation 549 [44%] bio-naïve; 692 [56%] bio-experienced). Median time to discontinuation was 32 months (95% CI 27-37) in bio-naïve patients and 23 (95% CI 18-29) in bio-experienced TNFi initiators which was significantly different based on the log rank test. Moderate or high disease activity based on Clinical Disease Activity Index (CDAI) was associated with being non-persistent within both subgroups, although the level of effect appeared stronger in bio-naïve PsA patients (Table). Bio-naïve patients with higher comorbidity burden had a higher, although not statistically significant, risk of being non-persistent. In contrast, bio-experienced patients with prior treatment with a conventional synthetic disease modifying anti-rheumatic drug (csDMARD) or higher degree of skin disease had higher risks of being non-persistent. Within both groups, patients with shorter disease duration were more likely to be persistent.

Covariates*	**Cox Proportional Hazards Models****	
	Biologic-Naïve **HR (95% CI)**	**Biologic-Experienced** **HR (95% CI)**
Modified Charlson comorbidity index***		
Presence of 1 comorbid condition (vs. none)	1.32 [0.81; 2.15]	0.84 [0.60; 1.19]
Presence of 2 or more comorbid conditions (vs. none)	2.50 [0.99; 6.29]	0.85 [0.47; 1.57]
PsA characteristics		
Disease duration	0.96 [0.92; 0.99]	0.99 [0.97; 1.00]
Prior treatment with a csDMARD	1.18 [0.78; 1.79]	1.40 [1.04; 1.89]
Concomitant prednisone use	1.42 [0.72; 2.83]	1.48 [0.99; 2.23]
Disease activity (time varying)		
Patient reported pain	1.00 [1.00; 1.01]	1.00 [0.99; 1.01]
Moderate disease activity (vs. LDA)	2.50 [1.47; 4.27]	1.62 [1.13; 2.32]
High disease activity (vs. LDA)	2.15 [1.11; 4.13]	1.60 [1.01; 2.53]
Physician global skin assessment	1.18 [0.74; 1.87]	1.38 [1.01; 1.87]

*PsA – psoriatic arthritis, LDA-low disease activity **Adjusted for female gender, race, age, BMI, and smoking status. ***Excludes PsA; dementia, kidney disease, hemiplegia and AIDS not included

Conclusion: Predictors of persistency differed in those who were bio-naïve versus bio-experienced when initiating TNFi.

Disease activity appeared to be a stronger predictor of non-persistence in those who were biologic-naïve as compared to those who were experienced.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Apremilast (APR) is an oral phosphodiesterase 4 inhibitor that helps regulate the immune response that causes joint inflammation and other manifestations of psoriatic arthritis (PsA), including skin disease. Primary findings from the PALACE 4 study (NCT01307423) demonstrated greater efficacy with APR vs. placebo in disease-modifying antirheumatic drug (DMARD)-naïve patients with active PsA.[1,2] We describe the long-term efficacy and safety of APR monotherapy in DMARD-naïve patients in PALACE 4 for up to 156 weeks.

Methods: Patients were randomized (1:1:1) to placebo, APR 30 mg BID (APR30), or APR 20 mg BID (APR20). Patients whose swollen and tender joint counts (SJC and TJC) had not improved by ≥20% at Week 16 were considered non-responders and were required to be re-randomized (1:1) to APR30 or APR20 if they were initially randomized to placebo, or continued on their initial APR dose. At Week 24, all patients remaining on placebo were re-randomized to APR30 or APR20. Double-blind treatment continued to Week 52 with open-label APR for up to 4 additional years.

Results: A total of 527 patients were randomized and received ≥1 dose of placebo (n=176), APR30 (n=176), or APR20 (n=175). Of the patients entering the third year of therapy, 88.0% (272/309) completed the Week 156 visit. At Week 52, 58.0% (119/205) of patients receiving APR30 and 55.4% (107/193) receiving APR20 achieved a 20% improvement in modified American College of Rheumatology (ACR20) response (Table). At Week 156, rates of improvement in PsA signs and symptoms and physical function were sustained, as shown by modified ACR20/ACR50/ACR70 responses, mean percent change in SJC/TJC, mean change in Health Assessment Questionnaire-Disability Index (HAQ-DI) score, proportion of patients with HAQ-DI exceeding the minimal clinically important difference (MCID) ≥0.30 threshold, achievement of Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) of 0 and dactylitis count of 0, and 75% and 50% reduction from baseline Psoriasis Area and Severity Index (PASI-75 and PASI-50) responses (Table). During Weeks >104 to ≤156, the most common adverse events (AEs) among APR-exposed patients were upper respiratory tract infection (3.2%) and nasopharyngitis (3.9%); serious AEs occurred in 5.2% of APR patients, and no opportunistic infections occurred. In

general, no change in the types of AEs and no increase in the incidence and severity of AEs were seen with longer-term exposure.

Conclusion: Over 156 weeks, APR monotherapy demonstrated sustained response and improvements in PsA signs and symptoms, including SJC, TJC, enthesitis, dactylitis, physical function, and psoriasis. APR continued to demonstrate an acceptable safety profile and was generally well tolerated. **References:** 1. Edwards et al. *Arthritis Rheum.* 2014;66(11 Suppl)S694-5. Abstract 1572. 2. SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Marine n-3 polyunsaturated fatty acids (PUFA) have anti-inflammatory effects and may be useful in the treatment of psoriatic arthritis. The effects of n-3 PUFA on inflammatory parameters and use of analgesics were examined in patients with psoriatic arthritis.

Methods: Patients with established psoriatic arthritis were included in this randomized, double blind, placebo-controlled study. Patients received the capsules of 3 g n-3 PUFA/d or 3 g olive oil/d for a 24-week period. Clinical status and use of analgesics were assessed as well as leukotriene formation were quantified at baseline and study end.

Results: One hundred and forty-five patients were randomised and 133 completed the study. After 24 weeks of supplementation participants in the n-3 PUFA group showed a significantly higher formation of leukotriene B_5 ($p < 0.001$) and 5-HEPE ($p < 0.001$) and a significantly lower formation of leukotriene B_4 ($p = 0.004$) compared to controls. Nonsteroidal anti-inflammatory drugs and paracetamol consumption was significantly reduced in the n-3 supplemented group compared to controls (p = 0.04). The n-3 PUFA group also had a significant reduction in disease activity score, tender joint count, enthesitis score and psoriasis area and severity index.

Conclusion: The present study, demonstrated a reduction in the formation of the inflammatory leukotriene B_4, increase in the less inflammatory leukotriene B_5 and reduction in use of nonsteroidal anti-inflammatory drugs and paracetamol after 24 weeks of n-3 PUFA supplementation. The results suggest that n-3 PUFA supplementation is an attractive adjunctive treatment for patients with psoriatic arthritis. Trial registration: NCT01818804

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis (PSO) and psoriatic arthritis (PsA) are chronic inflammatory diseases which are associated with increased cardiovascular (CV) diseases. Observational studies have found that TNFα inhibitors (TNFi) are associated with reduced CV events in PSO, however, the impact of TNFi on subclinical indices of CV disease has not been assessed prospectively.

Methods: We performed a two-stage study to understand the effect of TNFi on subclinical CV disease. We first assessed carotid plaque area by ultrasound in PSO and PsA patients (n=319, 66.4% PsA and 33.6% PSO only), who underwent baseline evaluation and follow-ups every 6-12 months, including assessment for CV risk, joint and skin disease and medications. Patients using biologic agents other than TNFi were excluded. Carotid arteries were assessed by ultrasound to measure total plaque area (TPA) at baseline and after 2-3 years. The average annual progression rate (APR) of atherosclerosis [(Follow-up TPA – baseline TPA)/ total years between visits] was the outcome of interest. Due to a statistically significant interaction between sex and TNFi therapy, we assessed APR for men and women separately. The findings from stage 1 led us to create an inception cohort to assess TNFi effect on vascular inflammation in PsA. In stage 2 we studied vascular inflammation using FDG PET/CT in PsA patients on TNFi (n=21) and age and sex matched PsA patients not on any biologics (n=13). This sample underwent clinical phenotyping and FDG PET/CT scans at baseline and 1 year to assess vascular inflammation, measured as target-to-background ratio (TBR). In both studies, statistical analyses included multivariable regression adjusting for CV risk factors and statins, and performing sex-TNFi therapy interaction.

Results: In the first stage, of the 319 patients 56.3% were men and the mean age was 54.5. 61.7% of the patients had at least one carotid plaque at baseline. At follow-up (mean duration 2.9 years), TPA progressed in 46% patients. There was no difference in TPA progression between PsA and PSO (p=0.73). Men had a significantly higher APR compared to women (2.4 vs. 0.6 mm^2, p<0.001). TNFi associated with a reduced APR (β=-2.25, 95% CI -3.45, -1.05, p<0.001) in men, beyond traditional CV risk, statins and DMARDs. However, there was no association between TNFi and APR in women (p=0.71). In the second stage, the mean age was 52 (52% men) with moderate to severe vascular inflammation by FDG PET/CT (average TBR 1.89). At 1 year, patients on TNFi had a reduction in TBR (mean±SEM 1.9±0.06 vs. 1.76±0.05, p=0.03), despite no major change in CV risk factors. However, those not on TNFi had no significant change in their TBR (1.86±0.06 vs. 1.89±0.07, p=0.32) and no difference between men and women was observed by TNFi treatment.

Conclusion: TNFi treatment was associated with reduced progression of carotid plaque and an improvement in vascular inflammation in a large two-stage study of PSO and PsA. This association was stronger in men than women suggesting a role for gender in CV disease progression. Our findings support the importance of TNFi treatment in potentially reducing CV risk; however, large randomized trials are needed to confirm these findings.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Although spinal involvement has been well studied in ankylosing spondylitis,[1] very few studies in psoriatic arthritis (PsA) have characterized patients with axial involvement. The objective of this analysis was to understand the prevalence and describe the baseline characteristics of PsA patients with and without axial involvement in the US-based Corrona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) registry.

Methods: This cross-sectional descriptive study included all patients with PsA enrolled in the Corrona PsA/SpA registry between March 2013 and March 2016 with non-missing data on axial involvement, defined as having a physician-reported presence of spinal involvement at enrollment, or an MRI or x-ray showing sacroiliitis. Descriptive analyses of patient demographics, clinical measures, patient-reported outcomes and treatment characteristics were reported at the time of enrollment for patients with vs without axial involvement. Statistical comparisons between subgroups were evaluated using *P* values from *t*-tests for continuous variables and chi-squared tests for categorical variables.

Results: As of March 2016, there were a total of 1530 patients with PsA in the Corrona PsA/SpA registry who had non-missing data on physician-reported axial involvement, including 192 patients (12.5%) with axial involvement and 1338 patients (87.5%) without axial involvement. Both subgroups were similar with regards to sex, race, body mass index, disease duration, overall presence of dactylitis and prevalence of most comorbidities (e.g., cardiovascular disease, any cancer, diabetes and serious infection). However, patients with axial involvement were younger (50.4 vs 54.4 years) and significantly more likely to have enthesitis (20.7% vs 19.2%), a history of depression (22.9% vs 12.6%) and biologic use (66.1% vs 54.3%) at enrollment compared to patients without axial involvement. Patients with axial involvement were also more likely to have moderate/severe psoriasis (body surface area > 3%) at enrollment compared with patients without axial involvement, and had worse disease as measured by nail psoriasis, enthesitis counts, achievement of minimal disease activity, AS disease activity and functional index scores, C-reactive protein levels and patient-reported outcomes (**Table**).

Conclusion: Data from the Corrona PsA/SpA registry showed that patients with PsA and axial involvement were more likely to have moderate/severe psoriasis with significantly higher disease activity at the time of registry enrollment compared to those without axial involvement. These findings demonstrate the overall impact of axial involvement on disease activity and highlight the importance of monitoring patients with PsA for signs of axial symptoms or spinal involvement on imaging.

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the rates of serious infections (SI) in psoriasis (PsO) pts with psoriatic arthritis (PsA) from PSOLAR, & assess risk with biologic therapy.

Methods: PSOLAR, an international, disease-based, observational study in which pts eligible for, or receiving conventional systemic & biologic agents for PsO are followed prospectively. Characteristics&cumulative incidence rates of SIs occurring within 91 days of biologic administration, for pts who reported PsA, including a subset with PsA confirmed by a joint-specialist are summarized. Cohorts were defined as & attribution was based on treatment exposure in the following order(regardless of sequence & duration):(1) ustekinumab (UST) (2)other sponsor biologic (primarily infliximab [IFX]) (3)non-sponsor biologic (primarily adalimumab/etanercept [ADA/ETN]),&(4)non-biologic therapies(NB) (including immunodulators(IMMs)[eg MTX, cyclosporine], phototherapy,&topical therapy). Exposure to any therapy higher in the order precluded inclusion in the lower cohorts. Multivariate analyses using Cox hazard regression were used to identify factors, including treatments, associated with time to first SI(using exposure within 91 days for biologics vs no biologic use]&for IMMs vs no IMM use]),without use of attribution rules.

Results: As of Aug 23, 2015, PSOLAR was fully enrolled with 12090 pts(48870 total pt-yrs [PY] of follow-up).Number of pts with reported PsA was overall 4315: 1551 UST, 754 IFX, 1650 ADA/ETN, 360 NB; of these pts, 1719 had confirmed PsA(689 UST, 346 IFX, 566 ADA/ETN, 118 NB). Baseline demographics & medical history were generally balanced across cohorts & were comparable to confirmed PsA subset; however, in overall PsA sub-group, more pts in NB cohort were >65yrs of age (UST9.9%, IFX14.2%, ADA/ETN12.4% , NB26.4%) & had a medical history of significant infections(UST29%, IFX35.3%, ADA/ETN28.7%, NB21.7%).In the overall PsA subgroup(18 152 PY of follow-up), rates of SIs/100 PY were:UST1.29, IFX3.13, ADA/ETN2.47,&NB2.29. Among the confirmed PsA subset, rates/100 PY: UST 1.27, IFX 2.64, ADA/ETN 2.42, NB 1.95. In the overall PsA subgroup, age, smoking, history of significant infection, diabetes, & use of biologics other than UST(as a combined group) were associated($p<0.05$) with increased risk for SI, no increased risk was observed with UST or with IMMs.In pts with confirmed PsA, a history of significant infections&use of biologics other than UST(as a combined group) were significantly associated($p<0.05$) with increased infection risk;UST&IMMs were not associated.Inherent bias with respect to observational data may apply. Variability in size&clinical features was noted among treatment groups. Incidence rates are not adjusted for differences. Biologics other than UST were not evaluated individually in statistical analyses.

Conclusion: Unadjusted rates of SIs showed general agreement between the 2 PsA subsets with numerically higher rates for IFX&ADA/ETN. Although some variability was noted in risk factors for 2 PSA groups(overall&confirmed), a history of significant infection & use of biologics other than UST (as a combined group) were found to be associated with increased risk for SIs for both groups. An increased risk was not observed with IMMs in comparison with no IMMs in either PSA group. Similarly, an increased risk was not observed with UST individually or in combination with other biologics in either PsA group.

SESSION INFORMATION

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To describe characteristics & potential risk factors(including treatment exposure) for all-cause mortality & malignancies (excluding NMSC) in psoriasis (PsO) patients (pts) with psoriatic arthritis (PsA) from PSOLAR.

Methods: PSOLAR is an international, disease-based, observational study in which pts eligible for or receiving conventional systemic & biologic agents for PsO are followed prospectively. Characteristics & adverse events for pts who reported PsA, including a subset with PsA confirmed by a joint-specialist are summarized. For characteristics & incidence rates, the cohorts were defined as & attribution was based on treatment exposure prior to/during registry in the following order(regardless of sequence & duration):(1)ustekinumab(UST) (2)other sponsor biologic(primarily infliximab[IFX])(3)non-sponsor biologic(primarily adalimumab/etanercept [ADA/ETN]),&(4)non-biologic therapies(NB)(including immunomodulators(IMM)[eg.MTX], phototherapy&topical therapy). Exposure to any therapy higher in the order precluded inclusion in the lower cohorts. Multivariate analyses using Cox hazard regression(without attribution bias)were used to identify factors associated with time to first malignancy&mortality[compared to no biologic use]&for IMM [compared to no IMM use].

Results: As of Aug 23, 2015, PSOLAR is fully enrolled with 12090 pts(48870 total pt-yrs [PY] of follow-up). Overall, 4315 pts reported having PsA:1551 UST, 754 IFX, 1650 ADA/ETN, 360 NB;of these, 1719 had confirmed PsA(689 UST, 346 IFX, 566 ADA/ETN,118 NB). Baseline demographics & medical history were generally balanced across cohorts; however, in overall PsA subgroup, more pts in NB cohort were >65yrs of age&had a medical history of cancer. In overall PsA subgroup, cumulative incidence rates/100PY for all-cause mortality: UST0.34, IFX0.37, ADA/ETN0.57, NB0.75; in statistical analysis: age, history of cardiovascular disease, history of diabetes&smoking were associated with increased risk of mortality($P<0.05$). Cumulative incidence rates/100PY for malignancy:UST0.57, IFX0.71, ADA/ETN0.60,& NB0.96. Statistical analysis identified the following significant($p<0.05$) risk factors for malignancy:severity of PsO, age, smoking,&history of malignancy. For confirmed PsA subset, cumulative incidence rates/100PY for all-cause mortality: UST0.29, IFX0.37, ADA/ETN0.44, NB0.44; age & smoking were associated with increased risk of mortality, Cumulative incidence rates/100PY for malignancy: UST0.53, IFX0.66, ADA/ETN0.96, NB 1.10;age was the only significant factor associated with increased risk of malignancy($p=<0.05$). Inherent bias with observational data may apply. Variability in group size & clinical features was noted.Incidence rates are not adjusted for differences in demographics & disease characteristics (adjustment for such key factors are included in statistical analyses). Statistical analyses interpretation may be limited due to number of deaths in subset of confirmed PSA (24).

Conclusion: Unadjusted rates of all-cause mortality & malignancies for biologics were generally comparable among both PsA subsets with the exception of generally numerically higher rates in pts in NB cohort. The common risk factors associated with mortality for the overall & confirmed PsA subsets were age & smoking; age alone was the common risk factor associated with malignancy. Biologics & IMM use were not associated with increased risk of mortality or malignancy.

Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Ixekizumab (IXE) is a high-affinity monoclonal antibody that selectively targets interleukin-17A. In a phase 3 study, IXE was superior to placebo (PBO) in achieving ACR20 responses at Week (Wk) 24 in biologic DMARD-naïve (bDMARD-naïve) PsA patients[1]. The objective of this analysis was to explore the association of early skin improvement with ACR responses among IXE-treated patients with both PsA and psoriasis (Ps).

Methods: In a phase 3, multi-center, double-blind randomized trial (SPIRIT-P1; NCT01695239), 417 bDMARD-naïve patients with active PsA were randomized to receive up to 24 wks of treatment of PBO (N=106), adalimumab 40 mg (ADA; active reference arm) once every 2 wks (Q2W; N=101), or IXE 80 mg Q2W (N=103) or Q4W (N=107) following an 160 mg initial dose at Wk 0. In PsA patients with moderate-to-severe Ps (≥3% body surface area [BSA]), ACR and Psoriasis Area and Severity Index (PASI) responses were analyzed up to Wk 24. Patients were demarcated into the following categories based on percent improvement from baseline: PASI:<50, PASI:50 to <75, PASI:75 to <90, and PASI:90 to 100. Missing ACR and PASI responses were imputed using non-responder imputation (NRI) and last observation carried forward (LOCF) methods, respectively. Logistic regression model was utilized to compare ACR response across PASI improvement categories.

Results: Of the 417 PsA patients enrolled, 267 patients (69.5%) had ≥3% BSA at baseline. In IXE treated patients (Q2W and Q4W combined; N=132), patients with skin improvement of PASI≥50 at Wk 4 had greater ACR20/ACR50/ACR70 responses at Wk 24 than patients who had a PASI<50 response at Wk 4 (see Figures). Similar observations were made in patients with ≥10% BSA (data not shown). For IXE- and ADA-treated patients, greater PASI improvement by Wk 24 paralleled greater ACR responses at Wk 24 (See Figures; data not shown).

Conclusion: In PsA patients with moderate-to-severe Ps, greater improvement of psoriatic lesions at Wk 24 of biologic treatment was associated with greater reductions in PsA disease activity as assessed by ACR responses. In IXE treated patients, early PASI responses were predictive of ACR responses at Wk 24. 1. Mease et al. ACR/ARHP Annual Meeting 2015; [abstract 977]

SESSION INFORMATION
Session Date: Monday, November 14, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: PsA is a chronic immune-mediated inflammatory disease associated with psoriasis, peripheral arthritis, enthesitis, dactylitis, and spondylitis. Ixekizumab (IXE) is an IgG4 mAb that binds with high affinity and specificity to the proinflammatory cytokine IL-17A. Data are presented for the phase 3 trial (SPIRIT P1) with IXE treatment of patients (pts) with active PsA. The objective was to evaluate the efficacy and safety of IXE when used alone or in combination with concomitant conventional DMARDs (cDMARDs).

Methods: A total of 417 bDMARD-naive adult pts were randomly assigned 1:1:1:1 to subcutaneous administration of 80-mg IXE every 4 wks (Q4W) or every 2 wks (Q2W), each starting with a 160-mg dose at Wk 0; adalimumab (ADA) 40 mg Q2W (active comparator); or placebo (PBO) during the Double-Blind Treatment Period (DBTP; Wks 0-24). Of these pts, 267 were receiving a concomitant cDMARD at baseline, 149 were not, and 1 did not receive study drug; pts were stratified by cDMARD use, and were to remain on their cDMARD through the DBTP. At Wk 24, efficacy was evaluated by ACR response; and progression of structural damage was assessed by the modified Total Sharp Score (mTSS). Safety assessments included the percentage of pts experiencing treatment emergent adverse events (TEAEs), serious adverse events (SAEs), and discontinuations due to adverse events (AEs). Efficacy analyses were conducted on the Intent to Treat Population, defined as all randomly assigned pts; safety analyses were conducted on the Safety Population, defined as all randomly assigned pts who received at least 1 dose of study drug. Fisher's test was used for treatment comparisons in ACR and AE data, and an analysis of covariance model was used for mTSS data. Missing values were imputed by nonresponder imputation for ACR data and by linear extrapolation for mTSS data.

Results: At Wk 24, compared with pts receiving PBO, significantly more pts receiving IXEQ4W or IXEQ2W (with/without concomitant cDMARD) achieved ACR20/50/70 responses (see Table for ADA results). Pts receiving IXEQ2W (with/without concomitant cDMARD) or IXEQ4W or ADA (with concomitant cDMARD) showed significantly less progression in mTSS from baseline compared with pts receiving PBO (Table). No treatment-by-subgroup effects were observed for ACR20/50/70 or mTSS (Table footnotes). In pts receiving concomitant cDMARDs, significantly more pts receiving IXE or ADA experienced ≥1 TEAE, compared with pts receiving PBO; the percentages of pts with SAEs or discontinuations due to an AE were comparable among treatment groups (Table).

Conclusion: IXE demonstrated efficacy in improvement of PsA signs and symptoms and structural inhibition in bDMARD naive pts with/without concomitant cDMARD use. With concomitant cDMARD use, although significantly more pts receiving IXE or ADA experienced ≥1 TEAE, compared with pts receiving PBO, the frequency of SAEs and discontinuations due to an AE were comparable among all treatment group.

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: PsA, a chronic immune-mediated inflammatory disease, can be progressive and destructive, resulting in physical deformities, impaired function, decreased quality of life, and increased mortality. Ixekizumab (IXE) is an IgG4 monoclonal antibody that binds with high affinity and specificity to the proinflammatory cytokine IL-17A. Data are presented from a phase 3 trial (SPIRIT P1; NCT01695239) with IXE in patients (pts) with active PsA. The objective is to explore the impact of IXE, as assessed by disease activity composite measures, up to 52 weeks (wks).

Methods: 417 bDMARD-naive adult pts with active PSA, were randomly assigned 1:1:1:1 to subcutaneous administration of either 80 mg IXE every 4 wks [Q4W] or every 2 wks [Q2W], each with a 160 mg starting dose at Wk 0; adalimumab (ADA) 40 mg Q2W [active comparator]; or placebo (PBO) in the Double Blind Treatment Period (DBTP; Wks 0-24). Of these pts, 381 continued into the Extension Period (EP; Wks 24-52). PBO- and ADA treated pts were randomly re-assigned (1:1) to 80 mg IXEQ4W or IXEQ2W at Wk 16 (inadequate responders) or Wk 24; ADA-treated pts started IXE, after an 8-wk wash-out period, at Wk 24 (inadequate responders) or Wk 32. Investigators were blinded as to the criteria for inadequate response. Disease activity was measured at Wks 24 and 52 by composite measures including the following: minimum disease activity (MDA) as measured with the Psoriasis Area and Severity Index (MDA_{PASI}) and with the static Physician Global Assessment of psoriasis (MDA_{sPGA}), and modified Composite Psoriatic Disease Activity Indices (CPDAI-12 and CPDAI 14 [see Table 1 footnote]). Analyses for the DBTP were conducted on the Intent-to-Treat Population, defined as all randomly assigned pts; analyses for the EP were conducted on the EP Population, defined as all pts who received at least 1 dose of study drug during the EP. In the DBTP, treatment comparisons were made by a logistic regression model for categorical data with missing values imputed by nonresponder imputation; a mixed model for repeated measures analysis was used for continuous data.

Results: At Wk 24, CPDAI 12 and CPDAI-14 total scores (assesses domains of peripheral arthritis, skin disease, enthesitis, dactylitis [and spinal disease for CPDAI-14 only]) for pts receiving IXEQ4W, IXEQ2W, or ADA, were significantly improved compared with results for pts receiving PBO (Table 1). Similarly, at Wk 24, significantly more pts receiving IXEQ4W, IXEQ2W, or ADA achieved MDA_{sPGA} and MDA_{PASI} compared with pts receiving PBO (Table 1),

and percentages of pts receiving IXEQ4W or IXEQ2W who achieved MDA_{sPGA} and MDA_{PASI} were sustained through Wk 52 (Table 2). Results for MDA_{sPGA} were similar to results for MDA_{PASI} within each treatment group.

Conclusion: IXE provides sustained improvement of disease activity, as measured by various composite measures, for up to 52 wks in bDMARD-naive pts with active PsA.

Table 1: Improvement in Composite Outcome Measures at Week 24 (Double-Blind Treatment Period)

Assessment	PBO N=106	ADA N=101	IXEQ4W N=107	IXEQ2W N=103
NRI:

SESSION INFORMATION

Session Date: Monday, November 14, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster II: Psoriatic Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: PsA has a negative impact on patients' quality of life, physical function, and work productivity. Ixekizumab (IXE) is an IgG4 mAb that binds with high affinity and specificity to the proinflammatory cytokine IL-17A. In this phase 3 trial (SPIRIT P1), previously reported results showed that IXE treatment resulted in significant improvements (compared with placebo [PBO]) at Week [Wk] 24 in the patient reported outcome (PRO) measures of HAQ – Disability Index (HAQ-DI), Short Form-36 Health Survey Physical Component Summary (SF-36 PCS), European Quality of Life 5 Dimensions Visual Analog Scale (EQ-5D VAS), and Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP; presenteeism, work productivity, and activity impairment).The objective was to evaluate whether an effect of IXE on improvement of PROs is also observed at Wk 52.

Methods: A total of 417 biologic DMARD (bDMARD)-naive patients (pts) with active PsA were randomly assigned 1:1:1:1 to subcutaneous administration of either 80 mg IXEQ4W or IXEQ2W, each with a 160 mg starting dose at Wk 0; adalimumab [ADA] 40 mg Q2W (active comparator); or PBO in the Double-Blind Treatment Period (DBTP; Wks 0 through 24). Of these pts, 381 continued into the Extension Period (EP; Wks 24-52). PBO- and ADA treated pts were randomly re-assigned (1:1) to 80 mg IXEQ4W or IXEQ2W at Wk 16 (inadequate responders) or Wk 24; ADA-treated pts started IXE after an 8-wk wash-out period at Wk 24 (inadequate responders) or Wk 32. Investigators were blinded as to criteria for inadequate response. Analyses for the EP were conducted on the EP Population, defined as all pts who received at least 1 dose of study drug during the EP. Missing values were imputed by nonresponder imputation for categorical data and modified baseline observation carried forward for continuous data.

Results: Baseline demographics and clinical characteristics were generally similar between treatment groups; population mean baseline (Wk 0) scores for HAQ-DI, SF-36 PCS, and EQ-5D VAS (Table) indicated impaired physical function and quality of life. Physician assessed clinical efficacy was shown by 69% of pts treated with IXE for 52 wks achieving ACR20 response. Pts receiving IXE (Q4W or Q2W) for 52 wks reported similar improvements in HAQ-DI, SF 36, EQ-5D VAS, and WPAI SHP (presenteeism, work productivity, and activity impairment) (Table) as reported at Wk 24, and the percentage of IXE pts with improvement from baseline HAQ-DI score ≥0.35 achieving minimally clinically important difference for HAQ DI was sustained at Wk 52 (Table) compared with Wk 24. At Wk 52, pts receiving ADA/IXE also showed similar improvements in ACR20 response and most PRO measures (Table) to those observed at Wk 24.

Conclusion: IXE provided sustained improvement through 52 wks in physical function, quality of life, and work productivity in bDMARD-naive pts with active PsA.

Table: Summary of Patient-Reported Outcomes at Baseline and Week 52 in Psoriatic Arthritis Patients Treated With Ixekizumab
