**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Non-adherence to medication has been shown to impact mortality, morbidity, and health care utilization in SLE and ranges from 40-80% depending on the methods used to assess compliance. Hydroxychloroquine (HCQ) is a key component of SLE therapy. HCQ levels are a sensitive method to assess medication adherence in lupus. Our study assessed the feasibility of HCQ measurement and its impact on SLE activity in a multiethnic, predominantly Hispanic, population.

**Methods :** SLE patients from the Columbia Lupus Center meeting ACR/SLICC criteria, treated with HCQ for >6 months, reporting adherence to HCQ were included. HCQ testing was done by high performance liquid chromatography on whole blood by the Exagen Laboratory. Non-adherence was defined as a HCQ level of < 500ng/ml. The association between HCQ and disease activity measured by SLEDAI-2K was evaluated in a multivariate model that included all variables showing an association at  $p < 0.2$  in univariate analysis (demographics, SLE variables, age, sex, race/ethnicity). Statistical significance was considered  $p \leq 0.05$

**Results :** 108 patients, average age 38 (range 19-66) and 91% female, 62% Hispanic, and average SLEDAI of 4.3 (range 0-20) were included. 41% of patients had HCQ<500 demonstrating non-adherence; 19% had undetectable levels. Of the patient demographics and SLE characteristics, Hispanic ethnicity, being primarily a Spanish speaker, having higher eGFR, organ involvement and a diagnosis of depression had a trend towards significance in univariate analysis (Table 1). There was a significant association between having had CNS involvement and higher HCQ levels. Higher SLEDAI was significantly associated with lower HCQ levels (Table 2) ( $p < 0.001$ ). After adjusting for age, sex, ethnicity, education, depression, smoking, organ involvement, current steroid use, and immunosuppression, HCQ levels were significantly associated with SLE disease activity measured by SLEDAI ( $p < 0.004$ ). Average adjusted SLEDAI in non-adherent patients was 5.8 (IQR 4.8, 6.8), and 3.3 in adherent patients (IQR 2.5, 4.2).

**Conclusion :** These data suggest that HCQ levels <500 ng/ml are significantly correlated with higher disease activity scores and explain 32% percent of the SLEDAI variability. Testing for HCQ levels is an easy and reliable way to evaluate medication adherence in SLE. Levels <500ng/ml should be discussed with the patients and the reasons for non-adherence should be further explored. A diagnosis of depression had a strong trend towards associating with non-compliance emphasizing the importance of screening and treating this co-morbidity.

## Fatigue in Systemic Lupus: The Role of Disease Activity and Its Mediators

**Desiree R Azizoddin**<sup>1</sup>, Meenakshi Jolly<sup>2</sup>, Joel A. Block<sup>3</sup> and Perry M. Nicassio<sup>4</sup>, <sup>1</sup>Department of Medicine and Behavioral Sciences, Rush University, Chicago, IL, <sup>2</sup>Rush, Chicago, IL, <sup>3</sup>Division of Rheumatology, Rush University Medical Center, Chicago, IL, <sup>4</sup>Cousins Center for PNI, UCLA, LA, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that leads to a variety of negative health outcomes. Though treatment continues to advance, fatigue remains one of the most salient, unaddressed patient complaints. Understanding the mechanisms of fatigue can help guide the development of interventions to improve health outcomes. The aim was to evaluate the role of six variables (disease activity, insomnia, depression, stress, pain, and physical functioning) towards fatigue in individuals with SLE.

**Methods:** 116 ethnically-diverse, primarily female participants (91%) with SLE, receiving care at university medical centers, completed assessments of disease activity, and quality of life outcomes (FACIT-FT, Insomnia Severity Index, Perceived Stress Scale (PSS-4), Pain Inventory, Depression-PHQ-9, and LupusPRO-physical function). All patients met ACR classification criteria for SLE and did not have concurrent diagnosis of fibromyalgia. Multivariate linear and stepwise regression analyses were conducted with fatigue (FACIT-FT) as the dependent variable and above six variables as independent variables.

### **Results:**

Mean(SD) age was 39.80(13.9) years; 50% were African American, 21% Caucasian, 13% Hispanic, 9% Asian, and 8% other. Mean(SD) FACIT-FT was 18.6(11.8). Collectively, these six variables explained 57% variance in fatigue; wherein depression, stress and pain were significant independent predictors of fatigue on the multivariate model, but not disease activity, sleep or physical health. Largest magnitude of effect on fatigue was with stress ( $\beta$  0.77, 95% CI 0.17, 1.38,  $p=0.01$ ) followed by depression ( $\beta$  0.66, 95% CI 0.21, 1.10,  $p=0.005$ ). On stepwise regression analysis, stress, depression and pain collectively explained 56% of variance in fatigue in SLE. All three were independent correlates of fatigue, and the largest contribution to fatigue was again from stress ( $\beta$  0.84, 95% CI 0.27, 1.42,  $P=0.005$ ), followed by depression ( $\beta$  0.79, 95% CI 0.44, 1.14,  $p<0.001$ ).

### **Conclusion:**

Stress and depression are the largest and independent contributors to fatigue among patients with SLE without concurrent fibromyalgia. Disease activity, sleep and physical health were not associated with fatigue in patients with SLE without concurrent fibromyalgia. Evaluation of stress and depression needs to be incorporated during assessment of SLE patients, especially in context of fatigue. This stress-depression-fatigue model needs further validation in a longitudinal study

## Lupus Low Disease Activity State: Can We Relax the Definition and Still Achieve Low Risk of SLE-Related Damage?

**Michelle Petri**<sup>1</sup>, Daniel Goldman<sup>2</sup> and Laurence S Magder<sup>3</sup>, <sup>1</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lupus low disease activity state (LLDAS) is a systemic lupus erythematosus (SLE) outcome measure that combines low disease activity and a 7.5 mg limit on prednisone. We have previously shown that there is a dose-response reduction in SLICC/ACR organ damage by percentage of time spent in LLDAS. We now show which components of LLDAS are most important.

**Methods:** Lupus low disease activity state (LLDAS) was defined by Franklyn et al as a SLEDAI ≤4, PGA ≤1.0, no major organ activity, and no new activity and prednisone use ≤7.5 mg/d. Using a large clinical cohort, we looked at the risk of organ damage among those who satisfied this definition 75% of the time. Then we looked at the risk of organ damage (by SLICC/ACR Damage Index) among those who satisfied modifications of this definition.

**Results:** Table 1 shows the risk of damage if LLDAS is present at 75% of previous visits, if some of the requirements for LLDAS are relaxed. If we define LLDAS in the standard way and patients satisfy this definition 75% of the time, damage is experienced in 0.62% of subsequent months. If we use the same definition but allow a prednisone dose of up to 10 mg/day, we still observed a relatively low risk of damage (0.59% per month) among those who achieve that standard 75% of the time.

Table 1: Risk of new damage in a person month in subgroups defined by LLDAS on treatment, after relaxing some of the requirements. The percentages refer to the risk of damage for months that meet the criterion in 75% of preceding follow-up.

Criterion	Number of months and instances of damage among those who satisfy the criterion to the left at least 75% of the person-time.		
	Number of person-months observed	Number of months with an increase in damage	Percentage of months in which damage occurred
LLDAS (original definition)	13,141	82	0.62%
LLDAS, but allow SLEDAI up to 5	13,198	82	0.62%
LLDAS, but allow SLEDAI up to 6	13,382	84	0.63%
LLDAS, but no SLEDAI requirement	13,382	84	0.63%
LLDAS, but allow Prednisone up to 10 mg/d	14,561	86	0.59%
LLDAS, but allow Prednisone up to 15 mg/d	15,721	97	0.64%
LLDAS, but allow Prednisone up to 20 mg/d	15,928	108	0.68%
LLDAS, but no limit on Prednisone	16,399	111	0.68%
LLDAS, but allow PGA up to 1.5	14,641	100	0.68%
LLDAS, but no PGA requirement	15,334	107	0.70%

Table 2 shows the risk of damage if some of the requirements for LLDAS are made more stringent. A more stringent SLEDAI or lower dose of prednisone did not result in a lower damage risk and reduced the number of patients who achieved those stricter goals. The lowest risk was seen if LLDAS was modified to require a PGA of 0 (risk=51%), but this stringent standard was only achieved for a small percentage of the follow-up.

Table 2: Risk of new damage in a person month in subgroups defined by LLDAS on treatment, after making some of the requirements more stringent. The percentages refer to the risk of damage for months that meet the criterion in 75% of preceding follow-up.

Criterion	Number of months and instances of damage among those who satisfy the criterion to the left at least 75% of the person-time.		
	Number of person-months observed	Number of months with an increase in damage	Percentage of months in which damage occurred
LLDAS (original definition)	13,141	82	0.62%
LLDAS, but require PGA $\leq 0.5$	8,221	46	0.56%
LLDAS, but require PGA $\leq 0.2$	1,922	12	0.62%
LLDAS, but require PGA=0	1,753	9	0.51%
LLDAS, but require SLEDAI $\leq 3$	12,115	72	0.59%
LLDAS, but require SLEDAI $\leq 2$	11,815	69	0.58%
LLDAS, but require SLEDAI $\leq 1$	7,943	46	0.58%
LLDAS, but require SLEDAI=0	7,624	45	0.59%
LLDAS, but require Prednisone $\leq 5$	12,482	76	0.61%
LLDAS, but require Prednisone=0	8,661	55	0.64%

**Conclusion:** Our findings suggest that a relaxed definition of LLDAS (allowing for greater levels of SLEDAI and higher doses of prednisone) might still be a realistic target for clinical care, if the goal is to reduce the risk of later organ damage.

## Validation of Remission and Lupus Low Disease Activity State As Predictors of Organ Damage in SLE

Michelle Petri<sup>1</sup>, Daniel Goldman<sup>2</sup> and Laurence S Magder<sup>3,4</sup>, <sup>1</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Epidemiology and Public Health, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>4</sup>Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Outcome measures that combine control of SLE activity and prednisone reduction are clinically relevant. A clinical goal in SLE is to reduce risk of long-term organ damage. We assessed whether two recently proposed disease activity outcomes were predictive of future damage.

**Methods:** For each month of follow-up in a large SLE cohort, we determined whether the patient was in Clinical Remission (as defined by the DORIS working group) or lupus low disease activity state (LLDAS) (as defined by Franklyn et al). Clinical Remission was defined as a PGA<0.5, clinical SLEDAI=0 and no prednisone or immunosuppressants. Clinical Remission on Treatment allowed for prednisone<=5mg/day and immunosuppressant use. LLDAS was defined as a SLEDAI <=4, PGA <=1.0, no major organ activity, and no new activity. LLDAS on treatment allowed for prednisone use <= 7.5 mg/d and immunosuppressants. Damage was defined using the SLICC/ACR Damage index.

**Results:** There were 81,118 person-months observed among 2,026 patients (92% female, 53% Caucasian, 39% African-American). Table 1 shows the rates of damage, per person month, in subgroups defined by Remission or LLDAS.

Table 1. Rates of new damage, in subgroups defined by past levels of disease activity

Percentage of Prior Months in:	Number of person-months observed	Number of months with an increase in SLICC/ACR Damage Index	Rate of damage per 100 person months	Rate Ratios	P-values

Not none, but < 25%	10,880	106	0.97	0.86 (0.69,1.07)	0.18
25% to 50%	5012	40	0.80	0.70 (0.51,0.98)	0.037
50% to 75%	8494	60	0.71	0.63 (0.48,0.83)	0.0010
75%+	7,527	46	0.61	0.54 (0.40,0.73)	<0.0001
<b>LLDAS on Treatment</b>	-	-	-	-	-
None	7,656	117	1.53	1.0 (Ref)	-
Not none, but < 25%	10,555	134	1.27	0.83 (0.65,1.06)	0.14
25% to 50%	12,686	129	1.02	0.66 (0.51,0.85)	0.0013
50% to 75%	18,151	133	0.73	0.48 (0.37,0.61)	0.0010
75%+	13,141	82	0.62	0.40 (0.30,0.54)	<0.0001

Damage rates were relatively low when LLDAS was achieved at least 50% of the time. These rates were similar to those experienced by patients who met a more stringent treatment restriction with Remission on Treatment at least

50% of the time.

**Conclusion:** Percent time in LLDAS had a clear dose response for rate ratios of organ damage. The equivalence of LLDAS and DORIS remission on treatment is welcome news, as LLDAS on treatment > 50% of the time is an easier goal to achieve (3 times more person-months observed in our cohort) and more realistic as a clinical trial outcome.

## **Lupus Low Disease Activity State Protects Against Most Subtypes of Organ Damage in SLE**

**Michelle Petri**<sup>1</sup>, **Daniel Goldman**<sup>2</sup> and **Laurence S Magder**<sup>3</sup>, <sup>1</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In SLE the most common types of organ damage are osteoporotic fractures and cataracts. Other types of organ damage, such as end stage renal disease, are more life-threatening. We asked whether achieving the Lupus Low Disease Activity State (LLDAS) was protective against all – or only some – types of organ damage in SLE.

**Methods:** LLDAS was defined as by Franklyn et al: SLEDAI ≤ 4, PGA ≤ 1, prednisone ≤ 7.5 mg/day, no major organ involvement (renal, CNS, serositis, vascular, or constitutional), no recent increase in disease activity. Each month of each follow-up was classified based on the proportion of prior months that the patient was in LLDAS. The rate of each damage event (expressed in rate per year) was calculated in each class. P-values were constructed to assess the significance of trends in rates by proportion of months in LLDAS based on a logistic regression model. If a patient had the specific damage prior to cohort entry, then they were not included. The patients were 92% female, 53% Caucasian, 39% African-American.

**Results:** Table 1 shows the specific type of organ by percent time that LLDAS was achieved, based on a logistic regression model treating percent time in LLDAS as a quantitative predictor.

Table 1: Rates of specific damage per person year and prior LLDAS experience

Damage Type	Number of events/Number of person years (Rate per 1000 person years)				P-value for trend

**Conclusion:** Time in LLDAS was protective against most major organ damage, including myocardial infarction, stroke, and end stage renal disease. It was not protective against DVT damage (likely because the initial DVT was due to antiphospholipid antibodies), pulmonary fibrosis, pulmonary hypertension, cognitive impairment, or malignancy. It was not protective against cataract, which is associated with lower doses of prednisone than the 7.5 mg cut-off of the LLDAS.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We assessed incident cancers in a large inception SLE cohort, and examined demographic and clinical factors, including tumor-related autoantibodies against proliferating cell nuclear antigen (PCNA) and centromere protein B (CENP-B).

**Methods:** Patients with new-onset SLE were enrolled at 32 centres. Incident cancers were recorded by physicians at annual visits, confirmed by chart review. Of 1,848 patients enrolled from 2000-2011, we studied 1,676 who had at least one follow-up visit. Multivariate survival regression was performed, with baseline demographics (age, sex, race), drugs (corticosteroids, anti-malarial drugs, immunosuppressives), smoking, SLEDAI-2K, and calendar year.

Serology was available in 29 cancer cases and 1114 cancer-free patients. Subjects were followed until death, last visit, or end of the interval for this analysis (August 2015).

**Results:** Of the 1,676 patients evaluated, the majority (88.7%) were female, and 828 (49.4%) were Caucasian. Mean age at SLE diagnosis was 34.6 (standard deviation 13.3) years. At baseline, 1085 (64.7%) patients were never-smokers, with the remainder being current (n=248) or ex-smokers (n=342). Mean follow up was 7 years,

We observed 45 cancers in 45 subjects, occurring at a mean SLE duration of 4.6 (SD 3.1) years. Cancers included breast (9), non-melanoma skin (8), lung (5), prostate (5), head and neck (4), hematologic (3) cervical (3), thyroid (2), melanoma (2) and one each of medulloblastoma, renal carcinoma, carcinoid, thymoma, and dermatofibrosarcoma. Baseline anti-PNCA and anti-CENP-B antibodies were respectively found in 80 (7.2%, 95% CI 5.8, 8.9) and 26 (2.2%, 95% CI 1.6,3.4) of cancer-free patients, and none of the 29 cancer cases where serology was tested (including all 5 lung cancers).

Univariate hazard regression suggested that across all cancers, events were more common in whites and older patients; similar trends were evident in the multivariate analyses, but 95% CIs around the adjusted hazard ratio, HR, estimates were relatively wide.

	Univariate	Multivariate
<b>Analyses for all cancers</b>	<b>HR (95% CI)</b>	<b>HR (95% CI)</b>
Age at enrolment	1.05 (1.03, 1.07)	1.04 (1.02, 1.07)
White	2.95 (1.52, 5.72)	2.03 (0.99, 4.14)
Disease duration	0.91 (0.39, 2.15)	0.83 (0.34, 2.05)
Current smoker	1.72 (0.85, 3.48)	1.55 (0.75, 3.19)
Ever used steroids	1.06 (0.51, 2.21)	1.66 (0.75, 3.67)
Ever used antimalarials	1.11 (0.59, 2.09)	0.92 (0.48, 1.78)
Ever immunosuppressives	0.84 (0.46, 1.54)	1.00 (0.51, 1.96)
SLEDAI 2K	0.94 (0.88, 1.00)	0.96 (0.89, 1.03)
Calendar year at enrolment	1.05 (0.94, 1.16)	1.05 (0.94, 1.17)

For lung cancer specifically, the adjusted hazard regression showed age and smoking were factors clearly associated with risk (adjusted HR for smoking 31.4, 95% CI 3.0, 327.1).

**Conclusion:** This was a first look at potentially predictive factors, including baseline levels of two tumor-associated antibodies, for cancer risk in a large inception SLE cohort. At a mean follow up time of 7 years, baseline smoking was more helpful in identifying future cancer events (specifically lung cancer), than baseline anti-tumor antibodies. However, additional work will assess a broader range of tumor-associated antibodies and follow-up over a longer period.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with systemic lupus (SLE) have altered cancer profiles compared to the general population, with a higher risk of some cancers (e.g. lymphoma) and apparently a lower risk of others (e.g. breast).

Tumor-associated antibodies to centromere proteins and other antigens have been reported in many types of cancers (including lymphoma and breast) and may serve as diagnostic or prognostic indicators. Our purpose was to compare the prevalence of an array of tumor-associated antibodies in SLE patients with and without cancer.

**Methods:** We performed a case-control study nested within a large cohort of SLE patients followed at a clinic in Montreal, Canada. These patients have been consecutively enrolled and followed yearly with sera stored at each visit. Cancer events were ascertained by linkage with the Quebec tumor registry. In this analysis, we performed a cross-sectional analysis of antibodies in 23 SLE patients who developed a new cancer after SLE cohort entry, and compared them to 23 SLE cancer-free controls, frequency matched for sex, race/ethnicity and time since cohort entry. We assessed antibodies that in the literature had previously been suggested as associated with cancer in rheumatic disease and/or general populations. These included, but were not limited to, antibodies against anti-centromere protein (CENP), *proliferating cell nuclear antigen* (PCNA), Scl-70, and RNA polymerase III.

**Results:** Of the cancers in the 23 SLE patients, 11 were lymphoma, 8 were breast, two were endometrial, and 1 each were colon and kidney. The average age at cancer diagnosis was 52.3 years (standard deviation, SD 13.1) and the median SLE duration at cancer diagnosis was 14 years. The vast majority (91.3%) of the SLE patients with cancer were white and all but two of the SLE cancer cases were women.

For all antibodies examined, there were trends for higher levels in SLE cancer cases as a group, versus cancer-free SLE controls. Certain antibodies were found more often in specific cancer types, such as anti-RNA Pol III antibodies in breast cancer, and anti-CENPF1, anti-CENPF-4, and anti-centromere antibodies in lymphoma.

**TABLE AND FIGURE SHOW MEDIAN LEVELS OF ANTIBODIES IN EACH GROUP**

	CENPF1 (n=18)	CENPF4 (n=19)	PCNA (n=21)	RNPC3 (n=20)	Scl- 70	Centromere	Th/To- Rpp38	RNA Pol III	Th/To- Rpp25	PM/Scl	BIC- D2
<b>breast</b>	56.5	111.5	33.5	87.5	69	41.5	50.25	<b>170.5</b>	25	84.25	30
<b>lymphoma</b>	63	<b>145</b>	39	46	85	<b>85</b>	59	132.5	21	77	26
<b>all</b>	63	117	39	71	70	45	53.5	138	25	82	27
<b>controls</b>	54	104	28	63	41	29	29	84	20	76	22

**Conclusion :** In the SLE patients with cancer, the levels of certain tumor-related antibodies tended to be higher than the levels in SLE patients who were cancer-free. This may suggest potential roles for these as cancer markers, but further research is needed.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

## Background/Purpose:

A recent study revealed ultrasound (US) findings indicative of enthesal involvement in a small group of patients with systemic lupus erythematosus (SLE), raising the hypothesis that enthesis could be a missing target in the evaluation of musculoskeletal manifestations in SLE. With the present study, we aimed at exploring by US the prevalence and distribution of lower limb enthesal abnormalities in a larger cohort of SLE patients, comparing the US features of SLE-enthesopathy with those of psoriatic arthritis (PSA) patients and of healthy subjects. We also examined the clinical and serologic associations of SLE-enthesopathy.

## Methods:

We included 165 patients: 65 with SLE, 50 with PSA and 50 healthy subjects. The physical examination and the US evaluation were performed in the same day by independent rheumatologists at the following anatomic sites: the patellar insertion of the quadriceps tendon, the proximal and distal insertions of the patellar tendon, the calcaneal insertion of the Achilles tendon and of the plantar fascia. The US pathological findings, identified according to the definition of the OMERACT US Task Force, were correlated with clinical enthesitis. US enthesitis scores, based on the scoring system proposed by D'Agostino et al., were correlated with disease activity indices, serologic and clinical parameters.

## Results:

We scanned 1650 entheses: 650 in SLE patients, 500 in PSA patients and in 500 in healthy subjects. The prevalence and distribution of the US abnormalities is reported in Table 1. In the patients with SLE, the US examination revealed one or more US abnormalities in 117 out of 650 entheses (18%) and in at least one enthesis of 44 out of 65 patients (67.7%). There was no statistical difference between SLE patients and healthy subjects about the US finding indicative of enthesal structural damage (enthesophyte, erosion, calcification), whereas US findings of “active” enthesitis (Doppler signal, hypoechogenicity, enthesal thickening) were found significantly higher in SLE patients than in healthy subjects, especially at the patellar and Achilles tendon insertions. There was a weak correlation ( $k=0.29$ ) between clinical enthesitis and the presence of at least one US enthesal pathological finding, which increased when clinical enthesitis was correlated only with Doppler signal ( $k=0.38$ ). D'agostino enthesitis scores correlated with age ( $p=0.005$ ,  $f^2=0.2$ ) and SLEDAI 2-k ( $p=0.002$ ,  $f^2=0.24$ ) and BILAG-MS ( $p=0.008$ ,  $f^2=0.17$ ).

	Quadriceps enthesitis			Patellar superior pole enthesitis			Patellar inferior pole enthesitis			Achilles enthesitis			Plantaris fascia enthesitis			SUM

## Conclusion:

This study revealed a considerable burden of enthesal abnormalities in SLE patients, especially at the patellar and Achilles tendon entheses. The US pattern of “active” enthesitis was the most frequently detected. Enthesal involvement in SLE patients correlated with high disease activity (as documented by SLEDAI 2-k) and with more severe musculoskeletal involvement, as evaluated by MS-BILAG.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Coronary atherosclerosis increases with age but is more prevalent in patients with systemic lupus erythematosus (SLE) independent of chronological age; this increased prevalence has been suggested to reflect accelerated biological aging in SLE. Telomeres protect chromosomal ends from shortening after replication, and telomere length is indicative of biological age. We examined the hypothesis that reduced telomere length, reflecting accelerated biological aging, is associated with inflammation, disease activity and damage, cardiometabolic risk factors, and coronary atherosclerosis in patients with SLE.

**Methods:** We performed a cross-sectional study in 126 patients with SLE. Telomere length was measured from whole blood DNA using real-time quantitative PCR as telomeric product to a single-copy gene product ratio (T/S ratio). Inflammation was assessed by high sensitivity C-reactive protein (CRP). SLE disease activity and damage were assessed by Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and the Systemic Lupus International Collaborating Clinics Classification Criteria (SLICC), respectively. Homeostatic Model Assessment (HOMA) was used to assess degree of insulin resistance. Framingham Risk Score (FRS) was determined based on the American Heart Association criteria. Coronary artery calcium score was measured by electron beam computed tomography. Spearman correlation and linear or logistic regression models adjusting for age, race, and sex were used to determine the association between telomere length and clinical variables.

**Results:** Patients with SLE were predominantly female (91%) and Caucasian (65%) with median age 41 years. Telomere length was inversely associated with age ( $\rho = -0.43$ ,  $P < 0.001$ ) and CRP ( $\rho = -0.31$ ,  $P < 0.001$ ,  $P_{adj} < 0.001$ ) but not with SLEDAI or SLICC scores (Table). Higher triglycerides ( $\rho = -0.21$ ,  $P = 0.02$ ,  $P_{adj} = 0.007$ ) and FRS ( $\rho = -0.43$ ,  $P < 0.001$ ,  $P_{adj} = 0.03$ ) were inversely associated with telomere length independent of age, race and sex. Systolic blood pressure and waist-hip ratio were inversely associated with telomere length, but the relationship was attenuated after adjustment. High-density and low density lipoproteins, diastolic blood pressure, HOMA, and coronary artery calcium score were not associated with telomere length (Table).

**Conclusion:** Telomere length was significantly inversely associated with chronological age in SLE; it was also inversely associated with some cardiometabolic risk factors such as triglycerides, FRS, and CRP independent of age,

race, and sex. However, coronary artery calcium score was not independently associated with telomere length, suggesting that factors other than accelerated biological aging are responsible for increased atherosclerosis in SLE.

Table. Relationship between telomere length and disease-related and cardiometabolic risk factors in SLE			
	Rho ( $\rho$ )	P	Adjusted P*
Age	-0.43	<0.001	-
SLEDAI	0.13	0.14	0.59

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Women with SLE have an increased risk of cardiovascular disease (CVD) and premature death. In the general population, moderate alcohol intake is associated with a cardioprotective effect. However, there is no data on the effect of alcohol intake in women with SLE, and it is unclear whether providers should advise SLE patients to avoid drinking. We examined the impact of alcohol consumption on risk of myocardial infarction (MI) and all-cause mortality in women with SLE in a general population setting. As a control lifestyle exposure, we also investigated the impact of current smoking on these endpoints.

**Methods:** We conducted a population-based cohort study of female patients with SLE using a medical record database representative of the general population of the UK. The exposure of interest was alcohol intake at cohort entry. Outcomes were incident cases of MI and all-cause mortality. We estimated hazard ratios (HR) of each outcome according to alcohol intake categories (i.e., 0, 1-14 [light-moderate drinking], and 15+ [heavy drinking] UK alcohol units/week [1 unit = 8 mg]). Multivariable Cox-proportional hazard models adjusted for age, smoking status, body mass index, duration of SLE, comorbidity index, and medication use.

**Results:** Among 2625 individuals with SLE (mean age 53.2 years), 1262 were non-drinkers, 1199 were light-moderate drinkers and 164 were heavy drinkers. Of each group by alcohol intake, 20.2%, 26.2% and 46.3% were current smokers, respectively. The mean duration of SLE at cohort entry was 9.3 years for non-drinkers, 8.8 years for light-moderate drinkers, and 8.2 years for heavy drinkers. Over mean follow up of 6.8 years, the overall mortality rates were 23.9, 12.8, and 19.5 deaths/1000 person-years (PY) for the non-drinkers, light-moderate drinkers, and heavy drinkers, respectively. Compared with non-drinkers, the multivariable HR of overall mortality for light-moderate alcohol intake was 0.69 (95% CI, 0.53-0.89). The multivariable HR of incident MI for light-moderate alcohol consumption was 0.53 (95% CI 0.28-1.00) relative to non-drinkers. In contrast, for current smokers, the multivariable HRs were 1.93 (95% CI 1.44-2.58) for mortality and 1.59 (95% CI 0.77-3.29) for incident MI.

**Conclusion:** These findings provide population-based evidence that women with SLE who consume light-moderate alcohol intake have lower incidence of MI and overall mortality when compared with non-drinkers. This protective effect from light-moderate alcohol use is seen in contrast with an increased risk of mortality associated with smoking, another lifestyle factor that correlates with alcohol intake including in this study population. For their cardioprotection and improved survival, women with SLE with light-moderate alcohol consumption may be advised that they do not need to refrain from alcohol intake, whereas smoking cessation should be strongly implemented.

**Table 1. Relation of Drinking Status to Mortality and Incident Myocardial Infarction in Women with Systemic Lupus Erythematosus**

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Studies have indicated that increased body mass index (BMI) is a risk factor for development of Chronic Kidney Disease (CKD). Obesity is a low grade inflammatory state which leads to CKD by lipotoxicity, increased leptin levels, cytokine mediated glomerular injury and fibrosis. Systemic Lupus Erythematosus (SLE) is associated with

high leptin levels and dyslipidemia. We studied BMI as a possible predictor for development of lupus nephritis in SLE.

## **Methods:**

We performed a retrospective cross sectional study on a longitudinal lupus cohort. Patients were enrolled from year 1987 to 2015. We compared the demographic information, clinical information, lab results between patients with and without lupus nephritis (Table 1) and between patients with SLE with and without obesity (Table 2). Mean and Inter- quartile ranges were reported for continuous variables, such as age and BMI value. T- test was used to compare patients between the groups. Number and percentages were shown for categorical variables and chi-square test was utilized for comparison.

## **Results:**

Total of 1362 patients with SLE fulfilling revised ACR criteria were included in this analysis; 60.9% were Caucasian and 32.8% African American. 596 had biopsy-proven lupus nephritis however 524 patients were excluded because they had proteinuria before or at cohort entry. Only first available BMI were analyzed: 32.7% were obese (BMI > 30 kg/m<sup>2</sup>), 27.2% overweight (BMI: 25 -29.9 kg/m<sup>2</sup>), 37.5% normal (BMI: 18.5 - 24.9 kg/m<sup>2</sup>) and 2.6% underweight (BMI < 18.5 kg/m<sup>2</sup>). 39.4% (537) patients were on steroids at first BMI measurement. Results are described in Table 1, 2 and 3.

## **Conclusion:**

Obesity was not associated with the development of lupus nephritis. Obese patients with SLE had lower disease activity as measured by SLEDAI, dsDNA titers and complement levels.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To assess the prevalence, risk factors and impact on mortality of primary respiratory disease in a large retrospective cohort.

**Methods:** All adult patients in the Spanish Rheumatology Society Lupus Registry (RELESSER) who meet  $\geq 4$  ACR-97 SLE criteria were retrospectively investigated for the presence of primary pleuropulmonary manifestations.

**Results:** A total of 3215 patients were included: 91% were female, their mean (SD) age at diagnosis was 37 yrs (13.5), and the median follow-up time was 136 (97.7) months.

At least one pleuropulmonary manifestation was present in 11.3% (365) of the patients (289 (79.2%) patients developed only one manifestation; the rest had two or more). The mean duration of SLE until the appearance of the first respiratory manifestation was 5.8 (SD: 8.3) years.

The most common manifestation was pleurisy, which occurred in 21.1% (680) of the patients, followed by acute lupus pneumonitis (or interstitial alveolitis/pneumonitis according with BILAG 2004 definition) in 3.6% (118); pulmonary thromboembolism (including lung infarction) 2.9% (95); primary pulmonary hypertension in 2.4% (79); diffuse interstitial lung disease (or pulmonary fibrosis according with SLICC ACR Damage Index 1996) 2% (65); alveolar hemorrhage (BILAG 2004 definition) 0.8% (28); and shrinking lung syndrome (BILAG 2004 definition) 0.8% (28).

Twenty six patients with acute lupus pneumonitis and six patients with alveolar hemorrhage finally developed interstitial lung disease/pulmonary fibrosis.

In the multivariable analysis, the variables independently associated with the presence of pleuropulmonary manifestation were older age at disease onset (OR 1.03; 95% CI 1.02-1.04), higher SLEDAI scores (OR 1.03; 95% CI 1.00-1.07), the presence of Reynaud's phenomenon (OR 1.41; 95% CI 1.09-1.84), secondary antiphospholipid syndrome (OR 2.20; 95% CI 1.63-2.96), anti-RNP positivity (OR 1.32; 95% CI 1.00-1.75), and the previous or concomitant presence of severe lupus nephritis (including classes III, IV, V and mixed III/IV + V) (OR 1.48; 95% CI 1.12-1.95), neuropsychiatric manifestations (OR 1.49; 95% CI 1.11-2.02), primary cardiac disease (OR 2.91; 95% CI 1.90-4.15), vasculitis (OR 1.81; 95% CI 1.25-2.62), hematological manifestations (OR 1.31; 95% CI 1.00-1.71) and gastrointestinal manifestations, excluding hepatitis (OR 2.05; 95% CI 1.14-3.66).

Sixty-one (1.89%) patients with pleuropulmonary manifestations died over the follow-up period. Although the mortality rate was low, the development of respiratory disease was associated with lower survival (survival rates 95.6% versus 82.2%;  $p=0.030$ ). After adjusting for known confounders in the multivariable Cox regression model pleuropulmonary manifestations remained a risk factor for diminished survival (HR: 3.13; 95% CI 1.56–6.28,  $p=0.001$ ).

**Conclusion:** Primary respiratory disease is not uncommon in patients with SLE and independently contributed to a decreased survival in these patients. This complication occurs mainly in patients with active and severe disease (with previous or concomitant major organ involvement other than lung) and seems to be associated with the positivity of antiphospholipid and anti-Sm antibodies.

Chong<sup>1</sup> and Victoria P Werth<sup>5</sup>, <sup>1</sup>Dermatology, University of Texas Southwestern Medical Center, Dallas, TX, <sup>2</sup>Dermatology, National Skin Centre, Singapore, Singapore, <sup>3</sup>Dermatology, University of Pennsylvania, Philadelphia, PA, <sup>4</sup>Department of Biostatistics and Epidemiology at the Hospital of the University of Pennsylvania, Philadelphia, PA, <sup>5</sup>University of Pennsylvania and the VA Medical Center, Philadelphia, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The natural disease course of patients with cutaneous lupus erythematosus (CLE) on standard-of-care treatments is not fully characterized. We sought to characterize their disease course by obtaining Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) scores in these patients over time. We identified clinical and demographic features associated with different disease activity and damage trends.

**Methods:** This was a prospective cohort study of patients with CLE who had CLASI scores collected from  $\geq 3$  study visits within a 2-year time period. Patients were recruited from outpatient dermatology clinics at University of Texas Southwestern Medical Center and University of Pennsylvania from January 2007 to August 2016. Disease activity and damage trends were evaluated by net area under the curve (AUC) in CLASI scores/time and change in CLASI scores/time (slope). We defined “improving” and “worsening” trends by net AUC/time  $\leq -4$  and  $\geq 4$ , respectively. If net AUC/time was between  $-4$  and  $4$ , we used the best-fit slope to classify “improving” ( $m \leq -1$ ), “worsening” ( $m \geq 1$ ) or “stable” ( $-1 < m < 1$ ) trends. These metrics were compared between patient subgroups separated by demographics and clinical characteristics using Mann-Whitney and Kruskal-Wallis tests (continuous variables) and chi-squared tests (categorical variables). Linear regression models were used to compare CLASI score trends between groups.

**Results:** 83 patients with CLE were included, with mean follow-up time of 3.6 years. 81.8% patients with initial CLASI activity (CLASI-A) scores  $\geq 10$  (N=33) had improving disease activity, compared with 16.0% of those with initial CLASI-A  $\leq 9$  (N=50). Patients with baseline CLASI-A  $\leq 9$  had higher percentages of stable (56.0% vs. 9.1%) and worsening disease activity (28.0% vs. 9.1%) than those with initial CLASI-A  $\geq 10$  ( $p < 0.0001$ ). Linear regression analyses showed significant improvement in CLASI-A scores over time in patients with baseline CLASI-A  $\geq 10$  ( $p < 0.0001$ ), baseline CLASI damage (CLASI-D)  $\geq 10$  ( $p = 0.0001$ ), African Americans ( $p = 0.049$ ), and CLE disease duration  $\leq 1$  year ( $p = 0.01$ ). 46.4% patients with baseline CLASI-D  $\geq 10$  (N=28) had improving disease damage trends, compared with 5.4% of those with initial CLASI-D  $\leq 9$  (N=55), respectively. Patients with baseline CLASI-D  $\leq 9$  had higher percentages of stable (67.3% vs. 35.7%) and worsening disease activity (27.3% vs. 17.9%) than those

with initial CLASI-A  $\geq 10$  ( $p=0.0003$ ). Patients with baseline CLASI-A or CLASI-D  $\geq 10$  showed negative net AUC/time and slopes (Table).

**Conclusion:** Most patients with high and low baseline CLASI-A and -D showed improving and stable trends, respectively. This natural disease course data may be used as historical controls for future clinical trials.

**Table. Net AUC/time and slope in sub-groups of patients with baseline CLASI scores  $\geq 10$  or  $\leq 9$**

	CLASI-A $\leq 9$ (N=50)	CLASI-A $\geq 10$ (N=33)	p-value	CLASI-D $\leq 9$ (N=55)	CLASI-D $\geq 10$ (N=28)	p-value

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Long-term SLE treatment is often complex due to changing clinical manifestations, disease fluctuation, and frequent medication changes. Treatment can be daunting especially to the 25-60% of SLE patients who have cognitive and neuropsychiatric deficits. Patients cannot collaborate in making effective and shared and informed choices with physicians without understanding their own baseline health status and treatment options. The

goal of this project was to identify the level of SLE patients' comprehension of their medication regimens and disease outcomes. To our knowledge, a disease comprehension questionnaire has never been used in SLE patients.

**Methods:** Patients > 18 years were recruited from The Ohio State University Lupus Vasculitis Glomerulonephritis (LVG) clinic. After IRB approval, patient demographics and medical history was collected. A 25 item true/false disease questionnaire (Tables 2) was developed, and a small focus group of SLE patients helped ensure feasibility, understanding and appropriate literacy. The comprehension questionnaire was administered to SLE patients in clinic during routine visits.

**Results:** 32 SLE patients completed the questionnaire. Patient characteristics are summarized in Table 1. Table 2 shows the frequency of incorrect answers. Approximately 33% of the patients did not know that heart disease was associated with SLE. Over 15% of patients did not know that SLE affected bone health and over 25% of the patients did not recognize the side effects of prednisone. On the other hand, 100% patients recognized SLE disease manifestations and management vary.

**Conclusion:** One-third of SLE patients did not recognize the burden of heart or metabolic bone disease associated with the diagnosis of SLE. In addition, SLE patients did not understand the myriad possible side effects of prednisone, one of the most common drugs prescribed for SLE. Patients appeared to not appreciate the gravity of disease comorbidities and medication side effects, however, they did appreciate the heterogeneity of the disease and its treatment. Similar studies with larger samples are needed to develop educational processes that ensure patient understanding leading to improved shared decision making.

Table 1 Patient Demographics	
Age, mean (years)	41
Gender % (female)	92%
Race	61% white, 39% nonwhite
Highest Education Completed	62% < / =HS, 38% > HS
Annual Household Income, median (\$)	\$32,500
HS (High School)	

<b>Table 2: True/ False Comprehension Questions (correct answer indicated immediately after each one)</b>	<b>% Incorrect</b>
All lupus patients should be on hydroxychloroquine (or similar medication) unless your doctor tells you to stop (True)	34.4
Heart disease is the number one cause of death of lupus patients (True)	34.4
All medications have some side effects (True)	34.4
Lupus does not increase the risk of heart disease (False)	21.9
Active lupus will not affect you or the baby during pregnancy (False)	21.9
Lupus can cause weakening of your bones (True)	21.9
If you have lupus and you smoke, its no worse for you then if you have lupus and you don't smoke (False)	15.6
Most patients need multiple medications to control their disease (True)	15.6
Controlling your lupus decreases your risk of disability (True)	12.5
Prednisone when stopped abruptly, can cause life threatening consequences (True)	12.5
If you know someone who has lupus, you can expect to have the same things happen to you (False)	9.4
Prednisone is not a steroid (False)	6.3
Exercise can improve your bone and heart health (True)	6.3
All patients with lupus will develop kidney disease (False)	6.3
Most people with lupus, when on the correct medication, can live a life similar to someone who does not have lupus (True)	6.3
Sun exposure does not increase your risk for lupus flares (False)	3.1
It is not important to monitor blood work regularly inpatients with lupus to see if their disease is active or not (False)	3.1
If your doctor suggests a medication and the medication does not work for you, then your doctor has failed you (False)	0
Lupus can never be cured, but can be managed (True)	0
Starting a new medication is a bad idea because you will definitely get the side effects (False)	0
Because your doctor prescribed a medication for you, it is guaranteed to work for you (False)	0
<b>True/False Questions about the medication: Prednisone</b> <b>(correct answer indicated immediately after each one)</b>	<b>% Incorrect</b>
This medication can cause worsening acne (True)	43.8
This medication does not affect your sugars (False)	40.6
This medication can cause easy bruising (True)	34.4
This medication does not cause weight gain (False)	31.3
This medication can causes changes to your hair (True)	25.0
This medication does not disrupt your sleep (False)	18.8

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** : Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease which can impact the central nervous system in multiple ways, including development of cognitive dysfunction. Cognitive dysfunction is commonly reported in SLE and difficult to detect. Currently used diagnostic methods including neurocognitive testing batteries are time consuming, costly and challenging to implement in clinic. This project used the Self-Administered Gerocognitive Exam (SAGE) screening test for cognitive impairment, a simple patient-completed paper test, validated for dementia, diabetes and other diseases but not SLE

### Methods:

The patient population included 118 patients participating in The Ohio State University Lupus, Vasculitis and Glomerulonephritis Registry. All subjects provided informed consent, completed the SAGE instrument and supplied demographic and medical history information. Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and Systemic Lupus International Collaborative Clinics Damage Index (SLICC-DI) were completed on all subjects. SAGE instruments, scored by a trained individual, were grouped into two categories: normal (SAGE score > 16) and abnormal (SAGE score ≤ 16). Univariate analysis was performed to assess the relationship between normal and abnormal SAGE scores and several clinical variables. Variables with  $p < 0.15$  from the univariate analysis were initially included in multivariable logistic regression modeling. Variables with  $p > 0.05$  were subsequently removed sequentially from multivariate model using the backward selection strategy.

**Results:** Of the 118 subjects in this study, 97 scored in the normal range (>16) and 21 scored in the abnormal range (≤ 16). Race, ethnicity, education level and household income were significantly associated by univariate analysis with normal versus abnormal SAGE scores at the  $p < 0.15$  level were initially included in the multivariable model (Table 1). Abnormal SAGE scores were associated with higher overall SLICC DI scores but not with a neuropsychiatric-specific SLICC DI score. In multivariable analysis there was an independent association between abnormal SAGE score and higher SLICC DI score (odds ratio (OR) = 1.44, 95%CI 1.01-1.11,  $p$ -value=0.03),

Hispanic ethnicity (OR=43.4, 95%CI 3.1-601, p-value=0.005) and lower household income (OR=11.9 for  $\leq$ \$15,000 vs  $>$ \$50,000, 95%CI 2.45-57.8, p-value=0.002).

**Conclusion:**

Study results show a significant independent relationship between neurocognitive impairment as measured by SAGE score and higher lupus related damage as measured by SLICC DI scores. Abnormal SAGE scores were associated with lower household income and Hispanic ethnicity, which may suggest language barriers and a need for a Spanish version of the instrument. Finally, the SAGE was feasible to measure in the clinic setting. Further validation studies in SLE are needed.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lupus nephritis (LN) usually develops within the first years of Systemic Lupus Erythematosus (SLE) onset and rarely after that. There are scarce studies comparing early *versus* late onset nephritis (before *vs.* five years of diagnosis). In the only two reports available, the lack of renal biopsy and inclusion of elderly patients in one and the non exclusion of concomitant APS and other associated autoimmune diseases in the other preclude a definitive conclusion about their findings. The aim of this study was to compare the severity and long-term outcome (after 7 years) in these two groups: early and late-onset nephritis.

**Methods:** 77 patients with biopsy-proven LN with more than 7 years of follow-up were included. Patients were divided in two groups: early-onset nephritis (n=62) and late-onset nephritis (n=15). Clinical and laboratorial data were obtained using a standardized electronic chart database protocol carried out at 1-6 months interval and established in 2000. In order to minimize bias, patients >50 years or with concomitant autoimmune diseases were excluded. Variables evaluated at the LN presentation were SLEDAI, creatinine, albumin, anti-DNA positivity and nephritis class. Variables evaluated at the long-term outcome (after 7 years) were SDI, creatinine, dialysis and mortality. T test, Fisher and Mann Whitney were used for comparison.

**Results:** The average time of LN presentation was  $0.9 \pm 1.4$  years for the early-onset group and  $10.6 \pm 3.6$  years for the late-onset group. Of note, both groups had similar nephritis duration ( $13.5 \pm 4.2$  *vs.*  $13.1 \pm 2.9$  years,  $p=0.69$ ) and comparable mean ages ( $30.1 \pm 10.5$  *vs.*  $35.4 \pm 10.0$  years,  $p=0.08$ ) allowing a more accurate comparison between groups. Regarding severity, groups were alike at nephritis onset: SLEDAI ( $8.5$  [min-max.: 4-22] *vs.*  $7$  [min-max.: 6-17]  $p=0.14$ ), creatinine ( $1.49$  mg/dl  $\pm 1.21$  *vs.*  $1.48 \pm 0.99$ ,  $p=0.95$ ); albumin ( $2.59$  mg/dl  $\pm 0.84$  *vs.*  $2.84 \pm 0.65$   $p=0.23$ ); proteinuria ( $5.27 \pm 4.7$  *vs.*  $3.95 \pm 2.1$  mg/dl,  $p=0.05$ ); proliferative nephritis ( $53\%$  [n=33] *vs.*  $40\%$  [n=6]  $p=0.37$ ). There was also no difference in the long-term outcomes between the groups: SDI ( $1$  [min-max.: 0 – 4],  $p=0.73$ ); creatinine ( $1.93$  mg/dl  $\pm 2.4$  *vs.*  $2.1 \pm 2.6$ ,  $p=0.34$ ); dialysis ( $16.1\%$  [n=10] *vs.*  $20.0\%$  [n=3],  $p=0.70$ ); mortality ( $14.5\%$  [n=9] *vs.*  $0\%$  [n=0],  $p=0.19$ ).

**Conclusion:** On the present study we demonstrated that late-onset nephritis is comparable to early-onset nephritis concerning clinical, laboratorial and histological features at presentation. In addition, we provided novel evidence that long-term outcomes in biopsy proven severe lupus patients without other associated autoimmune diseases are comparable in both groups. These findings suggest that treatment targets and therapeutic interventions should be the same for these patients.

## Autoimmune Diseases in Patients with Cutaneous Lupus Erythematosus

Elaine Kunzler<sup>1,2</sup>, Linda S. Hynan<sup>3</sup> and Benjamin F. Chong<sup>1</sup>, <sup>1</sup>Dermatology, University of Texas Southwestern Medical Center, Dallas, TX, <sup>2</sup>Northeast Ohio Medical University, Rootstown, OH, <sup>3</sup>Clinical Sciences, University of Texas Southwestern Medical Center, Dallas, TX

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Increased rates of co-existing autoimmune diseases in the systemic lupus erythematosus (SLE) population have been reported.<sup>1</sup> Little is known about the prevalence of autoimmune diseases in cutaneous lupus erythematosus (CLE) without SLE (CLE-only) patients. To address this knowledge gap, we sought to assess frequencies of and clinical factors associated with concomitant autoimmune diseases in patients with CLE-only.

**Methods:** A cross-sectional pilot study was conducted between November 2008 and February 2017 among patients enrolled in the Cutaneous Lupus Registry at University of Texas Southwestern Medical Center. Participants with CLE who met 4 out of 11 American College of Rheumatology (ACR) criteria for SLE were excluded. For each patient, we collected demographic and clinical information including concomitant autoimmune disease diagnoses, which were confirmed by other subspecialty records, and listed by Hayter and Cook.<sup>2</sup> The primary and secondary outcomes was presence of  $\geq 1$  autoimmune disease and individual autoimmune diseases, respectively. Univariable (e.g. chi-squared tests) and multivariable analyses (e.g. logistic regression) were used to compare differences in outcomes between CLE-only patients with and without co-existing autoimmune diseases.

**Results:** Of the 129 patients with CLE-only, 17.8% (23/129) were found to have a co-existing autoimmune disease. Rheumatoid arthritis and Sjogren's syndrome (3.1% each) were the most frequent autoimmune diseases, followed by Grave's disease and alopecia areata (2.3% each) (Table). Univariable analyses showed that CLE-only patients who were Caucasian ( $p=0.03$ ), non-smokers ( $p=0.008$ ), have subacute cutaneous lupus ( $p=0.04$ ), or have positive anti-nuclear antibodies ( $p<0.0001$ ) were more likely to have a concomitant autoimmune disease. Based on our multivariable analyses, CLE-only patients who were Caucasian (Odds ratio (OR):3.07,  $p=0.03$ ), had non-smoking histories (OR:3.34,  $p=0.02$ ), and had positive anti-nuclear antibodies (OR:5.03,  $p=0.002$ ) were highly associated with having autoimmune diseases.

**Conclusion:** Our cohort of CLE-only patients, particularly those with Caucasian race, non-smoking history, and anti-nuclear antibodies, showed higher prevalence of co-existing autoimmune diseases than what is reported in the general population (4.5%).<sup>2</sup> Patients with CLE-only should be monitored closely for development of concomitant autoimmune conditions.

Table 1: Frequencies of autoimmune diseases in patients with CLE-only

Autoimmune disease	CLE-only frequency (%) n = 129*
Rheumatoid arthritis	4 (3.1%)

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is an autoimmune disease with increased cardiovascular and infectious complications due to subclinical atherosclerosis, disease activity and treatment-related factors. The aim of this study was to identify risk factors for early infectious and non-infectious complications in SLE patients undergoing major surgery.

**Methods:** Retrospective comparative cohort study including patients with SLE ( $\geq 4$  ACR criteria) that underwent major non-cardiac surgery between 2010-2015, and non-SLE patients paired 1:1 according to age, gender and type of surgery. Demographics, comorbidities, SLE variables, preoperative laboratory and risk assessment were analyzed. Main outcome was development of infectious, non-infectious complications and mortality 30 days after surgery. Differences between groups were evaluated: Student t-test or Mann-Whitney U test (continuous variables); Chi-square or Fisher's exact test (categorical variables). Univariate logistic regression and multivariate analyses were done.

**Results:** 382 patients (191 SLE, 191 non-SLE) were included. Disease duration of SLE patients at surgery was 132 (0-468) months. **Table 1** shows characteristics of surgical SLE and non-SLE patients. Variables associated with infectious complications in SLE patients: use of prednisone (OR 1.81, 95%CI 1.13-2.90,  $p=0.01$ ); anemia (OR 2.43, 95%CI 1.45-4.08,  $p=0.001$ ); hypoalbuminemia (OR 2.58, 95%CI 1.55-4.30,  $p<0.001$ ), and lymphopenia (OR 2.43, 95%CI 1.52-3.89,  $p<0.001$ ). Multivariate analysis retained hypoalbuminemia, anemia and lymphopenia. Variables associated with non-infectious complications: anemia (OR, 1.93, 95%CI 1.03-3.64,  $p=0.03$ ) and hypoalbuminemia (OR 2.11, 95%CI 1.16-3.86,  $p=0.01$ ). More patients with SLE died ( $p=0.02$ ). **Table 2** shows characteristics of SLE patients with and without any postoperative complication. Variables associated with any complication: SLEDAI-2K (OR 1.1, 95%CI 1.01-1.20,  $p=0.02$ ); nephritis (OR 10.08, 95%CI 1.21-83.63,  $p=0.03$ ); use of aspirin (OR 2.68, 95%CI 1.19-6.02,  $p=0.01$ ); low C3 (OR 2.00, 95%CI 1.06-3.80,  $p=0.03$ ); anemia (OR 2.68, 95%CI 1.39-5.18,  $p=0.003$ ); hypoalbuminemia (OR 3.49, 95%CI 1.83-6.66,  $p<0.001$ ), and lymphopenia (OR 2.36, 95%CI 1.30-4.26,  $p=0.004$ ). Only use of aspirin was retained in multivariate analysis. More patients with complications died ( $p<0.001$ ).

**Conclusion:** SLE patients present higher frequency of postoperative early complications and mortality compared to non-SLE patients. Hypoalbuminemia, anemia, lymphopenia and use of aspirin are independent risk factors.

## **The Impact of Disease Characteristics on Habitual Physical Activity and Sedentary Behavior Among Patients with Systemic Lupus Erythematosus (SLE)**

**Alexandra Legge**<sup>1</sup>, Chris Blanchard<sup>1</sup> and John G. Hanly<sup>2</sup>, <sup>1</sup>Department of Medicine, Queen Elizabeth II Health Sciences Centre and Dalhousie University, Halifax, NS, Canada, <sup>2</sup>Division of Rheumatology, Department of Medicine and Department of Pathology, Queen Elizabeth II Health Sciences Centre and Dalhousie University, Halifax, NS, Canada

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with systemic lupus erythematosus (SLE) are at increased risk for atherosclerotic cardiovascular disease (ASCVD). As sedentary behavior and lack of physical activity are known ASCVD risk factors, we evaluated habitual physical activity levels among SLE patients using accelerometry. We also investigated the association between SLE disease characteristics and the amount of habitual physical activity and sedentary behavior performed by SLE patients.

**Methods:** For this cross-sectional study, patients were recruited from an SLE clinic at a single academic medical center. All participants met the ACR classification criteria for SLE. Validated instruments were used to measure disease activity (SLEDAI-2K), organ damage [SLICC/ACR Damage Index (SDI)], and functional status (HAQ). Laboratory data included ESR and serum CRP. Habitual physical activity was measured using triaxial accelerometers worn during waking hours for seven consecutive days. Minutes per day of sedentary time, light activity, and moderate-vigorous physical activity (MVPA) were recorded. SLE disease characteristics associated with time spent performing MVPA and time in sedentary behavior were identified using multivariable linear regression, adjusting for demographic factors including age, sex, race, and education.

**Results:** There were 109 SLE patients (92% female) with mean (SD) age 52.3 (14.5) years, SLEDAI-2K 2.1 (2.4), and SDI 1.5 (2.1). High levels of sedentary behavior were observed [mean (SD) sedentary time 10.1 (1.2) hours/day], accounting for 78.6% of total accelerometer wear time. Mean (SD) MVPA was low [32.6 (22.5) minutes/day]. Only 13/109 participants (11.9%) met the Canadian Physical Activity Guidelines for MVPA ( $\geq 150$  minutes/week in 10 minute bouts). In univariable linear regression, SLE disease characteristics significantly associated with MVPA performance included the SDI ( $\beta = -0.184$ ;  $p=0.006$ ), HAQ ( $\beta = -0.207$ ;  $p=0.001$ ), SLEDAI-2K ( $\beta = -0.183$ ;  $p=0.004$ ), and ESR ( $\beta = -0.208$ ;  $p=0.004$ ). In multivariable analysis, both the HAQ ( $\beta = -0.191$ ;

p=0.002) and SLEDAI-2K ( $\beta = -0.175$ ; p=0.005) remained significantly associated with time spent performing MVPA. Specifically, higher HAQ and SLEDAI-2K scores were associated with lower MVPA performance. After adjustment for MVPA performance, none of the SLE disease characteristics we evaluated were significantly associated with time spent in sedentary behavior.

**Conclusion:** SLE patients demonstrate suboptimal levels of habitual MVPA, as well as high sedentary behavior. Our results highlight the potential negative impact of disease activity and functional disability on habitual physical activity in SLE. The findings identify a subgroup of SLE patients at increased risk for physical inactivity and will help inform the design of effective interventions to improve habitual physical activity levels in this population.

## Habitual Physical Activity, Sedentary Behavior and Cardiovascular Disease Risk Burden in Systemic Lupus Erythematosus (SLE)

Alexandra Legge<sup>1</sup>, Chris Blanchard<sup>1</sup> and John G. Hanly<sup>2</sup>, <sup>1</sup>Department of Medicine, Queen Elizabeth II Health Sciences Centre and Dalhousie University, Halifax, NS, Canada, <sup>2</sup>Division of Rheumatology, Department of Medicine and Department of Pathology, Queen Elizabeth II Health Sciences Centre and Dalhousie University, Halifax, NS, Canada

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with SLE are at increased risk for atherosclerotic cardiovascular disease (ASCVD). As sedentary behavior and lack of physical activity (PA) have been identified as ASCVD risk factors in the general population, we investigated the relationship between habitual PA levels and estimated 10-year ASCVD risk among patients with SLE. We also evaluated the association between habitual PA levels and individual ASCVD risk factors in SLE.

**Methods:** For this cross-sectional study, patients were recruited from an SLE clinic at a single academic medical center. All participants met the ACR classification criteria for SLE. Patients were excluded if they had a prior history of ASCVD. Habitual PA was measured using triaxial accelerometers worn during waking hours for seven consecutive days. Minutes per day of total sedentary time, prolonged sedentary bouts ( $\geq 30$  uninterrupted sedentary minutes), light activity, and moderate-vigorous physical activity (MVPA) were recorded. Cardiovascular risk factors included body mass index, blood pressure, fasting glucose and lipid profile. Ten-year ASCVD risk was calculated using the 2013 American College of Cardiology (ACC) / American Heart Association (AHA) risk assessment tool. Associations between time spent in each PA category and calculated 10-year ASCVD risk were assessed using multivariable linear regression models. The relationships between PA at each intensity level and individual cardiovascular risk markers were also evaluated using multivariable linear regression, adjusting for age and gender.

**Results:** There were 100 SLE patients (mean  $\pm$  SD age  $52.4 \pm 14.4$  years, 92% female). Participants spent a total of 10.0 hours/day being sedentary, 2.2 hours/day engaged in light activity, and 29.8 minutes/day engaged in MVPA. Median (IQR) time spent in prolonged sedentary bouts was 35.4 (36.8) minutes/day, with 21% of participants spending  $> 1$  hour/day in prolonged sedentary behavior. Only 11% of participants met the Canadian Physical Activity Guidelines for MVPA ( $\geq 150$  minutes/week in 10 minute bouts). Regression models demonstrated that time spent in MVPA was inversely associated with calculated 10-year ASCVD risk ( $R^2 \Delta = 0.10$ ;  $p=0.001$ ). Time spent in prolonged sedentary bouts was positively associated with 10-year risk of ASCVD ( $R^2 \Delta = 0.06$ ;  $p=0.016$ ), independent of time spent in MVPA ( $R^2 \Delta = 0.03$ ;  $p=0.049$ ). MVPA performance was also inversely associated with both systolic ( $R^2 \Delta = 0.07$ ;  $p=0.005$ ) and diastolic blood pressure ( $R^2 \Delta = 0.07$ ;  $p=0.007$ ), after adjusting for age, gender, and antihypertensive use. Neither total sedentary time nor time spent in light activity were significantly associated with 10-year ASCVD risk, nor were they associated with any of the individual cardiovascular risk markers we evaluated.

**Conclusion:** Among patients with SLE, those at higher risk for ASCVD perform less MVPA. Prolonged sedentary behavior is associated with ASCVD risk in SLE, independent of MVPA performance. Our findings highlight the need for effective PA interventions to increase habitual MVPA levels and reduce prolonged sedentary time in this high-risk population.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The screening and diagnosis of Cognitive Impairment (CI) in Systemic Lupus Erythematosus (SLE) patients is often delayed. CI diagnosed according to the American College of Rheumatology (ACR)-SLE battery is associated with a remarkable administrative and cost burden. The Automated

Neuropsychological Assessment Metrics (ANAM) is a promising computerized battery of tests that is easy to administer. In our recent systematic review, we found a CI prevalence of 34% by ANAM (95% CI: 25-44%) and by the comprehensive batteries 38% (95% CI: 33-43%). We aimed to determine the prevalence of CI based on the ANAM (v4) GNS Battery using different definitions for CI.

**Methods:** Consecutive SLE patients, aged 18-65 years, who attended the University of Toronto Lupus Clinic between July 2016 and April 2017 and agreeing to participate were included. Patients were administered the ANAM (v4) GNS, which consists of 15 subtests that evaluate key neurocognitive domains (processing speed, attention, memory, visuospatial processing, and executive functioning). ANAM throughput scores were used to provide an estimate of ‘cognitive efficiency’. Patient scores were compared to a normative sample of age and gender-matched healthy controls to obtain z-scores. *Cognitive impairment* was operationalized on the ANAM as a z-score of  $\leq -1.5$  (as compared to controls) on  $\geq 2$  subtests, or  $\leq -2.0$  on  $\geq 1$  subtests. The finger tapping subtest scores for both dominant and non-dominant hands were averaged to calculate a single subtest z-score. The two subtests for simple reaction times were also averaged to calculate a single summary z-score for both tests. Descriptive statistics were used.

**Results:** Of the 105 patients, 90.6% female, 45.6% were Caucasian, 16.7% Blacks, 5.3% Asians and 32.6% others. The mean age at SLE diagnosis was  $28.0 \pm 10.0$  and lupus duration at enrolment was  $16.3 \pm 10.0$  years.

Thirty-eight (35.5%) patients had CI based on  $z \leq -1.5$  on  $\geq 2$  subtests and 43 (40.2%) patients based on  $z \leq -2.0$  on  $\geq 1$  subtests (Table 1). The prevalence of CI in each of the 15 subtests varied from 3.8-26.4% ( $z \leq -1.5$ ) and 0.9-17.0% ( $z \leq -2.0$ ) (Table 2).

**Conclusion:** A high prevalence of CI, varying between 35.5-40.2% ( $z \leq -1.5$  in  $\geq 2$  subtests and  $z \leq -2.0$  in  $\geq 1$  subtests respectively) was identified by the ANAM in this cohort of young SLE patients. The CI prevalence of 35.5-40.2% is similar to the reported prevalence with ANAM and the comprehensive batteries found in SLE literature. Future studies should address the validity of ANAM (v4) GNS Battery against ACR-SLE battery.

Table 1. Frequency of SLE patients with throughput z-scores of $\leq -1.5$ and $\leq -2.0$ (N=107)		
Number of Subtests	No. (%) of Patients that scored $z \leq -1.5$	No. (%) of Patients that scored $z \leq -2.0$
0	47 (43.9%)	64 (59.8%)

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

An EULAR/ACR –sponsored project is currently developing new weighted SLE classification criteria including laboratory/clinical items. Combinations of symptoms appear commonly in SLE arguing against lupus as one single disease entity. Moreover, if such “clusters (buckets)” exist this would distort the weightings. It is important to ensure the independence of potential criteria items from each other. We evaluated the interrelationship between candidate criteria items in 2 cohorts.

### Methods:

**International Early SLE Cohort:** 389 SLE patients diagnosed within the last 3 years, from 7 academic centers in Asia (Manila), Europe (Berlin, Pisa), North America (Boston, Chicago, Toronto) and South America (São Paulo). Data on all ACR 1997, SLICC 2012 and 30 additional items were collected.

Tetrachoric correlation coefficients (rho) assessed the association between different items of the same domain (rho 0.2-0.3 borderline and rho > 0.3 meaningful correlation). Mucocutaneous, hematologic and neurological items were examined to avoid overrepresentation.

**Euro-Lupus Cohort:** 1000 SLE patients from 12 universities (7 European countries). The baseline patient data set was used for the analysis. The complete correlation matrix of the Euro-Lupus clinical data was analyzed. The significant associations identified in the international cohort were validated in the Euro-Lupus cohort.

### Results:

Mucocutaneous items: Only malar rash resulted in a correlation  $\geq 0.2$  with photosensitivity, alopecia, and oral ulcers. Neurological items: Only seizure and the non-criteria symptom migraine showed a correlation  $\geq 0.2$ . Serologic items: A high degree of correlation was found for anti-Sm with anti-RNP, and anti-dsDNA, for anti-Ro with anti-La, and between anti-phospholipid antibodies. Other correlations are represented in **Table 1**.

With the exception of the correlation between malar rash and oral ulcers, all associations between mucocutaneous manifestations were independently confirmed in the Euro-Lupus cohort.

Correlation matrix of the Euro-Lupus cohort:  $\rho \geq 0.2$  were only found for fever with alopecia and with nephritis, for lymphadenopathy with fever and with hepatitis, and for Libman-Sacks endocarditis with cardiomyopathy (**Figure 1**).

**Conclusion:** Significant associations were observed among specific clinical and serologic criteria items in the international cohort, and these results were externally validated in the Euro-Lupus cohort. These results will be considered in the ongoing development of new SLE classification criteria.

<b>Table 1. Correlation with <math>\rho \geq 0.2</math> among cutaneous manifestations, neurological and serologic in the international early SLE cohort</b>		
<b>Manifestations</b>	<b>Items</b>	<b>Tetrachoric rho International cohort</b>
<b>Mucocutaneous</b>	Malar rash vs alopecia	0.250

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cognitive impairment (CI) is a common neurobehavioural manifestation of SLE. In our recent systematic review, the prevalence of CI was 38% (95% CI: 33-43%) with a wide variation (15-79%), which may be due to differences in CI definitions and selection of neuropsychological tests across studies. We aim to report the prevalence of CI in a large cohort using a comprehensive battery (CB) of tests in which we operationalized the classification of CI.

**Methods:** Consecutive consenting SLE patients, aged 18-65 years, who attended a single center (Jul 2016-Apr 2017) were recruited. Patients were administered a CB that evaluates the major cognitive domains: Manual motor speed and dexterity, simple attention and processing speed, visual-spatial construction, verbal fluency, learning and memory (visuospatial and memory), executive functioning (untimed and timed).

Patient scores were compared to a normative sample of age- and gender-matched healthy controls to obtain z-scores. CI was operationalized on the CB as a z-score of  $\leq -1.5$  (as compared to controls) on  $\geq 2$  domains,  $z \leq -2.0$  on  $\geq 1$  domain or either. Descriptive statistics were used.

**Results:** Of the 105 patients (91% female), the mean age at SLE diagnosis was  $28.4 \pm 10.2$  and disease duration at enrolment was  $15.0 \pm 10.1$  years. The prevalence of CI was 40.0% ( $z \leq -1.5$  in  $\geq 2$  domains), 44.8% ( $z \leq -2.0$  in  $\geq 1$  domains) and 55.2% for either.

Prevalence of patients with domain z-scores of  $\leq -1.5$  and  $\leq -2.0$  varied from 7.6-49.5% and 0-24.8% respectively (**Fig 1**). The most affected domain was learning and memory (visuospatial and memory) in 52 (49.5%) patients based on  $z \leq -1.5$  on  $\geq 2$  subtests and 26 (24.8%) patients based on  $z \leq -2.0$  in  $\geq 1$  subtest.

The prevalence of patients with subtest z-scores of  $\leq -1.5$  and  $\leq -2.0$  from 2.3-44.4% and 0.0-32.2% respectively (**Table 1**).

**Conclusion:** Prevalence of CI using our CB ranged between 40.0-44.8 % ( $z \leq -1.5$  in  $\geq 2$  domains and  $z \leq -2.0$  in  $\geq 1$  domains respectively) and 55.2% for either, which was higher than the pooled prevalence from previous reports of 38% . These differences in CI prevalence across studies could be attributed to different factors including the heterogeneity in patients' demographics/comorbidities, sample size, the use of different metrics to determine CI, and the lack of a standardized definition of CI. Further studies are required to identify the best definition for CI and its metrics.

**Figure 1. Prevalence of patients with domain z-scores of  $\leq -1.5$  and  $\leq -2.0$  (n=105)**

## **SLE Disease Activity Index Glucocorticosteroid Index (SLEDAI-2KG) Identifies More Responders Than Sledai-2K**

**Zahi Touma**<sup>1</sup>, Dafna D Gladman<sup>2</sup>, Jiandong Su<sup>3</sup>, Nicole Anderson<sup>4</sup> and Murray Urowitz<sup>4</sup>, <sup>1</sup>Rheumatology, University of Toronto, Division of Rheumatology, Institute of Health Policy, Management and Evaluation, Toronto, ON, Canada, <sup>2</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, <sup>3</sup>University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>4</sup>Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2K) is one of the most commonly used disease activity indices in clinical practice and research but this index doesn't account for severity within each descriptor. Moreover, in clinical trials, the use of standard of care (SoC), which includes glucocorticosteroid (GCS) often confounds trial results.

We developed and validated a novel lupus disease activity index, SLEDAI-2K GCS (SLEDAI-2KG), that describes disease activity while accounting for GCS dose. SLEDAI-2KG has the same descriptors as SLEDAI-2K in addition to a new descriptor “GCS” with different weight scores based on the dose of GCS. Furthermore, SLEDAI-2KG has a low administration burden and a simple scoring system similar to SLEDAI-2K.

We aimed to compare the performance of SLEDAI-2K and SGI in identifying responders in response to SoC.

### **Methods:**

Patients seen between January 2011 and January 2014, at a single lupus centre, with active disease (SLEDAI-2K  $\geq 6$ ) and on prednisone  $\geq 10$  mg/day, and with follow up visits within 5-24 months were studied. Treatment was determined based on the judgment of the treating rheumatologist.

Response to SoC therapy, at first follow up visit, was assessed by SLEDAI-2K and SLEDAI-2KG. Responders were defined based on the decrease in SLEDAI-2K and SGI score by  $\geq 4$ . The performance of SLEDAI-2K and SGI was also compared using different cut-off points; 5, 6 and 7. Descriptive analysis was used in the analysis.

## Results:

111 patients met the inclusion criteria of the study and were further analyzed. Patients' characteristics are represented in table 1. The mean age of the patients at baseline visit was  $35.75 \pm 11.51$  years and the SLE duration was  $9.02 \pm 7.74$ . The mean follow-up to 1<sup>st</sup> visit was  $7.68 \pm 2.95$  months. Mean SLEDAI-2K and SLEDAI-2KG at baseline was  $12.39 \pm 6.03$  and  $17.08 \pm 6.73$  respectively. The mean prednisone dose at baseline was  $22.94 \pm 14.19$  mg/day.

SLEDAI-2KG identified more responders at 6 months (92% vs. 84%) and at 12 months (89% vs. 76%) compared to SLEDAI-2K. SLEDAI-2KG also identified more responders with cut off points 5, 6 and 7 (Table 2).

## Conclusion:

The novel index, SLEDAI-2KG, is superior to SLEDAI-2K in identifying responders at 6 and 12 months accounting for steroid dose and thus adjusting for severity within each descriptor of SLEDAI-2K. **SLEDAI-2KG** has the ability to enhance analyses in clinical trials to differentiate between responders on minimal and moderate/large doses of GCS.

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Venous thromboembolism (VTE) is a major cause of mortality and morbidity in hospitalized patients. Hospitalized patients with autoimmune disorders are particularly at risk of VTE. The National Inpatient Sample database was analyzed to determine trends in rate of hospitalization and mortality from VTE in hospitalized systemic lupus erythematosus (SLE) patients to assess its impact.

**Methods:** 2003-2011 National Inpatient Sample database of Healthcare Cost and Utilization Project was queried to identify all adults (age ≥ 18 years) with SLE. SLE patients hospitalized with VTE as one of the top three diagnoses were identified. Demographic characteristics and in-hospital outcomes of this population were compared to SLE patients without a VTE diagnosis. Multivariate logistic regression analysis was used to obtain adjusted odds ratio (OR).

**Results:** The total number of hospitalized patients with SLE was 299,595 of which 6266 (2.09%) had VTE. Mean age of the study population was 51 years of and 89% were females. Mean age of SLE patients with VTE was lower than those without VTE (49 vs 51 years). Rate of VTE was higher in African Americans as compared to Caucasians or Hispanics (2.5% vs 2.0%) and in males when compared to females (2.9% vs 2.0%).

After adjusting for potential confounders, compared to those without VTE, SLE patients with VTE had significantly higher inpatient mortality (2.6% vs. 2.0%, OR 1.22 (CI 1.12 – 1.13,  $p = .001$ ), longer length of stay (LOS) (5 vs. 4 days, OR 2.29 (CI 2.23 – 2.35),  $p < .001$ ) and higher cost of hospitalization (\$26000 vs. \$20000, OR 1.46 (CI 1.39 – 1.55),  $p < .001$ ), greater disability at discharge (OR 1.31 (CI 1.27 – 1.35),  $p < .001$ ) (Table 1).

**Conclusion:** VTE in hospitalized patients with SLE is associated with significantly higher inpatient mortality, greater disability at discharge, increased length of stay and higher cost of hospitalization. In this database patients with SLE and VTE were younger. Male sex and African-American race may be associated with an increased risk of VTE in patients with SLE. This cross-sectional study would help in the development and implementation of appropriate prophylactic strategies in high risk SLE population. Further studies are needed to understand the effect of autoimmune diseases on VTE risk among hospitalized patients.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Childhood-onset SLE (cSLE) often presents with severe disease, managed with high-dose steroids. However, little is known about differences in long-term steroid toxicity between adults with cSLE and adult-onset SLE (aSLE). The goal of this study was to determine whether adults with cSLE are at increased risk for steroid-related and total disease damage as compared to aSLE, and whether they accumulate more disease damage over time.

**Methods:** Data derive from the 2005-2012 cycles of the Lupus Outcomes Study, a cohort of adults with SLE confirmed by chart review using ACR classification criteria, followed by annual telephone surveys. The Brief Index of Lupus Damage (BILD), a validated, patient-reported measure, was used to assess SLE-associated damage. Participants age 18-63 were included in the analysis (N=897). Those diagnosed at age < 18 years were defined as cSLE (N=113). Outcome variables included total BILD scores at baseline and follow-up (mean=6.3±1.7 years between assessments), and presence of steroid-related damage at any point during the study. Steroid-related damage was defined as a self-reported history of cataracts, osteoporosis, avascular necrosis (AVN) or diabetes mellitus (DM). Logistic regression and negative binomial regression were used to compare cSLE and aSLE groups, adjusting for sex, ethnicity, baseline age and baseline disease duration. General health predictors (hypertension, obesity) and medication predictors (steroid use ever) associated with steroid-related damage were included in the steroid damage analysis.

**Results:** Participants with cSLE were younger (mean age 32±10 vs. 47±10; p<0.001), more likely to be male (12% vs 7%; p=0.05) and less likely to be white (41% vs. 57%; p<0.001). Mean age at diagnosis was 14 (±3) for the cSLE vs. 33 (±10) for aSLE group. Median disease duration was 16 years (range 4-50) for participants with cSLE and 12 years (range 0-42) for aSLE. Nearly all participants reported a history of steroid use. There was no difference in unadjusted frequency of steroid-related damage between cSLE and aSLE groups (59% vs. 60%). However, in adjusted analysis, participants with cSLE were twice as likely to report steroid-related damage (72% vs. 58%, p<0.0001, OR 2.0, 95% CI 1.2-3.4). Steroid-related damage also increased significantly with increased disease duration for both groups (Figure 1). Mean damage score at baseline and increase in damage score over 6.3±1.7 year follow up did not differ between groups in unadjusted or adjusted analyses.

**Conclusion:** In this large cohort of adults with SLE, childhood-onset predicted increased risk of steroid-related damage. Participants with cSLE and aSLE continued to accumulate disease-related damage at similar frequencies over time. More aggressive use of steroid-sparing management strategies during childhood may be important to prevent increased risk of steroid-related damage in adulthood.

Figure 1: Adjusted frequency of steroid-related damage among adults with aSLE vs. cSLE by disease duration

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have previously observed associations between systemic lupus erythematosus (SLE) disease activity and heart rate variability (HRV) between 2 time points (1). We aim to prospectively test the hypothesis that HRV reflects longitudinal changes in clinical status and patient reported outcomes.

**Methods:** HRV was evaluated using a 5 min ECG in SLE patients who completed a minimum of 2 visits in an ongoing clinical trial. HRV parameters were calculated in the time domain (RMSSD and pNN50) and frequency domain [high frequency (HF), low to high frequency (LF/HF) ratio]. A mixed effects linear model with generalized

estimating equations was used to compare changes in HRV between paired visits and to examine linear associations between HRV and clinical scores. All models were adjusted for baseline HRV.

**Results:** Forty nine patients (age  $44.9 \pm 11.7$ , 46 female) were followed in 413 paired visits (median time between visits 1 month). BILAG was inversely associated with RMSSD ( $\beta = -1.39 \pm 0.01$ ;  $p < 0.0001$ ). BILAG, SLEDAI and PGA were directly associated with the LF/HF ratio ( $\beta = 0.96 \pm 0.02$ ;  $p < 0.0001$ ,  $0.42 \pm 0.10$ ;  $p < 0.0001$  and  $0.83 \pm 0.09$ ;  $p < 0.0001$ , respectively). Changes in BILAG were inversely associated with changes in RMSSD and pNN50 ( $\beta = -7.0 \pm 1.9$ ;  $p = 0.003$  and  $-1.6 \pm 0.04$ ;  $p < 0.0001$ , respectively). BILAG changes were also directly associated with changes in the LF/HF ratio ( $\beta = 0.78 \pm 0.05$ ;  $p < 0.0001$ ). Categorical improvement ( $\geq 1$  letter grade improvement in BILAG and no new BILAG A/B) occurred in 77 (19%) visit pairs (group 1) and no improvement or worsening in 335 (81%) (group 2). RMSSD and HF increased in group 1 vs. group 2 (group difference  $= -33.3 \pm 10.1$ ;  $p = 0.001$  and  $-30.9 \pm 4.1$ ;  $p < 0.0001$ , respectively), and the LF/HF ratio decreased in group 1 vs. group 2 (group difference  $= 3.1 \pm 0.8$ ;  $p = 0.002$ ). The average per visit changes in HRV in groups 1 and 2 are listed in Table 1.

Changes in Physical Component Summary (PCS) of SF36v2 were inversely related to changes in SLEDAI and PGA ( $\beta = -0.39 \pm 0.14$ ;  $p = 0.006$  and  $-0.19 \pm 0.02$ ;  $p < 0.0001$ , respectively). Changes in Mental Component Summary (MCS) were inversely related to changes in BILAG, SLEDAI and PGA ( $\beta = -0.23 \pm 0.07$ ;  $p = 0.0001$ ,  $-0.31 \pm 0.10$ ;  $p = 0.002$  and  $-0.08 \pm 0.03$ ;  $p = 0.008$ , respectively). PCS was related to HF ( $\beta = 0.67 \pm 0.28$ ,  $p = 0.01$ ) and MCS was inversely related to the LF/HF ratio ( $\beta = -0.11 \pm 0.03$ ,  $p = 0.0001$ ). Changes in PCS were related to changes in pNN50 ( $\beta = 0.21 \pm 0.05$ ,  $p = 0.0001$ ) and LF/HF ( $\beta = 0.17 \pm 0.06$ ,  $p = 0.003$ ) and changes in MCS were related to changes in HF ( $\beta = 1.57 \pm 0.18$ ;  $p < 0.0001$ ).

**Conclusion:** Changes in HRV reflect changes in clinical status and patient reported outcomes in patients with SLE. These data suggest that HRV may be a simple non-invasive tool used to gauge or predict clinical improvement in SLE. Further studies are warranted.

Table 1. Average per visit changes in HRV in groups 1 and 2.

Variable	Group 1	Group 2	P value
RMSSD	$2.9 \pm 1.2$	$-3.5 \pm 1.2$	$< 0.0001$
HF	$6.9 \pm 0.4$	$0.5 \pm 0.2$	$< 0.0001$
PNN50	$0.10 \pm 0.23$	$-0.15 \pm 0.20$	0.81
LF/HF	$-0.83 \pm 0.07$	$0.13 \pm 0.07$	$< 0.0001$

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** SLE patients have increased cardiovascular disease (CVD) risk, including higher risk of stroke, compared to age- and sex-matched diabetes mellitus (DM) patients. Although DM confers high risk of developing atrial fibrillation/flutter (AF), AF prevalence rates, a contributor to stroke, among SLE patients are unknown. We investigated rates and risks of AF hospitalization among SLE patients compared to age- and sex-matched DM and general Medicaid population.

**Methods:** We used Medicaid Analytic eXtract (MAX) data, containing all billing claims for Medicaid patients from the 29 most populated US states, 2007-2010. We included patients ages 18-65 in three separate cohorts: prevalent SLE, prevalent DM, and a non-SLE, non-DM general Medicaid cohort. We required >3 ICD-9 codes for SLE or DM, each separated by >30 days. Index date was the date of the 3<sup>rd</sup> diagnosis code. The general Medicaid cohort was selected by using non-SLE, non-DM ICD-9 codes on the same date as SLE index date. All cohorts required baseline period of 6 months of continuous Medicaid enrollment prior to the index date. Each SLE patient was matched to 2 DM, and 4 non-SLE, non-DM patients by age at index date, and sex. Subjects were followed from index date until death, disenrollment or end of follow-up. We used ICD-9 codes to identify outcomes of AF within primary or secondary hospital discharge diagnoses and calculated rates of first AF hospitalization events per 1,000 person-years. We used Cox regression models to calculate hazard ratios (HR) for first AF hospitalization events. In a secondary analysis, we excluded those with baseline AF.

**Results:** 40,212 SLE patients were matched to 80,424 DM and 160,848 general Medicaid patients. In all cohorts, 92% were female and mean age was 40.3 (+12.1) years. Mean follow up was 1.8 (+1.1) years for SLE, 1.8 (+1.1) years for DM, and 1.6 (+1.2) years for general Medicaid patients. Baseline CVD was prevalent in 18% SLE, 13% DM and 1% general Medicaid cohorts. Baseline prevalence of AF was 1% in SLE, <1% in DM and <1% in general Medicaid cohorts. Anticoagulant use was present in 7% of SLE vs 2% of DM patients ( $p<0.001$ ). Beta-blocker use was similar between SLE and DM cohorts (11% in both). AF hospitalization rates per 1,000-person years were similar in SLE vs DM, and nearly double that in the general Medicaid cohort (**Table**). The adjusted HR for first AF hospitalization was increased among DM (HR 1.9, 95% CI 1.6-2.3) and SLE (HR 1.4, 95% CI 1.1-1.8) patients compared to the general patients, and remained increased after excluding patients with baseline AF.

**Conclusion:** First AF hospitalization rate among SLE patients was double that of the general non-SLE, non-DM Medicaid population, and similar to the rate among age- and sex-matched DM patients. Adjusted HRs for first AF hospitalization among SLE patients was as high as in DM patients. As DM is a known AF contributor, the similarly elevated risk among SLE patients warrants further investigation.

**Table. Rates and Multivariable Hazard Ratios for Hospitalizations for Atrial Fibrillation/Flutter\* among SLE, and age- and sex-matched DM and General (non-SLE, non-DM) Medicaid Population, 2007-2010**

Cohort†	Events	Person-years	Rate‡ (95% CI)	HR§ (95% CI)	
				Including all patients	Excluding patients with baseline atrial fibrillation/flutter
<b>General Medicaid</b>	207	250,762	0.8 (0.7-1.0)	1.0 (ref)	1.0 (ref)
<b>SLE</b>	119	74,151	1.6 (1.3-1.9)	<b>1.4 (1.1-1.8)</b>	<b>1.5 (1.2-1.9)</b>
<b>Diabetes Mellitus</b>	240	147,584	1.6 (1.4-1.9)	<b>1.9 (1.6-2.3)</b>	<b>1.5 (1.2-1.8)</b>

\*Atrial fibrillation/flutter: By primary or secondary hospitalization ICD-9 diagnosis codes 427.31, 427.32

†Cohort: SLE cohort defined as >3 SLE ICD-9 codes (710.0), each separated by >30 days; DM cohort defined as >3 ICD-9 codes (249.XX, 250.XX, 357.2, 362.01-362.06, 366.41), 1:2 matched by age, sex to SLE cohort; General Medicaid cohort defined as any non-SLE, non-DM ICD-9 code on same date as SLE index date, 1:4 matched by age, and sex to SLE cohort

‡Rate: Rate of first atrial fibrillation/flutter hospitalization events per 1000 person-years of follow-up

§HR: Hazard ratio for first atrial fibrillation/flutter hospitalization event adjusted for: age, sex, race/ethnicity, US region of residence, zip-code level socioeconomic status, Charlson comorbidity index; Two separate Cox proportional hazard models: 1) including all patients, 2) excluding patients who had baseline atrial fibrillation/flutter diagnosis

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Leukopenia is commonly seen in SLE, but its predictors are not well understood, as it can be a result of disease activity or bone marrow suppression from immunosuppressive medications.

**Methods:** Data from 6071 visits in 1352 patients from a multinational lupus cohort were analysed. All patients met either ACR criteria (91%) or SLICC classification criteria (98.5%). Only patients with  $\geq 2$  visits were included in the analysis. Leukopenia was defined according to Common Terminology Criteria for Adverse Events (V3), of at least grade 2 (moderate) severity i.e. total white cell count  $< 3$  or lymphocyte count  $< 0.8$  or neutropenia  $< 1.5$ . The generalised estimating equation method was used to examine longitudinal associations of leukopenia with factors including demographics (age, gender, ethnicity, SLE family history), serology (low complement/anti-dsDNA positivity), disease characteristics such as SLE Disease Activity Index (SLEDAI-2k) score, flare, physician global assessment (PGA), damage accrual Lupus Low Disease Activity State (LLDAS), and medication use.

**Results:** Thirty-five percent of patients had at least one episode of leukopenia over 1585 patient-years (24% of all visits). SLEDAI-2k  $\geq 6$ , flare, and PGA  $> 1$  were all significantly associated with increased odds of leukopenia ( $p < 0.01$ ). Low complement and high ESR were also significantly associated with leukopenia ( $p < 0.01$ ). In contrast, LLDAS was significantly associated with reduced odds of leukopenia, with an unadjusted odds ratio (OR) = 0.71, 95% CI 0.62-0.81,  $p < 0.01$ .

The only immunosuppressant that was significantly associated with leukopenia was rituximab, OR 2.4, 95% CI 1.17-4.91,  $p = 0.02$ . Azathioprine and leflunomide use had weak associations with leukopenia but did not reach statistical significance in univariable analysis ( $p$ -value 0.09 and 0.08 respectively). Neither methotrexate or mycophenolate use was associated with leukopenia. After adjustment in multivariable analysis models, statistically significant associations with leukopenia remained for SLEDAI  $\geq 6$  (OR 1.33, 95% CI: 1.09 to 1.62;  $p < 0.01$ ), ESR  $> 25$  (OR ESR  $> 25$  = 1.36, 95% CI 1.14-1.61;  $p < 0.01$ ), rituximab (OR 3.11, 95% CI 1.45-6.65;  $p < 0.01$ ) and azathioprine use (OR 1.58, 95% CI 1.24-2.01;  $p < 0.01$ ); the association of LLDAS with reduced odds of leukopenia also remained significant (OR = 0.56, 95% CI: 0.46 to 0.68;  $p$ -value  $< 0.01$ ).

**Conclusion:** SLE disease activity is a significant predictor of leukopenia, and leukopenia is negatively associated with LLDAS. Of the medications commonly used in SLE, rituximab and azathioprine were significantly associated with leukopenia.

# Achievement of Lupus Low Disease Activity State (LLDAS) in the Early Phase of Systemic Lupus Erythematosus Prevent Damage Accrual

**Matteo Piga**, Alberto Floris, Giulia Cappellazzo, Alessandro Mathieu and Alberto Cauli, Unit and Chair of Rheumatology, University Hospital of Cagliari, Cagliari, Italy

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Asia-Pacific Collaboration Group has recently proposed the definition of Lupus Low Disease Activity state (LLDAS). This potential target in SLE treatment has been applied so far in a few longstanding SLE cohorts with not homogeneous disease duration. The present study aims to assess attainability and outcome of the LLDAS in the early stages of systemic lupus erythematosus (SLE) diagnosis and management.

**Methods:** LLDAS prevalence was evaluated at 6 (T1) and 18 (T2) months after treatment initiation (T0) in a monocentric cohort of 107 (median disease duration 9.7 months) prospectively followed Caucasian SLE patients. Reasons for failure to achieve LLDAS were also investigated. Multivariate models were built, using co-variables with  $p < 0.1$  at univariate analysis, to identify factors associated with failure to LLDAS achievement and to investigate the relationship between LLDAS and SLICC/Damage Index (SDI) accrual.

**Results:** Forty-seven (43.9%) patients were in LLDAS at T1 and 48 (44.9%) at T2. The most frequent unmet LLDAS criteria was the prednisolone dose  $\leq 7.5$ mg/day (unmet in 83% of no-LLDAS at T1). The disease manifestations with the highest persistence rate during follow-up were: increased anti-dsDNA (persistently present in 85.7% and 67.5% of cases at T1 and T2, respectively), low complement (73.2% and 66.3%) and renal abnormalities (46.4% and 28.6%). Renal involvement at T0 was significantly associated with failure to achieve LLDAS both at T1 (OR: 7.8, 95%CI: 1.41-43.40;  $p=0.019$ ) and T2 (OR: 3.87, 95%CI 1.41-10.6;  $p=0.008$ ). In regard of organ damage, 27 SDI-items (9 of them steroid-related) were recorded in 23 (21.5%) patients at T2. Presence of any organ damage ( $SDI \geq 1$ ) at T2 was significantly associated to no-LLDAS at T1 (OR: 5.01, 95%CI 1.51-16.63;  $p=0.009$ ) and age at diagnosis (OR: 1.05 per year, 95%CI 1.01-1.09;  $p=0.020$ ).

**Conclusion:** LLDAS is a promising target in the early stages of SLE management being attainable and negatively associated to damage accrual. However, it seems to poorly fit to patients with renal involvement and a greater consensus should be reached on the definition of significant serological disorders and minimal acceptable prednisolone dose.

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Hospital Readmissions For SLE In The United States: A National Database Study

**Background/Purpose:** Systemic lupus erythematosus (SLE) is associated with significant mortality and morbidity, and increased hospital readmissions. Data about readmissions among SLE patients on a national level in the United States is sparse. The aim of this study was to describe unplanned hospital readmission rates among adult SLE patients and assess predictors of readmission.

**Methods:** We analyzed the 2013 National Readmission Database (NRD) to quantify readmission rates among SLE patients. We identified comorbidities and reasons for unplanned 30-day readmissions using administrative codes. We then used survey logistic regression to elucidate predictors for unplanned readmissions using adjusted odds ratios (aOR) and 95% confidence intervals (CI).

**Results:** Among 7926 patients with SLE, 1641 had at least one unplanned 30-days readmissions (20.7%). 39% of readmissions were related to SLE (Figure 1A). Readmitted patients were more likely to be young, have glomerulonephritis (GN), chronic kidney disease (CKD), pericarditis, pleuritis, thrombocytopenia and longer length of hospital stay. Significant predictors of SLE included age 18-25 years, CKD, GN, pericarditis, psychosis, anemia, thrombocytopenia, length of stay > 4 days, patients having Medicare and Medicaid insurance, home health care and against medical advice discharges after adjusting for socio-demographics, comorbidities and hospital characteristic (Figure 1). Cost of hospitalization was \$12,522 in patients without readmission compared to \$15,716 for index admission in patients with readmission (Figure 2). Cost of readmission was an additional \$14,409.

**Conclusion:** In NRD, 20.7% of patients admitted with a primary diagnosis of SLE were readmitted within 30 days. This underscores the importance of close outpatient follow up in the post discharge period especially in high-risk patients with co-morbidities. Readmissions were associated with significant cost.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cardiovascular disease (CVD) is a leading cause of mortality in SLE and identifying those at risk remains challenging. While in the general population the Framingham Risk Score (FRS) and high-sensitivity CRP (hsCRP) are good predictors of CVD, in SLE their value remains controversial due to the known underperformance of the FRS and the variability of hsCRP levels. Interestingly high prevalence of nonspecific ST-T segment (NST-T) abnormalities was noted in an SLE inception cohort. While in the general population NST-T abnormalities are associated with increased risk of cardiovascular events, in SLE this association remains

unknown. Therefore, we sought to identify SLE characteristics associated with the modified FRS (mFRS) as a surrogate outcome for CVD, with a particular interest in NST-T and hsCRP.

**Methods:** Adult SLE patients without clinical CVD continuously seen at a University Lupus Center between April 2016 and March 2017, meeting 1997 ACR classification criteria for SLE were studied. Patient characteristics including demographics, SLE-specific features, medication use, traditional CVD risk factors, 12-lead electrocardiogram (EKG), and hsCRP, were ascertained. High-level hsCRP was defined as  $\geq 75^{\text{th}}$  percentile. Univariable and multivariable linear regression models were constructed to test the association of NST-T and high-level hsCRP with the mFRS.

**Results:** One hundred and thirty five SLE patients (baseline characteristics in table 1) were studied. In univariable analyses, presence of NST-T abnormalities (0.389,  $p=0.025$ ), high-level hsCRP (0.421,  $p=0.033$ ), and the SLICC/ACR Damage Index (SDI) (0.24,  $p=0.004$ ) were significantly associated with a higher mFRS. After adjusting for variables associated with NST-T abnormalities, hsCRP, and the SDI, respectively, including total protein, Female sex and use of methotrexate these associations remained statistically significant (NST-T:0.816, $p=0.024$ ; hsCRP75:0.527, $p=0.017$ ; and SDI:0.193,  $p=0.016$ )(Figure 1).

**Conclusion:** EKG nonspecific ST-T abnormalities, high-level hsCRP and the SDI are all independently associated with a higher mFRS in SLE patients without clinical CVD.

# Use of Emergency Department (ED) and Resulting Hospitalization By Patients with Systemic Lupus Erythematosus (SLE) in a Predominantly Afro-Caribbean Inner-City Cohort

**Maushmi Savjani**<sup>1</sup>, Justin Levinson<sup>2</sup> and Ellen M. Ginzler<sup>3</sup>, <sup>1</sup>Internal Medicine, Division of Rheumatology, Department of Medicine, SUNY Downstate Medical Center, Brooklyn, NY, <sup>2</sup>Medicine, Division of Rheumatology, Department of Medicine, SUNY Downstate Medical Center, Brooklyn, NY, <sup>3</sup>Rheumatology, Division of Rheumatology, Department of Medicine, SUNY Downstate Medical Center, Brooklyn, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Given the complexity, chronicity and associated co-morbidities, management of SLE poses a challenge. Despite established care in private and fellow/resident clinics, our patients often go to ED, resulting in inappropriate and costly hospitalizations. Our aim is to reduce ED visits with appropriate outpatient rheumatology care, instate appropriate ED rheumatology consults, and reduce unnecessary hospitalizations.

## Methods:

We reviewed SLE patients seen by the Rheumatology Division at least once from 7/2013 to 6/2015, quantifying ED visits and subsequent hospitalization or discharge from 1/2010 to 6/2015. We compared age at SLE diagnosis, SLE duration when first seen by us, and insurance status of “ED users” (at least 1 ED visit) with “ED non-users” (no ED visits). Frequency of ED rheumatology consults among hospitalized vs. discharged patients was noted. After introduction of education tools (Medical ground Rounds presentation of our data and implementation of required rheumatology rotation by our EM-IM residents), we re-assessed the relationship between ED visit frequency and clinic visits in ED user vs. non-users.

## Results:

363 SLE patients had 1700 ED visits (range 1-72), leading to 774 hospitalizations over a 5.5-year period. 25 excluded due to lack of data. Among 338 patients, 95 were ED non-users and 243 were ED users, totaling 1608 ED visits with 727 hospitalizations. Among ED users, 61(25%) had no hospitalizations; 34 (14%) were followed privately vs. 201(83%) in clinic. 33(35%) private and 62(65%) clinic patients had no ED visits (Table 1). Only 112 (7%) of ED visits had a rheumatology consult in the ED; 68 (61%) were hospitalized and 44 (39%) were discharged. Pre- and post-educational tools introduction data presented in Table 2.

## Conclusion:

Our SLE cohort had frequent ED visits followed by high rate of hospitalization. The difference in mean age at SLE diagnosis, mean SLE duration and insurance status between ED users vs. non-users was small. Only 14% of patients followed privately had any ED visits compared to 83% of clinic patients, yet the % of non-users was higher in clinic patients. Rheumatology consult was requested in only 7%, yet 39% resulted in discharge from the ED, potentially preventing unnecessary hospitalization. Pre- and post-educational tools showed reduction in ED visits and hospitalization among ED users, however, a decrease in clinic visits could be confounded by loss to follow-up. Consistent outpatient care in those not requiring hospitalization and case managers for high-risk patients should reduce inappropriate ED visits and subsequent hospitalizations.

**Table 1: Comparisons between ED Users vs Non-users from January 2010 to June 2015**

	ED users (at least 1 visit) n = 243	ED non-users (no ED visits) n = 95
Mean age at SLE Diagnosis (years)	30.89	32.30
Mean SLE duration when 1 <sup>st</sup> seen by Rheumatology Division (years)	3.59	4.81
Without Insurance	6 (2.4%)	5 (5.3%)
Followed Privately	34 (14%) => 143 ED visits => 51 hospitalizations	33 (35%)
Followed in Fellow/Resident Clinic	201 (83%) => 1465 ED visits => 676 hospitalizations	62 (65%)
Seen only as Inpatient Consultation	8 (3.3%)	-

**Table 2: Relationship between ED visit frequency and Clinic visits pre- and post-educational tools introduction (Medical Ground Rounds and Rheumatology Rotation requirement for EM-IM residents). Private patients and those seen only as inpatient consults were excluded.**

	Pre-intervention (July 2013 – June 2015)			Post-intervention (July 2015 – June 2017)		
	ED visits	Clinic visits	Hospital Admissions	ED visits	Clinic visits	Hospital Admissions

## **Body Mass Index and Disease Activity in Systemic Lupus Erythematosus- a Paradoxical Relationship?**

**George Stojan**<sup>1</sup>, Wei Fu<sup>2</sup> and Michelle Petri<sup>3</sup>, <sup>1</sup>Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Obesity is more common in patients with SLE compared to the general population. The prevalence of obesity among SLE patients is between 28 and 50 percent. Despite the high prevalence of obesity in this population, the effect of obesity on disease activity in SLE has not been studied. We hypothesized that the BMI at cohort entry was predictive of future disease activity and that changes in BMI during cohort follow up were associated with disease activity independent of corticosteroid treatment.

### **Methods:**

2406 patients in a prospective SLE cohort had their weight assessed at each visit. Patients were categorized into five predetermined groups based on weight: low (BMI<20 kg/m<sup>2</sup>), normal weight (reference, BMI 20-24.9 kg/m<sup>2</sup>), overweight (25-29.9 kg/m<sup>2</sup>), obese (BMI 30-34.9 kg/m<sup>2</sup>), and severely obese (BMI>35 kg/m<sup>2</sup>). To calculate adjusted mean of SLEDAI over time, we only included patients attending the clinic at 3 month intervals for a minimum of 3 visits. 1896 patients were included in the analysis. 1763 (93.0%) were females. Majority (53.0%) were Caucasians, 39.0% African American. A within-person analysis was then performed to assess whether a person's disease activity level changed if a person's BMI changed.

### **Results:**

Adjusted mean of SLEDAI over time did not differ between different BMI groups (table 1). SLEDAI significantly decreased by 0.03 with one unit increase in BMI (table 2). In Table 3, we calculated association between mean centered BMI (BMI – individual average BMI) and mean centered SLEDAI (SLEDAI – individual average SLEDAI) which showed a similar association.

Table 1. Adjusted Mean of SLEDAI Over Time by BMI at Entry Visit

BMI	N (%)	SLEDAI Mean (SD)	P value
Normal (Reference)	655(34.5)	2.7(2.4)	REF
Low	183(9.7)	2.9(2.2)	1
Overweight	531(28)	2.5(2.1)	1
Obese	290(15.3)	2.6(2.1)	1
Severely Obese	237(12.5)	2.5(2.1)	1

Table 2. Association of Disease activity with continuous BMI

	Mean difference (95% CI)	P value	Adj. Mean difference (95%CI)*	P value
BMI	-0.03 (-0.04, 0.01)	<0.0001	-0.03(-0.04,-0.02)	<0.0001

\* Adjust for age, race and prednisone at visit

Table 3. Association of mean centered SLEDAI with mean centered BMI

	Mean difference (95% CI)	P value	Adj. Mean difference (95%CI)*	P value
Mean Centered BMI	-0.06(-0.07,-0.05)	<0.0001	-0.06(-0.07,-0.05)	<0.0001

\* Adjust for age, race and prednisone at visit

## Conclusion:

Body weight at cohort entry was not predictive of future disease activity. There was an inverse correlation between changes in body mass index and disease activity even after adjusting for prednisone use. This is the first evidence to our knowledge of an obesity paradox in systemic lupus.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Cachexia is a syndrome that may accompany a range of diseases, including cancer, chronic heart failure, chronic obstructive pulmonary disease, and rheumatoid arthritis. It is associated with central and systemic increases of pro-inflammatory factors, and with decreased quality of life, poor responses to pharmacological treatment and shortened survival. Despite an abundance of data from other inflammatory diseases, cachexia in systemic lupus erythematosus remains a largely undescribed syndrome.

## **Methods:**

2406 patients in a prospective SLE cohort had their weight assessed at each visit. Patients were categorized into five predetermined groups based on weight: low (BMI<20 kg/m<sup>2</sup>), normal weight (reference, BMI 20-24.9 kg/m<sup>2</sup>), overweight (25-29.9 kg/m<sup>2</sup>), obese (BMI 30-34.9 kg/m<sup>2</sup>), and severely obese (BMI>35 kg/m<sup>2</sup>). Cachexia was defined based on modified Fearon criteria as 5% stable weight loss in 6 months without starvation relative to the average weight in all prior cohort visits AND/OR weight loss >2% without starvation relative to the average weight in all prior cohort visits and a BMI <20. Risk of cachexia within 5 years of cohort entry was based on Kaplan Meier estimates. Differences by patient characteristics were based on log-rank test.

## **Results:**

Table 1: Risk of Cachexia within 5 years of cohort entry

Patient Characteristic	Risk of Cachexia within 5 years of cohort entry (95% CI) <sup>1</sup>	P-value for difference by patient characteristic <sup>2</sup>
All (n=2452)	53% (51%, 56%)	
Age Group	60% (56%, 64%)	<0.0001
<30 (n=805)	51% (47%, 55%)	
30-44 (n=987)	46% (41%, 52%)	
45-59 (n=528)	57% (46%, 67%)	
60+ (n=132)		
Race	53% (50%, 57%)	0.050
White (n=1309)	63% (54%, 72%)	
Black (n=183)	52% (48%, 55%)	
Other (n=960)		
Sex	53% (51%, 56%)	0.62
Female (n=2266)	51% (42%, 60%)	
Male (n=186)		
Initial BMI	73% (66%, 79%)	<0.0001
<20 (n=220)	59% (55%, 68%)	
20-24.9 (n=782)	64% (59%, 68%)	
25-29.9 (n=632)	37% (33%, 41%)	
30+ (n=635)		

<sup>1</sup>Based on Kaplan-Meier estimates

<sup>2</sup>Based on a log-rank test.

Table 2: Rate ratio comparing those with prior disease manifestation to those without with respect to incidence of cachexia

Prior Disease Manifestation	Rate Ratio (95% CI)	P-value
Malar Rash	1.1 (0.9, 1.2)	0.41
Discoid Rash	0.8 (0.7, 0.9)	0.0002
Photosensitivity	0.9 (0.8, 1.0)	0.013
Oral Ulcers	1.0 (0.9, 1.1)	0.82
Musculoskeletal	0.8 (0.7, 0.9)	0.0023
Serositis	1.1 (1.0, 1.3)	0.027
Neurologic	1.1 (0.9, 1.4)	0.22
Renal	1.2 (1.1, 1.4)	0.0004
Hematologic	1.0 (0.9, 1.2)	0.59
Immunologic	1.1 (0.9, 1.3)	0.22
ANA	0.9 (0.7, 1.2)	0.68

Table 3: Rate ratio comparing those with recent activity to those without with respect to incidence of cachexia

Disease Activity in preceding 3 months as measured by components of SLEDAI	Rate Ratio (95% CI)	P-value
Skin activity	1.1 (0.9, 1.3)	0.25
Musculoskeletal activity	0.9 (0.8, 1.1)	0.51
Renal activity	1.3 (1.1, 1.5)	0.0048
Hematologic Activity	0.9 (0.7, 1.1)	0.34
Serositis Activity	1.2 (0.9, 1.7)	0.20
CNS activity	0.9 (0.6, 1.3)	0.53
Vasculitis Activity	1.2 (0.7, 1.9)	0.52
Constitutional Activity	1.3 (0.6, 2.9)	0.44

## Conclusion:

Within five years of cohort entry, half of the Hopkins Lupus cohort patients develop cachexia as defined by Fearon criteria; those younger than 30 years of age and those with a BMI below 20 are at highest risk of cachexia.

While patients with discoid rash and musculoskeletal manifestations were less likely to develop cachexia, renal lupus carried the highest cachexia risk.

Cachexia is an underrecognized syndrome in patients with lupus which is predominantly seen in patients with lupus nephritis. Further studies are needed to elucidate the implications of cachexia in the response to treatment, long term outcomes, quality of life, as well as its role as a potential cardiovascular risk factor in SLE.

/ : data is not sufficient for calculating odds ratios

## Conclusion:

Patients with low BMI at cohort entry are almost three times more likely to have retinal change and two times more likely to develop deforming or erosive arthritis.

Overweight patients at cohort entry are 70% more likely to have Infarction or resection of bowel and 58% more likely to develop cancer.

Obese patients at cohort entry are 68% more likely to develop cataract; almost three times more likely to have angina or coronary artery bypass; almost five times more likely to have venous thrombosis.

Severely obese patients at cohort entry are 59% more likely to develop cataract; almost two times more likely to have pulmonary hypertension; two times more likely to have angina or coronary artery bypass, and two times more

likely to have cardiomyopathy.

## **Sexual Function in Married Indian Women with Systemic Lupus Erythematosus**

**Benzeeta Pinto**<sup>1</sup>, Sandeep Grover<sup>2</sup>, Manish Rathi<sup>3</sup> and Aman Sharma<sup>4</sup>, <sup>1</sup>PGIMER, CHANDIGARH, India, <sup>2</sup>PGIMER, Chandigarh, India, <sup>3</sup>Department of Nephrology,, Postgraduate Institute of Medical Education and Research, Chandigarh, India, <sup>4</sup>Internal Medicine, Postgraduate Institute of Medical Education and Research, Chandigarh, India

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** This study was carried out to evaluate the impact of disease activity, damage, marital satisfaction, fatigue, psychiatric comorbidity and QoL on sexual function in women with SLE.

**Methods:** Hundred and twelve premenopausal married women with SLE were included in a one year prospective longitudinal study. Disease activity and damage were assessed using SELENA–SLEDAI and SLICC/ACR damage Index (SDI) respectively. Female sexual function index (FSFI) and Couple Satisfaction Index (CSI) were used to evaluate sexual function and marital satisfaction. QoL was assessed using LupusPRO. Depression, anxiety and Fatigue were assessed using Patient Health Questionnaire 9 (PHQ9), Generalised Anxiety Disorder 7 (GAD7) and Fatigue severity scale (FSS).

**Results:** The mean age was 34.0±6.8 years. Mean SELENA SLEDAI was 3.67±4.2 and mean SDI was 0.25±0.62. Median steroid dose was 7.5mg of prednisolone. Impaired sexual function was found in 60.7%. More than 90% of the patients reported problems in desire, arousal and lubrication (Table 1). Seventy four percent of the patients had dysfunction in one or more domains. SLEDAI and dose of steroids had a negative correlation with total score of FSFI (Table 2). The mean score of CSI was 130.39±26.17. Eighteen patients (16.1%) had CSI lower than the cut off score (104.5) suggestive of marital distress. There was a significant correlation between FSFI and CSI (r=0.343, p<0.001). There was a correlation between lupus symptoms, cognition, pain vitality, coping, satisfaction with care and total non HRQoL scores of LupusPRO and total score of FSFI (Table 3). On multivariate regression significant

predictors of sexual function were couple satisfaction, corticosteroid dose and SLEDAI (adjusted R square=0.349, p=0.014).

**Conclusion:** Sexual function is impaired in women with SLE. Disease activity and marital satisfaction were the most important factors influencing sexual function.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Systemic lupus erythematosus (SLE) is a chronic, autoimmune disease with a complex genetic etiology. Over 80 risk genes for SLE have been identified and some genetic variants have demonstrated association with specific disease manifestations, such as STAT4 and nephritis. The overall effect of a patient's hereditary risk factors on disease severity has so far not been studied. We therefore assessed the relationship between high genetic risk and development of organ damage in SLE.

### Methods:

Patients with SLE, who met at least 4 ACR criteria (n = 1012), were genotyped

using a 200K Immunochip SNP Array (Illumina). A genetic risk score (GRS) was assigned to

each patient based on the single nucleotide polymorphisms (SNPs) which in previous studies have shown association ( $p < 5 \times 10^{-8}$ ) with SLE according to Morris, *et al* (Nat Genet, 2016. 48(8): p. 940-6). For 32 loci the SLE GWAS SNP was available on the ImmunoChip. For each SNP, the natural logarithm of the odds ratio (OR) for SLE susceptibility was multiplied by the number of risk alleles in each individual. The sum of all products for each patient was defined as the GRS. Information regarding organ damage according to Systemic Lupus International Collaborating Clinics / American College of Rheumatology Damage Index (SLICC-DI), disease manifestations, antibody profile, medication, current disease activity, age at diagnosis and sex was retrieved from medical records. Statistical analyzes were performed using Statistica 13.2 (Statsoft).

### Results:

In an ordinal regression model, with SLICC-DI (0, 1, 2, 3, 4 and >4 points) as outcome and age and GRS as independent variables, an association was found between GRS and SLICC-DI (OR 1.16 (1.03-1.31),  $p = 0.015$ ). The relationship was more pronounced for patients under 60 years of age (OR 1.30 (1.11-1.52)  $p = 7.1 \times 10^{-4}$ ). Using a linear regression model, a negative relationship was observed between GRS and age at diagnosis ( $\beta = -0.13$ ,  $p = 1.5 \times 10^{-5}$ ). When analyzing the 11 SLE criteria (ACR-82) using a logistic regression model associations were observed between GRS and nephritis (OR 1.26 (1.09-1.45),  $p = 0.0015$ ), the immunological criteria (OR 1.31 (1.13-1.51),  $p = 3.2 \times 10^{-4}$ ) and arthritis (OR 0.84 (0.71-1.00),  $p = 0.044$ ). A high GRS was also associated with presence of anti-dsDNA (OR 1.37 (1.15-1.62),  $p = 9.4 \times 10^{-7}$ ) and low complement levels (OR 1.32 (1.03-1.68),  $p = 0.044$ ). No

association was observed between GRS and disease activity at the time of follow-up and there was no difference in GRS between men and women with SLE.

## Conclusion:

In patients with SLE, there is an association between a high genetic risk score and early disease onset. In addition, patients with high genetic risk scores have a higher risk of developing permanent organ damage compared to individuals with fewer risk genes. Our findings indicate that genetic profiling of patients with SLE may provide a tool for predicting severity of the disease.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

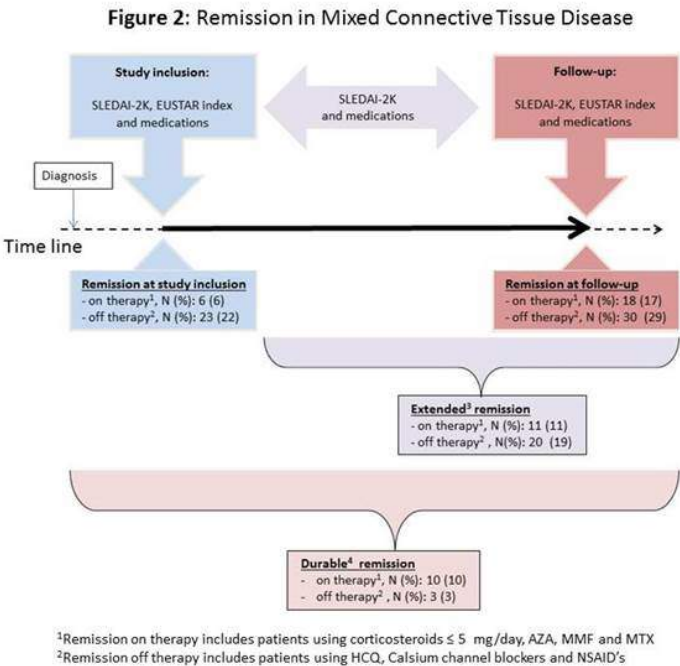

**Background/Purpose:** Ever since Mixed Connective Tissue Disease was presented as a distinct entity in 1972, it has been discussed whether MCTD represents an undifferentiated, transient or stable phenotype. Previous studies have been inconclusive regarding frequency of diagnostic converters (i.e. cases evolving from MCTD to another well-defined rheumatic disorder) potentially causing different research cohorts of SLE and SSc. The aims of this study were to evaluate the prevalence of MCTD patients evolving into another well-defined rheumatic disorder, and to assess the disease activity and prevalence of remission in MCTD patients after long term follow-up.

**Methods:** 118 patients were included from the Norwegian MCTD cohort. Patients were defined as having evolved from MCTD if the antibody profile together with the clinical features were compliant with another well-defined rheumatic disorder. Remission was defined by the combined presence of SLEDAI equal zero and EUSTAR less than 2.5. Possible predictors of stable phenotype and remission were assessed by logistic regression.

**Results:** The mean (SD) time between study inclusion and follow-up was 7 (2) years. 9 % of the MCTD patients had evolved into another specific rheumatic disorder (6 SLE, 4 RA, 3 SSc and 1 ASA, Fig. 1). The presence of puffy

hands before or at study inclusion predicted a stable MCTD phenotype at follow-up in univariate regression analysis (OR: 6.5, CI: 1.6 -27.1, P=.010). SLEDAI-2K scores were found to decrease over time and over 90% of patients had EUSTAR index activity < 2.5. The prevalence of remission was 28 % at inclusion and 46 % at follow-up. 30 % were in remission during the observational period and at follow-up (extended remission) and 13 % of patients were in remission at inclusion, during the observational period and at follow-up (durable remission, Fig. 2). One of the strongest predictors of remission was increasing FVC % pred at inclusion (Table 1).

**Conclusion:** Our results strengthen the view of MCTD as a distinct rheumatic condition as only a small proportion of patients evolved into another well-defined rheumatic disorder. Durable remission in MCTD is infrequent, however the SLEDAI-2K scores and EUSTAR activity index demonstrate that MCTD patients appear to have milder disease activity than SLE and SSc patients.

# SLICC Damage Index Is Associated with Tubulointerstitial Nephritis on Lupus Nephritis Biopsies

**Cianna Leatherwood,** Brigham and Women's Hospital, Boston, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## SLICC Damage Index is associated with Tubulointerstitial Nephritis on Lupus Nephritis Biopsies

Kristin D’ Silva, Paul Hoover, Gearoid McMahon, Sushrut Waikar, Helmut Rennke, Karen Costenbader

**Background/Purpose:** The presence of tubulointerstitial nephritis (TIN)on lupus nephritis renal biopsy has been associated with a poorer prognosis. Clinical factors associated with this biopsy finding have not been clearly defined. The purpose of this retrospective cohort study was to investigate clinical and laboratory characteristics associated with TIN in patients diagnosed with lupus nephritis. We predicted low C4, elevated 24-hour urinary protein and elevated dsDNA antibodies would be associated with the presence of TIN.

**Methods:** Biopsy reports of all renal biopsies performed at a single academic medical center between 1996 and 2015 showing Class II-VI lupus nephritis were reviewed. The definition of TIN included interstitial inflammation, tubular atrophy or fibrosis, and was abstracted from the biopsy report. All biopsies were interpreted by senior pathologists. Demographics, clinical variables and labs at the time of biopsy were assessed by chart review. Univariable analyses and then multivariable regression models were used to identify potential factors associated with tubulointerstitial nephritis.

**Results:** 165 initial lupus nephritis biopsies were identified; 119 had acute (n=5) or chronic interstitial nephritis (n= 97) or both (n=17). The average patient age was 36 years, 85% were female, and dsDNA antibody was positive in 85%. ISSN lupus nephritis biopsy classes overall were 9% II, 25% III, 40% IV and 24% V, and class was not statistically associated with presence of TIN. There were no statistically significant differences between groups in duration of SLE at biopsy, prior medications, age or race (**Table**). In univariable analyses, presence of TIN was associated with lower hemoglobin [10.5 vs. 11 g/dL, p= 0.02], higher creatinine [1.0 vs. 0.8 mg/dL, p= 0.01], higher 24-hour urinary protein (2.62 vs. 1.4 gm, p= 0.04], and higher SLICC damage index [4 vs. 2, p= 0.0016] compared to no TIN. Elevated SLICC damage index (DI) was associated with the presence of tubulointerstitial nephritis [OR 1.03 (95% CI 1.01, 1.05)] after controlling for age, race, sex, and 24-hour urinary protein.

**Conclusion:** TIN was a common finding on lupus nephritis biopsy and not associated with ISSN Class. Several laboratory findings related to more severe renal impairment were associated with TIN, but in multivariable models only SLICC-DI remained significantly associated. This suggests that increasing SLE-related systemic damage in lupus nephritis patients is associated with increased risk of TIN. Interestingly, SLE duration was not associated with TIN. Further work is needed to clarify the relationship between overall SLE damage and TIN in order to identify patients at highest risk for this potentially adverse pathology.

Table. Clinical Factors Potentially Associated with Tubulointerstitial Nephritis on Lupus Nephritis Biopsy			
	Tubulointerstitial nephritis (n= 119)	No Tubulointerstitial nephritis (n= 46)	p-value*
Age, mean	36 (±13)	38 (± 12)	0.55
Duration of SLE at biopsy (years), mean	6 (±8)	7 (±9)	0.58
Female, n (%)	101 (85%)	39 (85%)	0.98
Race			
White, n(%)	39 (35%)	18 (39%)	0.55
Black, n(%)	41 (36%)	13 (28%)	
Asian, n(%)	13 (12%)	6 (13%)	
Hispanic, n(%)	19 (12%)	7 (15%)	
Other	1 (1%)	2(4%)	
Laboratory Values			
Hemoglobin (g/dL), mean	10.5 (±2)	11 (±1.3)	0.02
Anti-dsDNA (IU/mL), median	172 [51, 488]	108 [24, 777]	0.61
Anti-RNP positive, n(%)	44 (44%)	19 (44%)	0.95
Antiphospholipid antibodies**	25 (25%)	8 (21%)	0.66
C4 (mg/dL), median	9 [6.5, 16.5]	9.5 [7, 15]	0.96
Creatinine (mg/dL), median	1.0 [0.7, 1.7]	0.8 [0.6, 1.0]	0.01
24-hr urinary protein (g/24 hr), median	2.62 [1.1, 4.5]	1.4 [0.5, 3.2]	0.04
Serum albumin, mean	3 (±0.7)	3.4 (±0.6)	0.004
Clinical factors			
Prior high dose glucocorticoid***, n(%)	39 (36%)	12 (30%)	0.49
Prior immunosuppression****, n(%)	29 (27%)	6 (15%)	0.19
Prior NSAIDs, n(%)	25 (23%)	11 (28%)	0.58
SBP ≥140mmHg or DBP≥ 90mmHg, n(%)	28 (25%)	6 (14%)	0.14
SLICC-DI score*****, median	4 [1,6]	2 [1,3]	0.002
*Continuous variables evaluated with t-test or Wilcoxon and binary and categorical variables were assessed using chi-squared tests or Fisher’s exact as appropriate.			
** positive vs. negative or not tested			
***glucocorticoid ≥ 20 mg/day for past 30 days			
**** receiving azathioprine, cyclophosphamide, mycophenolate mofetil, rituximab, cyclosporine or tacrolimus at the time of biopsy

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Lupus nephritis (LN) is an important cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE). An initial renal biopsy (RB) is currently recommended by most experts, but clinical practice varies. With recent changes in treatment paradigms for LN the role of RB in deciding treatment has been questioned. In addition, a recent systematic review found the interpretation of RB findings to be unreliable. Therefore, we systematically reviewed the evidence for an initial biopsy in LN patients.

### **Methods:**

Medline, Embase, Scopus, and Cochrane Library databases were searched using the search terms systemic lupus erythematosus, lupus nephritis and renal biopsy among others. The search was English-language restricted; randomized controlled trials (RCTs), observational, case control, cohort and cross-sectional studies were included. The quality of the studies was assessed using the Newcastle-Ottawa Scale and Quality in Prognostic Studies tool. Two reviewers reviewed citations for inclusion/exclusion at each stage (title, abstract and full text review).

### **Results:**

A total of 776 references were identified after removal of duplicates. No relevant RCTs were found. No studies directly examined the role of RB compared to clinical parameters (CP) in deciding treatment. No studies assessing renal outcome were found that included a comparator arm of patients without RB. Two related studies showed that RB added marginally to short and long-term prediction of renal outcome when added to CP alone; however these were >30 years old and used WHO criteria resulting in high risk of bias. Fifteen studies looked at clinicopathologic correlation of RB findings and CP. Most studies were relatively small, with large variation in populations studied,

CP reported, and outcome measures described; 7 were >25 years old. Results were conflicting. Several studies found that poor CP (acute renal failure, hypertension) showed good correlation with Class IV & V histology on RB, as well as poor renal survival. No clear correlation between degree of proteinuria and LN biopsy class was found. Three studies found that in the setting of low grade proteinuria and normal renal function, many patients had Class III, IV, or V LN on RB; 2 studies did not find a correlation between RB findings and proteinuria. Three studies found higher titres of anti-dsDNA antibodies correlated with proliferative LN, 1 study in Hispanic patients did not. Two studies found low C4 and higher c1q antibodies correlated with proliferative LN on RB. Two studies found that RB findings predicted renal outcome, 2 did not. In 4 studies, RB identified non-LN causes of renal disease; ranging in frequency from 5-9%. Four citations found thrombotic microangiopathy in addition to LN in 30-50% of patients.

### **Conclusion:**

The evidence that an initial RB changes management or prognosis in LN is of low quality due to high risk of bias. There is some evidence that RB may serve to identify non-SLE glomerular or other changes that influence management and outcome. As RB remains the clinical standard, is generally required for entry into clinical trials, and is being considered for inclusion in classification criteria, further research into the role, utility and reliability of RB is required.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The increased risk of premature cardiovascular disease (CVD) in systemic lupus erythematosus (SLE) patients has been well reported. Multiple series have demonstrated a higher incidence of accelerated subclinical atherosclerosis, carotid plaque formation, as well as myocardial infarction (M.I.) within these patients. Herein we report the 20-year incidence of cardiovascular events within a large prospectively followed single-institution female SLE patient cohort.

**Methods:** A single institution group of women previously diagnosed with SLE were prospectively followed. Baseline characteristics, including cardiovascular disease (CVD) risk factors (Framingham score, presence of carotid plaque, and carotid intima-media thickness), SLE specific risk factors (SLE diagnosis duration, Systemic Lupus International Collaborating Clinics (SLICC) damage score), and glucocorticoid use duration were collected. The incidence of CVD events (hard events: myocardial infarction (MI), coronary artery bypass graft (CABG), cerebrovascular accident (CVA), percutaneous transluminal coronary angioplasty (PTCA), fatal cardiac arrest ; soft events: transient ischemic attack (TIA), acute heart failure, angina, pulmonary embolus (PE)) were followed. Events and information were collected by chart review, patient interview, or National Death Index causes of death. A cox regression analysis was performed to identify independent risk factors for cardiovascular events (CVE's).

**Results:** A total of 289 SLE women were enrolled, 89 were removed from the analysis either due to previous CV events or being lost to follow-up. After a median follow-up of 18 years the overall incidence CVE's was 109 (hard: 43, soft: 66). Baseline Framingham Score ( $p<0.001$ ), carotid IMT ( $p=0.013$ ), carotid plaque ( $p=0.038$ ), SLE disease duration ( $p=0.002$ ), and glucocorticoid use duration ( $p<0.001$ ) significantly predicted an increased incidence of hard CVE's. The mean time to any first CVE was 9.5 years in patients with baseline carotid plaque versus 12 years in patients without carotid plaque. The mean time to any hard CVE was 6.9 years in patients with baseline carotid plaque versus 11.7 years in patients without carotid plaque.

**Conclusion:** To the best of our knowledge this data represents the longest follow up of CVE's in a large female SLE cohort. This data re-affirms the synergistic effect of SLE, carotid plaque, and traditional CV risk factors towards the development of CVE's.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The multi-organ sequelae of systemic lupus erythematosus (SLE) may include nephritis, alveolar hemorrhage, and cardiovascular disease. Our long term follow up of female SLE subjects has documented the incidence of cardiovascular events, and the predictive nature of carotid ultrasound. To our knowledge, there is a paucity of prospective comparative data of female SLE subjects with age and race adjusted controls. Herein we compare the 15-year incidence of cardiovascular events (CVE's) within a large prospectively followed single-institution female SLE and control subject cohort.

**Methods:** A cohort of women diagnosed with SLE, and a race adjusted group of controls were enrolled and prospectively followed for 15 years. Baseline CV risk factors including hypertension, diabetes, lipid panel, and Framingham risk score were assessed. Within the SLE cohort a Systemic Lupus International Collaborating Clinics (SLICC) score was recorded. CVE's and information were collected by chart review and subject interview.

**Results:** A total of 267 women without previous CV events (148 with SLE, and 119 controls) were included in the analysis. A total of 52 patients had a CVE, 48 SLE patients versus 4 control patients ( $p < 0.001$ ). The mean time to first CVE was 11.4 yrs in SLE women and 11.7 yrs in control women. SLE diagnosis at baseline was associated with more than 9-fold increased risk for any incident CV event ( $p = 0.002$ ), after adjusting for traditional Framingham risk score.

Within this SLE cohort, SLICC score was predictive of any CVE ( $p = 0.042$ ).

**Conclusion:** This comparative analysis demonstrates the increased incidence of CV events within SLE subjects. Further, the impact of SLE is independent of traditional risk factors including the Framingham risk score. This underscores the importance of proactive management of CVE risk in SLE subjects.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a complex autoimmune disease with a relatively unknown etiology. The quality and quantity of sleep has been shown to have significant impacts on health. However, the role of sleep in the etiology of human SLE has not been studied. We examined whether reported sleep duration at baseline was prospectively associated with transitioning to SLE at follow-up in individuals at risk for SLE, independent of early clinical manifestations associated with SLE such as depression, fatigue, anxiety, or medication use.

**Methods:** 436 individuals who reported having a relative with SLE but who did not have SLE themselves at baseline were evaluated again an average of 6.3 years later. Fifty-six individuals transitioned to SLE by follow-up (> 4 cumulative ACR criteria verified by medical record review). Sleep duration, medication use, and clinical manifestations such as depression, fatigue, anxiety, or prednisone use, were assessed by questionnaire; ACR criteria were confirmed by medical record. We dichotomized sleep duration as <7 hours of sleep a night or  $\geq 7$  hours of sleep a night, based on the Institute of Medicine recommendations. Generalized estimating equations, accounting for correlation within families, were used to assess associations between baseline sleep and the outcome of transitioning to SLE. In addition, to determine if the association between sleep duration and SLE was independent of early SLE symptoms, we additionally adjusted for other sleep associated variables at baseline, including depression, prednisone use, chronic fatigue, anxiety and number of ACR criteria. All multivariable models were adjusted for age, sex, and race.

**Results:** Sleeping less than the recommended 7 hours of sleep per night was greater in those who transitioned compared to those who did not transition to SLE (61% versus 34%,  $p=0.0002$ ; OR: 2.8, 95% 1.6-4.9). A higher proportion of those who transitioned reported sleep medication and prednisone use, depression, fatigue, and anxiety at baseline. Those who transitioned to SLE were more likely to sleep less than 7 hours a night at baseline than those who did not transition to SLE adjusting for age, sex and race (OR: 2.9, 95% CI 1.6-5.1) (Model 1 in Table 1). This association remained after adjustment for baseline conditions and early pre-clinical manifestations that could affect sleep, including prednisone use, depression, chronic fatigue, anxiety, and number of ACR criteria.

**Conclusion:** Lack of sleep may be associated with transitioning to SLE, independent of early clinical manifestations of SLE that may influence sleep duration. Sleep loss may deregulate immune responses, leading to increased inflammatory cytokines and increased white blood cell and natural killer cell counts. Further prospective evaluation of sleeping patterns and biomarkers in at-risk individuals is warranted.

Table 1. Less Than Seven Hours of Sleep a Night is Associated with Transitioning to SLE.

	Transitioned to SLE (Odds Ratio (95% CI))					
Baseline Characteristics	Model 1	Model 2	Model 3	Model 4	Model 5	Model 6
Sleep <7 hours	2.9 (1.6-5.1)	2.1 (1.1-4.2)	2.5 (1.4-4.6)	2.1 (1.1-3.9)	2.5 (1.4-4.5)	2.3 (1.2-4.5)
Prednisone Use	-	15.5 (7.7-31.4)			-	-
Self-reported depression	-	-	3.6 (1.9-6.7)		-	-
Self-reported chronic fatigue	-	-	-	18.3 (7.7-43.1)	-	-
Self-reported anxiety	-	-	-	-	2.8 (1.6-5.0)	-
ACR criteria:	-		-	-	-	1.0 (ref)
0-1						13.4 (5.3-34.3)
2						180.8 (27.8-1174.4)
3						
All models adjusted for age, sex and race (nonEA).

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** to assess relationship between smoking exposure and organ damage accrual measured by Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index for Systemic Lupus Erythematosus score (SLICC-SDI) in consecutive patients with systemic lupus erythematosus (SLE) from Argentina.

**Methods:** 623 consecutive SLE patients (fulfilling  $\geq 4$ , 1997 ACR criteria) were included in this cross-sectional study. Sociodemographic and disease related variables including SLICC-SDI score and smoking status were collected.

Patients currently smoking were considered “smokers”, and “non-smokers” those who never smoked and previous smokers.

SLICC-SDI was divided into 2 categories  $< 3$  and  $\geq 3$  severe damage (this cut off was previously reported in the literature).

Descriptive statistics and frequency distributions were used to describe the population studied. Chi-square was used to test differences between groups for categorical variables. Continuous variables were examined using student's t-test and Mann-Whitney (Wilcoxon) test for non-normally distributed variables. Univariate analyses and multivariate logistic regression model were calculated.

## Results:

623 patients were included in the analysis, 89% women, and median age was 38 (IQR 30-46) years. Eighty-four per cent were non-smokers and 16 % were current smokers. Fifty seven per cent were white, and 43% were non-white (mestizo and Amerindian). Seventy four per cent had >12 years of formal education.

Median disease duration was 9 years (IQR4-13). Median number ACR criteria met were 6 (IQR 5-7), mean SLICC-SDI score was 1.16 (SD 1.75) for non-smokers and 1.43 (SD 1.89) for current smokers (p 0.915).

Table 1 describes ACR criteria in smokers and non-smokers. Discoid lupus was significantly associated with smoking exposure.

SLE criteria	All patients n:623	Non-smokers n: 515	Current smokers n: 108	<i>p</i>
Malar rash, n(%)	445 (71)	372 (71)	73 (75)	0.465
<b>Discoid lupus, n (%)</b>	<b>67 (11)</b>	<b>51 (10)</b>	<b>16 (16)</b>	<b>0.053</b>
Photosensitivity, n (%)	432 (69)	366 (70)	66 (67)	0.641
Arthritis/arthralgias, n(%)	529 (85)	444 (85)	85 (87)	0.610
Ulcers, n(%)	268 (43)	220 (42)	48 (49)	0.194
Neurologic, n(%)	79 (13)	64 (12)	15 (15)	0.395
Hematologic disorder, n (%)	304 (49)	254 (48)	50 (51)	0.631
Serositis, n (%)	197 (32)	170 (32)	27 (28)	0.345
Renal disease, n(%)	279 (45)	240 (46)	39 (40)	0.273
Immunologic, n(%)	454 (74)	384 (74)	72 (73)	0.90
Antinuclear antibodies, n (%)	615 (99)	517 (99)	98(99)	0.905

Eighty-three per cent of patients had SLICC-SDI <3 and 17 % had  $\geq 3$ . In patients with SLICC-SDI  $\geq 3$ : 21% were smokers and 15% of patients with <3 SLICC-SDI were current smokers (p 0.081).

Univariate analysis comparing demographical and clinical characteristics of both groups are described in Table 2.

	All patients N=623	SLICC<3 N= 515	SLICC≥3 N=108	<i>p</i>
Female, n (%)	556 (89)	461(89)	95 (88)	0.636
White race, n (%)	317 (57)	271 (58)	45 (55)	0.639
<b>Age, years (median IQR)</b>	<b>38 (30-46)</b>	<b>36 (29-45)</b>	<b>43 (33-54)</b>	<b>&lt;0.001</b>
<b>SLE ACR criteria (median IQR)</b>	<b>6 (5-7)</b>	<b>6 (5-7)</b>	<b>7 (6-8)</b>	<b>&lt;0.001</b>
<b>Disease duration years (median IQR)</b>	<b>7 (4-13)</b>	<b>7 (3-12)</b>	<b>10 (6-16)</b>	<b>&lt;0.001</b>
<b>Age at diagnosis, years (median IQR)</b>	<b>28 (21-37.5)</b>	<b>28 (21-36)</b>	<b>30 (21-37.5)</b>	<b>0.05</b>
Education>12 years, n (%)	461 (74)	381 (74)	78 (72)	0.655
Current smokers, n (%)	98 (16)	77 (15)	23 (21)	0.081
Hydroxychloroquine (HCQ) , n (%)	579 (93)	479 (93)	100 (93)	0.761
Steroids, n (%)	467 (75)	386 (75)	85 (79)	0.409
<b>Cyclophosphamide (CF), n (%)</b>	<b>149 (24)</b>	<b>103 (20)</b>	<b>46 (43)</b>	<b>&lt; 0.01</b>
<b>Azathioprine (AZA), n (%)</b>	<b>181 (29)</b>	<b>134 (26)</b>	<b>49 (45)</b>	<b>&lt; 0.01</b>
Micofenolate mofetil, (MMF), n (%)	255 (21)	108 (21)	18 (17)	0.254

In the multiple regression analysis considering SLICC-SDI score  $\geq 3$  as dependent variable (adjusting by smoking exposure, age, sex, race, disease duration, > 12 years of education, corticosteroids, CF, AZA and HCQ exposure), we found that smoking (OR 1.90, CI 95% 1.04- 3.46,  $p$  0.035), age (OR 1.33, CI 95% 1.00-1.75,  $p$  0.044), and CF exposure (OR 2.64, CI 95% 1.41-4.97,  $p$  0.002) were associated to SLICC  $\geq 3$ .

**Conclusion:** Tobacco exposure, older age and cyclophosphamide use were associated to SLICC-SDI  $\geq 3$ .

## Cardiovascular disease in Systemic Lupus Erythematosus. The road to hell is paved with good intentions

Sophie Mavrogeni<sup>1</sup> and Loukia Koutsogeorgopoulou<sup>2</sup>, <sup>1</sup>CMR Department, Onassis Cardiac Surgery Center, Athens, Greece, <sup>2</sup>Department of Pathophysiology, Rheumatology Unit, National Kapodistrian University of Athens, Athens, Greece

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Accurate diagnosis of cardiovascular involvement in systemic lupus erythematosus (SLE) remains challenging, because echocardiography (echo), the cornerstone tool used, has serious limitations. We hypothesized that cardiovascular magnetic resonance (CMR) detects cardiac lesions in SLE patients, missed by echo.

**Methods:** Between 2005-2015, eighty asymptomatic SLE patients, aged 37±6 yrs, 72F/8M with normal echo, under treatment with antimalarials, have been evaluated using a 1.5 T system. LV-RV ejection fraction, T2 ratio (oedema imaging) and late gadolinium enhancement (LGE) (fibrosis imaging) were assessed. Acute and chronic lesions were characterised as LGE-positive plus T2>2 or T2<2, respectively. According to LGE, lesions were characterized as: a) diffuse subendocardial, b) subepicardial and c) subendocardial /transmural, due to vasculitis, myocarditis and myocardial infarction, respectively

**Results:** Abnormal CMR findings were identified in 22/80 (27.5 %) asymptomatic SLE patients with normal echo, including 4/22 with recent onset of silent myocarditis, 9/22 with past myocardial infarction (6 inferior and 3 anterior subendocardial infarction), 5/22 with past myocarditis (subepicardial scar in inferolateral wall) and 4/22 with diffuse subendocardial fibrosis (DSF), due to vasculitis. No correlation between CMR findings and inflammatory indices was identified.

**Conclusion:** CMR in asymptomatic SLEs with normal echo can assess occult cardiac lesions including vasculitis, myocarditis and myocardial infarction, missed by echo that can influence both rheumatic and cardiac treatment and further risk stratification; therefore, it should be included in the diagnostic algorithm of SLE.

## A Lupus Low Disease Activity State Is Associated with Reduced Flare, Lower Organ Damage Accrual, and Better Quality of Life in Patients with Systemic Lupus Erythematosus

**Ji-Hyoun Kang**<sup>1</sup>, Kyung-Eun Lee<sup>2</sup>, Dong-Jin Park<sup>1</sup> and Shin-Seok Lee<sup>1</sup>, <sup>1</sup>Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South), <sup>2</sup>Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South)

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To identify the potential predictors of a lupus low disease activity state (LLDAS), and the relationship between LLDAS and disease flare, organ damage, and quality of life in Korean patients with systemic lupus erythematosus (SLE).

**Methods:** The study followed 181 SLE patients from a single center for three years. LLDAS was defined as follows: (1) SLE Disease Activity Index (SLEDAI)-2K  $\leq 4$ , with no activity in major organ systems; (2) no new lupus disease activity compared with the previous assessment; (3) SLEDAI Physician Global Assessment  $\leq 1$ ; (4) a current prednisolone (or equivalent) dose  $\leq 7.5$  mg daily; and (5) well-tolerated standard maintenance doses of immunosuppressive drugs. We assessed data annually and divided 4 groups according to the number of LLDAS; LLDAS = 0, 1, 2, and 3. Univariate and multivariate analyses were performed to identify predictors of LLDAS.

**Results:** Of the 181 patients, 16.0% attained LLDAS on three consecutive years. Each group shows as follows; no LLDAS (n=30), LLDAS = 1 (n=60), LLDAS = 2 (n=62), and LLDAS = 3 (n=29). The patients who had higher number of LLDAS had shorter duration of symptoms, lower anti-histone antibody positivity, lower cumulative prescribed dose of prednisolone at baseline, lower mean PGA, lower mean SLEDAI, lower mean Mental Component Summary in SF-36, lower change in SLICC/ACR damage index, and a lower frequency of flare. In the multivariate analysis, LLDAS was significantly associated with lower mean PGA (OR = 0.671, 95% CI: 0.112–0.989,  $p = 0.019$ ) and a reduced risk of flare after adjusting for confounders (OR = 0.012, 95% CI: 0.001–0.448,  $p = 0.017$ ).

**Conclusion:** Attaining LLDAS was associated with an improved outcome, as represented by a decreased rate of disease flare, lower organ damage accrual, and better quality of life in Korean patients with SLE.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lupus Nephritis (LN) is a severe SLE manifestation, leading to a six-fold increased risk of death. This study aims to assess the outcome of patients with LN and the effect of change in management guidelines on outcome.

**Methods:** Retrospective analysis of all SLE patients with LN followed at the Tel Aviv Medical Center over a period of 20 years. Data included: sex, age at SLE diagnosis, age at LN diagnosis, number and timing of LN flares (rise in proteinuria to > 500 mg/d) and remissions (proteinuria < 500 mg/d and normal creatinine or < 10% of normal if baseline abnormal), creatinine, C3, C4 and anti-dsDNA at LN diagnosis, induction and maintenance therapy. Renal biopsy findings were obtained from pathology records. Patients with non-lupus related renal disease were excluded.

**Results:** LN was diagnosed in 90 patients (28% of the SLE cohort), F-76, M-14. The majority were Caucasian (n=81). Median follow up was 11.5 years, age at SLE diagnosis was 30.3±12 years, mean time to first LN episode was 3.3±5.6 years. LN was present at SLE diagnosis in 47 patients. Mean serum creatinine at diagnosis was >1.1 mg/dl in 35% and >2mg/dl in 10% of patients. At first episode mean proteinuria was 3230±2402 mg/d, C3 was 67.5±23.6 mg/dl, C4 was 13.1±9 mg/dl. Anti-dsDNA was positive in 80% of patients. Renal biopsies available for review (n=79) demonstrated: class III -19%, class IV - 48.1%, class V - 21.5%, class III+V- 5.1%, class IV+V - 3.8%, isolated antiphospholipid nephropathy- 2.5%. For induction treatment 95% received oral prednisone, 21% received additional IV pulse methylprednisolone, 43% - IV cyclophosphamide (CYC), 42% - mycophenolate mofetil (MMF), 19% - azathioprine, 9% - prednisone alone, 4% - rituximab, 11% - other (tacrolimus, cyclosporine, rituximab+CYC, azathioprine+cyclosporine). The regime of IV CYC (low / high dose) varied mainly depending on year of treatment (before / after 2009). Eighty-five percent received hydroxychloroquine (HCQ). Out of 7 patients who stopped HCQ, 5 had a LN flare. Maintenance therapy included MMF -50%, azathioprine-27%, high dose IV CYC -10%, prednisone alone -9%, other - cyclosporine, tacrolimus -4%. Remission was achieved in 79.9% of the patients. Among patients treated before 2009, 85.9% achieved remission, while in those treated since 2009, when use of MMF was more prevalent, 75% achieved remission. The mean time from LN presentation to remission was 2.7±2.9 years. Among patients who achieved remission, 29.6% experienced a flare after the induction phase: 81% flared once, 19% flared twice. The median time from remission to first flare was 4 years, and from second remission to second flare 3.5 years. Eleven patients (12.2%) developed ESRD, 6 were diagnosed before 2009. Six patients (6.7%) died (ESRD-1; infection-3; severe thrombotic event -1; brain hemorrhage-1), 5 of whom had been diagnosed > 10 years ago, 4 received high dose CYC induction therapy.

**Conclusion:** In this cohort of LN patients, a high percentage achieved remission (79.9%), however rates of remission and ESRD did not improve when comparing patients treated before or after 2009, suggesting that changes in treatment strategies during this period have not significantly changed the outcome of LN.

## Sleep Disturbances in Systemic Lupus Erythematosus (SLE)

**Patricia P. Katz**<sup>1</sup>, Sofia Pedro<sup>2</sup> and Kaleb Michaud<sup>3</sup>, <sup>1</sup>Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA, <sup>2</sup>National Data Bank for Rheumatic Diseases, Wichita, KS, <sup>3</sup>University of Nebraska Medical Center, Omaha, NE

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sleep disturbances (SD) are reported to be common in SLE, but relatively few studies have addressed the issue. We examined the frequency and severity of self-reported SD among individuals with SLE and identified predictors of SD.

**Methods:** Data were from the National Data Bank for Rheumatic Diseases (NDB), for which participants complete questionnaires every 6 months. In one questionnaire, items about the presence of physician-diagnosed obstructive sleep apnea (OSA) and restless-leg syndrome (RLS), use of continuous positive air pressure (CPAP) devices, and symptoms of RLS, as well as the Medical Outcomes Study Sleep Scale (MOS-S) were included. The MOS-S yields 5 subscales; results are shown here only for one (Sleep Problems Index I, SPI-I). Frequencies of reports of OSA, RLS, CPAP use, and RLS symptoms were tabulated. Multivariate regression analyses identified independent predictors of OSA and RLS (logistic regression) and SPI-I scores (linear regression). Potential predictors included age, sex, race, education, smoking, Rheumatic Disease Comorbidity Index (RDCI)<sup>1</sup>, chronic obstructive pulmonary disease (COPD), asthma, meeting fibromyalgia criteria, obesity (BMI  $\geq 30$  kg/m<sup>2</sup>), disease duration, pain, prednisone and other medication use, and disease activity (Systemic Lupus Activity Questionnaire, SLAQ<sup>2</sup>) and damage (Brief Index of Lupus Damage, BILD<sup>3</sup>).

**Results:** Subject characteristics are shown in Table 1 (n = 385). 24% reported physician-diagnosed OSA and 20% RLS, compared to ~2-4% and ~10%, respectively, in the general population. 14% used CPAP, and 33% had RLS symptoms. Mean SPI-I was 36.0 ( $\pm 34.1$ ), ~0.5 standard deviation higher than a population sample mean. Independent predictors of OSA were greater age, obesity, asthma, RDCI, and disease activity (Table 2). Predictors of RLS were RDCI and disease activity. Worse scores on SPI-I were associated with younger age, non-white race, higher RDCI, and greater pain and disease activity.

**Conclusion:** Both OSA and RLS were more common in SLE than in the population; SPI-I scores were also worse. Some predictors of SDs were similar to predictors in the population (age, obesity), but disease activity was also associated with SD. Research in SLE has linked SDs to worse outcomes. Previous research in other conditions suggests that SDs might also be a cause of increased disease activity through heightened inflammation. Further research is needed to tease out disease-specific causes and effects of SD in SLE.

## The Montreal Cognitive Assessment Questionnaire (MoCA): A Promising Screening Tool for Cognitive Dysfunction in SLE

Nathalie Chalhoub and Michael Luggen, Division of Immunology, Allergy, and Rheumatology, University of Cincinnati College of Medicine, Cincinnati, OH

First publication: September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cognitive dysfunction (CD) is among the most common neuropsychiatric manifestations in SLE. However, the diagnosis is oftentimes delayed and occasionally overlooked because of the lack of a sensitive and practical screening test. Several methods have been used to ascertain CD in patients with SLE, including traditional neuropsychological testing (NPT) and the Automated Neuropsychologic Assessment Metrics (ANAM), a computerized battery of symbol based tests measuring many of the same cognitive domains as NPT. Both are time-consuming, relatively costly, and not readily available. The Montreal Cognitive Assessment Questionnaire (MoCA) is a one-page performance-based screening test that has been validated to identify mild cognitive impairment in the elderly and, in preliminary work done by us, appeared to hold promise in SLE as well. This study aims to further evaluate the MoCA as a screening tool for the diagnosis of CD in SLE.

**Methods:** Patients with SLE fulfilling the American College of Rheumatology criteria were recruited. All subjects were administered the ANAM test and the MoCA questionnaire. MoCA scores were compared to the total throughput score (TTS) (correct responses/time for the responses), a standard measure of performance of the ANAM. Individual MoCA questions were also compared to TTS to identify the MoCA questions with the strongest correlation with CD. The classification of normal or abnormal by the ANAM was compared to that of the MoCA using various cutoffs. Sensitivity, specificity, likelihood ratios and predictive values were also computed at the various cut-offs for the MoCA.

**Results:** In total, 74 patients were evaluated. Of these, 15 (20 %) were identified by the ANAM as having cognitive dysfunction in comparison with 33 (44.6 %) by the MoCA using the standard cutoff of 26. The scores were significantly correlated ( $r=0.51$ ,  $p<0.001$ ). Six out of the 10 MoCA questions showed significant correlation with the ANAM score with the assessment of visuospatial and executive function being the most highly correlated with CD ( $p=0.000199$ ). Using the standard cutoff of 26, the sensitivity of the MoCA was 93%, specificity 68%, and negative predictive value 98%. All other cut-offs were inferior.

**Conclusion:** The MoCA appears to be a promising and practical screening tool for identification of patients with SLE at risk for cognitive dysfunction.

Table 1. MoCA Performance Characteristics

Cutoff	Sensitivity	Specificity	LR <sup>+</sup> <sup>a</sup>	LR <sup>-</sup> <sup>b</sup>	PPV <sup>c</sup>	NPV <sup>d</sup>
24	0.6	0.81	3.16	0.49	0.45	0.89

## Screening in Patients at High Risk of Hydroxychloroquine Retinal Toxicity

**Anna Viola Taulaigo**<sup>1</sup>, Maria Francisca Moraes-Fontes<sup>1</sup>, Eunice Patarata<sup>2</sup>, Sara Guerreiro Castro<sup>2</sup> and Arnaldo Dias-Santos<sup>3</sup>, <sup>1</sup>Unidade de Doenças Auto-imunes, Hospital Curry Cabral, Centro Hospitalar de Lisboa Central, Lisbon, Portugal, <sup>2</sup>Unidade de Doenças Auto-imunes, Hospital Curry Cabral, Centro Hospitalar de Lisboa Central (CHLC), Lisbon, Portugal, <sup>3</sup>Serviço de Oftalmologia, Hospital de Santo António dos Capuchos, CHLC, Lisbon, Portugal, Lisbon, Portugal

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Despite effectiveness and favourable safety profile, antimalarials have the potential to cause irreversible macular retinopathy and vision loss. Screening methods still vary among clinicians but have evolved over the last decade (1, 2) and the optimal dose of hydroxychloroquine (HCQ) is now set at  $\leq 5$  mg/kg real body weight, above which the risk of retinal toxicity increases (3). HCQ in Portugal comes only as a 400 mg pill and in 10 pills per package, both of which, are neither friendly for optimizing safe dosing nor for promoting compliance. Once a patient is in a high risk group, yearly follow-up is recommended. The aim of the study is to test the frequency of retinal hydroxychloroquine toxicity in a single-centre cohort.

### Methods:

Cross-sectional study conducted between January 2016 and May 2017, of a convenience sample of chronically compliant patients, characterized according to demographic and clinical phenotype, duration, current and cumulative dose of HCQ. The screening strategy consisted of automated threshold visual fields and objective test: spectral domain-OCT, fundus autofluorescence and multifocal electroretinogram. Toxicity was diagnosed on the basis of

compatible visual fields defects together with at least one positive objective test, upon confirmation. Univariate statistical analysis was performed using the Wilcoxon Mann-Whitney (WMW) and Chi-Square (CS) tests for non-parametric distributed data.

## Results:

Of the 62 patients screened, 32 (51%) had no prior ophthalmological examination. Median age was 46 years (y), IQR 37-60; range 27-83; 59 (95%) were female; the majority, 28 (45%) took HCQ due to SLE, 4 (6%) for Sjögren syndrome, 12 (19%) for UCTD, 11 (18%) for incomplete/cutaneous forms of lupus and 7 (11%) for other CTD. No patient had concomitant renal or liver disease. Median duration and cumulative dose were respectively 8 y (IQR 3 – 12; range 0,4 -31) and 1168 g (IQR 584 – 2044; range 36 -8760). Retinal toxicity was confirmed in 6 SLE- and further diagnosed in 1 non-SLE-patients; in all HCQ was stopped (overall: 2/7 screen naïve; 1/7 on tamoxifen; 1/7 with visual loss). Toxicity was correlated to disease ( $p=0,003$ ) and HCQ therapy ( $p=0,002$ ) duration, cumulative HCQ dose ( $p=0,001$ ) and SLE ( $p=0,04$ ) – Table I. Dose adjustments to  $\leq 5$  mg/kg were performed in 13 patients.

## Conclusion:

Using a standardised referral protocol for HCQ retinopathy screening led to cessation of therapy due to toxicity (11%) and adjustment of daily dosing (21%). This study serves as a reminder that regular adjustment of dose and retinal toxicity screening is mandatory in patients subjected to prolonged HCQ therapy and reinforces lobbying for more flexible dosages. In addition, HCQ toxicity raises the need for alternative therapies in patients with CTD.

Table I. Univariate analysis comparing patients according to retinal toxicity

Characteristic	Retinal toxicity (n=7)	No Retinal toxicity (n=55)	P value (*sig)	Statistical test
Age y (mean±SD)	50±11	49±16	0,764	WMW
Non-Caucasian (n, %)	1 (14)	7 (13)	1.000	CS
Disease duration y (mean±SD)	21±9	10±7	0,003*	WMW
Duration HCQ therapy y (mean±SD)	17±7	8±6	0,002*	WMW
Current HCQ > 5 mg/kg (n,%)	6 (86)	38 (69)	0,06	CS
Cumulative HCQ g (mean±SD)	2976±1381	1253±1339	0,001*	WMW

## Trajectories of Quality of Life in an Iception Cohort of Lupus Patients and Their Determinants

**William Fung**<sup>1</sup>, Lily Lim<sup>2</sup>, Jiandong Su<sup>3</sup> and Zahi Touma<sup>4</sup>, <sup>1</sup>Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>2</sup>Hospital for Sick Children, Toronto, ON, Canada, <sup>3</sup>University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>4</sup>Rheumatology, University of Toronto, Division of Rheumatology, Institute of Health Policy, Management and Evaluation, Toronto, ON, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Systemic lupus erythematosus (SLE) is a chronic disease with varying disease activity levels and morbidities over time; this can affect patients' health related quality of life (QoL). In clinical practice, we observed substantial heterogeneity in how patients' QoL evolve over time. This study aims to: 1) Determine if there are latent classes of QoL trajectories (T) among SLE patients as measured by the Medical Outcome Survey Short Form 36 (SF-36) and 2) Identify predictors of different latent class membership.

## Methods:

This is a single centre retrospective longitudinal inception SLE cohort. Annual SF-36 has been collected prospectively per clinical protocol. Only patients with  $\geq 3$  SF-36 questionnaires, and the 1<sup>st</sup> must be within 2 years of diagnosis were studied. The primary outcomes are the physical component (PCS) and mental component scores (MCS) of the SF36.

Group based trajectory model was performed using Proc Traj (SAS). One model each was fitted for the PCS and MCS. We tested 2 to 6 class solutions. The best model was determined by a combination of clinical plausibility and statistical criteria: number of patients in each group and model fitting statistic Bayesian Information Criterion (BIC). Models with the lowest BIC and groups containing  $> 5\%$  of the total sample size were selected as the final models. Predictive effects of baseline variables (listed in table 1) on class membership were tested by logistic regressions.

## Results:

171 patients with follow up to 10 years were analyzed. Patient characteristics are represented in table 1.

**For PCS**, 2 classes of T were identified: T1 low PCS with slight improvement over time (54.6%) and T2 persistently very low PCS (45.4%) (Figure 1). For **MCS**, 3 classes of T were identified: T1 persistently very low MCS (28.4%), T2 low MCS improving over time (32.4%) and T3 average MCS and improving over time (39.2%).

After adjusting for other factors, PCS T2 was significantly associated with older age at SLE diagnosis (OR 0.95 [95% CI 0.92-0.97, p 0.0001]) adjusting baseline disease activity (OR 1.04 [95% CI 0.998-1.09, p 0.06]) and antimalarial treatment (OR 0.36 [95% CI 0.09-1.49, p 0.16]). Regressions did not show significant results for MCS.

## Conclusion:

The physical (PCS) and mental health components (MCS) of SF36 follows distinct classes of trajectory in SLE. Some patients have persistently very low PCS and MCS while others show mild improvement from below average to near or above average scores. Younger age at lupus diagnosis was associated with better PCS trajectory (T2).

**Figure 1. SF-36 trajectories over time.** (A) PCS trajectories and (B) MCS trajectories over time.

## Factors Influencing on Health-Related Quality of Life in Female Systemic Lupus Erythematosus Patients with Fibromyalgia

**Kyung Min Ko**<sup>1</sup>, Jun-Ki Min<sup>2</sup> and Su-Jin Moon<sup>3</sup>, <sup>1</sup>Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of (South), <sup>2</sup>Bucheon St. Mary's Hospital, Division of Rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Bucheon, Korea, Republic of (South), <sup>3</sup>Bucheon St. Mary's Hospital, Division of rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Bucheon, Korea, Republic of (South)

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Health-related quality of life (HRQoL) among systemic lupus erythematosus (SLE) patients is reduced, and fibromyalgia contribute to the decreased HRQoL. The objective of the present study is to evaluate the contributing factors for reduced HRQoL in female SLE patients regarding the presence of fibromyalgia.

**Methods:** The HRQoL measurement was made using the SF-36 and Euroqol EQ-5D. Sleep quality, fatigue severity, fibromyalgia severity, and SLE disease associated variables were measured.

**Results:** : The scores of HRQoL, including overall scores as well as the physical component summary (PCS) and mental component summary (MCS), were lower in female SLE patients with fibromyalgia (n = 41), than in those without fibromyalgia (n = 111). SLE patients with fibromyalgia showed higher SLE disease activity, and more severe fatigue score, depressive mood and deteriorated sleep quality, compared with patients without fibromyalgia. In SLE patients with fibromyalgia, education level, severity of SLE organ damage, fatigue severity, sleep quality, depressive mood and fibromyalgia severity were significantly correlated with EQ-5D, whereas age, income, SLE disease activity, steroid dose, and disease duration were not correlated with EQ-5D. On the other hand, education level did not show significant correlation with EQ-5D in SLE patients without fibromyalgia. Multivariate logistic regression analysis revealed that depressive mood and SLE disease activity are independent contributing factors for deteriorated HRQoL in female SLE patients with fibromyalgia. In SLE patients without fibromyalgia, sleep quality in addition to SLE disease activity and depressive mood plays as a independent predictor for poor HRQoL.

**Conclusion:** The quality of life in SLE patients can be improved by managing depressive mood and improving sleep quality. Physicians may need to pay more attention to sleep both in patients with fibromyalgia and in those without fibromyalgia.

Table1. Logistic regression analysis to identify the contributing factors of deteriorated HR-QoL (T1 by EQ-5D vs T2 and T3) in female SLE patients with fibromyalgia (n = 41)

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While infections are a one of the main causes of mortality in systemic lupus erythematosus (SLE), the type of infections and the factors predisposing to them have not been properly evaluated. The aim of the present study was to identify predictive factors accounting for the different types of infections in SLE patients.

**Methods:** A multi-ethnic, multi-national cohort from nine countries was utilized for these analyses. The following type of infections were considered: skin, lung, urinary tract, digestive tract and gynecological. Cox regression models were used to evaluate the predictors of new infections (global and per organs involved) using a backward elimination procedure. Potential predictors were demographic factors, clinical manifestations, SLEDAI, SDI and treatment at baseline.

**Results:** Predictive factors of skin infections were dose of prednisone between 15 and 60mg/d (HR: 1.73; CI: 1.16-2.57) and  $\geq 60$ mg/d (HR: 1.63; CI: 1.01-1.91), lymphopenia (HR: 1.38; CI: 1.01-1.91), shorter disease duration at baseline (HR: 0.94; CI: 0.91-0.97), and previous infections (HR: 1.77; CI: 1.18-2.65). Predictive factors of lower airway infections were previous infections (HR: 2.39; CI: 1.38-4.13), lung involvement (HR: 2.81; CI: 1.38-5.71), and shorter disease duration at baseline (HR: 0.94; CI: 0.90-0.98). Predictive factors of urinary tract infections were higher damage at baseline (HR: 1.17; CI: 1.02-1.35), older age at diagnosis (HR: 1.02; CI: 1.01-1.03), shorter disease duration at baseline (HR: 0.93; CI: 0.89-0.96), female gender (HR: 3.03; CI: 1.11-8.23), and Mestizo ethnicity (HR: 1.98; CI: 1.29-3.04). Predictive factors of digestive tract infections were higher disease activity at baseline (HR: 1.05; CI: 1.02-1.08), lower socioeconomic status (HR: 2.1; CI: 1.02-4.40), and lower educational level (HR: 0.36; CI: 0.16-0.78). Predictive factors of gynecological infections were dose of prednisone between 15 and 60mg/d (HR: 2.05; CI: 1.05-3.99) and higher disease activity at baseline (HR: 1.03; CI: 1.01-1.07).

**Conclusion:** Female gender, older age at diagnosis, lower socioeconomic status, lower educational level, shorter disease duration, lymphopenia, previous infections, lung involvement, higher damage accrual, higher disease activity, dose of prednisone  $>15$ mg/d, and Mestizo ethnicity were predictive of at least one type of infection.

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Bone marrow mesenchymal stromal cells (BM-MSCs) are multipotent stem cells that can differentiate into chondrocytes, osteoblasts and adipocytes. SLE has been implicated as a stem cell disorder with impaired immunomodulatory function of SLE BM-MSCs and improvement of lupus nephritis with healthy MSCs transplantation has been suggested. However, the exact differentiation defects of SLE BM-MSCs have not been addressed, nor are the potential interventions studied. Our previous work indicates upregulation of IFN $\beta$  specific genes in human SLE bone marrow derived MSCs compared to normal bone marrow MSC. In addition, our data also

suggest that IFN $\beta$  and MAVS (Mitochondrial antiviral-signaling protein) form a positive feedback loop which leads to a senescence-like phenotype in SLE BM-MSCs and impairs MSC immunomodulatory function. Here we set out to investigate the differentiation defects of SLE BM-MSCs and potential intervention approaches.

**Methods:** The SLE patients recruited in this proposal satisfy the ACR classification criteria for SLE. BM-MSCs were isolated with Ficoll centrifugation (1.073 g/ml) and phenotyped using flow cytometry. *In vitro* studies included real-time PCR, western blotting and osteoblastogenesis analysis.

**Results:** We compared 3 age paired BM aspirates from healthy controls and SLE patients. BM-MSCs from SLE patients and healthy controls were isolated and cultured. The MSC surface markers are positive for CD73, CD90 and CD105, but negative for CD34 and CD45 in both healthy and SLE BM-MSCs after culture. No difference was observed in the surface markers between SLE and healthy BM-MSCs. However, SLE MSCs display significantly reduced osteoblastogenesis markers, such ALP (6 fold,  $p<0.05$ ), RUNX2 (8 fold,  $p<0.05$ ), OCN (4 fold,  $p<0.05$ ) and BSP (4 fold,  $p<0.05$ ). The osteoblast induction and ALP staining analysis for osteoblastogenesis also suggested a reduced differentiation with the SLE BM-MSCs. In contrast to the downregulation of osteoblast markers, the expression of IFN $\beta$  is increased 5 fold ( $p<0.05$ ) in SLE BM-MSCs. When BM-MSCs from healthy controls were treated with IFN $\beta$  for 6 hours, reduced ALP (12 fold,  $p<0.05$ ), RUNX2 (11 fold,  $p<0.05$ ), OCN (8 fold,  $p<0.05$ ) and BSP (7 fold,  $p<0.05$ ) were observed, suggesting that IFN $\beta$  plays an important role in inhibiting SLE BM-MSC differentiation into osteoblasts. Conversely, when IFN $\beta$  neutralizing antibody was applied to SLE BM-MSCs, the osteoblastogenesis markers were significantly enhanced.

**Conclusion:** IFN-I signature is an important feature of SLE. IFN $\beta$  has distinct features as compared to IFN $\alpha$ , higher affinity binding to IFN-I receptors, distinct gene transcripts and induction of senescence in non-hematopoietic cells. Our present work suggests that SLE BM-MSCs produce IFN $\beta$ , mediating a decrease in osteoblastogenesis capacity. Our work sheds lights on the SLE BM pathogenesis. Moreover, the successful rescue of the SLE BM-MSCs osteoblastogenesis defect with an IFN $\beta$  neutralizing antibody highlights IFN $\beta$  as a new potential therapeutic target for SLE treatment.

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Dendritic cells (DC) are the sentinel cells of the immune system that potently activate T-cells, making them important players in the pathophysiology of systemic autoimmune diseases. The most prominent alteration in the immune system of patients with systemic lupus erythematosus (SLE) or antiphospholipid syndrome (APS) is the upregulation of type I interferon (IFN) inducible genes, known as the IFN signature. This signature is related to disease activity and the occurrence of vascular disease and is considered a promising therapeutic target. Plasmacytoid DC (pDC) are held responsible for the increased type I IFN (IFN $\alpha$ ) production in SLE and APS, however, little is known on the molecular mechanisms that underlie increased type I IFN production by pDC in SLE and APS. Here we investigated the causes and consequences of increased type I IFN signaling on the dysregulation of both pDC and myeloid DC (mDC) in patients with SLE and APS.

**Methods:**

pDC and mDC were isolated from peripheral blood of patients with SLE (n=20), SLE+APS (n=10) and primary APS (PAPS, n=10) and healthy controls (n=12). RNA was extracted and used for RNA sequencing (RNAseq) to identify differentially expressed genes in pDC and mDC of SLE, SLE+APS and PAPS patients as compared with HC. Differential gene expression in pDC and mDC was compared between patients with (IFN-high) or without (IFN-low) a type I IFN signature. The effects of IFN $\alpha$  and TLR7 agonists on purified pDC were analyzed by RT-qPCR and flow cytometry. The effect of IFN $\alpha$  on cytokine production and the expression of T-cell stimulating molecules on pDC and mDC was measured by flow cytometry.

**Results:**

pDC and mDC shared an upregulation of type I IFN inducible genes in SLE, SLE+APS and PAPS as compared with HC. The expression of TLR7 and its downstream intermediates were increased in both pDC and mDC in all three patient groups as compared with HC. In pDC, not mDC, increased expression of TLR7 was confined to IFN-high patients (p<0.001). mDC of IFN-high patients showed an increased expression of genes involved in the activation of B- and T-cells (p<0.001). In vitro, IFN $\alpha$  upregulated TLR7 expression in pDC and augmented TLR7 mediated IFN $\alpha$  production. In contrast to pDC, in mDC IFN $\alpha$  priming enhanced TLR7 mediated TNF $\alpha$  production as well as the expression of T-cell stimulating molecules.

**Conclusion:**

IFN $\alpha$  has different effects on pDC and mDC. pDC of IFN-high SLE and APS patients are primed for type I IFN production through upregulation of TLR7. This results in a pathogenic loop of IFN $\alpha$  production by pDC, sustaining an increased activation status of both pDC and mDC in SLE and APS. Intervening in this loop potentially attenuates the dysregulation of DC in SLE and APS.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** Systemic Lupus Erythematosus (SLE) is a clinically diverse disease with a complicated pathophysiology highlighted in part by interferon (IFN) pathway dysregulation. Recent studies demonstrated that most pediatric SLE patients exhibit unabated IFN activities measured by microarray transcriptional scores. This study assessed the prevalence of these IFN active modules in adult SLE and determined association of these IFN active modules with lupus clinical features.

**Methods:** Gene expression profiles and associated IFN activities (IFN) of whole peripheral blood from 176 SLE patients who met ACR disease classification criteria were evaluated using modular transcriptional analysis based on Illumina Beadchip microarray data per ([PMC2727981](#)). ACR criteria and sub-criteria, clinical manifestations, comorbidities, and autoantibody positivity history were extracted from medical records by rheumatology trained investigators using a standard protocol. Lupus Severity Index (LSI) was calculated by two methods (Katz: 8330033; Montgomery: PMC4800735). Proportionality, chi-square, and mixed conditional logistic regression tests were used to analyze prevalence differences as well as to detect co-variate effects among different populations.

**Results :** One hundred patients were found to have active IFN pathways, while 76 patients had inactive IFN pathways by gene expression modules. Gender and ethnicity were not associated with IFN activation status in this adult SLE population. Patients with active IFN (mean: 29, range: 22 ÷ 44) had earlier disease onset than patients with inactive IFN (37.5, 28 ÷ 44;  $p < 0.05$ ). Patients with inactive IFN were more likely to report myalgias (68.7% vs 42.5%; Odds Ratio, 2.04) and arthralgias (79.1% vs 60%; OR, 3.23) compared to IFN active patients ( $p < 0.05$ ). However, hematologic (72.5% vs 35.8%; OR, 4.76;  $p < 0.001$ ) and renal (37.5% vs 10.4%; OR, 5.00;  $p < 0.001$ ) criteria were more common in IFN active patients. IFN active patients were also more likely to have autoantibody specificities to dsDNA (61.3% vs 28.5%; OR, 2.78;  $p < 0.01$ ), RNP (51.3% vs 14.9%; OR, 5.88;  $p < 0.01$ ), Ro (63.8% vs 14.9%; OR, 3.57;  $p < 0.01$ ), Sm (32.5% vs 10.4%; OR, 4.17;  $p < 0.01$ ), La (33.0% vs 11.9%; OR, 10.00;  $p < 0.01$ ), and Ribosomal P (11.3% vs 0.00%; OR, N/A;  $p < 0.01$ ) compared to IFN inactive patients. Overall, SLE patients with active IFN had higher Montgomery LSI [5.44, (4.65 ÷ 5.65) vs 5.07, (4.43 ÷ 5.65);  $p < 0.05$ ] and Katz LSI [4, (2.75 ÷ 6.00) vs 2, (1.5 ÷ 3.5);  $p < 0.001$ ] than IFN inactive patients.

**Conclusion:** In the current study, 57% of adult SLE patients had active IFN pathways and these patients were more like to have renal, hematologic, and immunologic involvement compared to IFN inactive patients and scored higher

on both SLE disease severity indices.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** Interferon (IFN) pathways are dysregulated in a subset of patients with systemic lupus erythematosus (SLE). IFN dysregulation likely contributes to SLE pathogenesis and influences the disease course.

This study examined correlations between IFN transcriptional modular scores, biologically relevant soluble mediators, and SLE disease activity in patients with or without the IFN signature.

**Methods :** Adult SLE patients (n=49) meeting  $\geq 4$  ACR classification criteria provided longitudinal samples at times of low (SLEDAI $\leq 6$ ) and high (SLEDAI $\geq 6$ ) disease activity. Immune pathway activity was evaluated by modular transcriptional analysis of Illumina Beadchip Microarray gene expression data in 98 patient samples and 20 age, race and gender matched healthy controls. Plasma soluble mediators (n=23) and antinuclear antibodies (n=11) were assessed by multiplex-bead based assays and ELISAs. Non-parametric paired tests were used for intra-individual univariate analyses, conditional logistic regression for multivariate analyses.

**Results :** Within a given individual, IFN signatures remained active and did not change with disease activity. In patients with active IFN signatures (n=29), several soluble mediators were elevated during high compared to low disease activity. These included MIG (median 168 pg/mL vs. 100 pg/mL;  $p<0.01$ ), IFN $\alpha$  (5.82 pg/mL vs. 3.69 pg/mL;  $p<0.01$ ), MCP1 (240 pg/mL vs. 209 pg/mL;  $p<0.01$ ), BLYS (1.88 ng/mL vs. 1.18 ng/mL,  $p<0.01$ ), TNFR1 (2.82 ng/mL vs. 1.98 ng/mL,  $p<0.05$ ) and TNFR2 (622 pg/mL vs. 552 pg/mL,  $p<0.01$ ). Additionally, patients with active IFN signatures showed higher M4.11 plasma cell module scores and dsDNA concentrations during high vs. low disease activity ( $p<0.05$ ). Periods of high disease activity in patients with active IFN signatures were best distinguished by M4.11 plasma cell module scores, BLYS, MIG and hemoglobin in multivariate logistic modeling ( $p<0.01$ ).

**Conclusion:** Although IFN activity correlates with disease severity in lupus populations, IFN module scores may not correlate significantly with intra-individual changes in disease activity. In contrast, plasma concentrations of IFN- and TNF-related soluble mediators significantly correlated with SLEDAI scores, suggesting that longitudinal monitoring of soluble mediators may be useful in individuals at increased risk of disease flares.

Figure 1. Scatter plot showing the significance of paired non-parametric analysis in IFN active subgroup. Color and size represent median % change of each soluble mediator from low disease visit to high disease visit intra-personally.

# Identification of Long Noncoding RNA RP11-2B6.2 As a Positive Regulator through Type I Interferon Pathway in Lupus Nephritis

**Yuanjia Tang**<sup>1</sup>, Zhuojun Liao<sup>1</sup>, Zhixin Xue<sup>1</sup>, Lingling Wu<sup>1</sup> and Nan Shen<sup>1,2,3,4</sup>, <sup>1</sup>Shanghai Institute of Rheumatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, <sup>2</sup>Center for Autoimmune Genomics and Etiology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>3</sup>Institute of Health Sciences, Shanghai Institutes for Biological Sciences (SIBS), Chinese Academy of Sciences (CAS) & Shanghai Jiao Tong University School of Medicine (SJTUSM), Shanghai, China, <sup>4</sup>Shanghai Institute of Rheumatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai, China

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Long noncoding RNAs (lncRNAs) have recently been identified to be tightly linked to diverse human diseases. Systemic lupus erythematosus (SLE) is a common autoimmune disease. Renal involvement is the most frequent and serious complication. Type I interferon (I IFN) and a group of inflammatory cytokines induced by type I IFN in human renal mesangial cells (HRMCs) play a vital role in lupus nephritis (LN). In this study we screened and investigated the contribution of the lncRNA RP11-2B6.2 to the pathogenesis of LN involved in the abnormal activation of type I IFN pathway.

## Methods:

The high throughput RNA-seq data from kidney biopsies of LN patients and controls was applied to screen for candidate lncRNA and confirm its relationship with clinical data. Rapid amplification of cDNA ends (RACE) was adopted to identify the full length and exact sequences of lncRNA. In situ hybridization was adopted to identify the lncRNA location of cell nucleus and cytoplasm. Quantitative real-time polymerase chain reaction (RT-qPCR) and western blotting was used to detect the RNA and protein expression of lncRNA and individual genes relevant to type I IFN pathway respectively. Dual-luciferase reporter assay was used to detect the promoter transcriptional activity of genes.

## Results:

The expression of lncRNA RP11-2B6.2 was significantly increased in the kidney tissues from LN patients compared with those from healthy controls, and positively correlated with the degree of disease activity and renal injury. Additionally, the expression of lncRNA RP11-2B6.2 can be stimulated by type I IFN. Silencing RP11-2B6.2 significantly reduced the expression of a group of interferon-stimulating genes (ISGs) including IFIT1, OAS1, etc., Furthermore, lncRNA RP11-2B6.2 affected the expression of IFN alpha and beta receptor subunit 1 (IFNAR1) and its promoter transcriptional activity, phosphorylation of Jak1 and Stat1, and the luciferase activity induced by interferon stimulated response element (ISRE).

## Conclusion:

Long noncoding RNA RP11-2B6.2 is a positive regulator of the type I IFN signaling pathway in LN. LncRNA RP11-2B6.2 may contribute to the pathogenesis of LN and provide a potentially therapeutic target.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Epigenetic changes in systemic lupus erythematosus (SLE) offer a potential explanation for the chronicity of disease. We previously found that interferon regulatory factor-1 (IRF1) binding sites were highly enriched in histone H4 acetylation (H4ac) peaks in SLE monocytes. IRF1 directly interacts with histone-modifying enzymes. IRF1 is a downstream immune response mediator that plays an important role in the interferon (IFN) pathway. IRF1 is highly inducible by prolactin (PRL), a hormone implicated in the pathogenesis of SLE. PRL is involved in immune response modulation through the JAK/STAT/IRF1 pathway. Our studies extend this by defining a pivotal role for PRL in induction of histone modifying enzymes that alter the balance of histone acetylation and IRF1 activation and downstream chromatin effects.

**Methods:** Primary monocytes and THP-1 cells were treated with recombinant human PRL. Flow cytometry for H4ac were run on the Accuri C6 with isotype controls. Real-time quantitative reverse transcription polymerase chain reaction (qRT-PCR) evaluated the effects of PRL stimulation on expression of HATs/HDACs and interferon-response genes. Western blot, immunoprecipitation and ChIP assays defined PRL effects on HAT/HDAC protein expression and interactions with IRF1. IRF1 knockdown experiments were performed using a lentivirus system.

### **Results:**

Flow cytometry found significantly increased total H4ac, H4K5, H4K8, H4K12, and H4K16 acetylation in primary monocytes stimulated by PRL.

qRT-PCR studies of HAT/HDAC expression patterns showed increases in PCAF, CBP, P300, GCN5 and ATF2 expression in THP-1 cells stimulated by prolactin that was time-dependent.

Western blot assays found that nuclear levels of IRF1, PCAF, p300, CBP, ATF2, TIP60, MOF and HBO1 increased with PRL stimulation; HDAC3 decreased with PRL stimulation.

IRF1 co-immunoprecipitation assays found IRF1-binding with PCAF, P300, CBP and ATF2 in both unstimulated and stimulated states. IRF1 interactions with p300, CBP and ATF2 increased at 1-2 hrs of PRL stimulation. ChIP assays revealed increased IRF1 binding to PRL-response genes TGF $\beta$  and ID1; increased H4ac was seen at the promoter of ID1 with PRL stimulation.

IRF1 knock-down experiments validated that PRL effects on HATs are IRF1-dependent. PRL-induced increases in the gene expression of PCAF, CBP, ATF2 and TIP60 were abrogated in the IRF1 knock-down cells as compared to controls.

PRL effects on the IFN signature genes were defined by qRT-PCR. CXCL10, IFIT1, IFIT3, B2M, OAS1 and CD40 expression levels were significantly increased by 4-hrs of PRL stimulation. Longer exposure to PRL stimulation also found further significant increases in the expression of IFIT1, IFIT3, CXCL10, MX1, B2M, CD40, OAS1, OASL and NOD2 after 2 wks.

**Conclusion:** Prolactin has long been associated with autoimmunity. These studies provide key insights into the mechanisms. These data demonstrate that prolactin stimulation induces IRF1 activation and a pattern of acetylated H4 that corresponds to the changes seen in SLE. We found dominant effects at the level of epigenetics, an area not previously explored with respect to prolactin effects in autoimmunity.

## **STAT4 Regulates Pathogenic IL-21 and IFN- $\gamma$ in Tfh Cells in Murine and Human Lupus**

**Fotios Koumpouras**<sup>1</sup>, XueMei Dong<sup>2</sup>, Jason Weinstein<sup>2</sup> and Joseph E. Craft<sup>3</sup>, <sup>1</sup>Internal Medicine, Rheumatology, Yale University School of Medicine, New Haven, CT, <sup>2</sup>Rheumatology, Yale University School of Medicine, New Haven, CT, <sup>3</sup>Department of Internal Medicine/Rheumatology, Yale University School of Medicine, New Haven, CT

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Follicular helper T cells (Tfh) cells regulate the germinal center (GC) response by delivery of contact-dependent interactions and cytokines including IL-4, IFN- $\gamma$  and IL-21. JAK-STAT signaling plays an important role in regulating these cytokines associated biological responses. Signal Transducer and Activator of Transcription proteins (STATs) are intracellular transcriptional factors that are activated and recruited to the cytokine receptors through phosphorylation by Janus Kinase (JAK).

There are several STATs (STAT1, STAT2, STAT3, STAT4, STAT5 and STAT6) in mammalian cells. STAT4 is the only STAT that demonstrates the genetic association to disease susceptibility in human systemic lupus by a number of Genome-Wide Association Studies. These genetic associations lie in the single-nucleotide polymorphisms (SNPs) among the noncoding regions. STAT4 SNP at rs7574865, which locates intron 3, is associated with increased

sensitivity to IFN $\alpha$  signaling and gene expression, and suggests that these genetic variants may affect disease susceptibility through the gene's transcription.

Role of STAT4 in disease pathology is still unclear. STAT-4 in human SLE has not been robustly studied.

**Methods:** B6.Sle1.Yaa mice were sacrificed at 2,4, and 6 months of age flow cytometry plots of Tfh cells or Th1 cells were obtained using FLOW. Flow cytometry plots of intracellular staining for the transcription factors Bcl6 and T-bet in Tfh cells over time were also performed. 40 ml peripheral blood was drawn during the clinical visit. Serum was separated and stored in -80 C. Mononuclear cells from the peripheral blood was isolated using Ficoll-Paque, suspended in serum with 10% DMSO and store in -80 degree for STAT4 assay.

**Results:** In young lupus mice, Tfh cells co-express the Tfh and Th1 cell transcription factors Bcl6 and T-bet, respectively; with a decline of both in Tfh cells as the disease progresses. However, Tfh cells continue to co-produce similar levels of both IL-21 and IFN- $\gamma$  during the progression of murine lupus. Transcriptional analysis of lupus-Tfh cells at different stages of disease revealed an increased STAT4 gene signature as the disease progresses. Moreover, we observed that lupus-Tfh cells continue to phosphorylate STAT4 (pSTAT4) as the disease worsens, consistent with the prolonged production of pathogenic IL-21 and IFN- $\gamma$ . In the blood of lupus patients, activated (CD4<sup>+</sup>CD45RA<sup>-</sup>) T cells also secrete IL-21 and IFN- $\gamma$ . STAT4 activity was measured in these cells using FLOW. Unstimulated CD4<sup>+</sup>CD45RA<sup>-</sup> T cells from lupus patients had an increase in pSTAT4 compared to that of healthy controls. Furthermore, pSTAT4 was further increased with IFN- $\alpha$  or IL-12 stimulation in the lupus patients compared to controls.

**Conclusion:** In SLE, T-bet and Bcl6 expression decline in Tfh cells, while increased STAT4-guided expression appears to drive pathogenic cytokine production, providing a potential therapeutic target for SLE.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lupus nephritis (LN) is one of the most severe types of organ involvement in systemic lupus erythematosus (SLE), despite the recent advances in immunosuppressive therapies. High type I interferon (IFN) is a heritable risk for SLE, and some previous studies have suggested a link between high IFN and lupus nephritis. However, little is known about the relationships between high levels of IFN and the subtypes of LN, and whether IFN is more associated with anti-dsDNA antibodies or with clinical nephritis.

**Methods:** We studied 197 EA SLE patients and measured type I IFN in sera by performing WISH IFN bioassay as described previously. Subtypes of LN were confirmed by renal biopsy review. Complements, anti-dsDNA and other auto-antibodies were measured in the clinical laboratory, and standard clinical cut-offs were used to define a positive result. Non-parametric analyses were used to compare IFN data with the antibody data.

**Results:** IFN level and SLEDAI score was positively correlated ( $r=0.30$ ,  $p<0.0001$ , Spearman) in our cross-sectional evaluation. EA subjects with a high levels of IFN (IFN score  $\geq 2$ ) were more likely to have renal manifestations compared to the subjects with a low levels of IFN (IFN score  $< 2$ ) ( $p<0.001$ , OR=3.4, Fisher's exact test). In addition, the incidence rate of class III/IV LN was significantly higher among patients with a high levels of IFN compared to the patients with low levels of IFN ( $p=0.0197$ , OR=5.1, Fisher's exact test). Notably, IFN level was significantly higher in active class III/IV LN compared to inactive class III/IV LN ( $p<0.001$  Mann-Whitney U) and this was not observed in non-class III/IV LN populations.. Positivity of ds-DNA antibody did not show significant difference between inactive class III/IV LN and active class III/IV LN, and the correlation between SLEDAI and IFN was driven by the dsDNA and complement variables.

**Conclusion:** Our data support an association between type I IFN and class III/IV nephritis that is independent of overall SLEDAI and anti-dsDNA antibodies, suggesting that IFN is involved in renal pathogenesis. These data also suggest that IFN could predict renal disease activity or the future risk of developing LN, especially class III/IV LN in EA SLE patients.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rare variants provide important opportunity for mechanistic insight as they carry substantial effect sizes and provide deep insight into disease etiopathogenesis. To date, several pathways have been identified as monogenic causes of SLE or similar syndromes of systemic autoimmunity, particularly with the severe manifestations of childhood onset SLE. In several other disease phenotypes, such as autism spectrum disorders, with severe presentation in childhood, exome-wide sequencing approaches of both unaffected parents and affected children have identified causal *de novo* mutations and thus identified novel genes that were not amenable to the GWAS approach. With this approach, we identified a novel SLE candidate gene, *ACACB*, which encodes the acetyl-CoA carboxylase beta subunit (ACC-beta) (see below). This enzyme functions in many tissues as a regulator of fatty acid oxidation and was previously defined as a key modulator of innate immune response through its role supporting the anabolic demands of activated dendritic cells.

**Methods:** In order to define *de novo* mutations in SLE, we performed an exome-wide sequencing study in a trio consisting of an SLE proband and her parents. Quality control and Mendelian errors were filtered using a validated analysis pipeline (CASSI) as previously described [1]. Functional studies of a gene containing a *de novo* variant, *ACACB*, were then performed using 5-(Tetradecyloxy)-2-furoic acid (TOFA), an inhibitor of ACACB. THP1-Blue ISG cells that have stable integration of an interferon regulatory factor (IRF)-inducible secreted alkaline phosphatase reporter construct were treated with TOFA to confirm a role for ACACB in type I interferon response (Invivogen). P-values presented were adjusted for multiple comparisons using the Holm-Sidak method with alpha = 0.05.

**Results:** Inhibition studies with TOFA revealed that type I interferon activity in response to several nucleic acid ligands was impaired in the setting of ACC-beta inhibition as measured by secreted alkaline phosphatase activity. Specifically, in comparison to vehicle treatment, TOFA treated cells demonstrated 10-20% dose-dependent reduction of type I interferon activity in response to the STING ligand cGAMP ( $P < 0.01$ ), 10-15% dose-dependent reduction of type I interferon activity in response to the transfection of the cytosolic DNA and RNA sensor ligand poly(dA:dT) ( $P < 0.01$ ) and non-significant trend towards dose-dependent reduction of type I interferon activity in response to the TLR-7/TLR-8 ligand R848 (resiquimod).

**Conclusion:** *ACACB* is a candidate SLE susceptibility gene for childhood onset SLE. Inhibition of the activity of ACC-beta, its product, modulates type I interferon response to several SLE autoantigen relevant pattern recognition receptor ligands. By defining *ACACB* as a candidate mutation in SLE, fatty acid beta-oxidation is defined as a potential novel druggable target for SLE therapy. ACC inhibitors in development to treat non-alcoholic steatohepatitis may find utility if repurposed to treat human SLE.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Systemic lupus erythematosus (SLE) is a chronic multi-systemic autoimmune disease, with a broad spectrum of clinical manifestations and unpredictable disease course with periods of flares and remission. Over the past few years, several biomarkers have been reported to be elevated in SLE, though the utility of these markers in monitoring disease progression remains unclear. The main objective of the current study is to assess the performance of serum FAS, sTNFR2, Igfbp2 and Ferritin as biomarkers for tracking lupus flares in non-renal SLE patients.

### Methods:

Serum samples were obtained over 4 consecutive visits (<4 months apart) from 29 SLE patients from Oklahoma Medical Research Foundation (OMRF). All patients met ACR requirements for diagnosis of SLE and none of them had lupus nephritis, though they had mucocutaneous and/or musculoskeletal disease manifestations. Serum FAS, sTNFR2, Igfbp2 and ferritin were assayed in all 29 patients by ELISA and related to SLEDAI and BILAG disease activity indices.

### Results:

All four tested serum proteins correlated significantly with SLEDAI and BILAG in SLE: FAS ( $r=0.36$ ,  $p<0.0001$  for SLEDAI &  $r=0.29$ ,  $p=0.0002$  for BILAG), Ferritin ( $r=0.13$ ,  $p=0.0494$  for SLEDAI &  $r=0.22$ ,  $p=0.0035$  for BILAG), Igfbp2 ( $r=0.24$ ,  $p=0.0013$  for SLEDAI &  $r=0.18$ ,  $p=0.0106$  for BILAG) and sTNFR2 ( $r=0.30$ ,  $p<0.0001$  for SLEDAI &  $r=0.19$ ,  $p=0.0112$  for BILAG). We next examined serial changes in all 4 biomarkers with changes in disease activity. In some patients 2-3 of the tested biomarkers were predictive of changes in disease activity while in others all 4 tested markers emerged as good indicators of disease activity changes. In studying a total of 72 patient follow-up intervals, FAS and Ferritin exhibited the highest concordance with concurrent disease activity (58-62%), followed by Igfbp2 (50%) and sTNFR2 (46%), all of which were superior to the performance of complement C3, C4 and anti-DNA. Furthermore, combining FAS to other tested molecules increased its ability to track concordant disease activity changes in SLE (81% for FAS±Ferritin; 76% for FAS±Igfbp2 and FAS±sTNFR2).

## Conclusion:

Serum FAS and Ferritin emerge as potential serum markers for predicting mucocutaneous and musculoskeletal disease flares in SLE patients.

# Soluble Programmed Cell Death Protein 1 As a Biomarker for Systemic Lupus Erythematosus

**Shinya Hirahara**, Yasuhiro Katsumata, Yasushi Kawaguchi and Hisashi Yamanaka, Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Programmed cell death protein 1 (PD-1/CD279) is a cell surface receptor that belongs to the extended CD28/CTLA-4 family and is expressed on T cells and pro-B cells. PD-1 plays an important role in down regulating the immune system by preventing the activation of T-cells. Soluble PD-1 (sPD-1), which is produced by the alternative splicing, can functionally block the regulatory effect of membrane-bound PD-1 on T cell activation. We aimed to retrospectively evaluate the usefulness of serum sPD-1 as a biomarker for systemic lupus erythematosus (SLE).

**Methods:** In the period from 2010 through 2016, serum samples from 74 hospitalized patients due to active SLE were retrieved from the Tokyo Women's Medical University SLE Biorepository. Serum samples from 20 patients with systemic sclerosis (SSc) were similarly retrieved from the Tokyo Women's Medical University SSc Biorepository and served as controls. Sera from 21 healthy subjects were also used as controls. These samples had been previously collected and stored for unspecified medical studies under general consents. All of the SLE and SSc patients fulfilled the 1997 revised ACR criteria for SLE and the 2013 ACR/EULAR criteria for SSc, respectively. We measured the levels of sPD-1 by enzyme-linked immunosorbent assay (ELISA) kit in sera of patients with SLE

and SSc, and healthy controls, and compared them. Clinical and laboratory data including the SLE Disease Activity Index 2000 (SLEDAI-2K) scores were also retrospectively collected from the medical records. Associations between the levels of serum sPD-1 and clinical information were retrospectively and statistically analyzed.

**Results:** In the study population with SLE patients, 69 were female, the median age was 35, the median anti-dsDNA antibodies titer was 9.9, and the median SLEDAI-2K score was 12. The levels of serum sPD-1 in SLE patients with SLEDAI-2K  $\geq 6$  were significantly higher than those in SLE patients with SLEDAI-2K  $< 6$ , patients with SSc, and healthy controls ( $p < 0.05$  in all comparisons), whereas there was no significant difference in other comparisons (Figure). Among the SLE patients, the levels of sPD-1 were moderately correlated with the titers of anti-dsDNA antibodies and the SLEDAI-2K scores, and were moderately and inversely correlated with the levels of C3 and C4. The levels of sPD-1 were significantly higher in SLE patients with arthritis, myositis, rash, mucosal ulcers, fever, thrombocytopenia, or leucopenia than those without ( $p < 0.05$  in all comparisons). In addition, the levels of sPD-1 were higher in patients positive for anti-dsDNA antibodies than those negative among SLE patients with SLEDAI-2K  $\geq 6$  ( $p < 0.01$ ). The sPD-1 levels decreased significantly following treatment among SLE patients ( $p < 0.05$ ).

**Conclusion:** The findings from the present study suggested that serum sPD-1 can serve as a new biomarker reflecting disease activity in patients with SLE.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

- **Background/Purpose:** Eukaryotic cells contain organelles called mitochondria that govern energy supply and control of cell death. Whereas damaged organs or activated cells can extrude their mitochondria, which is suggested to trigger innate immunity, it is less well known whether extracellular mitochondria are also recognized by the adaptive immune system.
- **Methods:** We improved methodologies for isolation of pure mitochondria from human and mouse cells and tissues, and designed ELISA to measure the presence of antibodies directed against mitochondrial outer membrane and mtDNA in mouse models, and patients with systemic lupus erythematosus (SLE) (n=170, Table 1), compared to controls (n=44) and patients with antiphospholipid syndrome (APS) (n=12) or primary biliary cirrhosis (PBC) (n=12). Carotid ultrasounds were available in 113 patients. Spearman's correlation analysis was used to explore whether antibody levels were associated with the following outcomes: SLEDAI-2K, SDI and carotid ultrasound plaques and intima-media thickness (CIMT) as surrogates for vascular damage.
- **Results:** Antibodies against mitochondrial outer membrane and mtDNA were increased in a mouse model of SLE. In humans, the levels of antibodies recognizing the outer mitochondrial membrane and mtDNA were significantly higher in SLE patients than in controls, APS patients and PBC patients (Table 2). Antibodies against mtDNA were associated with a lower likelihood of previous thrombotic events and higher disease activity measured by SLEDAI-2K, the latter being entirely explained by the high correlation between commercial assays for antibodies to double stranded DNA and our assay for mtDNA antibodies. While antibodies against the mitochondrial outer membrane were not associated with the measured disease characteristics, their presence was not completely explained by the presence of anti-cardiolipin, suggesting that other mitochondrial targets exist. Oxidation of the mitochondrial surface had no impact on autoantibody recognition of mitochondrial antigens.
- **Conclusion:** This study provides useful insights into optimized methodologies for assessing mitochondrial antibodies in mice and humans, providing an appreciation of the anti-mitochondrial antibody repertoire and its role in autoimmunity. These findings further support the concept that extracellular mitochondria provide an important source of circulating autoantigens that may be clinically relevant in SLE.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neutrophil (PMN) activation and neutrophil extracellular trap (NET) formation are implicated in the pathogenesis of Systemic Lupus Erythematosus (SLE), particularly in the acceleration of organ and vascular damage. Lupus neutrophils can drive B-cell activation and auto-antibody (Ab) production, at least in part, by production of type-I interferons and B-cell activating factor (BAFF) and, by exposing self-antigens (Ags), such as oxidized mitochondrial DNA and cardiolipin. The presence of anti-cardiolipin Abs in SLE patients has been associated with an increased risk of cardiovascular events due to atherosclerosis. Still, little is known about the potential link between neutrophil abnormalities, B-cell activation, and auto-Ab production. This study was undertaken to test whether PMN activation and NET formation contribute to increased BAFF levels and auto-Ab production in SLE patients.

**Methods:** BAFF levels were analyzed in serum samples from 60 SLE patients with varying levels of disease activity and 20 healthy controls (HC) by ELISA. Plasma levels of NETs and 8-OHdG were measured by ELISA. Anti-dsDNA titers complement and CRP levels were obtained from clinical records. Autoantibody reactivities were assessed by microarray.

**Results:** Mean BAFF levels were significantly higher in SLE patients, as compared to HC (2785.25 vs 924.29 pg/mL,  $p < 0.0001$ ). After defining a cut-off for BAFF levels at 1429.4 pg/mL (mean + 3<sub>SD</sub> HC), around 60% of SLE patients were identified to have elevated BAFF levels. No associations between BAFF titers and gender, ethnicity, and age at diagnosis were found. Although BAFF levels did not associate significantly with the overall SLEDAI scores, we found a significant correlation between BAFF levels and increased CRP levels, and decreased serum C3 and C4 levels, suggesting an association with ongoing immune complex (IC)-driven disease. Compatible with this hypothesis, levels of ICs, measured by an *in vitro* assay, correlated with BAFF levels ( $r=0.38$ ,  $p=0.02$ ). Asking if BAFF levels correlated with neutrophil activation, we observed that serum-mediated neutrophil activation, as well as the cell-free 8-OHdG DNA, an inflammatory NET-derived component, both correlated with BAFF levels ( $r=0.34$ ,  $p<0.05$  for both analyses), consistent with PMN activation contributing to elevated BAFF levels in SLE. Microarray data revealed positive correlations between BAFF levels and IgG autoreactivity against M2-mitochondrial antigen, sphingomyelin, phosphatidylinositol,  $\beta 2$  glycoprotein and cardiolipin.

**Conclusion:** We found an association between heightened BAFF production and markers of PMN activation and particularly increased levels of inflammatory oxidized DNA, compatible with the release of BAFF during NETosis. Our data support the hypothesis that neutrophils, through IC-mediated activation, release BAFF as well as key auto-Ags such as dsDNA and mitochondrial components, including cardiolipin, which may contribute to the production of pathogenic auto-Abs. These results provide new insights into how neutrophils and BAFF may contribute to the development of cardiovascular disease and help identify new effective therapies for SLE patients.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Up to 60% of SLE patients develop renal involvement, and renal injury is an important predictor of mortality in patients with SLE. Kidney biopsy is the gold standard for diagnosis of active lupus nephritis (LN), and active LN is associated with proteinuria, active urinary sediment and/or a rise in serum creatinine. Urine protein/creatinine ratio is often used to monitor LN activity over time, and proteinuria is accepted as the most effective predictor of the long-term outcome of LN. However, none of these measures has proved sufficient for identification and analysis of the biologic events that underlie the development of active LN. We analyzed extensive laboratory and clinical data and blood gene expression data in relation to urine protein to identify an informative measure of LN activity over time.

**Methods:** Forty-seven LN patients were studied. Clinical and laboratory data were collected for an average (range) of 6 (2-12) years. Longitudinal random urine protein/creatinine ratio data were compared to 72 laboratory and clinical parameters in a linear mixed model. Illumina HT-V4 Bead array data (3-13 time points/patient) were obtained from PBMC of 30 LN patients and compared to proteinuria and serum albumin levels.

**Results:** In a longitudinal analysis of LN patients, serum albumin was the parameter that was most significantly (negatively) correlated with proteinuria ( $p < 0.00001$ ). In addition, serum albumin correlated significantly with serum calcium, sodium, bilirubin, erythrocyte sedimentation rate (ESR), urine red blood cells (URBC) and urine white blood cells (UWBC) ( $p < 0.05$ ) in a multivariate model. In an analysis of longitudinal PBMC gene transcript data, proteinuria did not correlate with any transcript after correction for multiple testing (FDR 0.05). In contrast, serum albumin correlated with 120 transcripts in PBMC from LN patients. Functional analysis of the obtained genes indicates enrichment of transcripts specifically expressed in neutrophils (e.g., DEFA4, MMP8, MMP9, ELANE, ARG1) and genes related to cell-cycle and DNA-damage pathways ( $p < 0.01$ ).

**Conclusion:** Proteinuria is an indicator of worsening LN. However, its usefulness as a marker is limited by concurrent urinary tract infections, circadian rhythms, oliguria and other factors. Through study of a longitudinal series of LN samples we demonstrate that serum albumin levels negatively correlate with classical measures of renal involvement, including proteinuria, URBC, and UWBC and might herald a renal flare. Moreover, serum albumin levels identified gene transcripts in blood that may reflect significant molecular mechanisms that contribute to LN flare, allowing novel insights into the pathogenesis of LN.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Anti-dsDNA antibodies are highly specific for systemic lupus erythematosus (SLE) and often associate with lupus nephritis. Extracellular nucleosome DNA released from apoptotic or necrotic cells are thought to be the source of DNA autoantigens in SLE. Recent studies show that mitochondria DNA (mtDNA) may play an important role in driving the production of anti-DNA autoantibodies and type I interferons in SLE. Since mtDNA are rich in unmethylated CpG islands, mtDNA may represent a distinct class of autoantigens in SLE. The purpose of this study was to compare autoantibodies to mtDNA and nucleosome-associated DNA in SLE and their association with lupus nephritis and other disease parameters.

### **Methods:**

144 patients who fulfilled the 1997 American College of Rheumatology criteria for SLE were recruited at the University of Nebraska Medical Center (UNMC). 123 healthy controls (matched with SLE patients in demographics, about 80% female with an average age of 37, about 50% Caucasians, 30% African Americans, and 15% Hispanic) were recruited at the community of UNMC. Blood serum samples were tested for anti-mtDNA antibodies using Enzyme-linked immunosorbent assay (ELISA) with PCR-amplified human mtDNA as the capturing antigen. The anti-dsDNA NcX antibodies were determined using ELISA-based kit from Euroimmun. The data were summarized from three independent experiments.

### **Results:**

The anti-mtDNA antibodies are significantly higher in patients with SLE (n = 144, mean optical density units OD = 0.80; SD = 0.90) than healthy controls (n = 123, mean OD = 0.19; SD = 0.11) with a *p* value less than 0.0001 (by two-tailed Mann-Whitney test). Using the mean + 2 x SD of healthy controls as the cut off for positivity, 51.4% of

SLE patients are tested positive for anti-mtDNA antibodies while 41% of the same SLE cohort are tested positive for anti-dsDNA-Ncx. Anti-mtDNA antibody levels are also more significantly correlated with SLEDAI (Pearson  $r = 0.53$ ,  $p = 0.0001$ ), and reversely correlated with C3 and C4 levels (Pearson  $r = -0.4$ ,  $p = 0.0001$ ; Pearson  $r = 0.21$ ,  $p = 0.01$ , respectively) than anti-dsDNA-NcX antibody levels. Furthermore, increased percentage of SLE patients with active lupus nephritis were tested positive for anti-mtDNA (65%) than anti-dsDNA NcX (52%).

### Conclusion:

We have developed a simple anti-mtDNA ELISA assay that has 10% higher sensitivity for SLE and 13% higher sensitivity for active lupus nephritis, compared to the widely used anti-dsDNA NcX ELISA assay (Euroimmun). The anti-mtDNA antibodies also have better correlations with SLEDAI, C3, and C4 levels. Therefore, anti-mtDNA antibody may serve as an improved biomarker for SLE.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neuropsychiatric Systemic Lupus Erythematosus (NPSLE) is a severe complication of SLE, including a variety of neurological and psychiatric features. Previous studies have demonstrated the close relationship between NPSLE and inflammation. High mobility group protein B1 (HMGB1), a highly conserved protein secreted by innate immune cells in response to pathogenic products and released by injured or dying cells, occupies a central role in the pathogenesis of both sterile and infectious inflammation. Recent studies have shown an association between HMGB1 and chronic inflammation and autoimmunity. Toll-like receptor 4 (TLR4) is the primary receptor of endogenous extracellular HMGB1 in mediating macrophage activation, cytokine release, and tissue injury. HMGB1-TLR4 signaling pathway is the up-stream pathway of NF-KB, which could upregulate the expression of various cytokines and other inflammatory mediators. The objective of the study was to explore the potential mechanism of HMGB1-TLR4 axis in NPSLE.

**Methods:** The study population consisted of 107 SLE patients and 43 age- and sex-matched healthy controls. 73 SLE patients had active disease. 36 of these had NPSLE. Clinical and serological parameters were assessed according to routine procedures. HMGB1 and TLR4 levels were measured by ELISA. Statistical analyses were performed by using the chi-square test and the t-test.

**Results:** Central nervous system (CNS) manifestations accounted for 94% (34/36 patients), while involvement of the peripheral nervous system (PNS) was 6% (2/36 patients). The majority of the manifestations were Seizure disorders (n=17; 47.2%), Headache (n=12; 33.3%), Cognitive dysfunction (n=10; 27.8%), Psychoses (n=8; 22.2%). Within the group of active patients those with NP manifestations had higher HMGB1 levels (0.451 (0.292 to 0.583)) compared to active patients with non-NP manifestations (0.356 (0.098 to 0.436)). In patients with NP (0.429 (0.313 to 0.526)) and non-NP (0.375 (0.196 to 0.478)) manifestations during active periods of the disease, TLR4 levels significantly increased in comparison to the controls. TLR4 levels were significantly higher in active patients (0.401 (0.196 to 0.526)) compared to quiescent patients. There was a significant positive correlation between levels of HMGB1 and TLR4 in the total patients group ( $P<0.0001$ ,  $r=0.939$ ). We observed a correlation between HMGB1 levels and SLEDAI ( $P<0.0001$ ,  $r=0.804$ ). Also, TLR4 levels showed a significant correlation with SLEDAI ( $P<0.0001$ ,  $r=0.809$ ). HMGB1 levels correlated with anti-dsDNA levels ( $P<0.0001$ ,  $r=0.558$ ). Similarly, TLR4 showed a correlation with anti-dsDNA levels ( $P<0.0001$ ,  $r=0.522$ ). We observed a negative correlation in the total SLE group between C3, C4 and HMGB1 levels ( $P<0.0001$ ,  $r=-0.545$  and  $P<0.0001$ ,  $r=-0.270$  respectively). Also, TLR4 showed a significant negative correlation with C3 and C4 ( $P<0.0001$ ,  $r=-0.559$  and  $P<0.0001$ ,  $r=-0.285$  respectively).

**Conclusion:** Our data suggest that HMGB1-TLR4 axis plays an important role in the pathogenesis of SLE as well as NPSLE.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Human SLE is characterized by fluctuating serum levels of complement proteins. There are frequent copy number variations (CNVs) of complement C4A and C4B genes among different individuals. Previously, we demonstrated that C4A deficiency is a strong genetic risk factor for SLE. Our current objectives are

to investigate how CNVs of C4 contribute to the great variability of C4 serum levels and how deficiencies of C4A or C4B modulate the clinical presentations, including organ damage, of SLE.

**Methods:** Our study population included 499 patients from Hong Kong, who fulfilled  $\geq 4$  of the 2013 ACR/SLICC criteria for SLE. Among them 93% were women, the mean age of SLE onset was  $32.8 \pm 13.0$  years, and SLE duration was  $14.4 \pm 7.6$  years. Gene copy numbers (GCNs) of total C4 (C4T), C4A and C4B were determined by real-time PCRs. Serial serum levels over the past 5 years for C4 and C3 of each patient were retrieved through the laboratory data registry system. Serum C4 and C3 levels are shown as mg/100 ml (unit). Clinical manifestations and organ damage of SLE were correlated with CNVs of C4 genes and serum levels. Continuous data between groups were compared by t-tests and categorical data by  $\chi^2$  analyses. Logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals for effects of C4 CNVs on cumulative clinical manifestations of SLE and accrued organ damage, adjusted for durations of disease.

**Results:** Serum levels for C4 varied from 1-84 units (Median: 17) and for C3 from 8-314 units (Median: 86). There was a very strong correlation between C4 and C3 protein levels ( $R = 0.70$ ,  $p = 5.3 \times 10^{-75}$ ). The GCN of C4T varied between 2 and 9 with a median of 4 copies (54%), followed by 2 and 3 copies (21%). Each additional gene copy correlated to an increase of 4 and 6 units for the mean and maximum serum C4 levels, respectively. A higher GCN of C4T ( $\geq 3$  vs  $< 3$ ) was protective against the development of neuropsychiatric disorder over time [OR 0.45 (0.21-0.98),  $p = 0.04$ ]. A high GCN of C4L ( $\geq 3$  vs  $< 3$ ), or the absence of C4S (GCN=0), was negatively associated with the occurrence of thrombocytopenia [OR 0.64 (0.42-0.97),  $p = 0.04$ ]. A high GCN of C4B was associated with damage to any organ [OR 1.76 (1.05-2.93),  $p = 0.03$ ], but a high GCN of C4A ( $\geq 3$  vs  $< 3$ ) was associated with cardiovascular damage [OR 2.30 (1.06-5.00),  $p = 0.04$ ]. Among the SLE patients studied, 18.3% had persistently low levels of C4 (mean  $\leq 10.0$  units). These patients mostly had GCNs of C4T=2 or 3 [OR 4.02 (2.47-6.56),  $p = 4.7 \times 10^{-8}$ ], or C4B=0 or 1 [OR 3.06 (1.89-4.96),  $p = 9.0 \times 10^{-6}$ ]. Patients with persistently low C4 levels had increased prevalence of mucosal ulceration [OR 2.09 (1.15-3.78),  $p = 0.02$ ], lymphopenia [OR 1.76 (1.01-3.05),  $p = 0.045$ ] and gastrointestinal disorders [OR 2.52 (1.31-4.84),  $p = 0.005$ ].

**Conclusion:** CNVs of C4 genes confer great variability of serum C4 levels among SLE patients. While C4A deficiency contributes to genetic predisposition of SLE, persistently low levels of serum C4 among patients were strongly correlated with low GCN of total C4 and C4B deficiency. Elucidating C4-CNVs may have prognostic significance of SLE as high GCNs of C4B and C4A appeared to correlate with organ damage and cardiovascular disease, respectively.

## Cytokines and Autoantibody Cluster-Interaction in Systemic Lupus Erythematosus. a Systems Medicine Approach

Julian Barahona-Correa, Yovana Pacheco, Diana M. Monsalve, Manuel Rojas, Yhojan Rodríguez, Juliana Saavedra, Mónica Rodríguez-Jiménez, Ruben Mantilla, Carolina Ramírez-Santana, Nicolás Molano-González and **Juan-Manuel Anaya**, Center for Autoimmune Diseases Research (CREA), School of Medicine and Health Sciences, Universidad del Rosario, Bogota, Colombia

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Evidence supports the existence of different sub-phenotypes and the pivotal role of cytokines and autoantibodies in systemic lupus erythematosus (SLE). Cytokines interact in a highly complex network. Thus, understanding how these complex non-linear processes are connected and observed in real-life settings is a major challenge. Cluster approaches may assist in the identification of these sub-phenotypes, which represent such a phenomenon and may contribute to the development of personalized medicine. Therefore, we analyzed the relationship between autoantibodies and cytokine clusters in SLE.

**Methods:**

This was an exploratory study in which 70 consecutive women with established SLE (ACR 1997) were assessed. Clinical characteristics, including disease activity (by SLAQ), a 14-autoantibody profile (by IFI and ELISA), and a panel of 15 serum cytokines (by cytometric bead array) were measured simultaneously. Mixed-cluster methodology was used to define autoantibody and cytokine clusters. Bivariate and multivariate analyses, including a heteroscedastic regression model, were done to identify associations between clusters and related variables.

**Results:**

Three clusters of autoantibodies were defined (Figure 1): neutral, 2) aPL-dominant, and 3) ENA-dominant. Eight cytokines disclosed levels above the threshold (as compared to healthy controls), allowing to find 4 clusters (Figure 2): 1) neutral, 2) chemotactic, 3) IL-6/G-CSF dominant, and 4) IFN $\alpha$  /Pro-inflammatory. Further, the disease activity was associated with cytokine clusters (Figure 3A), which, in turn, were associated with autoantibody clusters (Figure 3B).

**Conclusion:**

These results support the existence of SLE cytokine-driven sub-phenotypes. They provide insight for a new taxonomy, encourage the practice of personalized medicine, and support proof-of-principle studies.

## Human C4 Gene Copy Number Influences Cell-Bound Complement Activation Product (CB-CAP) C4d in Systemic Lupus Erythematosus

Chau-Ching Liu<sup>1</sup>, Joseph Ahearn<sup>2</sup>, Amy Xiaojin Tang<sup>2</sup>, Yee Ling Wu<sup>3</sup>, CHACK-YUNG Yu<sup>3</sup> and Susan Manzi<sup>2</sup>,

<sup>1</sup>Lupus Center of Excellence, Allegheny Health Network Research Institute, Pittsburgh, PA, <sup>2</sup>Lupus Center of Excellence, Allegheny Health Network Research Institute, Pittsburgh, PA, <sup>3</sup>Center for Molecular and Human Genetics, The Research Institute at Nationwide Children's Hospital, Columbus, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Human complement C4 protein is the product of two isotypic genes C4A and C4B that are located on chromosome 6 in various copy numbers. Recent studies by us and others have demonstrated that cell-bound complement activation product (CB-CAP) C4d is a valuable diagnostic and monitoring biomarker for systemic lupus erythematosus (SLE). The current study was based upon the hypothesis that CB-CAP C4d levels may be influenced not only by SLE disease status but also by C4 gene copy number variation (CNV). Specifically, a low C4 gene copy number may lead to persistently low CB-C4d levels in some SLE patients, thereby reducing the diagnostic sensitivity of CB-C4d as biomarkers in such patients. This study was focused on elucidating the correlation between C4 gene CNV and CB-C4d levels in patients with SLE so as to improve the utility of CB-CAP biomarker assays for lupus diagnosis, monitoring and stratification.

**Methods:** We conducted a cross-sectional study of 195 SLE patients. Variations in gene copy numbers for total C4, C4A, and C4B genes were determined using various genotyping technologies. CB-C4d levels on peripheral blood cells of respective patients were measured by flow cytometry. Correlations between CB-C4d levels and C4 gene CNV were examined by statistical analysis using Kruskal-Wallis test and post hoc pairwise comparison as well as linear regression analysis (for continuous variables). Categorical variables were analyzed using Fisher's exact test or chi-square test.

**Results:** The results demonstrated that higher CB-C4d levels, particularly those of T cell-bound C4d (T-C4d) and B cell-bound C4d (B-C4d), were associated with increasing numbers of C4 genes. Patients with greater than 4 copies of the C4 genes were more likely to be in the highest quartile of T-C4d/B-C4d levels than were patients with fewer copies of the C4 genes. Remarkably, patients with no C4A genes (homozygous C4A deficiency) had normal/low T-C4d/B-C4d. Patients with partial C4 genetic deficiencies were more likely to be missed as false negatives using individual CB-CAPs (e.g. BC4d alone) for the diagnosis of SLE. Not all CB-CAPs were influenced equally by C4 CNV.

**Conclusion:** Together, results of the present study suggest a positive correlation of T-C4d and B-C4d levels with CNV of the C4 gene, particularly the C4A gene, in patients with SLE. These observations support our hypothesis that individual CB-CAP C4d levels such as TC4d and BC4d should be interpreted with simultaneous determination of C4 gene copy numbers as well as other CB-CAPs such as EC4d, PC4d, RC4d, etc. as components of lupus biomarker panels for diagnosis, monitoring and stratification.

## **Combining Medications That Lower Systemic Oxidative Stress Is Associated with Less Atherosclerosis in Systemic Lupus Erythematosus**

**Jim C. Oates**, Medical Service, Ralph H. Johnson VA Medical Center, Charleston, SC; Division of Rheumatology & Immunology, Department of Medicine, Medical University of South Carolina, Charleston, SC

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** No single medication has been demonstrated as effective in reducing atherosclerosis or cardiovascular events in systemic lupus erythematosus (SLE), possibly due to the heterogeneity of mechanisms leading to atherosclerosis. However, selecting medications that affect final common pathways to atherosclerosis may be effective. Oxidative stress induces endothelial dysfunction and oxidation of LDL, both of which increase atherosclerotic plaque formation. We hypothesized that medications associated with reduced oxidative stress will also have a reduced association with atherosclerosis and that combining medications will be associated with further reductions in atherosclerosis and oxidative stress.

## Methods:

SLE patients meeting ACR criteria with inactive disease (SLE

Disease Activity Index < 4) were enrolled. Bilateral carotid total atherosclerotic plaque area (TPA) was determined by ultrasound and reported as a percent of the mean (TPA%) for age and sex matched non-SLE controls in a large, high risk hypertension clinic. Serum was digested into amino acids and analyzed for durable oxidative modifications to serum protein tyrosine (ortho-tyrosine + meta-tyrosine (omTyr)) by high performance liquid chromatography and electrochemical detection as a surrogate marker for systemic oxidative stress and reported as (omTyr/Tyr)\*100,000. Concurrent medications associated with reduced omTyr were included in the analysis. Patients were categorized by the number of these medications (0-4) they were taking. Groups were compared by Mann-Whitney U tests, and correlations were performed by Spearman correlation.

**Results:** Among 50 SLE patients (90% female, 96% African American, median age=44), mycophenolate, (MMF) angiotensin converting enzyme inhibitor (ACE), statin, and hydroxychloroquine (HDQ) use were all associated with a trend to lower TPA% and omTyr (with ACE inhibitors associated with a significantly less TPA%, median(interquartile range) = 0 (0-24) vs. 116 (0-448),  $p = 0.02$ ). The number of these medications taken together trended to lower omTyr and TPA% (Figure) and correlated negatively with omTyr ( $r = -0.31$ ,  $p = 0.04$ ).

**Conclusion:** In other populations, both ACE and statins are associated with lower cardiovascular events and reduced oxidative stress. MMF reduces expression of inducible nitric oxide synthase, an enzyme source of oxidative stress that is overexpressed in lupus nephritis, while HDQ reduces oxidative stress and improves endothelial function in murine lupus and is associated with lower cardiovascular events in human SLE. This is the first study to our knowledge to evaluate its association with oxidative stress and atherosclerosis in human SLE. This cross sectional study inspires the hypothesis that combining medications chosen by their ability to reduce the sources of systemic oxidant stress may be more effective than any one medication to reduce atherosclerosis in SLE.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** SLE is a remarkably heterogeneous disease including diverging clinical symptoms, autoantibodies and genetic susceptibility. Hitherto unrecognized patterns may define sub-phenotypes with different pathogenesis and specific treatment needs. Based on autoantibody profile we therefore investigated phenotypic clusters and explored cluster associations with clinical manifestations and one of the most important genetic risk factors for SLE, *HLA-DRB1* alleles.

**Methods:** 908 SLE patients (fulfilling 1982 ACR criteria) of European Caucasian origin and 3654 age- gender- and ethnicity-matched healthy controls (HC) were included. We determined the occurrence of 13 autoantibodies: dsDNA, nucleosomes, ribosomal P, RNP68, RNPA, Sm, Sm/RNP, SSA52, SSA60, SSB, aCL-IgG/IgM and ab<sub>2</sub>GP1. *HLA-DRB1* typing was performed by sequence-specific primer polymerase chain reaction assay. Cluster analysis was done using Gower distance matrix, followed by partition around medoids cluster calculation and Silhouette metric for number of clusters validation. Chi-square test, odds ratios (OR), 95% confidence intervals and false discovery rate p value (p) were calculated for the association tests (within brackets).

**Results:** Four (1-4) clusters were defined based on autoantibody occurrence.

1) 29%, dominated by anti-SSA52/60/SSB positivity is strongly associated with *HLA-DRB1\*03* when compared to HC (4.1[3.4-4.9] p=6.4E-56) and other clusters (2.9[93.3-3.6] p=1.1E-19). Discoid lesions were more common vs. other clusters (1.8[1.3-2.6] p= 0.02).

2) 29 %, dominated by anti-SmRNP/Sm/DNA/RNPA/RNP68/nucleosome, was specifically associated with *HLA-DRB1\*15* when compared to HC (1.7[1.6-2.1] p=5.7E-6) and other clusters (1.5[1.1-1.9] p=0.01). Nephritis was common vs. other clusters (1.9[1.4-2.7] p= 2.E-03)

3) 24 %, dominated by anti-B2GP1/aCL-IgG/IgM, was associated with *HLA-DRB1\*04* when compared with other clusters (1.8[1.4-2.4] p=2E-4). More thrombotic events vs. other clusters were observed in this group (1.84 [1.3-2.6] p=0.01)

4) 18 % was negative for the 13 tested autoantibodies and was not associated with any specific *HLA-DRB1* alleles and it was not associated as risk factor for any of the evaluated clinical manifestations.

**Conclusion:** We demonstrate that immune-phenotypes/clusters in SLE can fit into a frame of *HLA-DRB1* alleles and that the overall association between SLE and *HLA-DRB1\*03* and *HLA-DRB1\*15* seems to be driven mainly by clusters 1 and 2, respectively. We also confirm previous observations that autoantibody clusters associate with

clinical symptoms. We believe that these results could be used to redefine SLE, determine predictive biomarkers and inclusion criteria for clinical trials.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The Modified Rodnan Skin Score (MRSS) assesses global dermal thickness through the examination of 17 body areas scored by clinical palpation using a 4 point Likert scale (0 = normal skin; 1 = mild thickness; 2 = moderate thickness; 3 = severe thickness). The MRSS, due to its reliability, reproducibility, validity and responsiveness to change, has been used as the primary outcome measure in numerous clinical trials in systemic sclerosis. It has been observed that finger MRSS scores remain relatively static over time in the context of clinical trials. We tested this clinical observation using our MRSS data and further tested the hypothesis that modifying the MRSS to exclude assessment of fingers would improve sensitivity to change of the MRSS.

### **Methods:**

This was a retrospective study using compiled MRSS data from three single institution investigator-initiated clinical trials. Sixty-one patients were followed for a total of 593 visits, with a mean of 9.7 visits per patient (range 2-19), and a median follow-up of 17.7 months (range 0.9 – 54.2 months). We compared the proportion of visits that demonstrates a change from baseline using finger-only MRSS (0-6) and a “fingerless” MRSS (0-45), using Fisher’s exact test. We used linear mixed effects modeling to evaluate whether the MRSS excluding finger scores changed at similar rates to finger-only MRSS scores over time. To assess the correlation between “fingerless” MRSS and “standard” MRSS (0-51), we used Spearman partial correlation.

### **Results:**

Finger-only MRSS were unchanged in 62% (331/532) of follow up visits whereas 45 point MRSS excluding fingers were unchanged in only 14% (72/532) of follow-up visits ( $p=0.009$ ). The finger-only MRSS scores did not show any significant change over time. However, the “fingerless” MRSS decreased by a mean of 0.24 points per month ( $p<0.001$ ). Although the 45 point MRSS are slightly lower given that fewer body parts are being assessed, the rate of change over time did not differ significantly from the standard 51 point MRSS with a correlation coefficient of 0.99.

## Conclusion:

Our study demonstrated skin scores of fingers show lower propensity for change than skin scores of other body areas. The rate of change of the MRSS excluding fingers was not significantly different than the standard MRSS, but may result in a greater percent change. Future studies should consider removing the finger skin score from the MRSS score to improve sensitivity to change over time and assess whether this better reflects changes in patient-level outcomes.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interstitial lung disease (ILD) is a common but fatal complication of systemic sclerosis (SSc). Gastroesophageal reflux disease (GERD) may be related to pathogenesis of ILD, but some study failed to show relationship between acidic GER and ILD. Our aims are to find relevant reflux parameters related to ILD in patients with SSc using high-resolution esophageal manometry (HRM) and multichannel intraluminal impedance and pH monitoring (MII-pH).

**Methods:** Of the consecutive 16 female patients with SSc, 9 patients showed ILD (SSc-ILD, median age 45 years, range 25-55) by HRCT and 7 patients didn't (SSc-N, age 49.5 y, 31-62). They all received esophageal HRM (Given Imaging, Los Angeles, CA, USA) and MII-pH (Sandhill Scientific, Inc.; Highland Ranch, CO, USA). We compared HRM parameters (Chicago ver 3.0) and MII-pH parameters including baseline impedance (BI) and post-reflux swallow-induced peristaltic wave (PSPW) index between two groups.

**Results:** SSc-ILD showed significantly low FVC%pred and DLCO% compared with SSc-N (mean± SD, 72.2±17.1% vs. 101.3±14.2; 56.1±12 vs. 71.9±13.2, respectively, P<0.05) In HRM, absent contractility, ineffective esophageal motility and normal peristalsis were 6, 2, 1 in SSc-ILD and 1, 4, 2 in SSc-N. LES pressure was significantly low in SSc-ILD compared with SSc-N (13.7±6.4 vs. 24.0±11.3 mmHg, p<0.05). IRP, DCI, and UES pressure were not different between two groups. In MII-pH, all reflux % time using pH and impedance according to acidity or position, number of reflux events, and proximal extent were not different between two groups. However, mean bolus clearance time was longer in SSc-ILD than SSc-N [median 14 sec (IQR 13-28) vs. 11 sec (8.5-12.8), p<0.05]. BI except the most distal esophagus were significantly low in SSc-ILD than SSc-N (1099.2±327W vs. 2066.1±754.6W, 1032.9±483.2W vs. 2118.4±724.2W, 1190.7±745.3W vs. 2498.3±528.2W, p<0.005; 1257.8±959.7W vs. 2695.7±841.2W, P<0.01; 1239.9±907.4W vs. 2327.9±542.3W, P<0.05 at 17, 15, 9, 7, and 5 cm above the LES). PSPW index was significantly low in SSc-ILD than SSc-N [median 0 (IQR 0-0.03) vs. 0.16 (0.07-0.45), p<0.05].

**Conclusion:** Pathogenic mechanisms of ILD in SSc may relate to proximal esophageal reflux (low proximal esophageal BI) and decreased clearance mechanisms due to esophageal involvement of SSc.

## Pathogenic Mechanisms of Esophageal Peristaltic Dysfunction By High Resolution Manometry in Patients with Systemic Sclerosis

**Hyun-Sook Kim**<sup>1</sup>, Yunseok Kim<sup>2</sup>, Jung Ran Choi<sup>3</sup> and Joon Seong Lee<sup>2</sup>, <sup>1</sup>Soonchenhyang university school of medicine, Seoul, Korea, Republic of (South), <sup>2</sup>Internal medicine, Soonchunhyang university Seoul hospital, Seoul, Korea, Republic of (South), <sup>3</sup>Department of Internal Medicine, Pohang St. Mary Hospital, Pohang, Korea, Republic of (South)

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pathogenic mechanisms of esophageal involvement in systemic sclerosis (SSc) were suggested as neural dysfunction due to impairment of microcirculation to intramural neuron in early stage, followed by atrophy of smooth muscle (SM) portion, and finally extensive fibrosis. According to the esophageal high resolution manometry (HRM) finding, there are three categories in SSc patients; normal peristalsis, ineffective esophageal motility (IEM), and absent contractility (AC). Our hypothesis is IEM of HRM finding in SSc patients may reflect neural dysfunction with/without SM atrophy and AC may reflect severe SM atrophy or extensive fibrosis. Aims of our study are to evaluate the esophageal reserved function of neuronal reflexes and muscle contractility in these three groups of SSc.

**Methods:** Patients diagnosed with SSc who underwent HRM during recent 3 years were retrospectively included (22 female, ages 25-75). Seventeen patients of them were underwent multichannel intraluminal impedance and pH (Imp-pH) study also. We analyzed LES pressure, HRM metrics according to the Chicago classification version 3, including distal contractile integral (DCI), DCI ratio of single swallow and multiple rapid swallow (MRS) test, and reflux parameters and the post-reflux swallow-induced peristaltic wave (PSPW) index by Imp-pH test. According to the HRM findings, patients were classified as 3 groups (normal HRM, n=5; IEM, n=8, and AC, n=9). We compared SM contractility by DCI, neuronal peristaltic reserve function by MRS test using HRM and the PSPW index using Imp-pH study in normal, IEM, and AC groups. Parameters among 3 groups were analyzed by ANOVA on ranks.

**Results :** DCI was significantly lower in AC and IEM group than normal group [median 0.00 (IQR 0.00-35.23), 172.80 (77.05-522.35), and 834.30 (789.85-2294.63) mmHg×s×cm respectively,  $p<0.001$ ]. DCI ratio of MRS/single swallow was lower in AC group than normal group [0.00 (0.00-0.08) vs. 1.00 (0.45-1.19),  $P=0.030$ ]. Other HRM parameters including LES pressure were not different among three groups. PSPW index was lower in AC group than IEM and normal groups [0.40 (0.00-1.90), 8.95 (3.20-16.70), and 17.60 (10.0-35.40) % respectively,  $p=0.023$ ]. PSPW appearance time until 120 seconds were tended to variable in IEM group and AC group than normal group [SD 34.28 (32.29-44.89), 27.60 (16.97-32.03) and 19.60 (17.95-28.02) seconds respectively,  $p=0.079$ ]. Other reflux parameters were not different among 3 groups.

**Conclusion:** The AC using HRM may reflect all of SM atrophy, fibrosis and neuronal dysfunction and the IEM using HRM may reflect SM atrophy and mild to moderate neuronal dysfunction in patients with SSc (Figure 1).

## **Different Cut-Offs for Renal Resistive Index Reflect Renal and Other Organ Involvement and Predict Worsening in SSc Patients**

**Cosimo Bruni**<sup>1</sup>, Vanessa Maestripieri<sup>2</sup>, Giulia Tesei<sup>3</sup>, Marco Chiostrì<sup>4</sup>, Serena Guiducci<sup>3</sup>, Silvia Bellando-Randone<sup>1</sup>, Maria Boddi<sup>4</sup> and Marco Matucci-Cerinic<sup>3</sup>, <sup>1</sup>Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Firenze, Italy, <sup>2</sup>Department of Internal Medicine, Division of Medicine for Care Complexity III, University of Florence, Florence, Italy, <sup>3</sup>Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Florence, Italy, <sup>4</sup>Department of Heart and Vessels, Division of Cardiology I, University of Florence, Florence, Italy

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Renal Resistive Index (RRI), measured by Doppler ultrasound, reflects changes in both renal vascular and tubular-interstitial compartments and systemic vascular compliance related to age and comorbidities (arterial hypertension, diabetes, hyperuricaemia, etc). As renal injury in younger decades may occur also for RRI <0.70, the use of this cut-off may underestimate. RRI was previously investigated in small SSc samples not considering possible confounding medical conditions. The objectives of the study were: to describe RRI in our SSc population, to test both fixed 0.70 RRI cut-off and SSc-age-adjusted cut-offs in reflecting renal and other organ involvement, to analyse the prognostic value of baseline RRI and RRI  $\Delta$  change in predicting clinical worsening.

**Methods:** SSc patients classified through ACR/EULAR 2013 criteria,  $\geq 18$  years were enrolled after informed consent. Baseline Data on RRI, laboratory, instrumental and therapeutic features were retrospectively collected. SSc-age-adjusted pathologic cut-offs were created dividing the population in age quartiles and considering RRI values >75<sup>th</sup> percentile as pathologic (Table 1A). Clinical worsening was defined in case of any event listed in Table 1B. Data were analysed as appropriate with SPSS vers. 20.0.

**Results:** 250 SSc patients (mean disease duration  $7.2 \pm 8.3$  years) were eligible. RRI showed significant correlations with age ( $\rho=0.56$ ,  $p<0.001$ ) and creatinine clearance ( $\rho=-0.38$ ,  $p<0.001$ ), as well as significant associations with general population RRI determinants. When considering RRI absolute value and 0.70 cut-off, only comorbidities, renal function, sPAP and E/A, DLCO and late NVC pattern were associated. Conversely, new SSc-age-adjusted RRI cut-offs could not detect early renal damage but were significantly associated with various disease related skin and lung fibrotic manifestations, as well as vasculopathic complications (Table 2A). After a mean follow-up of  $3.6 \pm 2.6$  years, while RRI absolute values and 0.70 RRI cut-off showed no significant value, SSc-age-adjusted RRI cut-offs were significantly predictive for cardiac, lung and renal worsening (Table 2B). On the other hand, RRI  $\Delta$  changes in 3 years (100 pts) and 5 years (60 pts), were not sensitive or predictive for worsening.

**Conclusion:** in clinical practice, different age-SSc-adjusted or non-adjusted RRI cut-offs may be used to evaluate renal and extrarenal involvement, resembling DLCO for parenchymal and vascular lung involvement. These RRI cut-offs may be considered as possible predictors of kidney, lung and cardiac worsening in SSc patients.

A

Age-SSc adjusted pathologic RRI cut-offs	
Age	Pathologic RRI
1° quartile $\leq 49$	$\geq 0.68$
2° quartile 50-59	$\geq 0.70$
3° quartile 60-69	$\geq 0.75$
4° quartile $\geq 70$	$\geq 0.78$

B

Definitions of worsening
a) Skin worsening as an increase of mRSS $\geq$ 5 units in two consecutive visits
b) Peripheral vascular worsening as the appearance of new digital ulcers or the worsening of nailfold videocapillaroscopy scleroderma pattern
c) Lung worsening as decline of FVC $\geq$ 15% or FVC<80% with new detection of ILD on chest HRCT or worsening of HRCT-ILD extent
d) Cardiac worsening as new onset of left ventricular failure requiring treatments or new onset of PAH confirmed on RHC or detection of severe ventricular arrhythmias on 24h EKG
e) Renal worsening as a new scleroderma renal crisis or reduction of creatinine clearance $\leq$ 30 ml/min.
f) Death

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Macrophages are the primary inflammatory cell type present in the systemic sclerosis (SSc) skin. Circulating monocytes can give rise to profibrotic inflammatory cells such as alternatively activated macrophages in the fibrotic end-organ such as skin and lung. Despite their importance, there are no previous studies examining the clinical correlates of peripheral blood monocyte count in SSc. The primary objective of the present study was to examine the association of monocyte count with clinical variables and survival in the prospective Genetics Versus Environment In Scleroderma Outcome Study (GENISOS) cohort.

### Methods:

Monocyte count was prospectively obtained at enrollment in 429 patients. All patients had disease duration less than 5 years (from the first non-Raynaud's phenomenon symptom) and fulfilled the 2013 ACR/EULAR criteria. Modified Rodnan Skin Score (mRSS) and forced vital capacity % predicted (FVC%) were also obtained prospectively. SSc related autoantibodies were determined in the divisional laboratory using gold standard methods. After mean follow-up of 8.3 years, 129 patients had died.

### Results:

The mean disease duration at enrollment was 2.4 years and the majority of patients had diffuse cutaneous involvement (60.4%). Higher monocyte count was associated with diffuse cutaneous disease type ( $b=59.4$ ,  $p=0.012$ ). Furthermore, higher monocyte count was significantly associated with higher baseline mRSS ( $r=0.17$ ,  $p=0.001$ ) while there was no correlation with baseline FVC%. There was a trend for association of higher monocyte counts with RNA polymerase III positivity ( $b=55.2$ ,  $p=0.055$ ) while there was no association with other SSc-related autoantibodies. Higher monocyte count also correlated with lower disease duration at the baseline visit ( $r=-0.11$ ,  $p=0.022$ ).

In the multivariable cox regression analysis after adjustment for age at enrollment, monocyte count was associated with higher mortality ( $p=0.028$ ). Next, patients were classified based on normal vs. high monocyte count as reported by the clinical laboratory. SSc patients with a high monocyte count had higher mortality even after adjustment for age and baseline mRSS (see Table).

### Conclusion:

Higher peripheral blood monocyte count was associated with shorter disease duration, more extensive skin disease, and higher mortality. This study provides clinical support for relevance of monocytes and bone marrow derived macrophages in SSc pathogenesis.

Clinical Variable	Hazard ratio	95% CI	p-value
High monocyte count at enrollment	2.65	1.07 - 6.57	0.035
Age at enrollment	1.02	1.01 – 1.04	0.003
mRSS at enrollment	1.01	0.99 – 1.02	0.243

## **An Evaluation of Two Novel Techniques Utilising a Smartphone Digital Camera in the Assessment of Nailfold Capillaries in Suspected Scleroderma-Spectrum Disorders: A Single-Center Cross-Sectional Study**

**Matthew Parker**<sup>1,2</sup>, Neil McGill<sup>1,2</sup> and Michael Oliffe<sup>1</sup>, <sup>1</sup>Rheumatology, Royal Prince Alfred Hospital, Sydney, Australia, <sup>2</sup>University of Sydney, Sydney, Australia

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Nailfold capillaroscopy is a non-invasive, sensitive and specific technique used in the diagnosis of scleroderma-spectrum disorders. Abnormalities predict progression from Raynauds phenomenon to connective tissue disease, sometimes years in advance, as well as serious complications such as pulmonary hypertension. Its inclusion in the most recent diagnostic criteria for systemic sclerosis enable them to perform better to identify patients with early systemic sclerosis in particular, important for prognostication, risk stratification, screening regimens and hopefully, in future, therapeutic intervention.

The current gold standard techniques are nailfold videocapillaroscopy and widefield microscopy. The equipment required for both remains expensive and relatively inaccessible, typically only available in centers with a special interest. Novel approaches utilizing new technologies may help improve accessibility to the wider rheumatology community.

We sought to evaluate the novel combination of a smartphone digital camera with two devices, a commercially produced lens attachment and a dermatoscope, with both techniques offering the possibility of a rapid bedside evaluation at a fraction of the cost of other techniques.

### **Objectives:**

The primary aim was to evaluate the diagnostic performance of digital photographs taken with a smartphone camera using both a lens attachment and, separately, a dermatoscope. The secondary aims were to assess the influence of prior capillaroscopy experience and familiarity with the novel techniques on diagnostic accuracy.

### **Methods:**

This was a single-center cross-sectional study. All patients referred for capillaroscopy between May 2016 and January 2017 were eligible for inclusion. Patients nailfolds were classified by widefield microscopy before proceeding, double-blinded, to have their nailfolds photographed using both novel techniques. Randomized

photographs were assessed after the completion of enrolment by three independent investigators. Sensitivity, specificity, inter- and intra-observer variability were calculated.

## Results:

65 participants contributed 1040 digital photographs for independent assessment by three investigators. The smartphone-lens technique performed with moderate sensitivity (65%; 58-72) and high specificity (90%; 84-96). The smartphone-dermatoscope technique performed with higher sensitivity (74%; 66-82) and excellent specificity (95%; 88-100) and was used more accurately by a novice. Prior assessor experience with nailfold capillaroscopy in general and prior experience with the novel techniques positively modulated the diagnostic accuracy.

## Conclusion:

New technologies, in this case utilising a smartphone camera, could help improve accessibility to nailfold capillaroscopy, an important diagnostic tool and putative biomarker in scleroderma-spectrum disorders, whilst retaining accurate results.

Capillaroscopy Experience		True Positive (n)	True Negative (n)	False Positive (n)	False Negative (n)	Sensitivity (CI)	Specificity (CI)
Novice	SMARTPHONE-LENS	12	36	6	11	52% (45-59)	86% (80-92)
	SMARTPHONE-DERMATOSCOPE	16	38	4	7	70% (62-78)	90% (84-96)
Intermediate	SMARTPHONE-LENS	15	41	1	8	65% (58-72)	98% (91-100)
	SMARTPHONE-DERMATOSCOPE	17	41	1	6	74% (66-82)	98% (91-100)
Expert	SMARTPHONE-LENS	15	38	4	8	65% (58-72)	90% (84-96)
	SMARTPHONE-DERMATOSCOPE	17	40	2	6	74% (66-82)	95% (88-100)

## Significance of Anti-Topoisomerase I Antibodies in Routine Clinical Testing

Anne E Tebo<sup>1</sup>, Robert L. Schmidt<sup>2</sup> and Tracy M. Frech<sup>3</sup>, <sup>1</sup>University of Utah, Salt Lake City, UT, <sup>2</sup>Pathology, University of Utah, Salt Lake City, UT, <sup>3</sup>Division of Rheumatology, University of Utah, Salt Lake City, UT

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The 2013 classification criteria for systemic sclerosis (SSc) provide 3 points (towards a 9 point diagnosis) for patients who have an anti-topoisomerase I (anti-Scl-70) antibody. From a clinical practice standpoint, in the absence of other stigmata of SSc, the significance of the presence of an anti-Scl-70 antibody result remains unclear. The purpose of this project was to determine the clinical relevance of anti-Scl-70 antibodies detected by multiplex testing for patients receiving routine clinical evaluation at our institution.

**Methods: Results** for patients positive for anti-Scl-70 antibodies (cut-off: >41 AU/mL positive) at the University of Utah over a period of 8 years were retrospectively reviewed. All patients with a positive anti-Scl-70 antibody had a manual chart review for other SSc classification criteria information.

**Results:** There were 3331 unique patient samples evaluated during the investigation period, 51 (1.53%) were positive for anti-Scl-70 antibodies with 5 patients lost to follow-up. Of the available anti-Scl-70 antibody-positive patients (n=46), 17 (37%) met the diagnostic criteria for SSc, 11 (23.9%) were diagnosed with other types of lung disease [sarcoidosis, pulmonary embolism, empyema, and constrictive bronchiolitis], the remaining patients had immune-mediated diseases [n=12] or no reported clinical diagnosis [n=6]. All anti-Scl-70 antibody patients with SSc were also positive for antinuclear antibodies (ANA) compared to those without disease (100% vs. 46.4%,  $p<0.0001$ ). The median level of anti-Scl-70 antibodies was significantly higher in patients with SSc compared to those without disease [158 AU/mL vs. 60 AU/mL,  $p<0.0001$ , Figure 1). Using logistic regression, an estimated probability of 1 for SSc was attained at anti-Scl-70 antibody level of approximately 200 AU/mL (Figure 2).

**Conclusion:** In this retrospective study, a positive ANA test and significantly elevated titers (>5x cut-off) of anti-Scl-70 may be predictive of SSc. The role of underlying lung pathology on the pathogenesis of developing a low titer anti-Scl-70 antibody without an ANA may warrant further study.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Systemic sclerosis (SSc) is a rare, multisystem autoimmune disorder. It is characterized by generalized microangiopathy, in the pathogenesis of which hypoxia and oxidative stress have been implicated. Tobacco inhalation increases free radicals and strongly promotes vascular damage. So far, data available with regards to a role of tobacco exposure with SSc severity and progression are scarce.

We aimed to assess the associations of smoking with the speed of worsening of organ manifestations, namely lung involvement (forced vital capacity, FVC; forced expiratory volume, FEV1/FVC ratio; diffusing capacity for carbon monoxide corrected for alveolar volume, DLCO/VA), skin involvement (modified Rodnan skin score; mRSS), and digital ulcers (DU) in the European scleroderma trials and research (EUSTAR) database.

## **Methods:**

Adult SSc patients from the EUSTAR cohort with a follow-up visit 12-24 months after the baseline visit and available data on their smoking habits were included.

The associations of smoking behavior (never smokers *vs* ex-smokers *vs* current smokers) with the change in disease manifestations between baseline and follow up were assessed using multivariable linear or logistic regression analyses adjusting for age, sex, autoantibody status, disease duration, SSc subset. Missing data were imputed using multiple imputations.

## **Results:**

Of the 3,319 patients included (mean age 57 years, standard deviation [SD] 14; 85% female; 29% diffuse SSc), 66% of patients stated that they never smoked, 23% were ex-smokers and 11% were current smokers. The average ex-smokers had smoked 18 pack-years (SD 21) during a time of 19 years (SD 12) and quit smoking 15 years (SD 13) ago. The average current smoker smoked 27 pack-years (SD 30) during a time of 30 years (SD 13).

On average, the FEV1/FVC ratio changed from 96.5 (SD 14) at baseline to 96.0 (SD 13) at follow up. In current smokers, the ratio decreased significantly faster during the observation period than in never smokers after adjustment ( $\beta=-4\%$ ,  $p<0.001$ ). This was not observed in ex-smokers ( $p=0.7$ ).

The DLCO/VA decreased on average from 78.4 (SD 17) to 76.8 (SD 17). The decrease of DLCO/VA during the observation period was not associated with smoking behavior.

The mRSS changed between baseline and follow-up from an average of 7.7 (SD 8) to 7.3 (SD 7); the change in mRSS was not strongly and clinically meaningfully associated with smoking behavior.

Smoking behavior was not associated with the presence of DU at baseline. The occurrence of new DU during the observation period in patients without any DU prior to or at baseline was negatively associated with current smoking (OR 0.5,  $p=0.03$ ) but not with previous smoking (OR 1.1,  $p=0.7$ ).

## Conclusion:

The adverse effect of smoking on bronchial airways that is known in the general population is replicated in the SSc population. The lack of a measurable adverse effect of smoking on the speed of worsening of cutaneous and pulmonary SSc manifestations argues against a major role of tobacco associated free radicals and vasoconstriction in the pathogenesis of SSc vasculopathy and fibrosis. Similarly, our data do not support an adverse effect of smoking on the presence or absence of DU.

## Effectiveness and Safety of Tacrolimus Following Intravenous Cyclophosphamide Pulse Therapy As the Treatment of Systemic Sclerosis-Associated Interstitial Lung Disease

**Yuki Ichimura**, Yasushi Kawaguchi, Kae Takagi, Akiko Tochimoto, Tomoaki Higuchi, Yasuhiro Katsumata and Hisashi Yamanaka, Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is the disease characterized by organ fibrosis with unknown etiology, and pulmonary involvement is one of major cause of death. However, the treatment of interstitial lung disease (ILD) in SSc is limited. Although intravenous cyclophosphamide pulse therapy (IVCY) is effective and widely used, the effect of the therapy does not last for a long time. In this reason, IVCY therapy followed by somewhat immunosuppressants may be needed, but it is uncertain which immunosuppressant is better for ILD in SSc. In Japan, tacrolimus, one of calcineurin inhibitors, is frequently used for the treatment of ILD in

polymyositis/dermatomyositis and idiopathic interstitial pneumonia. We examined the effect of sequential IVCY therapy followed by tacrolimus and low-dose corticosteroids in SSc-associated ILD (SSc-ILD).

**Methods:** This retrospective, observational study was performed in a single center in Japan. Twenty consecutive patients with SSc-ILD who received IVCY as first therapy in our hospital from April 2010 to March 2014 were enrolled. The protocol of IVCY is the dose of 400 to 500 mg/body surface area ( $m^2$ )/4 weeks and performed 3 to 6 times. In this study, we divided them two groups: treated with tacrolimus and low-dose corticosteroids following IVCY (TAC group); only low-dose corticosteroids after IVCY (IVCY group). We assessed the follow-up for 3 years after IVCY therapy in each group. Disease deterioration of ILD was defined as fulfilling more than 2 following criteria: deterioration of symptoms; expanding lung fibrosis in CT scan; DLCO decreasing more than 5% from baseline in lung function test. All data were collected from medical record retrospectively. Data analysis was assessed using JMP Pro 13.

**Results:** Ten patients were in TAC group, and other 10 patients IVCY group. Age ( $50 \pm 14$  year-old in TAC group vs.  $57 \pm 17$  year-old in IVCY group; mean  $\pm$  SD) and Duration of illness ( $2.6 \pm 3.5$  years vs.  $2.4 \pm 1.8$  years) were same in each group. No difference was observed in pulmonary function test at baseline in each group (%VC:  $79.5 \pm 16.1\%$  vs.  $87.4 \pm 18.8\%$ , %DLCO:  $59.5 \pm 11.5\%$  vs.  $63.7 \pm 14.6\%$ ). After 3-year follow up, 2 patients revealed disease progression, who were IVCY group. No case in Tac group showed disease progression. In TAC group, a case stopped taking tacrolimus due to adverse event, thrombocytopenia. Any cases in TAC group did not show neither renal crisis nor elevation of creatinine.

**Conclusion:** Tacrolimus following IVCY may be one of therapeutic choice for SSc-ILD, with good tolerance.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

To assess the associations between the 6-minute walk distance (6MWD) and various disease parameters in patients with systemic sclerosis (SSc).

### Methods:

Consecutive patients followed in our SSc National Reference Centre were included in this cross-sectional study if they fulfilled the 2013 ACR/EULAR criteria for SSc. Data were prospectively collected during a comprehensive evaluation that included a 6-minute walk test, clinical assessment, biological results, pulmonary function tests, transthoracic echocardiography, composite scores (EScSG-AI, Medsger, HAQ-DI) and treatments.

Associations of the 6MWD with various disease parameters were assessed by linear regression in univariate analyses, then in several multivariate models.

### Results:

The study population comprised 298 patients (females: 81%; mean age:  $58.2 \pm 13.3$  years old; limited cutaneous SSc: 82%; interstitial lung disease (ILD): 42%; pulmonary arterial hypertension (PAH): 6%). The 6MWD was significantly and independently associated with gender, age, initial heart rate, heart rate variation during the test, PAH and CRP levels. Muscle involvement, joint involvement and ILD were not independently associated with the 6MWD.

### Conclusion:

During SSc, the 6MWD is independently associated with heart rate variation (possibly implying a role for chronotropic incompetence in exercise intolerance), with PAH but not ILD (suggesting that pulmonary vasculopathy may have a greater impact than parenchymal involvement on functional limitation), and with global markers of disease activity. These results give further insight to clinicians on how to interpret the 6MWD in the context of SSc.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A topical therapy for either prevention or palliation of attacks would offer unique advantages to selected patients with Raynaud phenomenon (RP). This study used 0.9% nitroglycerine (NTG) in a microemulsion formulation compared to vehicle to investigate clinical and physiologic responses to repetitive controlled cold challenge in individuals with RP secondary to connective tissue disease (CTD).

**Methods:** 65 subjects with CTD including 32 with systemic sclerosis (SSc), agreed to stop ongoing Rx for RP. Routinized assessments included 30 minutes of acclimatization at 22.2° C +/- 2.2 followed by up to 16 minutes in a cold room maintained at 4.4° C +/- 2.2 and 60 minutes of recovery. Finger temperature was monitored at regular intervals and subjects completed 10 cm VAS scales for numbness, tingling and pain as well as for overall RP attack severity. A Main Raynaud Symptom (MRS; most bothersome symptom of pain, numbness, or tingling) was chosen for each individual based on their highest VAS score during a baseline cold challenge. Active Rx or vehicle as placebo was applied in a blinded randomized sequence 30 minutes prior to each cold challenge with each treatment studied twice. An optional second application during cold exposure was permitted. An enriched subset of subjects responding to NTG but not to placebo was identified from the results of the first paired cold challenges for a subanalysis of responses in the final two cold challenges.

## Results:

	Topical NTG	Vehicle	P Value
Main Raynaud Sx	-20.77 mm	-19.56 mm	0.64
% Responders*	33/64 51.6%	32/64 50%	0.93
MRS Enriched**	-18.70 mm	-13.76 mm	0.45
AUC Skin Temp***	857.5	848.0	NS

\* Responders – subjects with > 15 mm improvement in MRS VAS

\*\* Enriched Subset – Vascana response > 10 mm AND vehicle response < 15 mm on VAS during first paired cold challenge VAS

\*\*\* Area Under Curve - integral of skin temperature across time during cold exposure (degree-minutes)

**Conclusion:** Topical NTG was not superior to vehicle placebo in reducing symptoms of RP during controlled cold challenge. Although the VAS response in Main Raynaud Symptom was meaningful (-20.77 mm), response to placebo was of similar magnitude. This was also true of analysis of an enriched subset designed to exclude placebo responders. Skin temperature during cold challenge was chosen as an indirect measure of digital perfusion. The lack of difference in physiologic response mirrors the subjective measures. Placebo response remains a critical issue in RP trials. This is in spite of choice of a uniform population, personalization of definitions of response (self-selected MRS), a cold challenge designed to closely match in-life experiences and repetitive testing.

## **Efficacy of Rituximab for Connective Tissue Disease-Associated Interstitial Lung Disease: A Single Center Study of 28 Patients**

**Sunny Patel**<sup>1</sup>, Samina Hayat<sup>2</sup>, Gloria Caldito<sup>3</sup> and Kristen Erickstad<sup>1</sup>, <sup>1</sup>Rheumatology, Louisiana State University Health Sciences Center Shreveport, Shreveport, LA, <sup>2</sup>Rheumatology/Internal Medicine, Louisiana State University Health Sciences Center Shreveport, Shreveport, LA, <sup>3</sup>Neurology, Louisiana State University Health Sciences Center Shreveport, Shreveport, LA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Interstitial lung disease (ILD) is a severe pulmonary complication associated with connective tissue diseases (CTDs), resulting in substantial morbidity and mortality. Despite advances in immunosuppressive drugs, there remains limited data on treatment for this challenging clinical entity. This study aims to evaluate the efficacy of rituximab (RTX) in patients with CTD-ILD and determine factors correlated with outcomes at 6 and 12 months post-RTX.

### **Methods:**

We analyzed data for 28 patients with CTD-ILD, all of whom met ACR classification criteria for a specific CTD. ILD was confirmed by high-resolution CT chest (HRCT) and pulmonary function tests with forced vital capacity (FVC) and diffusion capacity of lung for carbon monoxide (DLCO). We compared the HRCT chest findings, %FVC and %DLCO at time of diagnosis and at 6 and 12 months post-RTX treatment. We classified the HRCT chest findings at diagnosis into 3 groups, from mild to severe, and used the same semi-quantitative scoring system to evaluate for changes after treatment with RTX. We defined change in %FVC and %DLCO where improvement is an increase in FVC $\geq$ 10% or DLCO  $\geq$ 15%, worsening is a decrease in FVC $\geq$ 10% or DLCO $\geq$ 15% and stabilization is a change in FVC<10% or DLCO<15%. Multiple patient characteristics (Table 1) were tested for their correlations with each outcome using separate univariate analysis with the chi-square/Fisher test or Wilcoxon rank sum test.

## Results:

Majority of the patients were female and African American with median age of 59. The median duration for CTD and ILD was 2 years and 1 year, respectively (Table 1). The proportions of patients whose FVC, DLCO and HRCT Chest status remained stable or improved post-RTX at 6 and 12 months were all significantly higher than 50% (Table 2). Furthermore, the proportions of patients who remained stable or improved were higher at 12 months than at 6 months. The median %change in FVC at 6 months was +3% and at 12 months was +3.5%. The median %change in DLCO at 6 months was +1.5% and at 12 months was +7%. Race, prior immunosuppressive drugs and CTD duration were all significantly associated with the observed outcomes (Table 3).

## Conclusion:

Based on this single center retrospective study, RTX appears to be an acceptable and effective therapy for CTD-ILD. RTX may help to fill an unmet therapeutic need for CTD-ILD and larger randomized clinical trials are needed.

Table 1: Summary Statistics<sup>1</sup> on Patient Characteristics and Outcomes (N=28)

Characteristic / Outcome	Number (%) or Mean $\pm$ SD, Median, Range	Number Non-missing

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic sclerosis (SSc) is characterised by fibrosis of the skin and underlying connective tissue structures, together with localised loss of subcutaneous fat. Oro-facial fibrosis in systemic sclerosis (SSc) is almost always present in established cases and has major impact on oro-facial function, facial appearance, and quality of life. Based upon theoretical rationale for antifibrotic potential and improvement in connective tissue bulk we have evaluated the benefit of autologous stem cell enriched lipotransfer in a large cohort of SSc patients with a mean follow up period of 12 months after treatment, and objective assessment of clinical benefit including validated outcome tools.

### **Methods:**

62 SSc patients with oro-facial fibrosis were assessed following oro-facial treatment with autologous stem cell enriched lipotransfer. Mean age was 56 ( $\pm 11,59$ ), 98% were female, 42% were affected by dcSS subset, and mean disease duration was 15,18 years ( $\pm 8,81$ ). Efficacy was assessed by pre- and post-operative mouth function (Mouth Handicap in Systemic Sclerosis Scale, MHISS), validated psychological measurements (Darriford Appearance Scale, DAS24; Hospital Anxiety and Depression Scale-anxiety, HADS; Brief Fear of Negative Evaluation Scale, BFNE; Visual Analogic Scale for mood, emotion, and distress, VAS), and volumetric assessment (3dMD imaging system).

### **Results:**

We found a significant improvement of mouth function (MHISS) ( $6.85 \pm 5.07$ ) ( $p < 0.0001$ ) and all the psychological measures: DAS 24 ( $12.1 \pm 9.5$ ) ( $p < 0.0001$ ); HADS-anxiety ( $2.8 \pm 3.2$ ) ( $p < 0.0001$ ), HADS-depression ( $2.0 \pm 3.1$ ) ( $p < 0.0001$ ); BFNE ( $2.9 \pm 4.3$ ) ( $p < 0.0001$ ); VAS ( $3.56 \pm 4.1$ ) ( $p < 0.0001$ ). Multiple procedures further improved MHISS ( $p < 0.05$ ), DAS ( $p < 0.0001$ ) and VAS ( $p = 0.01$ ) scores. Disease subset or concomitant immunosuppression did not appear to affect outcome measures. Injected volume was retained variably in all facial areas: cheeks (93.7%), nasolabial folds (81.9%), nose (67.4%), chin (68.2%), upper lips (35.5%) and lower lips (27.3%). Concurrent immunosuppressive treatment with did not appear to influence the safety of efficacy of lipotransfer.

### **Conclusion:**

Autologous stem cell enriched lipotransfer is a feasible treatment that reversed the effects of oro-facial fibrosis in SSc in this open cohort study. It has been shown to be both feasible and beneficial. Our findings warrant further testing in a randomised controlled trial.

# Using Electronic Health Record Algorithms to Accurately Identify Patients with Systemic Sclerosis

**Lia Jamian**, Leslie Crofford and April Barnado, Medicine, Vanderbilt University Medical Center, Nashville, TN  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is a rare, chronic, autoimmune disease with high morbidity and mortality. The electronic health record (EHR) represents a powerful tool to study rare disorders such as SSc. Currently, there are no validated algorithms to identify SSc patients in the EHR. We sought to develop algorithms that incorporated not only billing codes but also labs and keywords to identify SSc patients accurately.

**Methods:** We analyzed data from a de-identified version of Vanderbilt's EHR called the Synthetic Derivative (SD) that contains over 2.8 million subjects with longitudinal clinical data. Within the SD, we identified 1899 potential SSc patients with at least one count of the SSc ICD-9 (710.1) code. Of these potential subjects, we randomly selected 200 as a training set for chart review to identify true case status. A subject was defined as a case if diagnosed with SSc by a Vanderbilt or external rheumatologist, dermatologist, or pulmonologist. Potential subjects were then classified as either 1) cases, 2) not cases with alternative diagnoses noted, 3) unconfirmed if there was uncertainty in the diagnosis, or 4) missing if clinical documentation was missing. A priori, we selected the following potential algorithm components based on clinical knowledge and available data: SSc ICD-9 code, positive anti-nuclear antibody (ANA) (titer  $\geq 1:80$ ), and a keyword of Raynaud's phenomenon (RP) in the clinic notes. Positive predictive values (PPVs) and sensitivity were calculated for combinations of the above algorithm components.

**Results:** Of the 200 subjects in the training set, 81 were true cases on chart review, 65 not cases, 17 unconfirmed, and 37 with missing clinical documentation. The PPV for using 1 count of the SSc ICD-9 code was 50%, 68% for  $\geq 2$  counts, 82% for  $\geq 3$  counts, and 90% for  $\geq 4$  counts. PPVs increased when a positive ANA or RP keyword was added to the ICD-9 code. The algorithms with the highest PPVs of 96% were 1)  $\geq 4$  counts of the SSc ICD-9 code and RP keyword, 2)  $\geq 3$  counts of the SSc ICD-9 code and ANA positive and RP keyword, and 3)  $\geq 4$  counts of the SSc ICD-9 code and ANA positive and RP keyword (Table 1). The algorithm with the highest combined PPV of 81% and sensitivity of 95% was  $\geq 1$  count of the SSc ICD-9 code and RP keyword. **Conclusion:** We have developed novel algorithms to identify SSc subjects in the EHR using not only billing codes but also labs and keywords with a PPV of 96%. These algorithms will allow researchers to identify and study patients with SSc more efficiently and accurately in the EHR.

**Table 1.**

Algorithm*	Positive Predictive Value	Sensitivity
<b>Counts of the ICD-9 code (710.1)*</b>		
$\geq 1$	50%	N/A
$\geq 2$	68%	85%
$\geq 3$	82%	77%
$\geq 4$	90%	67%
<b>ANA positive<sup>‡</sup> AND <math>\geq 1</math> count of 710.1</b>	45 %	81%
ANA positive AND $\geq 2$ counts	70%	81%
ANA positive AND $\geq 3$ counts	88%	67%
ANA positive AND $\geq 4$ counts	93%	58%
<b>Raynaud's phenomenon (RP) keyword AND <math>\geq 1</math> count of 710.1</b>	81%	95%
RP keyword AND $\geq 2$ counts	91%	80%
RP keyword AND $\geq 3$ counts	94%	71%
RP keyword AND $\geq 4$ counts	96%	67%
<b>ANA positive AND RP keyword AND <math>\geq 1</math> count of 710.1</b>	74%	78%
ANA positive AND RP AND $\geq 2$ counts	94%	76%
ANA positive AND RP AND $\geq 3$ counts	96%	64%
ANA positive AND RP AND $\geq 4$ counts	96%	57%
<b>ANA positive OR RP keyword AND <math>\geq 1</math> count of 710.1</b>	49%	98%
ANA positive OR RP AND $\geq 2$ counts	72%	90%
ANA positive OR RP AND $\geq 3$ counts	89%	76%
ANA positive OR RP AND $\geq 4$ counts	93%	67%

\*All algorithms included at least one or more counts of the Systemic Sclerosis ICD-9 (710.1). <sup>‡</sup>ANA positive defined as titer  $\geq 1:80$ .

## **Nailfold Capillary Counts Are Associated with Clinical Manifestations in Connective Tissue Disease Japanese Patients**

**Atsushi Kondo**<sup>1</sup>, Tomohiro Kameda<sup>1</sup>, Mihar Izumikawa<sup>1</sup>, Hiromi Shimada<sup>2</sup>, Shusaku Nakashima<sup>1</sup>, Risa Wakiya<sup>1</sup>, Mikiya Kato<sup>1</sup>, Norimitsu Kadowaki<sup>1</sup> and Hiroaki Dobashi<sup>1</sup>, <sup>1</sup>Internal Medicine Division of Hematology, Rheumatology, and Respiratory Medicine, Kagawa University, Kagawa, Japan, <sup>2</sup>Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa University, Kagawa, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Connective tissue diseases (CTD) patients have various clinical manifestation including pulmonary hypertension (PH) and digital ulcer (DU). Especially, Raynaud's phenomenon (RP) is one of the common symptoms. On the other hand, "abnormal nailfold capillaries" are important as the findings that suggest RP associated with CTD. They are included in one of the items of classification criteria for Scleroderma (SSc) in 2013 Classification Criteria for Systemic Sclerosis (ACR/EULAR). Recently, some reports presented the usefulness of nailfold capillaroscopy (NFC) in SSc. NFC findings showed enlarged/giant capillaries, fresh or old haemorrhages, avascular areas, ramified/bushy capillaries. These findings are known as "scleroderma pattern" features. Additionally, there are some reports that nailfold capillary low density in SSc related with merger of DU, PH and interstitial pneumonia (IP).

In this study, we clarify the association between nailfold capillary density and clinical manifestation by analysis of the case in our institution.

### **Methods:**

We enrolled Japanese CTD patients including SSc, Systemic Lupus erythematosus (SLE), Mixed Connective Tissue Disease (MCTD), Sjögren's syndrome (SS), Dermatomyositis (DM) from May 2016 to May 2017 in our institution.

We measured total nailfold capillary count per 1μm from second to fifth finger by NFC "OptiPiX Capillaroscopy Clinic 1.7.x". In addition, we investigated relationship with NFC findings and clinical manifestation (or laboratory data) such as current and previous DU, RP, PH and IP.

### **Results:**

We enrolled 107 CTD patients (100 females, 7 males; 42 SSc, 25 SLE, 16 PM/DM, 9 MCTD, 16 SS). Total nailfold capillary counts significantly decreased in all CTD patients with current DU ( $\rho = -0.4333$ ,  $p = 0.0003$ ), previous DU ( $\rho = -0.4202$ ,  $p = 0.0004$ ), RP ( $\rho = -0.3350$ ,  $p = 0.006$ ) and PH ( $\rho = -0.3683$ ,  $p = 0.0023$ ). In addition, Total nailfold capillary counts associated with current DU ( $\rho = -0.3855$ ,  $p = 0.0477$ ) and previous DU ( $\rho = -0.4481$ ,  $p = 0.0191$ ) in

SSc patients and PH ( $\rho = -0.8281$ ,  $p = 0.0418$ ) in MCTD patients. There is no significant difference between “scleroderma pattern” features and clinical manifestation.

## **Conclusion:**

Our study revealed that total nailfold capillary counts were associated with clinical manifestation in CTD patients. We suggest that nailfold capillary density may predict clinical manifestation with CTD patients.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The diagnosis of systemic sclerosis (SSc) in the early stages of the disease is frequently a challenge. In 2001, LeRoy and Medsger proposed criteria for the classification of early SSc, defined by the presence of Raynaud's phenomenon (RP) associated with scleroderma specific antibodies and/or typical scleroderma changes on nailfold capillaroscopy (NFC). After the development of the 2013 ACR/EULAR classification criteria for SSc, which is more sensitive than previous, there are still a group of patients affected by early SSc who do not meet the 2013 ACR/EULAR criteria. Factors associated with disease evolution in these patients are not well recognized. This study aimed to evaluate the disease evolution and to identify predictors of evolution to definite SSc (ACR/EULAR classification criteria for SSc) in patients with early SSc.

### **Methods:**

In this prospective study 46 consecutive patients with early SSc (2001 LeRoy and Medsger criteria), were evaluated at baseline and at 3 years of follow-up. Clinical evaluation and widefield nailfold capillaroscopy using a stereomicroscope (10–40x magnification) were performed in all subjects at baseline and at the end of the study. At the end of follow-up, the fulfillment of the 2013 ACR/EULAR criteria was also assessed in each patient. The following parameters were determined by NFC: number of enlarged and giant capillaries, the number of microhaemorrhages, and the avascular score. The scleroderma pattern was classified as early, active and late.

### **Results:**

After 3 years, 34 patients with early SSc were reevaluated (mean age  $53 \pm 12.7$  years) and 12 patients were lost to follow-up. Eight (23.5%) patients with early SSc developed definite SSc. A higher frequency of puffy fingers at baseline was observed in the group of patients who developed definite SSc compared to those who did not (37.5% vs 0%, respectively;  $p=0.01$ ). A higher proportion of patients with early SSc who progressed to definite SSc presented a significant increase in the number of giant capillaries (50% vs 7.7%, respectively;  $p=0.02$ ) and a increase in the avascular score compared with those who remained with a diagnosis of early SSc (50% vs 0%, respectively;  $p=0.01$ ). A higher frequency of active pattern in NFC at baseline was also observed in patients who progressed to definite SSc compared with those who did not (57.1% vs 6.3%, respectively;  $p=0.02$ ). By multivariate analysis, increase in the number of giant capillaries (OR=12.0, 95% CI 1.6-88.7,  $p=0.02$ ), and an active pattern in NFC (OR=30.0, 95% CI 2.1-421.1,  $p=0.01$ ) were independent risk factors for developing definite SSc in patients with early SSc.

## Conclusion:

In this prospective study, patients with early SSc who developed definite disease showed a worsening in capillaroscopic parameters including an increase in the number of giant capillaries and in the avascular score during a follow-up of 3 years. The presence of an active pattern and an increase in the number of giant capillaries in NFC were independent predictive risk factors for developing definite SSc in patients with early SSc.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is characterized by fibrosis of the skin and visceral organs, especially digestive tract, and musculoskeletal involvement, which limit mobility/self-sufficiency of patients, and

can have a negative impact on body composition. The aim of our study was to assess body composition and physical activity of SSc patients and healthy controls (HC).

**Methods:** 59 patients with SSc [50 females, 9 males; mean age 52.1; disease duration 6.7 years; limited cutaneous (lcSSc,36)/diffuse cutaneous (dcSSc,23)] and 36 age-/sex-matched HC (30 females, 6 males, mean age 51.4) without rheumatic/tumor diseases or manifest cardiovascular event were included. SSc patients fulfilled ACR/EULAR 2013 criteria. Anthropometric parameters and body composition were assessed (by densitometry-iDXA Lunar, and by bioelectric impedance-BIA-2000-M), and physical activity was evaluated using Human Activity Profile (HAP) questionnaire. Routine biochemistry analysis was performed after 8 hours of fasting. Disease activity was evaluated by EUSTAR SSc activity score. Data are presented as mean±SD.

**Results:** Compared to HC, patients with SSc had significantly lower body-mass index (BMI: 26.4±3.3 vs. 22.4±4.3 kg/m<sup>2</sup>, p<0.0001) and body fat % assessed by both iDXA (BF%: 37.2±6.6 vs. 32.6±8.2%, p=0.0014) and BIA (BF%: 31.1±6.4 vs. 24.6±7.8%, p<0.0001), and a trend to decreased visceral fat weight (0.9±0.9 vs. 0.5±0.5kg, p=0.0670). Compared to HC, SSc patients demonstrated significantly decreased lean body mass assessed by both iDXA (LBM: 46.6±7.5 vs. 40.9±6.8kg, p=0.0003) and BIA (LBM: 53.2±8.7 vs. 47.7±7.0kg, p=0.0017), and increased extracellular mass/body cell mass (ECM/BCM) ratio (1.03±0.1 vs. 1.29±0.4, p<0.0001), which reflects worse muscle predispositions for physical exercise, aerobic fitness/performance, and usually increases with deteriorating nutritional status. Compared to HC, SSc patients had significantly lower bone mineral density (BMD: 1.16±0.10 vs. 1.05±0.11g/cm<sup>2</sup>, p<0.0001), and were currently able to perform less energetically demanding physical activities according to HAP score (84.7±6.6 vs. 64.1±17.2, p<0.0001). Disease activity negatively correlated with BF% (r=-0.324, p=0.014), and physical activity (HAP) positively correlated with BMD (r=0.276, p=0.034) and negatively with ECM/BCM (r=-0.625, p<0.0001).

**Conclusion:** Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our SSc patients, which are associated with their disease activity and physical activity, and could reflect their nutritional status, and gastrointestinal and musculoskeletal involvement.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In Systemic Sclerosis tight monitoring during the first years of disease is required in order to detect organ complications timely. Although a clear pathophysiologic role of disease specific auto-antibodies has never been confirmed, these antibodies are associated with distinct clinical futures, strongly indicating that their prevalence is of relevance. Therefore we aimed to evaluate to what extent disease specific auto-antibodies in Systemic Sclerosis improve clinical subsetting, identifying high-risk disease

**Methods:** Clinical clusters of patients were determined, using data from the Combined Care In Systemic Sclerosis cohort, Leiden University Medical Center. Hierarchical clustering based on Ward Method was performed on Principal Component Analysis scores of solely baseline clinical variables. To determine disease-risk, 5-year mortality rates since first non-Raynaud phenomenon were assessed. Prevalence of disease specific auto-antibodies in each cluster was studied. Second, the cluster process was repeated, taking auto-antibodies into account. Clinical and auto-antibody characteristics of obtained clusters were compared to clustering based on clinical variables alone.

**Results:** Of 407 patients, 91% (n=371) fulfilled ACR/EULAR 2013 criteria. Prevalence of auto-antibodies was: anti-centromere 37%, anti-topoisomerase 24%, anti-RNA polymerase III 5%, anti-fibrillarin 4% and anti-Pm/Scl 5%. Clinical cluster analysis identified 4 different clusters with two clusters showing higher than average mortality (resp. 17% and 7% vs. total group mortality of 4% (n=15)). Adding auto-antibody status to the cluster process resulted in 5 clusters, with an additional cluster 5 with frequent RNA polymerase III (18%, n=14; mortality rate 8%). The total number of patients clustered to a cluster with higher than average mortality-risk increased indicating the need of more intensive screening in a larger group of patients.

**Conclusion:** Auto-antibodies partially contribute to risk-stratification and clinical subsetting in Systemic Sclerosis. We hypothesize that additional characteristics of auto-antibodies like isotypes might reflect their pathophysiological role, and that the value of autoantibodies as biomarkers for severe disease might increase when adding these characteristics.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Involvement of skin and musculoskeletal system in systemic sclerosis (SSc) leads to loss of function, disability and reduced quality of life. Data on efficacy of non-pharmacologic care in SSc is very limited due to variety in studied interventions/outcomes. The aim of our study was to address the limitations of existing studies, and evaluate the effect of a controlled, long-term (24-week intervention, 24-week follow-up), intensive (1h physiotherapy + 0.5h occupational therapy twice weekly, and home-exercise for 0.5h 5x weekly), tailored physiotherapy programme on function/impairment of hands/face, and quality of life/disability in cohorts with a substantial number of SSc patients.

**Methods:** All patients fulfilled ACR/EULAR 2013 criteria, had skin involvement of hands/mouth, and were consecutively recruited from 2014 to 2016 at the Institute of Rheumatology in Prague. Both groups received educational materials and instructions for home exercise at baseline, however, only intervention group underwent the intensive physiotherapy programme. At months 0,3,6,12 all patients were assessed by a physician (physical examination, mRSS, EUSTAR SSc activity score, Medsger SSc severity score), and a physiotherapist blinded to intervention [validated measurements (dFTP-delta finger to palm, inter-incisor/inter-lip distance, grip strength using Baseline dynamometer); tests (HAMIS-Hand Mobility In Scleroderma)], patients filled out patient reported outcomes/questionnaires (CHFS-Cochin Hand Function Scale, MHISS-Mouth Handicap In SSc Scale, HAQ, SHAQ, SF-36) and provided blood for routine laboratory analysis and biobanking. Normality of data was tested, inter-group analysis was performed with 2-way ANOVA, and intra-group analysis by Friedman's test with Dunn's post hoc test.

**Results:** 25 SSc patients (22 female/3 male, 14 limited cutaneous (lc)SSc/11 diffuse cutaneous (dc)SSc, median of age 54.0 and disease duration 7.0 years, mRSS 12) were recruited into the intervention group (IG) and 29 patients into the control group (CG) (25 female/4 male, 16 lcSSc/13 dcSSc, median of age 49.0 and disease duration 5.0 years, mRSS 11). Compared to observed statistically significant deterioration in CG over the period of m0-m6, we found statistically significant improvement in dFTP, grip strength, HAMIS, inter-incisor and inter-lip distance (Table 1). Only numerical improvement in IG compared to numerical deterioration in CG, which have not reached statistical significance, were observed in patient reported outcomes (CHFS, MHISS, HAQ, SHAQ, SF-36).

**Conclusion:** Our physiotherapy program not only prevented the natural course of progressive deterioration of function of hands/mouth (observed in the control group), but led to a significant improvement in monitored parameters, which was clinically meaningful in a substantial proportion of patients.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interstitial lung disease (ILD) is a major contributor to morbidity and mortality in systemic sclerosis (SSc). We sought to identify the distribution of clinical characteristics, comorbidities, pulmonary disease patterns, and outcomes in a retrospective cohort of SSc-ILD.

**Methods:** A retrospective review of medical records was conducted to identify patients with SSc seen at a single tertiary referral center in 2000-2013 within 1 year of ILD diagnosis. All patients met the 2013 ACR/EULAR classification criteria for SSc. Patients were included only if at least 1 year of follow up data was available. Baseline demographics, comorbidities and clinical characteristics were collected, in addition to pulmonary function tests, lung imaging, and echocardiogram for 3 years after ILD diagnosis. Cox models were used to examine associations between potential risk factors and progression or mortality.

**Results:** A total of 126 patients with SSc-ILD were identified (87 [69%] female; mean age: 57.5, range 31-82 years). Based on high resolution chest CT (or biopsy when available), 108 (86%) were characterized as nonspecific interstitial pneumonia (NSIP), 17 (13%) as usual interstitial pneumonia (UIP), 1 as unclassifiable ILD. Pulmonary hypertension (PHTN) was noted in 44 (35%) at baseline, and this did not differ between ILD subtypes. Patients with UIP were more likely than those with NSIP to have chronic obstructive pulmonary disease (COPD) at baseline (24% vs 5%,  $p = 0.005$ ). 89% had limited cutaneous SSc, 7% had diffuse cutaneous, and 4% SSc sine scleroderma. SSc specific serologies (i.e., SCL-70, centromere, and/or RNA Pol III) were positive in 56 (46%) patients, somewhat more common in NSIP than UIP (49% vs 25%;  $p=0.07$ ). Baseline initial forced vital capacity (FVC) and diffusion capacity (DLco) were not significantly different between ILD subtypes. Progression to DLco < 40% predicted or too ill to perform DLco was noted in 39% (95% CI 30% – 48%) by 3 years and did not significantly differ between ILD patterns ( $p=0.64$ ). Risk factors for progression included baseline DLco ( $p < 0.001$ ), FVC ( $p = 0.001$ ) and PHTN ( $p = 0.002$ ). Only 5 patients progressed to FVC < 50% predicted. During a median of 5.0 years of follow-up, five-year survival was 86% (95% CI 80 - 92%), and was only marginally worse in UIP than NSIP (hazard ratio [HR]: 2.0;  $p=0.057$ ). Risk factors for mortality included comorbid COPD, hypertension and those identified for progression. The presence of inflammatory arthritis at baseline (16 patients, 13%) appeared to be a good prognostic indicator for mortality (HR 0.21, 95% CI 0.05 - 0.89).

**Conclusion:** Outcomes were overall somewhat better in SSc-ILD compared with those described in idiopathic pulmonary fibrosis, consistent with previous studies of connective tissue disease related ILD. ILD subtype had marginal prognostic significance in this cohort of patients with SSc-ILD. Baseline FVC and DLco, comorbid COPD, hypertension, and pulmonary hypertension at any time were risk factors for a poor prognosis. These findings

highlight the importance of a thorough baseline pulmonary evaluation in predicting outcomes in patients with SSc-ILD.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Forced vital capacity (FVC) and carbon monoxide diffusion (DLCO) are used to screen for systemic sclerosis associated interstitial lung disease (SSc-ILD). The purpose of this cross-sectional study was to determine the sensitivity, specificity, and negative predictive values (NPV) of FVC and DLCO thresholds for SSc-ILD on chest high-resolution computed tomography (HRCT) scans.

**Methods:** Patients fulfilled American College of Rheumatology 2013 SSc criteria and had undergone at least one HRCT and pulmonary function test (PFT). An experienced thoracic radiologist quantified ILD on HRCT. Receiver operating characteristic curves were generated to determine optimal % predicted FVC and DLCO cut-points, defined as the greatest combined sensitivity and specificity, for radiographic ILD. Established normal PFT thresholds and screening algorithms combining FVC and DLCO were evaluated. Sub-analysis was performed according to anti-topoisomerase I (Scl-70) autoantibody status.

**Results:** A total of 265 patients fulfilled study criteria (82% women, 49% diffuse cutaneous SSc, 30% +Scl-70), and 188 (71%) had radiographic ILD. Of those with ILD, 59 out of 188 (31%) had normal FVC (>80% predicted), and 65 out of 151 (43%) had normal DLCO (>60% predicted). There were 31 out of 214 (14%) patients who had

FVC and DLCO both within normal range. Predicted FVC  $\leq 80\%$  (sensitivity 0.69, specificity 0.74), and DLCO  $\leq 62\%$  (sensitivity 0.60, specificity 0.70) were the optimal thresholds for ILD (Table 1, Figure 1). All evaluated FVC and DLCO threshold combinations had a NPV  $< 0.70$  for radiographic ILD. In patients with positive vs. negative Scl-70, the NPV of % predicted FVC  $< 80$  (0.05 vs. 0.57) and DLCO  $< 60$  (0.10 vs. 0.48) was lower for radiographic ILD (Table 1).

**Conclusion:** Radiographic ILD is prevalent in SSc patients despite normal PFTs. No observed % predicted FVC or DLCO threshold combinations yielded a high NPV for SSc-ILD screening. A % predicted FVC  $\geq 80$  and DLCO  $\geq 60$  in SSc patients, especially those with positive vs. negative Scl-70 autoantibodies, should not obviate consideration of HRCT for ILD evaluation. However, it remains to be shown if detection of ILD in asymptomatic patients with normal PFTs improves clinical outcomes.

**Figure 1. Receiver Operating Characteristic Curves.** Receiver operating characteristic (ROC) curves for % predicted forced vital capacity (FVC) and diffusing capacity of the lung for carbon monoxide (DLCO) for associated radiographic interstitial lung disease (ILD) in systemic sclerosis.

**Table 1. Performance of pulmonary function test thresholds for prevalent radiographic interstitial lung disease on chest high resolution computed tomography images in patients with systemic sclerosis**

	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value
<b>Individual PFT Threshold – Entire cohort</b>				
<b>FVC % predicted (n=265)</b>

## Unique Characteristics of Scleroderma Among African Americans: A Population Based Study

**Sarah M. Compton**<sup>1</sup>, Richard M. Silver<sup>2</sup> and Diane L. Kamen<sup>3</sup>, <sup>1</sup>Internal Medicine, Medical University Of South Carolina, Charleston, SC, <sup>2</sup>Division of Rheumatology and Immunology, Department of Medicine, Medical University of South Carolina, Charleston, SC, <sup>3</sup>Medicine/Rheumatology & Immunology, Medical University of South Carolina, Charleston, SC

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Systemic sclerosis (SSc) is a rare autoimmune disease categorized on the basis of skin involvement as either limited or diffuse cutaneous SSc, the latter of which manifests in more severe skin and internal organ involvement. SSc disproportionately affects women and literature suggests African American (AA) patients experience autoimmune diseases differently than other ethnic/racial groups. We sought to validate these observations utilizing a longitudinal cohort of SSc patients, comparing disease characteristics between AAs and non-AAs.

**Methods:**

Data were collected as part of an ongoing IRB-approved longitudinal registry of SSc patients, including demographics, clinical disease manifestations and other medical history. Patients were seen over a 12-year period at a single academic center. Retrospective chart review was additionally performed to confirm age of onset, SSc disease type, and selected criteria for SSc to assess severity of disease. Pearson's chi-squared and Fisher's Exact testing were performed for categorical measures. Two-sample t-tests were performed for continuous measures. Significance was set at  $\alpha = 0.05$ .

**Results:**

A total of 236 patients with SSc (80.9% female, 35.2% AA) were identified. Demographics and clinical characteristics are shown in Table 1. AA patients developed SSc at a significantly younger age compared to the non-AA patient subset ( $41.8 \pm 13.3$  yrs.,  $48.7 \pm 13.2$  yrs., respectively,  $p < 0.01$ ). Females developed SSc at a younger age than males ( $45.1 \pm 13.9$  yrs.,  $51.3 \pm 11.0$  yrs,  $p < 0.01$ ). Diffuse SSc was significantly more common in AA patients ( $p < 0.01$ ). Males overall were more likely to have diffuse SSc than limited SSc (68.3%,  $p < 0.01$ ).

Interstitial lung disease was significantly more common in AA patients (68.5%,  $p = 0.02$ ). The higher prevalence of lung disease among AAs was not attributed to smoking status, as a significantly higher proportion of non-black SSc patients were smokers. Although not statistically significant, AA patients had a higher prevalence of restrictive lung disease based on forced vital capacity percent predicted  $< 70\%$  (46.0% versus 31.9%  $p = \text{NS}$ ). Overall mortality was 7.2% in AA patients compared to 3.9% in non-AA patients with SSc ( $p = \text{NS}$ ).

**Conclusion:**

In conclusion, we found that AA SSc patients tend to be younger and more often have diffuse cutaneous disease than non-AA SSc patients, consistent with findings among other AA populations. Although not statistically significant, AA patients trended towards a higher prevalence of restrictive lung pattern on pulmonary function testing and a higher mortality rate. These data support the conclusion that AAs have more severe disease with a more unfavorable SSc prognosis. Further investigation into the multifactorial causes for this disparity is needed in order to identify strategies to reduce them.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Objectives:** The aim of this study is to evaluate the usefulness of photoacoustic imaging (PAI) for quantitative analysis of the peripheral vascular bed in patients with systemic sclerosis (SSc).

**Background/Purpose:** PAI is a technique that uses the photoacoustic effect of living tissues. Pulsed short-length light waves excite the living tissue to produce strong ultrasonic waves in accordance with the absorbance of substances in the tissue. These ultrasonic waves can be detected with ultrasound probes, and reconstructed as an ultrasound image. Detecting the ultrasonic wave which is produced by 750 nm wavelength pulsed laser-excited hemoglobin enables small blood vessels of low flow velocities to be visualized without using contrast agents. The quantitative evaluation of digital vascular bed volume in patients with SSc may enable us to diagnose SSc earlier, and to determine the progression and severity of the disease.

**Patients and Methods:** Nine patients with SSc, two patients with systemic lupus erythematosus (SLE) complicating Raynaud's phenomenon as disease control (DC), and three healthy adult volunteers as healthy control (HC) were enrolled in the study. The volume of the vascular bed was measured in the proximal and distal sites of fingers 2–5 bilaterally using PAI.

**Results:** The volume of the digital vascular bed in 37 sites of SSc patients, 21 sites of HC, and 14 sites of DC could be obtained. All SSc patients showed a severely decreased digital vascular bed volume in both proximal and distal sites of all measured fingers, and the vascular bed volumes were significantly lower compared with HC. DC showed a tendency of decreased digital vascular bed, but not significantly compared with HC.

**Conclusion:** PAI is a useful device for determining digital vasculopathy by quantitative analysis of vascular bed volume. More data with clinical signs, and comparison with other modalities such as color Doppler sonography, will provide the information to determine the prognosis of peripheral ischemic damage, and the effectiveness of treatments to improve peripheral circulation.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Systemic sclerosis (SSc) is a systemic autoimmune disorder characterized by microvascular changes, excessive fibrous tissue deposition and systemic inflammation. Previous studies showed that systemic sclerosis is an

independent risk factor for coronary artery disease and involved not only accelerated epicardial atherosclerosis, but also small vessel disease and vasospasm. The aim of this study is to analyze the temporal trend of acute coronary syndrome (ACS) in hospitalized patients with SSc, mortality and other outcomes from 2005 to 2014. We also compared the in-hospital mortality in ACS hospitalizations in patients with and without SSc.

## **Methods:**

We conducted a retrospective study using data from National Inpatient Sample (NIS) from 2005 to 2014. Diagnoses were identified using International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes. Patients with a diagnosis of ACS (ICD 9 code 410 excluding 410.x2 and 411.1) and SSc (ICD 9 code 710.1) were included. Patients younger than 18 years old were excluded. Primary outcome was the temporal trend of the ratio of ACS hospitalizations compared to all-cause hospitalizations from 2005 to 2014. Secondary outcome was the temporal trend of age-adjusted in-hospital mortality, length of stay and total hospital charges over the study period of time. We also compared the age-adjusted in-hospital mortality in ACS hospitalizations in patients with and without SSc. Logistic regression was used for statistical analysis of hospitalization ratio and age-adjusted in-hospital mortality and linear regression was used for length of stay and total hospital charges.

## **Results:**

A total of 66,392 ACS hospitalizations in adult patients with SSc from 2005 to 2014 were identified. Compared with all-cause hospitalizations, the ratio of ACS hospitalizations were stable (3.57% in 2005 and 3.58% in 2014,  $p = 0.822$ ) among patients with SSc, while the ratio was decreased (3.76% in 2005 and 3.19% in 2014,  $p < 0.001$ ) among general adult populations. Age-adjusted in-hospital mortality was significantly higher in those with SSc compared to non-SSc (OR 2.25, 95% CI 1.95 - 2.60,  $p < 0.001$ ) and did not change significantly (16.99% in 2005 and 16.19% in 2014,  $p = 0.412$ ) from 2005 to 2014. Length of stay decreased significantly (7.42 days in 2005 and 6.13 days in 2014,  $p = 0.044$ ) and total hospital charges increased significantly (55,280 in 2005 and 76,486 in 2014,  $p = 0.001$ ) over the 10 year period.

## **Conclusion:**

Our study shows that ACS hospitalizations in SSc patients have more than doubled risk of death compared to those without SSc and both the ratio of ACS hospitalizations and age-adjusted in-hospital mortality failed to decrease over time. Our study highlights that there is a critical gap in preventing and treating ACS in SSc populations.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pulmonary arterial hypertension (PAH) is prominent as a vascular involvement in systemic sclerosis (SSc), which remains a leading cause of death in spite of current best treatments. As the pulmonary vascular disease (PVD) can be well compensated for, more than a half of the pulmonary circulation is impaired before early PAH is detected. Although recent studies focused on molecular basis of the PVD, the underlying mechanisms have not been fully elucidated, especially at early stage of SSc. In this study, we try to detect the subclinical PVD and to detect a gene co-expression network involved in the pathogenesis of exercise-induced PAH at early stage of SSc.

**Methods:** Total of 93 cases without PAH symptoms (NYHA I) with either Raynaud phenomenon (RP: n=80), skin sclerosis (n=51) or SSc-related autoantibody (anti-RNP: n=15, centromere: n=50, topoisomerase-1: n=3, RNA polymerase III: n=3) were enrolled. To detect the latent PAH, exercise DE with Master's two-step stress was carried out. Systolic PAP (sPAP) was determined by maximum velocities of tricuspid regurgitation jets, and exercise induced pulmonary hypertension (exPH) group was segregated from normal response group (exN) with using the definition of a sPAP greater than 40 mm Hg during exercise, or a exercise increase in sPAP by greater than 20 mm Hg<sup>1</sup>). Meanwhile, genome-wide gene expression analysis was performed with using whole peripheral blood from some of these patients (n=74). Total RNAs were extracted and multiplex sequencing was done. After quantifying the expressions of transcripts, co-expression modules were identified by weighted gene co-expression network analysis (WGCNA). And then, pathway enrichment analysis (PathVisio) was performed to investigate the module.

**Results:** In clinical test items, the level of serum BNP was high in exPH group, whereas there were no significant differences between exPH and exN group in the results of total skin score, pulmonary function and thermography after 0°C-stress test. The SSc-related autoantibody positive was a risk factor for exPH (odds ratio=1.62); especially, anti-RNP positive seems to be prominent (odds ratio=2.10). Based on the gene expression analysis, 19 co-expression modules were identified by WGCNA. Pathway enrichment analysis revealed that modules related with the titer of anti-RNP antibody were enriched with genes of type2 interferon signaling pathway.

**Conclusion:** The paradigm of SSc-PAH management should ideally be aimed at detecting early PVD and starting treatment prior to fulfilling the criteria for PAH. Although it remains a major challenge, individuals who require early therapeutic intervention are possible to be segregated by the follow-up with exercise DE. By this study, the crucial genes involved in the pathogenesis of exercise-induced PAH have not been completely elucidated. However, it is noteworthy that anti-RNP autoantibody, shown as an important risk factor for exercise-induced PAH, seemed to be related with type 2 interferon signaling pathway. It may show a hint for therapeutic intervention at the early stage of the disease to prevent the aggravation of PVD.

# Can Durometer Differentiate Limited Versus Diffuse Cutaneous Systemic Sclerosis?

Vivek Nagaraja<sup>1</sup>, Amber Young<sup>1</sup>, Veronica J. Berrocal<sup>2</sup> and Dinesh Khanna<sup>1</sup>, <sup>1</sup>Department of Medicine, University of Michigan Scleroderma Program, Ann Arbor, MI, <sup>2</sup>Department of Biostatistics- School of Public Health, University of Michigan, Ann Arbor, MI

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The durometer is a handheld device that measures the hardness of a surface. It has been used to measure skin hardness in patients with diffuse cutaneous systemic sclerosis (dcSSc), and was found to be feasible, reliable, and responsive to change in a trial and US cohort [1, 2]. The objective of this study is to assess if durometer can differentiate skin hardness in patients with limited cutaneous SSc (lcSSc) vs. dcSSc.

**Methods:** This is a single center cross-sectional study. Durometer assessment was performed at two areas – forearm and thigh by same observer. At each of these areas, three values were assessed and a median score was reported separately for each area. We assessed the correlation between durometer and mRSS at the forearm and thigh using the Pearson's correlation coefficient. Paired t-test was used to assess the difference in the mean durometer scores between sub-groups (with p-value less than 0.05).

**Results:** A total of 45 patients participated in this study – healthy controls (N=21), dcSSc (N=14), and lcSSc (N=10). Majority of patients were females across the groups (dcSSc 64%, lcSSc 80%, HC 76%). The mean (SD) durometer reading of 3 groups were: at the forearm, 19.22 for HC, 24.28 for lcSSc, and 34.53 for dcSSc; at the thigh, 19.39 for HC, 28.68 for lcSSc, and 31.04 for dcSSc. The mean [SD] overall mRSS was 3.89[2.47] in lcSSc and 16.38[7.5] in dcSSc. We found statistically significant correlations in the forearm measurements between median durometer scores and mRSS in dcSSc (0.56,  $p < 0.05$ ), but not in lcSSc (0.36,  $p = 0.34$ ). Durometer was able to differentiate lcSSc from dcSSc (median durometer scores 34.53 units vs. 24.28 units for lcSSc,  $p = 0.006$ ) but not in the thigh (median durometer scores 31.04 units vs. 28.68 units for lcSSc,  $p = 0.53$ ; Table).

**Conclusion:** Durometer was able to differentiate skin hardness in dcSSc vs lcSSc patients when measured in the forearm.

**Table: Mean [SD] durometer scores between the groups**

Location	Mean Durometer Scores			p-value
	HC	dcSSc	lcSSc	
Forearm	19.22 [2.75]	34.53 [7.88]		<0.001
	19.22 [2.75]		24.28 [8.19]	<0.09
		34.53 [7.88]	24.28 [8.19]	0.006
Thigh	19.39 [3.64]	31.04 [8.28]		<0.001
	19.39 [3.64]		28.68 [9.24]	0.01
		31.04 [8.28]	28.68 [9.24]	0.53

HC – healthy controls; DcSSc – diffuse cutaneous systemic sclerosis; LcSSc – limited cutaneous systemic sclerosis

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD) are leading causes of mortality in patients with systemic sclerosis (SSc). We aimed to determine factors associated with disease progression in SSc patients with concomitant ILD-PAH, PAH alone or ILD alone in the Scleroderma Cohort Singapore.

### **Methods:**

In this multi-centre study involving 3 tertiary Rheumatology institutions (January 2008 to June 2016), factors associated with progression in full vital capacity (predicted FVC  $\geq 10\%$  decrease from baseline), NT-proBNP ( $\geq 4x$

baseline) and New York Heart Association (NYHA  $\geq$ 1 class progression) were identified among SSc patients with ILD-PAH, PAH alone and ILD alone. Stepwise multivariable logistic regression analyses were performed to determine independent factors associated with worse outcomes. Inclusion criteria were fulfillment of the ACR 2013 classification criteria for SSc and significant pulmonary involvement. ILD was based on high resolution computed tomography scan and predicted FVC  $<70\%$ . Patients with suspected PAH based on echocardiographic systolic pulmonary arterial pressure (PAP)  $\geq 50$ mmHg, and definite PAH based on right heart catheterization findings of mean PAP  $\geq 25$ mmHg and pulmonary capillary wedge pressure (PCWP)  $\leq 15$  mmHg were included. In patients with PCWP  $>15$ mmHg, those with mixed pre- and post-capillary PH based on transpulmonary gradient  $>12$ mmHg were also included in the PAH group analyses.

## **Results:**

Among 541 subjects, 88 (16%) had ILD, 49 (9%) PAH and 44 (8%) concomitant ILD-PAH (Table 1). Of 93 patients classified to have PAH or ILD-PAH, 56 (60%) were based on echocardiography and 37 (40%) on right heart catheterization. Patients with ILD-PAH had increased risk of NT-proBNP progression; additionally, telangiectasia and baseline NYHA  $\geq$ II increased the risk of NT-proBNP progression. SSc disease duration and malabsorption increased the risk of NYHA progression. Reflux/ dysphagia and malabsorption increased the risk of FVC progression (Table 2).

## **Conclusion:**

SSc patients with concomitant ILD-PAH had worse clinical outcomes based on surrogate biomarker NT-proBNP. We also identified other risk factors associated with increased risk of disease progression in SSc patients with pulmonary involvement.

*Table 1.* Demographics and Clinical Characteristics

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Allogeneic STRO-3 immunoselected mesenchymal precursor cells (MPCs) derived from bone

marrow of healthy donors are a potent, homogeneous cell population which can be activated by pro- inflammatory cytokines to release factors which polarize pro-inflammatory monocytes and T cells to an anti- inflammatory state. This is the first in human trial to assess safety, tolerability and efficacy of MPC therapy in biologic refractory RA, a disease driven by monocyte and T cell activation.

## **Methods:**

Patients must have been positive for rheumatoid factor (RF) and/or anti-cyclic citrullinated peptide (anti-CCP3) antibodies but without extra-articular disease (other than RA nodules) and without severe functional limitation. ACR functional classes I, II and III were acceptable for entry. Safety endpoints were adverse events, vital signs, physical examination, clinical laboratory tests, ECG, and chest x-ray. Efficacy endpoints included ACR 20/50/70, ACR-N, ACR core components, HAQ and DAS28. Patients were randomized to receive one IV infusion of MPC 1 million cells/kg (n=16), 2 million cells/kg (n=16), or placebo (n=16) in 2 sequential dose cohorts. The primary study period was 12 weeks, with complete follow-up through 52 weeks.

**Results:** Patients in all 3 treatment groups were comparable in mean age (55 y), gender (73% women), duration of RA (13 years), and prior biologic exposure. MPC infusions were well- tolerated with no adverse infusion reactions and few serious adverse events noted during the 52-week study period, with 85% of patents completing all follow-up. HLA Class I sensitization was observed in MPC treatment groups, however without association with increased adverse events overall. We previously reported favorable efficacy results for both MPC groups at 12 weeks for ACR50 and ACR70 rates and ACR core components, with greater efficacy in the 2M/kg group (Durability of treatment effect observed at 12 weeks in the 2M/kg group was assessed by ACR-N and is shown to be significant compared to placebo through 12 and 39 weeks by time-integrated analysis of mean ACR-N area under the curve (AUC))

## **Conclusion:**

A single infusion of MPCs was well-tolerated in RA patients. While the efficacy results are

encouraging, further assessment including dose optimization is needed. The current trial is a unique early phase trial whose results show promise and support future development of MPCs for biologic-refractory RA patients, a subset of the RA population with substantial remaining medical need.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with systemic sclerosis (SSc) often display Raynaud's phenomenon, which causes digital skin ulcers. Since these ulcers are not associated with autoimmune factors, conventional immunosuppressive therapies, vasodilators, and anticoagulants are often ineffective. Extracorporeal shock wave therapy (ESWT) at low energy is shown to be effective in stimulating numerous growth factors endogenously, inducing angiogenesis and healing of injuries and wounds. This study evaluated ESWT for treatment of refractory skin ulcers caused by SSc and assessed its efficacy and safety.

**Methods:** We enrolled 60 patients with SSc and refractory digital ulcers with no response to intravenous prostaglandin E1 therapy at least 4 weeks. Of these, 30 were treated with ESWT and 30 received conventional treatment. Patients in the conventional treatment group were permitted to use any currently available therapies. Patients in the ESWT group continued pre-study treatments.

**Results:** The mean decrease in the number of ulcers at 8 weeks was 4.47 in the ESWT group and 0.83 in the conventional treatment group and the difference was significant ( $p<0.0001$ ). The proportion of subjects whose total number of ulcers decreased by 70% or more at 8 weeks was 26.7% in the conventional treatment group and 70.0% in the ESWT group and this was also significant ( $p<0.0008$ ). The average number of new ulcers in the 8 weeks after the start of treatment was 1.57 in the conventional group and 0.23 in the ESWT group. No serious adverse events associated with ESWT were reported during the study period.

**Conclusion:** After 8 weeks, ESWT demonstrated clinically meaningful improvement in SSc patients with refractory digital ulcers. This treatment is well-tolerated and minimally invasive, can be repeated without adverse effects, and requires no anesthesia. Overall, the results of our study suggest that ESWT is a novel and efficacious treatment that can be added to pharmacologic therapy.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Scleroderma (SSc) is a complex disease that involves activation of the immune system, vascular complications, and tissue fibrosis. Although the pathogenesis of this disease is largely unknown, epigenetic dysregulation has been implicated. In this study, we focused on the histone methyltransferase enhancer of zeste homolog 2 (EZH2), which is the catalytic component of the polycomb repressor complex 2 and mediates trimethylation of lysine 27 of histone 3 (H3K27me3). It has been reported that EZH2 regulates angiogenesis, and it is also involved in fibrosis. We hypothesize that EZH2 contributes to impaired angiogenesis and enhanced fibrosis in SSc, and inhibition of EZH2 improves these key events in SSc.

**Methods:** Dermal endothelial cells (ECs) and fibroblasts were isolated from biopsies from healthy subjects or patients with diffuse cutaneous SSc. EZH2 was overexpressed using an EZH2 vector. Inhibition of EZH2 was achieved by using EZH2 inhibitor DZNep or EZH2 siRNA. Angiogenesis was assessed by an *in vitro* Matrigel tube formation assay. The scratch wound assay was used to evaluate fibroblast migration. The effect of DZNep (50mg/kg/day for 14 days) *in vivo* was assessed in a bleomycin-induced skin fibrosis model. A t-test was used to compare differences between groups, and a p-value of <0.05 was considered significant. Genome-wide DNA methylation was evaluated using the Illumina Infinium Methylation EPIC BeadChip Array.

**Results:** EZH2 and H3K27me3 were significantly elevated in SSc ECs and fibroblasts compared to healthy controls. Overexpression of EZH2 in normal ECs led to significant decrease in tube formation, while decrease in EZH2 in SSc ECs, achieved by siRNA or DZNep treatment, restored normal angiogenesis. In SSc fibroblasts, DZNep treatment dose-dependently reduced *EZH2*, as well as pro-fibrotic *COL1A1*, *TGFBI*, and *FRA2*. In addition, DZNep significantly reduced pro-angiogenic genes *VEGF* and *FGF2*, as well as genes involved in DNA methylation, including *DNMT1*, *DNMT3A*, and *MECP2*. EZH2 inhibition in SSc fibroblasts also led to genome-wide changes in the methylome, and the expression of differentially methylated genes was confirmed by qPCR, including anti-fibrotic *IL7* and migration-involved *LRRC16A*, both hypermethylated and downregulated. In the scratch wound assay, DZNep-treated SSc fibroblasts showed wider wound width at 48 hours post-injury compared to untreated SSc fibroblasts. The gene expression profiles and scratch wound results were further confirmed in EZH2-overexpressing normal fibroblasts, as these cells showed a pro-fibrotic phenotype, mimicking what was seen in SSc fibroblasts. In a bleomycin prevention model, DZNep successfully prevented significant skin fibrosis to occur, assessed by both skin thickness and hydroxyproline analysis.

**Conclusion:** EZH2 is overexpressed in SSc ECs and fibroblasts, and this overexpression is profibrotic and results in impaired angiogenesis in this disease. Inhibition of EZH2 restored normal angiogenesis in SSc ECs, and normalized the pro-fibrotic phenotype in SSc fibroblasts as well as in an animal model. Targeting EZH2 or EZH2-regulated genes may open new therapeutic avenues for patients with SSc.

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Dipeptidyl-peptidase-4 (DPP4) has been reported to identify a dermal fibroblast lineage involved in scarring and its inhibition leads to reduced scar formation. Its role in tissue fibrosis, however, is unknown. The aim of the study was to characterize DPP4 positive cells and their mechanism of action and to evaluate the antifibrotic effect of DPP4 inhibition in different preclinical models of systemic sclerosis (SSc).

**Methods:** Expression of DPP4 in human and murine skin was analyzed by immunofluorescence and Western blot. Mouse fibroblasts were isolated and DPP4 positive cells properties were assessed. Two DPP4 inhibitors were tested in two concentrations administered oral in bleomycin-induced skin fibrosis and in sclerodermatous chronic graft-versus-host disease (scl-cGvHD) model. Pulmonary and dermal fibrosis was induced by bleomycin in DPP4 knockout (KO) mice and wildtype littermates. The antifibrotic effects were assessed by hydroxyproline assay, quantification of myofibroblasts and analyses of the dermal thickness. Fibrosis of the lungs was additionally evaluated by computer tomography scans (CT). Inflammatory infiltrates were assessed by CD45 staining.

**Results:** DPP4 positive fibroblasts were increased in fibrotic skin of SSc patients and also in murine models of fibrosis. DPP4 expression is induced by TGF- $\beta$  in an Erk-dependent manner. DPP4-expressing fibroblasts were activated and strongly expressed alpha smooth muscle actin (SMA) and stress fibers after TGF- $\beta$  stimulation. These cells also released increased amounts of collagen. Furthermore, DPP4-positive fibroblasts showed a higher proliferation rate and an increased migratory capacity. Pharmacological inhibition of DPP4 reduced the release of collagen and the expression of myofibroblast markers. DPP4-KO mice are less sensitive to bleomycin-induced pulmonary fibrosis as shown by milder changes on CT, reduced Ashcroft scores and reduced hydroxyproline content. DPP4-KO mice also show reduced skin fibrosis upon bleomycin challenge. Moreover, treatment with DPP4 inhibitors in pharmacologically relevant and well tolerated doses demonstrated potent antifibrotic effects in bleomycin-induced skin fibrosis and experimental scl-cGvHD mouse model with reduced dermal thickening, decreased collagen deposition and reduced myofibroblast counts. Treatment with DPP4 inhibitors also reduced leukocyte infiltrations into the skin. No anti-fibrotic effects of DPP4 inhibition were observed in DPP4-KO mice, confirming that the antifibrotic effects of DPP4 inhibitors are not mediated by off-target effects. Mechanistically, inhibition of DPP4 selectively interferes with the TGF- $\beta$  induced activation of ERK signaling, but does not inhibit TGF- $\beta$  induced SMAD signaling, or other non-canonical TGF- $\beta$  pathways involving Fra2, c-Jun, p38, Akt or STAT3.

**Conclusion:** DPP4 characterizes an activated subpopulation of fibroblasts in SSc. However, DPP4 does not only serve as an activation marker, but is also functionally required for fibroblast activation and tissue fibrosis. These results may have direct translational implications as DPP4 inhibitors are already in clinical use for diabetes.

# Effect of Anabasum (JBT-101) on Gene Expression in Skin Biopsies from Subjects with Diffuse Cutaneous Systemic Sclerosis (dcSSc) and the Relationship of Baseline Molecular Subsets to Clinical Benefit in the Phase 2 Trial

Viktor Martyanov<sup>1</sup>, Yolanda Nesbeth<sup>2</sup>, Guoshuai Cai<sup>1</sup>, Tammara A. Wood<sup>1</sup>, Jake Reder<sup>2</sup>, Scott Constantine<sup>3</sup>, Barbara White<sup>3</sup>, Robert F. Spiera<sup>4</sup> and Michael L. Whitfield<sup>1</sup>, <sup>1</sup>Department of Molecular and Systems Biology, Geisel School of Medicine at Dartmouth, Hanover, NH, <sup>2</sup>Celdara Medical, LLC, Lebanon, NH, <sup>3</sup>Corbus Pharmaceuticals, Inc., Norwood, MA, <sup>4</sup>Rheumatology, Hospital for Special Surgery, New York, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Anabasum (JBT-101) is a non-immunosuppressive, synthetic, CB2 agonist that resolves inflammation and fibrosis in animal models of SSc and reduces TGF- $\beta$  and collagen production by dcSSc fibroblasts. It showed evidence of clinical benefit in dcSSc in the Phase 2 trial JBT101-SSc-001 (NCT02465437). To provide additional data on the impact of anabasum on SSc, gene expression was analyzed in skin biopsies from trial subjects.

## Methods:

Gene expression data at baseline and end of treatment (Day 85) were used for differential gene expression, pathway enrichment and intrinsic subset assignment, comparing paired skin biopsies from anabasum-treated (N=23) and placebo-treated (N=13) subjects. Overall response was an ACR Composite Response Index in dcSSc (CRISS) score of  $\geq 0.2$  and skin response was a decrease in modified Rodnan Skin Score (mRSS)  $\geq 5$  points.

## Results:

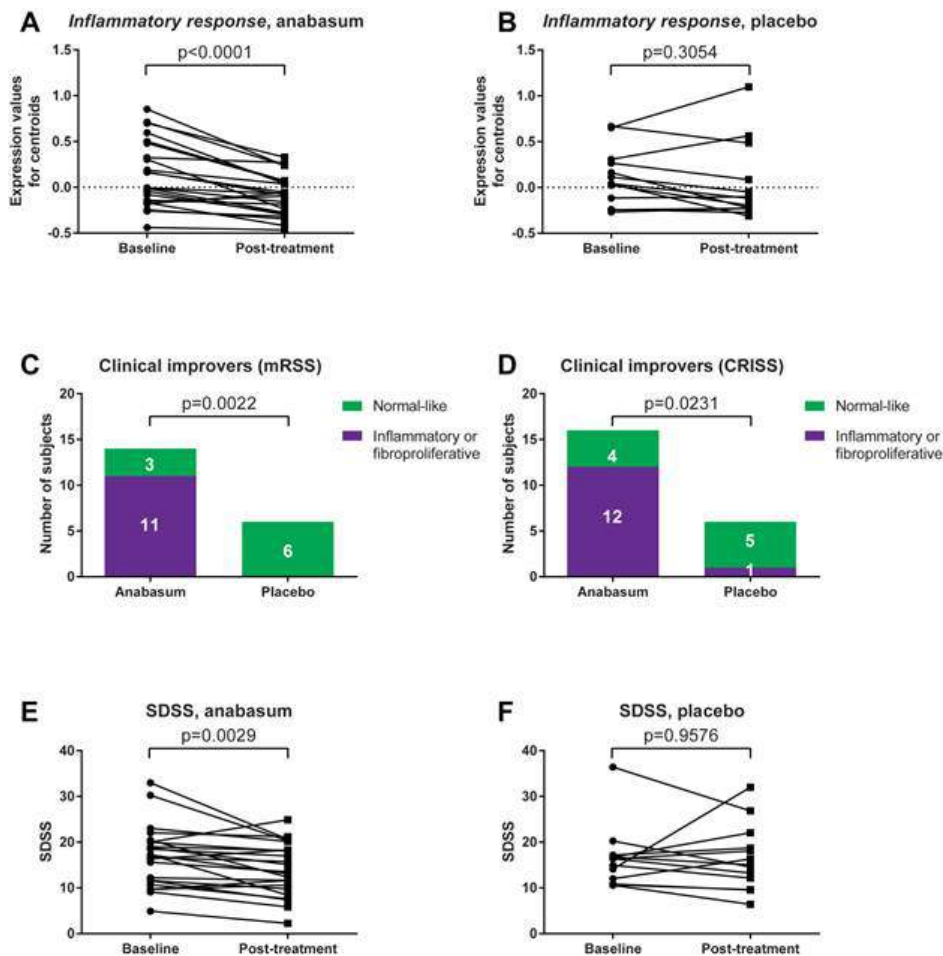

1937 genes were differentially expressed in anabasum arm (False Discovery Rate  $\leq 5\%$ ) from baseline to Day 85. Genes downregulated from baseline at Day 85 were enriched in *inflammatory response*, *extracellular matrix (ECM) organization*, *collagen metabolism*, *response to cytokine* and *angiogenesis* (Bonferroni-corrected  $p \leq 0.05$ ). Genes upregulated from baseline at Day 85 were involved in *lipid metabolism*. These changes were not observed in the placebo arm.

*Inflammatory response* and *ECM organization* pathways included many genes important in SSc (e.g. CCL2, CTGF, FN1, ICAM1, IL4R, PDGFB, TGFB1, THBS1, TIMP1 and TNC). *Inflammatory response* genes decreased in the anabasum arm (Figure 1A,  $p < 0.0001$ ) but not the placebo arm (Figure 1B,  $p = 0.3054$ ). Similar reduction was also observed for *ECM organization* genes ( $p = 0.0002$  for anabasum vs.  $p = 0.4840$  for placebo).

Most CRISS (83%) and all mRSS improvers in the placebo arm were assigned to normal-like intrinsic gene expression subset whereas in the anabasum arm most CRISS (75%) and mRSS (79%) improvers were classified as inflammatory or fibroproliferative (Figure 1C and 1D). Scleroderma Disease Severity Score (SDSS), a gene expression-based mRSS surrogate, decreased at Day 85 in anabasum-treated (Figure 1E,  $p = 0.0029$ ) but not placebo-treated subjects (Figure 1F,  $p = 0.9576$ ).

## Conclusion:

Anabasum induced clinically relevant molecular responses by modulating inflammatory and fibrotic genes and pathways consistent with the resolution of innate immune signaling. Changes in gene expression in the skin of anabasum-treated subjects were accompanied by improvement in CRISS, mRSS and SDSS. Majority of anabasum improvers had increased baseline inflammatory or fibroproliferative gene expression in skin whereas placebo improvers nearly all had increased normal-like gene expression at baseline. This suggests that the normal-like subset identifies subjects that are more likely to improve spontaneously. This report supports further clinical testing of efficacy of anabasum in dcSSc.

**Figure 1. Effect of anabasum (JBT-101) on gene expression in dcSSc.** Changes in *inflammatory response* pathway in anabasum (A) and placebo (B) arms. Clinical improvers by treatment arm and intrinsic gene expression subset as defined by mRSS (C) and CRISS (D). Changes in SDSS (quantitative surrogate of mRSS) in anabasum (E) and placebo (F) arm. For panels A/B and E/F, p-values are for paired t-test. For panels C and D, p-values are for Fisher's exact test.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Interstitial lung disease (ILD) is a life-threatening complication in SSc. In recent years, distinct genomic and molecular subtypes in SSc-ILD were identified and molecular targeted therapies are now within reach. However, personalized medicine approaches are still lacking since clinical tools for individualized patient stratification are not yet available. Here, we aimed to assess nuclear imaging of key molecular markers of inflammation and/or fibrosis as novel biomarkers for the stage-dependent assessment of ILD in the murine model of bleomycin (BLM)-induced lung fibrosis.

## Methods:

The expression of folate receptor  $\beta$  (FR- $\beta$ ), integrin  $\alpha_v\beta_3$  and somatostatin receptor 2 (SSTR2) were analyzed in lung biopsies from patients with idiopathic pulmonary fibrosis (IPF), SSc-ILD, and healthy subjects as well as from BLM-treated mice and saline-treated controls using immunohistochemistry and RT-PCR (n=4-11). Single Photon Emission Computed Tomography (SPECT) and Positron Emission Tomography (PET) were performed at days 3, 7, and 14 after BLM instillation using the integrin  $\alpha_v\beta_3$ -specific <sup>177</sup>Lu-c(RGDfK)-ligand, the FR- $\beta$ -specific <sup>18</sup>F-Azafool and the SSTR2-specific <sup>177</sup>Lu-DOTA-NOC. Additionally, <sup>18</sup>F-FDG-PET and pulmonary CT scans were performed. The specific lung uptake of the radiotracers over time was assessed by *ex vivo* SPECT or PET/CT scans and quantified by biodistribution studies (n=3-9).

## Results:

Expression of integrin  $\alpha_v\beta_3$ , FR- $\beta$  and SSTR2 was significantly elevated in lung tissues from patients with SSc-ILD and IPF at the mRNA or protein level (p<0.05). Similarly, FR- $\beta$  expression increased time-dependently in lungs of BLM-treated mice, but not of controls at the gene and protein level with highest expression at days 3 or 7, the

inflammatory stages of BLM-induced lung fibrosis ( $p < 0.01$ ). In contrast, expression of integrin  $\alpha_v\beta_3$  and SSTR2 was most strongly upregulated at days 7 and 14 at the protein, but not at the mRNA level in BLM-treated mice, and thus in the inflammatory and in the fibrotic stages ( $p < 0.01$ ).  $^{18}\text{F}$ -FDG-PET and lung CT scans detected changes of glucose metabolism and ILD morphology in BLM-treated mice. However, compared with these routinely employed, yet unspecific imaging techniques, molecular targeted imaging of integrin  $\alpha_v\beta_3$ , FR- $\beta$  and SSTR2 specifically detected ILD and discriminated lung inflammation and/or fibrosis in correspondence with the changes at the tissue level. The specific lung uptake of  $^{177}\text{Lu}$ -c(RGDfK)-ligand,  $^{18}\text{F}$ -Azafol, and  $^{177}\text{Lu}$ -DOTA-NOC as compared to the unspecific uptake of  $^{18}\text{F}$ -FDG in diseased lungs over time was shown by biodistribution studies and *ex vivo* lung scans.

## Conclusion:

Our data suggest that stage-dependent visualization of ILD with radiotracers that target key markers of lung inflammation and/or fibrosis shows promise for clinical application. As opposed to unselective imaging techniques such as  $^{18}\text{F}$ -FDG-PET and lung CT scans, the introduction of specific nuclear imaging biomarkers for individualized management of SSc-ILD patients could represent the first step towards precision medicine in SSc-ILD.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In light of heterogeneous clinical manifestations in systemic sclerosis (SSc), transcriptional analysis of fibrotic tissue and circulating leukocytes may illuminate conserved processes driving inflammation and fibrosis. Prior studies of sorted circulating monocytes and lymphocytes from patients with SSc revealed an interferon gene expression signature. We hypothesized that classical monocytes play an important role in SSc pathogenesis and are responsible for the observed interferon signature in SSc.

**Methods:** Whole blood was obtained from patients enrolled in the Prospective Registry of Early Systemic Sclerosis (PRESS) study, and from age-, sex-, and race-matched healthy controls. The PRESS cohort includes patients with early (< 2 years' duration since first non-Raynaud symptom attributed to SSc) diffuse cutaneous SSc (swollen hands or sclerodactyly PLUS  $\geq 1$  of the following: anti-topoisomerase I or anti-RNA polymerase III serum autoantibodies; proximal skin involvement; tendon friction rubs) who are recruited at participating US scleroderma centers. RNA was isolated from classical monocytes obtained by fluorescence-activated cell sorting and subjected to RNA-seq using Illumina NextSeq 500.

**Results:** We identified approximately 6500 genes that were differentially expressed in two or more patients ( $Z$  score  $> 2$ ) compared to healthy controls –this ensured inclusion of genes that are dysregulated only in a subset of the patient population. Hierarchical clustering of patients based on expression of these 6500 genes revealed three prospective disease subtypes, each with a distinct profile of disease-regulated genes. No significant clinical variables were attributable to any subtype, although there is a trend toward increased mRSS in the third subtype (S3). Subtypes one (S1) and two (S2) were both enriched for genes involved in chemotaxis/motility and regulated cell death; however, S1 was also associated with inflammation and cytokine production while S2 linked to TGF $\beta$  signaling and extracellular matrix remodeling. Genes upregulated in S3 were involved in myeloid activation. Furthermore, 19 previously reported interferon-related genes were significantly ( $p < 0.05$ ) upregulated in the patient cohort compared to controls. By examining interferon-related gene expression in the three subtypes, we observe subtype-specific upregulation in S1 (e.g. TIMP2), S1 and S2 (TIMP1 and OASL), S2 and S3 (IRF7), or S3 (OAS1).

**Conclusion:** We observed that transcriptional profiling of classical monocytes reveals patient subtypes with distinct disease-regulated genes. Interferon-related genes, which are upregulated globally in monocytes from SSc patients, are also upregulated in specific disease subtypes. These insights provide us with a framework through which to interrogate the transcriptional profile of sorted macrophages from skin biopsies and other fibrotic tissues, which will ultimately improve our understanding of systemic inflammation and end-organ fibrosis in SSc.

**Down-Regulation of microRNA-126 in Scleroderma Microvascular Endothelial Cells Enhances the Transition of Endothelial to Mesenchymal Cells (Endo-MT) Induced By TGF $\beta$  through Down-Regulating PI3/Akt Signaling Pathway By Targeting PIK3R2**

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

The accumulation of myofibroblasts in fibrotic tissue plays an important role in the pathogenesis of scleroderma (SSc) fibrosis. Recent studies have shown that myofibroblasts can originate from endothelial cells through Endo-MT. TGF $\beta$  is involved in the generation of tissue fibrosis through multiple pathways including Endo-MT. MicroRNA-126 (miR-126) is expressed mainly in microvascular endothelial cells (MVECs), and has been shown to inhibit TGF $\beta$  induced FoxO3/Smad 4 signaling by direct repression of phosphoinositol-3 kinase regulatory subunit 2 (PIK3R2), a negative regulator of the PIK3/Akt signaling pathway. In this study we investigated the expression levels of miR-126 and TGF $\beta$  Endo-MT responses in SSc and control MVECs.

## **Methods:**

MVECs were isolated from involved SSc skin and matched healthy subjects. The expression of miR-126 was detected by qPCR and in situ hybridization followed by quantitative densitometry analysis. Endo-MT was induced by TGF $\beta$ 1 (10ng/ml) for 48 hours and assessed by expression levels of Mesenchymal Mark genes which include CNN1(Sm-Calp), Collagen type1 (COL1), fibronectin (FN), NOTCH3 and vimentin (VIM) using qPCR. The expression levels of PIK3R2 were examined by qPCR and western analysis. The expression of miR-126 was inhibited in control-MVECs by transfecting cells with hsa-miR-126 inhibitor and enhanced in SSc-MVECs by transfecting cells with hsa-miR-126 Mimic.

## **Results:**

miR-126 expression levels in SSc-MVECs and skin biopsies were significantly down regulated by over 10 fold in SSc-MVECs and 2.32 fold in SSc skin when compared to control. Co-localization of miR-126 and endothelial specific marker CD31 were also observed in skin biopsies. The base line expression of mesenchymal marker genes was similar in SSc and control-MVECs. Addition of TGF $\beta$  to control MVECs resulted in increased mRNA expression levels of FN (1.75 folds  $\pm$  0.12), COL1 (2.11 folds $\pm$ 0.16), SM-calponin (1.65 folds  $\pm$ 0.10). Whereas an enhanced responses to TGF $\beta$  were seen in SSc-MVECs with 3.52 fold  $\pm$  0.32 for FN, 4.63 fold  $\pm$  0.50 for COL1 and 8.66 fold  $\pm$  0.68 for Sm-Calp. Control-MVECs transfected with miR-126 inhibitor repressed miR-126 expression levels by 78% for up to 96 hours as measured by qPCR. This was associated with significant upregulation of mRNA and protein expression levels of PIK3R2 and enhanced TGF $\beta$ -induced COL1, FN and Sm-Calp mRNA expression levels. Whereas overexpression of miR-126 by hsa-miR-126 Mimic transfection to SSc-MVECs resulted in upregulation of miR-126 expression levels and reduced expression of PIK3R2, it also resulted in significantly decreased TGF $\beta$ 1-induced COL1, FN and Sm-Calp mRNA expression.

## **Conclusion:**

The data demonstrate that miR-126 is a crucial regulator of TGF $\beta$ - induced Endo-MT. Down-regulation of microRNA-126 in SSc-MVECs enhances Endo-MT induced by TGF $\beta$  by directly targeting PIK3R2. Inhibition of miR-126 in control-MVECs resulted in increased Endo-MT responses to TGF $\beta$ , whereas forced expression of miR-126 in SSc-MVECs reduced TGF $\beta$ -Endo-MT responses. Upregulation of MiR-126 expression may be an effective therapeutic strategy in SSc and other fibrosis diseases in which Endo-MT plays a pathogenetic role.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Interstitial lung disease (ILD) is the leading cause of death in systemic sclerosis (SSc). Sirtuin1 (SIRT1) is a deacetylase with known anti-inflammatory and anti-fibrotic activity; the role of SIRT1 in SSc-ILD is unclear.

### **Methods:**

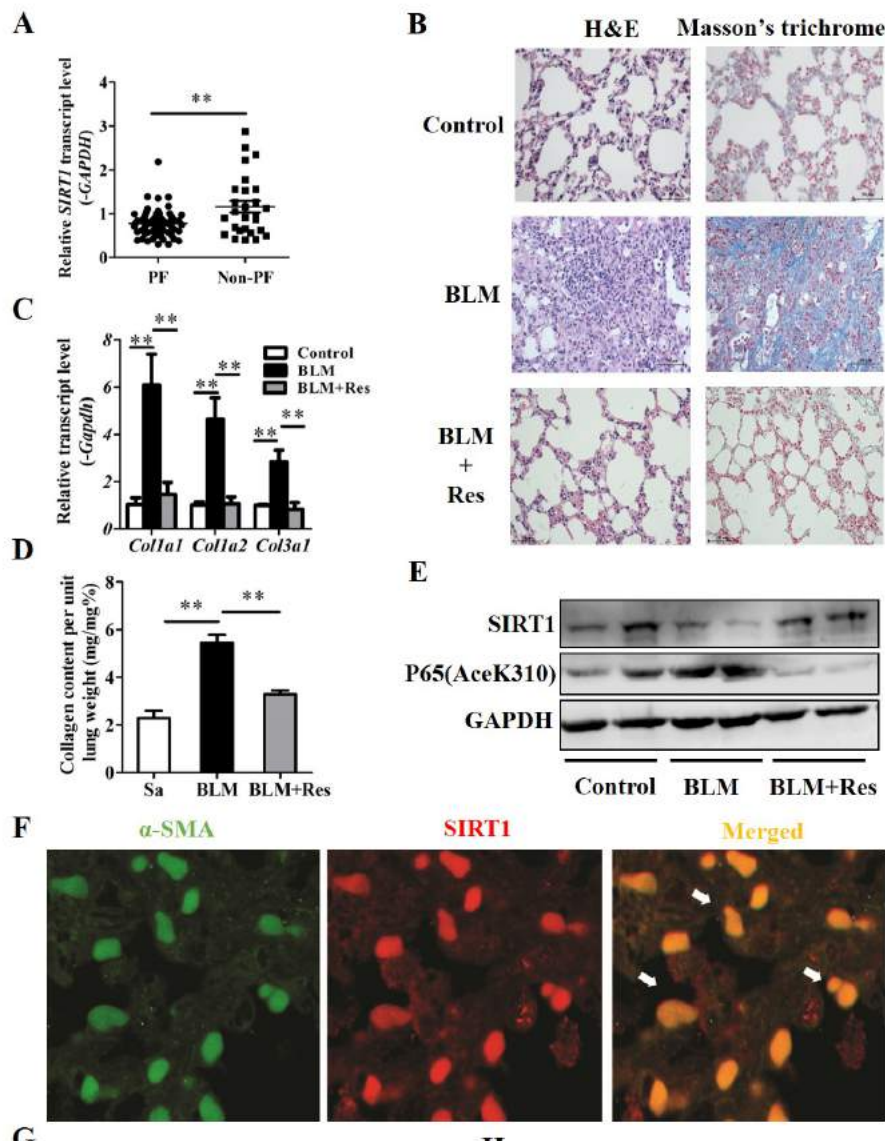

Total RNA was extracted from peripheral blood mononuclear cells (PBMCs) isolated from SSc patients (n=86). In *in vivo* studies, mice were administered intratracheal bleomycin (BLM) (2.5 U/kg) to induce pulmonary fibrosis. Resveratrol (Res, 25 mg/kg) was fed daily from the third day before BLM instillation for the Prevention Study or 10 days post-BLM for the Treatment Study. Histological analysis was performed to assess lung inflammation/fibrosis. Immunofluorescence staining was used to identify the cell type expressing SIRT1. For *in vitro* studies, human lung fibroblasts were treated with TNF- $\alpha$  (10 ng/ml)/TGF- $\beta$  (10 ng/ml) with or without SIRT1 activator (Res, 50  $\mu$ M)/plasmid or inhibitor (Nicotinamide, 20 mM) /siRNA. Real-time PCR or Western blotting was used to measure mRNA or protein level (including SIRT1, P65 acetylation, Smad3 and mTOR phosphorylation).

## Results:

The expression of SIRT1 in PBMCs of SSc patients with ILD (n=59) was significantly lower than that in SSc patients without ILD (n=27) ( $0.77 \pm 0.04$  vs.  $1.16 \pm 0.13$ , Fig.1A). Further analysis found the decreased expression of SIRT1 was correlated with dcSSc and the presence of ATA. In the *in vivo* studies, SIRT1 activation with Res reduced lung inflammation and fibrosis when it was administered either as prevention or as therapy, as evidencing by histological analysis (Fig.1B), decreased inflammatory gene expression and cytokine production as well as collagen production (mRNA level: *Col1a1* reduced 72.5%, *Col1a2* reduced 76.7% and *Col3a1* reduced 72.3%; collagen content reduced 39.8%. Fig.1C-D). SIRT1 was expressed in  $\alpha$ -SMA<sup>+</sup> myofibroblasts in mouse lung tissue, indicating an inhibitory effect of SIRT1 on myofibroblasts (Fig.1F). Moreover, SIRT1 activation or overexpression inhibited TNF- $\alpha$ -induced inflammatory responses *in vitro* while depletion of SIRT1 in fibroblasts enhanced inflammation; and these effects were related to the decrease or increase in the acetylation of NF- $\kappa$ B, respectively (Fig.1G). These results were consistent with data of our *in vivo* experiments that Res treatment increased SIRT1 expression level and activity and blunted NF- $\kappa$ B signaling (Fig.1E). In addition, SIRT1 activation or exogenous overexpression inhibited collagen production *in vitro* (Fig.1H) via inactivation of TGF- $\beta$ /Smad3 and mTOR signaling.

## Conclusion:

SIRT1 loss contributed to BLM induced pulmonary fibrosis and may play a role in SSc-ILD, while SIRT1 activation was effective for both the early (inflammatory) and late (fibrotic) stages of BLM induced fibrosis. Thus, SIRT1 could be a promising therapeutic target in the treatment of SSc-ILD.

**Figure 1. Involvement of SIRT1 loss in pulmonary fibrosis and SIRT1 increase/ activation attenuated pulmonary fibrosis.** **A**, Relative PBMC mRNA level of *SIRT1* in SSc patients with ILD vs. without ( $0.77 \pm 0.04$  vs.  $1.16 \pm 0.13$ ,  $p=0.0006$ ). **B**, Effect of Resveratrol on Bleomycin-induced lung inflammation and fibrosis. Magnification  $400\times$ . **C**, Relative collagen mRNA levels in lungs from control, Bleomycin or Bleomycin plus Resveratrol-treated mice. **D**, Lung collagen content determined by Sircol assay. **E**, SIRT1 protein and p65 acetylation (lysine310) were measured by Western blotting. **F**, Immunofluorescence of lung tissue showed co-localization of SIRT1 and  $\alpha$ -SMA. Magnification  $400\times$ . **G**, Human lung fibroblasts (MRC-5) were transiently transfected with SIRT1 plasmid or empty vector for 48 h. SIRT1 protein abundance and the acetylation of p65 were determined by Western blot analysis. **H**, Levels of SIRT1,  $\alpha$ -SMA and type I collagen protein were analyzed by Western blotting in TGF- $\beta$ -stimulated MRC-5 cells with or without Resveratrol (Res, 50  $\mu$ M) treatment. mRNA levels were normalized to GAPDH/Gapdh.  $**p<0.001$ . Mean  $\pm$  SEM;  $n=4-6$  mice per group. BLM, bleomycin; Res, Resveratrol; H&E, hematoxylin and eosin.

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The gastro-intestinal tract (GIT) is frequently involved in Systemic sclerosis (SSc). Perturbation in the gut microbiota may affect the body well-being and function and intestinal disbiosis has been associated with a number of autoimmune diseases, including SSc. To date no attempt has been made to characterize the functional consequences of intestinal disbiosis in SSc and autoimmunity.

### **Methods:**

A total of 59 SSc patients and 28 healthy controls (HCs) were included. Intestinal microbiota was studied via 16s-RNA sequencing on stool samples; in parallel, plasma metabolites were analyzed by high-performance liquid chromatography coupled to electrospray ionisation and quadrupole time-of-flight mass spectrometry (HPLC-MS-ESI-QTOF). Interaction models capable of explaining the disease were built via data mining algorithms with internal validation (20 x 10-fold cross-validation) and feature selection. Microbic and metabolic results were correlated by means of Spearman's rho and results corrected via 100K-fold permutation testing. The severity of intestinal symptoms was assessed via the UCLA GIT questionnaire.

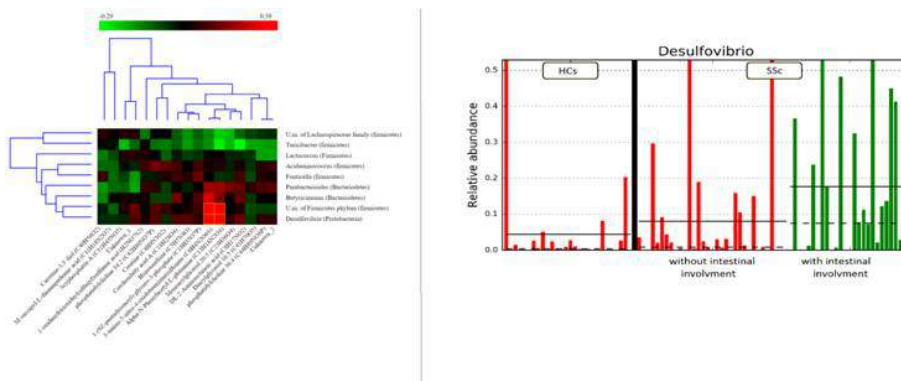

### **Results:**

random forest model showed that HCs and SSc patients differ at the genus taxonomic rank (AUROC =  $0.706 \pm 0.023$ ). Model reduction identified 9 genera relevant to the disease status (AUROC =  $0.711 \pm 0.042$ ). A naïve Bayes algorithm found a unique metabolic pattern associated with SSc (AUROC =  $0.707 \pm 0.029$ ) with just 17 relevant metabolites after feature selection (AUROC =  $0.744 \pm 0.029$ ). Cross correlation between the 9 genera and the 17 metabolites (Figure, left panel) found significant interactions between *desulfovibrio* and alpha-N-Phenylacetyl-L-glutamine ( $\rho = 0.389$ ,  $p_c = 0.03$ ) and 2,4-dinitrobenzenesulfonic acid ( $\rho = 0.39$ ,  $p_c = 0.029$ ). Gut microbiota of SSc patients was capable of explaining  $12.7 \pm 4.1\%$  of the variance of GIT scores. A model of 10 bacteria could jointly discriminate HCs and SSc patients with or without intestinal involvement (weighted AUROC =  $0.679 \pm 0.021$ ). Among these bacteria, *desulfovibrio* was significantly associated with the presence of intestinal involvement (figure, right panel).

### **Conclusion:**

SSc patients present unique microbic and metabolic fingerprints. SSc-related disbiosis is characterized by an increase in pro-inflammatory microbial groups which compete with commensal bacteria. This microbiomic shift may promote the accumulation of metabolites, including a sulfonate compound which has direct pro-inflammatory and immuno-modulating properties and that may serve as electron acceptor in anaerobic respiration of *desulfovibrio* strains. The toxic end-product of *desulfovibrio* respiratory metabolism (hydrogen sulfide) may contribute to intestinal damage and altered motility.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Scleroderma renal crisis (SRC), characterised by accelerated hypertension and acute kidney injury, is a life-threatening complication of systemic sclerosis (SSc). Most SSc cases have a disease-specific circulating antibody, including the anti Scl-70, anti-centromere and anti RNA polymerase III (ARA) antibodies. Previous studies confirm ARA as a powerful serological predictor of SRC, and cases of SRC more than 5 years after the diagnosis of SSc are rare. We developed an innovative approach to identify genetic susceptibility loci for SRC, comparing ARA positive patients with and without the occurrence of SRC.

### Methods:

From a well-characterised SSc cohort (n=415), we selected 100 ARA+ patients with more than 5 years of follow-up data. 50 had a history of SRC and 50 had not developed SRC. All cases were of northern European ancestry. Cases were genotyped using the Illumina Human Omni-express chip. Quality control checks were performed in PLINK (Hardy-Weinberg equilibrium  $p < 0.001$ ; genotyping rate  $> 90\%$ ). Based on the results of logistic regression analysis, ten SNPs were put forward for validation in a separate US cohort of 256 ARA+ patients (40 SRC+), using ThermoFisher TaqMan genotyping probes. Immunohistochemistry (IHC) was performed on SRC biopsy samples to identify proteins associated with our genes of interest.

## Results:

After quality control checks, 641,489 SNPs were analysed in the first cohort. In logistic regression analysis of our initial cohort, the SNPs within genes and gene regions most strongly associated with SRC were for POU2F1 ( $p = 4.12 \times 10^{-5}$ ), CTNND2 ( $p = 2.92 \times 10^{-5}$ ), HECW2 ( $p = 2.71 \times 10^{-5}$ ), GRIA3 ( $p = 2.16 \times 10^{-5}$ ) and GPATCH2L ( $p = 2.06 \times 10^{-5}$ ). The SNP within the GPATCH2L region was also significantly associated with SRC in our validation cohort ( $p = 0.025$ ). GPATCH2L polymorphisms have been associated with essential hypertension in previous GWAS analysis.

Polymorphisms in the CTNND2 gene have been demonstrated to be associated with pulmonary arterial hypertension, another vascular complication of SSc, in previous studies. We performed IHC for this protein on 8 renal biopsy samples from confirmed cases of SRC and 8 normal human kidney controls (see figure). Tubular epithelial staining was present in cases and controls. Glomerular staining was markedly increased in the SRC cases compared with controls, with 5 cases showing significant staining in this compartment compared with 0 controls (Fisher's Exact  $p = 0.026$ ).

## Conclusion:

A novel autoantibody-based extreme phenotype method identifies risk alleles for SRC within a rare disease cohort. Using genetic and histological validation methods we identify CTNND2 and GPATCH2L as candidates for investigation of SRC aetiopathogenesis.

Anti-CTNND2 antibody staining of renal biopsies:  
A. SRC B. Normal kidney control C. IgG control.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hedgehog acyltransferase (Hhat) catalyzes the attachment of the fatty acid palmitate onto Sonic Hedgehog (Shh), a modification essential for Shh signaling activity. Palmitoylation of Shh by Hhat is required for multimerization of Shh proteins to large signaling complexes, which is particularly required for exocrine Shh signaling. Hhat has been identified as a potential target for cancer therapy especially in malignancies characterized by Shh overexpression. Hedgehog signaling activates fibroblasts *in vitro* and *in vivo* and plays a prominent role in tissue fibrosis in Systemic sclerosis (SSc). The aim of this study was to evaluate the role of Hhat in the pathogenesis of SSc.

**Methods:** Expression of Hhat in human and murine skin was analyzed by immunohistochemistry and immunofluorescence. The effects of small interfering RNA (siRNA) induced knockdown of Hhat on TGF $\beta$  signaling were analyzed in cultured human fibroblasts *in vitro* and in the mouse models of bleomycin-induced skin fibrosis and DNA topoisomerase I (topo I) induced fibrosis *in vivo*. The anti-fibrotic effect on skin was assessed by hydroxyproline assay, alpha smooth muscle cells quantification and measuring the dermal thickness.

**Results:** Increased expression of Hhat was detected by immunohistochemistry in skin biopsies from SSc patients as compared to healthy volunteers, with a particularly strong expression in fibroblasts. The expression of Hhat was induced in fibroblasts *in vitro* and *in vivo* in a TGF $\beta$ -dependent manner. Stimulation with TGF $\beta$  increased the mRNA and protein levels of Hhat in cultured fibroblasts. Moreover, TGF- $\beta$  receptor I (TBR)-induced dermal fibrosis upregulated Hhat expression, whereas treatment with a specific inhibitor of T $\beta$ RI prevented the induction of Hhat in bleomycin-induced skin fibrosis. The TGF $\beta$ -induced upregulation of Hhat required Smad3 and knockdown of Smad3 prevented the stimulatory effects of TGF $\beta$  on Hhat expression. We also demonstrate that the TGF $\beta$ -dependent induction of Hhat is sufficient to promote hedgehog signaling with enhanced activity in reporter assays and increased transcription of hedgehog target genes such as *Ptch-1* and *Ptch-2*. Vice versa, inactivation of Hhat ameliorates the stimulatory effects of TGF $\beta$  on fibroblasts. Knockdown of Hhat by siRNA reduced collagen release and myofibroblast differentiation in TGF $\beta$ -stimulated fibroblasts. Moreover, inactivation of Hhat also ameliorated experimental dermal fibrosis. Knockdown of Hhat by injection of Hhat siRNA /atelocollagen complexes into the skin effectively ameliorated dermal thickening, reduced myofibroblast counts and decreased collagen content in bleomycin-induced fibrosis. Dermal fibrosis induced by challenge of mice with topoisomerase I was also ameliorated by knockdown of Hhat.

**Conclusion:** We demonstrate that Hhat is regulated in SSc in a TGF $\beta$ -dependent manner. Hhat in turn promotes hedgehog signaling, which directly contributes to the stimulatory effects of TGF $\beta$  on fibroblasts. Inactivation of Hhat reduces TGF $\beta$ -dependent fibroblast activation and ameliorates experimental fibrosis. These data provide first evidence that targeting Hhat may be a novel target for the treatment of fibrosis.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Recent data have implemented reactive oxygen species (ROS) in the etiology of interstitial lung disease (ILD) in systemic sclerosis. Recent data from bleomycin mice have suggested a role of large-scale somatically acquired mutations in mitochondrial DNA (mtDNA) and consecutive respiratory chain dysfunction as a trigger of ROS formation and lung fibrosis.

### **Methods:**

Lung biopsies from patients with idiopathic interstitial pneumonitis and systemic sclerosis (n=31) were analyzed for mitochondrial functions and compared with biopsies from 13 healthy controls (HC). From 17 patients we had simultaneous biopsies from the upper and lower lung.

### **Results:**

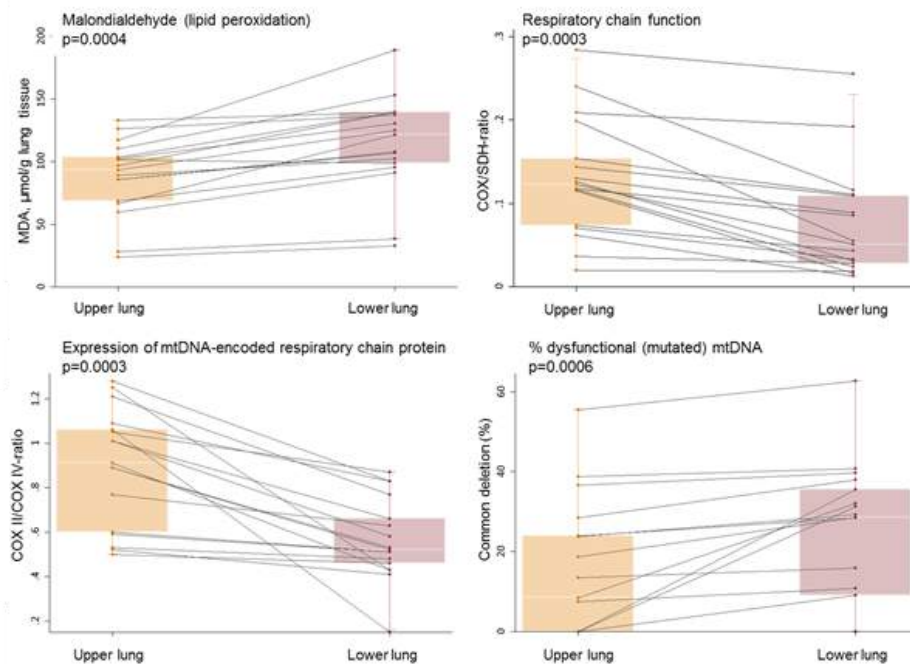

Malondialdehyde as a marker of ROS formation was increased in ILD ( $p=0.007$ ). The median proportion of mtDNA containing the pathogenic common deletion was 22.5% in ILD patients, compared to 0% in HC. This translated into a 3.8-fold diminishment of mtDNA-encoded cytochrome c-oxidase (COX2), but not nucleus-encoded (COX4) respiratory chain subunits in ILD compared to controls ( $p<0.0001$ ) and a 33% diminishment of mtDNA-encoded cytochrome c-oxidase activity ( $p=0.001$  vs. controls). In all patients, the more fibrotic lower lungs had significantly more malondialdehyde ( $p=0.0004$ ), mtDNA deletions ( $p=0.0006$ ), and cytochrome c-oxidase dysfunction ( $p=0.0003$ ) than the less-fibrotic upper lung counterparts. Conversely, lower lungs had significantly less ( $p=0.0003$ ) mtDNA-encoded COX2 subunits in comparison to non-mtDNA-encoded COX4 subunits (Figure). There was no association of any mitochondrial parameter with smoking status or age, and no difference between biopsies from patients with systemic sclerosis and non-specific interstitial pneumonitis.

### **Conclusion:**

Our data support a role of mtDNA-mutations and consecutive respiratory chain dysfunction as a trigger and perpetuator of ROS formation in both, idiopathic interstitial pneumonitis and ILD of patients with systemic sclerosis.

**Figure.** Mitochondrial parameters in lung biopsies simultaneously obtained in both, upper and lower lungs, of patients with fibrotic lungs. Lines connect values of the same patient.

## TGF $\beta$ -Dependent Upregulation of XIAP Fosters Fibroblast Activation and Tissue Fibrosis By Promoting Canonical Wnt Signaling

**Christina Bergmann**<sup>1</sup>, Ludwig Hallenberger<sup>1</sup>, Amelie Brandt<sup>1</sup>, Benita Merlevede<sup>1</sup>, Clara Dees<sup>2</sup>, Chih-Wei Chen<sup>3</sup>, Christian Beyer<sup>1</sup>, Oliver Distler<sup>4</sup>, Georg Schett<sup>5</sup> and Jörg Distler<sup>6</sup>, <sup>1</sup>Department of Internal Medicine 3 and Institute for Clinical Immunology, Friedrich-Alexander-University of Erlangen-Nuremberg and University Hospital Erlangen, Erlangen, Germany, <sup>2</sup>Department of Internal Medicine 3 and Institute for Clinical Immunology,, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany, <sup>3</sup>Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Erlangen, Germany, Erlangen, Germany, <sup>4</sup>Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, <sup>5</sup>Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Erlangen, Germany., Erlangen, Germany, <sup>6</sup>Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Aberrant activation of profibrotic pathways is a key feature of systemic sclerosis (SSc). Extensive evidence characterizes TGF $\beta$ - and canonical WNT-signaling as key drivers of fibroblast activation. The crosstalk between those pathways, however, remains largely enigmatic. A better understanding of the interplay of different profibrotic pathways may be key to the development of effective targeted therapies.

XIAP (X-linked inhibitor of apoptosis protein) is an ubiquitously expressed member of the IAP protein family with important functions in tissue turnover and cell motility. XIAP was recently described as positive regulator of canonical Wnt signaling in embryogenesis. The aim of this study is to characterize the role of XIAP in fibrotic disease in SSc and to analyze the effects XIAP inhibition *in vitro* and *in vivo*.

### **Methods:**

XIAP-expression was analyzed by qPCR, IF and Western blot. XIAP was targeted pharmacologically with Embelin. The activation of the canonical Wnt pathway was assessed by analyses of Wnt target genes and by TOPflash/FOPflash luciferase reporter assay. The interaction of XIAP with TLE3 was analyzed by co-immunoprecipitation. *In vivo*, XIAP inhibition was analyzed in three different models of fibrosis.

### **Results:**

The expression of XIAP is increased in the skin of SSc patients compared to matched healthy individuals with a particularly prominent staining in fibroblasts. In addition, XIAP-expression is increased in experimental fibrosis models. The induction of XIAP in SSc in experimental fibrosis was mimicked by TGF $\beta$  in cultured fibroblasts. Moreover, targeted inhibition of TGF $\beta$  signaling prevented the induction of XIAP in experimental fibrosis. The upregulation of XIAP augmented the stimulatory effects of recombinant WNT proteins on fibroblasts. Inhibition of XIAP reduced the Wnt1-induced activation of normal dermal fibroblasts with reduced expression of myofibroblast markers and decreased collagen release. In addition, XIAP inhibition reverted the activated fibroblast phenotype in SSc fibroblasts. Inhibition of XIAP also demonstrated potent antifibrotic effects in experimental fibrosis in bleomycin-induced dermal fibrosis, in Topoisomerase-I-induced (TopoI) dermal and pulmonary fibrosis and in Wnt10b-transgenic mice. The inhibitory effects of Embelin on fibroblast activation were associated with impaired canonical WNT signaling with reduced TCF-dependent transcription in reporter assays and reduced levels of WNT target genes such as *Axin2* in cultured fibroblasts and in fibrotic tissues. Mechanistically, we demonstrate that XIAP interacts with the endogenous antagonist TLE3 to regulate canonical WNT signaling.

### **Conclusion:**

XIAP is upregulated in SSc fibroblasts in a TGF $\beta$ -dependent manner and promotes fibroblast activation by fostering canonical WNT signaling. XIAP thus serves to integrate TGF $\beta$ - and WNT signaling as two core pathways in SSc. XIAP-inhibition demonstrated antifibrotic effects *in vitro* and *in vivo* in non-toxic concentrations. Inhibition of XIAP may thus be a novel approach to target aberrant canonical WNT signaling in fibrotic diseases.

## Skin Commensal Bacteria Might Affect Wound Repair in SSc By Preventing Fibroblast Activation and By Provoking Chronic Inflammatory Reaction

Masaya Yokota<sup>1</sup>, Janine Schniering<sup>1</sup>, Oliver Distler<sup>2</sup> and Britta Maurer<sup>3</sup>, <sup>1</sup>Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Switzerland, Zurich, Switzerland, <sup>2</sup>Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, <sup>3</sup>Department of Rheumatology, Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Chronic digital ulcers (DU) due to peripheral microangiopathy are a major complication in systemic sclerosis (SSc). Chronic wounds are often enriched in bacteria without overt clinical signs of infection and inflammation. Current treatment comprises vasodilation, local disinfection, mechanical wound cleaning and antibiotics. Data on the role of skin commensal bacteria on wound repair are conflicting with both beneficial and detrimental effects. A recent study provided evidence for previously unknown direct interactions between skin bacteria, dermal cells and extracellular matrix proteins even in normal skin. Therefore, we investigated whether skin commensal bacteria might be involved in wound healing responses in SSc.

**Methods:** Wound swabs of SSc patients with DU (n=36) were subjected to microbial analysis. The presence of skin commensals in human skin sections processed under sterile conditions was examined by Gram stain and IF. Dermal fibroblasts isolated from healthy controls (HC; n=4) and patients with diffuse cutaneous SSc (dcSSc; n=3) were stimulated with heat-killed *S. epidermidis* (HKSE) and *S. aureus* (HKSA). The concentration of IL-6, IL-8 and MCP-1 (monocyte chemoattractant protein-1) in cell culture supernatants was measured by ELISA. Expression of collagen type 1 (COL1A1) and alpha-smooth muscle actin ( $\alpha$ -SMA) was evaluated by qPCR, ELISA and Western blotting. Expression of stress fibers and  $\alpha$ -SMA was examined by phalloidin staining and IF. Cell proliferation was evaluated with a colorimetric assay. Contractility was analyzed by collagen gel contraction assay.

**Results:** Superficial and deep wound swabs (n=60) showed that 65% of wounds were primarily colonized with skin commensals including SA and SE. Gram-stain and IF of skin sections of HC and dcSSc (n=3 each) revealed Gram-positive bacteria in the deeper dermis and the epidermis. Upon HKSE/A stimulation, the secretion of IL-6 and IL-8 was increased in both HC and dcSSc fibroblasts, but MCP-1 was increased in dcSSc only. In HKSE/A-stimulated dermal fibroblasts, expression of  $\alpha$ -SMA on mRNA and protein level was decreased in both HC (0.53/0.56-fold, p<0.05 each) and dcSSc (0.62/0.60-fold, p=0.06 each) whereas expression of COL1A1 was not changed. Moreover, simultaneous stimulation with HKSE and TGF- $\beta$  revealed an inhibitory effect of HKSE on TGF- $\beta$ -induced  $\alpha$ -SMA expression on mRNA and protein level in both HC (0.69-fold, p=0.06) and dcSSc (0.49-fold, p=0.06). HKSE-stimulated fibroblasts also showed increased proliferation in dcSSc, but less in HC (1.85-fold vs. 1.27-fold, p=0.20). Accordingly, the expression of stress fibers was more abundant in dcSSc compared to HC. The contractility of

dermal fibroblasts upon HKSE stimulation was decreased in both HC and dcSSc (relative gel area to untreated cells; 116% vs. 114%).

**Conclusion:** Skin commensals inhibit the activation of dermal fibroblasts, but provoke strong inflammatory responses and increase proliferation. Our data indicate that bacterial exposure of dermal fibroblasts might result in chronic activation of innate immune responses with detrimental effects on wound repair.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Animal studies indicated bone marrow-derived cells as a source of pathological myofibroblasts in fibrosis of multiple organ including lungs, heart, skin and kidney. Monocytes are implicated in the pathogenesis of systemic sclerosis (SSc), however the detailed role of specific monocyte subsets in multi-organ fibrogenesis in SSc remains unclear. The aim of this study was to determine the contribution of circulating monocytes in the onset and progression of multi-organ fibrosis in SSc.

### Methods:

Endomyocardial biopsies (n=10 each) from SSc patients and healthy controls were screened by immunohistochemistry. CD14<sup>+</sup> monocytes isolated from peripheral blood of SSc patients and healthy donors were differentiated towards a myofibroblast phenotype by stimulation with TGF- $\beta$ 1, IL-4, IL-10 and IL-13 [10ng/ml each]. In addition, CD14<sup>+</sup> monocytes were co-cultured in 2D and 3D models with dermal fibroblasts originated from SSc patients or healthy subjects, or with adult healthy cardiac fibroblasts. TGF- $\beta$  signalling was blocked by SD208 (TGFB1), A83-01 (SMAD2) and (5Z)-7-Oxozeaenol (TAK1) inhibitors. Gene expression and protein secretion were evaluated by qPCR, Western blot, protein array, immunofluorescence and ELISA.

**Results:** The myocardium, lungs and skin of SSc patients revealed an extended collagen I deposition and the presence of CD14<sup>+</sup> elongated cells in the fibrotic tissue. Stimulated monocytes acquired a myofibroblast-like phenotype with increased expression of collagen I (p<0.0001), fibronectin (p<0.05), and  $\alpha$  smooth muscle actin ( $\alpha$ -SMA) in comparison to untreated cells. Similarly, CD14<sup>+</sup> monocytes exposed to dermal or cardiac fibroblasts acquired spindle shape and expressed higher levels of profibrotic genes. The process of monocyte-to-myofibroblast differentiation employed both canonical and non-canonical TGF- $\beta$  signalling pathways. Blocking of the TGF- $\beta$  receptor I and canonical SMAD-dependent pathway resulted in the abrogation of collagen I secretion by monocytes (p=0.002). In contrast, TAK1 inhibitor decreased fibronectin expression, while having no effect on collagen I expression. CD14<sup>+</sup> monocytes from SSc patients were characterised by higher secretion of CXCL10 (p<0.001), which was significantly decreased after cytokine stimulation (p<0.001). Additionally, a tendency towards higher secretion of CCL20, CCL22, Leukemia Inhibitory Factor and Neurotrophin-3 was observed for SSc monocytes.

**Conclusion:** Here we demonstrated the capability of peripheral blood monocytes to differentiate towards the functional myofibroblast phenotype, designating these cells as one of the potential sources of pathological tissue myofibroblasts in SSc. Additionally, these cells sustained pro-fibrotic cytokines secretion, highlighting their important regulatory functions in the fibrogenesis in SSc.

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** *Fli1* deficiency, a potential predisposing factor of systemic sclerosis (SSc), induces SSc-like phenotypes in dermal fibroblasts, endothelial cells, keratinocytes, and macrophages. However, it is still unclear how *Fli1* deficiency affects the phenotype of platelets. Hence we aim to investigate the biological effect of *Fli1*-deficient platelets *in vivo* by utilizing megakaryocyte/platelet-specific *Fli1* (*Fli1* MPcKO) knockout mice (*Fli1*<sup>flox/flox</sup>; *Pf4*-Cre).

**Methods:** Wound was generated by 8-mm punch device on the back skin of mice. Vascular structure was visualized by FITC-dextran injection. mRNA expression of target genes and collagen contents were assessed by quantitative reverse transcription PCR and hydroxyproline assay, respectively.

**Results:** Since *Fli1* MPcKO mice macroscopically appeared normal, wound healing experiments were applied. Wound closure was accelerated in *Fli1* MPcKO mice at Day 2 compared with control littermates, although there was no significant difference in the overall duration of wound closure between these two strains. When the expression profile of tissue remodeling-related factors was evaluated, interferon- $\gamma$  expression was significantly decreased in *Fli1* MPcKO mice on Day 2. In the epithelized skin, collagen contents and the number of newly formed vasculature were much greater in *Fli1* MPcKO mice than in control littermates. In addition, the number of  $\alpha$ -smooth muscle actin-positive fusiform cells was increased in *Fli1* MPcKO mice. Importantly, a mild skin injury, such as subcutaneous injection of PBS, induced extensive tissue fibrosis in *Fli1* MPcKO mice.

**Conclusion:** Megakaryocyte/platelet-specific *Fli1* deficiency promotes wound healing through the induction of myofibroblast differentiation and angiogenesis at least partially due to the downregulation of interferon- $\gamma$ . The activation of platelets with altered phenotype may contribute to the development of pathological skin fibrosis, including SSc.

## **TGF- $\beta$ -Induced Tissue Fibrosis in TBR1caCol1Cre Transgenic Mice Is Abrogated By the Second Generation Tyrosine Kinase Inhibitor SKI-606 (Bosutinib)**

**Peter J. Wermuth** and Sergio A. Jimenez, Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Bosutinib (SKI-606), a second-generation tyrosine kinase inhibitor that blocks the activity of the BCR-ABL kinase responsible for Philadelphia chromosome positive chronic myeloid leukemias, also inhibits the activity of the Src family of nine non-receptor tyrosine kinases. Activation of Src kinases via phosphorylation of their catalytic regions can be stimulated by PDGF and TGF- $\beta$  resulting in strong profibrotic cascade signaling. Furthermore, Src kinases are major regulators of the profibrotic activity of focal adhesion kinase (FAK), which promotes the differentiation of quiescent fibroblasts to activated myofibroblasts. Thus, the purpose of this study was to test the antifibrotic activity of Bosutinib *in vivo* on TGF- $\beta$  induced skin and pulmonary fibrosis employing the well-characterized TBRI<sup>ca</sup>Col1Cre transgenic mouse model of tissue fibrosis.

**Methods:** TBRI<sup>ca</sup>Col1Cre transgenic mice with a tamoxifen-inducible constitutively active TGF $\beta$  receptor 1 allele in cells expressing Cre recombinase under the control of the Col1a promoter were implanted with subdermal osmotic pumps dispensing either 2.5, 5.0 or 10.0 mg/kg/day of Bosutinib or with pumps dispensing saline as a control for 8 weeks following tamoxifen activation of constitutive TBRI expression. Skin sections and lungs isolated from control and Bosutinib-treated animals (n=6 per group) were analyzed by histopathology following hematoxylin/eosin and Masson's trichrome staining, measurement of tissue hydroxyproline content, and by evaluation of the expression of genes associated with tissue fibrosis, and myofibroblast differentiation and activation.

**Results:** Constitutive TGF $\beta$ -1 signaling in Col1a-expressing cells induced severe cutaneous and pulmonary tissue fibrosis in untreated mice. In contrast to mice receiving saline-containing pumps, a strong decrease in TGF- $\beta$ -induced collagen deposition in the dermis and lungs was observed in response to Bosutinib treatment by histopathological analysis of these tissues. Quantitative assays for collagen content showed that control untreated mice displayed a 1.5 fold increase in hydroxyproline levels in skin and a 1.9 fold increase in the lung following tamoxifen administration. These increases were abrogated in a dose-dependent manner in mice receiving Bosutinib. The marked increase in expression of genes associated with tissue fibrosis and with transdifferentiation and activation of myofibroblasts observed following tamoxifen administration was also abrogated in a dose-dependent fashion in response to Bosutinib.

**Conclusion:** Cutaneous and pulmonary fibrosis induced in mice carrying an inducible constitutively active TBRI receptor transgene was abrogated in a dose-related manner following administration of the tyrosine kinase inhibitor Bosutinib as assessed by histopathology, measurements of tissue hydroxyproline content, and analysis of expression levels of profibrotic and myofibroblast activation-associated genes. These results demonstrate that the BCR/ABL and Src kinase inhibitor Bosutinib may be a potential therapeutic agent for tissue fibrosis in SSc and other fibroproliferative disorders.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Long noncoding RNAs (lncRNAs) are a class of transcripts regulating gene expression. We have recently identified a novel lncRNA, H19X, which was upregulated in the skin of patients with SSc. We also demonstrated that TGF $\beta$  regulates H19X expression and is a key mediator of myofibroblast development and extracellular matrix synthesis. Here we aimed to assess whether (1) H19X is a general regulator of TGF $\beta$ -driven fibrotic diseases and (2) H19X upregulation in SSc dermal fibroblasts is anti-apoptotic and pro-proliferative thereby favoring fibrosis.

**Methods:** To study the function of H19X in apoptosis and proliferation of dermal fibroblasts we silenced H19X using locked nucleic acid oligonucleotides (LNA GapmeRs) followed by microarray analysis, qPCR, BrdU cell proliferation assay, Caspase 3/7 apoptosis assay and scratch assay. Cells were treated with 10 ng/ml TGF $\beta$ . Lung tissues were obtained from patients with SSc and idiopathic pulmonary fibrosis (IPF) undergoing organ transplantation, and from healthy controls (HC). Fibrotic gut tissues were obtained from patients with Crohn's disease undergoing gut resection. Expression of H19X was analyzed by qPCR.

**Results:** H19X expression was significantly increased in SSc interstitial lung disease and IPF patients versus HC (n=11 each, p<0.05). A significant H19X overexpression was also detected in fibrotic gut tissue from patients with Crohn's disease versus control (n=10 and 4 respectively; p<0.05). Furthermore, H19X was found to be increased in physiological wound healing tissue versus HC samples (n=11 and 8 respectively; p<0.05). Upregulation of H19X was paralleled by an upregulation of PAI-1, indicating TGF $\beta$  pathway activation in these tissues.

H19X knockdown followed by microarray analysis (n=5) showed that “FAS signaling pathway”, “cyclins and cell cycle regulation”, “regulation of cell cycle progression by Plk3”, and “free radical induced apoptosis” were among the pathways with the highest number of significantly enriched genes (p<0.005). Apoptosis markers like BCL2, IGFBP3 and FAF1 (n=5, p<0.05) were significantly downregulated in H19X-silenced fibroblasts. These results indicated that targeting H19X might have a pro-apoptotic effect on fibroblasts. Functional studies of apoptosis confirmed enhanced fibroblast apoptosis after H19X silencing and TGF $\beta$  stimulation (n=5, p<0.05). In addition to decreased apoptosis, increased fibroblast proliferation might also favor fibrosis. Indeed, H19X downregulation led to reduced fibroblast proliferation as measured by BrdU assay (n=5, p<0.05). Scratch assays (n=5) showed that H19X knockdown decreased TGF $\beta$  reduced wound healing.

**Conclusion:** H19X supports TGF $\beta$ -driven fibrosis by inducing proliferation and reducing apoptosis of fibroblasts. These effects are not limited to SSc, but also apply to a wider range of fibrotic diseases. Our results highlight the role of the novel lncRNA H19X as an important profibrotic mediator in TGF $\beta$  mediated processes.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Anti-nuclear antibodies (ANA) are present in approximately 90% of sera from systemic sclerosis (SSc) patients and play an important role in the diagnosis and prognosis of SSc. Recently, a novel autoantibody targeting the Cytoskeleton-Like **B**icaudal **D** Protein Homolog **2** (BICD2) has been described in SSc. Studies to date on BICD2 show a significant overlap with anti-centromere antibodies. We aimed to analyze the B-cell epitopes of anti-BICD2 antibodies and to study the clinical associations of this antibody in SSc.

### **Methods:**

Serum pools with (n=2) and without (n=1) anti-BICD2 antibodies, assayed by an addressable laser bead-based immunoassay (ALBIA) with recombinant BICD2, were used for epitope discovery with peptide arrays covering the

full-length amino acid sequences of CENP-A, CENP-B and BICD2. The identified candidate sequences were then utilized to synthesize synthetic, biotinylated, soluble peptides for ALBIA. The peptides were tested on five groups of patients [BICD2(+)/CENP-A(+) (n=15), BICD2(-)/CENP-A(+) (n=10), BICD2(+)/CENP-A(-) (n=5), BICD2(-)/CENP-A(-) (n=10), and healthy individuals (n=7)]. A total of 451 well characterized SSc patients were used to establish sero-clinical associations.

## Results:

Epitope mapping revealed a serine/proline-rich nonapeptide SPSPGSSLP comprising amino acids 606–614 localized to a non-coiled coil domain of BICD2 as the core epitope. This epitope had 29.6% identity and 55.6% similarity to a peptide in CENP-A (TGTPGPSRRGP) within which GPSRR was previously identified as a key CENP-A epitope. Among the five groups of patients tested for reactivity with the BICD2 derived epitope, the highest reactivity was observed in BICD2(+)/CENP-A(+) sera followed by the BICD2(-)/CENP-A(+) group. In the BICD2(+)/CENP-A(-) group, one patient showed moderate reactivity. No reactivity was observed in the BICD2(-)/CENP-A(-) group or in HI. Next, we compared the reactivity to recombinant BICD2 (aa 606-821) with the BICD2 and the CENP-A derived peptides using spearman correlation. We observed a significant correlation between antibodies to the BICD2 and the CENP-A derived peptide ( $r=0.70$ ;  $p<0.0001$ ), to a lesser extent between CENP-A peptide and recombinant BICD2 ( $r=0.42$ ;  $p<0.0001$ ) and between recombinant BICD2 and the BICD2 peptide ( $r=0.59$ ;  $p<0.0001$ ). Inhibition experiments demonstrated that the anti-CENP-A peptide reactivity could be abolished with the BICD2 derived peptide and *vice versa*. However, some sera also had reactivity to the recombinant BICD2 protein that could not be inhibited by CENP-A peptide, indicating that there might be additional BICD2 specific epitopes. Anti-BICD2 antibody positive SSc patients (without other SSc specific antibodies) showed significantly higher prevalence of myositis ( $p=0.003$ ) and less bacterial overgrowth ( $p=0.043$ ).

## Conclusion:

In the present study, we first describe a linear B-cell epitope on BICD2 which shows sequence homology and cross-reactivity with an epitope on CENP-A, which explains the strong serological overlap between anti-BICD2 and anti-centromere antibodies. Anti-BICD2 antibodies may have additional diagnostic and prognostic properties beyond currently known SSc-specific antibodies.

Nuclear Magnetic Resonance based Metabolomics Study Identifies Highly Discriminatory Metabolites in 87 Systemic Sclerosis Patients

**Background/Purpose:**

Proton based Nuclear Magnetic Resonance ( $^1\text{H}$  NMR) can identify concentration of hundreds of small molecules in body fluids. A hypothesis-free approach was used to analyze metabolic perturbations in sera of Systemic Sclerosis (SSc) to identify potential biomarkers of the disease.

**Methods:**

Sera from 87 patients meeting ACR 1980 criteria for Systemic Sclerosis, and 40 age and sex similar controls, was analyzed using  $^1\text{H}$  NMR spectroscopy coupled with multivariate statistical analysis.

**Results:**

There was clear distinction between SSc and healthy controls on Partial Least Square-Discriminate Analysis (PLS-DA) [ $R^2 = 0.98$ ]. Several metabolites of discriminatory relevance were identified, and further evaluated using analysis of variance (ANOVA) and Receiver Operator Curve (ROC) analysis. Methylamine, nitrosodimethylamine (NDMA), citrate and malonate were 4 metabolites that had maximum area under curve ( $\text{AUC} > 0.95$ ) in distinguishing SSc from controls [Figure 2]. Methylamine and NDMA were uniformly elevated almost exclusively in SSc patients. Figure 3 shows Orthogonal PLS-DA of limited versus diffuse disease; or patients with or without interstitial lung disease (ILD).

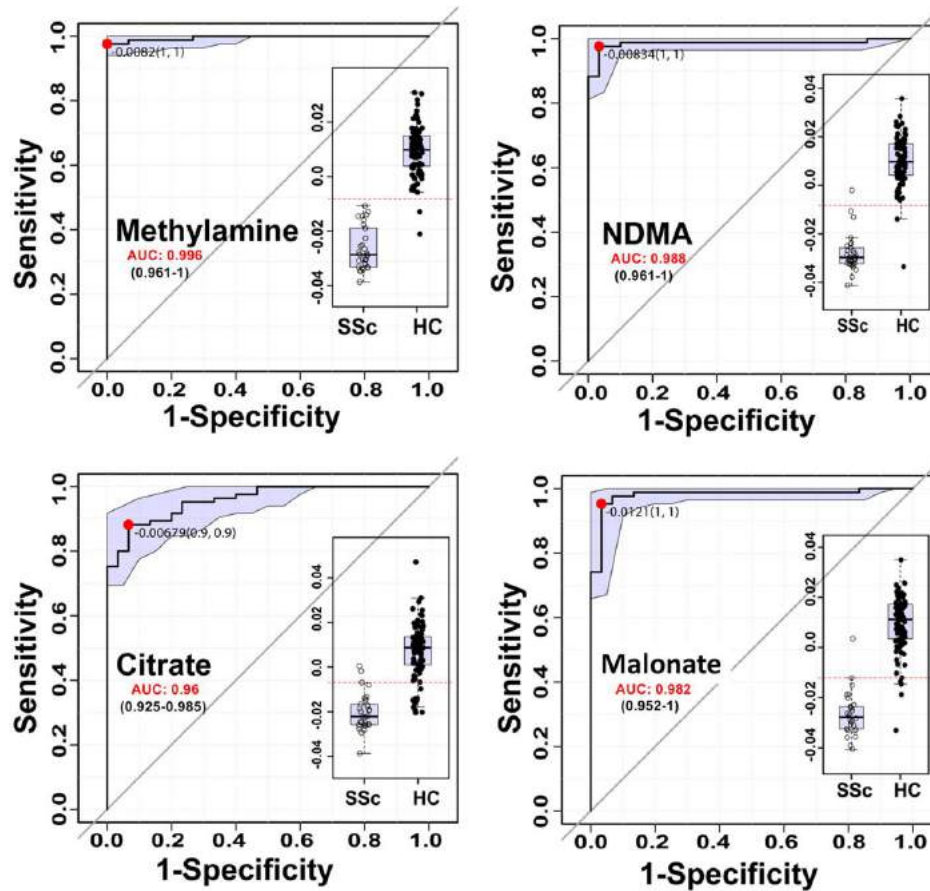

**Conclusion:**

$^1\text{H}$  NMR based metabolomics identified metabolites that have high discriminate value for SSc. The potential of these molecules as biomarkers, or their possible roles in disease pathogenesis need to be explored.

Figure 1: Representative 800 MHz  $^1\text{H}$  NMR spectra d(0.75-4.65) of serum from SSc and from controls

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The anti-aging deacetylase enzymes SIRT1 and SIRT3 show potent anti-fibrotic activity, and their expression and function are markedly deregulated in patients with systemic sclerosis (SSc). SIRT activity is exquisitely regulated by cellular metabolism and requires the ubiquitous cofactor nicotinamide adenine dinucleotide (NAD<sup>+</sup>). Cellular NAD<sup>+</sup> levels must be maintained by balanced biosynthesis and degradation, the latter mediated by NADase enzyme CD38. Elevated CD38 levels in aging contribute to decline of NAD<sup>+</sup> levels, resulting

in mitochondrial dysfunction and metabolic abnormalities. We hypothesize that SSc-associated SIRT dysfunction might be linked to elevated CD38 expression and NAD<sup>+</sup> catabolism, contributing to persistent fibroblast activation and unresolving fibrosis.

**Methods:** CD38 expression was measured in skin biopsies. Expression and regulation of CD38, collagen, αSMA and p300, and Smad and SIRT and FAK activation were examined in normal and SSc fibroblasts treated with CD38 inhibitors and nicotinamide riboside (NR), an orally bioavailable NAD<sup>+</sup> precursor.

**Results:** SSc skin biopsies showed elevated CD38 mRNA expression. A CD38 coexpression module of 194 genes was able to differentiate SSc from control biopsies. Levels of CD38 in the skin correlated with MRSS. Moreover, explanted SSc skin fibroblasts showed 3-fold increased CD38 expression compared to age-matched healthy controls. Recombinant human CD38 caused suppression of SIRT deacetylase activity, while augmenting TGF-β-induced fibrotic responses. In contrast, CD38 inhibition or genetic ablation resulted in reduced fibrotic responses. Supplementation of fibroblasts with NR increased cellular NAD<sup>+</sup> level, and mitigated fibrotic responses induced by TGF-β. Moreover, NR supplementation markedly reduced Smad-dependent transcriptional activity via suppression of lysine acetylation mediated through coactivator p300. Modulation of age-dependent spontaneous and inducible fibrotic responses in mice by ablation of CD38 or NR supplementation, both of which augment NAD<sup>+</sup> levels, is under investigation.

**Conclusion:** NAD<sup>+</sup> levels appear to be critical in determining the amplitude/duration of tissue fibrosis through mechanisms that involve the SIRT deacetylases, and declining NAD<sup>+</sup> plays a role in age-related tissue fibrosis. Elevated expression of the NAD<sup>+</sup>-consuming enzyme CD38 in lesional tissues in SSc is likely contributes to NAD<sup>+</sup> depletion, impaired SIRT function and unchecked fibroblast activation in these patients. Boosting NAD<sup>+</sup> levels using novel selective pharmacological CD38 inhibitors, NR supplementation, or augmented NAD<sup>+</sup> biosynthesis via the salvage pathways, are promising novel approaches to the treatment of SSc.

## **Insulin-like Growth Factor Binding Protein-4 Exerts Anti-Fibrotic Effects and Its Levels Are Reduced in SSc-Associated Lung Fibrosis**

Yunyun Su<sup>1</sup>, Stanley Hoffman<sup>2</sup> and Carol A. Feghali-Bostwick<sup>3</sup>, <sup>1</sup>Medicine, Division of Rheumatology and Immunology, Medical University of South Carolina, Charleston, SC, <sup>2</sup>Division of Rheumatology and Immunology, Medical University of South Carolina, Charleston, SC, <sup>3</sup>Division of Rheumatology and Immunology, Division of Rheumatology and Immunology, Medical University of South Carolina, Charleston, SC, United States, Charleston, SC

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Background/Purpose:**

The Insulin-like growth factor (IGF) system plays an important role in cellular growth, proliferation, differentiation, apoptosis and transformation; IGF binding proteins (IGFBP) exert cell and tissue-specific effects in an IGF-dependent and independent manner. For example, IGFBP-3 and -5 are increased in dermal and pulmonary fibrosis associated with systemic sclerosis (SSc), induce extracellular matrix (ECM) production, and promote fibrosis *in vitro* and *in vivo*. We sought to examine the effects of another member of the IGFBP family, IGFBP-4, on ECM production and fibrosis.

**Methods:**

Primary human fibroblasts were cultured from lung tissues of patients with SSc-associated lung fibrosis and from normal donors. Lung fibrosis was induced in C57BL/6J mice using bleomycin. Quantitative real time PCR was used to measure mRNAs levels in lung tissues of patients with SSc and normal donors. Immunoblotting was used to examine proteins levels. Suppression of IGFBP-4 in primary fibroblasts using gene-specific siRNA was used to examine the effects of loss of function. A replication-deficient adenovirus expressing IGFBP-4 was used for gain of function studies.

**Results:**

IGFBP-4 mRNA levels were significantly decreased in pulmonary fibroblasts of patients with SSc compared to those of normal donors. Production of ECM components including fibronectin, collagen and tenascin C, was significantly reduced by endogenous expression of IGFBP-4 and exogenous recombinant IGFBP-4 in a dose-dependent manner. The anti-fibrotic activity of IGFBP-4 also blocked TGF $\beta$ -induced ECM production. Expression of IGFBP-4 inhibited ECM production *ex vivo* in human lung and skin in organ culture. *In vivo*, IGFBP-4 reduced bleomycin-induced collagen production and histologic evidence of fibrosis. Silencing IGFBP-4 expression to mimic levels observed in SSc lung fibroblasts resulted in increased ECM production. Gene expression array analysis of IGFBP-4-treated primary human lung fibroblasts showed a reduction in the levels of the chemokine receptor CXCR4 and the pro-fibrotic factor CTGF. IGFBP-4 also reduced CXCR4 and CTGF protein levels.

**Conclusion:**

IGFBP-4 exerts anti-fibrotic effects by reducing the levels of the chemokine receptor CXCR4 and the levels of the pro-fibrotic factor CTGF. Thus reduced IGFBP-4 levels in SSc lung fibroblasts may contribute to the fibrotic phenotype via loss of IGFBP-4 anti-fibrotic activity. Our findings suggest that IGFBP-4 is an anti-fibrotic factor whose effects can be harnessed for the development of therapies to reduce fibrosis in SSc.

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Systemic sclerosis (SSc) is a connective tissue disease of unknown etiology. Using human skin as an *ex vivo* organ model of fibrosis is an attractive tool to examine mechanisms underlying fibrosis and assess the potential effect of anti-fibrotic therapies. We have previously shown that a single injection of TGF- $\beta$  induced dermal fibrosis in human skin *ex vivo*. In this study, we examined the effect of Bleomycin (BLM).

**Methods:** Human skin was stimulated with BLM using two different methods: injection and immersion. For the injection method, normal human skin was obtained from residual tissue following plastic surgery. Subcutaneous fat tissue was removed and skin tissue was cut into 1.5 cm x 1.5 cm sections. Skin tissues were injected intradermally with a total volume of 100  $\mu$ l of 1 $\times$ PBS: BLM (1 or 10 mU/ml) or 1 $\times$  PBS as a vehicle control. Skin samples were cultured in an air-liquid interface with the epidermal side up. The culture medium was replaced after 72h. After 7 days, skin tissue corresponding to an area with 8-mm diameter centered around the injection site was harvested with a disposable 3 mm punch. For the immersion method, normal human skin was cut with a disposable 3 mm punch, and punches were cultured in medium containing BLM (1 or 10 mU/ml) or 1 $\times$  PBS as a vehicle control. Skin tissues were harvested after 48 hours or 7 days post-treatment for real-time PCR and hydroxyproline assay, respectively.

**Results:** BLM significantly increased hydroxyproline levels and dermal thickness in a dose-dependent manner 7 days after injection. BLM had a similar effect on skin punches immersed in media for the same duration. The increase in hydroxyproline was paralleled by increased dermal thickness and Masson Trichrome staining. qRT-PCR analysis revealed that the expression levels of fibrosis-related genes, collagen 1A1, fibronectin, CTGF, and TGF $\beta$ 1, were significantly increased in BLM-treated skin compared with control skin.

## Conclusion:

Our findings show that BLM induces fibrosis in human skin and higher doses of BLM are more effective at inducing significant increases in collagen content, expression of fibrosis-associated genes, and dermal thickness. Moreover, immersing skin in medium containing BLM is more effective at inducing dermal fibrosis than intradermal BLM injections. BLM treatment using the immersion method may be an attractive tool for the functional analysis of skin fibrosis in human skin in organ culture, providing a tool with direct relevance to human fibrotic skin disease.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

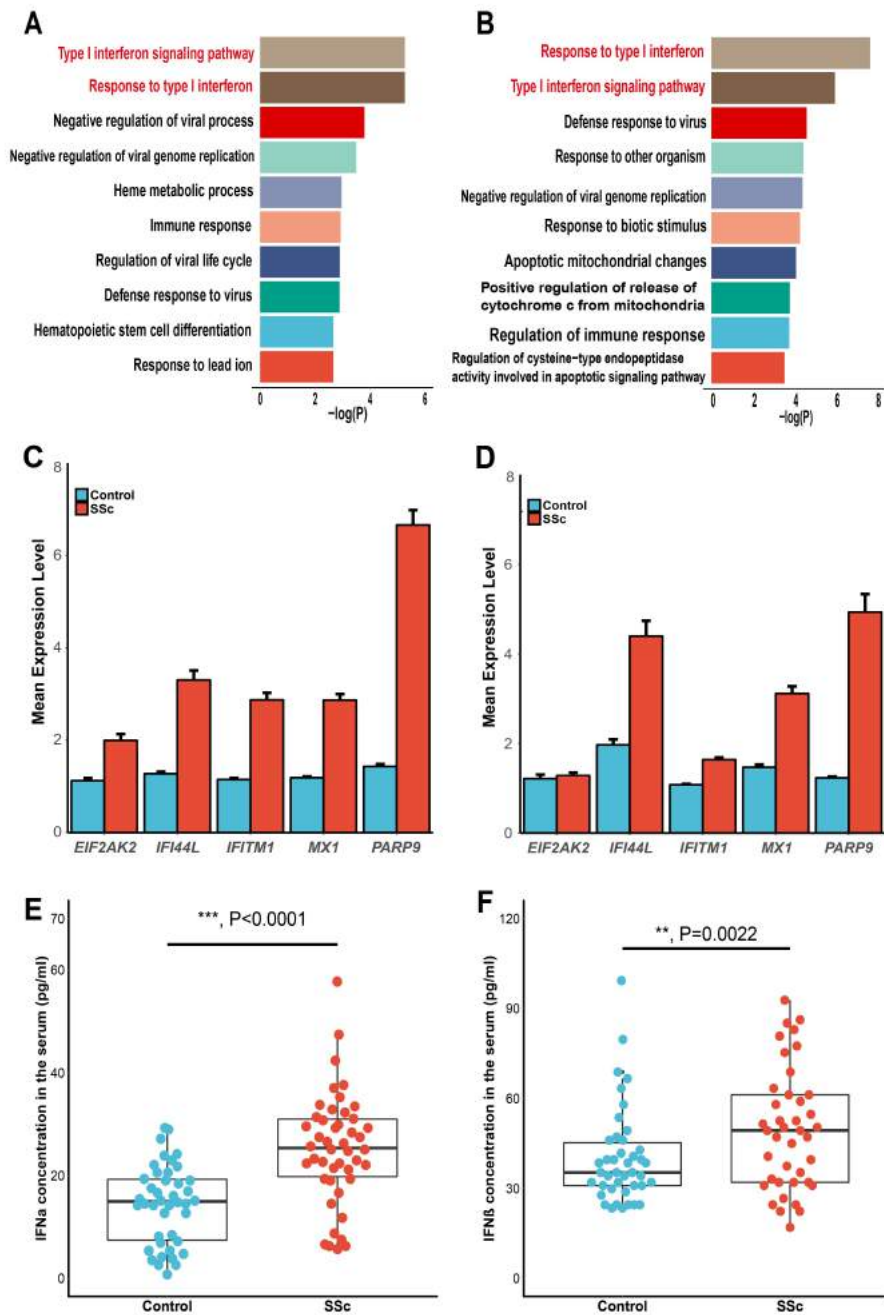

**Background/Purpose:** Systemic sclerosis (SSc) is a complex systemic autoimmune disease caused by complicated interaction between genetic, epigenetic and environmental risk factors. Evidence showed epigenetic modifications, including DNA methylation, play an important part in the regulation of gene expression and the pathogenesis of a large number of autoimmune diseases such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). However, variations of DNA methylation in SSc have not been comprehensively investigated, especially for subtypes of the immune cells separately. To examine the methylation status in CD4<sup>+</sup> and CD8<sup>+</sup> T cells of SSc, we performed genome-wide DNA methylation microarray study in Chinese SSc patients and matched controls.

**Methods:** CD4<sup>+</sup> and CD8<sup>+</sup> T cells were obtained from SSc patients (n =24) and from age- and sex-matched healthy controls (n =24). All patients met the 2013 criteria for SSc established by the ACR/EULAR. Illumina Infinium HumanMethylation450 BeadChip was utilized for DNA quantification. The significantly differentially methylated sites (DMS) were validated using targeted bisulfite sequencing in an extended cohort consisting of 43 SSc patients and 41 controls (including 12 cases and 12 controls from the initial group). The expression profiles of the differentially methylated genes were measured by RT-PCR. In addition, the serum level of type I interferon-alpha/beta in SSc patients and controls was also quantified by ELISA.

**Results:** In the discovery stage, type I interferon (IFN)-associated genes were significantly hypomethylated and type I IFN signaling pathway was most significantly enriched in both CD4<sup>+</sup> and CD8<sup>+</sup> T cells of SSc patients compared to controls, suggesting an abnormality of the type I IFN pathway in SSc patients (Fig 1-A, B). In the second stage, the significantly hypomethylation status of five type I IFN-associated genes (*EIF2AK2*, *IFI44L*, *IFITM1*, *MX1*, *PARP9*) was validated (by targeted bisulfite sequencing). Moreover, the upregulation of these genes was also shown in both CD4<sup>+</sup> CD8<sup>+</sup> T cells of SSc patients (by RT-PCR) (Fig 1-C, D). Further, the serum levels of type I IFN-alpha/beta were also elevated in SSc patients over controls (by ELISA) (Fig 1-E, F). The significant correlations between gene expression, DNA methylation and serum level of type I IFN-alpha/beta were also confirmed, though showing different patterns between CD4<sup>+</sup> and CD8<sup>+</sup> T cells.

**Conclusion:** Hypomethylation and upregulation of type I IFN-associated genes were observed in both CD4<sup>+</sup> and CD8<sup>+</sup> T cells of SSc patients. The serum level of type I IFN-alpha/beta was elevated in SSc patients and correlated significantly with the methylation and expression of its associated genes. It is suggested that hypomethylation of type I IFN-associated genes may be involved in the pathogenesis of SSc.

**Figure 1** Higher serum level of type I IFN α/β along with the altered methylation and expression of IFN-associated genes in SSc patients. Panel A-B represents the 10 most significantly enriched gene pathways in CD4<sup>+</sup> and CD8<sup>+</sup> T cells based on the hypomethylated DMRs, respectively. Panel C-D represents the gene expression profiles of the five interferon-associated genes in CD4<sup>+</sup> and CD8<sup>+</sup> T cells, respectively. Panel E-F represents the serum levels of type I IFN α/β in SSc and control samples.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Localized scleroderma (LS) has both inflammatory and fibrotic components contributing to its effect on the skin and underlying tissue. The understanding of the pathophysiology driving this process is limited, though there is evidence supporting T cell involvement in both systemic sclerosis (SSc), its related disease, and LS. Recent studies in SSc have focused on skin homing T cells in the circulating peripheral blood which may be directly contributing to disease progression and skin inflammation with subsequent fibrosis (1). We aim to study this same concept in LS and investigate skin homing cells that may contribute to skin inflammation and reflect activity at lesion sites.

## Methods:

PBMCs were isolated from 10 pediatric LS subjects with paired active/inactive blood specimens (20 samples total), and were analyzed at rest and after PMA/ionomycin stimulation. Flow cytometry was performed to characterize T cells using antibodies for T cell subsets (CD3, CD4, CD8, CD28), T memory cells (CD45RO), T trafficking and adhesion (CXCR3, CCR4, CCR6, CD62L), and skin homing cells (CCR10 and CLA). Selected intracellular T<sub>H</sub>1 and T<sub>H</sub>2 cytokines (IFN- $\gamma$ , TNF- $\alpha$ , and IL-13) were also measured. Cell populations were compared between LS active and inactive disease states using paired Wilcoxon Signed-Ranks Test.

## Results:

The proportion of CD4<sup>+</sup> (T<sub>H</sub>) and CD8<sup>+</sup> (T<sub>C</sub>) T cells among total PBMC were not significantly different between active and inactive disease states. However, there was a significant increase in the proportion of skin homing CCR10<sup>+</sup> T<sub>C</sub> (Fig.1A) in samples collected during active disease. In addition, both CCR10<sup>+</sup> T<sub>C</sub> and CCR10<sup>+</sup> T<sub>H</sub> cells produced inflammatory cytokine populations, IFN- $\gamma$ , that were significantly increased in the active disease state compared to the inactive disease state (Fig 1B).

## Conclusion:

This is one of the first studies to examine circulating cell immunophenotypes in pediatric-onset localized scleroderma, with emphasis on examining the association of T skin homing cell subtypes with disease activity. These findings suggest increased skin homing (CCR10<sup>+</sup>) of inflammatory cytokine producing subpopulations of T<sub>C</sub> and T<sub>H</sub> cells in active disease (Fig 1). In adult SSc, IL-13<sup>+</sup>, and not IFN- $\gamma$ <sup>+</sup>, CD8<sup>+</sup>CCR10<sup>+</sup> cells appear to be the skin homing cell type that propagates disease (1), emphasizing possible biological differences in scleroderma phenotypes; more inflammatory, T<sub>H</sub>1/T<sub>C</sub>1 phenotype in LS and the more fibrotic, T<sub>H</sub>2/T<sub>C</sub>2 phenotype, in SSc.

Determining active disease status in patients with scleroderma may allow targeting of key immune components to prevent damage and disfigurement.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :**

Morphea, also known as localized scleroderma, encompasses a group of idiopathic sclerotic skin diseases. MicroRNAs (miRNAs) are a large family of highly conserved noncoding genes that play a fundamental role in biological processes by controlling protein expression by binding to protein-coding messenger RNAs, resulting in translational repression or mRNA degradation [REF]. Besides intracellularly, miRNAs are also found in several biological fluids, including serum. We aimed to investigate serum levels of miRNAs in morphea. **Methods:**

Serum was collected from patients affected by morphea. Disease subtypes were classified according to Zulian and Laxer, with the addition of Eosinophilic Fasciitis (EF) as a distinct subtype. Two independent cohorts of patients were established. A discovery cohort, consisting of 22 morphea patients and 14 healthy controls (HCs), was used for miRNA profiling in serum, by TaqMan Real-time quantitative Polymerase Chain Reaction (RT-qPCR) on an OpenArray, which allowed simultaneous analysis of 758 miRNAs. The mean relative fold change (FC) was calculated for the group of morphea patients and HC, and compared between the two groups via Student's t-test. A selection of 8 miRNAs were found to be differentially expressed between the patients and healthy controls ( $P < 0.05$ ; selection based on lowest P-values). These targets were selected for technical and biological validation, by miRNA-specific TaqMan RT-qPCR, in an independent cohort of 29 morphea patients and 9 HCs. **Results :**

The mean FC of the individual miRNAs from the discovery cohort are displayed in figure 1. Technical validation was achieved for all selected 8 miRNAs; supporting the array results. Serum levels of miR-30d and miR-423-5p were significantly elevated in patients, compared to healthy controls in both the discovery cohort [miR-30d: mean FC 1.4,  $P$  0.003; miR-423-5p: mean FC 1.659,  $p$  0.001] and the independent validation cohort [miR-30d: mean FC 2.28,  $P < 0.001$ ; miR-423-5p: mean FC 1.500,  $p$  0.0103] (Figure 2). The remaining 6 targets did not show significantly altered levels in the validation cohort. Most interesting, both miR-30d and miR-423-5p were especially increased in patients affected by more severe subtypes, such as linear morphea and eosinophilic fasciitis.

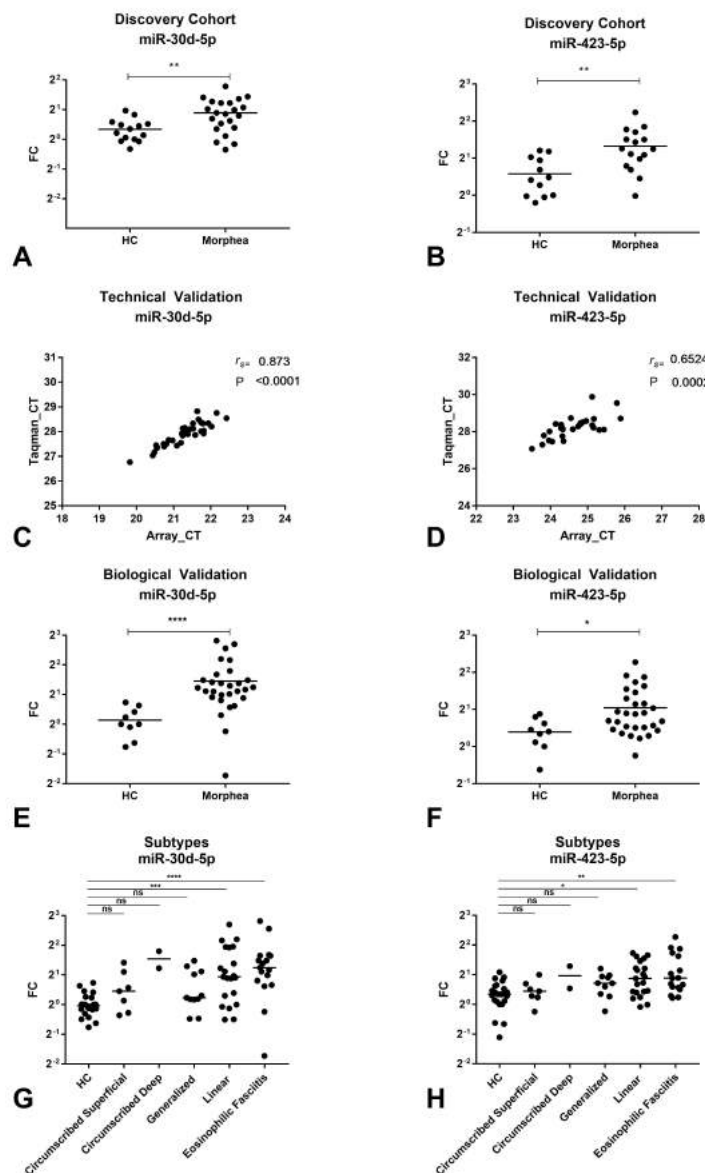

**Conclusion :**

Serum levels of miR-30d and miR-423-5p were significantly higher in morphea compared to healthy controls in 2 independent cohorts. In addition, more severe subtypes such as linear morphea and EF showed increased levels of these 2 targets, as compared to milder subtypes.

**Figure 1** Volcano Plot of discovery cohort. Mean fold changes (FC) of morphea group (n=22) versus healthy control samples (n=14). Mean FC are displayed on X-axis and corresponding P-values, on a log<sub>10</sub>-scale, are displayed on the y-axis. Targets depicted in red were selected for replication in an independent cohort of morphea patients.

**Figure 2. A & B)** Array results of the discovery cohort (morphea n=22; HC, n=14) for miR-30d and miR423-5p. **C & D)** Technical validation of miR-30d and miR423-5p; correlation between array Ct-values and Ct-values from miRNA-specific TaqMan RT-qPCR in same serum samples. **E & F)** Biological replication in an independent cohort (morphea n=29, HC n=9). **G & H)** Serum levels in different disease subtypes after merging the discovery and replication cohort.

## IL-6 Mediates Activation of Macrophages in Patients with Systemic Sclerosis

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Activated macrophages (MØs) have been implicated as regulators of fibrosis in patients with systemic sclerosis (SSc), and we have shown that MØs from SSc patients are activated under basal conditions, releasing elevated levels of IL-6, CCL2, and TGF- $\beta$ . Because MØs are plastic and may be modulated by local micro-environmental factors, it is likely that activation of MØs in SSc is regulated by the interplay of many factors. In this study, we identify a critical role for IL-6 in the regulation of human SSc MØ activation, and provide evidence for a molecular mechanism by which MØ and fibroblast-derived IL-6 supports the pro-fibrotic immuno-phenotype of these cells.

## Methods:

Plasma and PBMCs were obtained from whole blood of 6 SSc patients (disease duration <5 years) and from 5 healthy age and gender-matched control subjects following informed written consent. CD14<sup>+</sup> monocytes were isolated from PBMCs using magnetic bead selection, and were cultured with either autologous or allogeneic plasma for 7 days to differentiate the cells into MØs. To demonstrate specificity of IL-6-mediated effects on SSc MØ activation, MØ differentiation was performed in indicated cultures in the presence of anti-IL-6 neutralizing antibody or isotype control. For reciprocal activation studies, SSc MØs were co-cultured with fibroblasts using Transwells. RNA expression in MØs and fibroblasts was analyzed using genome-wide analysis and RT-PCR, and protein expression and secretion were monitored using flow cytometry and by ELISA.

**Results:** Healthy age and gender-matched control MØs differentiated in plasma from SSc patients recapitulate the immuno-phenotype of MØs derived from SSc patients. Intriguingly, when MØs from SSc patients are differentiated in healthy control plasma, the pro-fibrotic activation profile of these cells is abrogated, suggesting SSc MØ activation arises from soluble factors present in the local micro-environment. Analysis of signaling pathway activation in SSc MØs demonstrates constitutive phosphorylation of STAT3 in these cells, consistent with IL-6 activation. Differentiation of SSc MØs in the presence of anti-IL-6 neutralizing antibody results in loss of basal MØ activation—i.e. loss of CCL2 and IL-6 production. To identify the potential mechanism by which IL-6 mediates SSc MØ activation, we assessed expression of regulators of fibrosis and immune activation. We now show that IL-6 upregulates expression of IL-4Ra in SSc MØs, and that stimulation with IL-4/IL-13 results in enhanced production of CCL2 in an IL-6-dependent manner.

**Conclusion:** IL-6 mediates pro-fibrotic activation of SSc MØs, as blockade of IL-6 abrogates production of CCL2 and IL-6 in these cells. Our results suggest a potential mechanism by which IL-6 mediates these effects, as IL-6 upregulates expression of IL-4Ra, and stimulation of SSc MØs with IL-4/IL-13 results in enhanced CCL2 expression in an IL-6-dependent manner. These results implicate a role for IL-6 in the induction of the pro-fibrotic

activation profile of SSc MØs, and suggest targeted intervention against the signaling pathways that underlie MØ activation may be therapeutically beneficial in ameliorating SSc disease.

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is an auto-immune disorder leading to destructive tissue fibrosis. Abnormal responses of SSc T cells to lipid antigens and low molecular weight phospho-antigens have been observed but not extensively explored. We determined how exposure to cardiolipin, a lipid auto antigen, and zoledronate (zol), an inducer of intracellular phospho-antigens (e.g isopentenyl pyrophosphate), affect cytokine secretion and activation of SSc T cells. We focused on non-conventional innate gd T cells since these: 1. Are oligoclonally expanded in SSc 2. infiltrate damaged organs, and 3. include lipid reactive Vdelta (d)1<sup>+</sup> and phospho-antigen reactive Vgamma (g)9<sup>+</sup> gammadelta (gd) T cells.

**Methods:** Peripheral blood mononuclear cells (PBMC) were isolated by ficoll hypaque density centrifugation from 12 SSc patients (SScp) and 13 healthy controls (HC). Expression of CD25, a marker of activation, on Vg9<sup>+</sup>, Vd1<sup>+</sup> and total CD3<sup>+</sup> T cells in PBMC cultured for at 2X10<sup>6</sup> cells/ml 96 hour in RPMI-1640 tissue culture medium supplemented with 10% fetal bovine serum, penicillin streptomycin, and glutamine, (TCM) containing 100 international units of interleukin (IL)-2 and added reagents as indicated, was measured by flow cytometry - as were cell surface binding of CD1d tetramers, and effects of monoclonal antibody (mAb) mediated blockade of CD1d. Intracellular production of anti fibrotic [interferon (IFN) g] and pro fibrotic [IL- 4] cytokines was measured by flow cytometry after overnight incubation of PBMC in medium with added reagents.

**Results:** Secretion of IFN $\gamma$  (but not IL-4) was suppressed in SSc relative to HC CD3<sup>+</sup> and Vg9<sup>+</sup>, but not Vd1<sup>+</sup> T cells cultured in TCM alone. However, both Vd1<sup>+</sup> and Vg9<sup>+</sup> T cell IFN $\gamma$  secretion in SSc were relatively reduced by adding cardiolipin (2.5 mg/ml), which, by contrast, augmented IL-4<sup>+</sup> SSc Vg9<sup>+</sup> T cells. Moreover, IFN $\gamma$ <sup>+</sup> SSc Vg9<sup>+</sup> T cells were relatively suppressed by zol (2mMol), consistent with subset restricted specific effects of cognate antigens. Conversely, %CD25<sup>+</sup> CD3<sup>+</sup> and Vd1<sup>+</sup>, and to a lesser degree Vg9<sup>+</sup> T cells, were elevated significantly in 96 h cultured SSc PBMC compared to HC. Moreover, cardiolipin and zol respectively, significantly suppressed SSc but not HC %CD25<sup>+</sup> Vg9<sup>+</sup> and Vd1<sup>+</sup> (but not total %CD25<sup>+</sup> CD3<sup>+</sup>) T cells suggesting antigen driven cross inhibitory effects by these gd T cell subsets. These effects could be partially reversed by culture with zol + cardiolipin, whereas this combination more strongly amplified both CD25<sup>+</sup> gd T cell subsets of HC. Importantly, SSc and HC Vd1<sup>+</sup> T cells > Vd1<sup>-</sup> T cells were highly reactive with lipid presenting CD1d – tetramers. Furthermore, a CD1d - blocking mAb decreased the zol + cardiolipin enhancement of %CD25<sup>+</sup> Vd1<sup>+</sup> T cells in SSc PBMC cultures

**Conclusion:** SSc patient Vd1<sup>+</sup> and Vg9<sup>+</sup> T cell subsets exhibit disturbed and interactive responses to cardiolipin and zol *in vitro*, mediated in part by CD1d. Thus, the abnormal perception of cardiolipin and phospho-antigens by gd T cells may play a role in the immune pathology in SSc, notably that of pathological fibrosis, warranting further study.

## The Characteristic T-Cell Receptor-Mediated Signaling of Peripheral Blood T Cells in Dermatomyositis and Polymyositis

Yasuhiro Shimojima<sup>1</sup>, Dai Kishida<sup>2</sup> and Yoshiki Sekijima<sup>2</sup>, <sup>1</sup>Department of Medicine (Neurology and Rheumatology), Shinshu University School of Medicine, Matsumoto, Japan, <sup>2</sup>Department of Medicine (Neurology and Rheumatology), Shinshu University School of Medicine, Matsumoto, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

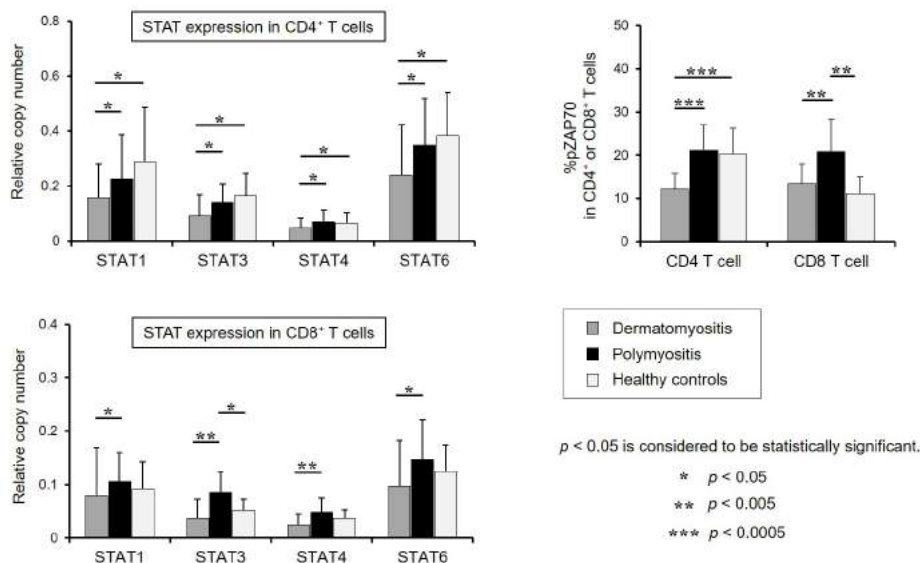

**Background/Purpose:** In dermatomyositis (DM) and polymyositis (PM), the characteristics of T cell expression in peripheral blood have been previously described; especially, decreased expression of interferon- $\gamma$  (IFN- $\gamma$ ) and interleukin-17 (IL-17) producing CD4<sup>+</sup> T cells was significantly demonstrated in the acute phase of DM. However, the mechanism underlying the decrease in circulating IFN- $\gamma$  and IL-17 producing CD4<sup>+</sup> T cell expression is still unknown. The purpose of this study was to investigate the T-cell receptor (TCR)-mediated intracellular signaling in peripheral blood T cells in DM and PM.

**Methods:** Peripheral blood T cells from 86 patients with DM (n = 57) and PM (n = 29), as well as from 28 healthy controls, were used for experimental investigations. T-cell subtypes and TCR-induced phosphorylated zeta-chain-associated protein kinase 70 (pZAP70) were analyzed by flow cytometry. Signal transducer and activator of transcription (STAT) and some inhibitory factors in T cells stimulated with anti-CD3/CD28 beads were also investigated by quantitative real-time polymerase chain reaction.

**Results:** Counts of CD3<sup>+</sup>, CD4<sup>+</sup>, and CD8<sup>+</sup> T cell were significantly lower in DM than in PM ( $p < 0.0005$ ). Moreover, STAT and pZAP70 expression in CD4<sup>+</sup> T cells significantly decreased in DM ( $p < 0.05$ ), whereas that in CD8<sup>+</sup> T cells significantly increased in PM ( $p < 0.05$ ) (**Fig.1**). Lower expression of forkhead box transcription factor (FoxP3) was also demonstrated in DM than in both PM and HC ( $p < 0.005$ ). Especially in DM, a positive correlation between CD4<sup>+</sup> T cell counts and STAT expression was detected ( $p < 0.05$ ). In addition, low CD4<sup>+</sup> T cell counts as well as reduced STAT expression were prominent in patients with interstitial lung disease ( $p < 0.05$ ). STAT and pZAP70 expression significantly improved after clinical remission in both DM and PM ( $p < 0.05$ ), although expression of FoxP3 remained suppressed. Besides, upregulation of suppressor of cytokine signaling-3 (SOCS3) and downregulation of interleukin 6 signal transducer (IL6ST) in CD4<sup>+</sup> T cells were observed in both DM and PM ( $p < 0.05$ ); however, no significant improvements were detected after clinical remission.

**Conclusion:** STAT expression and TCR-proximal signaling in CD4<sup>+</sup> T cells were suppressed in DM, whereas those in CD8<sup>+</sup> T cells were induced in PM, suggesting that TCR-mediated signaling may be a key pathway to determine the characteristics of peripheral blood T cells in DM and PM. Furthermore, upregulation of SOCS3 and downregulation of IL6ST and FoxP3 in CD4<sup>+</sup> T cells cause an imbalance in intracellular signaling which may be associated with the development of DM.

## Increased Differentiation Resistance of Regulatory T Cells to Endoplasmic Reticulum Stress in Systemic Lupus Erythematosus Patients

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Defects of regulatory T cell (Tregs) mainly contribute to loss of tolerance to self-antigen which is significantly implicated in the pathogenesis of systemic lupus erythematosus (SLE). We investigated proportion of Tregs in the peripheral blood mononuclear cells (PBMCs) of patients with SLE and differentiation difference of induced Tregs in vitro under the presence or absence of endoplasmic reticulum (ER) stress, which is one of the causal factors triggering lupus flares, compared with that of healthy controls (HCs).

**Methods:** We isolated the PBMCs of 26 SLE patients and 26 HCs (Table 1). The percentage of CD4<sup>+</sup>CD25<sup>+</sup>FoxP3<sup>+</sup> Tregs was analyzed using flow cytometry. The PBMCs were incubated with anti-CD3/CD28 beads, supplemented with transforming growth factor- $\gamma$  and interleukin-2 to induce differentiation of Tregs, with or without tunicamycin for 24 hours.

**Results:** The percentage of Tregs in the PBMCs of SLE patients was lower than that in the HCs (4.1  $\pm$  1.0 versus 4.4  $\pm$  1.5 %,  $p=0.5$ ). The induced differentiation of Tregs increased in both groups, and the increased proportion was greater in the SLE group (327  $\pm$  234 versus 221  $\pm$  96%,  $p=0.04$ ). Incubation with tunicamycin in the Tregs differentiation process also increased the proportion of Tregs in both groups (227  $\pm$  186 versus 92  $\pm$  57%,  $p=0.001$ ), and the increased proportion was higher in the SLE group. We also compared the incremental differences between exposure of ER stress and no exposure of ER stress. In SLE patients, the smaller difference was observed (39  $\pm$  46%) compared with HC group (73  $\pm$  53%) with statistical significance (Figure 1).

**Conclusion:** The baseline percentage of Tregs was lower in SLE patients than in HCs. However, when Treg differentiation was induced, the differentiation was more increased in SLE group and incremental difference between under the condition of ER stress and absence of ER stress was also smaller in SLE group. The exaggerated differentiation of Tregs in SLE patients may reflect less susceptibility or more resistance to ER stress in SLE lymphocytes on the process of Tregs differentiation.

**Table 1. Baseline Characteristics of SLE patients and HCs**

	SLE (n=26)	HCs (n=26)
Age Mean (SD)	40.9 (11.0)	35.9 (5.7)

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To compare microarray gene analysis of patients with Giant cell arteritis to patients with Takayasu arteritis.

**Methods:** We performed comparative microarray gene analysis of purified CD4+ T cells of TA (n=14) and GCA (n=15) patients.

**Results:** We found that purified CD4+ T cells of GCA and TA patients exhibit distinct RNA signatures. Sixty-seven genes were differentially expressed, among which CXCR5, CCR6 and CCL20 were shown to be significantly up-regulated in CD4+ T cells of TA patients as compared to those of GCA. Flow cytometry analysis confirmed that CXCR5+ CD4+ cells, defined as T Follicular Helper cells (TFH), were significantly higher in TA patients as compared to GCA and healthy donors (HD) [median proportion of CXCR5+ CD4+ T cells of 15.4 (10;30.8) in TA versus 5.3 (1.4; 12.2) in GCA (p<0.0001) and 9.7 (5.6; 12.5) in HD (p=0.0001)]. Among TFH subpopulations, TFH-17 (defined as CCR6+ CXCR5+ CD4+ T cells) was specifically increased in TA [4.52 (1.07; 13.35) in TA vs 0.69 (0.13; 2.16) in GCA (p=0.0001) and 2.3 (0.3; 4.2) in HD (p=0.02)]. The analysis of inflammatory aortic lesions revealed the presence of tertiary lymphoid structures, composed of CXCR5+, CD4+, PD-1 and CD-20 cells in TA whereas such organized inflammatory infiltrates were uncommon in GCA aortic lesions. We demonstrated an increased peripheral B cell immune response in TA, as the number of peripheral B cells is increased in TA compared to GCA. CXCR5+ CD4+ T cells in TA patients have specific characteristics of TFH, as they help B cells to differentiate into memory B cells, to proliferate and to secrete IgG.

**Conclusion:** Patients with TA differ from patients with GCA in microarray gene analysis of purified CD4+ T cells. Our data provide evidence of the critical role of TFH in pathogenesis of inflammatory lesions in TA and suggest the role of antigenic trigger.

### Brain Infiltrating CD4 T Cells Have a Pathogenic T Follicular Helper-Like Phenotype in Neuropsychiatric Lupus

Shweta Jain<sup>1</sup>, Ariel D Stock<sup>2</sup>, Fernando Macian-Juan<sup>2</sup> and Chaim Putterman<sup>1,2</sup>

<sup>1</sup>Division of Rheumatology, Department of Medicine, Albert Einstein College of Medicine and Montefiore Medical Center, Bronx NY 10461.

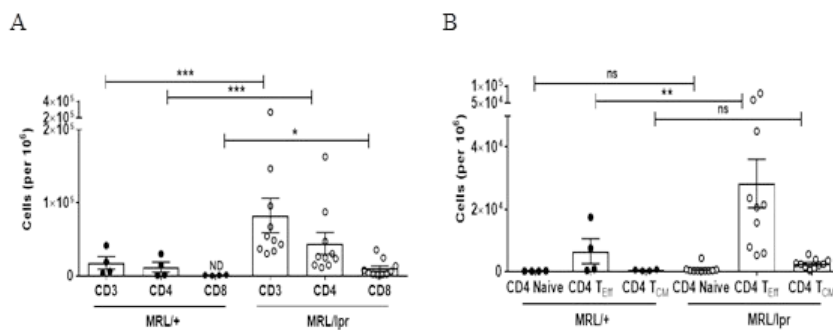

<sup>2</sup> The Departments of Microbiology & Immunology and Pathology, Albert Einstein College of Medicine and Montefiore Medical Center, Bronx NY 10461.

**Background/Purpose:** The pathogenesis of neuropsychiatric systemic lupus erythematosus (NPSLE) is complex, yet incompletely understood. While the role of T cells is well defined in systemic disease, their involvement in NPSLE has not been carefully studied. Therefore, the aim of this study was to characterize the CD4 T cell populations present in the brain of MRL-lpr/lpr (MRL/lpr) mice, a spontaneous lupus mouse model which exhibits many parallels to human NPSLE.

**Methods:** T cells infiltrating the brain of female MRL/lpr mice with active neuropsychiatric disease (16-18 weeks of age) were characterized, and subset identification was done by multiparameter flow cytometry, PCR, and cell culture.

**Results:** We found extensive infiltration of T cells in the brain of female MRL/lpr mice, almost exclusively limited to the choroid plexus, the site of the brain-CSF barrier. MRL/lpr mice had significant CD4 T cell infiltration as compared to MRL/+ controls (10% of the total cells vs 0.1%,  $p < 0.01$ ). Most of the infiltrating CD4 T cells in MRL/lpr females had an activated phenotype. Specifically, infiltrating CD4 T cells constituted an effector phenotype (80% of CD4<sup>+</sup> cells;  $p < 0.01$ ). Importantly, CD4 T cells displayed a T follicular helper cell (T<sub>FH</sub>) like phenotype, as evidenced by their surface markers (CD4<sup>+</sup>ICOS<sup>+</sup>CXCR5<sup>+</sup>PD1<sup>+</sup>) and secretion of a signature cytokine, IL-21, *in vitro* and *in vivo*. Interestingly, CD4 T<sub>FH</sub> cells also secreted significant levels of IFN- $\gamma$  and expressed Bcl-6, thereby conforming to a pathogenic T helper population that drives disease progression. On the other hand, the regulatory

axis comprising CD4 T regulatory cells and T follicular regulatory cells was downregulated in MRL/lpr choroid plexus.

**Conclusion:** These results imply that

accumulation of pathogenic CD4 T follicular helper cells in the brain of MRL/lpr mice may contribute to the neuropsychiatric manifestations of SLE, and suggest this T cell subset as a novel therapeutic candidate.

Figure: T cells infiltrate the choroid plexus of MRL/lpr mice. (A) Single cell suspensions from choroid plexus of 16-18 week old female MRL/+ (n=4) and MRL/lpr (n=10) were stained for the presence of CD3, CD4 and CD8 T cells. (B) CD4 gated cells were characterized as effector (CD4 T<sub>Eff</sub>; CD4<sup>+</sup>CD44<sup>+</sup>), naïve (CD4<sup>+</sup>CD62L<sup>+</sup>), and central memory phenotypes (CD4 T<sub>CM</sub>; CD4<sup>+</sup>CD44<sup>+</sup>CD62L<sup>+</sup>). Values indicate mean±SEM of cells per million and each dot represents one mouse. \* p<0.05, \*\* p<0.01, \*\*\*p<0.0001

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pathogenic immune cell types and functions have not been identified yet in rheumatoid arthritis (RA). This is explained by the impact of disease heterogeneity on study power and by the limited number of immune markers tested so far. Our lack of understanding of RA pathophysiology results in practising trial and error medicine with the prescription of biologic drugs: 30% of patients fail to respond to the first drug prescribed. Using the world-wide largest prospective cohort of RA patients undergoing treatment with biologics, we aim to identify immunological signatures of RA endotypes using a T cell mass cytometry (CyTOF) panel to define treatment response groups at baseline.

**Methods:** Peripheral blood mononuclear cells (PBMCs) are isolated from patients enrolled in the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS) prior to treatment with a biologic drug. One hundred RA patients with a DAS28 > 5.1 are enrolled prospectively each year in addition to healthy controls. Treatment response is assessed at 3, 6 and 12 months. PBMCs are stimulated for 4 hours using anti-CD3/anti-CD28 beads and stained with a 37-channel CyTOF panel which includes intracellular cytokines, transcription factors and co-stimulatory molecules to allow a detailed characterization of the function of T-cells (including Th1, Th2, Th17 and Treg). Data will be analysed using in house developed unbiased advanced computational strategies and clustering algorithms to define cellular clusters agnostically (Raychaudhuri's lab). Our in house analytical pipeline (MASC: "Mixed model association of single cells") will be compared with conventional biaxial gating and commercially available packages like CITRUS.

**Results:** Preliminary data on 10 healthy controls (HC) and 10 RA patients were available for analysis. Traditional biaxial gating showed large differences in the proportions of both Th1 cells (1-9 % in RA and 5-15 % in HC) and Th17 cells (0-9 %) within and between RA and HC. Depending on IFN $\gamma$  and IL-17A expression in CD4<sup>+</sup> T cells, individuals could be classified into 4 immunophenotypes: 'Th1', 'Th17', 'double positive', and 'double negative'. CITRUS identified 3 clusters of cells which were significantly different in abundance between the HC and RA groups. As an example, one cluster was CD4<sup>+</sup>CD38<sup>+</sup>, had characteristics of regulatory T cells and was less abundant in RA. Preliminary analysis of the drug response data showed a strong increase in Th1 cells in responders seen only after *in vitro* stimulation, together with an increase of CD40L<sup>+</sup> CD4<sup>+</sup> and CD40L<sup>+</sup> CD8<sup>+</sup> T-cells.

**Conclusion:** These preliminary analyses show the potential of our study design to capture RA heterogeneity at the single cell level. Importantly, sample size needs to be increased and analytical algorithms further developed, which

is achievable between now and November 2017. The systematic quantification of intracellular cytokines in targeted cell types is likely to identify cell functions involved in RA pathogenesis and treatment response.

## **An Abundance of Butyrate-Producing Bacterium in the Intestine and Increased Foxp3 Gene Expression of T Cells in Patients with Relapsing Polychondritis**

**Jun Shimizu**<sup>1</sup>, Takao Kubota<sup>2</sup> and Noboru Suzuki<sup>3</sup>, <sup>1</sup>Department of Immunology and Medicine, St. Marianna University School of Medicine, Kawasaki, Japan, <sup>2</sup>The Japan Self Defense Forces Central Hospital, Tokyo, Japan, <sup>3</sup>Department of Immunology and medicine, St. Marianna University School of Medicine, Kawasaki-shi, 216-8511, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Helper T cell subsets including Th17 cells and regulatory T (Treg) cells play a role in the adaptive immune response. RORC and Foxp3 are master regulators of Th17 and Treg cells, respectively, and the gene expressions are suggested to be unstable in vivo. Th17 cells re-differentiated into unconventional Th1 cells (Th17/Th1 type cell conversion) and Treg cells converted into Th17 cells (Treg/Th17 type cell conversion) in experimental transplantation models. The converting T cells were more pathogenic in the lesions than conventional cells.

Recently, researchers found that gut microbes had close relationships with Th17 cell and Treg cell induction in the animals and humans. Intestinal colonization of segmented filamentous bacteria and short chain fatty acid (SCFA)-producing bacteria induce Th17 and Treg cells, respectively, and modulates the systemic inflammation of diseased mice. SCFAs in the intestine are important not only as Treg cell differentiators but also as major energy sources for the colonic wall.

We have reported characteristic features of gut microbiota and Th17/Th1 type T cell conversion shown in patients with Behcet's disease (PLoS One 2016;11:e0153746, Clin Rheumatol 2016;35:1857–63). The metagenomics suggested an intestinal depletion of SCFAs in the patients. We then analyzed fecal metagenomic and T cell gene expression data of patients with relapsing polychondritis (RP).

**Methods:** We explored fecal microbiota of 10 patients with RP and 16 normal individuals (NI) by sequencing of 16S rRNA gene. We calculated relative abundance of bacterial taxa using QIIME software. We stimulated peripheral

blood mononuclear cells of 9 RP patients and 10 NI with lectin and measured Th17/Treg cell-related gene expressions.

**Results:** The sequencing data showed that the family Ruminococcaceae and the species *Faecalibacterium prausnitzii* increased significantly in RP patients compared with NI. The species is one of the major butyrate (a SCFA)-producing bacteria of the human intestine. RP T cell gene expression analyses revealed that *Foxp3* gene expression increased remarkably in RP patients compared with NI. We observed that *RORC* gene expression increased significantly with antigen stimulation in RP patients. Thus, RP T cells were suggested to demonstrate Treg/Th17 type cell conversion in the in vitro assay.

**Conclusion:** We consider that RP-specific gut microbes with the increased butyrate production may induce and maintain Treg cells in the intestine. The gut differentiated RP Treg cells may associated with subsequent inflammatory processes and their conversion into pathogenic Th17 cells in the absence of butyrate.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Mechanisms regulating the autoimmune response in rheumatoid arthritis (RA) are not well understood. However, it is known that T CD4<sup>+</sup> lymphocytes play a pivotal role initiating and perpetuating the synovial and systemic chronic inflammation found in the disease. Methotrexate (MTX) is the most commonly used Disease-modifying antirheumatic drugs (DMARD) in RA patients. Regrettably, less than thirty percent of these patients do not respond to MTX and need to initiate additional treatments. The potential role of CD4<sup>+</sup> T lymphocytes in the MTX clinical response in early RA remains unknown.

The objective of this study is to evaluate the relevance of the pattern of IFN $\gamma$ , IL-4 and IL-17A production by naïve (T<sub>N</sub>), central memory (T<sub>CM</sub>), non-terminated effector memory (T<sub>NTEM</sub>) and terminated effector memory (T<sub>TEM</sub>) CD4<sup>+</sup> T cells for the clinical response to MTX in recently diagnosed DMARD naïve RA patients.

## Methods:

The number of IFN $\gamma$ , IL-4, and IL-17A producing CD4<sup>+</sup> T lymphocytes, and in their T<sub>N</sub>, T<sub>CM</sub>, T<sub>NTEM</sub> and T<sub>TEM</sub> subsets in fourty DMARD naïve recently diagnosed RA patients were assayed using a multiparametric flow cytometry. The patients were treated with weekly MTX and the clinical response to the treatment was established after six month of MTX follow up. The patients were classified as responders or non-responders. We also studied twenty-five age and sex-matched healthy subjects as controls. Peripheral blood mononuclear cells (PBMC) were obtained and stimulated during six hour with phorbol-myristate-acetate and ionomycin. To study the intracellular cytokine production by CD4<sup>+</sup> T lymphocyte subsets, we used monoclonal antibodies specific for the surface antigens CD3, CD4, CD45RA, CD27 and cells were fixed and permeabilized, and simultaneously stained with IFN $\gamma$ , IL-4, and IL-17 intracellular cytokines. We acquired in a FACS Aria-II flow cytometer and analyzed by FACS Diva and Flow-Jo software.

## Results:

At basal pretreatment conditions, MTX non-responder RA patients showed a significant increased number of CD4<sup>+</sup>IL-17<sup>+</sup>T lymphocytes with respect to responder RA patients, explained by an expansion of the CD4<sup>+</sup>IL-17<sup>+</sup>T<sub>N</sub> and CD4<sup>+</sup>IL-17<sup>+</sup>T<sub>CM</sub> subsets. The number of CD4<sup>+</sup>IFN $\gamma$ <sup>+</sup> T lymphocytes was significantly increased in MTX non-responder RA patients with respect to that of responders. This elevated CD4<sup>+</sup>IFN $\gamma$ <sup>+</sup>T lymphocyte number was due to an increase in the CD4<sup>+</sup>IFN $\gamma$ <sup>+</sup> T<sub>N</sub>, CD4<sup>+</sup>IFN $\gamma$ <sup>+</sup> T<sub>CM</sub> and CD4<sup>+</sup>IFN $\gamma$ <sup>+</sup> T<sub>NTEM</sub> subset numbers found in non-responder RA patients. There were not significant differences in the CD4<sup>+</sup>IL-4<sup>+</sup>T lymphocyte numbers between MTX responder and non-responder AR patients at basal conditions.

## Conclusion:

Recently diagnosed DMARD naïve RA patients who eventually do not respond to MTX treatment show an abnormal increased numbers of the circulating IL-17A and IFN $\gamma$  producing T<sub>N</sub> and T<sub>CM</sub> CD4<sup>+</sup> lymphocytes with respect to MTX responder RA patients. These IL-17A and IFN $\gamma$  abnormalities in naïve T CD4 lymphocytes might be a good biomarker for the clinical response to MTX in DMARD naïve recently diagnosed RA patients.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Innate-like T cells comprise on average 10-15% of peripheral T cell and have T-cell receptors (TCRs) that engage ligands other than classic HLA class I or class II molecules displaying peptide. These cell types are characterized by a poised state at baseline, enabling rapid cytokine production upon stimulation. Innate-like T cells include natural killer T (NKT) cells, mucosal associated invariant T (MAIT) cells, and  $\gamma\delta$ T cells, which in turn are divided into subsets based on their TCR $\delta$  gene expression (V $\delta$ 1, V $\delta$ 2, V $\delta$ 3, etc). The exact ligands for most  $\gamma\delta$ TCR subsets are not clear, and there are indications that  $\gamma\delta$ T cells can be activated independently of the TCR via NKG2D, which binds stress-induced ligands such as MICA and MICB, which are expressed in inflammatory synovium.

**Methods:** Synovial fluid mononuclear cells were collected from patients with clinical diagnoses of seropositive rheumatoid arthritis (RA), seronegative RA, spondyloarthritis (SpA), and juvenile idiopathic arthritis (JIA). Peripheral blood mononuclear cells were collected from patients with seropositive RA, seronegative RA, SpA, and JIA and from healthy controls (HC). We assessed the frequency and phenotypes of V $\delta$ 1, V $\delta$ 2, and other  $\gamma\delta$ T cells using flow cytometry. We also stimulated synovial fluid mononuclear cells with CD3/CD28 beads or with phorbol myristate acetate (PMA) and ionomycin and measured cytokine production by V $\delta$ 1 and V $\delta$ 2 cells by intracellular cytokine staining. Statistics were performed by Kruskal-Wallis test.

**Results:** V $\delta$ 1 cells are enriched in synovial fluid from patients with JIA ( $7.61 \pm 4.07\%$  vs  $0.78 \pm 0.57\%$  in HC blood,  $p < 0.05$ ), whereas non-V $\delta$ 1/V $\delta$ 2  $\gamma\delta$ T cells are elevated in synovial fluid from seropositive RA ( $7.20 \pm 4.05\%$  vs  $0.48 \pm 0.15\%$  in seropositive RA blood,  $p < 0.01$ ). While a high frequency of all  $\gamma\delta$ T cell subsets expressed NKG2D, other surface markers differed between  $\gamma\delta$ T cell subsets and between blood and synovial fluid  $\gamma\delta$ T cells. For example, CD69 was expressed at a high frequency on all three  $\gamma\delta$ T cell subsets from synovial fluid from all four types of autoimmune arthritis but not from blood. CD25 is expressed at a higher rate among non-V $\delta$ 1/V $\delta$ 2  $\gamma\delta$ T cells from seropositive RA synovial fluid than from any of the other synovial fluid groups or from blood ( $36.7 \pm 16.4\%$  vs  $8.8 \pm 2.2\%$  in seropositive RA blood,  $p < 0.01$ ). PD-1 was expressed by about half of V $\delta$ 1 and non-V $\delta$ 1/V $\delta$ 2  $\gamma\delta$ T cells from blood and was upregulated mainly on non-V $\delta$ 1/V $\delta$ 2  $\gamma\delta$ T cells in synovial fluid. V $\delta$ 2 cells, in contrast, expressed PD-1 at a low frequency in both blood and synovial fluid. Upon stimulation with PMA and ionomycin, both V $\delta$ 1 and V $\delta$ 2 cells from synovial fluid of all four types of autoimmune arthritis produced IFN $\gamma$  and TNF at robust frequencies. However, only V $\delta$ 1 cells produced IL17A, with a frequency similar to CD4 T cells.

**Conclusion:** These findings suggest that V $\delta$ 1, V $\delta$ 2, and non-V $\delta$ 1/V $\delta$ 2  $\gamma\delta$ T cells represent cell populations with distinct functions in the blood and synovial fluid from patients with autoimmune arthritis. Additional studies are needed to further elucidate their roles in RA pathogenesis.

# Fc-Derived Immunodominant Peptides Stimulate Natural Regulatory T Cells: A New Avenue to Overcome Defects in the Fc Antigen Processing and Restore Immune Regulation in Rheumatic Diseases

Alessandra Franco, Pediatrics, University of California San Diego School of Medicine, La Jolla, CA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The mechanisms of action of intravenous purified immunoglobulins (IVIG) in acute Kawasaki disease (KD) have been investigated in our laboratory and have led to a surprising revelation about the antiinflammatory effects of the constant region (Fc) of the IgG1 molecule: the expansion of Fc-specific natural (n) regulatory T cells (nTreg). This is the most relevant efferent arm of the immune response induced by IVIG in these patients as the development of arterial complications (CAA) correlates with lack of Fc-specific nTreg after therapy. We previously identified 16 Fc-derived peptides (15 amino acids long) that expand nTreg in vitro from KD patients after IVIG and healthy adult controls and determined their HLA binding affinity. Here we studied the response in vitro to the 16 most immunogenic Fc peptides in PBMC from KD subjects after IVIG, adult rheumatoid arthritis (RA) subjects and healthy adult donors to rank their immunodominance for pre-clinical development.

## Methods:

The immunogenicity of Fc peptides was tested in vitro by stimulating PBMC with individual Fc peptides and Fc protein as a control ( $4 \times 10^5$  cells /w in 96 flat bottomed plate) and by screening at day 4 for nTreg expansion with two analyses: 1) FACS staining to enumerate CD4<sup>+</sup> CD25<sup>high</sup> T cells and 2) measurement of IL-10 by ELISA in culture supernatants.

## Results:

nTreg from KD and RA patients responded poorly to the whole Fc protein but did respond to Fc peptides. KD subjects after IVIG, and healthy donors showed a similar pattern of nTreg response to Fc peptides. Fc 181-195 that binds multiple class II HLA alleles was immunodominant in the three cohorts. After IVIG, the large majority of KD patients recognize Fc 51-65 and Fc 56-70, which are promiscuous for HLA binding. Fc 21-35, with a monogamous HLA restriction to a common allele in the general population, was also immunodominant in the three cohorts. In the KD cohort, peptide-specific nTreg responses were documented even in children who developed CAA and whose PBMC failed to respond to the intact Fc after IVIG treatment.

## Conclusion:

KD subjects prior to IVIG and RA subjects showed poor nTreg response to the intact Fc, but an excellent response to Fc peptides. These results highlight a possible defect in the antigen processing that jeopardizes immune regulation in rheumatic diseases that can be restored by immunodominant pan-HLA Fc peptides.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Patients with auto-immune or inflammatory diseases (AID) treated by immune check-points inhibitors (ICI) are intrinsically susceptible to develop immune related adverse events (irAE). We conducted this study to describe and analyze the tolerance and efficiency of anti-PD-1 antibodies in AID patients and to look for a clinical association between these preexisting immune conditions and patient's outcome.

### **Methods:**

We described patients with AID treated by ICI and conducted a prospective study in patients receiving anti-PD-1 antibody included in the registry REISAMIC ("Registry of Severe Adverse Events of Immunomodulating Monoclonal Antibodies in Oncology") between 1st June 2014 and 31th December 2016. We analyzed the association between preexisting autoimmune disorder and irAE-free survival and overall survival.

### **Results:**

We described 54 AID patients treated by ICI (mainly anti-PD-1 antibodies) including 45 AID patients which were analyzed and compared to non-AID patients among 397 patients from the registry REISAMIC. Cancer diagnoses included melanoma in 40 cases (74,1%), NSCLC in 10 cases (22,2%) and other cancers in 4 cases (2 renal cell

carcinoma and urothelial carcinoma). Preexisting autoimmune or inflammatory diseases were vitiligo (n=17, 31,5%), cutaneous psoriasis (n=13, 32,5%), auto-immune thyroiditis (n=8, 20%), Sjögren syndrome (n=4, 10%), rheumatoid arthritis (n=4, 10%), auto-immune cytopenia (n=3, 17,5%), spondyloarthritis (n=2, 5%), multiple sclerosis (n=2, 5%) hidradenitis suppurativa (n=2, 5%), and in one case each: myasthenia gravis, polymyalgia rheumatica, polyarteritis nodosa, sarcoidosis, chronic cutaneous lupus, type 1 diabetes, primary nephrotic syndrome, acute tubulo-interstitial nephritis and aseptic abscesses syndrome. 10 patients had two concomitant different AID (18.5%). In 23 cases (42.6%), patient presented at least one grade 2 CTCAE irAE. Among them, 13 irAE (57%) were associated with a preexisting AID: increase of cutaneous psoriasis, development of psoriatic arthritis and pustular psoriasis, extension of vitiligo, hyperthyroidism, exacerbation of Sjögren's syndrome, myasthenia crisis, polyarthritis or mesenteric abscesses leading to death. Eleven patients developed irAE which were not associated with the AID. 33 patients (61.1%) were alive at the last follow-up with a median time of 6.3 months (range 4.1-9.7 months). 19 patients (35.2%) pursued anti-PD-1 treatments at last follow-up with a median time of 4.9 months (range 3.4-7 months).

The irAE free survival was shorter in AID patients (median=5.4 months) as compared with non-AID patients (median=13 months,  $p=2,1.10^{-4}$ ). Overall survival in AID patients did not differ to the one observed in non-AID patients ( $p=0.38$ ).

## Conclusion:

In patients treated by anti-PD-1 antibodies, autoimmune and inflammatory diseases was associated with a higher risk of immune related adverse events and particularly flares which could be severe and fatal. AID and non-AID patient's overall survival were not different. These points increase the importance of networks of collaborations between oncologists, organs specialists, and clinical immunologists to improve patients care.

## Involvement of T Helper 17 Cells in Inflammatory Arthritis Depends on the Host Intestinal Microbiota

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The intestinal microbiota has been associated with psoriatic and rheumatoid arthritis. One of the major effects of microbiota is the induction of mucosal T helper 17 (Th17) cells. We therefore reasoned that the efficacy of Th17-targeted therapies in arthritis may depend on the host microbiota. Previous studies focused on the role of the cytokine interleukin-17A (IL-17), rather than Th17 cells, by using IL-17 inhibitors or IL-17-deficient mice. Therefore, the role of Th17 cells, which produce multiple pro-inflammatory mediators in addition to IL-17, is not yet fully understood. The aim of this study was to determine the role of Th17 cells, beyond the cytokine IL-17, in arthritis, and to investigate whether Th17 cells are differentially involved in arthritis depending on the microbiota present.

**Methods:** We established conditional Th17-deficient mice, which exhibit a CD4-Cre-induced floxing of a part of the *Rorc* allele that encodes the Th17 master regulator ROR $\gamma$ t. We compared the development of collagen-induced arthritis in Th17-deficient (CD4-Cre<sup>+</sup> *Rorc*<sup>flox/flox</sup>) littermate mice, either colonized with known Th17 cell inducers segmented filamentous bacteria (SFB) or harboring the SFB-free Jackson microbiota. The abundance of Th1 and Th17 cells and the production of IL-17, IFN $\gamma$  and GM-CSF were quantified by flow cytometry and multiplex cytokine assay.

**Results:** CD4-Cre<sup>+</sup> T cells and Gr1<sup>+</sup> neutrophils being the main alternative sources of IL-17. Despite this increased total IL-17 levels, conditional Th17-deficient mice developed a less severe arthritis compared with Th17-sufficient mice when intestinal microbiota comprised SFB. This suggests a role for Th17 cells in inflammatory arthritis distinct from IL-17. Accordingly, synovial inflammation, cartilage destruction and proteoglycan depletion were reduced in SFB-colonized Th17-deficient mice. While the production of IL-17 by joint-draining lymph node cells stimulated with PMA and ionomycin was similar between Th17-sufficient and -deficient mice, cells from the latter group produced significantly less IL-17 upon antigen-specific stimulation with type II collagen. Furthermore, the production of GM-CSF, another Th17 cell-derived cytokine, was significantly lower in the lymph nodes of Th17-deficient mice, an effect associated with the protection against arthritis. Importantly, substitution of the intestinal microbiota with SFB-free Jackson microbiota resulted in the loss of Th17 cell dependency of arthritis as Th17-sufficient and -deficient mice showed similar disease progression under this condition.

**Conclusion:** These data suggest that Th17 cells may mediate inflammatory arthritis partly through IL-17-independent mechanisms. Our observations also suggest that the involvement of Th17 cells in arthritis depends on the composition of the microbiota present in the host. Therefore, a microbiome-guided stratification of rheumatoid or psoriatic arthritis patients might improve the efficacy of Th17 (or IL-17)-targeted therapies.

## **Serine Arginine/Rich Splicing Factor 1 (SRSF1) Increases IL-2 Production in T Cells By Increasing the Expression of NFAT and c-Fos**

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** T cells from patients with systemic lupus erythematosus (SLE) produce insufficient amounts of the vital cytokine IL-2, and the molecular mechanisms leading to this defect are not fully known. IL-2 deficiency is critical in autoimmunity, because it is not only important for T cell responses but also for the maintenance and function of regulatory T cells (Tregs). We previously identified a novel role of the multifunctional protein serine arginine-rich splicing factor 1 (SRSF1) in the regulation of IL-2. We showed that SRSF1 is decreased in T cells from SLE patients, and associates with severe disease activity. Importantly, force expression of SRSF1 into SLE T cells rescues IL-2 production. We showed that SRSF1 enhances IL-2 production via transcriptional activation, however the molecular mechanisms underlying this regulation are not fully known. SLE T cells exhibit aberrant expression/function of the IL-2 regulating transcription factors NFκB, c-jun/c-fos (AP1) and NFAT. Here we asked whether SRSF1 controls IL-2 through the regulation of these factors.

**Methods:** T cells were isolated by negative selection from peripheral blood from healthy donors. SRSF1 was overexpressed in human T cells by transient transfection. T cell-restricted conditional *Srsf1*-cko mice were generated by crossing *Srsf1*-flox mice with *d.Lck.Cre* mice. Expression levels of NFAT, c-fos, and NFκB were assessed by quantitative RT-PCR and western blotting. To determine the recruitment of transcription factors to the IL-2 promoter, reporter-chromatin immunoprecipitation (R-ChIP) assays were performed in human T cells by transfection of an IL-2-promoter luciferase construct and SRSF1 overexpression. Cross-linked DNA-protein complexes were immunoprecipitated with appropriate antibodies, and purified DNA was amplified by quantitative PCR. T cells were stimulated with anti-CD3/CD28 or PMA and Ionomycin, and IL-2 production measured by intracellular cytokine staining and ELISA.

**Results:** Overexpression of SRSF1 enhanced IL-2 expression in human T cells. Further, SRSF1 overexpression led to increased mRNA and protein levels of NFAT and c-fos but not NFκB. In parallel, T cells from *Srsf1*-cko mice produced lower amounts of IL-2 and showed decreased expression levels of NFAT after stimulation with anti-CD3/CD28. To ask if SRSF1 affects the recruitment of NFAT and c-fos to the IL-2 promoter, R-ChIP assays were performed using SRSF1-transfected human T cells. An increased recruitment of NFAT and c-fos to the IL-2 promoter was observed in SRSF1-transfected compared to control-transfected cells. These results indicate that SRSF1 increases expression of NFAT and c-fos and their recruitment to the IL-2 promoter to increase transcriptional activity of IL-2.

**Conclusion:** SRSF1 increases the expression of NFAT and c-fos transcription factors to activate IL-2 production. These results suggest that decreased SRSF1 represents an important molecular defect which contributes to the IL-2 deficiency in SLE.

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

We have previously identified two dichotomous CD4 pathogenic subsets in both T effector (CPLs: Circulating pathogenic like lymphocytes) and T regulatory (iaTreg: inflammation associated Treg) compartments that are both HLA-DR<sup>+</sup>, antigen experienced, pro-inflammatory, correlating with disease activity and sharing strong TCR sequence oligoclonality with synovial T cells from JIA patients. Despite being two functionally disparate T cell subsets, their phenotype and association with clinical fate suggests that these functionally discordant subsets may originate from a common precursor. To elucidate the common pathogenic gene drivers and their associated network of pathways within these two pathogenic subsets, we decided to perform next generation RNA sequencing on sorted CPLs and iaTregs and their conventional Teff/Treg counterparts.

## Methods:

CPLs were sorted as CD3<sup>+</sup> CD4<sup>+</sup> CD14<sup>-</sup> HLADR<sup>+</sup> CD25/CD127 Teff gate, and iaTregs were sorted as CD3<sup>+</sup> CD4<sup>+</sup> CD14<sup>-</sup> HLADR<sup>+</sup> CD25<sup>hi</sup>/CD127<sup>low</sup> Treg gate with FACs Aria II from n=8 active JIA PBMCs. As a comparative control, similar HLADR<sup>-</sup> counterparts were respectively sorted from the same patients. Sorted cells were lysed and extracted for RNA, and cDNA libraries were ran on the Illumina HiSeq High output platform. RNA-Seq raw reads were mapped to human genome using STAR aligner with default options and reads were summarised at gene level by feature Count programme. Differential expression analyses were performed using edgeR package, and pathway enrichments under R statistical environment and Reactome.

## Results:

Comparative gene expression analysis, between CPLs vs iaTreg and that of the common pool of Teff vs Treg, and phylogenetic association analysis suggests both CPLs and iaTreg are uncoupled and group separately from their conventional T cell compartments. TCR sequence oligoclonality in CPLs/iaTregs versus that of the common Teff/Treg pool reinforce the presence of a common selection pressure. Pathway enrichment analysis reveal similar dysregulated pathways (IFN-g, PD1, CD28 costimulation) within T cell signalling. Furthermore, weighted gene correlation network analysis (WGCNA) identified strongly coordinated HLA-DR gene network modules and suggests these networks as potential drivers of pathogenic T cell subsets from conventional subsets. Gene set enrichment analysis suggest that HLA-DR module genes are involved in TNFA signalling, inflammatory response,

complement, and apoptosis. Transcription factors (TFs) gene regulatory network (TF-GRN) analysis identified the key regulatory molecules driving the convergence of pathogenic CPL and iaTreg populations. Global TF-GRN network analysis identified FOXP3, CEBP, SPI and E2F1 as key TFs driving the Teff, Treg to pathogenic iaTreg and CPLs, respectively.

## Conclusion:

These mechanistic data strongly suggest shared pathogenic and developmental pathways for two T cell subsets and are strongly associated with clinical fate in autoimmune human arthritis. These pathways are probably shaped from a shared precursor in an inflammatory microenvironment.

## Autophagic Memory in Stress Experienced Human T Cells

**Pavanish Kumar**<sup>1</sup>, Jorg van Loosdregt<sup>2</sup>, Suzan Saidin<sup>1</sup>, Bhairav Paleja<sup>1</sup> and Salvatore Albani<sup>1</sup>, <sup>1</sup>SingHealth Translational Immunology and Inflammation Centre (STIIC), Duke-NUS Medical School, Singapore, Singapore, <sup>2</sup>Laboratory for Translational immunology, University Medical Center Utrecht, Utrecht, Netherlands

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Autophagy is central to many key immune related pathways, dysregulation of which has been associated with rheumatoid arthritis (RA), cancer and neurodegenerative diseases. Autophagy is required for memory T cell generation and maintenance. Previous studies from our group showed higher levels of autophagy in CD4<sup>+</sup> T cells from RA patients. Flow cytometry analysis of T cells from healthy individual indeed showed higher autophagy levels in memory CD4 and CD8 cells after activation, compared to naive T cells. However the basal level of autophagy was similar in both cell types, suggesting a memory for autophagy. Here, we hypothesise that T cells which experience immunological encounters and activation, attain, when compared to naive cells, heightened autophagic levels when a similar stimulus is encountered again, a phenomenon, which we term “autophagic memory” which may be pathogenically relevant.

### Methods:

To dissect the molecular mechanisms of autophagic memory, we trained human T cells in low serum medium, to elicit stress-induced activation, for 5 days. The cells were then cultured in 10% serum media for 100 generations and

subjected to RNAseq and Methylome analyses at various time points. Primary cells from RA patients were sorted using flowcytometry followed by quantitative PCR analyses.

## Results:

RNA-sequencing and methylome analysis of the trained and control cells at 5, 30, 70 and 100 generations identified clusters of genes stably up or down regulated in trained cells compared to control cells until the 30th generation. These short term expression minor (STEM) gene expression profiles represented pathways related to stress, immunity and metabolism, all of which are critical contributors to the onset and modulation of the autophagic process. A transcription factor gene network reconstruction at the system level using ENCODE and HTRIB data identified intersecting key regulatory genes for autophagic memory. Specifically, some key genes with roles in autophagy were also shown to be epigenetically modified in response to the starvation stimulus that was sustained over 30 generations suggesting a role for these genes in retention of autophagic memory. Importantly, gene expression analyses of primary CD4+T cells from RA patients recapitulated this observation, demonstrating a clinically relevant molecular signature that could contribute to autophagic memory in these cells.

## Conclusion:

We describe here epigenetic and transcriptional elements which determine and control persistence of autophagic memory in experienced T cells. Based on our data which are reproducible both in healthy and diseases samples, we suggest that autophagic memory is an integral part of efficient activation of memory T cells, and it also contributes to persistence of T cell mediated inflammation in autoimmunity.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** mTORC1 drives the proinflammatory expansion of T helper (TH) type 1, TH17 cells and controls fibroblast proliferation, typical features of Takayasu arteritis (TA) pathogenesis. Molecular pathways involved in arterial lesions of TA are unknown.

**Methods:** We evaluate pathway activation in the mammalian target of rapamycin complex (mTORC) and the nature of cell proliferation in the vessels of patients with TA by using double immunostaining, western blot and flow cytometry.

**Results:** Proliferation of both endothelial cells and vascular smooth-muscle cells was shown in vascular lesions in TA. The vascular endothelium of proliferating aorta vessel from patients with TA showed indications of activation of the mTORC1 pathway. In cultured vascular endothelial cells, sera from patients with TA stimulated mTORC1 through the phosphatidylinositol 3-kinase (PI3K)–AKT pathway. Activation of mTORC was also found in Th1 and Th17 cells both systemically and in the blood vessels. Patients with TA exhibited a diminished AKT phosphorylation in Tregs. Inhibition of mTOR pathway with rapamycin increase Treg and decrease CD4+IFN+, CD4+IL17+ and CD4+IL21+ cells in patients with TA.

**Conclusion:** Our results suggest that the mTORC pathway is involved in the vascular lesions of Takayasu arteritis. Rapamycin could restore T cells homeostasis in patients with TA.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Autoimmune diseases such as RA are driven by an aberrantly activated immune system and an imbalance between pro- and anti-inflammatory cells, resulting in tissue damage and functional disability in patients. In the blood of treatment-naïve early RA patients, especially CCR6+ Th memory cells, including Th17 and Th17.1 cells, are

elevated and more activated compared to healthy controls. Therefore, blocking the full pathogenic potential of CCR6+ Th memory cells to restore the immunological balance in RA is an important challenge. The active vitamin D metabolite 1,25(OH)2D3 can inhibit the various pro-inflammatory cytokines produced by CCR6+ Th memory cells. However, whether 1,25(OH)2D3 also change the phenotype and functional properties of these CCR6+ Th memory cells is not fully elucidated and is the objective of this study.

## **Methods:**

CCR6+ Th memory cells, excluding Tregs, from treatment-naïve early RA patients or healthy controls were sorted and cultured for three days with or without 1,25(OH)2D3 in the presence of anti-CD3 and anti-CD28. After that they were harvested for microarray analysis, RT-PCR, ELISA or flow cytometry. The cultured cells were also used in functional suppression assays, transwell migration assays and exposed to synovial fluid from active RA patients to test phenotype stability.

## **Results:**

Microarray analysis of 1,25(OH)2D3-treated CCR6+ Th memory cells from treatment-naïve early RA patients showed that production of pro-inflammatory factors such as IL-17A, IL-17F, IFN $\gamma$ , IL-22, IL-26 and the Th17-related transcription factor RORC is inhibited. In contrast, anti-inflammatory factors such as IL-10 and CTLA4, but not FoxP3, are induced. To address whether these formerly pathogenic cells also have regulatory capacities, we evaluated their capacity to suppress proliferation of autologous CD3+ T cells. Interestingly, the 1,25(OH)2D3-treated CCR6+ Th memory cells were equally capable of suppressing proliferation of CD3+ T cells as classical Tregs. This confirms that the committed CCR6+ Th memory cells can change their phenotype from pro- to anti-inflammatory with regulatory capacity. Furthermore, we found that the shift in phenotype did not affect their potential to migrate towards the site of inflammation, since 1,25(OH)2D3-treated CCR6+ Th memory cells migrated equally well towards synovial fluid in a transwell migration assay compared to control-treated cells. Finally, we addressed the stability of the change in phenotype. When cells have been exposed to 1,25(OH)2D3 for three days, the anti-inflammatory phenotype is maintained for at least 7 days. Importantly, the cells retain this phenotype upon exposure to an inflammatory environment, modeled by synovial fluid.

## **Conclusion:**

For the first time we show here that human committed pro-inflammatory CCR6+ Th memory cells can shift towards an anti-inflammatory cell with functional regulatory capacities. Furthermore, these cells can migrate towards synovial inflammation and keep their anti-inflammatory phenotype in this environment. Thereby, these 1,25(OH)2D3 treated CCR6+ Th memory cells can contribute to restoring the immunological balance and inhibiting synovial inflammation in RA.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Activation of polyclonal CD4<sup>+</sup> T cells and B cells is a hallmark of human and murine lupus, which suggests a global defect in the maintenance of T and B cell tolerance. Recent studies unveil a central role of T follicular helper (T<sub>FH</sub>) cells that is critical in providing help to B cells in the overproduction of pathogenic auto-antibodies leading to tissue damage in systemic lupus erythematosus (SLE). Casitas B-lineage lymphoma proto-oncogene-b (Cbl-b) is an E3 ubiquitin ligase which has been shown to increase the activation threshold of immune cells. Bcl-6 is the master transcription regulator that controls the differentiation of naïve T cells into T<sub>FH</sub> cells. A link between Cbl-b/ Bcl-6 and SLE has not been established.

**Methods:** Peripheral blood mononuclear cells (PBMCs) were isolated from healthy subjects and patients with active or inactive SLE as determined by SLEDAI scores. CD4<sup>+</sup> cells prepared from PBMCs were stained for CXCR5, ICOS, PD-1, and Cbl-b and mean fluorescent intensity (MFI) of Cbl-b was determined for positive cell populations. Additionally, immunoprecipitation (IP) was performed with PBMC lysates from healthy subjects with anti-human Bcl-6 monoclonal antibody, and then probed with rabbit anti-human Cbl-b.

**Results:** Flow cytometry analysis gating on CXCR5<sup>+</sup>, ICOS<sup>+</sup>, PD-1<sup>+</sup> T<sub>FH</sub> cells demonstrated significantly lower MFIs of Cbl-b in SLE patients relative to healthy controls ( $P < 0.05$ ). Moreover, Cbl-b levels were lower in active SLE patients than those with less disease activity. At the molecular level, preliminary IP data show that Cbl-b forms a complex with Bcl-6 in human T<sub>FH</sub> cells

**Conclusion:** The association of Cbl-b and Bcl-6 suggests that Cbl-b could be the E3 ubiquitin ligase for Bcl-6. Down regulation of Cbl-b in the T<sub>FH</sub> cells of patients with SLE may be the primary cause of heightened T<sub>FH</sub> and germinal center B cells in lupus and the decreased expression of Cbl-b could serve as a biomarker for lupus flares.

Ongoing studies examine Cbl-b expression prospectively in SLE patients who have a remitting relapsing disease course and the functional implication of down regulation of Cbl-b on human T<sub>FH</sub> cells.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ANCA-associated vasculitis (AAV) is rare, with a worldwide reported annual incidence ranging from 1.2 to 2.0 cases per 100,000 individuals and a prevalence of 4.6-18.4 cases per 100,000 individuals. To date, precise data on AAV incidence, prevalence, and mortality are lacking in the United States (US). We aimed to estimate the incidence, prevalence and mortality rates of AAV and its subsets, granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA), in a US based adult population.

### **Methods:**

All medical records of patients with a diagnosis or suspicion of AAV in a geographically defined region of the US from January 1, 1996 to December 31, 2015 were reviewed. Incidence and prevalence rates were calculated using population denominators for persons aged  $\geq 18$  years from the US Census with age- and sex-adjustment to the 2010 US white population. Survival rates were compared with expected rates in the population.

### **Results:**

Of 58 incident cases of AAV, 23 (40%) were GPA, 28 (48%) MPA, and 7 (12%) EGPA. Overall, 28 (48%) were women, 57 (98%) were Caucasian, with a mean (SD) age at diagnosis of 61.1 (16.5) years. ANCA was negative in 5 (9%) patients; 34 (61%) were MPO-ANCA and 17 (30%) were PR3-ANCA positive.

The annual incidence of AAV from 1996 through 2015 was 3.3/100,000 population (95%CI:2.4-4.1). GPA, MPA and EGPA incidence was 1.3 (95%CI:0.8-1.8), 1.6 (95%CI:1.0-2.2), and 0.4 (95%CI:0.1-0.6), respectively. Incidence rates by ANCA type were: 0.9 (95%CI: 0.5-1.4) for PR3-AAV, 2.0 (95%CI: 1.3-2.6) for MPO-AAV, and 0.3 (95%CI: 0.0-0.5) for ANCA-negative AAV.

There were 44 patients with prevalent AAV on January 1, 2015 for an overall prevalence rate of 42.1/100,000 (95%CI: 29.6-54.6). Prevalence by clinical diagnosis and ANCA type was: 21.8 (95%CI: 12.9-30.8) for GPA, 18.4 (95%CI: 10.1-26.7) for MPA, 1.8 (95%CI: 0.0-4.4) for EGPA, 19.0 (95%CI: 10.6-27.3) for PR3-AAV, 19.2 (95%CI: 10.8-27.7) for MPO-AAV, and 2.8 (95%CI: 0.0-6.1) for ANCA-negative AAV.

Standardized mortality ratios (SMR) for AAV overall, and EGPA, MPA and MPO-AAV were increased (2.04, 16.6, 2.04 and 2.17 respectively,  $p < 0.05$ ); whereas mortality of GPA and PR3-AAV did not differ from general population (SMR 0.93 and 1.09, respectively). No death was recorded in ANCA-negative AAV.

**Conclusion:** The annual incidence of AAV in the US is 3.3/100,000, with a prevalence of 42/100,000, remarkably higher than previous reports. In contrast with most of the previous European studies, GPA and MPA have similar incidence rates, and MPO-AAV has a higher incidence than PR3-AAV. Mortality of MPA and EGPA, but not GPA is higher than the general population. The presence of MPO-ANCA is a marker of poor survival.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

ANCA-associated vasculitides (AAV) are characterized by inflammation and necrosis of small-sized vessels. Because cardiovascular disease (CVD) is a leading contributor to morbidity and mortality, we assessed the CVD and thrombotic disease risk among newly diagnosed patients with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) in a US based adult population.

## Methods:

Patients with incident AAV in a geographically defined region of the US from January 1, 1996 to December 31, 2015 were previously identified by medical record review. For each incident AAV patient, 3 comparators of similar age and sex without AAV were randomly selected from the same population and assigned an index date corresponding to the AAV incidence date.

Medical records of cases and comparators were reviewed for CVD events which included coronary artery disease (CAD), heart failure (HF), atrial fibrillation (AF), cerebrovascular accident (CVA), peripheral vascular disease (PVD), and thrombotic non-cardiac vascular events, which included deep vein thrombosis (DVT), and pulmonary embolism (PE). CVD definitions were based on physician diagnosis. Data on baseline CVD risk factors, including smoking status, body mass index, diabetes mellitus, hypertension and dyslipidemia, were also collected. Cox models adjusted for age, sex and calendar year were used for comparisons between groups.

## Results:

There were 58 incident cases of AAV (48% women, 98% Caucasian, mean age 61.1 years) and 174 non-AAV comparators (48% women, 95% Caucasian, mean age 61.2 years). Among cases, 23 (40%) were GPA, 28 (48%) MPA, and 7 (12%) EGPA, mostly ANCA positive (MPO-ANCA 34 [61%], PR3-ANCA 17 [30%]).

Baseline total cholesterol (median 179.0 mg/dL for AAV; 191.0 mg/dL for comparators;  $p=0.026$ ) and current smoking (5% vs 19%;  $p=0.036$ ) were lower in AAV than comparators, while the other CVD risk factors were not significantly different between the 2 groups. After adjustment for age and sex, hypertension was more frequent in MPA than GPA or EGPA patients at AAV diagnosis (79% vs 43% and 29%,  $p<0.05$ ).

The prevalence of CVD and thrombotic events before the index date was not significantly different between the 2 groups. During median follow-up of 6.0 years for AAV and 6.7 years for comparators, CVD events developed in 14 AAV patients and 17 comparators corresponding to a  $>3$  fold increased risk of CVD in AAV (hazard ratio [HR] 3.37, 95% confidence interval [CI]: 1.64-6.91). By subtypes, risks were elevated for CVA (HR 8.16, 95%CI: 2.45-27.15;  $p<0.001$ ), cardiac events (CAD, HF or AF) (HR 2.95, 95%CI: 1.42-6.12;  $p<0.005$ ), but not PVD. The HR for non-cardiac vascular disease was 3.33 (95% CI: 0.86-12.86), significantly increased for DVT (HR 6.44, 95%CI: 1.20-34.66) but not for PE (HR 1.33, 95%CI: 0.23-7.60). Increased CVD risks compared to non-AAV were observed in MPA (HR 2.74, 95%CI: 1.02-7.35) and MPO-AAV (HR 2.85, 95%CI: 1.07- 7.57), but not in GPA or PR3-AAV.

## Conclusion:

Despite a lower prevalence of some CVD risk factors at baseline, patients with AAV are at higher risk for incident CVD and DVT following AAV diagnosis.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

In the epidemiology of ANCA-associated vasculitis (AAV), an obvious difference between European and Asian populations has been reported. According to the clinical classification, granulomatosis with polyangiitis (GPA) is predominant in UK, while microscopic polyangiitis (MPA) is predominant in Japan. Based on the ANCA specificity, most of Japanese AAV are myeloperoxidase (MPO)-ANCA positive, whereas more than half of UK AAV patients are proteinase 3 (PR3)-ANCA positive. Differences in the genetic background between populations may play a role in such epidemiological differences. Thus far, *HLA-DPB1\*04:01*, *SERPINA1* and *PRTN3* are associated with GPA in the Caucasian populations, while *HLA-DRB1\*09:01* haplotype with Japanese MPO-ANCA positive AAV.

*TNFSF4* encodes OX40 ligand (OX40L), which is expressed on endothelial cells and antigen presenting cells and plays a role in T cell activation through OX40. A single nucleotide polymorphism (SNP) rs2205960 G>T, located upstream of *TNFSF4*, has been associated with upregulation of OX40L, and with susceptibility to systemic lupus erythematosus (SLE) in the British, Chinese, and Korean populations.

Based on substantial sharing of susceptibility genes among multiple autoimmune diseases, and potential role of OX40L-OX40 interaction between T cells and endothelial cells, we considered *TNFSF4* as an attractive candidate for a susceptibility gene to AAV. No association study has been reported between AAV and *TNFSF4*. In this study, we conducted an association study of rs2205960 in Japanese AAV.

## Methods:

Case-control association analysis was performed on 467 Japanese AAV patients and 1100 healthy controls under the allele model, using chi-square test. The P values were corrected for multiple testing using Bonferroni correction. The patients were classified into 285 MPA, 92 GPA, 56 eosinophilic granulomatosis with polyangiitis, and 34 were unclassifiable, according to the European Medicines Agency (EMA) algorithm. With respect to ANCA specificity, PR3-ANCA were positive in 62 patients, and MPO-ANCA in 376 patients.

## Results:

The results are shown in Table 1. Significant association was detected in PR3-ANCA positive (P=0.00583,  $P_{\text{Bonferroni}}$ =0.032, odds ratio [OR]=1.75), but not in MPO-ANCA positive, patients. In addition, tendency towards association was detected in GPA (P=0.0507, OR=1.41). When the GPA patients were classified according to the ANCA specificity, association was preferentially detected in PR3-ANCA positive GPA (P=0.0213, OR=1.81) than in MPO-ANCA positive GPA (P=0.326, OR=1.32). The risk allele was T, which was the same as in SLE.

## Conclusion:

Association of a *TNFSF4* upstream region SNP rs2205960T with PR3-AAV in a Japanese population was detected for the first time. This allele seemed to be more strongly associated with PR3-ANCA positivity than with the clinical classification of GPA.

Table 1. Allelic association of <i>TNFSF4</i> rs2205960 with AAV subsets in a Japanese population						
rs2205960 G>T	n	MAF (%)	P	$P_{\text{Bonferroni}}$	OR	95%CI
MPO-ANCA positive AAV	376	20.6	0.527		1.07	0.87-1.31
PR3-ANCA positive AAV	62	29.8	<b>0.00538</b>	<b>0.032</b>	1.75	1.17-2.61

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Response to rituximab (RTX) is variable in patients with ANCA-associated vasculitis (AAV), and predictors of treatment efficacy/relapse risk would be useful. Previous studies have shown that RTX pharmacokinetics (PK) is associated with treatment efficacy in patients with lymphoma. The objectives of this work were to study the determinants of RTX PK in patients treated for AAV and its association with clinical outcomes.

### Methods:

This study included 88 patients from the RTX in ANCA-Associated Vasculitis (RAVE) trial who received the full dose of RTX (4 weekly 375 mg/m<sup>2</sup> infusions) and had available serum samples. RTX was quantified using two different assays: a traditional ELISA and a recently developed mass spectrometry-based assay (referred to as miRAMM). We analyzed week (W)2, W4, W8, W16 and W24 serum levels and the trapezoidal area under the curve (AUC) integrating baseline, W2, W4, and W8 levels. We explored potential determinants of RTX PK using univariate and multivariate analysis, and analyzed the association of RTX PK with clinical outcomes: achievement of complete remission at 6 months (defined by a BVAS/WG score of 0 with no prednisone), time to relapse in patients who achieved complete remission, and B-cell depletion duration.

### Results:

RTX quantifications using ELISA and miRAMM were highly correlated, but miRAMM measured consistently higher serum levels, suggesting its ability to detect total serum RTX (including free and complexed rituximab). RTX PK was highly variable between patients, with W2 levels ranging between 43 and 259 µg/mL and AUC ranging between 2,668 and 17,513 µg/mL by miRAMM. W2 RTX levels and AUC were significantly lower in males and in newly-diagnosed patients, and were negatively correlated with body surface area, baseline B-cell count, and BVAS/WG. In multivariate analyses, the main determinants of RTX PK were sex and new diagnosis. Patients with a new diagnosis had higher baseline B-cell counts and BVAS/WG. Patients reaching complete remission at month 6 had similar mean RTX levels compared to patients who did not reach complete remission (W2 level by miRAMM: 136±44 vs 139±46, p=0.76; AUC: 8420±2875 vs 8558±3452, p=0.85). Patients with higher RTX levels generally experienced longer B-cell depletion durations, but RTX levels at the different time-points and AUC were not associated with time to any relapse or time to severe relapse. Similar results were observed when using rituximab quantification by miRAMM and by ELISA.

### Conclusion:

Despite the body-surface-area-based dosing protocol, PK-RTX is highly variable among patients with AAV, its main determinants being sex and newly diagnosed disease. We did not observe any relevant association between PK-RTX and clinical outcomes. The monitoring of serum rituximab levels does not seem clinically useful in AAV.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The incidence of first-time venous thromboembolic events (VTE) is high in granulomatosis with polyangiitis (GPA). The incidence of recurrent VTE in these patients has not been studied. The risk of VTE recurrence has been reported in other groups of patients and it is important as it affects recommendations for extended anticoagulation therapy. The aim of this study is to determine the incidence rate of recurrent VTE in GPA.

### **Methods:**

A retrospective chart review was performed in patients with GPA and at least one VTE from a single Vasculitis Center from 2002 to 2016. Our inclusion criteria: 1) 1990 ACR criteria or 2012 Revised International Chapel Hill nomenclature for GPA, 2)  $\geq 2$  follow-up visits in our center, 3)  $\geq 1$  VTE documented during the study period, 4) VTE occurrence after diagnosis of GPA or within three months before GPA diagnosis. Kaplan-Meier was used to estimate second VTE event-free survival rates. Disease (GPA) activity was defined as BVAS/WG score of  $\geq 1$ .

### **Results:**

84 out of 137 patients with GPA and at least one VTE met inclusion criteria. Median age at the time of GPA and first VTE was 56 and 57 respectively. Majority were Caucasian (97.6%) and male gender (56%). Incidence rate for second VTE was 8.4 events per 100 patient years (95% CI 5.7-12.3) over a median duration of 2.4 years (0.6-5.5 years) observation period. The cumulative recurrence rates at 3, 6, 12 months, 3 and 5 years were 9.7%, 13.8%, 15.1%, 27.1 %, and 27.1% respectively. Median time-to-second event was 10.6 years, shorter for patients with BVAS at diagnosis  $\geq 15$  when compared to BVAS  $< 15$  group (7.5 vs 11.3 years - $p=0.0042$  by Log-Rank test-). 89.3% of first VTE and 57.7% of second VTE occurred when disease was active ( $p<0.001$ ). Median BVAS at first event was 8.5 vs 4.0 at second event ( $p=0.030$ ). Male and upper extremity deep vein thrombosis were associated with higher risk of recurrence (Odds ratios: 2.9 [95% CI: 1.1-8.0] and 6.0 [95%CI: 1.6-22.3] respectively). Lung involvement at GPA diagnosis was associated with lower risk for recurrence (odds ratio: 0.33 [95%CI: 0.12 – 0.95]). ANCA positivity was not associated with an increased risk of recurrence.

### **Conclusion:**

GPA patients have a high rate of VTE recurrence compared to the general population with unprovoked VTE (8.4 vs 3.9 recurrent events per 100 patient years) (Kyrle PA, et al. Lancet. 2010). Recurrent events were not always related to clinically apparent active disease. Our results suggest that VTE in GPA is a recurrent disease, more so during the first three years after first event. Prospective studies are needed to address adequate duration of anticoagulation in this population.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ANCA-associated vasculitides (AAVs) are potentially life-threatening diseases rarely observed in childhood. Whether AAVs in children (cAAVs) differ from adult-onset AAVs (aAAVs) is still not known. This study was undertaken to investigate differences in clinical presentations and disease outcomes between cAAV cases and matched aAAV controls.

**Methods:** Demographic and clinical data and disease outcomes of consecutive patients (age <18 years at diagnosis) with cAAVs satisfying ACR, PRINTO/EULAR classification criteria and/or the revised Chapel Hill Nomenclature for Vasculitides were compared to a randomly selected sample of aAAV patients from the French Vasculitis Study Group (FVSG) registry. Cases and controls were matched for the following features: AAV (granulomatosis with polyangiitis [GPA], microscopic polyangiitis [MPA] or eosinophilic granulomatosis with polyangiitis [EGPA]), sex, year of enrollment and duration of follow-up after diagnosis. Prospectively collected information included medications, and disease activity and damage as assessed by the Birmingham Vasculitis Activity Score (BVAS) and the Vasculitis Damage Index (VDI), respectively. Relapses, survival rates and causes of death were analyzed. Kaplan–Meier curves and the log-rank test were used to analyze predefined-outcome differences between cases and controls. STROBE guidelines for reporting observational studies were applied.

**Results:** Thirty-five cAAV cases (25 GPA, 4 MPA, 6 EGPA) were compared with 151 aAAV controls (106 GPA, 17 MPA, 28 EGPA). Respective median ages (range) were 14 (2–17) vs. 53 (18–87) years, with median AAV follow-up durations of 71 and 64 months (P=0.49), respectively. At study entry, children had less frequent myalgias (P=0.005) and peripheral neuropathy (P<0.001) but were more frequently febrile (P<0.05). Their respective rates of renal involvement were comparable (13 (37%) vs. 73 (48%); P=0.31). Initial GPA-associated ischemic abdominal pain and nasal cartilage damage were more common in cAAVs than aAAVs (P<0.05). Their first remission-induction regimens were comparable (P=0.13), most frequently combining glucocorticoids and an immunosuppressant. During follow-up, cAAV patients had a higher overall relapse rate (24.5 vs. 18.7 flares per 100 patient-years; P<0.05) and, at last visit, had accumulated more damage, mostly ENT sequelae (P=0.001), associated with longer maintenance therapy (P=0.03) than for aAAV controls. Four (11.4%) cAAV and 13 (8.6%) aAAV patients died (P=0.54).

**Conclusion:** cAAVs are severe diseases, characterized by a higher relapse rate, more accrued damage, mostly ENT sequelae, and longer maintenance therapy than aAAVs.

## Safety of Methotrexate and Low-Dose Trimethoprim-Sulfamethoxazole in Patients with ANCA-Associated Vasculitis

Hiromichi Tamaki<sup>1</sup>, Robert Butler<sup>2</sup> and Carol A. Langford<sup>3</sup>, <sup>1</sup>Rheumatology, Cleveland Clinic, Cleveland, OH, <sup>2</sup>Department of Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH, <sup>3</sup>Rheumatic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Vasculitis Poster II: ANCA-Associated Vasculitis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

### Background/Purpose:

Low-dose trimethoprim-sulfamethoxazole (LDTS, 160mg-800mg 3x/week or 80mg-400mg/day) is effective for prevention of *Pneumocystis jiroveci* pneumonia (PCP), a serious opportunistic infection seen in patients with ANCA-associated vasculitis (AAV) receiving immunosuppression. There have been rare reports of profound cytopenias when therapeutic-dose TS (160mg-800mg 2x/day) was added to methotrexate (MTX), raising concern about whether LDTS could be given for PCP prophylaxis in AAV patients receiving MTX. This study sought to examine the safety of MTX+LDTS in a well characterized cohort of patients with AAV.

### Methods:

A retrospective chart review was performed of AAV patients treated with MTX at our Center 2002-2017. Clinical variables and laboratory data were collected in RedCap. Kaplan-Meier curves were constructed of drug discontinuation by group with differences compared using the Log-rank test and Wilcoxon test. Side effects were compared using chi-square, Fisher's exact test, or ANOVA.

### Results:

130 patients were included: MTX only (N=33), MTX+LDTS (N=97). Demographics are summarized in Table 1. The rate of discontinuation for MTX was similar between the two groups (Figure 1), with no differences seen in the 5 identified reasons for discontinuation: side effects, infection, switching to another medication for active disease, MTX withdrawal after sustained remission, and patient discontinuation. The overall occurrence of side effects was similar (8.6% [MTX only] vs 7.1% [MTX+LDTS], P=0.32). Thrombocytopenia (3.8% [MTX only] vs 1.1% [MTX+LDTS], P< 0.001) and gastrointestinal side effects (3.9% [MTX only] vs 1.6% [MTX+LDTS], P=0.005) occurred more frequently in those on MTX only but there was no difference in the frequency of leukopenia (0.8% [MTX only] vs 1.0% [MTX+LDTS], P=0.72), transaminitis (6.4 % [MTX only] vs 6.2 % [MTX+LDTS], P=0.88), hospitalization for suspected infection (2.5% [MTX only] vs 1.9.% [MTX+LDTS], P=0.52). One patient on MTX 25mg/week + LDTS had Grade 4 neutropenia that occurred following rituximab and moderate renal insufficiency.

### Conclusion:

In our AAV cohort, the frequency of MTX discontinuation and side effects was similar in patients treated with MTX alone or combined with LDTS. As this study only examined those receiving LDTS, these observations do not extend to those receiving higher doses of TS together with MTX. These results provide support that MTX can safely be combined with LDTS for PCP prophylaxis in AAV. As serious bone marrow suppression can occur with MTX use, with or without LDTS, close laboratory monitoring remains important.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ANCA-associated vasculitis (AAV) are heterogeneous disorders with a clinical presentation that may range from a full-blown disease to incomplete forms with isolated organ involvement. In particular, interstitial lung disease (ILD) may represent the only clinically evident involvement in some patients. Aim of our work was to describe AAV patients with isolated ILD focusing on their clinical characteristics, long-term outcome and clinical-serological associations.

**Methods:** In this single center study we collected epidemiologic, demographic, clinical, laboratory and serological data of AAV patients, excluding patients with diagnosis of EGPA. We recorded disease activity at the disease onset by Birmingham Vasculitis Activity Score (BVAS) and damage by using the Vasculitis Damage Index (VDI).

**Results:** Fifty-four patients with AAV (M:F=32:22, mean age at diagnosis 55.1±5.2 years) were enrolled. Twenty-nine patients were ANCA-MPO positive, while 25 were ANCA-PR3 positive. Eight ANCA positive patients (8/54, 14.8%) presented ILD as the main clinical feature of AAV (5 ILD as the only manifestation). The ILD pattern at lung CT was “non-specific interstitial pneumonia” (NSIP)-like in 2 patients and “usual interstitial pneumonia” (UIP)-like in 6 cases. Seven patients were ANCA-MPO positive while 1 was ANCA-PR3 positive. ILD patients presented a higher mean age at the disease onset compared to non-ILD subjects (65.63±7.36 vs 53.3±15.49 p=0.04), lower creatinine values (0.78±0.13 vs 1.77±2.1 p=0.018) and a lower BVAS at the disease onset (BVAS 3.75±2.49 vs 13.71±6.7 p=0.013). In the long-term follow-up (mean follow-up: 8.31±9.24 years), none of the ILD patients presented an end-

stage renal disease (vs 6 in non-ILD patients) or disease flares (vs 26 in non-ILD cases). The final VDI was lower in ILD patients when compared to non-ILD patients (VDI  $2.12 \pm 0.83$  vs  $3.71 \pm 2.41$   $p=0.004$ ). Moreover, no deaths were observed in the ILD group (vs 7 in non-ILD).

**Conclusion:** Patients with AAV presenting ILD seem to present a different phenotype compared to patients with a complete form of AAV. ILD patients presented lower disease activity at the onset, lower prevalence of complications, lower damage and an overall better prognosis compared to non-ILD patients. Further prospective studies in larger cohorts may clarify whether patients with isolated ILD should be classified as a distinct subset or an incomplete form of AAV.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Randomized-controlled trials (RCTs) showed rituximab's (RTX) noninferiority to cyclophosphamide for induction therapy of severe ANCA-associated vasculitides and significantly lower relapse rate than azathioprine maintenance. However, those RCTs enrolled granulomatosis with polyangiitis (GPA) and microscopic polyangiitis patients, who might need to be studied separately, and selected patients with low preexisting comorbidities that preclude generalization. This open-label, real-life, single-center cohort study was undertaken to assess efficacy of RTX induction-and-maintenance therapy for GPA patients.

**Methods:** All consecutive adults with GPA who received  $\geq 1$  RTX infusions for induction (April 2005–December 2016) at Cochin National Referral Center for Vasculitis were included. Patients had to satisfy the ACR classification criteria or revised Chapel Hill Nomenclature for GPA. Those enrolled in prospective trials were ineligible. After remission, preemptive low-dose RTX maintenance was given. Kaplan–Meier estimations of relapse-free survival were tested for significance with log-rank tests. Cox regression with time-dependent covariates was used to identify predictors of relapses, serious adverse events (SAEs) or serious infections.

**Results:** During the study, 114 patients, with relapsing (65%) or refractory/grumbling (22%) active GPA, received RTX induction therapy; 100 were given  $\geq 1$  RTX maintenance infusions and 90 received 500 mg every 6 months. The median [IQR] prednisone dose at first RTX infusion was 30 [20–50] mg/day. After the first RTX infusion, median follow-up was 3.6 [1.6–5.8] years; respective 1- and 2-year remission rates were 83.7% and 86.4%; respective 1-, 2-, and 3-year relapse-free survival rates were 93% (95% CI 88–98), 85% (78–92) and 82% (74–90); and the 2-year RTX-retention rate was 74% (SE 5%). Respective SAE or serious infection rates were 8.1 and 4.9 per 100-patient-years. Two patients died. Univariate analyses identified pure granulomatous disease ( $P=0.017$ ), refractory/grumbling vs. new-onset/relapsing GPA ( $P<0.001$ ), pachymeningitis ( $P=0.048$ ) or estimated glomerular filtration rate  $>60$  ml/min ( $P=0.005$ ) as factors associated with less likely remission. Multivariate analyses retained subglottic stenosis (HR 4.88, 95% CI 1.79–13.25;  $P=0.002$ ), ENT involvement (HR 2.91, 1.37–6.20;  $P=0.01$ ), skin involvement (HR 5.20, 2.18–12.44;  $P=0.0003$ ) and refractory/grumbling vs. new-onset/relapsing GPA (HR 4.73, 1.04–21.43;  $P=0.05$ ) as independent predictors of relapse. Only the prednisone dose over time was associated with SAEs or serious infections (HR 1.03, 1.01–1.05 and HR 1.06, 1.02–1.09, respectively; both  $P<0.005$ ).

**Conclusion:** Cohort studies and RCTs provide complementary information. The 2-year 74% RTX-retention rate with relatively low toxicity in this real-life setting has important implications. The glucocorticoid dose was the major factor associated with SAEs, even in this cohort whose median dose at inclusion was already lower than that used in the pivotal RCTs.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adverse events, rather than active vasculitis, are the greatest threat to patients with ANCA-associated vasculitides (AAVs) during the first year of therapy but long-term data on the risk of serious infections are scarce. **Results** of the randomized-controlled WEGENT trial demonstrated that, after cyclophosphamide-induction therapy, methotrexate or azathioprine is a comparable option to maintain granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) remission but, at long-term follow-up, relapses and serious adverse events (SAEs) remain matters of concern.<sup>1,2</sup>

**Methods:** The long-term outcomes of 126 WEGENT trial patients were ascertained, including survival, immunosuppressant use and serious infections. Follow-up began at trial inclusion and continued until the last follow-up visit, death or 10 years postinclusion, whichever occurred first. Demographic, clinical and laboratory parameters at trial entry were evaluated as potential prognostic factors for serious infection in univariable and multivariable models. Analyses were adjusted to the length of follow-up.

**Results:** Among the 126 trial participants, long-term follow-up information was available for 124 (98.4%); 27 (21.4%) died before 10 years of follow-up and 14 (11.1%) were lost-to-follow-up. Median follow-up was 11.9 (95% confidence interval [95% CI] 11.3–12.5) years. At 10 years, 68 patients had had at least 1 serious adverse event (SAE), including 31 serious infections (requiring hospitalization) for 25 (20%), corresponding to a 2.5 per 100 patient-years incidence rate. At inclusion, mean ( $\pm$  standard deviation) age of the patients who would develop serious infections was  $62.0 \pm 13.1$  vs.  $57.6 \pm 12.7$  for those who did not ( $P=0.051$ ). Median (Q1–Q3) time to infection was 2.3 (0.2–4.2) years postinclusion. The most frequent serious infections were 15 lung infections and 5 sepses. Infection led to 4 (3%) deaths (at mean age  $74.5 \pm 6.5$  years), occurring a mean of  $4.7 \pm 3.4$  years postinclusion. The 10-year overall survival rate was

77.5% [95% CI 70.4–85.4%] and the 10-year survival rate without SAE was 42.7% [95% CI 34.8–52.4%]. Univariable analysis variables significantly associated with serious infection at the 20% threshold were age, AAV entity, ANCA-negativity, pulmonary involvement, fewer pre-inclusion cyclophosphamide infusions and lower cumulative cyclophosphamide dose. Multivariable analyses retained AAV (incidence rate ratio GPA vs. MPA 3.60 [95% CI 1.05–12.3];  $P=0.043$ ) and previous cumulative cyclophosphamide dose (0.78 [95% CI 0.67–0.91];  $P=0.002$ ) as being significantly prognostic of serious infection.

**Conclusion:** The results of this long-term analysis confirm that serious infections are responsible for high morbidity and potential mortality during long-term AAV-patient follow-up. Serious infections represent nearly half of SAEs and led to the deaths of 3% of the patients. Further studies should examine newer strategies to prevent infections in AAV patients.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rituximab was proven to be superior to azathioprine as maintenance therapy for ANCA-associated vasculitides (AAVs) at month 28 of MAINRITSAN-1 trial follow-up. Because of rituximab's high cost, we conducted ancillary cost-utility and cost-effectiveness analyses.

### **Methods:**

The multicenter, prospective, open-label randomized-controlled MAINRITSAN-1 trial included 115 patients in France between 2008 and 2012. We collected all hospital healthcare resources used: hospitalizations, consultations, drugs, tests. The costs of AAV-related inpatient and outpatient care were based on hospital codes. Quality of life was evaluated with the Medial Outcomes Study Short Form-36 questionnaire.

We calculated the incremental cost-utility (ICUR) and cost-effectiveness ratios (ICER) and their corresponding acceptability curves. Costs were assessed from the perspective of the French National Health Insurance, using 2016 reimbursement tariffs, expressed in euros. Deterministic sensitivity analyses assessed uncertainty over side effects and rituximab cost. Costs drivers were tested with a generalized linear model.

**Results:** Out of 115 patients enrolled in the trial, 3 were excluded from the economic study. The Table reports resource use and costs at trial month 28. Rituximab's higher cost was partly offset by fewer relapses, side effects and follow-up expenses. The 28-month ICER was €13,092 per relapse avoided and the 28-month ICUR was €57,127/QALY. Relapses, side effects and renal impairment were major cost determinants.

	Azathioprine		Rituximab

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Pulmonary involvement in microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA) includes pulmonary nodules (PN), diffuse alveolar hemorrhage (DAH), and infiltrates attributed to vasculitis, each of which can co-exist.

The primary aim of this study was to determine the frequency of patients with both PN and DAH within the Vasculitis Clinical Research Consortium (VCRC) Longitudinal Study cohort. Additionally, it was determined whether patients with both PN and DAH had higher

mortality or experienced a higher frequency of disease flares as compared to patients with only PN, only DAH, only infiltrates, or patients with GPA/MPA without these pulmonary manifestations.

## Methods:

Data were extracted from the VCRC Longitudinal Study cohort. All patients in the cohort satisfied the modified ACR classification criteria for GPA or Chapel Hill Consensus definition of MPA. Pulmonary manifestations were classified as per assessment by site investigators and reported to the database via a standard protocol.

## Results:

Of 736 patients with GPA/MPA in the cohort, 250 (34.0%) never developed pulmonary findings and 486 (66.0%) developed lung manifestations (Figure 1). If PN were not the first lung manifestation of the 343 patients to ever develop nodules, only 20 (5.8%) patients developed them at a later date. If patients had DAH as their initial manifestation, only 4 (2.2%) patients developed PN later in their disease course. PN and DAH were noted to be contemporaneous in 71 (14.6%) of patients. Nine patients (2.6%) with PN first went on to develop DAH, compared with 4 (2.4%) of patients who had infiltrates first.

Patients with GPA/MPA without pulmonary findings experienced 0.77 deaths/100 patient-years, which was comparable to patients with PN alone at 0.66/100 patient-years ( $p=0.79$ ), DAH alone at 0.89/100 patient-years ( $p=0.78$ ), and PN and DAH together at 0.69/100 patient-years ( $p=0.83$ ). In patients with each of PN, DAH and infiltrates there were 1.84 deaths/100 patient-years, or 3 deaths out of 32 patients ( $p=0.25$ ).

Patients without pulmonary findings had disease flares at a rate of 8.68/100 patient-years. PN alone had a flare rate of: 5.71/100 patient-years ( $p=0.07$ ), DAH alone: 7.54/100 patient-years ( $p=0.92$ ), PN and DAH: 7.96/100 patient-years ( $p=0.80$ ). Those with each of PN, DAH and infiltrates had a flare-rate of 23.31/100 patient-years ( $p<0.01$ ).

## Conclusion:

Presentation with PN and DAH, but not infiltrates, occurs at a frequency of 10.5% in patients with GPA/MPA. Such patients have similar outcomes compared to patients without lung manifestations of vasculitis, those with only PN, or those with only DAH. However, those subjects who ever manifested each of PN, DAH and infiltrates during the course of their illness are at higher risk of flare.

**Figure 1.** Distribution of pulmonary nodules, diffuse alveolar hemorrhage and infiltrates in GPA and MPA. Areas of intersection represent the number of patients who ever had pulmonary nodules and DAH (cANCA n=62, pANCA n=5); pulmonary nodules and infiltrates (cANCA n=64, pANCA n=13); DAH and infiltrates (cANCA n=31, pANCA n=7); pulmonary nodules, DAH and infiltrates (cANCA n=20, pANCA n=3). Other pulmonary findings are not shown. DAH = diffuse alveolar hemorrhage. cANCA = cytoplasmic antineutrophil cytoplasmic antibodies. pANCA = perinuclear antineutrophil cytoplasmic antibodies

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Eosinophilic granulomatosis with polyangiitis (EGPA) is characterized by the preceding history of type I allergic disorders, mostly bronchial asthma, followed by the development of vasculitis affecting mainly peripheral nervous system. Whereas MPO-ANCA is detected in approximately 60% of patients with EGPA, its relationship with clinical manifestations remains unclear. We carried out a retrospective cohort study on patients in Tokyo metropolitan area to compare the clinical features between MPO-ANCA positive and negative EGPA.

**Methods:** All the patients fulfilled the diagnostic criteria for EGPA of the Japanese research committee of intractable vasculitis. Certificated medical records for application of medical subsidy between 2007 and 2010 were reviewed.

**Results:** A total of 131 patients were collected, aged  $59.3 \pm 15.9$  years (Mean  $\pm$  SD) (47 males, 84 females). The preceding allergic symptoms were bronchial asthma with or without allergic rhinitis in 96.9%, and allergic rhinitis alone in 3.1%. Peripheral neuropathy (mostly mononeuritis multiplex) was observed in 96.9%. MPO-ANCA was positive in 53 patients (40.4%). There were no significant differences in ages and gender between MPO-ANCA (+) patients and MPO-ANCA (-) patients. As to the vasculitic manifestations, arthritis and glomerulonephritis were more prevalent in MPO-ANCA (+) patients than in MPO-ANCA (-) patients (32.1% vs 17.9% [ $p=0.0612$ ] and 24.5% vs 2.6% [ $p=0.0001$ ], respectively, whereas there were no significant differences in frequencies of other manifestations, including purpura, fever, body weight loss, gastrointestinal bleeding, and cardiopulmonary involvement. Peripheral blood eosinophil counts and serum rheumatoid factors were significantly higher in MPO-ANCA (-) patients than in MPO-ANCA (+) patients, whereas there were no significant differences in white blood cell counts, platelet counts and serum IgE. Cyclophosphamide appeared to be administered more frequently in MPO-ANCA (+) patients than MPO-ANCA (-) patients (54.7% vs 48.7% [ $p=0.0710$ ]), whereas there were no significant differences in the use of steroid pulse therapy (54.7% vs 48.7% [ $p=0.5937$ ]).

**Conclusion:** The results underscore the differential features between MPO-ANCA (+) and MPO-ANCA (-) EGPA, especially the higher prevalence of arthritis and glomerulonephritis in the former. Thus, the data indicate that MPO-ANCA (+) EGPA has features comparable to microscopic polyangiitis, although further studies are needed to delineate the mechanisms of differences in eosinophil counts and rheumatoid factors.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ETS Proto-oncogene 1, transcription factor (ETS1) is a transcription factor involved in immune responses. Genome-wide association studies on systemic lupus erythematosus (SLE) in Chinese populations identified the association of *ETS1* polymorphism in 3' untranslated region, rs1128334 A allele, which was associated with lower *ETS1* expression. Recent studies indicated that many susceptibility genes are shared by multiple autoimmune diseases. In this study, we examined whether *ETS1* is associated with ANCA-associated vasculitis (AAV) in a Japanese population.

**Methods:** Association of rs1128334 was tested in 466 Japanese patients with AAV and 1099 healthy controls by logistic regression analysis under the additive model. AAV patients were classified into 285 microscopic polyangiitis (MPA), 92 granulomatosis with polyangiitis (GPA), 56 eosinophilic GPA, and 33 unclassifiable AAV, according to the European Medicines Agency (EMA) algorithm. Among the patients, 376 were positive for MPO-ANCA and 62 for PR3-ANCA. Expression levels in *ETS1* mRNA in the whole peripheral blood were compared between 8 AAV patients and 14 healthy controls.

**Results:** When the patients were classified according to the EMA classification, rs1128334 A was significantly increased in GPA (P=0.0060, P<sub>c</sub>=0.030, odds ratio [OR] 1.54, 95% confidence interval [CI] 1.13-2.10) when compared with healthy controls. With respect to the ANCA specificity, significant association was observed in PR3-ANCA positive AAV (P=0.0042, P<sub>c</sub>=0.021, OR 1.72, 95% CI 1.19-2.49). Expression analysis indicated that *ETS1* mRNA levels were decreased in AAV (P=0.0024).

**Conclusion:** *ETS1* polymorphism was suggested to be associated with susceptibility to GPA and PR3-ANCA positive AAV in a Japanese population.

Table 1. Association of *ETS1* polymorphism with AAV in a Japanese population.

<i>ETS1</i> rs1128334	A/A	A/G	G/G	A allele	P	P <sub>c</sub>	OR(95%CI)
EMA classification							
GPA(n=92)	20(0.217)	50(0.543)	22(0.239)	90(0.489)	0.0060	0.030	1.54 (1.13-2.10)
MPA(n=285)	53(0.186)	138(0.484)	94(0.330)	244(0.428)	0.072	0.36	1.19 (0.98-1.44)
EGPA(n=56)	7(0.125)	30(0.536)	19(0.339)	44(0.393)	0.90	1.0	1.03 (0.69-1.52)

## **Time to Diagnosis of ANCA-Associated Vasculitides : Data from French Vasculitis Study Group Registry**

**Caroline Morbieu**, Maher Banjari, Benjamin Terrier, Pascal Cohen, Claire Le Jeunne, Luc Mouthon, Xavier Puéchal and Loïc Guillevin for the French Vasculitis Study Group, National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP-HP, Université Paris Descartes, Paris, France

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Diagnosing ANCA-associated vasculitides (AAVs) can be challenging. Their clinical presentations are numerous and the time to diagnosis may range from days to years.<sup>1,2</sup> The impact of delayed diagnosis on AAV outcome has not been established. This study was conducted to assess the first-symptom-to-diagnosis times for patients with granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA).

### **Methods:**

Adults diagnosed with new onset GPA or MPA between 2005 and 2015 and followed at Cochin National Referral Center for Vasculitides were selected from the French Vasculitis Study Group (FVSG) Registry. Patients were excluded when the date and first symptom were incomplete. First symptom (systemic vs ENT), clinical and laboratory findings, Birmingham Vasculitis Activity Score (BVAS) at diagnosis, time to diagnosis and Vasculitis Damage Index (VDI) at last visit were collected from the FVSG registry's database and medical records. The first symptom had been systematically assessed by the treating physician at diagnosis. Data are expressed as median, interquartile range. Pearson and Mann-Whitney tests were used to analyze data.

### **Results:**

Among 257 patients screened, 29 were excluded. The study population comprised 228 patients: 169 with GPA and 59 with MPA (median age at diagnosis 55 years [42–65]; M/F sex ratio 0.81). At diagnosis, their median BVAS was 12 [7–18], 44% had renal involvement and 22% had 2009 Five Factor Scores  $\geq 1$ . The median time to diagnosis was 5.1 [2.1–16.2] (range 0.1–356) months, for which GPA and MPA did not differ significantly. Among AAV patients' first symptoms, 174 (76%) were systemic and 54 (24%) were ENT, with longer times to diagnosis when ENT was the first symptom (8.65 vs 4.1 systemic;  $P < 0.0001$ ). The median time from first ENT to first systemic symptom was 6.1 [3.6–33] months. The time to diagnosis was significantly longer in women (6.1 vs 4.1 men;  $P < 0.05$ ) and in the absence of renal involvement (6.1 vs 3.2 renal involvement;  $P < 0.01$ ). No association was found between time to diagnosis and age, date of diagnosis, BVAS at diagnosis, or VDI at last visit. Thirty-nine (17%) patients, mostly with GPA (27, 69%), were diagnosed  $> 24$  months after the first symptom, which was mainly arthritis/arthralgias ( $n = 9$ ), retroorbital tumor ( $n = 5$ ), purpura/livedo ( $n = 5$ ), thoracic nodules ( $n = 5$ ), ENT ( $n = 5$ ) or others ( $n = 10$ ). Corticosteroids (4 patients) or immunosuppressants (3 patients) were prescribed before AAV diagnosis.

## Conclusion:

The time to AAV diagnosis remains long, especially when the first symptom involves ENT. ANCA testing might shorten the time to diagnosis, and should be considered even in pauci-symptomatic patients.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** MicroRNAs (miRNAs) are small RNA molecules (~22 nucleotides) that participate in post-transcriptional gene regulation. miRNAs have potential both as biomarkers for diagnosis and prognosis and as therapies. Few studies have examined plasma miRNA expression in patients with anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV); those that have focused on microarray and PCR-based analyses of a limited number of candidate miRNAs. Our objective was to determine which plasma miRNAs are altered in AAV compared to patients with inflammatory autoimmune disease and also control subjects using an unbiased approach: high throughput small RNA sequencing.

**Methods:** This pilot study included 10 patients with AAV, 13 controls with inflammatory disease (4 with rheumatoid arthritis and 9 with systemic lupus erythematosus), and 5 controls without inflammatory disease. Stored plasma was used to extract RNA and construct RNA sequencing libraries. Sequencing was done on Illumina NextSeq500. High quality reads were mapped to the human GRCh38 genome using Bowtie. MiRBase21.0 was used to quantify miRNAs. The abundance of miRNA expression was compared between AAV and both groups of control subjects by DESeq2 with 5% false discovery rate and adjustment for multiple comparisons by the Benjamini and Hochberg method. Potential miRNA pathway targets were explored with TargetScanHuman v7.1 and Ingenuity Pathway Analysis.

**Results:** Mean age was 64 years  $\pm$  11 years among patients with AAV, 43  $\pm$  12 years among inflammatory disease controls, and 58  $\pm$  13 years among control subjects. All groups were predominately Caucasian. Active disease was present in 60% of patients with AAV and 69% of inflammatory disease control subjects. Among patients with AAV, 100% were ANCA positive, 60% were positive for anti-proteinase 3 antibody and 40% were positive for anti-myeloperoxidase antibody. Of 209 reliably mapped miRNAs, 15 were significantly differentially expressed ( $\geq 2$ -fold) in patients with AAV compared to both control groups (Table). Of these, miR-21-5p and miR-17-5p are both predicted to target TGFBR2, a gene associated with various vascular phenotypes; and miR-146a-5p is predicted to target TLR9, a gene containing variants associated with AAV.

**Conclusion:** Several plasma miRNAs are differentially expressed in patients with AAV compared to patients with inflammatory autoimmune disease and controls. Further validation is necessary to confirm these findings.

Table. Significant differential microRNA expression in patients with ANCA-associated vasculitis compared to controls with and without inflammatory disease.

	AAV vs Inflammatory Controls		AAV vs Noninflammatory Controls

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The purpose of this study was to validate the recently proposed ACR EULAR 2017 classification criteria of GPA in a real life cohort of ANCA associated vasculitis (AAV).

**Methods:** The proposed ACR EULAR 2017 criteria of GPA were applied to patients diagnosed to have AAV according to European Medicines Agency (EMA) algorithm. The level of agreement between the two criteria was assessed using Cohen's kappa, and positive and negative percent agreement (PPA and NPA).

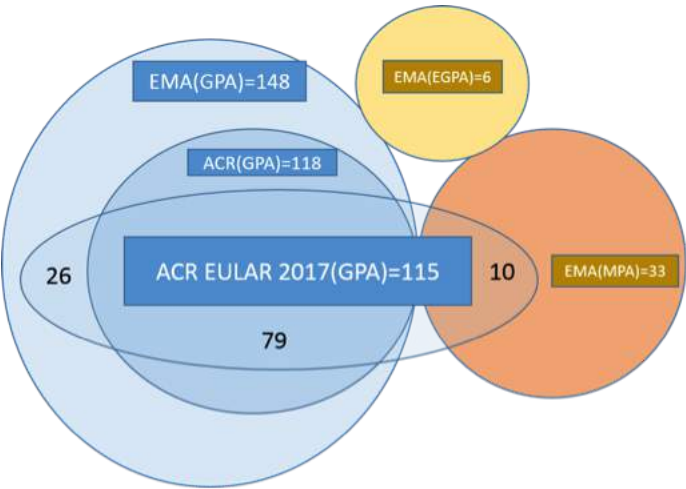

**Results:** 187 patients with mean age of 41.5±15.0 years were included. Female: male ratio was 1:0.8. ANCA by IIF was done in all patients and was positive in 142(cANCA -97, pANCA -45) . PR3/MPO ELISA was available in 118 patients(PR3-71, MPO- 31). Using EMA algorithm EGPA was diagnosed in 6, GPA in 148 and MPA in 33. With ACR 1990 criteria, GPA was diagnosed in 118 patients while with ACR/EULAR 2017 criteria 115 were classified as GPA. ACR/EULAR 2017 had better agreement with EMA (kappa-0.35, PPA-91.3 and NPA-40.2) than ACR criteria (kappa 0.15, PPA -68.6 and NPA -45.8). The sensitivity and specificity of ACR/EULAR 2017 against EMA GPA was 70.9% and 74.3% respectively. Ten out of thirty three MPA patients were reclassified as GPA by ACR/EULAR 2017 criteria. Out of 43 patients who were GPA by EMA algorithm but not by ACR EULAR 2017 criteria, 37 had lung and renal involvement (DCVAS score 2), three had sinus and renal involvement (DCVAS score 3) and three had lung involvement with MPO positivity (DCVAS score 2). This resulted in low NPA of ACR EULAR 2017 criteria with EMA algorithm.

**Conclusion:** Within the limits of a retrospective design, the study showed fair agreement with high PPA but low NPA of ACR/EULAR 2017 criteria with EMA algorithm.

**Table 1.** Reclassification of various AAV patients (EMA and ACR 1990) by ACR EULAR 2017 provisional criteria of GPA

ANCA associated vasculitis	No. of patients (n=187, %)	Reclassified as GPA by ACR/EULAR 2017 criteria
ACR 1990 GPA	118(63.1)	79
EMA GPA	148(79.1)	105
EMA MPA	33(17.6)	10
EMA EGPA	6(3.2)	0

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The pauci-immune nature of typical lesions in ANCA associated vasculitis (AAV) has led to the belief that complement does not play a role in the pathogenesis of this disease. Activation of the alternative complement pathway is necessary for the development of glomerulonephritis in murine models. The complement deposition in renal biopsies of patients with AAV was correlated with increased renal damage.

We hypothesized that there is greater morbidity, mortality and worse renal outcomes in hypocomplementemic patients with AAV compared to those who have normal complement values at the onset of the disease.

Our purpose was to compare clinical manifestations, laboratory values, histological type, renal prognosis and mortality in normal and hypocomplementemic patients with AAV.

**Methods:** Retrospective, observational, analytical study. Data from the medical records of patients over the age of 18 were evaluated between the years 2000-2017. Patients with diagnosis of AAV who met the criteria of ACR 1990 Classification or Chapel Hill Consensus Conference 2012 were included. Hypocomplementemia was defined as C3 values below 80 mg/dl or C4 below 15 mg/dl. Chi-square or Fisher's exact test was used for dichotomous variables as appropriate. P-value <0.05 was considered statistically significant. Logistic regression analysis was used to identify predictors of survival.

**Results:** We analyzed 87 patients with AAV (female 56.2%, mean follow-up 24 months, mean age at onset of the disease 49 years  $\pm$  14.9 SD). Most frequent type of vasculitis was Granulomatosis with polyangiitis (49.4%).

Hypocomplementemia was determined in 7/57 patients (12.28%) and was significantly associated with renal damage (p: 0.034 OR 12.8 CI95% 0.69-236) particularly with decreased glomerular filtrate (p: 0.045 OR: 8.2 CI 95% 0.92-74.0). A higher prevalence of proteinuria greater than 1 gr/24 hs was observed in hypocomplementemic patients 57% vs 25% (p: 0.068).

All renal biopsies were classified as pauci-immune glomerulonephritis. Average number of glomeruli affected was 13 [IQR 25-75% (7-17)], predominating the sclerosing type (44%). The degree of interstitial fibrosis, tubular atrophy (52%) and vascular damage (57%) was mild. In 3 samples we observed deposits of immunocomplexes (IgG+), complement (C3+) or fibrinogen by immunofluorescence. These patients showed creatinine values above 4 mg/dl. There were no statistically significant differences in renal histology between groups (p: 0.091).

There was no association between hypocomplementemia and other organic damage or laboratory values.

Mortality rate was 18% (16/87), without differences between groups (p: 0.300).

**Conclusion:** Hypocomplementemia was associated with increased renal damage: decreased glomerular filtrate and greater values of proteinuria; as reported in the literature. We did not find any other statistically significant difference between groups.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Standard management of ANCA-associated vasculitis (AAV) involves treatment with immunosuppressive agents for at least 18 months. Treatment beyond 18 months reduces the rates of relapses but effect on health-related quality of life (HRQoL) is not known. The objective of this study was to assess the effect of treatment with immunosuppressive agents on HRQoL among patients with AAV that have had a sustained remission for at least 18 months.

**Methods:** Data from a multicenter longitudinal study of patients with AAV were used. Subjects came for quarterly- or annually-scheduled study visits. Disease activity was assessed by the Birmingham Vasculitis Activity Score for Wegener's Granulomatosis (BVAS/WG), and medication use was recorded. Recording of ANCA status, previous disease flares, and a comprehensive cumulative list of disease manifestations was done at the initial study visit. Sustained remission was defined as enrollment in the cohort for 18 consecutive months without any detectable disease activity. Immunosuppressive medication use was defined as use of azathioprine, infliximab, methotrexate, mycophenolate mofetil, or rituximab. HRQoL was assessed with the physical component (PCS) and mental (MCS) summary scores of the Short Form 36 (SF-36) which have a normal distribution with a mean of 50 and standard deviation of 10 in the general population. The effect of immunosuppressive treatment was calculated with a linear regression model adjusted for age and sex, and additionally adjusted for ANCA type, organ involvement, and previous history of disease flare. General estimating equations were used to account for multiple visits from each subject.

**Results:** Data from 434 subjects that came for 1,679 study visits were used. At 979 visits (59%) subjects were receiving immunosuppressive agents. The median follow-up time was 1.84 years (Inter-Quartile Range 0.73 – 3.25). The mean age was 55.3 years (standard deviation 14.8) and 55% were women. The mean SF36 scores in were 43.8 and 50.3 for PCS and MCS, respectively. Use of immunosuppressive agents was associated with 2.17 (p=0.02) lower score for PCS and 0.43 (p=0.64) lower scores for MCS. Additional adjustment for ANCA type, organ involvement, and previous history of disease flare minimally affected the findings with 1.97 (p=0.03) and 0.28 (p=0.61) lower scores for PCS and MCS, respectively.

**Conclusion:** Among patients with AAV who have had sustained remission for 18 months long-term use of continued immunosuppressive medications is not associated with additional improvement in HRQoL.

## Cocaine and ANCA Associated Vasculitis-like Syndromes – a Case Series

**Sujith Subesinghe**<sup>1</sup>, Sander van Leuven<sup>2</sup>, Leena Yalakki<sup>3</sup>, Shirish Sangle (Joint First Author)<sup>3</sup> and David P. D'Cruz<sup>3</sup>, <sup>1</sup>Rheumatology and Lupus, Guy's and St Thomas' Hospitals NHS Foundation Trust, London, United Kingdom, <sup>2</sup>Rheumatology, Radboud University, Nijmegen, Netherlands, <sup>3</sup>Louise Coote Lupus Unit, Rheumatology and Lupus, Guy's and St Thomas' Hospitals NHS Foundation Trust, London, United Kingdom

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Cocaine is a potent illicit stimulant and may trigger a pseudovasculitis mimicking idiopathic ANCA vasculitis. We describe the clinical and serological manifestations of patients presenting with cocaine pseudovasculitis from the experience of a single tertiary rheumatology centre.

### **Methods:**

The electronic patient record and clinic correspondence of 14 patients presenting consecutively between 2000 and 2017 to Guy's and St. Thomas' Hospitals London with cocaine pseudovasculitis were analysed. All patients disclosed a history of chronic habitual cocaine use. All patients had blood samples analysed for ANCA antibodies, inflammatory markers, haematology and biochemistry profiles. Eleven patients had CT sinus imaging, 8 had chest CT scans. Ten patients had tissue biopsies (renal, skin or nasal/sinus) during clinical work-up.

### **Results:**

There were 10 male and 4 female patients, median age 39 years (range 25-52 years). The mean duration of cocaine use prior to presentation was 9.6 years (range 6-15). Twelve patients had significant sinus thickening or erosive nasal disease. Other multi-system manifestations included vasculitic rashes, pulmonary lesions and peripheral neuropathy. All patients had positive ANCA titres at presentation, persisting in 8 subjects despite clinical remission and drug cessation. Four patients had unusual ANCA patterns (P-ANCA, PR3 positive) with persistently positive ANCA on repeat assessment. Acute and chronic inflammatory changes were noted in all biopsy samples but no granulomas were visualised in the patients who underwent sinus or nasal biopsy. All patients were managed with corticosteroids +/- methotrexate and co-trimoxazole, 2 patients received cyclophosphamide.

The baseline demographics, laboratory assessments, serological status and clinical manifestations (including histological findings where available) are presented in the table. Four patients had positive urinary screens confirming recent cocaine exposure (patients 11 - 14).

### **Conclusion:**

Cocaine induced vasculitis may be difficult to distinguish from idiopathic ANCA vasculitis. Cocaine induced disease is usually associated with localised rather than multi-system involvement. Advanced erosive nasal septal defects, atypical ANCA patterns, and urinary drug screen may be helpful to identify the cocaine induced pseudovasculitis. Complete drug cessation may negate the need for potent immunosuppressive agents. Early referral to drug rehabilitation services may be helpful.

## Incidence, Predictors, and Outcome of Diffuse Alveolar Hemorrhage in Patients with MPO-ANCA Positive Microscopic Polyangiitis: A Multi-Center Retrospective Cohort Study

**Takashi Kida**, Shunya Kaneshita, Takuya Inoue, Amane Nakabayashi, Yuji Kukida, Kazuki Fujioka, Hidetake Nagahara, Makoto Wada, Takahiro Seno, Masataka Kohno and Yutaka Kawahito, Inflammation and Immunology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

In patients with microscopic polyangiitis (MPA), a variety of pulmonary lesions including diffuse alveolar hemorrhage (DAH), airways disease and interstitial lung disease (ILD) have been reported. Although DAH is a severe complication of MPA, its etiology and prognosis are poorly understood. The purpose of this study was to identify incidence and predictors of DAH and to evaluate its impact on clinical outcome in patients with MPA, focusing on the association of airways disease with DAH.

### Methods:

We conducted a multi-center retrospective cohort study of patients with myeloperoxidase anti-neutrophil cytoplasmic antibody (MPO-ANCA) positive MPA at three institutes (Kyoto Prefectural University of Medicine, Japanese Red Cross Kyoto Daiichi Hospital, and Matsushita Memorial Hospital) from January 2006 to June 2015. All patients met the Chapel Hill Consensus Conference definition of MPA. DAH was diagnosed on the basis of bronchoscopy, CT findings, and hemoptysis. We evaluated chest CT images at the onset of MPA and examined the presence of airways disease and ILD. We assessed the associations of airways disease with DAH using odds ratio (OR) and 95% confidence interval (95% CI) estimated from logistic regression adjusted for other baseline characteristics, including age, sex, smoking history, antithrombotic drug use, ILD, rapidly progressive glomerulonephritis (RPGN), nerve involvement, gastrointestinal involvement, the five factor score (FFS), the Birmingham vasculitis activity score (BVAS), MPO-ANCA titer. We compared Kaplan-Meier survival curves between the 2 groups with or without DAH using the log-rank test and hazard ratio estimated by Cox proportional hazards model.

Results:

We included 123 consecutive patients with MPO-ANCA positive MPA. DAH was confirmed in 37 (30%) patients, and 33 of them presented DAH at the diagnosis of MPA. In the univariate analyses, airways diseases, absence of ILD, absence of nerve involvement, FFS and BVAS were associated with DAH (Figure 1). In the multivariate analysis, only airways disease (adjusted OR, 3.47; 95% CI, 1.29-9.37) was independently associated with DAH. Airways disease was found in 22 of 37 patients with DAH, and was already pointed out prior to the onset of MPA/DAH in 17 of them. The overall survival rates for patients with DAH were significantly lower than patients without DAH (HR, 3.45; 95% CI, 1.65-7.21) (Figure2).

Conclusion:

DAH frequently occurred in patients with airways disease, and was associated with increased mortality. Airways disease may be involved in the cause of DAH.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

ANCA-associated vasculitis (AAV) is a cause of multi-organ disease in all ages, but peaks at ages 65-74. Limited data is available on the characteristics of AAV in the elderly. Our aim is to compare clinical and serological presentations, treatment regimens, and survival outcomes between younger and older AAV patients.

## Methods:

A retrospective review of patients younger and older than 65yrs [( $<65$ grp); ( $\geq 65$ grp), respectively] diagnosed with AAV was conducted at our institution between 2005 and 2016. Data on demographics, organ system involvement, ANCA-MPO/PR3 serology, BVAS, Vasculitis Damage Index (VDI), 5 Factor Score (FFS) and treatment was recorded. Chi square tests of association and two-sample t-test for group mean differences were used to compare groups. Survival was assessed using Cox proportional hazard ratio and Kaplan-Meier estimates.

## Results:

The cohort included 93 patients [52% ( $<65$ grp); 48% ( $\geq 65$ grp)]. The mean age at diagnosis was  $59 \pm 20$  years (range 16-91). Specifically, the age of the  $<65$ grp was  $43 \pm 14$  compared to  $76 \pm 7$  for  $\geq 65$ grp. Median follow-up was 4.6 years in the  $<65$ grp and 2.0 years in the  $\geq 65$ grp. There were no significant differences in gender, race, BMI, or smoking status. At diagnosis,  $\geq 65$ grp had 3 times as many comorbidities as  $<65$ grp ( $p < 0.0001$ ). The  $\geq 65$ grp also had more renal involvement (73 vs 50%;  $p = 0.02$ ). The  $<65$ grp had more sinus (79 vs 44%;  $p = 0.001$ ) and skin (38 vs 18%;  $p = 0.03$ ) involvement. There were no differences in lung, ocular, neurologic, cardiovascular, gastrointestinal, musculoskeletal, constitutional, or hematologic/DVT findings. The elderly were also more likely to be MPO+ (69% MPO vs 31% PR3) whereas the younger were mostly PR3+ (17% MPO vs 83% PR3) ( $p < 0.001$ ).

Twenty percent of  $\geq 65$ grp was hemodialyzed initially compared to 2 percent of  $<65$ grp ( $p = 0.01$ ). There was no difference in use of plasmapheresis, pulse steroids, cyclophosphamide (CYC) or rituximab (RTX). However, over the course of their illness, 21% of  $<65$ grp received both CYC and RTX vs none of the  $\geq 65$ grp ( $p < 0.001$ ).

Although there was no significant difference between BVAS at presentation or VDI, the FFS at presentation was 2 times greater in the  $\geq 65$ grp vs  $<65$ grp group ( $p < 0.0001$ ). Interestingly, although both the mortality and FFS were increased in the  $\geq 65$ grp, when this data was adjusted for age, the FFS did not have a significant association with the hazard of death ( $p = 0.67$ ) in the elderly. Although relapse was higher in the  $<65$ grp (56 vs 27%;  $p = 0.0115$ ), mortality was greater in the  $\geq 65$ grp (98 vs 63%,  $p < 0.001$ ). There were no differences in complications.

## Conclusion:

Our data indicate that clinical manifestations of AAV differ with age at presentation. There is also a striking age-related difference in distribution of ANCA subtype. While relapse was higher in younger patients, mortality was greater in the  $\geq 65$ grp, possibly due to higher co-morbidity at presentation. A better understanding of the characteristic pattern of presentation between younger and older patients with AAV may have implications for appropriate management and help improve outcomes in this cohort of patients.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cardiovascular involvement in ANCA-associated vasculitis (AAV) including microscopic polyangiitis (MPA), eosinophilic granulomatosis with polyangiitis (EGPA) and granulomatosis with polyangiitis (GPA), has long been regarded as rare, yet a wide spectrum of abnormalities have been reported, with prevalence figures ranging from 5–60% of patients depending on the series and diagnostic methods applied. To investigate the prevalence and prognostic relevance of cardiovascular involvement in an AAV population of MPA, EGPA and GPA patients.

**Methods:** In a retrospective cohort study, 143 MPA, 46 GPA and 45 EGPA patients were analyzed. Birmingham vasculitis activity (BVA) score of all patients were calculated. Demographic and clinical characteristics of patients with and without AAV-related cardiovascular involvement were compared. Statistical analysis was done using SPSS version 22.0 for Windows.

**Results:** Within the cohort of 234 AAV patients, median follow-up times were 5.6 years for the MPA patients (age at diagnosis  $55 \pm 17$ , range 12–83 years) and 5.2 years for the GPA patients (age  $53 \pm 16$ , range 12–82 years) and 4.8 years for the EGPA (age  $48 \pm 17$ , range 11–76 years). The percentages of cardiovascular involvement in patients with MPA, GPA and EGPA were 29.4%(42/143), 37.0% (17/46), and 35.6%(16/45), respectively. There is no significant difference among the three groups in terms of cardiovascular involvement. The common cardiovascular event in these 75 patients that can be observed is congestive heart failure (28/75), followed with valve disease (27/75), pericardial effusion (17/75), arrhythmia (17/75), cardiomyopathy (6/75) and angina (5/75). Univariate logistic regressions showed that age at diagnosis ( $P=0.002$ ; 95% CI 2.922–12.221), sex ( $P=0.03$ ; 95% CI 0.959-0.998), higher BVA score ( $P<0.001$ ; 95% CI, 3.063–6.429) and poor respiratory function at remission ( $P=0.013$ ; 95% CI 1.282–8.595), respectively correlated with AAV patients with cardiovascular involvement. Mortality rate was 4.2% in AAV patients (10/243); 7 out of 10 death cases had cardiovascular involvement. There was a statistical significance of mortality between the patients with and without cardiovascular involvement.

**Conclusion:** In this retrospective study, the MPA, GPA and EGPA groups showed comparable mortality. AAV patients with cardiovascular involvement appeared at greater risk of premature death, with increased risk in males, elder age, higher BVA score and poor respiratory function at remission.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Protocolized and non-protocolized repeat renal biopsies are rarely performed in ANCA glomerulonephritis. Their role in predicting long term renal outcomes and aiding in clinical decisions have not been deeply analyzed. The aim of this study was to evaluate usefulness of renal re-biopsy in patients with ANCA glomerulonephritis in treatment decisions and the role of hematuria as a sign of active disease

**Methods:** We included retrospectively all patients with biopsy-proven ANCA glomerulonephritis: granulomatosis with polyangiitis (GPA), granulomatosis with polyangiitis and eosinophilia (GPAE), microscopic polyangiitis (PAM) and renal limited vasculitis (RLV) between January 2002 and May 2017. We analysed patient's baseline characteristics, induction and maintenance treatments, renal response after induction and time to renal relapse/rebiopsy. Histology of re-biopsies was reviewed and correlation with clinical findings (hematuria) and first biopsy histology was analyzed. Histological classification was made according to 2010 classification criteria for ANCA glomerulonephritis (four categories: focal, crescentic, mixed and sclerotic). Data of physicians' decisions after rebiopsy was collected

**Results:** 60 patients (77% females) were included. Of those, 15 (25%) underwent renal re-biopsy during the follow up based on clinical manifestations. Mean time until re-biopsy was 38.4 months (SD 20.4). In the re-biopsy group, 73% of patients had new onset hematuria vs. 7.5% in the no-rebiopsy group ( $p=$ ). New onset or worsening proteinuria was present in 73% of patients in the re-biopsy group (40% and 33% respectably) vs. only 2.5% in the no-rebiopsy group. Decline in the GFR was present in 60% of patients in the re-biopsy group vs. 2.5% in the other. When analysing histological changes in the repeat biopsy we didn't find a correlation between active lesions (crescents, necrosis etc.) and hematuria. All patients that underwent repeat biopsy were considered to be active but renal histology showed progression in terms of chronicity and rare active histological lesions (table 1). Despite this lower percentage of active lesions, in 67% of patients, physicians made a treatment change, initiating a new induction therapy regimen and achieving renal response in 85% of patients.

**Conclusion:** Renal histology in repeat biopsies did not showed active lesions justifying clinical renal manifestations that lead to re-biopsy. In spite of this, physicians made a change in treatments in the majority of cases after rebiopsy. Patients who presented with new onset hematuria, proteinuria and worsening in the GFR had a good response to this new induction treatment achieving renal laboratory remission in 85% of patients. Role of histological findings in rebiopsies has to be further analyzed.

TABLE 1. Comparison of histological classification in the first and second renal biopsy

	FIRST BIOPSY*	SECOND BIOPSY
	N=15	N=15
Histological classification, n (%)		
- Focal	5 (33)	5 (33)
- Crescentic	6 (40)	1 (7)
- Mixed	4 (27)	5 (33)
- Sclerotic	0 (0)	4 (27)

\*only patients who underwent a second biopsy

# New Use for an Old Drug: Hydroxychloroquine for the Treatment of ANCA Associated Vasculitis

**Alina Casian**<sup>1</sup>, Rachel Jones<sup>2</sup>, Ruzaika Cader<sup>3</sup>, Alan D. Salama<sup>4</sup>, Shirish Sangle<sup>5</sup>, David Jayne<sup>6</sup> and David P. D'Cruz<sup>7</sup>, <sup>1</sup>Lupus Unit, Guy's Hospital, London, United Kingdom, <sup>2</sup>Nephrology, Addenbrooke's Hospital, Cambridge, United Kingdom, <sup>3</sup>Nephrology, Norfolk and Norwich Hospitals, Norfolk, United Kingdom, <sup>4</sup>Centre for Nephrology, University College London, London, United Kingdom, <sup>5</sup>Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, United Kingdom, <sup>6</sup>Vasculitis and Lupus Clinic, Department of Medicine, University of Cambridge, Cambridge, United Kingdom, <sup>7</sup>Louise Coote Lupus Unit, Rheumatology and Lupus, Guy's and St Thomas' Hospitals NHS Foundation Trust, London, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

To assess retrospectively the efficacy and safety of hydroxychloroquine in patients with ANCA associated vasculitis.

There is an unmet need for a corticosteroid sparing, non-toxic therapy in ANCA vasculitis (AAV), as up to 50% of patients relapse by 5 years and 20% have sub-optimal disease control. Hydroxychloroquine (HCQ) has been effective and safe in autoimmune diseases such as systemic lupus erythematosus and rheumatoid arthritis but no systematic studies have been carried out to assess its role in vasculitis. There is mechanistic rationale for the effectiveness of HCQ in AAV, in view of its effect on immune mediators involved in vasculitis pathogenesis including Toll-like receptors, pro-inflammatory cytokines, autoreactive B and T lymphocytes.

**Methods:** Patients were identified by searching our departmental vasculitis databases and electronic clinical records. Thirty patients received HCQ +/- corticosteroids and immunosuppressants. We assessed the effect of HCQ on clinical symptoms and corticosteroid doses required.

**Results:** Thirty patients with ANCA+ vasculitis were treated with hydroxychloroquine (median dose 400 mg daily) for an average of 4.6 years. Median age was 56.5 years.

Fifteen patients had a diagnosis of granulomatosis with polyangiitis (GPA) with +PR3-ANCA, whilst 13 were diagnosed with microscopic polyangiitis (MPA) with +MPO-ANCA and 2 patients had eosinophilic granulomatosis with polyangiitis (eGPA) with +MPO-ANCA.

The systems involved were: joints (20 patients), kidneys (12), ear-nose-throat (11), skin (11), eyes (5), lungs (4), peripheral nerves (3) and gastrointestinal system (1). Twenty-nine out of 30 patients were treated with other maintenance immunomodulatory agents in addition to HCQ (See Table 1).

Twenty three out of 30 patients (76.7%) reported benefits attributed to HCQ ranging from amelioration of joint pains (n=17) to reduction of corticosteroid doses (4), frequency of vasculitic flares (3) and fatigue (1). The effects of HCQ were unclear in 6 patients and 1 reported no symptomatic improvement.

Two patients experienced transient gastrointestinal side effects with HCQ, 1 patient developed haemolysis associated with rise in bilirubin, 1 asymptomatic QT interval prolongation resulting in discontinuation of HCQ. No major other adverse events were reported.

**Conclusion:** The majority of patients reported symptomatic benefits associated with HCQ treatment, especially improvement of joint pains. Vasculitic relapses were less frequent in some patients, with a reduction in corticosteroid doses. HCQ was used mostly as adjunctive therapy in addition to other immunomodulatory agents and was usually well tolerated. Future randomized controlled clinical trials are needed to establish the role of HCQ in ANCA+ vasculitis.

Concomitant Immunosuppressive therapy	Number of Patients
Nil	1
Prednisolone	16
Rituximab	9
Methotrexate	7
Azathioprine	6
Mycophenolate mofetil (MMF)	4
Tacrolimus + MMF (Renal transplant)	1
Mepacrine	1

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Identification of a biomarker to predict relapse in eosinophilic granulomatosis with polyangiitis (EGPA; Churg-Strauss) would enhance the ability to personalize treatment options and improve outcomes. Periostin is a protein which facilitates eosinophil-mediated inflammation and fibrosis and is involved in other eosinophilic syndromes. This study examined the value of serum periostin in identifying disease relapse in patients with EGPA.

### Methods:

Participants enrolled in a multicenter, prospective cohort of patients with EGPA who met the 1990 American College of Rheumatology classification criteria for Churg-Strauss syndrome were included in this study if they had a relapse (defined as BVAS > 0) during follow-up. Serum levels of periostin were measured, using the Elecsys® Periostin assay (Roche Diagnostics, Penzberg Germany), at relapse visit as well as 2 pre- and 2 post-relapse visits, if available. Periostin level between visits (pre- vs relapse, post- vs relapse, all remission vs relapse) were compared using Student's t-test. Mixed-effect models were used to examine the association between periostin levels and

relapse, with the patient as the random effect to allow for assessment of changes within-patient, and adjusting for ANCA status (positive or negative ANCA), active asthma at visit, and time from relapse visit.

### **Results:**

There were 49 patients included in the study: 14 (29%) were anti-myeloperoxidase-ANCA positive and 25 (51%) had experienced a relapse at some point prior to enrollment. Although there was no significant difference in periostin levels at relapse compared to all remission visits (60 vs 58 ng/ml,  $p = 0.41$ ), the periostin levels were significantly higher in patients with EGPA compared to previously published levels using the same assay measured in healthy controls and patients with asthma (**Figure 1**). No significant difference was found comparing the periostin level between pre-visit vs relapse visit ( $p=0.59$ ) or post-visit vs relapse visit ( $p=0.20$ ). In the mixed-effect models, periostin level, change in periostin, and percent change in periostin were not associated with relapse (beta coefficient 0.007 [95% CI -0.07, 0.08]  $p=0.87$ , -6.1 [95% CI -13.9, 1.7]  $p=0.13$ , and -0.03 [95% CI -0.14, 0.07]  $p=0.55$ , respectively).

### **Conclusion:**

Periostin levels in EGPA are higher than other previously studied cohorts, specifically healthy populations and patients with asthma, and are relatively stable over time. Serum periostin does not discriminate active from inactive disease in EGPA.

**The Utility of the ACR/EULAR 2017 Provisional Classification Criteria for Granulomatosis with Polyangiitis in Korean Patients with Antineutrophil Cytoplasmic Antibody-Associated Vasculitis**

**Juyoung Yoo**, Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

#### Background/Purpose:

We applied the ACR/ EULAR 2017 provisional classification criteria for granulomatosis with polyangiitis (GPA) to 150 Korean patients with previously diagnosed Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and investigated how many patients with AAV were reclassified as GPA.

#### Methods:

We included patients with 30 GPA, 30 eosinophilic GPA (EGPA) and 90 microscopic polyangiitis (MPA) patients. Patients can be classified as GPA, when the sum of scores is more than 5.

#### Results:

The mean age of 150 patients with AAV was 60.1 years old, and 101 patients (67.3%) were women at diagnosis. Overall, 33 of 150 patients with AAV (22.0%) were classified as GPA according to the 2017 provisional criteria for GPA. The 2017 provisional criteria for GPA dropped 10.0% of previously diagnosed GPA patients and the major factor to drop 3 GPA patients was the deletion of 2 items of the 1990 criteria, urinary sediment and infiltrates on chest radiograph. Meanwhile, one of 30 patients with EGPA (3.3%) and 5 of 90 patients with MPA (5.6%) were newly classified as GPA based on the 2017 provisional criteria for GPA. Also we could find that items of the 2017 provisional criteria to contribute to reclassifying EGPA and MPA patients as GPA were PR3-ANCA, mass-like lung lesion and nasal congestion in Korean patients with AAV.

**Conclusion:** Use of the 2017 provisional criteria for GPA excluded 10.0% of previously classified GPA patients and newly classified 3.3% of EGPA patients and 5.6% of MPA patients as GPA in Korean patients with AAV.

## Adverse Events for Discontinuation of Immunosuppressants and Outcome of Their Re-Administration in Patients with Antineutrophil Cytoplasmic Antibody-Associated Vasculitis: A Single Center Study in Japan

**Takamasa Murosaki**, Takeo Sato, Yoichiro Akiyama, Katsuya Nagatani and Seiji Minota, Department of Internal Medicine, Division of Rheumatology/Clinical Immunology, Jichi Medical University, Shimotsuke, Japan

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The combination of immunosuppressants and glucocorticoid is recommended for the treatment of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). However, adverse events of immunosuppressants sometimes hamper the

sufficient therapy. Clarification of adverse events, comparison of the incidence, and the outcome of re-administrations among immunosuppressants were the aims of the study.

**Methods:** The data of AAV-patients from 2005 to 2016 in our hospital were analyzed retrospectively. They included patients-demographics, ANCA subtype, use of immunosuppressants, the adverse events that caused their discontinuation, and the outcome of their re-administration.

**Results:** 162 patients were found to have AAV during that time; 132 were positive for myeloperoxidase-ANCA, 25 for proteinase 3-ANCA, and 5 for both. Among 162 patients, 93 (57.4%) were treated with both glucocorticoid and immunosuppressants. In 38 of 93 (40.9%), 44 immunosuppressants were discontinued due to adverse events; 3 patients received 2 immunosuppressants and 1 patient received 4 in the course of the treatment. Median (min.-max.) time from beginning to stopping immunosuppressants was 0.9 (0.3-96) months. 75.0% of the patients with kidney involvement and 38.6% of the patients without it discontinued immunosuppressants ( $p = 0.003$ , Chi-square test). The immunosuppressants discontinued were cyclophosphamide in 24 (54.4%), azathioprine in 6 (13.6%), mizoribine in 4 (9.1%), methotrexate in 3 (6.8%), rituximab in 2 (4.5%), and others in 5 times (11.6%). The adverse events were 21 infections (42.9%), 13 cytopenias (26.5%), 6 hepatotoxicities (12.2%), and 9 others (28.4%); 7 patients experienced 2 adverse events and 1 patient experienced 5. The infection included reactivation of cytomegalovirus (42.9%), respiratory tract infections (33.3%), sepsis (9.5%), and others (8.7%). The incidence of adverse events of cyclophosphamide, azathioprine, mizoribine, methotrexate, and rituximab was 31.6%, 21.4%, 23.5%, 17.6%, and 20.0%, respectively ( $p = 0.75$ , Fisher's exact test). The types of adverse events were different among immunosuppressants; infection and cytopenia, hepatotoxicity, and sepsis were most common in cyclophosphamide, azathioprine, and mizoribine, respectively. Among 38 patients who discontinued immunosuppressants, 11 were re-administered the same drugs (28.9%), 14 others (36.8%), and 13 none (34.2%). Median (min.-max.) time to re-administration was 2.0 (0-60) months.

**Conclusion:** The discontinuation of immunosuppressants due to adverse events was not rare in AAV-patients. One third of the patients who discontinued immunosuppressants were re-administered the same drugs without serious outcomes after recovery from adverse events. Kidney involvement was a risk of IS discontinuation and close monitoring of kidney involvement was mandatory in AAV-patients on immunosuppressants. Although no difference was observed in the incidence of adverse events, clinical presentation of adverse events was diverse among immunosuppressants.

Soriano<sup>1</sup>, <sup>1</sup>Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, CABA, Argentina, <sup>2</sup>Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, CABA, Argentina, <sup>3</sup>Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ANCA-associated vasculitides are rare diseases and epidemiological data on them is scarce. Our objective was to estimate incidence and prevalence rates of Granulomatosis with Polyangiitis (GPA) and Microscopic Polyangiitis (MPA) using data from a university hospital-based health management organization (HMO) in Latin America

**Methods:** Multiple methods for case finding were used to ensure complete ascertainment: (a) patients with diagnosis of vasculitis in HMO electronic medical records, (b) patients with an ANCA, proteinase-3 or myeloperoxidase positive test in laboratory database, (c) patients who consumed azathioprine, cyclophosphamide, methotrexate, mycophenolate or rituximab, from the administrative HMO

drugs database, (d) patients with a renal biopsy performed from pathology registry. GPA was diagnosed if fulfilling ACR 1990 criteria or a clinical diagnosis was made by an experienced rheumatologist; MPA if diagnosed by a rheumatologist in concordance with Chapel Hill 2012 consensus. Renal limited vasculitis (RLV) ANCA-P positive was considered along with MPA. Global, age-specific, and sex-specific incidence and prevalence rates were calculated for members of the HMO. Incidence study followed members with continuous affiliation  $\geq 1$  year from January 2000 to January 2015 until he/she voluntarily left the HMO, GPA or MPA were diagnosed, death, or study finalization. Prevalence was calculated on January 1, 2015 and only patients still on treatment at that time were considered for calculation

**Results:** 19 incident cases of GPA and 28 of MPA were identified from January 2000 to January 2015. Patients' characteristics are shown in table 1. During this period, a total of 349,775 HMO persons contributed a total of 2,073,438 person-years. Incidence rates were measured as cases per 1,000,000 person-years. GPA and MPA overall incidence rate were 9 (CI 5–13) and 14 (CI 9–19) respectively. Incidence rates were greater in women [GPA 11 (CI 5–17) and MPA 17 (CI 10–24)] than in men [GPA 6 (CI 1–11) and MPA 8 (CI 2–14)]. Age-specific incidence rates in both female and male patients peaked in the seventh decades of life in our population. On January 1, 2015, 10 GPA and 7 MPA prevalent cases were identified from a denominator population of 135,750 HMO members. Prevalence rates were 7.4 per 100,000 (CI 2.8–12) for GPA and 5.2 per 100,000 (CI 1.3–9) for MPA. Prevalence rates were higher in ages over 70 for both sexes and both diseases

Table 1. Incident cases of GPA and MPA characteristics

	Granulomatosis with Polyangiitis (n=19)	Microscopic Polyangiitis (n=28)
Female, n (%)	14 (73.7)	21 (75)
Mean age at diagnosis, years (DS)	69.8 (11.3)	73.6 (13.2)
Global Incidence per 1,000,000 patients-year (CI 95%)	9 (5–13)	14 (9–19)
ANCA-C positive, % (CI 95%)	78.9 (52.7–92.7)	14.3 (5.1–33.9)
ANCA- P positive, % (CI 95%)	15.8 (4.6–42.2)	82.1 (62.1–92.8)
Clinical features, % (CI 95%)		
Nasal /sino-nasal involvement	42.1 (21.1–66.5)	14.3 (5.1–34)
Hearing loss/reduction	52.6 (29.2–75)	10.7 (3.2–30)
Cartilagenous involvement	10.5 (2.3–37.1)	0
Red eye	15.8 (4.6–42.2)	0
Renal involvement	84.2 (57.8–95.4)	100
Nodules, mass or cavitation in chest CT	36.8 (17.3–62)	0
Interstitial Lung Disease	5.3 (0.1–26)	21.4 (8.3–40.9)
Alveolar hemorrhage	15.8 (4.6–42.2)	10.7 (3.2–30.1)
Skin vasculitis	15.8 (4.6–42.2)	10.7 (3.2–30.1)
Arthritis	31.6 (13.7–57.3)	7.1 (1.6–26.3)
Peripheral neuropathy	15.8 (4.6–42.2)	3.6 (0.4–23.7)
Renal limited vasculitis	0	60.7 (40.6–78.5)
Fulfillment of ACR 1990 GPA criteria	42.1 (21.1–66.5)	NA
Fulfillment of GPA 2017 provisional criteria	89.5 (62.9–97.7)	NA
Follow-up time after diagnosis, years, median (RIC)	4.9 (2.4–7.8)	2.6 (0.7–6.1)
Mortality, n (%)	9 (47.4)	12 (42.9)
- Infections	- 3	- 6
- Cardiovascular	- 3	- 1
- Cancer	- 2	- 1
- Vasculitis	- 0	- 1
- Others	- 1	- 3

**Conclusion:** In this first study from Latin America, incidence and prevalence rates were in ranges of previous reports from other sites of the world. In our population GPA and MPA were more frequent in women and in older ages (over 70), and incidence of MPA was higher than GPA

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** *Pneumocystis jirovecii* pneumonia (PCP) is a fatal complication in antineutrophil cytoplasmic antibody-associated vasculitis (AAV). However, the current situation of prophylactic treatment of PCP and its effects on patients with AAV remain unknown. Therefore, we aimed to elucidate the current situation of prophylactic treatment and incidence of PCP in Japanese patients with AAV.

**Methods:** This study was conducted using the database of the RemIT-JAV-RPGN study. The current study included 321 patients who were registered from 53 tertiary care institutions in Japan and were newly diagnosed with AAV between April 2011 and March 2014. AAV was diagnosed based on the European Medicines Agency (EMA) algorithm. The exclusion criteria were as follows: age < 20 years, recurrent AAV, serological evidence of hepatitis B or C virus infection, and a history of malignancy. During the 2-year observation period, we examined the incidence of PCP, frequency of the usage and side effects of prophylactic drugs for PCP, and backgrounds of patients developing PCP.

**Results:** Of the 321 patients, 2 were excluded due to the lack of follow-up data. The mean age of the 319 patients was 69 ± 13 years, and 140 patients (44%) were males. Using the EMA algorithm, we identified 27 patients (8%) with eosinophilic granulomatosis with polyangiitis, 53 (17%) with granulomatosis with polyangiitis, 198 (62%) with microscopic polyangiitis/renal limited vasculitis, and 42 (13%) with unclassifiable disorders. The mean initial daily dose of prednisolone (PSL) was 40 ± 13 mg, and methylprednisolone (mPSL) pulse therapy was administered to 145 (45%) patients. Concomitant cyclophosphamide (CY) was administered during the initial 3 weeks of remission induction therapy in 105 (33%) patients. Most patients received prophylactic treatment of PCP along with immunosuppressive agents. Trimethoprim-sulfamethoxazole (TMP-SMX) and pentamidine were administered to 81% and 5% patients, respectively, during the initial 3 months. The percentage of patients treated with TMP-SMX and pentamidine gradually decreased. The following side effects of TMP-SMX were observed: cytopenia, 7 patients; drug eruption, hyponatremia, peripheral neuropathy, and liver function disorder, 2 patients each; and renal dysfunction, 1 patient. No side effect of pentamidine was recognized. During the 2-year observation period, 176 severe infections occurred in 111 (35%) of the 319 patients. Bacterial pneumonia was most frequently observed (34 times), followed by cytomegalovirus infection (28 times). However, PCP occurred only 9 times in 9 patients, and its incidence occupied only 5% of the total severe infections. However, of 26 patients who died, 13 patients died from infectious diseases, of which 4 were due to PCP. The mean age of 9 patients with PCP was 73 ± 10 years and 6 were males. The median duration (min-max) to PCP onset was 96 (15-626) days. The mean initial daily dose of PSL was higher in patients in whom PCP occurred than in those in

whom it did not occur ( $54 \pm 24$  mg/day vs.  $41 \pm 12$  mg/day). The rates of mPSL pulse and concomitant CY therapies were equal in both groups of patients.

**Conclusion:** Although the incidence of PCP onset is low in Japanese patients with AAV, the mortality rate is high.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Eosinophilic granulomatosis with polyangiitis (EGPA) (Churg–Strauss) is characterized by pulmonary and systemic small-vessel necrotizing vasculitis, vascular and/or extravascular granulomas, eosinophilia and tissue infiltration by eosinophils, occurring in individuals with asthma. Glucocorticoids (GCs) effectively control the disease, but relapses and/or GC-dependence are frequent, leading to immunosuppressant and/or biological therapy use. We examined off-label biological therapy use for relapsing and/or refractory EGPA.

**Methods:** This retrospective nationwide study included patients with EGPA meeting ACR criteria and/or Chapel Hill Consensus Conference definitions. Treatment efficacy and safety were recorded. Remission was defined as the absence of asthma and/or sinonasal exacerbations and vasculitis manifestations with a prednisone dose  $\leq 7.5$  mg/day, and partial response as requiring  $>7.5$  mg of prednisone daily.

**Results:** Thirty-three patients (22 men, 11 women; median age 50 years) were included. Thirteen (39%) received rituximab (RTX) and 20 (61%) omalizumab (OMA). Previous treatments were: methylprednisolone infusions (54%), oral GCs (100%), IV cyclophosphamide (60%), azathioprine (75%), methotrexate (24%), mycophenolate mofetil (6%), plasmapheresis (6%) and/or co-trimoxazole (33%). RTX was mainly prescribed for pulmonary involvement (92%), sinusitis (69%), peripheral neuropathy (61.5%) and cardiac involvement (46%). OMA was prescribed for pulmonary involvement (90%) and sinusitis (90%). At inclusion, median (range) BVAS for the RTX and OMA groups, respectively, were 4 (0–19) and 2 (0–9). After median follow-up of 20 months, remissions, partial responses and therapeutic failures, respectively, were 38%, 23% and 38% for RTX recipients, and 40%, 20% and 80% for the OMA group. Median

BVAS dropped to 0 for both groups. A GC-sparing effect was obtained for both groups but was greater for RTX recipients: median GC dose decreased from the baseline 16 mg/day to 15 at 3 months, 10 at 6 and 12 months and 7.5 at the last follow-up vs. 12.5 mg/day to 11.25 at 3 months, 12 at 6 months, 10 at 12 months and 9 at the last follow-up for the OMA group. Two patients stopped RTX because of severe asthma flares and another because of refractory disease. Eleven patients stopped OMA: 2 because of vasculitis relapses, 2 for severe asthma flares, 4 had refractory disease and 3 achieved remissions. The latter 3 patients then took azathioprine; no relapses occurred after discontinuing OMA. The only minor side effect, nausea, occurred in the RTX group.

**Conclusion:** The results of this study suggest that RTX and OMA may achieve GC-sparing in relapsing and/or refractory EGPA, but the latter remains frequent.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Granulomatosis with Polyangiitis (GPA) is a form of systemic vasculitis with necrotizing granulomatous inflammation commonly involving upper and lower respiratory tracts, necrotizing glomerulonephritis and other organ systems. Limited literature has addressed the prognostic factors impacting on patients with GPA due to relative small sample size of previous studies. The aim of this study is to identify potential risk factors associated with overall in hospital mortality among patients diagnosed with GPA.

### **Methods:**

This is a retrospective analysis based on the 2005- 2014 National Inpatient Sample, the largest publically available inpatient database in the United States. The database is composed of discharge-level data from approximately 8 million hospitalizations annually. The inclusion criteria were patients diagnosed with GPA. There were no exclusion criteria. The outcome of interest was in-hospital mortality. Multivariate logistic regression analysis adjusting for age, gender, race, comorbidities and specific system involvement was performed to evaluate for independent associations between variables of interest and in-hospital mortality. Diagnoses were identified using validated ICD-9-CM codes. Analysis was performed using STATA version 14.2.

### **Results:**

A cohort of 103,701 patients diagnosed with GPA was included. The mean age was 60 years and the overall in hospital mortality rate was 4.69%. Our study revealed that older age (OR 1.04, p<0.001) was associated with increased in-hospital mortality among patients with GPA requiring hospitalization, while African-American race was associated with less mortality rates (OR 0.59, p=0.012) compared with Caucasian patients. Preexisting comorbidities or specific systemic involvements associated with increased in-hospital mortality were: congestive heart failure (OR 1.25, p=0.039), neutropenia (OR 1.69, p=0.043), coagulopathy (OR 2.02, p<0.001), acute kidney injury (OR 1.68, p<0.001), acute respiratory failure (OR 9.56, p<0.001), sepsis (3.51, p<0.001), gastrointestinal bleed (OR 1.90, p<0.001), intracranial hemorrhage (OR 7.96, p<0.001) and ischemic stroke (OR 2.75, p<0.001). However preexisting hypertension (OR 0.77, p=0.004), diabetes mellitus (OR 0.77, p=0.013), chronic lung disease (OR 0.75, p=0.004) and anemia (OR 0.64, p<0.001) were

associated with less in-hospital mortality. Other comorbidities that were not associated with in-hospital mortalities were: chronic kidney disease (OR 1.07,  $p=0.52$ ) and chronic liver disease (OR 0.91,  $p=0.75$ ).

## Conclusion:

Clinical characteristics, preexisting comorbidities and major systemic involvements should be considered in the prognostication and risk stratification of patients diagnosed with GPA. Future prospective studies can be considered for further validation.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pituitary involvement in granulomatosis with polyangiitis (GPA) is rare with an incidence of approximately 1%. Objectives were: (1) Describe ten new cases of pituitary involvement in GPA seen at Canadian healthcare institutions; (2) Perform a literature review of pituitary involvement in GPA and compare previously reported cases with our series.

**Methods:** We surveyed members of the Canadian Vasculitis Research Network (CanVasc; 18 centers across Canada) for patients with GPA and pituitary disease. Cases were defined based on: (1) Clinical characteristics consistent with GPA; (2) Pituitary MRI/pituitary histology consistent with GPA, with or without hormonal dysfunction; (3) Exclusion of alternative causes of pituitary disease. Clinical details were collected using a standardized record form. We performed a literature search of the following databases: Medline, Embase, Scopus, and Proquest, using “granulomatosis with polyangiitis” and “pituitary” as keywords.

### Results:

Our case series included 10 patients (9 female, 1 male). Mean age at GPA diagnosis and presentation of pituitary disease were: 33.8 years (range 13 to 56) and 35.3 years (range 18 to 56), respectively. Five patients presented with pituitary disease at GPA diagnosis; mean time from GPA to pituitary disease diagnosis was 3.4 years for the remaining five. Nine patients were ANCA positive (PR3 for 8, MPO for 1). Diabetes insipidus (DI) was the most frequent hormonal dysfunction observed ( $n = 8$ ). Hypogonadism and central hypothyroidism were seen in 3 and 2 patients, respectively. Pituitary hormone testing was normal in 2 patients (presenting with pituitary mass only). All patients had GPA involvement at other sites including ENT ( $n = 8$ ), pulmonary ( $n = 6$ ), and renal ( $n = 4$ ). Eight patients received therapy including glucocorticoids alone ( $n = 1$ ), with IV cyclophosphamide (CYC,  $n = 2$ ), oral CYC ( $n = 3$ ) or rituximab ( $n = 1$ ), or a combination of mycophenolate mofetil and tacrolimus ( $n = 1$ ). All patients had systemic disease remission on follow-up. Hormonal deficiencies were persistent after treatment in all patients with pituitary dysfunction at baseline. Our literature review yielded 67 other cases of pituitary involvement in GPA. The largest series included 9 patients. A limitation of our series, and previous case reports, is the lack of pituitary histology to definitively exclude an alternative cause for pituitary disease arising concurrently with GPA. Tissue is rarely obtained unless there is a surgical indication (e.g. compression of the optic chiasm) or a diagnostic dilemma exists, such as in isolated pituitary GPA.

**Conclusion:** This new and large case series of pituitary disease and GPA, together with previously reported cases, suggest: (1) Pituitary disease may be diagnosed concurrent to systemic GPA or later; (2) Pituitary disease is rarely isolated; (3) Posterior pituitary dysfunction

is the most common disease manifestation; (4) Pituitary disease does not seem to negatively impact the global prognosis; (5) Pituitary dysfunction and need for hormone supplementation are often irreversible.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Granulomatosis with polyangiitis (GPA) is a relapsing autoimmune disease affecting small- to medium-sized blood vessels. B cells are thought to play an important antibody-independent role in GPA patients. Immunosuppressants are used to induce remission at initial onset of disease, and subsequently used as maintenance treatment. Mycophenolate mofetil (MMF) was found to be effective for both induction and maintenance of remission in GPA; although, azathioprine (AZA) is superior as maintenance therapy compared to MMF. Little is known about the effect of these commonly used drugs on B cell cytokine production. We hypothesized that the differences in the efficacy of MMF and AZA could be the result of differential effects on B cell cytokine production. Therefore, we studied the effects of MMF and AZA on *in vitro* B cell cytokine production.

### **Methods:**

We assessed the *in vitro* effect of the active compounds of MMF (MPA) and AZA (6-MP) on B cell cytokine production. PBMCs of twenty untreated GPA patients in remission and twenty age- and sex-matched healthy controls (HCs) were isolated. PBMCs were cultured with CpG and 3 uM MPA or 6-MP. After 3 days, PBMCs were restimulated with Ca-I and PMA for 5h in the presence of BFA, stained for intracellular IL-6 and IL-10 and measured by flow cytometry. In addition, to determine whether *in vivo* use of MMF or AZA influences *in vitro* B cell cytokine production, PBMCs from 14 patients in stable remission were cultured and stimulated as mentioned above. From each patient two samples were analyzed, one when patients were not treated and one when patients were receiving either MMF (n=4) or AZA (n=10). For comparison, PBMCs from 14 matched HCs were analyzed simultaneously.

### **Results:**

MPA significantly decreased the frequency of IL-10+ and IL-6+ B cells in HCs and GPA patients, compared to CpG alone (p<0.001) and CpG+6-MP (p<0.001). PBMCs from GPA patients that were actively treated with MMF or AZA, tended to have a reduced IL-10+ B cell frequency compared to PBMCs from the same donors that did not receive treatment (p=0.1) or healthy controls (p=0.09). This reduction in IL-10+ B cells was only seen in MMF- and not in AZA-treated patients (p=0.09). In contrast, no effect of MMF or AZA was found on IL-6+ B cells (%).

### **Conclusion:**

The decrease in *in vitro* B cell cytokine production in the presence of mycophenolic acid might explain why this agent is less effective as maintenance therapy in GPA. Further research is needed to elucidate whether this *in vitro* finding is clinically relevant.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis Poster II: ANCA-Associated Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Most patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) achieve clinical remission after induction therapy. However, even among patients who achieve remission, induction therapy sometimes must be changed or prolonged, or prednisone may be required to maintain remission. A decision support tool to better define patients with harder-to-control disease would help guide clinicians when starting therapy.

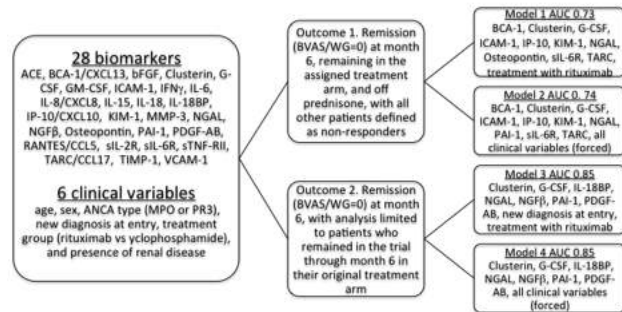

**Methods:** Twenty-eight serum proteins representing diverse aspects of the biology of AAV were measured at screening (during active disease) in 181 patients enrolled in the Rituximab in ANCA-Associated Vasculitis (RAVE) clinical trial. Two outcomes were used to test the ability of a combination of these biomarkers to predict optimal response to therapy: 1) “complete remission,” the primary endpoint of the RAVE trial, defined as remission (Birmingham Vasculitis Activity Score for Wegener’s granulomatosis [BVAS/WG]=0) at month 6, remaining in the assigned treatment arm, and off prednisone, with all other patients defined as non-responders; 2) remission (BVAS/WG=0) at month 6, with analysis limited to patients who remained in the trial through month 6 in their original treatment arm, and did or did not re-start prednisone at or before month 6. Demographic and clinical variables included age, sex, ANCA specificity (MPO or PR3), new diagnosis at entry, treatment (rituximab vs cyclophosphamide), and presence of renal disease. Models were developed using least absolute shrinkage and selection operator (lasso) regressions with leave-one-out cross-validation. Variables included all biomarkers in addition to demographic and clinical information.

**Results:** All subjects had severe active vasculitis (median BVAS/WG= 8) at screening. Sixty-two percent (112/181) achieved complete remission at month 6. A combination of 10 serum biomarkers and treatment with rituximab provided the best predictive ability for complete remission at 6-month (areas of under the curve [AUC] = 0.73), see Figure. Among 155 patients who remained on study protocol at month 6 in their original treatment group, 130 were in remission. A combination of 7 biomarkers, new diagnosis at entry, and rituximab treatment provided highest accuracy in predicting remission at month 6 (AUC = 0.85). Forcing additional demographic and clinical information did not improve accuracy in either model (AUC = 0.74 and 0.85).

**Conclusion:** A combination of several biomarkers during active disease could provide a useful tool to predict patients with AAV who will achieve optimal response to induction therapy. Further validation studies are needed to test the clinical utility of this panel of biomarkers.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Plenary Session II

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Primary Sjögren's syndrome (pSS) is a systemic, progressive autoimmune disease characterized by formation of ectopic germinal centers in exocrine glands and secretory gland dysfunction. A subset of patients also develops extraglandular manifestations. CFZ533 is a novel monoclonal antibody that potently and selectively blocks CD40, a co-stimulatory pathway receptor essential for germinal center reactions and other immune mediated functions implicated in pSS pathogenesis. We conducted a randomized, double-blind, placebo-controlled, multi-centric, partial cross-over Phase IIa Proof of Concept (PoC) study to evaluate the safety, tolerability and efficacy of CFZ533 in patients with pSS.

**Methods:** Clinically active (EULAR Sjögren's Syndrome Disease Activity Index [ESSDAI]  $\geq 6$ ) pSS patients were randomized to receive four doses of 3 mg/kg s.c. CFZ533 or placebo (2:1, Cohort 1) or 10 mg/kg i.v. CFZ533 or placebo (2:1, Cohort 2) over 12 weeks in Period 1. Four additional doses of 3 mg/kg s.c. CFZ533 or 10 mg/kg i.v. CFZ533, respectively, were administered in an open label extension (Period 2) for 12 weeks. Key outcomes included safety and efficacy as assessed by change in ESSDAI after 12 weeks treatment. In addition, measurements of pharmacokinetics and pharmacodynamics (PK/PD) of CFZ533, EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), Multi-dimensional Fatigue Inventory (MFI), Physician's Global Assessment, Patient's Global Assessment, SF-36, and biomarkers of pSS were monitored.

**Results:** Forty-four patients were enrolled: 8 patients received 3 mg/kg s.c. CFZ533 and 4 placebo in Cohort 1 and 21 received 10 mg/kg i.v. CFZ533 and 11 placebo in Cohort 2. While PK/PD was as expected in the CFZ533 10 mg/kg i.v. cohort based on healthy volunteer data from the first in human trial, CFZ533 exposure appeared lower than expected in the 3 mg/kg s.c. cohort, likely due to target mediated disposition. Overall, CFZ533 was safe and well tolerated, and the majority of AEs were mild or moderate. There was a single serious AE (bacterial conjunctivitis) in the 3 mg/kg s.c. cohort that was not related to study drug. In Cohort 1, ESSDAI was observed to improve by approximately 2 points from mean baseline scores of approximately 12 in both placebo and 3 mg/kg s.c. groups, with therefore no evidence of treatment difference ( $\Delta$ ESSDAI=0.68, 95% CI = -4.71 – 6.46). However in Cohort 2, the improvement in ESSDAI from mean baselines of approximately 11 was observed to be 6.35 in the 10 mg/kg i.v. group compared to 1.27 in the placebo group, with the modelled difference between groups of  $\Delta$ ESSDAI=5.64 (95% CI=1.02 – 10.58) strongly favoring the CFZ533 i.v. treatment. Improvements in other measures such as ESSPRI, MFI, Physician's Global Assessment, and Patient's Global Assessment and decreases in the germinal center-related serum biomarker CXCL13 were also observed in the 10 mg/kg i.v. CFZ533 group.

**Conclusion:** In this proof of concept study, testing a blocking, non-depleting anti-CD40 antibody for the first time in primary Sjögren's syndrome, results suggest that CFZ533 may offer a new treatment modality in clinically active pSS.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Plenary Session II

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Use of biologic therapies for rheumatoid arthritis (RA) in pregnancy is common. There is theoretical concern that these medications could interfere with postnatal immune function in the infant.

**Methods:** The Organization of Teratology Information Specialists (OTIS) Autoimmune Diseases in Pregnancy Project enrolled pregnant women from U.S. or Canada with or without RA in a prospective observational cohort study. Women were followed with 3-4 telephone interviews; medical records were abstracted from the delivery hospital, obstetric and specialty providers; follow-up data were obtained from the pediatrician through 1 year of age. Maternal use of biologic medications including start/stop dates was captured, and questions were asked about serious/opportunistic infections in the infant. These were defined as an infection requiring hospitalization or any of the following: neonatal sepsis, invasive fungal infection, x-ray proven pneumonia, meningitis, bacteremia, pneumocystis, septic arthritis, osteomyelitis, tuberculosis, herpes, listeria, legionella, mycobacteria, systemic cytomegalovirus, or abscess. We estimated relative risks (RR) and 95% confidence intervals (CI) using generalized estimating equations. We further stratified comparisons by gestational timing of last dose of the biologic after 24 and 32 weeks gestation, respectively.

**Results:** Between 2004-2016, 1,184 pregnancies ending in live born infants, including 73 infants of twin pregnancies, were followed to 1 year postpartum (252 with RA treated with a biologic in pregnancy, 463 with RA but no treatment with a biologic in pregnancy, and 469 with no chronic diseases). Of those in the RA biologic group, 97 (38.4%) took their last dose in the 1st or 2nd trimester and 155 (61.5%) received their last dose in the 3rd trimester (Figure). Serious or opportunistic infections were reported in 7/252 (2.8%) of infants born to women with RA treated with a biologic, 18/463 (3.9%) of infants born to women with RA not treated with a biologic (RR 0.71, 95% CI 0.30, 1.71), and 12/469 (2.6%) of those infants whose mothers had no chronic diseases (RR 1.09, 95% CI 0.43, 2.72). Restricting the group treated with a biologic to women whose last dose was sometime after 24 weeks gestation, 6/155 (3.9%) reported infant infections in the biologics group compared to 18/463 (3.9%) in the RA comparison group (RR 1.00, 95% CI 0.40, 2.48). Further stratification at 32 weeks gestation resulted in infections reported in 5/143 (3.5%) in the RA biologics group compared to the 3.9% in the RA untreated group (RR 0.90, 95% CI 0.34, 2.39).

**Conclusion:** We found no evidence of increased risk of serious/opportunistic infections in infants in this sample. These data are reassuring for pregnant women who require treatment with a biologic medication. However, it is possible that less serious infections occur more frequently, and further research is needed.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Plenary Session II

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** A transmissible agent has long been suspected in the pathogenesis of SLE, yet the potential contribution of members of the intestinal microbiome to the immune abnormalities in active SLE has not previously been investigated. We therefore characterized the gut microbiota of patients with SLE, with special interest in those with Lupus nephritis (LN), a clinical feature too commonly associated with great morbidity and early mortality.

**Methods:** Blood and fecal samples from SLE patients were obtained, with the exclusion of patients with selective IgA deficiency, or history of prior cytotoxic drugs, or antibiotics within four months. Fecal 16S rRNA next generation sequencing was performed. Sera samples were profiled for autoantibodies. In addition, sera from two independent lupus cohorts were studied for validation.

**Results:** Compared to controls, the intestinal microbiome from SLE patients (N=61) showed decreased species richness diversity. The microbiota of patients in clinical remission (based on SLEDAI) were most similar to healthy controls, while reductions in taxonomic complexity were most pronounced in those with high disease activity. Notably, SLE patients had an overall 5-fold greater representation of a particular species in the *Blautia* genus of the *Lachnospiraceae* family of obligate anaerobic Gram-positive cocci. There were reciprocal significant contractions of two other commensal species with putative protective properties. Abundance of the *Lachnospiraceae* species significantly correlated with serum IgG to a cell wall moiety from a strain of this same species (P=0.002, N=61, Spearman) but not with 7 other strains. There was also a significant correlation between the distribution of SLEDAI scores and levels of these circulating anti-strain IgG antibodies (P=0.02, N=48). Using bacterial antigen treated with DNase/proteinase K, levels of IgG anti-strain antibodies were significantly higher in those with active nephritis at time of sampling compared to SLE without renal activity (Cohort 1 P=0.01 N=48; Cohort 2 P=0.006, N=28, Mann-Whitney). Levels of anti-strain antibodies also significantly correlated with high-titer serum IgG to native DNA (P<0.0001, N=27), and inversely correlated with C3 and C4 (each P<0.01, N=61). High titers of these anti-bacterial antibodies were found in patients with active Class III, IV and V LN (Cohort 3).

**Conclusion:** These findings suggest a novel paradigm for the pathogenesis of LN in which specific strains of common intestinal commensal bacteria contribute to the immune-complex mediated disease process responsible for glomerulonephritis (GN). This is reminiscent of poststreptococcal GN, although in LN the postulated intestinal bacterial dysbioses and microbial expansion appear to occur without outward signs and symptoms of clinical infection.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Plenary Session II

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** It is not known whether TNF blockers can be stopped in non-radiographic (nr-axSpA) patients who are in remission. In ABILITY-1, adalimumab (ADA) significantly improved clinical response vs placebo (PBO) in patients (pts) with nr-axSpA. ABILITY-3 (NCT01808118), reported here, assessed if ADA can be discontinued or should be continued in nr-axSpA pts in sustained remission after a 28-wk open-label period.

**Methods:** ABILITY-3 enrolled adult pts diagnosed with nr-axSpA, fulfilling ASAS criteria but NOT modified New York criteria who had objective evidence of active MRI inflammation in the SI joints or spine or elevated high-sensitivity CRP at screening, active disease at baseline (ASDAS  $\geq 2.1$ , BASDAI  $\geq 4$ , total back pain  $\geq 4$ ), and inadequate response to  $\geq 2$  NSAIDs. Pts who achieved ASDAS inactive disease (ASDAS  $< 1.3$ ) with open-label ADA 40 mg every other wk at wk 16, 20, 24, and 28 were randomized to 40-wk, double-blind PBO (withdrawal) or ADA (continuation) in period 2. The primary efficacy endpoint was the proportion of patients who did not experience a flare (ASDAS  $\geq 2.1$  at 2 consecutive study visits) during period 2. Secondary endpoints were also assessed up to wk 68 (nonresponder imputation).

**Results:** Of 673 enrolled pts, 305 (45%) were randomized to double-blind treatment (**Table**). A significantly greater proportion of patients treated with ADA vs PBO had no flares (70% vs 47%;  $P < 0.001$ ) at wk 68; the relative risk of flare with treatment withdrawal was 1.77. Time to flare analysis showed significantly lower risk of flare for ADA vs PBO (**Figure**). At wk 68, significantly greater proportions of ADA vs PBO patients achieved secondary endpoints, except for HAQ-S (**Table**). Among pts who received ADA at any time, 77% reported adverse events (AEs) and 4% reported a serious AE; nasopharyngitis (17%), upper respiratory tract infection (12%), worsening of axSpA (9%), headache (8%), and diarrhea (6%) were the most common. During period 2, incidence of AEs was similar for ADA and PBO (65% vs 69%), incidence of serious AEs was higher for PBO vs ADA (7% vs 1%), and the most common AEs in both the ADA and PBO groups were nasopharyngitis (16% vs 13%), upper respiratory tract infection (13% vs 8%), and worsening of axSpA (6% vs 14%; none serious).

**Table. Baseline Characteristics and Efficacy Outcomes at Week 68**

\*Baseline characteristics at overall study baseline (wk 0) unless indicated otherwise.

<sup>†</sup>Nonresponder imputation for wk 68 values; only data prior to rescue included.

<sup>‡</sup>Mixed effect Model Repeat Measurement.

*P* value using analysis of variance (baseline) or 2-sided Pearson chi-square test (wk 68 vs lead-in open-label baseline). *P* value for HAQ-S and BASFI change from baseline using analysis from 2-sided repeated measures model with fixed effect of treatment.

**Figure. Time to Flare by Week 68**

**Conclusion:** In pts with nr-axSpA who achieved sustained remission with ADA, continued therapy was associated with significantly more patients maintaining remission and lower disease activity than treatment withdrawal. These results support the continuation of ADA therapy after achievement of sustained remission. Safety findings were consistent with the established safety profile of ADA.

## Dose Intra-Articular Injection of Corticosteroids Increase the Risk of Knee Osteoarthritis Progression? Data from the Osteoarthritis Initiative

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Plenary Session II

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Although intra-articular injection of corticosteroids (IAIC) has been one of the modalities of treatment for symptomatic knee OA, the recommendations for its use are inconsistent. Recently, a randomized clinical trial (RCT) reported that IAIC didn't significantly improve pain, but instead resulted in greater cartilage volume loss compared with saline injections. To examine this unexpected finding in a real-life non-trial setting, we investigated IAIC in relation to knee radiographic osteoarthritis (ROA) progression in a prospective cohort study.

**Methods:** We conducted a propensity score matched cohort study to examine the effect of IAIC on the risk of knee ROA progression using data collected from the Osteoarthritis Initiative up to 8 years follow-up. Eligible subjects consisted of those who had at least one knee with a K/L grade of 2 or 3 and did not have IAIC at baseline. We identified subjects with incident knee IAIC during the study period. Knee ROA progression was defined as K/L grade worsening or knee replacement therapy during the follow-up. We used logistic regression model to calculate propensity scores for IAIC within each 1-year time block. The predictors for IAIC in the logistic regression model included age, sex, BMI, education, WOMAC pain score, knee injury history, physical activity level, NSAIDs use and K/L grade. Up to four knees without IAIC were propensity score matched to a knee with incident IAIC within each 1-year accrual block. Subjects were followed to the date of ROA progression, lost to follow-up, death or end of the follow-up, whichever came first. We plotted cumulative risk of ROA progression using Kaplan–Meier curves for each cohort accounting for competing risk. We fitted a Cox proportional-hazards model to examine the relation of IAIC to the risk of ROA progression.

**Results:** Baseline characteristics were well-balanced between IAIC and non-IAIC cohorts (**Table 1**). Risk of ROA progression was higher among knees with IAIC (60.86 per 1000 person-years) than those without IAIC (38.02 per 1000 person-years) during the follow-up (**Figure 1**). Compared with knees without IAIC, the hazard ratio of ROA progression for knees with IAIC was 1.60 (95%CI: 1.21 to 2.12). The associations appeared stronger among women (HR=1.71, 95%CI: 1.22 to 2.40) than men (HR=1.38, 95%CI: 0.84 to 2.28) although the effect estimate in men was not statistically significant owing to relatively small sample size (**Table 1**).

**Conclusion:** We found that knees with IAIC experienced higher risk of knee ROA progression than those without IAIC in a real-life setting, consistent with the recent RCT results.

Table 1. Hazard ratios for the risk of knee osteoarthritis progression associated with intra-articular corticosteroids injection

	Injection (n=134)*		Non-injection (n=498)**		Hazard ratio (95%CI)
	No. Progression	Incidence progression (1000 person- years)	No. Progression	Incidence progression (1000 person- years)	
All patients*	58	60.86	132	38.02	1.60 (1.21, 2.12)
By sex					
Male	17	55.47	46	38.57	1.38 (0.84, 2.28)
Female	41	63.42	86	37.73	1.71 (1.22, 2.40)

No., number.  
\*mean age=62.7±8.9, female ratio=65.7%, body mass index=29.8±5.5.  
\*\*mean age=63.2±8.5, female ratio=67.9%, body mass index=29.9±4.8.  
†Baseline characteristics (age, sex, body mass index, activity level, WOMAC pain score, education level, knee injury history, NSAIDs use rate, baseline K/L grade and K/L grade when accepting the injection) were well-balanced between injection and non-injection cohorts (all P values>0.05).

## **Improved Survival with Transplantation in Granulomatosis with Polyangiitis in the United States: Data from the US Renal Data System**

### **Background/Purpose:**

Granulomatosis with polyangiitis (GPA) is a common cause of glomerulonephritis and leads to end-stage renal disease (ESRD) in approximately 25% of patients. GPA is an accepted indication for transplantation and has comparable outcomes when compared to patients with ESRD due to other immune-mediated conditions. However, transplantation is a limited resource and the survival benefit of transplantation compared to remaining waitlisted has not been previously evaluated.

### **Methods:**

We identified all incident cases of ESRD due to GPA (ICD9=446.4) in the United States Renal Data System (USRDS) who were waitlisted for a renal transplant between 1995 and 2014. The USRDS captures nearly all patients with ESRD in the US and requires that nephrologists report the ESRD cause (ICD-9 code). The USRDS includes details regarding demographics, comorbidities, and waitlist and transplant dates and statuses. It also includes details on date and cause of death. All patients were followed until death or January 1, 2016. We restricted our analysis to patients waitlisted for transplant to limit the potential bias of confounding by indication. We used a pooled logistic regression with transplantation as a time-varying covariate to estimate the relative risk (RR) and 95% confidence intervals (CIs) of death among those transplanted compared to those who remained on the waitlist. We adjusted for sociodemographic covariates (e.g., age, gender) as well as comorbidities (e.g., diabetes, cardiovascular disease (CVD)). We assessed differences in cause of death using cause-specific hazard models to estimate hazard ratios (HRs) and 95% CIs.

### **Results:**

During the study period, 1,556 patients with ESRD due to GPA were waitlisted for a renal transplant and 977 (63%) of these patients received a transplant. The majority were male (60%) and white (84%). Average age at ESRD onset, waitlisting, and transplant were 47.3 ±16.5 years, 49.3 ±16.4 years, and 47.8 ±17.2 years, respectively. The average time from ESRD diagnosis to being waitlisted was 1.5 ±2.2 years. Total follow up time was 6.8 ±4.7 years. Overall, 444 deaths occurred. In fully-adjusted analyses, transplanted patients had a 59% lower risk of death compared to those who remained on the waitlist (RR 0.41, 95% CI 0.34-0.49). In fully adjusted cause-specific analyses, patients transplanted had a lower risk of cause-specific death from CVD (HR 0.06, 95% CI 0.03-0.1) and infection (HR 0.3 95% CI 0.2-0.6). There was no difference in the risk of cause-specific death from cancer (HR 0.5 95% CI 0.2-1.2).

### **Conclusion:**

In this nationwide study of ESRD due to GPA, renal transplantation was associated with a significantly reduced risk of death compared to remaining on the waitlist. Our findings highlight the importance of identifying barriers to transplantation in this patient population. Additionally, evaluating management strategies to reduce the risk of CVD and infection in patients on the waitlist will likely improve survival.

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis: Unexpected Effects from "Well-Known" Molecules

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

Sphingosine 1-phosphate (S1P), a bioactive lysophospholipid, is important for vascular homeostasis via signaling through S1P receptors. HDL-bound apolipoprotein M (ApoM) is a physiological S1P carrier that activates endothelial S1P<sub>1</sub> receptors, thereby increasing barrier function. ApoM-S1P also limits endothelial cell expression of adhesion molecules and activation of NF- $\kappa$ B in response to TNF- $\alpha$ . We tested a novel biologic S1P<sub>1</sub> receptor agonist, ApoM-Fc loaded with S1P, for its ability to protect the endothelial barrier in response to immune complex (IC) and neutrophil (PMN)-mediated injury in vitro and in vivo.

### Methods:

Barrier function of human umbilical vein endothelial cells (HUVECs) in response to IC and C5a activated PMNs +/- ApoM-Fc was assessed by Electric Cell-substrate Impedance Sensing (ECIS). Phosphorylation of myosin light chain2 (p-MLC2) and VE-Cadherin staining in HUVECs after treatment with activated PMNs +/- ApoM-Fc was assessed by immunofluorescence (IF). The reverse arthus reaction (RAR) was performed in skin in mice treated locally with S1P<sub>1</sub> agonists and antagonists. Lung RAR was performed in WT and *ApoM*<sup>-/-</sup> mice and mice with an inducible endothelial cell deletion of S1P<sub>1</sub> (ECKO). ApoM-Fc (100  $\mu$ g, IP) or PBS was administered to WT mice 2 hrs before lung RAR. PMNs and red blood cells in bronchoalveolar lavage fluid (BALF) were quantified. Lung weights and Evans blue (EB) were measured.

### Results:

Activated PMNs decreased HUVEC resistance in ECIS and increased p-MLC2 and VE-Cadherin junction disassembly as assessed by IF. ApoM-Fc prevented the loss of barrier function (mean increase 224 $\pm$ 28 Ohms, n=4) in a sustained manner (>8 hrs) and markedly reduced PMN-induced p-MLC2 and loss of VE-Cadherin. In contrast, a mutated ApoM-Fc construct that does not bind S1P was not protective. S1P also attenuated IC-mediated injury in vivo. S1P<sub>1</sub> agonist CYM-5442 decreased EB leak and skin weights after RAR compared to PBS treated controls (20 vs 27 mg, n=15-20, p<0.0001) and W146, a S1P<sub>1</sub> antagonist, increased EB leak and skin weights after RAR (24 vs 21 mg, n=12; p=0.02). S1P<sub>1</sub> ECKO mice showed markedly increased lung RAR compared to controls: EB extravasation (157 vs 95  $\mu$ g/g, n=3-5 mice; p=0.04), BAL WBCs (1.0 vs 0.6  $\times 10^3/\mu$ l, n=8-11; p=0.03), and lung mass (330 vs 265 mg, n=5-6; p=0.0007). *ApoM*<sup>-/-</sup> treated with local administration of W146 to partially block S1P<sub>1</sub> also showed more intense lung RAR than WT controls treated with W146, consistent with increased vascular vulnerability to injury. Importantly, delivery of S1P in vivo with ApoM-Fc was able to limit lung RAR with reduction in BALF WBCs and RBCs and decreased extravasated EB compared to PBS treated controls.

### Conclusion:

These data demonstrate that stimulation of endothelial S1P<sub>1</sub> receptor by ApoM-HDL-S1P protects barrier integrity of the microvessels when challenged by IC-mediated vascular injury. S1P<sub>1</sub> receptor agonism represents a novel target to limit inflammation-induced injury in SLE and other IC mediated diseases. Moreover, because ApoM-Fc does not induce lymphopenia, unlike most other S1P<sub>1</sub> agonists, it could be used concomitantly with immunosuppressive therapies.

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## Background/Purpose:

Activated macrophages are found in the inflamed and hyperplastic synovial RA tissue. Macrophages are the main producers of high levels of pro-inflammatory cytokines such as TNF $\alpha$  and IL6. However, the mechanisms of TNF $\alpha$  overexpression are still unknown. Recent findings showed that the 5-methylcytosine (5-mC) modification of DNA can be converted to 5-hydroxymethylcytosine (5-hmC) through the activation of the family of Ten-Eleven-Translocation (TET1-3) enzymes. In the current study, we investigated the 5-hmC modification in macrophages stimulated with lipopolysaccharide (LPS) and characterized the function of TET1-3 enzymes during inflammation.

## Methods:

The leukemic monocytic cell line THP-1 was differentiated into macrophages in the presence of 50nM phorbol myristate acetate (PMA). THP-1 derived macrophages were stimulated with 10 ng/ml LPS at different time points (0h, 2h, 4h, 6h, 24h). The global 5-hmC levels were quantified by DNA dot blot assay. Hydroxymethylated DNA immunoprecipitation (hMeDIP) and chromatin immunoprecipitation assays for TET1 were applied to analyze the levels of 5-hmC in the TNF $\alpha$  promoter. THP-1 derived macrophages were transfected with TET1,2,3 siRNA and then stimulated with 10ng/ml LPS for 2 hours. TNF $\alpha$  and IL6 levels were measured in the supernatants by ELISA.

## Results:

The undifferentiated monocytes (THP-1) had the lowest basal levels of 5-hmC. The highest levels of 5-hmC was observed after 24 hours of PMA stimulation after which the monocytes had differentiated into macrophages. Furthermore, we searched for changes in 5-hmC at the promoter of TNF $\alpha$  and found a significant increase in THP-1 derived macrophages (n=3, p<0.05).

THP-1 derived macrophages were stronger responders to LPS than the monocytes for all inflammatory cytokines tested. For each stimulation time point, we measured the 5-hmC modification by hMeDIP and found a time depend increase in the level of 5hmC at the TNF $\alpha$  promoter. The 5-hmC enrichment of the TNF $\alpha$  promoter was significantly higher in THP-1 derived macrophages than THP-1 monocytes (n=3, p<0.05).

Then, we knocked down TET1 in THP-1 derived macrophages before stimulating the cells with LPS. Most importantly, TET1 inhibition reduced the stimulatory capacity of macrophages as shown by the significantly reduced mRNA and protein levels of pro-inflammatory cytokines (TNF $\alpha$ , IL-6, n=3, p<0.05). In contrast, siTET2 and siTET3 did not reduce the expression levels of TNF $\alpha$  and IL-6.

Since the function of TET1 enzymes is to hydroxylmethylate the cytosine residues in gene enhancers and promoters, we measured the levels of 5-hmC at the promoter of TNF $\alpha$  and IL6 by hMeDIP. siTET1 transfected macrophages had significantly lower 5-hmC enrichment in comparison to control cells upon LPS stimulation (n=3, p<0.05). Furthermore, we found direct binding of TET1 at the promoter of TNF $\alpha$  by TET1 ChIP assay (2.5 TET1 fold enrichment versus IgG control, n=3).

## Conclusion:

For the first time, we showed that TET1 contributes to the sustained activation of macrophages through the regulation of 5-hydroxymethylation in the promoter of TNF $\alpha$ . The TET1 enzyme could be a promising target to study in macrophages from RA patients.

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis: Unexpected Effects from "Well-Known" Molecules

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

TNF and IL-17A are proinflammatory cytokines critically involved in the pathogenesis of psoriatic arthritis (PsA). Currently, targeting TNF is the first choice of a biologic disease-modifying antirheumatic drug (bDMARD) in PsA. However, up to 30% of patients receiving anti-TNF monotherapy fail to respond and require switching to a second TNF-inhibitor or bDMARD with a different mode of action. Strategies targeted at neutralizing IL-17A have been shown to have beneficial effects on skin, enthesitis, dactylitis and joint inflammation. Here, we explore the effect of neutralizing IL-17A versus anti-TNF on the expression of proinflammatory cytokines and metalloproteinases (MMPs) and whether dual-therapy targeting TNF and IL-17A may have superior activity than treatment with either agent alone.

### Methods:

An allogeneic co-culture system was used comprising synovial fluid T helper (Th) memory cells and synovial fibroblasts (SF), derived from patients with active PsA. Anti-CD3/CD28 stimulation was used during culture, and anti-IL-17A antibody (Secukinumab), anti-TNFalpha antibody (Adalimumab), or the combination were added. PsA unstimulated synovial Th memory cells co-cultured with PsA SF were included as a control group as well as an isotype antibody control group. After 72 hours, supernatants were harvested for ELISA and cells were lysed for qPCR analysis.

### Results:

Anti-TNF Ab treatment had no effect on IL-17A levels and neutralization of IL-17A did not influence the TNF production in the co-culture system. Both anti-TNF and anti-IL-17A single treatment significantly inhibited the production of IL-8 and reduced the mRNA expression of IL-1beta. Interestingly, neutralizing IL-17A resulted in a significant suppression of IL-6 levels which was not reduced by anti-TNF. Anti-TNF inhibited the production of MMP-3 and only the combination of anti-TNF and anti-IL-17A resulted in a significant suppression of MMP-1 levels and MMP-9 mRNA expression. MMP-13 mRNA expression was significantly suppressed by anti-TNF but not by anti-IL-17A, however, neutralizing both IL-17A and TNF showed a significant improvement in downregulating MMP-13 mRNA expression compared to single cytokine treatment. Moreover, anti-IL-17A reduced RANK mRNA expression that was significantly more suppressed compared to anti-TNF alone. However, no additive effect was noted for the combination blocking. Interestingly, only neutralizing both IL-17A and TNF significantly reduced the mRNA expression of RANKL. OPG mRNA expression was not influenced by anti-IL-17A and/or anti-TNF treatment.

### Conclusion:

Neutralizing IL-17A or TNF in the PsA synovial T cell – SF co-culture system resulted in overlapping but also distinct effects on proinflammatory cytokine expression. TNF inhibition markedly suppress different MMPs with mostly an additional effect upon neutralization of IL17A. Neutralization both IL-17A and TNF is needed to downregulate RANKL expression which changes the RANKL/OPG balance. Together, these preliminary data suggest that dual therapy targeting IL-17A and TNF may be superior in their activity to protect against erosive arthropathy in PsA than treatment with either agent alone.

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis: Unexpected Effects from "Well-Known" Molecules

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** High interleukin-22 (IL-22) levels are detected in serum and synovial fluid of rheumatoid arthritis (RA) patients and have been shown to positively correlate with disease activity markers and more erosive disease. The role of IL-22 in autoimmunity and inflammation appears to be greatly contradictory, being both pro- and anti-inflammatory. Previous work in other disease models suggested that the presence of IL-17 determines the inflammatory effect of IL-22, being protective in the absence and pathogenic in the presence of IL-17. The purpose of our study was to further unravel the role of IL-22 during experimental arthritis, in particular focusing on the cytokine interactions within the inflammatory environment.

**Methods:** To investigate the potential of IL-22 to drive joint inflammation and destruction, IL-22 was overexpressed in murine knee joints using an adenoviral construct (AdIL-22), and synovial biopsies and whole joints were collected for mRNA/protein expression analysis and histological scoring of joint pathology. To study the interaction of IL-22 within the disease cytokine network, AdIL-22 was injected intra-articularly as single cytokine, or combined with a second vector overexpressing TNF $\alpha$ , IL-17 or IL-1 $\beta$ . Furthermore, we studied the effect of local IL-22 overexpression on two experimental arthritis models: SCW and K/BxN serum transfer arthritis. Our second strategy involved using IL-22-deficient mice, which were crossed with IL-1Ra-deficient mice that spontaneously develop T cell-driven arthritis. Besides the effect of IL-22-deficiency on arthritis incidence and severity, we also investigated how the lack of IL-22 signaling affected the responsiveness to anti-IL-17 therapy in this IL-17-driven model.

**Results:** Despite the significantly enhanced synovial mRNA expression of pro-inflammatory and pro-destructive genes like IL-6, KC, S100A8 and RANKL, surprisingly IL-22-overexpression did not result in any sign of joint pathology in the knee joints of naïve mice. Furthermore, IL-22 neither aggravated disease severity during both models of innate immune-driven experimental arthritis, nor did it affect IL-17-, IL-1 $\beta$ -, or TNF $\alpha$ -induced joint inflammation when overexpressed in combination with other cytokines. Interestingly, in comparison to the spontaneous arthritis development in classical IL-1Ra<sup>-/-</sup> mice, the absence of IL-22 significantly reduced disease incidence and severity in this model. While the arthritis incidence in regular IL-1Ra<sup>-/-</sup> mice reached up to 95% at the age of 15 weeks, IL-22<sup>-/-</sup> x IL-1Ra<sup>-/-</sup> mice only showed 50% disease onset. In line with suppressed disease severity, anti-hnRNP autoantibodies were lowered in IL-22<sup>-/-</sup> x IL-1Ra<sup>-/-</sup> mice. No effects were observed on T cell responses. Remarkably, in the absence of IL-22 the therapeutic efficacy of anti-IL-17 treatment on arthritis progression in these mice was lost.

**Conclusion:** This study not only confirms the pro-inflammatory role of IL-22 in the development and progression of experimental arthritis, it also demonstrates a novel role in the formation of anti-hnRNP antibodies. Finally, we demonstrated that IL-17 is not a determinant for the pro- or anti-inflammatory character of IL-22 in experimental arthritis.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis: Unexpected Effects from "Well-Known" Molecules

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** High interleukin-22 (IL-22) levels are detected in serum and synovial fluid of rheumatoid arthritis (RA) patients and have been shown to positively correlate with disease activity markers and more erosive disease. The role of IL-22 in autoimmunity and inflammation appears to be greatly contradictory, being both pro- and anti-inflammatory. Especially the anti-inflammatory properties of IL-22 are not well understood. The purpose of our study was to investigate the anti-inflammatory and immune-suppressive effect of IL-22 during experimental arthritis.

**Methods:** Collagen-induced arthritis was induced in DBA-1 mice by immunization and booster with bovine collagen type II (CII). After booster, but before arthritis onset, IL-22 was overexpressed either locally or systemically using an adenoviral construct (AdIL-22) or Luciferase as control (AdLuc). 1x10<sup>7</sup> plaque-forming units (PFU) of the adenoviruses were injected intra-articularly (i.a.) for local overexpression, or 3x10<sup>8</sup> PFU of adenoviruses were injected intravenously (i.v.) for systemic overexpression in immunized mice without clinical signs of CIA, and mice were sacrificed 10 days later. Macroscopic scoring and histological analysis was performed, and mRNA expression and protein production of various pro- and anti-inflammatory mediators was determined in synovial tissue, spleen, and serum.

**Results:** Local overexpression of IL-22 by injection of AdIL-22 in the knee joint of CII-immunized mice resulted in an unaltered arthritis incidence and severity as compared to the control virus AdLuc. Accordingly, no changes in mRNA expression or protein production were observed in mice locally overexpressing IL-22. In contrast, systemic overexpression of IL-22 potently reduced disease incidence and severity, which was also confirmed by histological analysis (See Figure 1). Mice overexpressing IL-22 systemically showed significantly lower mRNA levels of IFN $\gamma$  and SOCS3, and protein levels of IFN $\gamma$ , TNF $\alpha$ , MIP1 $\alpha$ , and IL-10.

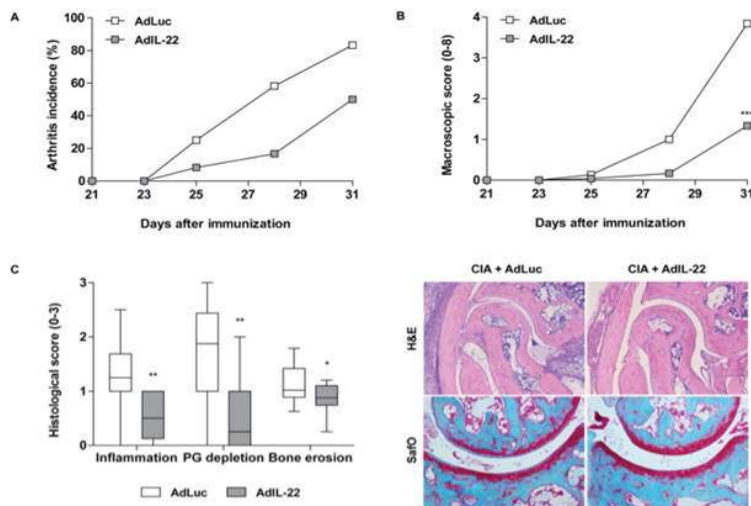

Figure 1. Systemic IL-22 overexpression reduces arthritis pathology.

**Conclusion:** With this study, we revealed clear anti-inflammatory effects of IL-22 overexpression during collagen-induced arthritis, which are completely dependent on the systemic route of administration. Additionally, we were the first to show that this protective effect of IL-22 during experimental arthritis is likely orchestrated via up-regulation of the negative regulator SOCS3.

### Background/Purpose :

pSS is characterized by a strong IFN signature, ectopic germinal centers formation and a chronic blood lymphopenia. IL-7 plays a central part in T cells homeostasis and in lymphoid structures organization. We aimed to assess the role of IL-7 in pSS pathogenesis.

### Methods :

IL-7 serum level was assessed in 372 pSS patients and 73 paired controls. Primary cultures of salivary gland epithelial cells (SGEC) from patients and controls were stimulated by Poly I:C 30 ng/ml, IFN- $\alpha$  600UI/ml, IFN- $\gamma$  5ng/ml and IFN- $\lambda$  (IL-28) 25ng/ml for 72 hours. IL-7 secretion was tested in culture supernatant by ELISA. IL-7 expression after 24 hours stimulation was assessed by

quantitative RT-PCR. IL-7 and its receptor's expressions were evaluated in RNA-Seq analysis from cells from salivary glands biopsies (SGB) and PBMC.

## Results :

pSS patients had higher serum IL-7 levels than controls:  $7.56 \text{ ng/ml} \pm 8.52$  (mean  $\pm$  SD) versus  $4.86 \text{ ng/ml} \pm 5.59$ ;  $p < 0.0001$ . A positive correlation with B cells activation markers, IFN-induced chemokines and disease activity markers was observed. In multivariate analysis, serum IL-7 level was associated with CXCL13, anti-SSA, RF,  $\kappa$  light-chain and low C4.

SGEC stimulation with Poly I:C, IFN- $\alpha$ , - $\gamma$  and - $\lambda$  induced IL-7 protein secretion in the supernatant ( $p = 0.002$ ,  $p = 0.004$ ,  $p = 0.007$ ,  $p = 0.004$  respectively) (Figure 1). A trend for a greater IL-7 production in pSS patients compared to controls was observed. IL-7 expression was confirmed by quantitative RT-PCR. Among cell subsets purified ex vivo from SGB and PBMC, RNA-Seq analysis showed a greater expression of IL-7 by epithelial cells of patients compared to controls ( $p = 0.03$ ). No difference was observed regarding T and B cells either from biopsies or PBMC. IL-7 receptor expression was equivalent between patients and controls. Analysis of T cells exhaustion profile and IL-7 intracellular signaling are on-going.

## Conclusion :

Our data demonstrate that IL-7 is secreted within the target tissue of pSS by SGEC after stimulation by IFNs. This IFN/IL-7 pathway can be involved in the organization of ectopic germinal centers found in pSS. But more importantly, since IL-7 is one of the major controller of homeostasis of T cells, this IFN/IL-7 pathway could be involved in the persistent lymphopenia which is a hallmark of the disease, either by favoring exhaustion of T cells or by an impaired function of the IL-7 intracellular signaling. Both mechanisms are currently explored and will be presented.

Figure 1: IL-7 secretion after a 72 hour-stimulation of SGEC

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Treat to target (TTT) is a recommended strategy in the management of rheumatoid arthritis (RA), but its uptake in routine rheumatologic care in the US is sub-optimal. We carried out an RCT of a Learning Collaborative (LC) to facilitate implementation of TTT. In the first phase, TTT implementation increased 46% in the intervention group. Herein, we report on the second phase in which the Phase I intervention sites were observed without intervention and additional sites received intervention.

**Methods:** We recruited 11 rheumatology sites (49 providers) from the US and randomized them into 2 groups: 5 sites received the LC intervention over the first 9 months (Phase I) and the other 6 sites received the intervention over the subsequent 9 months (Phase II). The LC included a face-to-face meeting, 8 learning sessions via webinar, use of a web-based tool for sharing results of plan-do-study-act cycles, and monthly collection of improvement measures. The primary outcome was the change in TTT implementation over 9 months, measured using a chart review before the intervention and then again after. TTT implementation included 4 items: shared-decision making, choice of a target, use of a disease activity measure (DAM), and changing treatments based on the target and DAM. It was scored on a 0-100% scale based on the presence/absence of these items. Phase II analyses allowed us to examine: 1) the sustainability of improvement in TTT among the Phase I intervention teams, and 2) predictors of TTT improvement across the 11 teams. Analyses accounted for clustering within site using Generalized Estimating Equations.

**Results:** The chart review included 636 RA patients seen by teams during the Phase I or II intervention periods. These patients had mean age 61, 81% were female, and 79% seropositive. At baseline, mean TTT implementation score was 11% in the Phase I intervention arm and 13% in the Phase II intervention arm (see Table 1). After the intervention, TTT implementation improved in the Phase I intervention arm to 57% and to 58% in the Phase II intervention arm (both P-values < 0.001). TTT implementation among the five Phase I intervention teams decreased slightly from 57% to 52% (P = 0.1). Predictors of greater improvement in TTT included not having NP/PA at site, the RA provider being a trainee, and academic affiliation of the site (see Table 2).

**Conclusion:** Improvement in TTT remained relatively stable over a 9-month post-intervention period. Several predictors of improvement in TTT implementation were identified at the site and provider level that might be used to guide interventions.

Table 1: Absolute Change in Implementation of Treat to Target and Components at Patient Visits in TRACTION Trial

	Phase I Intervention				Phase II Intervention			
	Month 0	Month 9	Month 18	Change (0→9)	Month 0	Month 9	Month 18	Change (9→18)
Primary Outcome								
Implementation score	11.1%	57.1%	52.4%	46.0%	11.0%	13.3%	58.0%	44.7%
Visits with components present								
Treatment target	0.6%	45.6%	51.0%	45.0%	0%	1.0%	52.1%	51.1%
Disease activity measure	20.0%	89.1%	70.7%	69.1%	30.2%	34.2%	85.1%	50.9%
Shared decision-making†	51.3%	85.9%	43.4%	34.6%	24.5%	29.8%	67.0%	37.2%
Treatment decision‡	0.6%	27.8%	36.7%	27.2%	0%	1.0%	36.5%	35.5%

The number of visits included differed by Phase and by month of assessment. For Phase I, there were 320 visits at month 0 and at month 9, and 300 visits at month 18. For Phase II, there were 321 visits at month 0, and 316 visits at month 9 and 18.† The shared decision-making criteria did not apply to all visits when no decisions were being made about changing targets or changing treatments. The number of visits when shared decision-making applied for the Phase I intervention group: 115 at month 0, 184 at month 9, and 99 at month 18. For the Phase II intervention group: 102 at month 0, 94 at month 9, and 112 at month 18. ‡ Treatment decision based on target and disease activity measure.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Current RA guidelines recommend treating to a target of remission or low disease activity (RM/LDA) state. In a prior quality improvement (QI) project, our practice increased documentation of Rapid3 in provider notes to 92%. This QI project was developed to improve the percentage of our RA patients in RM/LDA, as measured by Rapid3. We also aimed to understand providers' attitudes and use of the Rapid3 in practice.

### **Methods:**

We reviewed charts of established (>1 prior visit) RA patients over an 8-month period to assess use of Rapid3 in decision-making. We recorded Rapid3 presence and value, relevant co-morbidities (FM, OA and mood-disorders) and whether a change in therapy was made. Using Plan-Do-Study-Act (PDSA) methodology, we introduced the following interventions to improve utilization: education through Grand Rounds, modification of electronic medical record templates and reminder emails to providers. Charts were analyzed at baseline, between interventions and at the conclusion of all interventions. We surveyed providers at baseline and at project completion regarding habits and attitudes towards Rapid3 in clinical practice.

### **Results:**

Of 539 patient encounters with established RA, Rapid3 was documented in 501 encounters (93%). About 55% had at least 1 relevant co-morbid condition (182 patients with OA, 79 with FM, 74 with mood disorders); 295 had 1 co-morbidity, 34 had 2 co-morbidities and 6 had 3 co-morbidities. At baseline 38/139 (27%) were in RM/LDA. Our interventions resulted in 123/362 (34%) patients in RM/LDA (Figure 1). At almost every time point, percent of patients achieving RM/LDA was highest in patients with RA and no co-morbidities (Figure 1). Our survey of 18 providers found only 17% felt Rapid3 accurately reflected RA disease activity most of the time; 78% agreed Rapid3 changed their clinical management <10% of the time. Providers indicated the greatest challenges in using of Rapid3 were "score does not represent RA activity" and "other co-morbidities."

### **Conclusion:**

We sustained documentation rates of Rapid3 above 90%. The percent of patients in RM/LDA slightly improved, but this intervention was limited by short duration. We found very low provider confidence that the Rapid3 reflected RA activity, and it was infrequently used as a treatment target. The presence of any selected co-morbidities demonstrated a lower likelihood of achieving RM/LDA by Rapid3; FM and mood disorder had the greatest impact. Rapid3 may be most useful in patients without these co-morbidities. In the future, a "correction factor" for co-morbidities in scoring of Rapid3 may improve accuracy and provider use.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Vulnerable populations with autoimmune rheumatic diseases are at higher risk for disparities in care. To address these health inequalities we developed and evaluated 2 initiatives at an adult rheumatology clinic, which is the safety net for a diverse, urban population. We used the Institute for Healthcare Improvement (IHI) Model for Improvement to implement and assess pneumococcal (PCV13) vaccination among patients receiving immunosuppression and rheumatoid arthritis (RA) disease activity measurement.

**Methods:** Performance on the PCV13 vaccine was calculated as the proportion of patients receiving immunosuppression who were vaccinated. The RA disease activity measurement was the percentage of patients with outpatient RA encounters who received a clinical disease activity index (CDAI) score. For PCV13 vaccination, our clinic team utilized an interdisciplinary conference and nurse-led physician chart reminders (starting 2/2016). For RA disease activity, we reconfigured the electronic health record and utilized quarterly physician performance feedback (starting 6/2016). Control charts were used to examine performance of these measures over time. Vertical lines indicate time points of quality initiatives as described above. A series of at least 8 data points over the control limit (horizontal line) was indicative of significant improvement.

**Results:** The patient population studied had a median age of 58; 73% were women and 89% were racial/ethnic minorities. Over a 27-month period, PCV13 vaccination rates increased from 0.6% to 85% (Figure 1). Over a 12-month period, documentation of CDAI measurement at clinic visits increased from 45% to 91% (Figure 2).

**Conclusion:** Both quality initiatives were successful in significantly increasing pneumococcal vaccination rates and RA disease activity documentation. Using the IHI Model for Improvement and an intraprofessional team approach, we were able to dramatically improve performance on two important measures of health care quality for patients with rheumatic diseases.

**Disclosure:** A. Aguirre, None; L. Trupin, None; M. Margaretten, None; S. Goglin, None; J. Yazdany, None.

## Time to First Appointment Among Young Adults Transitioning from Pediatric to Adult Rheumatologic Care in a Safety Net Population

Nicole Bitencourt<sup>1</sup>, Una E. Makris<sup>1,2</sup>, Tracey Wright<sup>3,4</sup> and E. Blair Solow<sup>1</sup>, <sup>1</sup>UT Southwestern Medical Center, Dallas, TX, <sup>2</sup>Department of Medicine, VA North Texas Health Care System, Dallas, TX, <sup>3</sup>Pediatrics/Rheumatology, UT Southwestern Medical Center, Dallas, TX, <sup>4</sup>Texas Scottish Rite Hospital for Children, Dallas, TX

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

For young adults with a chronic rheumatic illness transitioning from pediatric to adult care, the transfer to new system can be daunting; these challenges are heightened in a socioeconomically at-risk population. As part of a quality improvement project, we characterized the time from referral to first clinic visit with adult rheumatology in a large public safety net healthcare system. Further, we sought to describe factors that may influence time to first visit.

### Methods:

A chart review was performed which identified 65 patients between ages 17 and 21 who were transitioning into adult care between 3/2014 and 4/2017. Data regarding time from referral to first scheduled appointment with adult rheumatology, as well as time from last pediatric visit to first adult visit was extracted and examined. Variables potentially related to time to first visit were also obtained and compared using the two-tailed t-test, including information as it related to referral patterns, medication adherence, and no-show rates.

### Results:

Refer to Table 1 for demographic information. The average time from first referral to first scheduled appointment with adult rheumatology was 193 days, while time to the first actual visit was 221 days. Nearly half (45%) were seen more than 180 days following their last visit with pediatric rheumatology (Figure 1). Time to adult rheumatology visit was significantly longer if someone other than a pediatric rheumatologist placed the referral to adult rheumatology. Lengthier time between appointments was seen in patients with documented medication non-adherence at the first appointment. Young adults who no-showed to their first adult rheumatology visit were more likely to have had a lapse in coverage compared to those who came to their first scheduled appointment (Figure 2).

**Conclusion:**

Patients transitioning into adult rheumatologic care in a large public safety net system experience significant delays to their first adult visit, which may adversely impact medication adherence and show rates. We plan to shorten the time to first appointment by blocking slots for transitioning patients. Further, we will disseminate information on how to acquire medical coverage and navigate our safety net system in a timely, coordinated fashion.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The importance of patient-reported outcomes is increasingly recognized both in clinical care and in research. PROMIS is an NIH-supported collection of patient-reported outcome measures, covering a variety of domains that are designed without disease specificity. While 'short forms' have been studied in juvenile idiopathic arthritis (JIA), PROMIS computer adaptive tests (CATs) have not. This study evaluates whether PROMIS CATs correlate with disease activity in patients with JIA.

**Methods:** A convenience sample of patients with JIA (N = 21) were recruited from a single center. Patients aged 10-17 years completed all available pediatric PROMIS CATs, and parents of patients aged 2-9 years completed all available parent proxy PROMIS CATs (fatigue, pain interference, peer relations, anxiety, depressive symptoms, and mobility). Correlation of the CATs t-scores with disease activity, as measured by the Juvenile Disease Activity Score-71 (JADAS-71), (0-101, higher being worse) was evaluated using Spearman correlation coefficients.

**Results:** All families approached completed the PROMIS CATs: 13 patients and 8 parents (Table 1). Median age was 12.7 years (range 1.3 – 18.6 years), and mean JADAS-71 score was 9.58 (SD 2.07). 69% of patients completed PROMIS CATs remotely via smartphone.

Anxiety ( $r = 0.74$ ,  $p = 0.006$ ), depressive symptoms ( $r = 0.84$ ,  $p < 0.001$ ), and pain interference ( $r = 0.64$ ,  $p = 0.018$ ) CATs correlated strongly with JIA disease activity (Table 2). Among parent proxy CATs, only anxiety correlated with disease activity ( $r = 0.71$ ); however the association was not statistically significant.

**Conclusion:** Our results demonstrate that the PROMIS CATs are feasible to administer in an outpatient pediatric rheumatology setting. Anxiety, depressive symptoms, and pain interference were significantly correlated with disease activity, even though mean disease activity was relatively low. This underscores the negative effect on quality of life of even mild disease. Parent proxy CATs showed poor correlations with disease activity, suggesting parents are inaccurate in assessing important aspects of their child’s health. Larger prospective studies are needed to evaluate the sensitivity of PROMIS CATs to change in disease activity over time.

**Session Title:** Measures and Measurement of Healthcare Quality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Corticosteroids (CS) are commonly used for rheumatologic conditions, and known to cause systemic adverse events (AEs), particularly when used at high doses for prolonged periods. The burden, the incidence of AEs, and associated costs were assessed across varying levels of CS exposure.

**Methods:** Patients with a diagnosis of select autoimmune and inflammatory diseases between 1/1/2006 and 9/30/2015 were selected from a de-identified claims database. Patients with  $\geq 60$  days of continuous CS use were stratified into three prednisone-equivalent dose cohorts:  $\leq 7.5$  mg/day ("low dose"),  $> 7.5 \leq 15$  mg/day ("medium dose"), or  $> 15$  mg/day ("high dose"). These groups were compared with patients with  $< 60$  days of CS use. Outcomes were assessed from the first day of a patient's highest dose episode until the earliest of 30 days after the end of continuous use, plan disenrollment, or end of study period. The incidence of AEs and costs during follow up were compared across cohorts.

**Results:** Among the 167,165 included patients, one-third had  $< 60$  days of CS use, 4% had low, 5% had medium, and 4% had high dose use of  $\geq 60$  days. High and medium-dose CS use varied among the conditions: PM/DM (37%), lupus (19%), and RA (19%) (Exhibit 1). Compared to patients in the  $< 60$  days cohort, risks of AEs (new cases) were several folds higher in the high-dose cohort: myocardial infarction (incidence rate ratio [IRR] 3.8), pneumonia (IRR 4.1), glaucoma (IRR 2.3), and hypertension (IRR 2.4). Most AEs had increasing incidence with higher-dose use (Examples shown in Exhibit 2). Across the three  $\geq 60$ -day cohorts, AEs occurred at an average of 2.3-6.7 months after the initiation of the CS episodes; AEs developed more quickly for patients with high-dose than medium- or low-dose CS use. All treatment cohorts had higher AE-related medical costs than disease-related medical costs (Exhibit 3). AE-related medical costs accounted for approximately 30% of the mean annualized total healthcare costs (27% for  $< 60$  day patients, 33% for high-dose patients).

**Conclusion:** This study quantified and demonstrated a dose-relationship for the risks of and time to AEs as well as the costs of prolonged CS use. Among patients who are exposed to high-doses, considerations to reduce their reliance on CS may provide clinical and economic benefits.

**Exhibit 1. Treatment cohorts****Exhibit 2. Adverse event incidence rate during the follow-up period****Exhibit 3. Annualized patient healthcare costs**

	High dose	Medium dose	Low dose	<60 days
Total all-cause healthcare costs (including medical and prescription drug costs)	\$68,408	\$35,498	\$31,900	\$32,690
Adverse event-related medical costs	\$22,807	\$10,632	\$9,342	\$8,947
Disease-related medical costs	\$16,151	\$6,846	\$5,399	\$4,133
Disease-related prescription drug costs	\$2,066	\$3,491	\$3,749	\$1,507
Non-adverse event or disease-related healthcare costs	\$59,434	\$27,160	\$23,910	\$28,132

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

The Flare-RA questionnaire was developed and validated in French (1) for assessing the occurrence of a flare of rheumatoid arthritis (RA) during a 3-month period, and cross-culturally adapted for the English, Spanish and Danish languages. The objective was to assess its cross-cultural equivalence in dimensionality and scale calibration, conditioning its validity.

**Methods:** Patients included in studies in each of 4 countries (2 cohort studies and 2 clinical trials) were age 18+ years, had RA according to 2010 ACR criteria, were in routine care in three studies and attended a tele-health consultation in one study. Flare occurrence during the most recent 3 months was assessed at baseline and at 3 months of follow-up using the Flare-RA 11-item questionnaire. Flare was measured in two dimensions, namely arthritis-related (5 items) and general (6 items) subscales scoring from 0 (no flare) to 10 (maximum flare). Statistical analysis used exploratory and confirmatory factor analyses to determine dimensionality. Rasch modelling for scale calibration was used to search for differential item functioning (DIF) for countries, sex, and flare anchor (yes/no) using RUMM 2030®.

### Results:

Overall, 571 patients (by center: 75, 105, 138 and 253) with mean±SD age 56.9±13.5 years and 75.3% female were included. Self-perception of a flare was reported by 39.9% of patients. Baseline RA disease activity varied by center. Mean DAS28 scores for each center were 2.1±0.8, 2.5±1.2, 2.9±1.2 and 3.6±1.4. Flare-RA items did not show any ceiling effect; mean score was 2.9±2.7 for arthritis-related and 2.5±2.6 for general subscales.

Principal component analysis showed a consistent first factor (65.7% variance), and demonstrated a strong bi-dimensional structure (75.8% variance)(figure). This dimensionality was stable over time and across countries in confirmatory analysis.

The Rasch partial credit model for subscales showed no local dependency, good person separation index (range 0.76–0.87) and good ordering of scale modalities. Only one item on “pain killer intake” performed less well, with less balanced ordering. Two items presented some misfit (fit residual>|2.5|) for each subscale. It was decided to keep them for clinical relevance. Finally, there was some significant but moderate DIF for countries in 7 items, all being uniform DIF. No interaction (DIF) was seen by sex, and only 2 minor DIF with flare anchor.

### Conclusion:

This international effort confirms the solid bi-dimensional structure of the Flare-RA questionnaire, with arthritis-related and general subscales, and its good scale measurement properties. There was a slight DIF that might be investigated in larger samples, but it nevertheless can be used as a quantitative scale. These findings demonstrate that the Flare-RA questionnaire has validity for measurement and for international comparison across cohorts and clinical trials.

## A Cluster Analysis Approach to Patient-Physician Discordance in Rheumatoid Arthritis Activity Evaluations Optimally Differentiates and Predicts Clinical, Functional and Quality of Life Outcomes

George Karpouzas<sup>1</sup> and Sarah Ormseth<sup>2</sup>, <sup>1</sup>Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, <sup>2</sup>Rheumatology, Harbor-UCLA Medical Center, Torrance, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

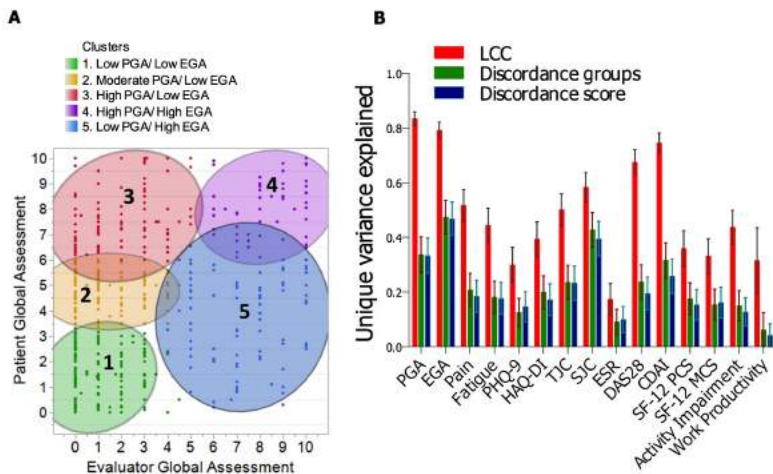

**Background/Purpose:** Patients and physicians commonly differ in their evaluations of rheumatoid arthritis (RA) activity. However, clinically meaningful thresholds for such discordance or validation of their ability to optimally predict clinical and functional outcomes are lacking. We used an unbiased clustering approach to classify cases based on patient (PGA) and physician/evaluator (EGA) global assessments of RA activity. We first examined whether such an approach could generate distinct patient groupings with diverse clinical phenotypes. We subsequently explored whether this approach could explain a higher variance in clinical and functional parameters of interest compared to traditional discordance definitions.

**Methods:** We performed latent class cluster (LCC) analysis in 538 patients with established RA to identify patient subgroups based on PGA and EGA ratings (measured on 10-cm visual analogue scales). Conventional discordance definitions included a continuous score (PGA-EGA) as well as a threshold-based one; with the latter, patients were classified into three groups: concordant (PGA-EGA within  $\pm 3$ cm), positively discordant (PGA-EGA  $> 3$ cm) and negatively discordant (PGA-EGA  $< -3$ cm). We used  $R^2$  values to compare the explanatory power of regression models using LCC-generated solution or conventional discordance definitions to predict outcomes of interest.

**Results:** LCC analysis yielded a five-group solution (Fig 1A). Groups were distinct and reflected different pairings of PGA and EGA scores: (1) Low PGA/Low EGA (33%); (2) Moderate PGA/Low EGA (21%); (3) High PGA/Low EGA (19%); (4) High PGA/High EGA (10%); and (5) Low PGA/High EGA (17%). Classification accuracy was 98.3%. ANCOVA confirmed differences in

characteristics among LCC groups (Table 1). The High PGA/High EGA group fared worst overall, with patient outcomes similar or worse than the High PGA/Low EGA group and clinician-evaluated indices comparable to or worse than the Low PGA/High EGA group. The explanatory power of the LCC-based solution significantly outperformed conventional discordance definitions predicting all measured outcomes (Fig 1B).

**Conclusion:** Our findings highlight the validity and advantages of an LCC approach in quantifying the relationship between patient-physician global activity assessments, based on two simple measures collected in routine practice. LCC-generated groups differed significantly across clinical, functional and quality of life outcomes, and identified patients in greatest need of adjunctive treatments targeting pain, fatigue and psychological distress.

**Figure 1. A.** Latent class cluster (LCC) analysis yielded five distinct patient groups based on different pairings of PGA and EGA scores. **B.** The LCC group solution explained significantly higher unique variance (incremental  $R^2$ ) amongst several disease-related parameters than traditional discordance definitions, above and beyond that accounted for by RA duration, gender, RF positivity, Fibromyalgia, irreversible articular damage, prednisone use, and DMARD use. Error bars represent 95% confidence intervals. PGA: patient global assessment of disease activity, EGA: Physician/evaluator global assessment of disease activity, PHQ-9: 9-item patient health questionnaire reflecting depression, TJC: tender joint count, SJC: swollen joint count, ESR: erythrocyte sedimentation rate, DAS28: disease activity score based on 28 joint count, CDAI: clinical disease activity index, SF-12 PCS: 12-item short form physical component score, SF-12 MCS: 12-item short form mental component score.

## Patient-Reported Outcomes and Damage Predict Mortality in Lupus

**Desiree R Azizoddin**<sup>1</sup>, Meenakshi Jolly<sup>2</sup>, Patricia P. Katz<sup>3</sup> and Edward H. Yelin<sup>4</sup>, <sup>1</sup>Department of Psychology, Loma Linda University, Loma Linda, CA, <sup>2</sup>Rush, Chicago, IL, <sup>3</sup>Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA, <sup>4</sup>Medicine/Rheumatology, University of California San Francisco, San Francisco, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Physician-assessed disease activity and damage predict mortality in systemic lupus erythematosus (SLE). Patient-reported outcomes (PROs) are known predictors of mortality in other chronic diseases, but this relationship has not been examined in SLE. This analysis assessed whether PROs predict mortality in patients with SLE.

### Methods:

Data from 728 participants in the UCSF Lupus Outcomes Study were evaluated to determine if PROs at one point in time ("baseline", 2007) would predict subsequent mortality. Mortality was determined as of December 2015. PROs included the 8 subscales of the SF-36 (Physical Function, Role Physical, Pain, General Health, Vitality, Social Function, Role Emotional, and Mental Health), and depressive symptoms measured with the Center for Epidemiologic Studies Depression scale (CESD). Covariates were age, gender, race/ethnicity, poverty, disease duration, self-reported disease activity (Systemic Lupus Activity Questionnaire, SLAQ), and self-reported disease damage (Brief Index of Lupus Damage, BILD). BILD has previously shown good correspondence with physician-assessed disease damage. Univariate Cox regression analyses first examined each PRO as a predictor of subsequent mortality. Multivariate Cox regression analyses including covariates were then conducted for each PRO separately.

**Results:** Mean (SD) age was 50.6 (12.6) years; 671 (92.2%) participants were women. Ethnic composition was 68.5% Caucasian, 9.2% Hispanic, 7.3% African American, and 9.5% Asian. Baseline demographics, disease and PROs are shown in Table 1A. Mean (SD) follow up was 74.6 (23.2) months. There were 71 (9.1%) deaths. In univariate analyses, all PROs except the SF-36 Mental Health subscale and CESD were associated with mortality. In multivariate analysis, patient-reported physical function at initial screening independently predicted mortality after controlling for all other covariates (Table 1B), such that the odds of death were 3.5% lower for every increased point rating in physical health on the SF-36 Physical Function score [Hazard Ratio (HR) 0.97, 95%CI (0.94,0.99)  $p < 0.01$ ].

**Conclusion:** Self-reported physical function was independently predictive of mortality in SLE, even after adjusting for demographics (including poverty) and disease (duration, activity and damage). Tracking PROs, particularly patient-reported function, in clinical settings may add important information to improve patient long-term outcomes.

Table 1. A. Demographics and general characteristics (n=728) B. Multivariate Cox Proportional hazard regression analysis of mortality at 8 years

	M	SD	N	%
A.				
Female			671	92.2
Age (years)	50.6	12.6		
Ethnicity				
Caucasian			499	68.5
Hispanic			67	9.2
African American			53	7.3
Asian			69	9.5
Other			40	5.5
Below Poverty			80	11.0
BMI	26.8	6.8		
Disease activity	4.2	2.7		
Disease duration	16.7	8.4		
Disease damage	2.3	2.2		
Deceased			71	9.8
SF36 Physical Function	39.4	12.7		
B.				
Predictor	Hazard Ratio	95% CI	<i>p</i>	
Female	2.51	1.18, 5.35	.02	
Age	1.04	1.02, 1.07	.00	
Below Poverty	.086	.40, 1.84	.69	
Disease Duration	1.02	.99, 1.04	.28	
Disease Activity	.10	.89, 1.12	.98	
Disease Damage	1.23	1.12, 1.36	.00	
SF-36 Physical Function	.97	.94, .99	.01	

Note: A. Relates to demographics and general characteristics. B. Relates to Multivariate Cox Proportional hazard regression analysis of mortality at 8 years. SLE disease activity is rated as 10-point Likert scale of patient rated disease activity; Disease damage is rated on the Brief Index of Lupus Damage (BILD); Below poverty calculated by US federal government guidelines; 36-Item Short Form Survey (SF-36) including only physical function domain. All scores were

rated at Time 1. Deceased status was evaluated throughout 8-year study progression. HR = Hazard Ratio. 95% CI = 95% Confidence Interval. SLE disease activity is rated as 10-point Likert scale of patient rated disease activity; Disease damage is rated on the Brief Index of Lupus Damage (BILD); Below poverty calculated by US federal government guidelines; 36-Item Short Form Survey (SF-36) including only physical function domain. All scores were rates at T1.

## Construct Validity of RAPID3 for Measurement of Disease Activity in Psoriatic Arthritis

Jessica A. Walsh<sup>1</sup>, Christine Willinger<sup>2</sup>, M. Elaine Husni<sup>3</sup>, Soumya M. Reddy<sup>4</sup>, Jose U. Scher<sup>5</sup> and Alexis Ogdie<sup>6</sup>, <sup>1</sup>Division of Rheumatology, University of Utah, Salt Lake City, UT, <sup>2</sup>University of Pennsylvania, Philadelphia, PA, <sup>3</sup>Cleveland Clinic, Cleveland, OH, <sup>4</sup>Department of Medicine, Division of Rheumatology \*contributed equally, New York University School of Medicine, New York, NY, <sup>5</sup>New York University School of Medicine, New York, NY, <sup>6</sup>Medicine/Rheumatology and Epidemiology, University of Pennsylvania, Philadelphia, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The Routine Assessment of Patient Index Data (RAPID3) was developed and validated for rheumatoid arthritis (RA). Little data exist on the use of RAPID3 in psoriatic arthritis (PsA). The objective of this study was to assess the construct validity (the ability of an instrument to measure the concepts it attempts to measure) of RAPID3 through investigation of its correlation with other validated measures of disease activity, physical function, and life impact among patients with PsA.

**Methods:** Patients with PsA were enrolled in the Psoriatic Arthritis Research Consortium (PARC) between 2015-2016. PARC is a longitudinal observational cohort study conducted at four institutions: University of Pennsylvania, Cleveland Clinic, New York University, and University of Utah. Standardized data are collected and entered into a Research Electronic Data Capture database. All sites collected RAPID3 and provider-assessed outcomes, including tender and swollen joint counts, provider global assessment of overall health, and provider global assessment of arthritis. Three sites administered the Short Form 12 (SF12), and two sites collected the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue scale, Psoriatic Arthritis Quality of Life (PsAQoL) index, Dermatology Life Quality Index (DLQI), Work Limitations Questionnaire (WLQ), and Work Productivity and Activity Impairment (WPAI) questionnaire. Licenses have been obtained for the use of the SF-12 and the WLQ. Only baseline data were included in this cross-sectional analysis. Construct validity was assessed with Spearman's correlation coefficients between RAPID3, other PROs, and provider-assessed disease activity measures.

**Results:** Among 401 PARC participants with RAPID3 scores, 275 had SF12 scores, and 208 had full set of surveys. Of those with complete surveys, the mean age was 51.5 and 57% were female. The RAPID3 was highly correlated with the PSAID9 ( $r=0.90$ ) and BASDAI (0.89) (Table). RAPID3 was also correlated with the SF12 physical component score ( $r=0.73$ ), the FACIT-F ( $r=0.75$ ), the work limitations questionnaire ( $r=0.70$ ), tender joint count ( $r=0.43$ ), and swollen joint count ( $r=0.43$ ).

**Conclusion:** RAPID3 has good construct validity in PsA and measures disease impact more broadly than physical function and pain. RAPID3 scores strongly correlated with the PSAID, a PRO with specific questions addressing many facets of life impact (e.g., pain,

function, fatigue, sleep, coping, anxiety and depression). The moderate correlations between RAPID3 and provider-assessed outcomes demonstrated that patients interpreted their disease states differently than their providers.

**Table. Correlations between instruments in a cross-sectional setting of PsA patients.**

	RAPID3	PSAID9	PSAQoL	SF-12 PCS	BASDAI	FACIT-F	WLQ	Physician Global	Physician Arthritis
PSAID9*	0.90

Swollen Joint Count	0.43	0.38	0.29	-0.25	0.35	-0.24	0.27	0.53	0.71
Tender Joint Count	0.42	0.38	0.30	-0.29	0.37	-0.25	0.29	0.51	0.61
Pain	0.93*	0.89	0.67	-0.65	0.86	-0.69	0.61	0.60	0.59
Patient Global	0.95*	0.82	0.69	-0.64	0.84	-0.70	0.65	0.54	0.56

Spearman's correlation coefficients are shown in this table. Yellow indicates a strong correlation (rho 0.8-1.0) and blue a good correlation (0.6-0.79).

\*PSAID9 is presented but the results were nearly identical for PSAID12

\*\*Note that pain and global assessment are part of the RAPID3 so the correlation is expected to be high.

\*\*The productivity score of the Work Limitations Questionnaire is shown here. The WLQ index had nearly identical coefficients.

Additional Abbreviations: PSAID9=Psoriatic Arthritis Impact of Disease; PSAQoL=Psoriatic Arthritis Quality of Life; SF-12 PCS = Short Form 12 Physical Component Score; BASDAI = Bath Ankylosing Spondylitis Disease Activity Index; Physician global and Physician arthritis refer to the physician global assessments for overall health and arthritis respectively.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The BILD<sup>1,2</sup> was developed and validated as a measure of SLE organ damage for use in epidemiologic studies in which administration of the SLICC Damage Index (SDI) by physicians is not feasible. This analysis examines the criterion validity and other performance characteristics of the BILD in 4 racial/ethnic groups.

**Methods:** Data were from the California Lupus Epidemiology Study (CLUES), a population-based, multi-ethnic SLE cohort. Subjects participated in a research clinic visit during which the SDI was completed by a physician and completed a structured interview administered by a trained interviewer in which BILD was administered. Race and ethnicity were self-reported. Prevalence-adjusted

bias-adjusted kappa (PABAK) coefficients were calculated to determine item-by-item agreement between physicians and subjects. Spearman correlation coefficients examined relationships between BILD and SDI scores. Construct validity was evaluated by examining relationship of sociodemographic, disease-specific, general health, and health care utilization factors with BILD scores. BILD scores are not normally distributed, so were divided into rough quartiles for these analyses and differences tested using analysis of variance or chi-square analysis. All analyses were performed separately for each of 4 racial/ethnic groups: white (W), Hispanic (H), African American (AA), and Asian (AS).

**Results:** The sample (n=281) was 29% W, 23% H, 11% AA, and 37% AS; 89% female; mean age 45 ( $\pm$ 14) years; 22% with education  $\leq$ high school; 12% with poverty-level income; mean disease duration 16 ( $\pm$ 10) years. 85% of interviews were completed in English. Correlations with SDI ranged from 0.45 for AA subjects to 0.80 for AS subjects (Table). All PABAK coefficients were  $>0.75$ , with the exception of 1 item for H subjects. For each racial/ethnic group, individuals with higher BILD scores had disease of longer duration; were less likely to be working; had poorer self-rated health, physical functioning and pain interference; reported more physician visits during the previous year; and were more likely to have been hospitalized in the previous year. No differences were seen by education or health literacy. Among H and AS groups, no differences were seen in BILD performance by language of administration.

**Conclusion:** The BILD functioned reasonably well in all 4 racial/ethnic groups, regardless of language of administration. Correspondence with physician-completed SDI was moderate to good; correlations were lower for AA and H patients where sample size was smaller. Future research will examine the source of discrepancies (patient or physician reports). Results provide further support the use of the BILD in observational and epidemiologic research, including among racial/ethnic minorities.

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Patient Outcomes, Preferences, and Attitudes I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

**Background/Purpose:** The Arthritis Research UK Musculoskeletal Health Questionnaire (MSK-HQ) is a recently developed patient reported outcome measure (PROM) for use across patients with different musculoskeletal conditions. The initial development included a detailed scoping exercise and qualitative development phase involving both patients and clinicians. This study provides the first validation of the MSK-HQ in inflammatory arthritis.

**Methods:** 287 adults with an established diagnosis of inflammatory arthritis were recruited from six centres in England. Patients completed the MSK-HQ and other PROMs at baseline and again after 3 months. The MSK-HQ consists of 14 items relating to facets of musculoskeletal health including pain, fatigue, physical function, symptom interference, sleep, self-efficacy and psychological well-being rated using a four point ordinal scale from 'not at all' to 'extremely'. Construct validity was assessed using item response theory (IRT) methods. Specifically, a graded response model examined the functioning of each item with respect to underlying musculoskeletal health. Concurrent validity of the MSK-HQ total score was considered in relation to the Health Assessment Questionnaire (HAQ), as well as Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) Impact of Disease Scales in disease subgroups (RAID & PsAID). Test-retest reliability was considered over three months.

**Results:** The MSK-HQ was approximately normally distributed with no evidence of floor or ceiling effects. A unidimensional structure was confirmed though two items (understanding & self-efficacy) were less weakly related to the overall construct. Reliability across the range of responses was high (alpha 0.93). The total scale score correlated highly with the HAQ in all patients ( $r=-0.81$ ), RAID in those with RA or undifferentiated patients ( $n=218$ ,  $r=-0.88$ ), and PsAID in PsA patients ( $n=43$ ,  $r=-0.88$ ). Test-retest reliability over three months was good in those with stable disease (intraclass correlation= $0.73$ ).

**Conclusion:** In this study, we have provided further support for the validity and reliability of a new musculoskeletal health PROM in people with inflammatory arthritis. The tool compares well to existing PROMs, with the added advantage of lacking the floor effect of HAQ. The major advantage of the MSK-HQ is it is not disease specific and has high content validity in rheumatological conditions. The MSK-HQ score will be of value in clinical rheumatology practice, providing a measure which can be used across disease areas.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## Background/Purpose:

To report the 5-year immunogenicity of a quadrivalent human papillomavirus (HPV) vaccine (GARDASIL) in patients with systemic lupus erythematosus (SLE).

## Methods:

Female SLE patients and healthy controls, aged 18-35 years, who received GARDASIL in the year 2011 and sero-converted 12 months post-vaccination were followed for the persistence of immunogenicity at 5 years. Antibodies to HPV serotypes 6,11,16,18 were repeated at 5 years using an IgG immunoassay developed on a Luminex microsphere platform (total IgG LIA; Merck Research Laboratory). The rate of sero-reversion was compared between patients and controls. Factors associated with sero-reversion of the anti-HPV antibodies were studied by statistical analyses.

## Results:

50 SLE patients (age 25.8±3.9 years) and 50 controls (25.8±3.9 years) were vaccinated with Gardasil in 2011. The sero-conversion rates of anti-HPV serotypes 6,11,16 and 18 in patients and controls were 82%, 89%, 95%, 76%, and 98%, 98%, 98%, 80%, respectively, at month 12 post-vaccination. Among those subjects who sero-converted and were available for follow-up, persistence of the antibodies to HPV serotypes 6,11,16 and 18 at 5 years was present in 24/27 (89%), 26/31 (84%), 32/34 (94%), 24/25 (96%) of the SLE patients and 32/33 (97%), 32/33 (97%), 32/32 (100%) and 23/24 (96%) of the controls, respectively. Moreover, antibody titers to HPV serotypes 6 and 16 at 5 years were significantly lower in SLE patients than controls. Seven (21%) SLE patients had sero-reversion of any one of the four anti-HPV antibodies (6,11,16 or 18) at year 5 post-vaccination. Patients who sero-reverted had received a significantly higher cumulative dose of prednisolone (13.0±5.34 vs 4.63±4.59 grams; p=0.002), mycophenolate mofetil (1050±1180 vs 238±49.5 grams; p=0.007) and tacrolimus (375±580 vs 268±1180 mg; p=0.03) during the 5-year follow-up than those with persistence of immunogenicity. These sero-reverted patients had also received a non-significantly higher cumulative dose of cyclophosphamide (1.97±5.22 vs 0.43±2.24 grams; p=0.27). In addition, sero-reverted patients had more SLE flares in the 5-year follow-up period compared to those with persistence of immunogenicity (3.14±1.21 vs 1.89±1.28; p=0.03). Among 64 flares in patients with persistent anti-HPV antibodies and 26 flares in those with sero-reversion, renal flares occurred more frequently in the latter group of patients (16% vs 38%; p=0.02).

## Conclusion:

Immunogenicity of the quadrivalent HPV vaccine was retained in 79% of SLE patients at 5 year post-vaccination. Antibody titers to HPV serotypes 6 and 16 were significantly lower in SLE patients than controls. Patients who had more SLE flares, especially renal flares, and had received higher cumulative doses of glucocorticoids, mycophenolate mofetil and tacrolimus were more likely to have sero-reversion of one or more anti-HPV antibodies.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** There is a need for effective and safe treatment during pregnancy in women affected by chronic active inflammatory diseases such as rheumatoid arthritis. Adequate disease control is crucial to ensure the best fetal and maternal health, and to reduce the risk of adverse pregnancy outcomes. Anti-TNFs are an effective therapeutic option, but because most cross the placenta they are often stopped during pregnancy. Certolizumab pegol (CZP), due to its Fc-free molecular structure, is not expected to undergo active placental transfer compared to other antibody-based anti-TNFs. This study aimed to accurately measure the level of placental transfer of CZP from mothers to infants using a highly sensitive CZP-specific assay.

**Methods:** CRIB (NCT02019602) was a pharmacokinetic (PK) study of pregnant women ( $\geq 30$  weeks [wks] gestation) receiving commercial CZP (maintenance dose) for an approved indication; the last dose was given within 35 days prior to delivery. Blood samples were collected from mothers, umbilical cords, and infants at delivery, and infants again at Wks 4 and 8 post-delivery. CZP concentration was measured with a highly sensitive, CZP-specific electrochemiluminescence immunoassay validated in plasma (lower limit of quantification [LLOQ]=0.032  $\mu\text{g/mL}$ ;  $>10$ -fold lower than assays used in prior CZP PK studies).

**Results:** Of 21 CZP-treated pregnant women screened, 16 entered the study (Table A). Maternal CZP plasma levels at delivery were within the expected therapeutic range (median [range]=24.4 [5.0–49.4]  $\mu\text{g/mL}$ ). Of the 16 infants, 2 were excluded from the per-protocol set: 1 due to missing data at birth, and 1 due to implausible PK data (inconsistent with a pediatric CZP PK model). Of the remaining 14 infants, 13 had no quantifiable CZP level at birth ( $<0.032$   $\mu\text{g/mL}$ ) and 1 had a minimal CZP level of 0.042  $\mu\text{g/mL}$  (infant/mother plasma ratio=0.0009); no infants had quantifiable levels at Wks 4 and 8 (Figure). Of the 16 umbilical cord samples, 1 was excluded due to missing data; 3/15 had quantifiable CZP levels (max=0.048  $\mu\text{g/mL}$ ). No anti-CZP antibodies were detected in mothers, umbilical cords, or infants. The infants of CZP-exposed mothers had a safety profile consistent with that of unexposed, similar-age infants (Table B).

**Conclusion:** Using a highly sensitive assay, CZP levels were below LLOQ in 13/14 infant blood samples at birth, and all samples at Wks 4 and 8. This indicates no to minimal placental transfer of CZP from mothers to infants, suggesting lack of *in utero* fetal exposure during the third trimester. These results support continuation of CZP treatment during pregnancy, if anti-TNF therapy is considered necessary.

**Table A:** Baseline characteristics of mothers and infants

Median (min, max), unless stated otherwise	All mothers (n=16) [a]
Age, years	31 (18, 40)

## A Systematic Review of the Impact of Anti-Rheumatic Drugs upon Male Fertility and Paternal Exposure Peri-Conception

Julia D Flint<sup>1</sup>, **Maria Mouyis**<sup>2</sup> and Ian Giles<sup>3</sup>, <sup>1</sup>Medicine, University College London, London, United Kingdom, <sup>2</sup>Rheumatology Department, Northwick Park Hospital, London, United Kingdom, <sup>3</sup>Centre for Rheumatology, University College London, Centre for Rheumatology, University College London, UK, London, United Kingdom

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## **Background/Purpose:**

There is limited evidence relating to the impact of disease modifying anti-rheumatic drugs (DMARDs) upon male fertility and on pregnancies conceived by men with rheumatic disease. Safety concerns of reduced fertility and increased risk of adverse pregnancy outcomes frequently limits the prescription of these drugs in men wishing to conceive. These concerns however, arise based mainly from animal or in vitro experimental data and should be weighed against the beneficial effects of DMARD treatment in controlling active inflammatory disease that itself increases the chance of conception. Given that human in-vivo data pertaining to fertility and peri-conception safety is limited we conducted a systematic review of available evidence to update information on this subject and guide counselling in this situation.

## **Methods:**

A systematic search of PubMed and Embase was carried out in September 2016 to find relevant peer-reviewed papers, using keywords for fertility / spermatogenesis / conception, men, and disease modifying or biologic drugs commonly prescribed in patients with rheumatic disease. Exclusion criteria included review articles, abstracts, animal and in-vitro studies, studies of cancer chemotherapy or pre/peri-pubertal exposure only, and non-English language papers. The search yielded 644 papers, and the titles/abstracts were screened independently by MM and JF, duplicates removed and 174 potentially relevant papers selected for full text review.

## **Results:**

A total of 74 papers were included in the final analysis. Papers included 19 case reports, 15 case series, 2 mechanistic studies, 36 cohort studies, 1 RCT and 1 meta-analysis and covered the impact on fertility of over 553 male exposures to relevant drugs, and over 948 pregnancies conceived during paternal exposure to these drugs. Only 26 papers had a comparator group. Results for the individual drugs are shown in *table 1*. Overall there was no firm evidence of harm to fertility or pregnancy outcomes with paternal exposure to anti TNF, azathioprine, cyclosporine A, hydroxychloroquine, leflunomide, methotrexate, mycophenolate mofetil or rituximab. The quality of evidence for all drugs (using the GRADE approach) is 'low' or 'very low'. There was no evidence found pertaining to the effects of male exposure to IVIG, tacrolimus, golimumab or abatacept on fertility or pregnancy outcomes. Many papers noted a correlation between active inflammatory disease and poor sperm quality, with seminal parameters improving when disease was well controlled.

## **Conclusion:**

These results present provide further reassurance as to the safety of DMARDs, in particular methotrexate, for men trying to conceive and will be useful when counselling men about risks of anti-rheumatic drugs to fertility and pregnancies, and following accidental conception.

Table 1: Results of Systematic Study of Paternal Exposure in men trying to conceive.

Drug	No. studies of fertility / conception (total male exposures)	No. studies of pregnancy outcomes (total pregnancies exposed)	Outcome / conclusions
Anti-TNF: adalimumab	6 (30)	2 (>6)	Improved control of inflammatory disease with anti-TNF therapy was generally associated with improved semen parameters. There were 2 case reports noting a co-incident decrease in sperm quality with anti-TNF therapy, and 2 small studies (total 13 exposures) suggesting a possible non-significant link between infliximab and reduced sperm motility or abnormal morphology, but there were multiple confounding factors and limitations to these studies.  These papers were all too small to draw firm conclusions about safety in pregnancy, but none reported rates of adverse pregnancy outcomes that were significantly higher than would be expected.
Anti TNF: certolizumab	0	2 (>33)	
Anti TNF: etanercept	5 (9)	4 (>45)	
Anti TNF: infliximab	6 (78)	8 (>39)	
Anti TNF: combined (Wallenius 2015)		1 (110)	
Azathioprine	7 (>28)	7 (>331)	The majority of papers were reassuring about the effect of azathioprine on semen parameters. The majority of papers do not raise a concern regarding pregnancy outcomes; only 1 paper reported a slightly higher malformation rate in exposed vs unexposed pregnancies. However, even in this paper, none of the 19 exposures that had occurred within 3 months of conception resulted in a malformation.
Cyclophosphamide	10 (>103)	2 (>15)	Universal reporting of reduced sperm counts and fertility which improves on stopping cyclophosphamide in most cases. Pregnancy data is inconclusive with only one paper reporting 5 positive conceptions, 7 pregnancy losses and 2 live births, but this was a survey and likely susceptible to selection and recall bias.
Cyclosporin A	2 (>2)	1 (1)	The very limited available evidence did not suggest an effect of Cyclosporin A on fertility. There was only a case report of one successful pregnancy and birth.
Hydroxychloroquine (HCQ)	1 (1)	1 (12)	There was only one case report of the effect of HCQ on fertility, with multiple confounders. A national registry cohort study reported malformations in 1/12 babies with paternal exposure to HCQ <3 months prior to conception, lower than the western population malformation rate of 2-4%.
Leflunomide		2 (2)	In one case report the father was on leflunomide for 6 months prior to conception and during the pregnancy with no barrier protection used. One healthy baby was born. The second report was inconclusive.
Methotrexate (MTX)	7 (48)	12 (302)	Aside from 2 case reports of oligospermia, the other 5 larger studies concluded that there was no impact of MTX on fertility. There is also now a reasonable body of reassuring evidence relating to paternal MTX exposure: only one small cohort study reported a major malformation amongst the 3 paternal exposures to MTX, whereas the other 11 papers (299 exposures) reported no link with adverse pregnancy outcomes or congenital malformations.
Mycophenolate mofetil (MMF)	1 (4)	0	There was only one cohort study of men with SLE, including 4 MMF exposures. This suggested a link between impaired fertility and active SLE, but not MMF exposure.
Rituximab	0	1 (11)	Pregnancy outcome data is limited but reassuring: Of the 11 reported exposures (2 weeks-1 year prior to conception), there were 2 miscarriages, 7 live births and 2 ongoing pregnancies at the time of publication.
Sulfasalazine	29 (250)	9 (>151)	The vast majority of data comes from inflammatory bowel disease patients. Almost all studies noted poor sperm parameters in patients treated with sulfasalazine, but in most cases these resolved on stopping treatment. It must also be noted that infertility is not universal and most papers reported no adverse pregnancy outcomes attributed to sulfasalazine exposure.

**Disclosure:** J. D. Flint, None; M. Mouyis, None; I. Giles, None.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that primarily affects women during the childbearing years. Among its protean manifestation, pregnancy complications including premature delivery and preeclampsia are common. Most studies of pregnancy outcomes in women with SLE focus on complications occurring in the second half of pregnancy rather than evaluating spontaneous abortions (Sab, or miscarriage) that generally occur before 14 weeks of gestational age. While Sab occurs in up to 20% of all pregnancies and sporadic Sab is often attributed to karyotypic or genetic anomalies, it is possible that women with SLE experience higher rates of Sab than healthy women, and this may have an immunologic basis. The presence of the antiphospholipid antibody syndrome is the most commonly recognized risk factor for pregnancy morbidity; as late pregnancy morbidity or >3 consecutive Sab itself meets criteria for the syndrome. We sought to understand the incidence of Sab in a large cohort of SLE women, their unaffected sisters, and unrelated unaffected women.

**Methods:** Clinical data and stored sera from the Lupus Family Registry and Repository of 1608 parous women between ages 20-45 including SLE patients (by ACR criteria, n=832), sisters of SLE patients (n=337), and unaffected, unrelated women (n=439) were utilized. Complete reproductive history, including gestational age and outcome of all pregnancies, was available as was standardized SLE serologies. Additional autoantibodies, related to exposure to paternal antigens, included antibodies against HLA class I and II, and antibodies directed at minor histocompatibility antigens on the Y-chromosome and their X-homologues were assessed. Ratios of the number of Sab to the total numbers of pregnancies were compared between the three groups. Regression models were developed to better understand the role of auto-or allo-immunization and risk of Sab. Analyses were repeated using the subset of 1050 women who were APL negative.

**Results:** Both women with SLE and their unaffected sisters had higher Sab to total pregnancy ratios than healthy women in a dose-dependent fashion: Odds Ratio (OR)=1.43 (p=0.000049) for SLE and OR=1.28, (p=0.019) for sisters. Preliminary multivariate regression analyses found that only group and +APL antibodies were significantly associated with increased Sab, neither other standard SLE antibodies nor antibodies against HLA, HY, or HX were significant.

When women with +APL were removed from the analyses the Sab ratio remained significantly different for SLE (OR=1.37, p=0.0156), but not for sisters (OR=1.11, p=0.4029) compared to healthy women. Prevalence of autoantibodies did not modify the result in multivariate models.

**Conclusion:** SLE women have higher rates of Sab than healthy women, and sisters of SLE patients have intermediate rates. Autoantibodies do not explain these differences.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

Pre-pregnancy cardiovascular health has been associated with preeclampsia during pregnancy, as well as future cardiovascular disease (CVD). Preeclampsia is related to endothelial dysfunction, hypertension, permanent vascular damage and increased arterial stiffness in the mother, factors associated with future CVD. It is unclear whether pregnancy unmasks endothelial vulnerability to injury which manifests as preeclampsia or whether the preeclampsia itself causes damage leading to CVD. Patients with SLE are at increased risk for

preeclampsia as well as CVD and stroke. However, the relationship between these conditions has not been thoroughly examined among women with SLE.

#### Methods:

Using a population-based Swedish register linkage, we identified all singleton pregnancies in the Medical Birth Register (1987-2012) among mothers with prevalent SLE and a large general population comparator (non-SLE). SLE was defined as <sup>2</sup> SLE ICD-coded visits (inpatient, outpatient non-primary care, or both) with at <sup>1</sup> visit coded by specialist who manages SLE. Primary CVD outcomes included any recorded MI or stroke based on ICD10 codes in the Patient or Death Register. Power permitting, stroke and MI were considered separately. Multivariable-adjusted stratified Cox models estimated hazard ratios and 95% confidence intervals (HR, 95% CI) among all deliveries, using robust variance estimators to account for autocorrelation (multiple pregnancies), time-varying covariates, and calendar year as the stratification variable. Preeclampsia and maternal hypertensive disorders were time-varying, such that once a woman was exposed to a preeclampsia-complicated pregnancy, she remained exposed. Sensitivity analysis restricted to first births only. HRs and 95% CIs estimated the association between preeclampsia and CVD in SLE vs non-SLE. We calculated the relative excess risk due to interaction (RERI) to assess for non-additivity.

#### Results:

Among 1207 SLE pregnancies, 19.4% were preeclampsia-exposed compared to 6.9% of the 18784 non-SLE pregnancies. SLE mothers were more likely to have pregestational hypertension and diabetes, renal disease, and DVT/pulmonary embolism. Among women with SLE, these pregestational comorbidities were more common in those with preeclampsia (renal disease history in 37% vs. 9% among normotensives). Any preeclampsia was associated with a 2.7-fold increased rate of CVD in both women with SLE and from the general population (RERI=18.8 (-5.3 to 42.9)). We found a significant interaction on the additive scale for stroke as the outcome (RERI=35.2 (1.1, 69.5); preeclampsia was associated with a roughly 4.5-fold increased rate of stroke in SLE but not associated with stroke in non-SLE.

#### Conclusion:

We confirmed that women with preeclampsia are at increased risk of future CVD, regardless of whether they had SLE during pregnancy or not. There was an excess risk of stroke specifically among women with SLE when compared to women from the general population.

## Rates of Contraceptive Use and Unintended Pregnancy in Teen Girls Prescribed Teratogenic Medications

**Kimberly Hays**<sup>1</sup>, Kit Simpson<sup>1</sup>, David Bundy<sup>1</sup>, Elizabeth Wallis<sup>1</sup> and Natasha M. Ruth<sup>2</sup>, <sup>1</sup>Pediatrics, Medical University of South Carolina, Charleston, SC, <sup>2</sup>Rheumatology, Medical University of South Carolina, Charleston, SC

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Reproductive aged women with rheumatic diseases are often prescribed teratogenic medications. These medications pose a serious threat to the mother and fetus. Rates of contraceptive use and unintended pregnancy among teen girls taking teratogenic medications are not well described.

**Methods:** Medicaid claims data from 12 de-identified US states, between 2013-2015, was used to create an inception cohort of teen girls aged 15-19 prescribed teratogenic medications. Teens received a prescription for at least 1 of 8 teratogenic medications used in the management of pediatric rheumatic disease. Teratogenic medications were defined as FDA category D or X. We identified teratogenic medications commonly prescribed to teens for a variety of conditions: cyclophosphamide, enalapril, leflunomide, lisinopril, losartan,

methotrexate and mycophenolate. Cyclosporine was also included (category C). Teens entered the cohort upon receiving a teratogenic medication prescription and were followed for 12 months or until the end of 2015. Outcome of interest was pregnancy. Covariate of interest was contraceptive use, which was evaluated by prescription claims for any type of prescription contraceptive. We identified a sub-group of teens with rheumatic diseases, as determined by outpatient visits with at least two diagnostic codes consistent with a rheumatic disease. Data were analyzed using SAS version 9.4.

**Results:** 4853 teen girls aged 15-19 met criteria for inclusion, 36.6% Black, 4.8% Hispanic, 13.6% other and 45.1% White. There were 368 pregnancies comprising 7.5% of the cohort, 26 resulted in abortion. Pregnancy by race was statistically significant (7.6% Blacks, 9.1% Hispanics, 4.7% other, and 8.3% Whites,  $p < 0.0185$ ). Of the total pregnancies, 50% occurred in girls aged 15-17, with 19 year olds having the most pregnancies. In pregnant teens, exposure days to teratogenic medications ranged from 117 days to 326 days, with 19 year olds having the shortest time on teratogenic medications prior to pregnancy. In this cohort, 52% were prescribed contraception during the analysis period. Contraception by race was statistically significant (50.5% Blacks, 37.9% Hispanics, 44.8% other, and 58.1% of Whites,  $p < 0.001$ ). In teens with unintended pregnancies, 75% did not receive a prescription for contraception prior to pregnancy. Approximately 10% of this cohort was identified as having a rheumatic disease, with SLE being the largest percentage (70%).

**Conclusion:** Contraceptive prescriptions in teens on teratogenic medications were low and a significant number of teens had unintended pregnancies. While only 10% of the individuals were identified as having a rheumatic disease based on ICD-9 coding, this number is likely higher as we were very specific in the ICD-9 codes chosen. Teen pregnancy is a serious population health risk especially in patients with chronic rheumatic disease on teratogenic medications. Future analyses will compare contraception and pregnancy rates in our cohort to teens not on teratogenic medications. This analysis highlights the importance of reproductive health education including improved access to contraception for patients on teratogenic medications.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects II: Treatment Patterns

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Treatment recommendations aim to improve outcomes in rheumatoid arthritis (RA) through early identification and a treat-to-target approach. We examined recent trends over the past decade including patient characteristics, treatment strategies and disease activity in the first year of follow-up in a large Canadian early inflammatory arthritis (EIA) cohort.

**Methods:** Data were from individuals with EIA (RA or probably RA <1-year of symptom duration) enrolled in an ongoing prospective multi-center cohort study between 2007 and 2016 and had complete DAS28 measures at 6 and 12-months. Protocolized visits include clinical assessments, questionnaires, and laboratory investigations every 3 months for the first year. Treatment is at the discretion of the treating rheumatologist, and cohort investigators met annually to discuss means to improve outcomes. We examined trends in patient characteristics, early treatment strategies with conventional(cs) and biologic(b) DMARDs and disease activity outcomes over 12-months (12M). Multivariable logistic regression was used to identify predictors of failure to achieve low disease activity (LDA) or remission (REM) by 12M.

**Results:** Over 10 years, 2822 EIA patients were enrolled who were mostly female (70%) and Caucasian (80%). At study entry, 86% met 1987 or 2010 ACR/ EULAR RA criteria; mean(sd) age was 54(15), symptom duration was 6(3) months. Most were treated with csDMARDs (92%), often with MTX, as monotherapy or in combination with csDMARDs (77%); 29% were prescribed oral steroids and 27% IA or IM steroids. Baseline patient characteristics changed slightly over time with increases in age, male sex, education, income, and declines in current smoking (all p's <0.01). Baseline obesity rates, comorbidities and RA characteristics (serology, inflammatory markers, joint counts and disease activity indices) remained stable. Most (87%) entered in moderate or high disease activity (MDA or HDA), and disease activity at 6 and 12M markedly improved over calendar time (Figure 1). DAS28 REM at 12M increased by over 30% (range 39% to 73%, p<0.0001), and 20% more achieved LDA or REM by 6M (range 48% to 68%, p<0.0001) (Figure 1). Time trends in treatment showed earlier titration of MTX dosing to 20mg+, increases in subcut vs. oral MTX, earlier MTX combo therapies and more rapid escalation to bDMARDs all p's <0.05). Older age, female sex, lower education, non-white, overweight/obese BMI, and more comorbidities were associated with an inadequate response (persistent MDA or HDA) at 12 months (all p's<0.05).

**Figure 1 Recent Time Trends ((2007-2016) in DAS28 Remission, and Low Disease Activity including Remission over 12-Months in Patients with Early Inflammatory Arthritis**

**Conclusion:** This study of Canadian EIA patients over time suggests that earlier, more intensified treatment promoted in practice recommendations has resulted in lower disease activity and a greater proportion of patients reaching the target of therapy. Nevertheless 25-30% of patients still did not achieve LDA or REM by 12M.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects II: Treatment Patterns

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Methotrexate (MTX) remains a cornerstone therapy in the management of rheumatoid arthritis (RA), but patterns of adherence, intolerance, and inadequate response are not well characterized in real-world settings. We compared the characteristics and reasons for MTX discontinuation in patients (pts) with RA who received MTX either as monotherapy or in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs).

**Methods:** This analysis included pts enrolled in a US RA registry initiating MTX, who were naïve to targeted immune modulators (TIMs; biologics and small molecules). Cox proportional hazards models estimated the hazard ratio (HR) associated with MTX discontinuation and, in a separate analysis, TIM initiation, adjusting for potentially confounding factors. The reasons for MTX continuation were summarized descriptively, conditional on non-missing data.

**Results:** A total of 2144 RA pts initiated MTX (monotherapy: 69%; csDMARD users: 31%). csDMARD users were more likely to be Caucasian, non-Hispanic, have higher education, be employed full time, and have commercial insurance. Compared with MTX monotherapy, csDMARD users had lower Clinical Disease Activity Index (CDAI) scores (19.6 vs 16.9,  $p<0.0001$ ), less disability as measured by the modified Health Assessment Questionnaire (mHAQ  $<0.5$ ; 59% vs 70%,  $p<0.0001$ ), longer duration of RA (3.8 vs 5.4 years,  $p<0.0001$ ), and were less likely to be on a higher dose of prednisone ( $\geq 10$  mg/day; 33% vs 22%,  $p<0.0001$ ). The proportion of MTX monotherapy pts that discontinued MTX was 24% (1 year), 37% (2 years), and 46% (3 years), and was not significantly different from csDMARD users. The hazard of MTX discontinuation decreased as age at RA onset, duration of disease, and baseline CDAI increased (Table). After adjusting for potential confounding variables, an increased hazard of MTX discontinuation was associated with being disabled, retired, or regular alcohol use. MTX discontinuation was less likely in pts with older age, longer duration of RA, or higher baseline CDAI (Table). At 12 months, 27% of MTX monotherapy and 18% of csDMARD users had initiated a TIM. MTX monotherapy users were 39% more likely to have initiated a TIM by Month 12 compared with csDMARD users (HR 1.39; 95% CI 1.19, 1.59). However, after multivariable adjustment, the association between MTX monotherapy and TIM initiation was attenuated (HR 1.15; 95% CI 0.94, 1.41). The most common reasons reported for discontinuing MTX were safety/tolerability (48%) and other reasons (29%), rather than lack of efficacy (15%).

**Conclusion:** Despite the well-recognized role of MTX in RA management, approximately 30% of pts with RA discontinue MTX within 1–2 years after initiation. Strategies are required to better identify pts with suboptimal adherence to MTX and predict those most likely to not tolerate MTX, in order to optimize overall RA treatment.

**Table. Patient characteristics associated with MTX discontinuation/TIM initiation**

	Adjusted HR (95% CI)*
Combination csDMARDs + MTX (relative to MTX monotherapy)	0.95 (0.79, 1.14)
Age at RA onset (per 5 years)	0.94 (0.91, 0.97)
Duration of RA (per 5 years)	0.92 (0.87, 0.97)
Baseline CDAI (per 6-unit increment)	0.96 (0.92, 0.99)
Disabled (relative to full-time employment)	1.33 (1.01, 1.75)
Retired (relative to full-time employment)	1.37 (1.11, 1.69)
Alcohol (relative to none)	
1–3 units/week	1.22 (1.00, 1.47)
1–2 units/day	1.53 (1.14, 2.05)
3+ per day	2.03 (1.14, 3.63)

\*Also adjusted for mono/combo therapy, baseline patient-reported pain, baseline mHAQ, ethnicity, insurance,

baseline history of csDMARD use, and baseline prednisone use/dose

**Session Title:** Rheumatoid Arthritis – Clinical Aspects II: Treatment Patterns

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Despite a decline in the incidence of orthopedic surgeries for rheumatoid arthritis (RA) in recent years, joint replacement remains an option for patients with treatment refractory disease seeking symptomatic relief and functional improvement. Although multiple factors influence the need for joint surgery in RA, it is unclear if there are sex differences in the incidence and trends of large versus small joint surgery rates in RA over time.

**Methods:** A retrospective medical record review was performed of all orthopedic surgeries following first fulfillment of 1987 ACR criteria for adult-onset RA in 1980-2013 among residents of a geographically defined area with follow up until death, migration or July 1, 2016. Surgeries were classified as small (wrist, hand, foot) or large (shoulder, elbow, hip, knee, ankle) joint. Trends in incidence of joint surgeries over time by sex were examined using Poisson regression models.

**Results:** The study included 739 women and 338 men with RA (mean age at incidence ( $\pm$ SD) 55.9 $\pm$ 15.6 years). During a median follow up of 10.7 years, 90 women and 22 men underwent at least one small joint surgery (SJS) and 141 women and 63 men underwent at least one large joint surgery (LJS). The cumulative incidence of SJS was significantly higher in women (14.4% by 15 years after RA incidence; 95% confidence interval [CI]: 11.3-17.4%) than men (7.6% at 15 years; 95% CI: 4.3-10.8%;  $p=0.008$ ), but no sex differences were noted in the cumulative incidence of LJS (20.2% at 15 years among women; 95% CI: 16.8-23.6% and 18.8% among men; 95% CI: 13.8-23.5%;  $p=0.55$ ). The rates of small joint surgery declined in both sexes from 2000 onward (Figure 1;  $p=0.002$ ), with no differences in trends between women and men ( $p=0.73$ ). LJS rates were similar among both sexes (Figure2;  $p=0.85$ ) and there was no evidence of a trend over time among both sexes combined ( $p=0.87$ ).

**Conclusion:** Women with RA had a higher rate of SJS compared to men, although there is a declining trend in SJS rates over time in both sexes. There were no sex differences in rates of LJS, which is in contrast to higher rates of hip and knee arthroplasties seen in women compared to men in the general population<sup>1,2</sup>. This study also confirmed an absence of increase in rates of LJS among patients with RA during the study period.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects II: Treatment Patterns

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** In the absence of biomarkers predicting response to a specific therapy, the choice of second biologic is based mostly on habit and availability of an alternative agent. Traditionally, a second anti-TNF was the preferred option, but recent registry data point to better responses and retention if a drug with a different mode of action is prescribed. The aim of this study was to assess the long-term retention of abatacept and TNF inhibitor (TNFi) following first biologic (b)DMARD inadequate response in RHUMADATA<sup>®</sup> registry patients with RA.

**Methods:** Data from RHUMADATA<sup>®</sup> patients with RA prescribed either abatacept or TNFi as the second bDMARD after January 1, 2006 were analyzed. Patients were followed until treatment discontinuation or January 9, 2017 cut-off. Patient characteristics were compared using descriptive statistics, bDMARD discontinuation rates using Kaplan–Meier methods, and proportional hazard models were used to identify predictors of treatment discontinuation.

**Results:** Data for 92 and 194 patients prescribed abatacept or a TNFi, respectively, as second-line treatment were extracted. No clinically significant differences in baseline characteristics were noted between treatment groups. Most patients were women (76.2%), average age (SD) was 45.1 (13.3) years at diagnosis and disease duration 10.8 (9.0) years. Most patients were stopping an anti-TNF agent: 83% of those who were switched to abatacept and 97% of those who were prescribed a second anti-TNF. Overall, 77.6% of patients stopped their first bDMARD after >6 months of treatment (secondary failure). Significant differences in retention between abatacept and TNFi groups (logrank  $p=0.0002$ ) were observed (Table, Figure). Results remained unchanged for patients treated with TNFi only in first line, and primary/secondary failure of the first bDMARD did not affect sustainability of the second agent. Lack of efficacy (57.7%) and AEs (16.5%) were the most commonly cited reasons for treatment discontinuation.

**Conclusion:** Abatacept has better sustainability over a second line TNFi in RA patients having failed one prior bDMARD.

**Session Title:** Rheumatoid Arthritis – Clinical Aspects II: Treatment Patterns

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Highly effective, targeted DMARD therapies with different mechanisms of action are available for RA. Translating precision medicine into clinical practice requires treatment-specific predictive models, with a goal of individualized, targeted therapy. Therefore, we created separate predictive models for response to abatacept (ABA) or adalimumab (ADA), using baseline biomarker (BM) data from the head-to-head AMPLE study.<sup>1</sup>

**Methods:** Predictive models were built using demographic data, baseline disease characteristics and several BMs, including RF, cyclic citrullinated peptide-2 (CCP2) and BMs from the multi-biomarker disease activity test as predictor variables and 'polar' clinical responses as the response variables. The polar responses were defined as patients (pts) who, after 1 year of treatment, achieved an ACR70 response or failed to achieve an ACR20 response. The elastic net method<sup>2</sup> was used to build separate predictive models for ABA and ADA responders using their respective clinical data with 6-fold cross-validation (CV) repeated 10 times. Parameter tuning for model selection was based on a fixed alpha of 0.95 and varying levels of lambda. The final model was selected based on the lambda with maximum mean area under the curve (AUC) across all folds of CV. Glmnet<sup>3</sup> and caret<sup>4</sup> packages in R were used for model-building purposes.

**Results:** Predictive models generated included 13 variables for ABA and 11 for ADA. Of all the variables, resistin, vascular cell adhesion molecule-1, sex, CCP2 and pt-reported disease activity were unique to the ABA predictor, whereas matrix metalloproteinase-1, physician-reported disease activity and disease duration were unique to the ADA predictor. The variables common to both models showed the same association (positive or negative) but differing magnitude with response. AUC by receiver operating characteristic curves were used to assess the performance of the predictive models. The performance (AUC) of the ABA model on the ABA and ADA arms was 0.855 and 0.530, respectively (Figure a, b). The performance (AUC) of the ADA model on the ADA and ABA arms was 0.860 and 0.631, respectively (Figure c, d). This indicates that the models are very specific for their respective treatment and not for the other treatment.

**Conclusion:** Response-to-treatment predictive models were generated using baseline data from AMPLE that were highly specific to their respective treatment. This suggests that treatment-specific response predictors could be developed and should be considered, and highlights the value of head-to-head studies in predictive biomarker generation. Further testing on validation datasets is warranted.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects II: Treatment Patterns

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:**

Evidence supports a therapeutic window of opportunity in early rheumatoid arthritis (RA), during which DMARD therapy most effectively improves clinical outcomes. The 2010 ACR/EULAR classification criteria for RA require that seronegative (i.e., RF- and ACPA-) patients have more joint involvement at diagnosis than patients who are seropositive (i.e., RF+ and/or ACPA+). We hypothesized that seronegative patients experience a delay in diagnosis and, thus, a delay in treatment initiation when compared with seropositive patients, potentially causing them to miss the therapeutic window of opportunity.

#### **Methods:**

A retrospective study was performed of a population-based cohort of patients with incident RA between 2009-2013 who fulfilled either the 1987 or 2010 classification criteria. A trained nurse abstractor unaware of the hypothesis collected data from the complete medical records. Patients were classified as either seronegative or seropositive as above. Time to fulfillment of both 1987 and 2010 classification criteria, first treatment with DMARD, and first remission were calculated from the time of first documented joint swelling. Health Assessment Questionnaire (HAQ), Disease Activity Score 28 (DAS28-CRP), and Simplified Disease Activity Index (SDAI) were compared between the groups. Remission was defined according to the 2011 ACR/EULAR Boolean-based definition.

#### **Results:**

156 patients were included; 113 were seropositive and 43 seronegative. Age, sex, smoking status, and obesity did not differ between groups. Median time from first documented joint swelling to fulfillment of the 1987 (100 vs. 3 days,  $p=0.003$ ) and 2010 (58 vs. 0 days,  $p=0.011$ ) criteria was significantly longer in seronegative than seropositive patients. The median time from first documented joint swelling to first DMARD was also significantly longer in seronegative patients (129.5 vs. 16 days,  $p=0.003$ ). Methotrexate was the first DMARD for 97 patients (62%), with no significant differences between groups.

Patients were followed for a median of 4.9 years, during which disease activity measures were available for a median of 7 visits per patient, with no significant differences between groups. Time to first biologic DMARD was similar between the groups. Seronegative patients experienced persistently higher DAS28-CRP (mean difference: 0.46,  $p=0.027$ ), SDAI (mean difference: 4.9,  $p=0.009$ ), and HAQ disability index (mean difference: 0.25,  $p=0.020$ ) over time, adjusting for age, sex and time from fulfillment of 2010 criteria. Time to first remission was later in seronegative than seropositive patients (hazard ratio: 0.47, 95% CI 0.24, 0.94). At 5 years after fulfillment of 2010 criteria, fewer seronegative than seropositive patients achieved  $\geq 1$  remission (32 vs. 50%,  $p=0.034$ ).

#### **Conclusion:**

Patients with seronegative RA experience delay in diagnosis, according to both the 1987 and 2010 classification criteria, and delay in initiation of DMARD therapy. Patients with seronegative RA also experience persistently higher disease activity and delayed remission, suggesting that these patients miss the therapeutic window of opportunity more frequently than patients with seropositive RA.

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## Background/Purpose:

Remission induction with methotrexate (MTX) and a moderate-dose, step-down scheme of Glucocorticoids (GC), (COBRA Slim strategy), showed equally high remission rates at year 1 and a more favourable safety profile compared to DMARD combinations, even at a higher step-down GC dosage, in patients with early Rheumatoid Arthritis (eRA). Objectives were to compare response rates, disease activity states and medication use, 2 years after induction with different intensive combination strategies, focusing on the high-risk population from CareRA.

**Methods:** CareRA is a two-year prospective investigator-initiated multicentre RCT. csDMARD naïve eRA patients were stratified into a high- or low-risk group based on classical prognostic markers. High-risk patients (n=289) were randomized to 1/3 arms: 1) COBRA Classic: MTX+Sulphasalazine+60mg prednisone tapered over 6 weeks to 7.5mg daily; 2) COBRA Slim: MTX+30mg prednisone tapered over 5 weeks to 5 mg daily; 3) COBRA Avant-Garde: MTX+Leflunomide+30mg prednisone tapered over 5 weeks to 5 mg daily. From week 28, GC were tapered and stopped at week 34. From week 40, DMARD monotherapy was aimed for. A treat-to-target approach was applied per protocol until year 1 and afterwards at the discretion of the rheumatologist. Co-primary endpoint was proportion with DAS28-CRP<2.6 ("remission"), other efficacy measures were HAQ=0, DAS28-CRP change, ACR20/50/70 and clinically meaningful HAQ response (ITT analysis). Adverse events related to therapy (AEs) were registered, as well as RA medication use. Missing data were imputed by last observation carried forward.

**Results:** The proportion of high-risk patients with DAS28-CRP<2.6 at year 2 remained high and did not differ between the Classic (65.3%), Slim (73.5%) and Avant-garde (73.1%) group (p=0.369). Of patients with a DAS28-CRP<2.6 at year 1, 54.7% in Classic, 67.8% in Slim and 70.2% in Avant-Garde retained a DAS28-CRP<2.6 at every trimonthly evaluation until year 2. Persistently high and comparable ACR50 response rates were achieved in all groups. The total numbers of AEs related to study therapy, were 209 in 72 Classic patients, 164 in 69 Slim patients and 208 in 74 Avant-Garde patients (p=0.029). During the CareRA study, biologicals were started in 44 high-risk patients (15.2%): 18 Classic, 11 Slim and 15 Avant-Garde patients. At year 2, most patients were on MTX monotherapy: 67% in Classic, 63% in Slim and 49% in Avant-Garde. Only 14% of the high-risk population was taking oral GCs at year 2 at an average dose of 6.4mg prednisone equivalent.

**Conclusion:** All groups showed persistently high response rates and favourable disease activity states, 2 years after remission induction with csDMARDs and GCs in a treat to target setting. COBRA Slim showed comparable efficacy and ability to achieve sustained disease control with less adverse events, compared to DMARD combinations with GC at moderate or high induction dosages.

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** In patients (pts) with active RA and inadequate response (IR) to DMARDs, phase 3 studies demonstrated efficacy of baricitinib (2-mg and 4-mg). Larger, more rapid treatment effects were observed with baricitinib 4-mg. The objective of this study was to investigate the effects of baricitinib dose step-down in patients who achieved sustained disease control with baricitinib 4-mg.

**Methods:** Pts with RA who completed a baricitinib phase 3 study could enter a long-term extension (LTE) study. In the LTE, pts who received baricitinib 4-mg for  $\geq 15$  months and who achieved sustained low disease activity ([LDA] - CDAI score  $\leq 10$  for pts from RA-BUILD, RA-BEAM, RA-BEACON) or remission (CDAI  $\leq 2.8$  for DMARD-naïve pts from RA-BEGIN) at 2 consecutive visits  $\geq 3$  months apart were re-randomized in a blinded manner to either continue baricitinib 4-mg or step down to 2-mg. Pts could be rescued (to baricitinib 4-mg) if CDAI  $> 10$ , or  $> 2.8$  for pts from RA-BEGIN. Efficacy and safety were assessed through 48 weeks following re-randomization.

**Results:** The majority of pts in both groups maintained the state of LDA or remission over the 48-week period. However, dose reduction to 2-mg resulted in significant increases in disease activity at 12, 24, and 48 weeks. Dose reduction also resulted in a more rapid time to relapse (defined as loss of step-down eligibility criteria) with significantly more pts relapsing over 48 weeks compared to the 4-mg group. Rescue rates were 9.6% for baricitinib 4-mg, and 18.3% for baricitinib 2-mg. Most rescued pts could regain LDA or remission with the 4-mg dose. Dose reduction was associated with a numerically lower rate of non-serious infections; rates of serious adverse events and adverse events leading to discontinuation were similar across groups.

**Conclusion:** These data indicate disease control was better maintained on the 4-mg dose than 2-mg. Nonetheless, most stepped-down pts could maintain LDA or remission, or recapture control with return to the 4-mg dose if needed. Stepping down to a dose of 2-mg daily may be a reasonable consideration for some pts after having achieved sustained LDA or remission on the 4-mg dose.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** IL-6 involvement has been reported in glucose metabolism.<sup>1-4</sup> Sarilumab, a human mAb blocking the IL-6R $\alpha$ , was evaluated for treatment of RA in 3 clinical trials: MOBILITY, TARGET, and MONARCH. This analysis examined effects of sarilumab or placebo (Pbo), plus DMARDs, on fasting glucose and glycosylated hemoglobin (HbA<sub>1c</sub>) in patients with RA, with and without diabetes.

**Methods:** Fasting glucose and HbA<sub>1c</sub> data were collected during 2 Pbo-controlled studies of sarilumab + DMARDs: MOBILITY and TARGET. Studies excluded patients with HbA<sub>1c</sub>  $\geq 9.0\%$ . Patients with baseline (BL) and  $\geq 1$  post-BL sample were included in post hoc pooled analyses and categorized as diabetic (DIAB) or non-DIAB based on medical history of diabetes or prior use of antidiabetic medication. Changes from BL in fasting glucose, HbA<sub>1c</sub>, and weight were analyzed with a linear regression model. Spearman rank correlation coefficient was calculated for changes in glucose, HbA<sub>1c</sub>, and high-sensitivity (hs)-CRP. Changes in these parameters were stratified by clinical response. Clinical meaningfulness was based on comparison with results of clinical trials with antidiabetic medications.<sup>5</sup>

**Results:** The DIAB group (n=179) compared with the non-DIAB group (n=1803) had higher BL body weight (mean  $\pm$  SD, kg: 84.8  $\pm$  21.4 vs 74.6  $\pm$  18.8) and a larger proportion of patients with BMI  $\geq 30$  kg/m<sup>2</sup> (56.7% vs 31.9%). Mean fasting glucose and HbA<sub>1c</sub> at BL were similar across treatment groups (Pbo, and sarilumab 150 and 200 mg every 2 wks [q2w]) but higher in the DIAB group than in the non-DIAB group (Table). Patients in the DIAB group had a greater reduction in fasting glucose at wk 24 compared with those in the non-DIAB group. Decreases in HbA<sub>1c</sub> occurred in non-DIAB and DIAB sarilumab-treated groups but not with Pbo. The treatment effect was largest in the DIAB group. At wk 24, the change in HbA<sub>1c</sub> was -0.43% in the DIAB (sarilumab 200 mg q2w) group and +0.17% in the DIAB (Pbo) group (-0.69% mean difference;  $P < 0.001$ ). Reductions in fasting glucose and HbA<sub>1c</sub> were observed in sarilumab-treated DIAB subgroups independently of changes in hs-CRP, ACR50, or DAS28-CRP remission status, and despite increases in mean body weight. The overall safety of sarilumab did not differ between DIAB and non-DIAB patients with RA.

**Conclusion:** Sarilumab + DMARDs reduced fasting glucose and HbA<sub>1c</sub> in DIAB and HbA<sub>1c</sub> in non-DIAB patients with RA, independent of changes in body weight, hs-CRP, ACR50, or DAS28-CRP remission status at wk 24. In DIAB patients, the difference in HbA<sub>1c</sub> reduction between sarilumab 200 mg q2w and Pbo was clinically meaningful.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

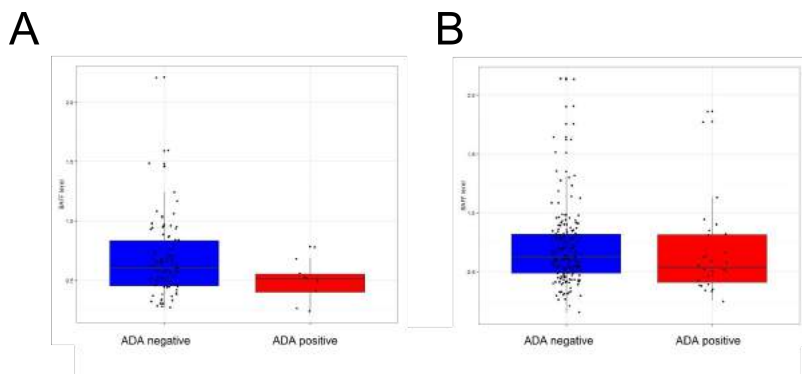

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Immunization against TNF Inhibitors (TNFi) is observed in 30-50% of patients with inflammatory rheumatic diseases. With most TNFi, anti-drug antibodies (ADA) lead to rapid decrease of drug concentration that cause relapses. One of the identified factors of prevention of ADA is the co-prescription of methotrexate (MTX). In preliminary data from animal models, MTX is dramatically more efficient in preventing TNFi immunogenicity in B-cell Activating Factor (BAFF) overexpressing mice. The mechanism of interaction between MTX and BAFF could be an increase of the ectoenzyme CD73 expression induced by BAFF which may favor the transformation of AMP (released from the cell by MTX) in adenosine, a powerful immune-regulatory mediator. The goal of this study is to investigate in the clinics a possible interaction between MTX and BAFF to prevent ADA against TNFi.

**Methods:** Patients from the ABIRISK study, which is designed to prospectively identify risk factors of ADA against TNFi were included in this study. Patient's underlying disease was Rheumatoid Arthritis, (RA) Inflammatory Bowel Disease (IBD) or Juvenile Inflammatory Arthritis (JIA). Patients were considered treated by MTX when this treatment was concomitantly administered with the newly introduced TNFi. Baseline serum was used for BAFF assay. Free BAFF serum levels were quantified using a new highly sensitive Errena immunoassay system based on single molecule counting. ADA were screened at 3, 6, 12 and 24 months post TNFi therapy using a modified Theradiag© assay. Patients with at least one time point with ADA detection were considered immunized (ADA+). Comparisons of BAFF levels among different subsets of patients were performed using Welch' test.

**Results:** Serum BAFF quantification was performed in 383 patients (191 RA, 173 IBD and 19 JIA) who had undergone at least one dosage of ADA. In the 103 patients (91 RA and 12 IBD) treated with MTX, 9 (8.7%) developed ADA versus 28 (13.5%) in the non-MTX treated patients. In the 103 MTX-treated patients, the level of BAFF was significantly lower (0.49ng/mL) in ADA+ patients than in ADA- patients (0.69ng/mL  $p=0.02$ , Fig 1A). The removing of 3 patients with a low level of ADA against etanercept reinforces the association between low serum BAFF level and ADA ( $p=0.006$ ). Conversely, in the 208 non-MTX treated patients, there was no significant difference in the serum level of BAFF between ADA+ and ADA- patients ( $p=0.65$  Fig 1B).

**Conclusion:** These clinical data support the preliminary findings we have got in mice on an interaction between MTX and BAFF for preventing ADA formation. Patients treated with TNFi and MTX who do not develop ADA have a higher serum BAFF level than patients who develop ADA. Conversely, serum BAFF level has no influence on ADA formation in non MTX-treated patients. Thus, MTX might require high BAFF levels to prevent immunization against TNFi.

## Evaluation of Pneumococcal and Tetanus Vaccine Responses in Patients with Rheumatoid Arthritis Receiving Baricitinib: Results from a Long-Term Extension Trial Substudy

**Kevin Winthrop**<sup>1</sup>, Clifton O. Bingham III<sup>2</sup>, John D. Bradley<sup>3</sup>, Maher Issa<sup>3</sup>, Rena Klar<sup>4</sup> and Cynthia E. Kartman<sup>3</sup>, <sup>1</sup>Oregon Health and Sciences University, Portland, OR, <sup>2</sup>Rheumatology, Johns Hopkins University, Baltimore, MD, <sup>3</sup>Eli Lilly and Company, Indianapolis, IN, <sup>4</sup>Quintiles IMS Holdings, Inc., Durham, NC

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Clinical guidelines recommend pneumococcal and tetanus vaccinations in patients (pts) with RA.<sup>1</sup> Baricitinib (bari) is an oral, selective Janus kinase (JAK) 1/JAK 2 inhibitor and is approved in the EU for the treatment of moderately to severely active RA in adults. The objective of this substudy was to evaluate pneumococcal conjugate and tetanus toxoid vaccine responses in pts with RA receiving bari. These vaccines elucidate predominantly T-cell-dependent humoral antibody responses.<sup>2</sup>

**Methods:** Eligible RA pts in a Phase 3 long-term extension (LTE) trial (RA-BEYOND) in US/Puerto Rico receiving bari 2 or 4 mg with or without concomitant MTX were enrolled. Baseline antibody titers were measured and pts were vaccinated with Prevnar 13® (Pneumococcal 13-valent Conjugate Vaccine [Diphtheria CRM197 Protein]; Wyeth; PCV13) and Boostrix® (Tetanus Toxoid Vaccine, Reduced Diphtheria Toxoid, and Acellular Pertussis Vaccine, Adsorbed; GlaxoSmithKline Biologicals; Tdap). The primary endpoints were the proportion of pts achieving a satisfactory humoral response defined as 1) a  $\geq 2$ -fold increase in anti-pneumococcal antibody titers in  $\geq 6/13$  serotypes and 2) a  $\geq 4$ -fold increase in anti-tetanus titers at 5 wks post-vaccination.

**Results:** Of the 106 pts, 80% were female, 32 (30.2%) were taking glucocorticoids, with a mean age of ~55 yrs and a mean duration of RA ~12 yrs; 89% (N=94) were taking bari+MTX and 11% (N=12) were taking bari without MTX. Most pts (97% PCV13/96% Tdap) completed the evaluations (Table 1). The small size of the bari without MTX group precluded subgroup analysis; response in the overall group is reported here. Over two-thirds of pts (68.0%; 95% CI, 58.4, 76.2) achieved a positive response in  $\geq 6/13$  PCV13 serotypes (Table 1). Forty-three percent (43.1%; 34.0, 52.8) achieved a  $\geq 4$ -fold increase in anti-tetanus titers and 73.5% (64.2, 81.1) achieved a  $\geq 2$ -fold increase (Table 1). Through 12 weeks post-vaccination, 7 pts (6.6%) reported injection site events possibly related to vaccination. Two pts reported moderate pain. There were no serious adverse events (AE) related to the vaccine. (AE monitoring in the LTE trial was on-going.)

**Conclusion:** The proportions of pts on long-term bari (89% were on concomitant MTX) who achieved satisfactory humoral response five weeks post-vaccination were 68% for pneumococcal conjugate vaccine and 43% for tetanus toxoid vaccine (a  $\geq 4$ -fold increase). These responses are broadly in line with responses to PCV13,<sup>3</sup> 23-valent pneumococcal polysaccharide vaccine (PPSV23),<sup>4,5</sup> and tetanus toxoid vaccines<sup>2,5</sup> described for other contemporary RA therapies.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

Fluctuations in disease activity due to short-term situational effects and measurement errors are important considerations for evaluation of individual clinically meaningful therapeutic response in daily practice in patients with rheumatoid arthritis (RA). To address this aspect, we established a statistical approach to determine a critical difference (d<sub>crit</sub>) that defines valid criterion for response as assessed by the Disease Activity Score-28 joints (DAS28-ESR)<sup>1</sup>. In this analysis, DAS28<sub>d<sub>crit</sub></sub> response was evaluated post-hoc from a RCT (ADACTA<sup>2</sup>) comparing Tocilizumab (TCZ) to Adalimumab (ADA) treatment.

### Methods:

Patient population was derived from ADACTA<sup>2</sup> with active RA treated with monotherapy of TCZ (8mg/kg) and ADA (40 mg e.o.w.). 325 patients were analyzed. DAS28<sub>d<sub>crit</sub></sub> response of 1.8 was used as cut off for an individual important improvement of DAS28 derived from the established statistical approach on validation of DAS28<sub>d<sub>crit</sub></sub> response<sup>1</sup>. The cohort was used to calculate the proportion

achieving DAS28<sub>dcrit</sub> response at every study visit (BL up to week 24). DAS28 dcrit response was compared to standard disease activity measurements. Achievement of DAS28<sub>dcrit</sub> response at multiple visits in individual patients (not consecutive) was evaluated.

## Results:

Patient population of both treatment arms was comparable in disease activity at baseline, balance of gender and pretreatment. In the TCZ group, 53.8% of the patients achieved DAS28<sub>dcrit</sub> response at week 4, 75.2% at week 8, 82.7% at week 12, 84.5% at week 16, 89.5% at week 20 and 90.1% at week 24. In the ADA group, 36.6% achieved DAS28<sub>dcrit</sub> response at week 4, and 44.8% at week 8, 48.6% at week 12, 51.4% at week 16, 63.0% at week 20 and 59.1% at week 24 (Table 1). In the TCZ group, 88.3% of patients achieved DAS28<sub>dcrit</sub> response at least at 3 visits, 77.9% at least at 4, 65.5% at least at 5 and 37.2% at least at 6 visits; for the ADA group, 67.8% at least at 3, 53.0% at least at 4, 40.9% at least at 5 and 22.6% at least at 6 visits.

## Conclusion:

The established critical differences for DAS28 (DAS28<sub>dcrit</sub>) of 1.8 was confirmed in an independent cohort of ADA-treated patients<sup>1</sup>. In the RCT ADACTA<sup>2</sup>, for the cut-off of 1.8, high percentages of patients achieved this level of response even early after initiation of TCZ-treatment (week 4 and 8) compared to ADA treatment. Stability of TCZ treatment effect was shown by approx. 78% of the patients (compared to 53.0% for ADA) with at least 4 visits out of 6 with DAS28<sub>dcrit</sub> response.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Psoriatic arthritis (PsA) disease activity score (PASDAS) assessing multiple facets of PsA was demonstrated to distinguish treatment effect, perform better in statistical terms than traditional joint-only indices<sup>1</sup> and could be used as a treatment target in clinical trials in PsA. Secukinumab significantly improved the signs and symptoms of PsA over 104 weeks (wks) in the FUTURE 2 study.<sup>2</sup> This *post-hoc* analysis assessed the ability of secukinumab to achieve low disease activity (LDA) or remission (REM) using PASDAS through 104 wks in the FUTURE 2 study.

**Methods:** FUTURE 2 study design has been previously published.<sup>2</sup> PASDAS index is derived from physician's global VAS, patient's global VAS, SF-36 PCS, tender and swollen joint counts, Leeds enthesitis count, dactylitis count and CRP level with validated cut-points for high disease activity (HDA  $\geq 5.4$ ), moderate disease activity ( $3.2 < \text{MoDA} < 5.4$ ),  $1.9 < \text{LDA} \leq 3.2$  and  $\text{REM} \leq 1.9$ .<sup>3</sup> PASDAS was assessed in the overall population and in patients (pts) stratified by prior anti-TNF use (naïve vs inadequate response [IR]) and disease duration ( $\leq 2$  years vs  $> 2$  years since first PsA diagnosis) and reported using mutually exclusive categories at group level and as observed analysis.

**Results:** PASDAS score at baseline was similar across the three treatment groups. In the overall population at Wk 16, PASDAS REM, LDA, and MoDA were achieved in: 15.6%, 22.9%, and 49.0% of pts, respectively, treated with secukinumab 300 mg; 15.2%, 19.2%, and 42.4%, respectively, with secukinumab 150 mg group vs. 2.3%, 13.8%, and 44.8%, respectively with placebo (PBO). At Wk 104, REM was achieved in 22.9% and 14.3% pts treated with secukinumab 300 and 150 mg, respectively. The proportion of pts achieving PASDAS derived criteria at Wks 16 and 104 by anti-TNF status is reported in the figure. The proportion of pts achieving PASDAS REM/LDA at Wks 16 and 104 was similar, irrespective of time since first diagnosis, for both secukinumab doses.<sup>4</sup> Secukinumab treated pts achieving PASDAS REM had significantly greater improvements in function, physical and mental health quality of life, and fatigue compared to HDA through Wk 104.<sup>5</sup>

**Conclusion:** PASDAS REM and LDA were achieved in 38.5% and 34.4% pts treated with secukinumab 300 and 150 mg, respectively, vs 16.1% in placebo group at Wk 16, with approximately 50% pts achieving PASDAS REM and LDA in both secukinumab groups at Wk 104. A higher proportion of anti-TNF-naïve pts treated with secukinumab achieved PASDAS REM or LDA than anti-TNF-IR through Wk 104. Secukinumab treated pts achieving PASDAS REM had significantly greater improvements in function, quality of life, and fatigue.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Nails are frequently involved in psoriasis and represent one of the most difficult to treat manifestations of the disease. This study evaluated the comparative efficacy of ixekizumab (IXE) and ustekinumab (UST) in the treatment of nail lesions during a head-to-head trial, IXORA-S.

**Methods:** In this Phase 3b, multicenter, randomized, double-blinded, parallel-group trial (IXORA-S, NCT02561806), patients with moderate-to-severe plaque psoriasis were randomized (1:1) to receive either IXE (160-mg starting dose, then 80 mg every 2 weeks for 12 weeks followed by 80 mg every 4 weeks; N=136) or UST (45 mg/90 mg weight-based dosing at Weeks 0, 4 and every 12 weeks thereafter per label; N=166). The primary endpoint was to determine if IXE was superior to UST, as measured by the proportion of patients achieving  $\geq 90\%$  improvement in Psoriasis Area and Severity Index (PASI 90) after 12 weeks of treatment. Nail Psoriasis Severity Index (NAPSI) was used to assess fingernail psoriasis for all patients presenting with nail involvement at baseline (NAPSI $>0$ ), and these patients were included in the present analysis. Each fingernail was scored for bed and matrix psoriasis, then scores were added to obtain total NAPSI fingernail scores ranging from 0 (no nail psoriasis) to 80 (severe nail psoriasis). Categorical data were assessed using logistic regression with weight and geographic region as factors at Weeks 12 and 24 and Fisher's exact test at other time points. Missing data were imputed using non-responder imputation. Least squares (LS) means (95% CI) were calculated for NAPSI and treatment groups compared using covariance analysis with weight, geographic region, and baseline NAPSI score as factors.

**Results:** At week 12, a significantly higher proportion of patients treated with IXE achieved PASI 90 relative to UST (72.8% [n=99] vs 42.2% [n=70],  $p<0.001$ , respectively), thereby achieving the primary endpoint of IXORA-S.<sup>1</sup> At baseline, 84 IXE-treated (61.8%) and 105 UST-treated (63.3%) patients in IXORA-S had nail psoriasis. Mean NAPSI score at baseline was 28.3 (standard deviation [SD]: 19.9) for IXE-treated and 24.6 (SD: 20.1) for UST-treated patients. Statistically significant differences in percentage of patients achieving NAPSI=0 were first seen at Week 16, with 26 (31.0%) IXE-treated patients and 18 (17.1%) UST-treated patients reaching complete resolution of nail psoriasis ( $p=0.037$ ). At Week 24, LS mean change from baseline NAPSI was -19.9 (-22.3, -17.5) and -13.2 (-15.4, -11.0) for patients treated with IXE and UST, respectively ( $p<0.001$ ), and 41 (48.8%) patients treated with IXE achieved NAPSI=0 compared to 24 (22.9%) patients treated with UST ( $p=0.012$ ).

**Conclusion:** Complete resolution of nail psoriasis was seen in significantly greater percentages of patients treated with IXE compared to UST at Week 24, even though improvement was observed in both groups over 24 weeks. Twenty-four weeks may be too early for full evaluation of nail psoriasis, and continued improvement can be expected through one year.

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Secukinumab (SEC) improved the signs and symptoms of AS in 2 Phase 3 studies (MEASURE 1 and 2).<sup>1,2</sup> Here, we present interim results through 104 weeks (wks) from the MEASURE 3 study (NCT02008916), the first Phase 3 study assessing efficacy and safety of subcutaneous (SC) maintenance therapy with 300 or 150 mg SEC following intravenous (IV) loading.

**Methods:** 226 patients (pts) were randomized to IV SEC 10 mg/kg (baseline, Wks 2 and 4) followed by SC SEC 300 or 150 mg every 4 wks (IV→300/150 mg), or matched placebo (PBO). At Wk 16, PBO pts were re-randomized to SC SEC 300 or 150 mg. Primary endpoint was ASAS20 response rate at Wk 16. Secondary endpoints included ASAS40, hsCRP, ASAS 5/6, BASDAI and ASAS partial remission (PR). Non-responder imputation through Wk 16 and multiple imputation for binary variables and mixed-effect model for continuous variables through Wk 104 were used. Analyses by prior anti-TNF therapy use (anti-TNF-naïve and -inadequate response or intolerance [IR]) were pre-specified and reported as observed at Wk 104. Efficacy results at Wk 104 are reported for pts originally randomized to SEC. Safety analyses included all pts who received ≥1 dose of SEC.

**Results:** 84.2% (64/76; SEC IV→300 mg) and 77.0% (57/74; SEC IV→150 mg) pts completed 104 wks of treatment. ASAS20 response rate was significantly greater at Wk 16 (primary endpoint) in SEC IV→300 mg and IV→150 mg groups vs PBO. All secondary endpoints were met at Wk 16, except ASAS PR in the IV→150 mg group. Improvements achieved with SEC in all clinical endpoints at Wk 16 were sustained through Wk 104 (Table and Figure). ASAS20/40 and ASAS PR responses by anti-TNF status are shown in Table. At Wk 104, response rates on more stringent clinical endpoints (e.g. ASAS PR) were higher with the 300 mg dose, particularly in the smaller group of anti-TNF-IR pts. Safety profiles of both SEC doses were similar through Wk 104 (mean±SD exposure: 633.8±165.4 days [300 mg] and 644.5±135.4 days [150 mg]). Exposure-adjusted incidence rates over the entire treatment period in the combined group of SEC doses for *Candida* infections, serious infections/infestations, and uveitis were 1.0, 1.0, and 0.3 per 100 pt-years, respectively. No cases of inflammatory bowel disease, including Crohn's disease or ulcerative colitis, were reported.

**Conclusion:** SEC (300 and 150 mg) provided rapid and significant improvements in the signs and symptoms of active AS, with responses sustained through 104 wks. SEC was well-tolerated with a safety profile consistent with previous reports.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Psoriatic arthritis (PsA) is clinically heterogeneous, with broad phenotypes of musculoskeletal (MSK) involvement including peripheral arthritis, enthesitis, dactylitis, and axial involvement. Sacroiliitis (SI) in PsA can be unilateral or bilateral in contrast with ankylosing spondylitis which appears to be commonly bilateral. It has been suggested that specific Human Leukocyte Antigen (HLA) allele can present with either unilateral or bilateral sacroiliitis in PsA, HLA-B\*27 with symmetrical SI, HLA-B\*08 with unilateral or asymmetrical SI.

Our objectives were a) to determine the pattern of progression of sacroiliac joint involvement in PsA (unilateral versus bilateral; b) to determine the predictors of progression of sacroiliac joint involvement (symmetrical versus asymmetrical)

### **Methods:**

A retrospective cohort analysis was conducted in patients followed in a large PsA clinic from 1978 to 2016. The participants were assessed at 6 to 12-month intervals according to a standard protocol. The collected information included demographics, medical history, radiological results, HLA allele, and PsA-related outcomes. Radiographs were performed at 2-year intervals. A statistical model was developed to assess for development of SI. Polychotomous logistic regression was used to assess the effect of HLA alleles.

### **Results:**

A total of 1431 PsA patients were analysed. Three hundred and eight patients had SI (23%); 125 (9%) patients with unilateral SI; 17% of patients were HLA-B\*27 positive, table 1. On analysis of the radiological result based on HLA alleles; 85 patients had bilateral asymmetrical SI, 29 (34%) were HLA-B\*27 positive. 176 patients had symmetrical SI, 33 (22%) were HLA-B\*27 positive. HLA-B\*08 had similar proportion of patients in each category. In the bilateral SI group (20% in asymmetric, 16% in symmetric), 18% in the unilateral group. Interestingly, HLA-C\*07 which has not been reported before accounted for more SI both in the unilateral and bilateral group, table 2.

Using polychotomous logistic regression, controlling for gender, HLA-B\*27 positive patients had significantly higher odds of bilateral involvement compared to no sacroiliac joint involvement (OR = 2.42, 95% CI: 1.05, 5.56; p=0.038)

### **Conclusion:**

HLA-B\*27 is associated with bilateral sacroiliac joint involvement in PsA. Patients with HLA-C\*07 are found to have more axial disease compared to the other HLA alleles.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Low grade bone marrow edema (BME) was reported in the sacroiliac joints (SIJ) of up to 25% of healthy individuals and mechanical back pain patients, challenging the imaging discrimination from early spondyloarthritis (SpA) [1]. Potential explanations range from mechanical stress lesions to vascular signals and anatomical SIJ variants. There is little evidence as to whether physical strain, e.g. sports, heavy labour work, or multiparity may trigger SIJ BME. The goal of this study was to determine BME frequency and anatomical distribution in 8 SIJ regions in hobby and professional athletes.

**Methods:** The sample consisted of 2 cohorts of 20 healthy hobby runners (HR) before and after running and 22 professional ice hockey players (IP) from the Danish premier league: HR/IP 40%/100% men; mean age (SD) 27.2 (5.4)/25.9 (4.6) years; mean BMI (SD) 22.6 (1.5)/25.7 (1.6) kg/m<sup>2</sup>. Semicoronal MRI scans of the SIJ with T1SE and STIR sequences were obtained in HR before and 24 hours after a running competition over 6.2 km (mean duration 35.4 minutes, mean speed 10.4 km/h), and in IP at the end of the competitive season. The scans were assessed for BME independently by 3 blinded readers (AGJ, AZ, UW) according to the quadrant based MORPHO module ([www.carearthrititis.com](http://www.carearthrititis.com)). Paired images of HR were read blinded to timepoint. 7 MRI scans (2 paired images) of SpA patients under TNF treatment served to mask readers. A pre-test reader calibration used MRI scans from 11 patients with active sacroiliitis and 9 healthy volunteers. Reader agreement was assessed by ICC (3, 1). Descriptive analysis comprised mean frequency of SIJ quadrants with BME and their distribution in 8 anatomical SIJ regions: upper/lower ilium and sacrum, subdivided in anterior and posterior slices, as concordantly recorded by the majority ( $\geq 2/3$ ) of readers.

**Results:** Agreement among 3 readers for SIJ BME was excellent in calibration (ICC 0.93) and moderate in athletes (ICC 0.59) due to low frequency of BME. The mean number (SD) of SIJ quadrants showing BME was 3.1 (4.2)/3.1 (4.5) in HR before/after running, and 3.6 (3.0) in IP. The posterior lower ilium was the single most affected region, followed by the anterior upper sacrum, consistently across 2 cohorts of athletes.

**Table 1.** Frequency and anatomical distribution of SIJ quadrants with BME in 2 cohorts of athletes. Abbreviations. n (%) with  $\geq 1/2/3/4$  SIJ Q: number of subjects (%) with  $\geq 1/2/3/4$  SIJ quadrants with BME as reported by  $\geq 2/3$  readers.

Cohort	SIJ quadrants	Upper Ilium		Lower Ilium		Upper Sacrum		Lower Sacrum		All subjects
		Anterior	Posterior	Anterior	Posterior	Anterior	Posterior	Anterior	Posterior	
HR before	Mean SIJ Q (SD)	0.1 (0.4)	0.1 (0.3)	0.2 (0.7)	1.4 (1.9)	0.5 (0.9)	0.1 (0.4)	0.3 (0.6)	0.5 (1.6)	3.1 (4.2)

HR after	Mean SIJ Q (SD)	0.2 (0.4)	0 (0.1)	0.3 (0.8)	1.2 (1.7)	0.5 (1.0)	0.2 (0.7)	0.3 (0.7)	0.5 (1.6)	3.1 (4.5)
	n (%) with $\geq 1$ SIJ Q	2 (10.0)	0	2 (10.0)	9 (45.0)	3 (15.0)	2 (10.0)	3 (15.0)	1 (5.0)	16 (80.0)
	n (%) with $\geq 2$ SIJ Q	0	0	1 (5.0)	6 (30.0)	2 (10.0)	1 (5.0)	0	1 (5.0)	14 (70.0)
	n (%) with $\geq 3$ SIJ Q	0	0	1 (5.0)	3 (15.0)	2 (10.0)	0	0	1 (5.0)	8 (40.0)
	n (%) with $\geq 4$ SIJ Q	0	0	1 (5.0)	1 (5.0)	0	0	0	1 (5.0)	5 (25.0)
IP	Mean SIJ Q (SD)	0.1 (0.4)	0.1 (0.3)	0.5 (0.8)	1.9 (1.9)	0.6 (1.1)	0.1 (0.4)	0.2 (0.6)	0.1 (0.6)	3.6 (3.0)
	n (%) with $\geq 1$ SIJ Q	0	1 (4.5)	7 (31.8)	13 (59.1)	3 (13.6)	0	3 (13.6)	0	20 (90.9)
	n (%) with $\geq 2$ SIJ Q	0	0	4 (18.2)	11 (50.0)	2 (9.1)	0	1 (4.5)	0	15 (68.2)
	n (%) with $\geq 3$ SIJ Q	0	0	0	6 (27.3)	2 (9.1)	0	0	0	12 (54.5)
	n (%) with $\geq 4$ SIJ Q	0	0	0	3 (13.6)	1 (4.5)	0	0	0	11 (50.0)

## Conclusion:

In hobby and professional athletes, BME showed on average in 3-4 SIJ quadrants. The posterior lower ilium was the single most affected SIJ region, followed by the anterior upper sacrum. These findings in healthy controls help refine thresholds for a positive SIJ MRI in early SpA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

Inflammation shown on MRI of the sacroiliac joint (MRI-SI) is prevalent in axSpA ( $\pm 30\%$ ) but the specificity is not well known, hence we compared MRI-SI of healthy individuals and those with known mechanical strain acting upon SIJ.

### Methods:

Three trained, blinded readers randomly scored MRI-SI of 172 subjects: 47 healthy individuals (1); 47 age- and gender-matched axSpA patients (with a confirmed positive MRI by central readers) from the SpondyloArthritis Caught Early (SPACE) cohort; 47 age- and gender-matched CBP patients (irrespective of MRI results) from the SPACE cohort; 7 women with postpartum back pain; and 24 frequent runners. The readers scored MRIs according to the ASAS/OMERACT and SPARCC definitions. MRIs were considered positive when at least two of the three readers agreed. SPARCC scores are the mean SPARCC scores of all three readers.

### Results:

The three reader pairs agreed in 75.6-79.9% of the cases on the presence/absence of BME (Cohen's  $\kappa$  0.48-0.59), SPARCC scores correlated well (ICCs 0.824-0.964). Of the healthy volunteers, 11 out of 47 (23.4%) had a positive MRI-SI, compared to 43 out of 47 (91.5%) of the positive axSpA patients and 3 out of 47 (6.4%) CBP patients. Of the runners, 3 out of 24 (12.5%) -and of the women with postpartum back pain 4 out of 7 (57.1%)- had a positive MRI-SI. The mean (SD) SPARCC scores were 1.7 (2.4) (healthy individuals), 20.9 (13.7) (positive axSpA patients), 0.8 (1.4) (CBP patients), 0.8 (1.1) (frequent runners) and 4.5 (6.3) (postpartum patients) (Figure 1). When a SPARCC score  $\geq 2$  was used as a cut-off for positivity, 12 out of 47 healthy volunteers (25.5%), 46 out of 47 positive axSpA patients (97.9%), 5 out of 47 CBP patients (10.6%), 4 out of 24 runners (16.7%) and 4 out of 7 women with postpartum back pain (57.1%) were declared positive. When a SPARCC score  $\geq 5$  was used as a cut-off score, these figures were 4 out of 47 healthy volunteers (8.5%), 41 out of 47 positive axSpA patients (87.2%), 1 out of 47 CBP patients (2.1%), 0 out of 24 runners and 2 out of 7 women with postpartum back pain (28.6%). 'Deep' BME-lesions (increase in signal  $\geq 1$  cm from the articular surface) were not found in healthy volunteers, CBP patients and runners, but in 38 out of the 47 positive axSpA patients (80.9%) and in one out of 7 women with postpartum back pain (14.3%).

### Conclusion:

A substantial proportion of healthy individuals has a positive MRI-SI according to the ASAS/OMERACT definition. High SPARCC scores ( $\geq 5$ ) rarely occur in healthy individuals, CBP patients and runners. 'Deep' (extensive) lesions seem exclusive of sacroiliitis in axSpA patients.

Figure 1. Percentage of positive MRI-SI and total SPARCC scores, each dot represents one individual.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Multiple studies have demonstrated that commensal bacteria play an immunoregulatory role and that gut dysbiosis is associated with inflammatory diseases. This study was conducted to test the hypothesis that gut dysbiosis plays a role in SLE. We have used a congenic model of lupus, the B6.Sle1.Sle2.Sle3 (TC) mice, which share >95% of their genome with B6 controls to ask if differences in microbiota between could synergize with lupus susceptibility genes to modulate autoimmune pathology.

**Methods:** The 16S rDNA sequences of fecal bacteria were compared between the two strains. Global fecal and serum metabolomic profiles were obtained using high-resolution mass spectrometry (Thermo Q-Exactive) coupled with ultra-high performance liquid chromatography. Tryptophan (Trp) metabolites were quantified with the same instruments relative to internal standards. Germ-free (GF) B6 mice were populated with fecal contents from either B6 or TC mice, and evaluated 4 weeks later. TC and B6 mice were treated with an antibiotic cocktail starting at 6 weeks of age and evaluated after 6 months of treatment. B6 and TC mice were either housed separately or co-housed in a mixed strains environment at weaning and evaluated 6 months later. B6 and TC mice were fed with Trp-deficient, Trp-supplemented (1%) and control chow starting at 2 months of age and evaluated 7 months later. Immunophenotypes were evaluated by flow cytometry. Serum and fecal antibodies were measured by ELISA. Kidney and gut pathology was evaluated by histology.

**Results:** TC and B6 mice have a different distribution of gut bacteria based on 16S rDNA sequencing. The colon and duodenum of aged TC mice showed a significant amount of immune cell infiltrate, which correlated with the severity of renal pathology. TC fecal transfers to GF B6 mice showed that microbiota from aged TC mice was sufficient to induce the production of serum anti-dsDNA IgG. TC microbiota also expanded germinal center (GC)-like organization in Peyer's patches and follicular helper T (TFH) cells in the mesenteric lymph node. These changes were not observed with microbiota from young pre-disease TC mice. Treatment of TC mice with antibiotic cocktail significantly delayed anti-dsDNA IgG induction and expanded Treg and follicular regulatory T (TFR) cells. Co-housing TC and B6 mice revealed significant interactions between susceptibility genes and microbiota. Remarkably, the frequency of TFH cells was decreased in co-housed TC mice, corresponding to a drastic reduction of autoantibodies and amelioration of renal disease. Co-housed TC and B6 mice showed a similar fecal metabolome profile, which was significantly different from those of independently housed mice. Trp metabolites were among the metabolites found at different levels between TC and B6 stools. Similarly to what has been reported by others in SLE patients, TC mice have increased levels of serum and fecal kynurenine, one of Trp metabolites, as compared to B6. Accordingly, a Trp-supplemented chow accelerated autoimmune pathology in TC mice.

**Conclusion:** Overall, our results show that a dysregulated gut microbiota amplifies lupus pathogenesis in mice, and suggest that this is mediated at least in part by bacteria modifying Trp metabolism.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** A disintegrin and metalloprotease 17 (ADAM17) controls ecto-domain shedding of TNF $\alpha$  and epithelial-growth factor ligands (EGFR) such as heparin-binding EGF (HB-EGF). TNF $\alpha$  and HB-EGF have both been implicated in kidney injury of systemic lupus erythematosus (SLE), yet targeting ADAM17 is limited by its essential role in protecting the skin and intestinal barrier. In contrast, mice lacking the inactive Rhomboid 2 (iRhom2), a key regulator of ADAM17 in myeloid cells, have normal development but are protected from TNF $\alpha$ -dependent septic shock and Rheumatoid Arthritis. iRhom2-deficient mice appear normal because the related iRhom1 supports ADAM17-dependent skin and intestinal barrier protection. Here, we sought to determine whether iRhom2/ADAM17 pathway contributes to the pathogenesis of lupus nephritis (LN).

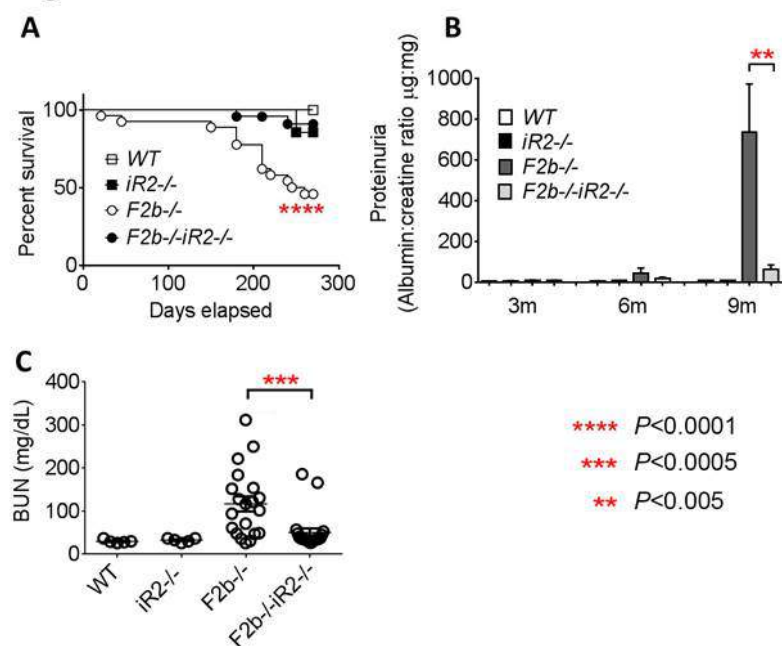

**Methods:** iRhom2 (gene name *Rhbd2*) deficient mice were crossed with *Fcgr2b*<sup>-/-</sup> lupus-prone mice. Development of anti-dsDNA Abs and kidney injury was monitored by assessing proteinuria, BUN, kidney inflammatory cell infiltration, renal deposition of immune complexes and complement and histology. Molecular mechanism of renal damage was studied using RNA-sequencing analysis. Activation of iRhom2, ADAM17 and EGFR signaling was determined by qPCR and western-blot. To corroborate the contribution of both TNF $\alpha$  and EGFR signaling to renal injury, we treated *Fcgr2b*<sup>-/-</sup> mice with murine p75TNFR<sup>II</sup>-Fc or an EGFR tyrosine kinase inhibitor.

**Results:** Deficiency of iRhom2 almost completely protected *Fcgr2b*<sup>-/-</sup> mice from mortality (Fig. 1A). Development of severe proteinuria and elevated blood urea nitrogen (BUN) in aged *Fcgr2b*<sup>-/-</sup> (*F2b*<sup>-/-</sup>) mice were ameliorated by iRhom2 deficiency (*iR2*<sup>-/-</sup>) (Fig. 1B, C). Glomerular and tubulo-interstitial damage and inflammatory cell infiltrates (neutrophils, monocytes and T cells) in *Fcgr2b*<sup>-/-</sup>-kidneys were markedly and significantly reduced in the absence of iRhom2, while anti-dsDNA Ab production and renal

deposition of IgG and C3 were minimally affected. These data suggest that iRhom2 targets the effector arm in SLE, rather than preventing development of autoimmunity. Strikingly, transcriptome profiling of mouse kidneys identified epithelial-mesenchymal transition (EMT) and TNF signaling as top pathways activated in *Fcgr2b*<sup>-/-</sup> kidneys, along with marked upregulation of *Tnf* and *Hbegf* transcripts in these kidneys. This is confirmed by findings that kidney damage in *Fcgr2b*<sup>-/-</sup> mice was associated with increased renal expression of phospho-EGFR and phospho-ERK1/2, which was significantly diminished in the absence of iRhom2. Finally, blockade of TNF- $\alpha$  or EGFR in protected *Fcgr2b*<sup>-/-</sup> mice from kidney injury.

**Conclusion:** Our findings provide the first evidence that iRhom2, a major regulator of ADAM17, plays a critical role in the pathogenesis of LN, most likely by processing TNF $\alpha$  and EGFR ligands in the diseased kidneys.

## Selective Inhibitors of Nuclear Export Prevent Lupus Progression By Targeting Germinal Center Formation and Autoreactive Antibody Secreting Cells

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** There is great interest in developing new treatment approaches for systemic lupus erythematosus (SLE), but the biologic therapies under investigation over the past several years have yielded variable results. Recently the nuclear export protein Exportin 1 (XPO1, also known as CRM1) has surfaced as an attractive target for the treatment of malignancies and autoimmune disorders. Selective Inhibitor of Nuclear Export (SINE) compounds are potent, orally available and well tolerated XPO1 inhibitors that have shown potent activity in human phase I/II clinical trials against various hematologic malignancies. SINE compounds exert apoptotic and anti-inflammatory effects by mediating nuclear retention of important XPO1 cargos like the NFκB pathway regulatory protein, IκB. Based on the central role of NFκB signaling in the activation of immune cells in SLE, we evaluated the therapeutic efficacy of SINE compounds in murine SLE.

#### Methods:

Cohorts of nephritic NZB/W F1 lupus-prone female mice, with established disease (elevated anti-dsDNA antibody titer and proteinuria) were treated with low or high dose KPT-350 (5 or 7.5 mg/kg, respectively) or a vehicle control three times per week for 8 weeks (n=8 per group). Proteinuria was monitored and kidney histology assessed. Spleen, bone marrow (BM), and kidney cells were harvested and analyzed by flow cytometry. Antibody secreting cells (ASCs) and germinal centers (GCs) were enumerated and measured by ELISpot and immunofluorescent staining. Serum samples and RNA were collected for Luminex assay and qPCR.

**Results:** Treatment with SINE compounds significantly prevented increases in proteinuria (proteinuria scores: Control:  $2.12 \pm 1.12$ ; SINE (5 mg/kg):  $1.06 \pm 0.49$ ; SINE (7.5 mg/kg):  $0.85 \pm 0.55$ ) and drastically decreased IgG deposition and kidney pathology. Prevention of kidney damage was associated with a remarkable disruption of splenic GC, a significant reduction in the number of auto-reactive ASC, and a decrease in the accumulation of auto-reactive ASC in the inflamed kidney. Reduced numbers of plasma cells (PCs) in the inflamed kidney are likely due to the drastic decrease in the expression of molecules critical for PC attraction (CCL2, CXCL9, CXCL10, CXCL11) and survival (BAFF, APRIL). The potent effect of SINE compounds on GC and auto-reactive ASC is noticeable as early as 1 week after starting therapy. However, kinetics studies showed that a more pronounced elimination of GC and auto-reactive ASC is achieved after 8 weeks. Although SINE therapy has a drastic impact on spleen architecture, recovery experiments showed that complete recovery of immune cells in spleen occurred by 4 weeks. The reversible impact of SINE compounds on SLE provides a potential window of time for immunization of lupus patients.

**Conclusion:** SINE compounds have demonstrated efficacy in a murine model of SLE by reducing generation, survival and function of auto-reactive immune cells. It is likely that inhibition of the canonical NFκB pathway underlies KPT-350's inhibitory effect. Together, our findings suggest the potential of SINE compounds to have a significant impact on disease progression in SLE.

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Neuropsychiatric symptoms of systemic lupus erythematosus (NP-SLE), including headaches, cognitive dysfunction and psychiatric disorders, appear in up to 75% of SLE patients and may be among the earliest signs of SLE. However, these non-specific symptoms make diagnosis/treatment of NP-SLE problematic. Microglia are the resident innate immune cells in the brain and accumulating evidence points to this population as a source of neurotoxic factors that drive pathology of multiple neurodegenerative diseases. However, relatively little is known about microglia in the context of NP-SLE. We have shown that CD11c-specific deletion of caspase 8, an enzyme in the Fas pathway classically linked to apoptosis initiation and necroptosis suppression, induces a SLE-like

disease that originates in part from heightened dendritic cell activation. We find that caspase 8 deletion extends to microglia, as these cells can express CD11c. To this end, we examined the neurological consequences of microglial caspase 8 deletion.

**Methods:** Mice with caspase 8 flanked by *loxP* sites (*Casp8<sup>fl/fl</sup>*, WT) were bred to mice expressing Cre under control of the CD11c gene promoter (*Cre<sup>CD11c</sup>*) to generate *Cre<sup>CD11c</sup>Casp8<sup>fl/fl</sup>* mice. Mice were subjected to a battery of tasks at Northwestern University's Behavioral Phenotyping Core. MRI was performed at Northwestern University's Center for Translational Imaging. Cellular infiltration into the brain was assessed using 10-color flow cytometric analysis. RNAseq analysis was performed on sorted microglia.

**Results:** With age, *Cre<sup>CD11c</sup>Casp8<sup>fl/fl</sup>* mice develop an inflammatory disease reminiscent of both classic murine models of SLE and human SLE. Strikingly, *Cre<sup>CD11c</sup>Casp8<sup>fl/fl</sup>* mice also exhibit neurological deficits during the Morris water maze, pre-pulse inhibition, contextual fear conditioning and rotarod tasks that indicate hippocampal and cerebellar abnormalities. Increased vascular permeability in *Cre<sup>CD11c</sup>Casp8<sup>fl/fl</sup>* mice, as evidenced by Dynamic Intravascular Contrast Agent MRI, correlates with increased leukocyte infiltration seen by flow cytometric analysis. This infiltration resembles that of an acute model of traumatic brain injury, wherein physical damage to the brain promotes leakage of the blood-brain barrier. However, in our case, this breach is the direct result of CD11c-specific caspase-8 deletion and chronic systemic inflammation. GO analysis of differentially expressed genes reveals that transcriptional profiles of young caspase 8-deficient microglia are enriched for genes involved in *amyloid precursor protein metabolic and catabolic processes* and *Notch receptor processing*, while profiles of 10-12 month old caspase 8-deficient microglia are enriched for genes involved in *inflammatory and immune responses*.

**Conclusion:** These data substantiate a novel mechanism whereby caspase-8 controls microglial function at both early and late stages of SLE to prevent NP-SLE manifestations and highlight microglial defects as a potential mechanism underlying the pathogenesis of NP-SLE. We intend to leverage our transcriptional data to further interrogate how defective microglial function incites NP-SLE.

## Amelioration of Neuropsychiatric Systemic Lupus Erythematosus By Fingolimod-Mediated Sphingosine-1-Phosphate Receptor Modulation

Elise Mike<sup>1</sup>, Ariel Stock<sup>1</sup> and Chaim Putterman<sup>2</sup>, <sup>1</sup>Microbiology and Immunology, Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY, USA, Bronx, NY

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** While the pathogenesis of neuropsychiatric SLE (NPSLE) is not fully understood, critical aspects of disease development include neuroinflammation and loss of brain barrier integrity. Fingolimod, a sphingosine-1-phosphate (S1P) receptor modulator, is approved for the treatment of multiple sclerosis. Through functional antagonism of S1P receptors, fingolimod prevents lymphocyte egress from lymphoid organs. In addition to reducing CNS infiltration by peripheral lymphocytes, fingolimod also exhibits direct neuroprotective effects such as preserving brain barrier integrity and decreasing pro-inflammatory cytokine secretion by astrocytes and microglia. Given these effects, we hypothesized that fingolimod would attenuate neurobehavioral deficits in MRL-lpr/lpr mice, a validated NPSLE model.

**Methods:** Ten-week-old female MRL-lpr/lpr mice were treated thrice weekly with fingolimod (3 mg/kg) or vehicle alone (n=16/group) by intraperitoneal injection. After 4 weeks of treatment, mice were assessed for alterations in cognitive function or emotionality. The object placement and object recognition tests were performed to assess visuospatial and recognition memory. The swim test was used to assess despair-like immobility. Brains were paraffin-embedded for histological analysis and immunohistochemical staining.

**Results:** Fingolimod-treated mice exhibited significantly improved preference for novel object placement when compared with control-treated mice (67±5% vs. 51±4.8%, *p*=0.024), demonstrating maintenance of visuospatial memory. Moreover, fingolimod-treated mice displayed less despair-induced immobility (57±2.7% vs. 45±4.2%, *p*=0.019), indicating that fingolimod mitigates the depression-like

phenotype. Immunofluorescent staining revealed a significant reduction in B and T cell infiltration of the choroid plexus in fingolimod-treated mice (Figure 1). Finally, fingolimod reduced perivascular and periventricular leakage of serum albumin, supporting improved barrier functionality. Systemic effects of fingolimod included a significant decrease in splenomegaly and lymphadenopathy, but surprisingly without a change in circulating anti-DNA titers.

**Conclusion:** Fingolimod treatment ameliorates cognitive dysfunction and depressive-like behavior in MRL-lpr/lpr mice, and reduces CNS lymphocytic infiltration and brain barrier leakiness. Our results highlight a novel role of S1P in the pathogenesis of NPSLE and point to S1P receptor modulation as a potential therapeutic target.

**Figure 1.** Fingolimod reduces B and T cell infiltration in the choroid plexus of lpr mice. DAPI staining shows severe cellular infiltration of the third ventricle of control lpr mice (A) that was absent or significantly reduced with fingolimod treatment (B). Additional staining revealed extensive B220+ B cell (magenta) and CD3+ T cell (green) infiltration in control mice (C) that was attenuated in treated mice (D). 20x magnification. Scale bar length is 20  $\mu$ m.

Jacob**<sup>1</sup>, <sup>1</sup>Division of Rheumatology, Keck School of Medicine of University of Southern California, Los Angeles, CA, <sup>2</sup>Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY, <sup>3</sup>Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY, USA, Bronx, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** BAFF is a vital survival and differentiation factor for B cells. In human SLE, clinical efficacy with any of 4 different BAFF antagonists is modest at best. This limited ability of BAFF antagonists to control disease activity in human SLE points to a substantial BAFF-independent component. In stark contrast to this substantial BAFF-independent component to human SLE, disease in currently utilized murine SLE models is highly BAFF-dependent. To investigate the *in vivo* BAFF-independent component to SLE, we generated a murine model in which *SLE clinical disease* develops in the absence of BAFF.

**Methods:** Starting with C57BL/6 mice that express a human *Bcl2* transgene (Tg) in their B cells (thereby permitting B cell survival even in the absence of BAFF), we introgressed this Tg into NZM 2328 (NZM) mice genetically deficient in BAFF (NZM.*Baff*<sup>-/-</sup>) to generate NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice. Expression of human BCL2 and lymphocyte profiles were assessed by FACS; serologic profiles were assessed by ELISA; renal immunopathology was assessed by immunofluorescence and histology; and clinical disease was assessed by testing for severe proteinuria and death. To determine whether NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice are sensitive to restoration of BAFF, NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice were crossed with NZM wild-type (WT) mice to yield BAFF-expressing NZM.*Baff*<sup>+/-</sup>.*Bcl2*<sup>Tg</sup> mice.

**Results:** Since SLE in NZM WT mice (and in humans) is predominantly a disease of females, only female mice were studied. In comparison to their NZM.*Baff*<sup>-/-</sup> littermates and to age-matched NZM WT mice, NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice selectively over-expressed BCL2 in their B cells. Whereas NZM.*Baff*<sup>-/-</sup> mice harbored decreased percentages and numbers of total B cells, follicular B cells, marginal zone (MZ) B cells, and plasma cells in comparison to NZM WT mice, these (other than MZ B cells) were restored in NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice to at least WT levels. NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice developed increased serum levels of IgG autoantibodies (anti-chromatin and anti-dsDNA), increased glomerular deposition of IgG and C3, and increased glomerular and tubulointerstitial pathology, culminating in severe proteinuria and death. The time course for development of SLE features in NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice was even more rapid than that in NZM WT mice. Whereas NZM WT mice start to develop severe proteinuria at 5-6 months of age, with 50% being affected by 7 months, NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice develop severe proteinuria as early as 3 months of age, with 50% of the mice being affected by 4 months. Whereas NZM WT mice begin dying at 6 months of age, with 50% mortality at 7-8 months, NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice die as early as 3 months of age, with 50% mortality at 4.5 months. SLE disease in NZM.*Baff*<sup>+/-</sup>.*Bcl2*<sup>Tg</sup> mice is even more severe, with 100% mortality at 5 months, thereby pointing to both BAFF-dependent and BAFF-independent components to disease in NZM.*Baff*<sup>+/-</sup>.*Bcl2*<sup>Tg</sup> mice.

**Conclusion:** BAFF may be dispensable to development of disease as long as B cell survival is preserved via a BAFF-independent pathway. This may help explain the limited and variable clinical success with BAFF antagonists in human SLE. In addition, NZM.*Baff*<sup>-/-</sup>.*Bcl2*<sup>Tg</sup> mice should serve as a powerful murine model for the study of BAFF-independent SLE.

Izmirly<sup>5</sup>, <sup>1</sup>Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>3</sup>Division of Rheumatology, Allergy and Immunology, UCSD School of Medicine, La Jolla, CA, <sup>4</sup>Lupus Foundation of America, Washington DC, DC, <sup>5</sup>Rheumatology, New York University School of Medicine, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design and Outcome Measures

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The primary endpoint in SLE trials is usually response to therapy at a landmark visit. However, during a trial, patients may alternate between response and non-response states. Duration of response would therefore be important to assess, but the optimal approach for estimating response duration has not been determined. Analyzing response duration only among responders at a landmark visit can result in selection bias. Drop-outs and missed visits further complicate estimation of response duration. We addressed these issues with a multi-state Markov (MSM) model that was fit to quantify response duration and assess baseline predictors of transitions into and out of response in SLE patients receiving standard of care (SoC).

**Methods:** Data on 759 SLE patients with active disease (SLEDAI ≥ 6 at entry) randomized to SoC in 52 week trials was obtained from the Collective Data Analysis Initiative (CDAI) database of the Lupus Foundation of America. The following monthly response endpoints (without medication stipulations) were analyzed: SRI-4, SRI-5, SRI-6, and BICLA. A MSM model allowing for bi-directional transitions between response and non-response states was fit to estimate the probability of being in response at 52 weeks,

average duration of response (sojourn time) and mean total time in response. Predictors of attainment and loss of SRI-5 response were also identified.

**Results:** Based on the MSM model, the probability of being in response at 52 weeks ranged from 42% (SRI-6) to 61% (SRI-4), higher than conventional 52 week landmark response rates that assume non-response for missing data. The estimated mean duration of response ranged from 20.4 weeks (BICLA) to 31.5 weeks (SRI-4). Mean total time in response over 52 weeks based on all patients was 16.4 - 24.8 weeks. After adjusting for baseline SLEDAI score, patients with lower anti-dsDNA titers were more likely to achieve and maintain SRI-5 response ( $p < 0.001$ ). Younger age ( $p < 0.001$ ) and higher protein/creatinine ratio ( $p < 0.001$ ) were associated with higher frequency of SRI-5 response but also shorter response duration. Response duration was also shorter in patients who were non-White ( $p < 0.001$ ), had longer history of disease ( $p = 0.03$ ), and lower lymphocyte count ( $p = 0.001$ ) at baseline.

Responder Index	Landmark response rate at 52 weeks	Probability in response at 52 weeks from MSM (95% CI)	Mean sojourn time in response (95% CI)	Mean total time in response (95% CI)
SRI-4	45.9% (95% CI: 42.3%-49.5%)	61.0% (95% CI: 58.3%-63.5%)	31.5 weeks (95% CI: 28.5-34.8)	24.8 weeks (95% CI: 23.7-25.9)
SRI-5	33.6% (95% CI: 30.2%-37.1%)	43.6% (95% CI: 40.8%-46.3%)	25.7 weeks (95% CI: 23.1-28.7)	17.1 weeks (95% CI: 16.0-18.1)
SRI-6	32.5% (95% CI: 29.2%-36.0%)	41.7% (95% CI: 38.8%-44.7%)	24.3 weeks (95% CI: 21.9-27.1)	16.4 weeks (95% CI: 15.3-17.5)
BICLA	38.0% (95% CI: 33.4%-42.7%)	50.2% (95% CI: 47.1%-53.5%)	20.4 weeks (95% CI: 18.1-23.0)	21.2 weeks (95% CI: 19.7-22.5)

\*Dropouts and missing data imputed as non-response. Among patients with 1A or 2B at baseline

**Conclusion:** Factors associated with greater disease severity were consistently associated with shorter response duration on SoC, despite exhibiting variable effects on the probability of achieving response at a given time. Response duration might therefore provide a more discriminating measure to distinguish effective investigational treatments from background SoC, although this remains to be tested. Multi-state models make better use of complex longitudinal clinical trial data and provide a more comprehensive view of the response profile and the role of patient characteristics in different aspects of response.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design and Outcome Measures

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Randomized controlled trials (RCTs) of new SLE treatments are hampered by the lack of effective outcome measures that are responsive to change and clinically relevant. To address this, we developed a new Multivariable Lupus Outcome Score (LuMOS) from raw data from a previous RCT and validated it using data from an independent trial.

### Methods:

The new LuMOS formula was developed by analyzing raw data of two pivotal RCTs: BLISS-52 and BLISS-76, the basis for approval of belimumab for treatment of SLE. Using data from BLISS-76 as the learning dataset, we optimized discrimination between outcomes for patients treated with 10mg/kg belimumab (BM-10mg) *versus* placebo over the first 52 weeks of follow-up. LuMOS was developed through multivariable logistic regression analyses that combined *a priori* inclusion of some variables, such as change in SLEDAI  $\geq 4$

points, with forward selection of others. The final model was selected using the Akaike Information Criterion. Performance of LuMOS was assessed using an independent validation dataset from the BLISS-52 RCT. For each belimumab trial, we tested significance of the differences in the mean LuMOS in the Active Treatment *versus* Placebo groups. To compare discriminatory ability of LuMOS with the conventional SLE Response Index (SRI-4), used as the primary outcome measure in both BLISS trials, we relied on Effect Size (ES = Cohen's d = mean difference divided by within-group standard deviation).

**Results:**

The final LuMOS model incorporated reduction in SELENA-SLEDAI  $\geq 4$  points, increase in C4 concentration, decrease in anti-dsDNA Ab titer, and changes in BILAG organ system manifestations: no new symptoms or no worsening in renal and improvements in mucocutaneous components. Decreases in prednisone doses and increases in C3 concentration, included based on clinical considerations, had very minor impacts on total LuMOS. In all analyses of BLISS-76 and BLISS-52 RCTs, mean LuMOS were significantly higher ( $p < 0.0001$ ) for BM-10mg and BM-1mg treatment groups than placebo. LuMOS also found significant differences between active treatment and placebo when SRI did not, as for BM 1mg in BLISS-76. The ES were consistently and significantly much higher, and p-values systematically much lower with LuMOS compared with SRI (Table 1).

**Conclusion:**

The proposed evidenced-based LuMOS developed with data from BLISS-76 and validated with data from BLISS-52 exhibits superior capacity to discriminate responders from nonresponders, compared to the SRI-4. Use of LuMOS may improve the efficiency and power

**Table 1**

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design and Outcome Measures

**Background/Purpose:** Remission in SLE is a desirable target, however there is no gold standard for the definition of remission. An international task force agreed on various definitions of remission in SLE (DORIS) [1]. Our aim was to apply these definitions on a clinical trial.

**Methods:** This is a post-hoc analysis of a prospective randomized controlled trial (RCT) in SLE, the BLISS-76 clinical trial [2]. We have applied two DORIS definitions (Table 1) at three time points, week (wk) 24, 52 and 76. The patient could be in remission *on* or *off* treatment. Remission *on* treatment allowed maintenance anti-malarials, low dose glucocorticoids (GCs) (prednisone  $\leq 5$  mg/day or equivalent), maintenance immunosuppressives and maintenance biologics. Remission *off* treatment allowed maintenance anti-malarials only. Additionally, we applied each definition where the remission *on* treatment allowed a GC dose  $\leq 10$  mg/day (not a part of the original DORIS-definitions).

**Results:** There were 819 patients enrolled in BLISS-76. The baseline characteristics are shown in Table 2. The proportions of patients that fulfilled remission according to the above definitions are shown in Table 3. The highest point prevalence (9.5%) was when definition 1a *on* treatment was applied at wk 76. As expected, even more patients fulfilled definition 1a when a GC dose  $\leq 10$  mg/day was allowed at wk 76 (13.8%). More patients fulfilled the remission criteria when clinical SLEDAI was used compared to when BILAG was used. When serology (anti-DNA antibodies and complement) was taken into consideration (definitions 1b and 3b), less patients fulfilled remission. Very low numbers of patients ( $\leq 1\%$ ) fulfilled remission off treatment.

**Conclusion:** Overall, few patients fulfilled remission according to these definitions. More patients fulfilled the definitions when serology was excluded and when a higher dose of GCs was allowed.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design and Outcome Measures

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Clinical trial evaluations in SLE have been problematic, in part due to glossary-based outcome measures that provide imperfect thresholds for grading flares or improvement. Visual analogue scales (VAS) allow refined scaling of change in disease severity, grounded in real world clinical observation, but have been inconsistent in practice when used over time or by different raters. The SELENA SLEDAI Physician's Global Assessment (SSPGA) is a VAS with severity anchors and a simple but specific protocol for scoring designed to improve inter-and intra-rater consistency. The Rapid Evaluation of Activity in Lupus (LFA-REAL<sup>TM</sup>) extends the SS PGA structure by providing separate scales for each active symptom, supporting evaluation of patient progress in individual symptoms, organs, or total disease activity. We compared performance of SS PGA and LFA-REAL<sup>TM</sup> to accepted SLE trial outcome measures during an ongoing trial in SLE.

**Methods:** Disease activity (SLEDAI, BILAG 2004, SS PGA and LFA-REAL<sup>TM</sup>) was evaluated at consecutive monthly visits in an investigator-initiated, double-blind, placebo controlled trial of abatacept (trial results pending). Validation of total scores and change in SSPGA and REAL vs SLEDAI and BILAG were examined by Spearman Correlation. ROC curve analysis (SAS) was applied to compare changes in SSPGA and LFA-REAL<sup>TM</sup> to frequently used dichotomous SLE trial endpoints, SRI-4 and BICLA.

**Results:** 50 patients [47 female, mean age (SD) 45 (11.6) years] were assessed at 528 visits. Changes in disease activity compared to baseline were examined in 478 visit pairs. Total SSPGA and REAL scores strongly correlated to each other ( $r=0.936$ ), as well as to total SLEDAI and BILAG [SS PGA:  $r=0.742$  (SLEDAI),  $r=0.776$  (BILAG). REAL:  $r=0.778$  (SLEDAI),  $r=0.813$  (BILAG); all  $p<0.0001$ ]. Changes in SS PGA and LFA-REAL<sup>TM</sup> at each visit compared to screening correlated to each other ( $r=0.857$ ) as well as to changes in SLEDAI and BILAG [Delta SS PGA:  $r=0.678$  (Delta SLEDAI),  $r=0.624$  (Delta BILAG); Delta LFA-REAL<sup>TM</sup>:  $r=0.686$  (Delta SLEDAI), and  $0.700$  (Delta BILAG); all  $p<0.0001$ ]. Changes in SS PGA and LFA-REAL<sup>TM</sup> were very strongly related to the dichotomous SRI-4 and BICLA endpoints by ROC analysis ( $p<0.0001$  for all) (Table 1). Mean (95% CI) improvement in SS PGA reflecting SRI-4 was 37.3mm (35.4 to 39.3mm) and for LFA-REAL<sup>TM</sup> 52mm (48.9 to 55.1mm). Unlike SS PGA, LFA-REAL<sup>TM</sup> could be correlated to BILAG individual organ scores with musculoskeletal scores  $r=0.842$  and mucocutaneous  $r=0.826$  ( $p<0.0001$  for both).

**Conclusion:** When scored by protocol standards, both the SS PGA and LFA-REAL<sup>TM</sup> are reliable surrogates of commonly used endpoints in SLE trials. Both instruments are easy to score and understand, and could be employed as continuous or dichotomous endpoints. The LFA-REAL<sup>TM</sup> provides an advantage of individualized scoring at the symptom or organ level.

Table 1. AUC of changes in LFA-REAL<sup>TM</sup> and PGA in relation to SRI-4 and BICLA.

	SRI-4	BICLA
$\Delta$ LFA-REAL <sup>TM</sup>	0.8758	0.8517
$\Delta$ SS PGA	0.8946	0.9126

## Subsetting Systemic Lupus Erythematosus By Interferon Gene Signatures and Serologies (anti-dsDNA and Low Complement) Uncovers Significant Clinical Diversity

**Michelle Petri**<sup>1</sup>, Steven Watts<sup>2</sup>, Richard Higgs<sup>2</sup>, MaryAnn Morgan-Cox<sup>2</sup> and Matthew D Linnik<sup>3</sup>, <sup>1</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>2</sup>Eli Lilly and Company, Indianapolis, IN, <sup>3</sup>Immunology, Lilly Biotechnology Center, San Diego, CA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design and Outcome Measures

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Personalized therapy in systemic lupus erythematosus (SLE) will require identifying SLE subsets that will benefit from different targeted therapies. Belimumab, for example, has the highest response rates in those with low complement and high anti-DNA, whereas anifrolumab (anti-interferon receptor alpha) has the highest response rates in those with the interferon alpha gene signature.

**Methods:** Objective molecular and biochemical baseline parameters were obtained to characterize SLE patients in two large multinational trials (n=2262 patients). Patients were categorized with three dichotomous baseline parameters: IFN gene signature, anti-dsDNA, and C3/C4.

**Results:** Table 1 shows the different subgroups of those with or without interferon gene signature grouped by serologies. Table 2 contains the p-values.

Table 1.

\*p-values are from pairwise tests

Comparing negative interferon gene signature with the four interferon gene signature positive groups showed that interferon gene signature negative patients were more likely to have musculoskeletal activity than interferon gene signature positive Groups 1, 3, and 4; and more likely to have mucocutaneous activity than Group 2. Comparing Group 2 (interferon gene signature alone with no serologies) versus the other three interferon gene signature positive groups showed that the other groups had more activity and required more treatment. However, Group 2 was more likely than the other interferon gene signature groups to have musculoskeletal and mucocutaneous activity.

**Conclusion:** Subsetting SLE by BOTH interferon alpha gene signature AND serologies is much more informative than just the interferon alpha gene signature alone. There is tremendous, highly statistically significant clinical diversity within the interferon positive subgroups. This suggests that results for clinical trials of interferon targeted therapy should include such subset analyses.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design and Outcome Measures

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** LN is a common, deleterious manifestation of systemic lupus erythematosus (SLE) and despite recent advances in treatment remains the most significant end organ injury contributing to morbidity and mortality. Recent studies suggest at the 12-month mark post initial treatment, proteinuria  $<0.7\text{g/day}$  is predictive of favorable long term renal outcome. Using a large multi-ethnic SLE cohort, we assessed if the level of serum albumin and urine protein-to-creatinine ratio (uPCR) at 12-month mark was predictive of long-term renal outcome.

**Methods:** Data were obtained from the NYU SAMPLE biorepository/registry of 750 patients fulfilling SLE criteria, 249 with renal involvement. 83 met inclusion criteria of renal bx with at least 4 years of yearly f/u serum and urine data. Adverse renal outcome (ARO) was defined as doubling of creatinine (or final creatinine  $>4$  if initial creatinine  $>2.5$ ), ESRD or need for transplantation. Included patients had to be ARO free for the first year ( $\pm 1$  month). Spearman correlation coefficient(S) was estimated between albumin and uPCR at 12 months and Kaplan-Meier curves and Cox models used to evaluate the predictive role of each in ARO-free survival. ROC curves were constructed to generate optimal cutoff points for sensitivity and specificity (based on Youden indices) for albumin and uPCR at 12 months. P-values of  $\leq 0.05$ , 2-side were considered statistically significant.

**Results:** Of the 83 subjects, 78% were female; median age  $37.0 \pm 0.9$ , 10% white, 35% black, 14% Asian, 41% Hispanic. ISN/RPS Class represented: 42% V, 53% III&IV, 5% II. Median albumin and uPCR were 3.9 (Range: 2.1-4.9) and 0.86 (Range: 0.06-5.96). Albumin and uPCR values at 12 months were negatively correlated ( $S=-0.4$ ,  $p=0.0002$ ). There were 14 AROs in the 36 months follow-up period, with a 21% cumulative ARO rate. Univariate Cox models found albumin (hazard ratio (HR)=0.15) and uPCR at 12 months ( $\text{HR}=1.43$ ) as significant predictors of ARO. When evaluated jointly, only albumin at 12 months was significant ( $\text{HR}=0.14$ ). The ROC of albumin alone generated an area under the curve (AUC) of 0.92 with an optimal 12-month albumin cutoff of 3.7, predicting ARO-free at 48 months post-bx with a sensitivity of 91% and specificity of 85%.

**Conclusion:** Serum albumin at 1 year predicted ARO-free status with high sensitivity and specificity 4 years after induction treatment, outperforming uPCR. uPCR sensitivity and specificity in our analysis contrasts with other reports as the definition of ARO is more clinically relevant for avoiding renal replacement risk and has a shorter interval of follow-up. It remains to be determined if preservation of serum albumin, despite proteinuria, reflects a non-inflammatory state, if selectivity for non-albumin proteinuria represents less glomerular injury, or if non-albumin proteins are less injurious to the tubulointerstitium.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis II: Biomarkers and Disease Activity

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** To evaluate serum cytokine and chemokine profiles in patients with ANCA-associated vasculitis (AAV) classified by ANCA specificity (proteinase 3 (PR3)-ANCA *versus* myeloperoxidase (MPO)-ANCA) or by clinical diagnosis (granulomatosis with polyangiitis (GPA) *versus* microscopic polyangiitis (MPA)).

**Methods:** A panel of 29 soluble mediators involved in the pathogenesis of AAV was tested in active AAV patients at inclusion in a large randomized clinical trial. The levels of each biomarker were compared between groups within each classification system, ANCA type (PR3-AAV vs MPO-AAV) and clinical diagnosis (GPA vs MPA). Multivariable analyses corrected for age, sex, and renal insufficiency (eGFR<60ml/min/1.73m<sup>2</sup>) were also performed, with each biomarker as the dependent variable and ANCA type/clinical diagnosis as the explanatory variables of interest.

**Results:** The 186 subjects included 92 male and 94 female patients with median age 52 (IQR 44-66; range 15-92), all of whom had severe disease: median BVAS/WG 8 (IQR 5-10, range 3-23). Among these patients, 140 had been diagnosed with GPA and 46 with MPA; 124 were positive for anti-PR3 and 62 for anti-MPO. In each pair of groups (AAV clinical diagnosis, ANCA type) median BVAS/WG levels and number of patients on steroid or immune-suppressive treatment were not significantly different ( $p>0.05$  in all comparisons). Levels of 9 mediators were significantly higher in PR3-AAV (IL-6, GM-CSF, IL-15, IL-18, IL-8, TARC, IL-18Bb, sIL-2Ra, NGFb;  $p<0.05$ ), compared to 4 cytokines that were higher in MPO-AAV (sIL6R, sTNFR II, NGAL, ICAM-1;  $p<0.05$ ). In contrast, only 6 cytokines (IL-6, GM-CSF, IL-15, IL-18, sIL-2Ra, NGFb;  $p<0.05$ ) were higher in GPA than MPA, and 3 (Osteopontin, sTNFR II, NGAL;  $p<0.05$ ) were higher in MPA than GPA. Although not formally compared, for nearly all biomarkers the difference between PR3-AAV/MPO-AAV was larger than that between GPA/MPA (**Figure**). The multivariate analysis showed that 8 soluble mediators (IL-15, IL-8, IL-18Bp, NGF-b, ICAM-1, TARC, Osteopontin, KIM-1;  $p<0.05$ ) distinguished with more accuracy AAV patients when grouped for ANCA type rather than for clinical diagnosis.

**Conclusion:** According to serum biomarkers, ANCA specificity better discriminates distinct subsets of patients when compared to clinical diagnosis, suggesting important differences in underlying pathophysiology and justifying stratification of patients by ANCA specificity for treatment trials. Moreover, these findings suggest that expression of certain combination of cytokines and chemokines may be driven by and/or potentially impact pathways more active in PR3-AAV than in GPA, MPA and MPO-AAV, irrespective of severity of the disease.

**Figure.** Serum biomarkers' association with ANCA type and AAV clinical diagnosis groups (PR3-AAV vs MPO-AAV and GPA vs MPA).

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis II: Biomarkers and Disease Activity

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Magnetic resonance imaging (MRI) and  $^{18}\text{F}$ -fluorodeoxyglucose positron emission tomography (PET) may provide unique or redundant information in large vessel vasculitis (LVV). The study objective was 1) to assess agreement between interpretation of MRA and PET for disease activity and disease extent and 2) to determine MRA features associated with PET activity.

### **Methods:**

An observational cohort of patients with giant cell arteritis (GCA) or Takayasu's arteritis (TAK) were prospectively recruited, along with a comparator group (patients with vasculopathy or healthy controls). Subjects underwent clinical assessment, MRA, and PET within 24 hours. Imaging and clinical assessments were performed blinded to each other. A radiologist and two nuclear medicine physicians with vascular imaging expertise evaluated the MRA and PET studies for evidence of active vasculitis. To evaluate disease extent, the aorta and primary branches were divided into 15 vascular territories. Vascular involvement within each territory was defined on MRI as presence of wall thickness (black blood sequences), edema (STIR sequences), stenosis, occlusion, or aneurysm. Vascular involvement on PET was defined as visual FDG uptake in each arterial territory > liver. Agreement was assessed by percent overall agreement, Cohen's kappa, and McNemar's test. Multivariable logistic regression was used to test which factors on MRA were associated with PET interpretation of disease activity.

### **Results:**

68 patients (GCA=26; TAK=24; Comparator=18) contributed 115 paired PET/MRA studies. A total of 1398 vascular territories were evaluated. Scans were interpreted as active disease in 76 PETs and 77 MRAs. 80 studies showed agreement (70%, Cohen's kappa=0.32) between PET and MRA. In 35 studies with disagreement, PET demonstrated disease activity in 17 studies and MRA in 18 studies (McNemar's  $p=1.00$ ). Clinical disease status was associated with PET scan interpretation ( $p=0.01$ ) but not MRA interpretation ( $p=0.52$ ). More comparators were interpreted as active vasculitis by MRA versus PET (50% vs 11%,  $p=0.03$ ). 782 territories showed agreement (56%, Cohen's kappa=0.17) for disease extent between PET and MRA. Of the 608 territories with disagreement, MRA demonstrated disease in more territories than PET (513 vs 95, McNemar's  $p<0.01$ ). Territories with PET disease activity were positively associated with edema (OR=1.36, 95%CI=1.10-1.70,  $p<0.01$ ) and wall thickness (OR=1.17, 95%CI=1.01-1.37,  $p=0.04$ ) but not associated with stenosis (OR=0.07, 95%CI=0.33-0.96,  $p=0.33$ ).

### **Conclusion:**

There was fair agreement in the interpretation of PET and MRA findings for disease activity, but PET interpretation, and not MRA interpretation, was associated with clinical assessment. MRA detects disease activity and damage, thus identifying a greater extent of vascular involvement compared to PET. These data suggest that PET and MRA provide complementary information in LVV. In situations where PET is not available, increasing number of arterial territories with edema and wall thickness on MRA could be a surrogate for PET scan activity.

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis II: Biomarkers and Disease Activity

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Patients with granulomatosis with polyangiitis (GPA) are prone to disease relapse. Changes in anti-neutrophil cytoplasmic autoantibodies (ANCA) levels can predict relapses in individual patients to some extent. Plasmablasts are considered precursors of ANCA-producing plasma cells and are therefore expected to be involved in GPA. This study aimed to determine whether patients at risk for relapse could be distinguished based on increased plasmablast frequency during remission.

### **Methods:**

90 proteinase 3 (PR3)-ANCA positive GPA patients in remission were monitored for relapses for up to 6.3 years. Moreover, 48 healthy controls (HCs) were included. The B cell phenotype was determined at inclusion by flow cytometry, serum ANCA levels were measured with both indirect immunofluorescence and the Phadia ImmunoCAP 250 analyzer. Spontaneous and stimulated *in vitro* PR3-ANCA production by isolated PBMCs, after 12-day stimulation with or without CpG-ODN, BAFF and IL-21 was measured with Phadia ImmunoCAP 250 analyzer. The frequency of plasmablasts at inclusion of future-relapsing (F-R) and non-relapsing patients (N-R) was compared and the median frequency of plasmablasts was related to relapse-free survival.

### **Results:**

27 of the 90 patients (30%) relapsed after on average 1.64 years (median: 1.75; range: 0.07-3.78) since inclusion. The median frequency of circulating plasmablasts was significantly increased in F-R patients (median: 2.39%, range: 0.6-16.3%) compared to N-R patients ( $p=0.0014$ , median: 1.03%, range: 0.1-12.5%) and HCs ( $p=0.0208$ , median: 1.33%, range: 0.5-7.6%). The actuarial survival analysis showed a higher percentage of plasmablasts at inclusion was related to decreased relapse-free survival during follow-up ( $p<0.0001$ ). 70% of the patients with  $\geq 2.39\%$  plasmablasts eventually experienced a relapse during study follow-up compared to 19% in the  $<2.39\%$  plasmablast group. At inclusion, no significant correlation was found between plasmablast frequency and ANCA titer, serum PR3-ANCA or *in vitro* PR3-ANCA production.

### **Conclusion:**

Our data suggest that an increased plasmablast frequency during remission is related to a higher frequency of disease relapses in GPA patients. However no correlation with ANCA levels was found. In conclusion, plasmablast frequency might be a helpful biomarker to identify patients in remission at risk for relapse.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis II: Biomarkers and Disease Activity

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Granulomatosis with Polyangiitis (GPA) is characterized by vasculitis in lungs, kidneys and the ear, nose and throat region. Regular monitoring and treatment adjustments are needed, as disease activity tends to fluctuate over time. Unfortunately, good markers for disease activity are lacking, leading to over- and undertreatment. Immunoglobulin G4 positive (IgG4+) B-cells and plasma cells are implicated in the pathogenesis of GPA. Recently, we developed a test that indirectly measures the presence of IgG4+ B-cells/plasma cells in blood by measuring the IgG4:IgG RNA ratio<sup>1</sup>. We hypothesized that this test could serve as a disease activity marker in GPA. Here we test the IgG4:IgG RNA ratio in peripheral blood as a disease activity marker in GPA.

**Methods:** 29 PR3-ANCA positive GPA patients were included. Mean age was 53 years, 55% were female, and 41% had active disease. For each patient ESR, CRP, BVAS, and PR3-ANCA-titre was measured. Active disease was defined as BVAS  $\geq 3$ . We also included 10 healthy controls (HC) and 63 patients with other immune mediated inflammatory diseases (systemic lupus erythematosus (SLE) (n = 24), rheumatoid arthritis (RA) (n = 19), primary sclerosing cholangitis (PSC) (n = 20)). The IgG4:IgG RNA ratio in peripheral blood samples was measured using a validated qPCR test<sup>1</sup>.

**Results:** The median IgG4:IgG RNA ratio was significantly higher in the GPA cohort (6.0; IQR 2.7-19.8) compared to all controls: 1.2 in SLE (0.7-3.3;  $p < 0.0001$ ), 2.5 in RA (IQR 0.7-4.1;  $p < 0.05$ ), 1.6 in PSC (IQR 1.0-2.8;  $p < 0.01$ ) and 1.3 in HC (IQR 0.6-1.8,  $p < 0.001$ ). In addition, the median IgG4:IgG RNA ratio was significantly higher in active disease (20.7; IQR 14-28.5) compared to remission (3.5; IQR 1.9-5.5) ( $p < 0.0001$ ). An IgG4:IgG RNA ratio of 9.3 differentiated perfectly between active disease and remission (AUC 1.000). The IgG4:IgG RNA ratio ( $p < 0.0001$ ) outperformed other disease activity parameters such as ESR ( $p < 0.05$ ), CRP ( $p < 0.01$ ) and PR3-ANCA titre (ns) in detecting active disease. The height of the IgG4:IgG RNA ratio significantly correlated with height of the BVAS (Spearman  $r = 0.78$ ,  $p < 0.0001$ ).

**Conclusion:** The IgG4:IgG RNA ratio distinguishes active GPA from GPA in remission with excellent specificity and sensitivity. Moreover, the ratio shows a significant correlation with disease severity and outperforms other disease activity parameters. Retesting in a prospective study is indicated to validate the IgG4:IgG ratio as a novel marker of disease activity in GPA.

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis II: Biomarkers and Disease Activity

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Takayasu arteritis (TA) is a large vessel vasculitis of unknown pathogenesis. The current serological and radiological parameters used to assess disease activity are not highly specific and there is a need for a relevant biomarker. In our previous study [1], NMR based serum metabolomics had revealed distinctive metabolic signatures in patients with TA compared to age/sex matched healthy controls and SLE [2]. In this study we investigate whether these distinctive metabolites correlate with disease activity.

**Methods:** Patients with TA fulfilling ACR criteria were assessed for disease activity using ITAS A (ESR), with a score of <sup>3</sup>4, considered as active. The serum metabolic profiles of active and inactive TA patients obtained with an 800 MHZ NMR spectrometer were compared using multivariate orthogonal partial least-squares discriminant analysis (OPLS-DA) to identify metabolites that related to disease activity [based on PLS-DA VIP(variable importance on projection) score >1.5 and permutation test, p-value < 0.01].

**Results:** 98 patients were categorized into active (45) and inactive (53) groups - median age 27 years in both groups and female to male ratio 3.5:1 and 4.9:1 respectively. The majority had class V disease. Mean duration of illness was  $8.8 \pm 13.2$  years in active TA and  $5.2 \pm 5.6$  years in inactive TA group. An exquisite separation in OPLS-DA score plot showed metabolic differences between active and inactive TA patients (**Fig. 1A**). The key metabolites with highest discriminatory potential (VIP score > 1.5) which were **elevated in active TA** were glutamate, N-acetyl glycoprotein (NAG), glucose, phosphoglyceride, glycerol, leucine whereas lactate, choline, low/very-low density lipoproteins (LDL/VLDL) were **decreased**. Receiver operating characteristic (ROC) curve analysis revealed glutamate and NAG had the highest potential to discriminate active from inactive TA (area under the curve 0.775 and 0.769 respectively ( $p$ -value<0.0001) (**Fig. 1B, 1C**). The spectra did not correlate with current therapy but did alter when disease activity changed on follow-up.

**Figure 1:** (A) 2D score plot obtained from OPLS-DA analysis of 1D  $^1\text{H}$  NMR spectra. The receiver operating characteristic (ROC) curve analysis performed to evaluate area under ROC curve (AUC) of Glutamate (b) and NAG (c), showing discriminatory potential of Glutamate and NAG metabolite, based on univariate (box plot) and ROC curve analysis.

**Conclusion:** This large cohort of patients revealed metabolic profiles discriminating between clinically active and inactive TA patients. It suggests glutamate and NAG have strong potential as biomarkers for disease activity in TA and may serve as a guide to therapy. We are now working to further validate these results in longitudinal studies.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Vasculitis II: Biomarkers and Disease Activity

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose :**

Epidermal growth factor (EGF) mediates distal tubular epithelial cell function and regeneration. Monocyte chemoattractant protein-1 (MCP-1) participates in recruitment of leukocytes to areas of inflammation. Urinary EGF (uEGF) and MCP-1 (uMCP-1) predict active and chronic renal disease in primary glomerulopathies. This study examined the utility of uEGF and uMCP-1 as biomarkers of renal disease in patients with ANCA-associated vasculitis (AAV).

### **Methods:**

Data from patients with AAV enrolled in a prospective multicenter cohort were included. uEGF and uMCP-1 were measured at baseline, an active renal disease visit (index), 1-2 visits prior to and after the index visit, and at 1 year follow-up. Chronic kidney disease (CKD) was defined as  $\text{eGFR} < 60 \text{ mL/min/1.73 m}^2$  for  $>3$  months. Index was defined as the first visit with a new/worse BVAS/WG renal item since prior visit. uEGF and uMCP-1 were converted to  $\log_2$  uEGF/urinary creatinine and  $\log_2$  uMCP-1/urinary creatinine ratios for all analyses. To assess the association of each biomarker with disease activity, a mixed effect model was used, adjusting for ANCA type (MPO or PR-3), albumin/creatinine ratio, eGFR, and visit type. To assess time to CKD outcome, a Cox proportional hazard model was used, adjusting for sex, age, race, ANCA type, albumin/creatinine, and eGFR.

### **Results:**

At baseline, 165 of 544 (30%) patients had CKD. For each unit increase in baseline uEGF/Cr there was a lower risk of CKD [HR=0.62, (0.43, 0.88),  $p=0.01$ ]. After adjusting for sex, age, race, ANCA type, eGFR, and albumin/Cr, the percentage of patients surviving without CKD was significantly lower ( $p<0.01$ ) in patients with lower uEGF at baseline (Quartile 1) compared to patients with higher levels of uEGF at baseline (Quartile 4) (**Figure 1**). Higher baseline uMCP-1/Cr didn't predict risk of CKD [HR=1.14, (0.88, 1.48),  $p=0.33$ ]. In the same adjusted model, the percentage of patients surviving without CKD was not significantly different ( $p=0.06$ ) in patients with lower uMCP-1 at baseline (Quartile 1) compared to patients with higher levels of uMCP-1 (Quartile 4) (**Figure 2**).

112 patients had active renal disease. uEGF/Cr levels did not significantly differ between pre-, post-, and index visits. Compared to index visit, uMCP-1/Cr was lower at pre- and post-index visits ( $p=0.04$  and  $p<0.01$ , respectively) after adjusting for the mixed effect model variables.

### **Conclusion:**

In patients with AAV, uEGF predicts progression to CKD independently of urine albumin/creatinine and eGFR. uMCP-1, but not uEGF, is associated with renal disease activity. uEGF and uMCP-1 are useful biomarkers in AAV.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Orthopedics and Rehabilitation Science

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Low back pain (LBP) is a common and debilitating problem. There are currently very limited pharmacological treatments for LBP. Vertebral endplate subchondral bone abnormalities (Modic abnormalities (MC)) are consistently associated with LBP and could be a potential treatment target. Previous research suggests that bone active agents, such as zoledronic acid (ZA) may be effective for knee bone marrow lesions and back pain. No evidence is available for denosumab (DN). This study aims to compare the effects of ZA and DN on LBP in patients with MC.

**Methods:** Adults aged  $\geq 40$  years with significant LBP ( $>6$  months) and MC (type 1, 2 or mixed) were randomised to receive either ZA (5mg/100ml) or DN (60mg), or placebo. The chief outcomes were change in pain assessed by Visual Analogue Scale (VAS, 0-100) and size of MC measured on MRIs of T12-S1 vertebrae over 6 months. Other outcomes included: change in pain assessed by the LBP Rating Scale (RS, 0-30), disability by the Roland-Morris Disability Questionnaire (RMDQ, 0-24), and quality of life by Assessment of Quality of Life (AQoL, 0-48) after 3 and 6 months. Repeated measures regression was performed to analyse the change in outcomes.

**Results:** 103 participants (39% females, mean age 59.8 yrs) were enrolled. At baseline, mean (SD) VAS, and RS scores were 57.1 (18.3) and 17.6 (5.0), and the median total MC area was 538 mm<sup>2</sup>. Subjects were generally well matched at baseline. Table 1 presents the findings for the chief and other outcomes. Compared to placebo, VAS scores decreased by clinically significant amounts in both the ZA and DN groups after 6 months, but the change was not statistically significant (p=0.13 and 0.06 respectively). There was little reduction in areal MC size and no difference between groups. LBP RS scores were significantly reduced compared to placebo in the ZA group after 3 (-3.5, 95%CI -6.2 to -0.8) and 6 months (-3.3, 95%CI -5.9 to -0.7), and in the DN group after 6 months (-3.0, 95%CI -5.7 to -0.3). Improvements in disability (RMDQ) occurred in the ZA group after 3 months (-2.1, 95%CI -4.0 to -0.2). Time course analysis suggested ZA treated patients had lower VAS pain scores after one month and DN after 2 months. Both therapies were more effective for VAS pain after 6 months in those with smaller Modic area and milder disc degeneration as classified at screening, and DN was more effective for VAS pain in patients with type 1 MC (Fig 1). Adverse events were more frequent in the ZA group; primarily flu-like symptoms and headaches.

**Conclusion:** These pilot findings suggest that both ZA and DN may reduce LBP associated with MC but do not change MC size over 6 months.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Orthopedics and Rehabilitation Science

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Degenerative lumbar spinal stenosis (DLSS) is a leading cause of pain, disability and loss of independence in older adults. It is caused by age related osteoarthritic changes to the lumbar spine resulting in spinal canal narrowing and compression to the spinal nerves. Neurogenic claudication is the clinical syndrome caused by DLSS and reduced walking ability is its hallmark feature. Effective non-surgical approaches for DLSS are unknown. The main objective of this study is to compare the ability of 2 self-management training programs to improve walking capacity in DLSS.

**Methods:** Eligible consenting participants with neurogenic claudication with DLSS and limited walking ability (<30 minutes) were randomized to a 6-week (w) comprehensive self-management training program or a self-directed self-management training program with a single educational session. Both groups received a pedometer, an exercise manual and video with instructions on daily home exercises and self-management strategies recommended to be followed for life. The primary outcomes were objective continuous walking distance in meters (m) in 30 minutes assessed by the Self-Paced Walk Test (SPWT) at 8w, 3, 6 and 12 months following randomization; and the proportion of participants achieving at least 30% improvement (minimal clinically important difference, MCID) in the SPWT. Secondary outcomes included the Zurich Claudication Questionnaire (ZCQ), the Oswestry Disability Index and the Numeric Pain Scale for low back and leg pain. Intention-to-treat analysis was performed for all outcomes.

**Results:** Fifty-one participants were randomized to the comprehensive and 53 to the self-directed group. At 8w, the mean improvement in walking distance was 502m in the comprehensive group and 211m in the self-directed group, with an adjusted mean treatment effect of 345.4m; 95% confidence interval [CI], 150 to 660.6; P=0.0006. At 12 months the mean improvement in walking distance from baseline was 675m in the comprehensive group and 201m in the self-directed group with a between-group adjusted mean difference of 473.2m; 95% CI, 203.9 to 742.4; P = 0.0007. At 8w, 85% versus 61%, adjusted relative risk (RR), 1.4; 95% CI, 1.1 to 1.8; P= 0.008, and at 12 months, 81% versus 59%, adjusted RR, 1.4; 95% CI, 1.1 to 1.8; P= 0.018, of participants achieved the MCID in the SPWT in the comprehensive versus the self-directed group respectively. At 12 months all secondary outcomes showed significant improvement from baseline in both groups with the comprehensive group demonstrating significantly greater improvement in the ZCQ functional scale, adjusted mean difference of -0.27; 95% CI, -0.49 to -0.04, and in the combined functional and symptom ZCQ scale, adjusted mean difference of -0.48; 95% CI, -0.90 to -0.06 compared to the self-directed group.

**Conclusion:** Both self-management training programs showed significant improvement in walking distance with the comprehensive program demonstrating superior improvement in walking distance and proportion of participants meeting the MCID at each follow-up. The large improvement in walking distance in comprehensive group was sustained at 12 months without additional interventions beyond the initial comprehensive training program.

## Validating Patient Reported Outcomes in Older Veterans with Chronic Back Pain

**Rabih Nayfe**<sup>1</sup>, Matthieu Chansard<sup>2</sup>, Thiru Annaswamy<sup>3</sup>, Katharine McCallister<sup>2</sup>, Liana Fraenkel<sup>4</sup>, Eric Mortensen<sup>5</sup> and Una E. Makris<sup>6</sup>, <sup>1</sup>Department of Medicine, UT Southwestern Medical Center, Dallas, TX, <sup>2</sup>Clinical Sciences, UT Southwestern Medical Center, Dallas, TX, <sup>3</sup>Physical Medicine & Rehabilitation, VA North Texas Health Care System, Dallas, TX, <sup>4</sup>Rheumatology,

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Orthopedics and Rehabilitation Science

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Chronic back pain is the second most common reason for a physician's visit and results in significant physical and psychosocial consequences in older adults. Identifying appropriate, efficient and reliable patient reported outcome measures is critical for research and clinical purposes. The NIH's Patient Reported Outcomes Measurement Information System (PROMIS) instruments provide robust patient-reported outcome measures; however, these have not been compared to validated "legacy" instruments in older adults with chronic back pain. This study aims to evaluate convergent validity and time to completion (TTC) of PROMIS as compared to "legacy" instruments (both self-reported).

**Methods:** We enrolled older Veterans (age 60+) with chronic back pain with/without leg pain ( $\geq 3$  months) scheduled for lumbar epidural steroid injections. Participants completed PROMIS computer adaptive test (CAT) item banks and corresponding "legacy" instruments in the following domains: pain interference, behavior and intensity; functional status; depression and anxiety; fatigue; sleep and social functioning. Convergent validity between PROMIS and "legacy" instruments was evaluated using Pearson correlation coefficients in a correlation matrix. Paired sample t-tests compared average TTC between both instruments.

**Results:** Participants included 71 Veterans who were on average 67 years old, 94% men, 73% non-Hispanic white, 16.9% African American. Over half were obese with mean BMI 32, 25% reported multi-site pain and 59% were diagnosed with depression, anxiety and/or PTSD. The majority (69%) reported pain duration  $\geq 5$  years with  $\sim 93\%$  reporting associated radiculopathy. Pearson correlations between PROMIS and "legacy" instruments are listed in Table 1 and show moderate to strong convergent validity, with the exception of social functioning domains. PROMIS items had significantly shorter TTC than "legacy" items across all domains (Table 2).

**Conclusion:** PROMIS measures, especially for depression, anxiety, fatigue and sleep domains, have strong convergent validity in older Veterans with chronic back (and associated leg) pain. Moreover, PROMIS measures require less time to complete. Given time efficiency of using PROMIS, along with strong convergent validity, PROMIS instruments are a valid and practical choice for both research and clinical purposes.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Orthopedics and Rehabilitation Science

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Exercise is an established treatment to improve pain and physical function in adults with knee osteoarthritis (KOA), which is a leading cause of disability affecting 14 million adults. Most adults with KOA do not adhere to long-term exercise, abating benefits. The literature lacks well-controlled studies evaluating approaches to improve long-term exercise adherence. We conducted a randomized controlled trial (RCT) in people with KOA where both groups received the same evidence based exercise protocol and differed only in adherence interventions. Two-year adherence was the primary outcome. The intervention group received theoretically informed automated interactive telephone calls to coach and motivate subjects to adhere to the exercise protocol; both control and intervention arms received recorded telephone reminders to continue with the exercise protocol. Here we report on an ancillary study to this RCT that explored experiences, feelings and perspectives of subjects related to long-term adherence to exercise and use of technology

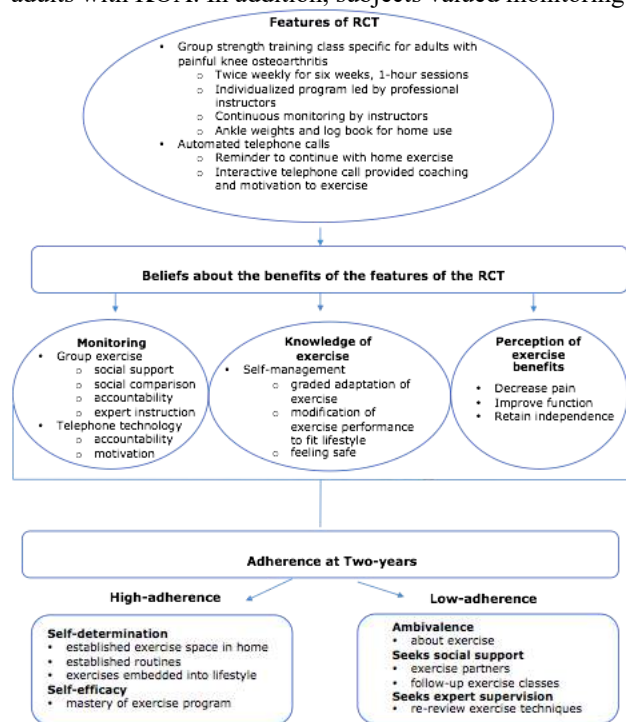

**Methods:** Qualitative design informed by grounded theory using semi-structured interviews. Consecutive participants of the RCT were purposely recruited and enrolled. Participants were >50 years with knee pain, self-report doctor diagnosed KOA, and not strength training for previous 6 months. Data collection: Post the RCT final assessment, 1-1 interviews were conducted (n=25, mean age 67 and BMI 31, 77% female) using guiding questions to elicit participants' views on exercise experiences and impressions of technology to foster adherence to exercise. Participants were categorized into low-, or high- adherence groups according to a self-assessment questionnaire. Data analysis: constant comparative methods. Initial coding related to participants' experiences on adherence to exercise

and use of technology. Focus coding explored the meaning of data represented in the initial codes that more deeply reflected participants' experiences regarding motivation toward exercise and home exercise abilities. Third level of coding compared high-adherence data to low-adherence at 2 years, and intervention compared to control groups.

**Results:** Three themes were identified: monitoring, knowledge of exercise, and beliefs about benefits of exercise. Participants with high-adherence appeared self-determined with a sense of self-efficacy. Participants with low-adherence expressed ambivalence about the benefits of exercise and desired more social support. Figure 1 provides more details. These results were independent of group assignment.

**Conclusion:** This study provides new evidence that promoting self-determination may improve long-term exercise adherence among adults with KOA. In addition, subjects valued monitoring provided by the group exercise approach and automated telephone technology.

## Identifying Vulnerable Patient Populations Based on Age and Physical Function on Clinical Outcomes Following Total Knee Arthroplasty

Jesse Christensen<sup>1</sup>, Andrew Kittelson<sup>2</sup>, Brian Loyd<sup>3</sup>, Jackie Del Giorno<sup>4</sup>, Brian Burnikel<sup>5</sup> and Jennifer Stevens-Lapsley<sup>6</sup>, <sup>1</sup>University of Utah, SLC, UT, <sup>2</sup>Rehabilitation Science PhD Program, University of Colorado Anschutz Medical Campus, Aurora, CO, <sup>3</sup>University of Colorado Anschutz Medical Campus, Aurora, CO, <sup>4</sup>ATI Physical Therapy, Greenville, SC, <sup>5</sup>Steadman Hawkins Clinic of the Carolinas, Greenville Health Systems, Greenville, SC, <sup>6</sup>University of Colorado, Anschutz Medical Campus, Aurora, CO

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Orthopedics and Rehabilitation Science

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Total knee arthroplasty (TKA) has historically been viewed as a surgical procedure of last resort for older adults suffering with chronic arthritis. However, rates of TKA in younger, more medically complex patients have increased over the last several decades. A growing body of literature indicates that younger patients are less satisfied with their functional ability relative to older counterparts. The purpose of this study was to characterize this problematic subpopulation by examining whether a younger, poorer functioning subgroup differs in preoperative characteristics of health status, psychological status, or knee function, compared to others undergoing the procedure.

**Methods:** We conducted a retrospective analysis of clinically-collected data from 181 patients (57% female, mean age 64.8 yrs. + 8.9, mean BMI 33.3 + 7.1 kg/m<sup>2</sup>) undergoing TKA and subsequent rehabilitation between January 2013 and August 2015. Using these data, we constructed a categorical variable to represent age and function, by dichotomizing age (younger than 65 vs older than 65) and postoperative (6-week) Timed Up and GO (TUG) time (median split at 8.65 seconds). This resulted in 4 subgroups: younger/poorer TUG (n=36), younger/better TUG (n=42), older/poorer TUG (n=46), older/better TUG (n=39). Analysis of Covariance was then performed to compare subgroups, with the younger/poorer group as the reference group. The following preoperative measures were examined across groups: health status (comorbidity score, body mass index), psychological status (depression, pain catastrophizing) and knee function (quadriceps strength, surgical knee range of motion).

**Results:** After controlling for sex, the younger/poorer function subgroup demonstrated significantly worse quadriceps strength and pain catastrophizing scores relative to both young and old high-functioning subgroups. This subgroup also demonstrated worse depression scores relative to the older/better TUG subgroup relative to the younger/better TUG subgroup. No significant differences were seen in knee range of motion or comorbidity scores between any of the subgroups.

**Conclusion:** A clinical picture emerges of a subgroup that is relatively young and poor functioning following surgery. Preoperative characteristics of this subgroup included poorer psychological status (worse pain catastrophizing and depression scores) and reduced quadriceps strength. These factors could be incorporated into treatment strategies to maximize outcomes in this problematic, but growing patient demographic.

## **Feasibility and Preliminary Effects of a Novel Rehabilitation Strategy to Improve Hand and Arm Function in Systemic Sclerosis**

Susan L. Murphy<sup>1</sup>, Mary Barber<sup>2</sup>, Kristen Homer<sup>3</sup>, Carole Dodge<sup>2</sup> and Dinesh Khanna<sup>4</sup>, <sup>1</sup>Physical Medicine & Rehabilitation, University of Michigan, Ann Arbor, MI, <sup>2</sup>Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, MI, <sup>3</sup>Department of Internal Medicine, Rheumatology Division, University of Michigan, Ann Arbor, MI, <sup>4</sup>University of Michigan, Ann Arbor, MI

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Orthopedics and Rehabilitation Science

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Individuals with systemic sclerosis (SSc) suffer from limited arm and hand function due to skin thickening and contractures. Evidence-based medical rehabilitation strategies for these issues remain limited. Standard treatments of heat massage, and exercise are recommended but are primarily focused on the hand, not taking into account wrist, elbow, and shoulder contractures. In addition the rehabilitation treatments do not often target the skin scarring that underlies contracture formation. The purpose of this study was to determine the feasibility and preliminary effects of a novel treatment approach to improve arm and hand function in patients with scleroderma with both arm and hand contractures.

**Methods:** Participants with early SSc with arm and hand contractures were recruited from our Scleroderma Clinic. The intervention involved eight in-person weekly sessions with an occupational therapist and involved heat, mobility and range of motion exercises, and the use of the Physiotouch®, a negative pressure device that is commonly used at our center in other patient populations for mobilizing tissue with positive effects on the lymphatic system and skin mobilization. Feasibility was assessed by determining participant flow

through the trial including the number of people enrolled who were eligible, and the number of people that adhered to the entire treatment protocol. A secondary goal was to examine preliminary effects on arm and hand function using the QuickDASH disability measure. Primary outcomes were measured at baseline and 8 weeks with an intermediate assessment at 4 weeks post baseline.

**Results:** The sample (N = 16) had a mean age of 46 (range 22-67), was 88% female, and 44% indicated being from racial minority group. The sample are diffuse scleroderma subset with a mean Rodnan skin score of 17.9 (+/- 10.1), and a mean QuickDASH score was 53.4 (+/- 22.7), which is almost three standard deviations above the population mean. Of those screened in-person, 95% were eligible, and 90% were enrolled. 50% have currently adhered to the entire protocol. 50% of our sample who have so far completed treatment at 8 weeks had improvements on the QuickDASH (n = 8) which ranged between 6-13 points, the mean improvement was statistically significant (t=6.6, df=7, p = .0001). Participants reported positive outcomes of the treatment such as improved coordination, fluidity of movement, not dropping things, and pain improvement.

**Conclusion:** This intervention is feasible despite the burden of traveling to the center for 8 in-person visits and led to improvements in half of the participants. This study would benefit from bolstering home rehabilitation components and future work will need to compare those who receive this treatment to a control group.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Education/Community Programs

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Internet-based information is important for patients and their caregivers. For the past 4 years, our academic medical center's Center for Scleroderma, Vasculitis & Myositis (SVM) has produced monthly email NewsBlasts to provide information to our patients and their caregivers. The Newsblasts are distributed by email free of charge to subscribers. We conducted a survey evaluating what information is most important to our subscribers, and we compared responses from patients and caregivers. Additionally, we queried caregivers as to what they thought patients would perceive as most valuable, and compared those responses to patient's self-reported perceptions.

**Methods:** All SVM NewsBlasts were placed into 2 broad categories, and then into 1 of 6 sub-categories. NewsBlasts were categorized as Disease-Focused or Psychosocial-Focused. Within the Disease-Focused category were the following sub-categories: Organ System Complications & Mechanisms of Disease, Treatment, and Disease-Related Research. Within the Psychosocial-Focused category were the following sub-categories: Healthcare Access & Delivery, Patient Support, and Self Help / Lifestyle. A survey was created, in which users ranked the sub-categories from 1 (most important) to 6 (least important). Also, all caregivers – rheumatologists, nurses, social workers, and friends and family – were required to rank how important they thought each sub-category was to their patients or relative. The rankings submitted by patients and those submitted by Physicians were compared using Wilcoxon tests.

**Results:** The survey was sent via email to our 476 subscribers. A total of 177 (37%) recipients opened the email, and 77 (44% of opens, 16% overall) clicked the survey link. Of those recipients that opened the link, 53 responses were complete and included in the analysis. The respondent demographics are as follows: 32/53 (60%) patients; 13/53 (25%) rheumatologists; 3/53 (6%) nurses and social workers; 5/53 (9%) friends and family.

On average, patients assigned the Disease-Focused category a rank of 2.75±0.75, compared to a rank of 4.25±0.75 for the Psychosocial-Focused category (p <0.0001). However, rheumatologists predicted that patients would rank Psychosocial-Focused information as more

important than Disease-Focused information ( $3.33 \pm 0.62$  vs.  $3.67 \pm 0.62$ ,  $p=0.05$ ). Rheumatologists predicted that patients would assign the Disease-Focused category a rank of  $3.67 \pm 0.62$ , while patients themselves assigned the Disease-Focused category a rank of  $2.75 \pm 0.75$  ( $p=0.002$ ). Caregivers overall, when including nurses, social workers, friends and family in addition to rheumatologists, lacked consensus when ranking the relative importance of Disease-Focused and Psychosocial-Focused information. No single sub-category was ranked as significantly more or less important by respondents.

**Conclusion:** Patients found Disease-Focused information to be most important. Rheumatologists wrongly thought that patients would rank Psychosocial-Focused information as most important. These results emphasize the importance of patient feedback regarding what information is deemed of most value when selecting and developing content for future patient education materials.

## **If Mobile Advertising Is the Future, the Future Is Now: Productivity of Digital Ads By Terminology and Delivery Device.**

**Teresa J. Brady**<sup>1</sup> and Kamil E. Barbour<sup>2</sup>, <sup>1</sup>Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Education/Community Programs

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

CDC is pilot-testing a multi-modal marketing campaign to promote self-management education (SME) as a chronic disease management strategy. The campaign targets adults ages 45-75 with any chronic condition, including arthritis. The campaign includes both earned and paid media (i.e., radio, out-of-home, print, and digital advertising) with a call-to-action to visit [www.cdc.gov/LearnMoreFeelBetter](http://www.cdc.gov/LearnMoreFeelBetter) to learn more about SME.

Formative audience research indicated that consumers preferred “ongoing” over “chronic” to describe their health condition, but paradoxically, they used “chronic” when describing their condition.

One element of the paid media campaign strategy is the presentation of digital ads (similar to pop-up ads) to desktop computers, tablets, and smart phones to consumers likely to have chronic conditions. Digital ads were used in the first 9 weeks of the campaign pilot-test (January 23-March 26, 2017).

The purposes of this observational study are to determine whether: 1) “ongoing” or “chronic” terminology in ads is more productive, and 2) ads presented via desktop computer or mobile device (tablet, smartphone) are more productive.

### **Methods:**

Two versions of the digital ads were produced; ads were identical except for the use of “ongoing” or “chronic.”

A commercial vendor distributed the digital ads to consumers likely to have a chronic disease using a proprietary algorithm that used demographic and consumer spending data to identify consumers likely to have chronic conditions.

Ad productivity was defined as visits to the campaign home page and data was collected using Site Catalyst, a web analytics software program.

Productivity was measured in 3 ways:

1. Click thru Rate: Percentage of people who clicked on the ad out of all exposed to ad;

2. Cost per Click: Total costs to run ad to the device divided by number of clicks;
3. Minutes on Site: Average number of minutes spent on the site by those who clicked through from ad to campaign website.

#### Results:

A total of 8,887 visits (from all sources) were made to the campaign home page during the first flight of digital ads. The following table reports productivity of digital ads by Click-Thru Rate, Cost per Click and Minutes on Site for ads using “ongoing” or “chronic” terminology.

	Click-Thru Rate (CTR)		Cost per Click (CPC)		Minutes on Site (MoS)	
	Mobile	Desktop	Mobile	Desktop	Mobile	Desktop
“Chronic”	0.36%	0.13%	\$0.87	\$3.08	6.36	2.12
“Ongoing”	0.34%	0.13%	\$0.90	\$3.04	6.06	2.03

#### Conclusion:

Results were consistent across all 3 measures of productivity. Although audience research suggested that consumers prefer “ongoing” to “chronic” in describing their health condition, ads using either term were similarly productive in prompting consumers to visit the campaign home page. Ads can use either “ongoing” or “chronic” to describe long-term health conditions with equal effectiveness.

However, ads appearing on mobile devices were nearly 3 times as productive as ads appearing on desktop computers across all 3 measures. If dollars are limited, placing digital ads on mobile devices, rather than desktop computers, will be a better investment.

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Education/Community Programs

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

#### Background/Purpose:

Rheumatology is a cognitive specialty requiring years of clinical exposure and hands-on training to manage complex patients. However, there is no current standardized training model or understanding of the educational needs of an NP/PA entering rheumatology. An ACR-

Association of Rheumatology Health Professionals (ARHP) task force (TF) was created to identify how best to prepare and train NP/PAs for rheumatology practice. A needs assessment was conducted to obtain data from experienced NP/PAs to inform the development of a curriculum for NP/PAs in their first year of rheumatology practice.

#### Methods:

A Survey Monkey invitation was sent to current ARHP NP/PA members (n=317) by ARHP staff. The survey consisted of four multiple choice demographic questions to include years of experience in rheumatology, diseases treated, and practice setting(s). Five open ended questions were: best practices for learning joint injection technique, knowledge, skills, attitudes, and resources needed in the first year of rheumatology practice. An initial invitation was followed by a reminder one week later.

#### Results:

Response rate was 27% (87 responses). Regarding rheumatology years of experience, most respondents (45%) reported practicing < 5 years and 23% reported practicing > 15 years. Top ten rheumatic diseases that NP/PAs reported treating, in rank order, were RA, PsA, SLE, CTD, OA, gout, PMR, AS, FM and myositis. Most respondents worked in an outpatient setting (80%); treated new (74%) and follow-up (98%) patients; and treated adults (84%). Respondents also reported having research (36%) and teaching (37%) duties. Most respondents reported prescribing traditional (98%) and biologic (93%) DMARDs while a majority (69%) prescribe opioid analgesics. Elements deemed most important for a new rheumatology NP/PA were: **KNOWLEDGE** - disease states, recognizing disease presentation, and differential diagnoses; **SKILLS** - musculoskeletal physical examination and joint injection; **ATTITUDE** - openness to learning, knowing limitations and willingness to ask questions. The most impactful resource that contributed to NP/PA success was a physician preceptor and access to educational resources.

#### Conclusion:

The NP/PA needs assessment demonstrated the depth and breadth to which NP/PAs are utilized in rheumatology practices and provides the underpinnings of training elements needed to ensure successful assimilation of NP/PAs into rheumatology practice. To meet the educational needs of NP/PAs new to rheumatology, educators need to focus on adequately preparing NP/PAs to: treat many diseases predominate in rheumatology; see inpatients and outpatients; maintain a varied clinical workload, to include new patients; ensure training in musculoskeletal exam and joint injections; establish a mentoring relationship with a rheumatologist; and offer adequate clinical resources. These aspects should be included in any rheumatology curriculum for NP/PAs.

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Education/Community Programs

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Rheumatic diseases are complex conditions often affecting multiple organ systems needing treatment by expert health care providers. These providers function in multi-disciplinary teams for the most optimal patient outcomes. Significant rheumatology workforce shortages are prevalent and are expected to increase over the next decade. While rheumatologists receive rheumatology specific post-graduate training during fellowships, other health professionals have no formalized training pathway in rheumatology after completing their formal education. The ACR and the ARHP have recognized the need to provide rheumatology specific educational opportunities for health professionals who participate in the care of persons with rheumatic disease by creating online educational products. These online educational products are the *Advanced Rheumatology Course (ARC)*, the *Fundamentals of Rheumatology Course (FRC)*, and *Rheumatology e-Bytes*. These module based educational activities are intended to provide foundational, intermediate and advanced levels of content to meet the needs of health professionals with varying educational and career experience. The aim of this study is to describe the utilization of these educational products and summarize the feedback obtained from the *ARC* and *FRC* participants.

**Methods:** Data from *ARC* and *FRC* utilization and evaluations were obtained. Analyses of the available information were conducted. *ARC* participant data from December 2008 to December 2015 were reviewed. *FRC* participant data from October 2012 to December 2015 were reviewed. *Rheumatology e-Byte* data were not evaluated due to its recent release in January 2017.

**Results:** Since their debut, both the *ARC* and *FRC* have been highly utilized as evidenced by the geographic, gender, and profession diversity of learners. (Table 1) Those who have completed *ARC* and *FRC* modules have rated their participation in these activities as formative, aiding in their increase of confidence in assessing, managing, and evaluating persons with rheumatic disease. (Table 2) International rheumatology health professionals have also taken advantage of these quality educational tools.

**Conclusion:** The ACR and ARHP have capitalized on the advances in technology to provide enhanced learning opportunities to the rheumatology community. The ACR and ARHP online educational products have been successful in educating nurses, nurse practitioners, physician assistants and other health professionals.

Table 1: Demographics for Online Educational Module Participants, 2008-2015

Primary Discipline (n=1000)	Advanced Rheumatology Course (ARC)		Fundamentals of Rheumatology Course (FRC)		Both Courses	
	Frequency	Percent	Frequency	Percent	Frequency	Percent

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Education/Community Programs

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Current guidelines for the treatment of rheumatoid arthritis (RA) underscore the importance of an early and targeted approach to control inflammation. We describe initial experiences in recruiting RA patients (target n=300) from clinic sites versus an online patient support network into a randomized trial comparing the effectiveness of two educational interventions designed to enhance informed decision-making.

**Methods:** Participants are recruited from four clinic sites and CreakyJoints, an online patient support network. Eligibility criteria include: physician-diagnosed RA, moderate/high disease activity per the RAPID3, eligible for treatment escalation per provider, and internet access. Two interventions are being evaluated: (1) DrugFactsBoxes, which provide quantitative information concerning potential medication benefits and harms, and (2) Gist Reasoning Training, which is designed to help patients develop the skills needed to process complex information (e.g., the nature of scientific uncertainty). Data are collected by telephone interviews and on-line questionnaires. Because data collection is currently underway, this presentation focuses on the results of recruitment efforts.

**Results:** CreakyJoints sent 3,094 emails to their online community from January through March 2017, inviting members to participate in the study. Of these, 979 (31.6%) emails were opened and 269 (8.6%) people clicked a link in the email taking them to the study website. A total of 156 (58.0%) of the CreakyJoints members who visited the website emailed study staff expressing interest in participating, 139 met study eligibility criteria, and 96 have completed baseline data collection. During this same time period, 34 participants were recruited via the four clinic sites and completed baseline data collection. Compared to participants recruited via clinic sites, those recruited via CreakyJoints are less likely to be African-American (7% versus 22%,  $p = 0.02$ ) or Hispanic (3% versus 14%,  $p = 0.02$ ) and have greater RA knowledge (Means: 85.1 versus 75.4,  $p < 0.0001$ ) and higher health literacy as assessed by the Newest Vital Sign (Means: 83.5 versus 73.7,  $p = 0.02$ ). Participants recruited via CreakyJoints, versus clinic sites, were equally likely to be women (95% versus 91%,  $p = 0.46$ ), have completed college (55% versus 61%,  $p = 0.59$ ), and be using a DMARD (12% versus 6%,  $p = 0.28$ ).

**Conclusion:** Recruitment from an online support community is feasible and efficient. Online participants may differ from clinic participants in some sociodemographic characteristics. Better understanding of these differences is needed to improve the generalizability of results generated from online communities and clinic sites to maximize the external validity of research findings.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Education/Community Programs

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

## Background/Purpose:

Studies show telephone peer support has been used to address a range of health concerns in people living with chronic illness. A phone evaluation was conducted with participants of a national toll-free phone peer counseling service. Ongoing since 1988, this service provides emotional support for people with SLE and their loved ones, by trained volunteers living with SLE. The evolution of this program has been presented at prior ACR/ARHP, including the impact of a revised curriculum on a new cohort of peer volunteers staffing the service.

## Methods:

A 60-item survey, with Likert scale & open-ended questions was administered to callers who were matched with a peer-counselor between 2015-2017. The survey captured demographics, satisfaction with the screening process & their peer counselors, SLE management/ coping & overall service impact. Surveys were completed by phone interviews with a volunteer not directly connected to program.

## Results:

Of the 32 users outreached to 23 (72%) completed the survey. The majority (89%) of respondents were female, 47% identified as Black/African-American, 35% White, 31% Hispanic & 18% some other race. Callers' ages ranged from 30-80, with 67% ages 40-59. Most respondents were unemployed (43%) & 39% employed part/full time. Almost half of the callers (47%) were married, 94% had SLE & diagnosed for > 12 years. When asked about their initial reasons for calling 68% indicated emotional support & SLE education & resources (63 %). Most participants were satisfied (90%) with the screening call with the social worker. When asked about initial expectations of their first call, callers shared, "I wanted to know more about SLE" & "have someone to listen & guide me." Most callers indicated their expectations were met (95%). Callers shared that having someone knowledgeable about SLE (72%) was the most valuable aspect of the call. Most callers (52%) had > 12 calls with their peer counselor & 95% were satisfied (77% very; 18% moderately) with their match.

In relation to coping, 85% indicated that they have coped better with their SLE since being matched & 81% agreed they had a better understanding of SLE. 88% respectively attributed this to utilization of the program. When asked about depression 66% reported feeling less depressed since starting the service with a majority of callers (78%) crediting the service for this change. Callers also reported feeling less isolated (71 %) with 73% indicating this was also a result of the service. One caller shared, "I feel less alone."

When asked if their communication & or relationship with their doctor improved since using the service 58% said yes & 100% indicated that the program was responsible for this. When asked about the single most helpful part of using the service responses included, "you know you can call the line & there is someone to listen" & "knowing support is a phone call away." Most (94%) indicated they would recommend the service to others.

## Conclusion:

Despite limitations due to a small sample size, results indicate continued satisfaction & positive impact, with slight increases since last evaluation. Results point to the continued relevance of a phone support service that is easily accessible & can connect people with SLE & their loved ones to support & resources.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Epidemiology and Public Health: Prevention, Recognition, and Treatment

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The preclinical period of rheumatoid arthritis (RA) is characterized by elevated inflammatory biomarkers but it is unclear whether inflammatory diet may contribute to RA risk. We aimed to examine whether a dietary pattern associated with inflammatory biomarkers predicts subsequent risk of RA using the Nurses' Health Study (NHS) and NHS II.

**Methods:** We prospectively followed 79,988 women in NHS aged 38-63 years at 1984 and 93,585 women in NHS II aged 27-44 years at 1991, who were free from RA or other connective tissue diseases. Lifestyle, environmental, and anthropometric information were collected at baseline and updated biennially. Dietary data were obtained from validated food frequency questionnaires at baseline and approximately every 4 years during follow-up. RA cases were self-reported and confirmed by a connective tissue disease screening questionnaire and medical record review according to the 1987 ACR criteria. Seropositive RA was defined as positive rheumatoid factor or anti-citrullinated peptide antibody and was determined by medical record review. The inflammatory dietary pattern was measured by the Empirical Dietary Inflammatory Index (EDII), a weighted score including 9 pro- and anti-inflammatory food groups, which was predictive of 3 plasma inflammatory biomarkers (CRP, IL-6 and sTNFR2). Higher (more positive) scores indicate more pro-inflammatory diets and lower (more negative) scores indicate anti-inflammatory diets. We pooled the data from both cohorts to examine the association between cumulative averaged EDII and risk of RA among younger ( $\leq 55$  years) and older age groups ( $> 55$  years) since diet has been shown to have different effects on RA risk according to age of onset in previous studies. The EDII was categorized according to baseline quartile cutoffs. Time-varying Cox regression models were used to calculate the hazard ratios and 95% confidence intervals (CI) after adjusting for potential confounding factors.

**Results:** During 34 years of follow-up, we identified 1,188 incident RA cases. Among women  $\leq 55$  years old, a higher EDII was associated with a higher RA risk: HRs (95% CI) across increasing quartiles of EDII score were 1.00 (reference), 1.16 (0.87 to 1.53), 1.38 (1.05 to 1.81) and 1.43 (1.08 to 1.89) (p-trend 0.007). After additional adjustment for BMI, the observed results were attenuated. When further stratifying by serostatus, the significant association was observed only for seropositive RA (p-trend: 0.028) (Table). There was no significant association for RA among women aged  $> 55$  years (p for EDII-age interaction  $< 0.01$ ).

**Conclusion:** In these two large prospective cohort studies, inflammatory dietary pattern was associated with increased risk of developing RA among young and middle-aged women. The observed association may be partially mediated through BMI.

**Table. Hazard ratios (95% CI) for incident RA according to EDII quartiles in Nurses' Health Study (NHS, 1984-2014) and Nurses' Health Study II (NHS II, 1991-2013), (n=1188 cases)**

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Epidemiology and Public Health: Prevention, Recognition, and Treatment

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Gout patients have an increased risk of type 2 diabetes mellitus (T2DM), cardiovascular disease (CVD), and chronic kidney disease (CKD); however, it is not known whether this risk is modifiable by reducing levels of serum uric acid (SUA). Therefore, we aimed to evaluate the association between changes in SUA levels over time and the risk of incident T2DM, CVD, and renal function insufficiency in gout patients.

**Methods:** We designed an observational cohort study among gout patients aged > 40 years using data from Optum Clinformatics database with available laboratory results (2004-2015). Index date was defined as the first SUA measurement  $\geq 6.8$  mg/dl after 6 months of continuous health plan coverage,  $\geq 1$  gout diagnosis and no use of urate lowering treatment during this time. The exposure of interest was change in SUA level, which measured as a cumulative variable updated monthly. Three separate outcomes were assessed during the post-index period: 1) incident T2DM, 2) incident CVD (a composite endpoint of myocardial infarction, stroke, or coronary revascularization), 3) renal insufficiency (reduction in the estimated glomerular filtration rate of  $\geq 30\%$  from baseline). Hazard ratios (HR) and 95% confidence intervals (CI) were derived using marginal structural models with stabilized inverse probability treatment weights accounting for baseline confounders including age, gender, hyperlipidemia, hypertension, and >20 other medical conditions and medication use as well as >10 time-varying confounders including serum creatinine, blood urea nitrogen, glycated hemoglobin, and urate lowering drugs.

**Results:** Among 26,341 patients with gout, the average age was 62 and 75% were men. The median baseline SUA was 8.6 mg/dl (interquartile range (IQR) 7.7 to 9.5) and the median level of SUA reduction over an average follow-up of 33 months was 1 mg/dl (IQR: 0 to 2.7). The incidence rates/100 person-years (95% CI) were 1.63 (1.51-1.75) for T2DM, 0.77 (0.70-0.84) for CVD, and 4.32 (4.14-4.49) for renal insufficiency. The HR (95% CI) per 3 mg/dl reduction in SUA was 1.07 (0.91-1.24) for T2DM, 1.01 (0.81-1.27) for CVD, and 0.89 (0.81-0.98) for renal insufficiency.

**Conclusion:** Reduction in SUA in patients with gout may be associated with a reduced risk of renal insufficiency, but we did not find an association with T2DM or CAD. These findings suggest that aggressive SUA lowering approaches may slow renal disease progression but it is less clear whether such approaches will reduce the risk of T2DM or CAD in gout patients.

**Table- Association between cumulative changes in uric acid over time and outcome events of interest in gout patients, Optum Clinformatics data 2004-2015**

Outcome	Event counts and incidence rates			Hazard ratio (95% confidence interval) for 3 mg/dl reduction in serum uric acid during the follow-up period	
	Number of events	Total person years of follow-up	Incidence rates/100 person years (95% CI)	Unadjusted estimates	Marginal structural model estimates
Diabetes mellitus	749	45,972	1.63 (1.51-1.75)	0.85 (0.76-0.94)	1.07 (0.91-1.24)
Composite cardiovascular endpoint <sup>1</sup>	470	60,910	0.77 (0.70-0.84)	0.90 (0.79-1.03)	1.01 (0.81-1.27)
Renal insufficiency <sup>2</sup>	2,373	54,981	4.32 (4.14-4.49)	0.68 (0.63-0.72)	0.89 (0.81-0.98)
<sup>1</sup> Myocardial infarction, Ischemic stroke, revascularization					
<sup>2</sup> 30% reduction in glomerular filtration rate from baseline

## Novel Approach to Arthritis Surveillance Suggests a Much Higher Prevalence of Arthritis Among US Adults Than Previous Estimate

**S. Reza Jafarzadeh** and David T. Felson, Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Epidemiology and Public Health: Prevention, Recognition, and Treatment

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Current national estimates of arthritis prevalence in the United States rely on a single survey question about doctor-diagnosed arthritis from the National Health Interview Survey (NHIS) without using survey information on joint symptoms. In a validation study of these NHIS questions, some persons with only joint symptoms were found to have arthritis when examined by trained rheumatology nurses who excluded those with asymptomatic findings. The validation study suggested that the current surveillance definition of doctor-diagnosed arthritis had only 53% sensitivity among adults between 45-64 years of age resulting in missing nearly half of arthritis cases in that age group. The substantial misclassification as a result of the current imperfect surveillance definition would result in a marked underestimation of prevalence. We aimed to estimate arthritis prevalence, using the term ‘true’ to represent estimates that are adjusted for the imperfect sensitivity and specificity of the current surveillance definition, and the term ‘apparent’ to represent ordinary proportion estimates which fail to so adjust.

**Methods:** Using the 2015 NHIS, we developed a Bayesian multinomial latent class model for arthritis surveillance criteria based on NHIS questions on joint symptoms and whether symptom duration exceeded three months in addition to a question about doctor-diagnosed arthritis. The NHIS questions explicitly ask subjects to exclude back and neck pain from the reports of joint pain or arthritis.

Our Bayesian approach accounted for the imperfect (i.e. <100%) sensitivity and specificity of each criterion in addition to accounting for the correlation between chronic joint symptoms and doctor-diagnosed arthritis in the survey.

**Results:** Of 33,672 participants in the 2015 NHIS, 19.3% (2,242/11,597) of men and 16.7% (2,294/13,697) of women between 18-64 years of age reported joint symptoms without doctor-diagnosed arthritis; estimates were 15.7% (545/3,474) and 13.5% (660/4,904), respectively, for those ≥65 years old. Bayesian posterior estimates and the corresponding 95% probability intervals (PI) for the 'true' prevalences in the 4 sub-populations stratified by age and sex are presented in the Table. Based on our estimates of 'true' prevalence, arthritis affected 91.2 (of 247.7; 36.8%) million adults in the US in 2015, which included 61.1 (of 199.9; 30.6%) million persons between 18-64 years of age. Our estimate for arthritis prevalence in 2015 is 68% higher than that previously reported based on the doctor-diagnosed arthritis question of 54.4 (22.7%) million adults.

**Conclusion:** Arthritis prevalence in the US population has been substantially underestimated, especially among adults <65. Our results may partially explain recent surge in arthritis-related healthcare utilizations such as total knee replacement, especially among younger adults.

Table. Estimates for the Prevalence of Arthritis Among US Adults in 2015

Sex	Age (Years)	'Apparent' Prevalence of Doctor-Diagnosed Arthritis in NHIS (Individuals)	'True' Prevalence of Arthritis (95% Bayesian Probability Interval)	US Adults with Arthritis Based on 'True' Prevalence (Millions)
Men	18-64	15.0% (1,740/11,597)	29.9% (23.4%, 42.3%)	29.8 (of 99.6)
Women	18-64	20.0% (2,734/13,697)	31.2% (25.8%, 44.1%)	31.3 (of 100.0)
Men	≥65	43.5% (1,511/3,474)	55.8% (49.9%, 70.4%)	11.8 (of 21.1)
Women	≥65	55.1% (2,704/4,904)	68.7% (62.1%, 79.9%)	18.3 (of 26.7)

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Epidemiology and Public Health: Prevention, Recognition, and Treatment

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Asian women accounted for more than 40% of incident breast cancer (BC) worldwide. While aromatase inhibitors (AIs) significantly reduce recurrence of breast cancer (BC) and improve disease-free survival in post-menopausal women with hormone receptor-presenting BC, over one-third of AI users in randomized controlled trials developed arthralgia. Little is known about the risk of AI-induced arthralgia among Asian women with BC in real-world settings. Our objective was to compare the risk of AI-induced arthritis/musculoskeletal problems (A/MSK) between use of AIs vs. tamoxifen in a large Taiwan administrative claims dataset having >99% national coverage and ~23 million enrollees. **Methods:** In a retrospective cohort study using Taiwan Catastrophic Illness Patient Datasets and Taiwan National Health Insurance Research Datasets, we identified BC women (ICD-9 code: 174) that newly initiated AIs (anastrozole, exemestane and letrozole) or tamoxifen (TAM) from 2007 to 2012. We examined three A/MSK -related outcomes of interest within a year after therapy initiation, including women having 1) prescription pain relievers (i.e., non-steroidal anti-inflammatory drugs [NSAIDs], acetaminophen and opioids), 2) diagnosis of any type of arthritis (ICD-9: 710-719), or 3) carpal tunnel syndrome (CTS) or trigger fingers (TF; ICD-9: 354.0, 727.03). Individuals having outcome episodes that occurred within 3 months prior to AI/TAM initiation were excluded. We applied Greedy methods to match AI users with up to 5 TAM users on age and prior use

of taxane therapy. To ensure the robustness of our results, we estimated the association between A/MSK risk and AI use compared to TAM use using conditional logistic regression, cause-specific Cox regression and competing risk regression models. **Results:** Among 40,761 BC women initiating endocrine therapy from 2007 to 2012, 15.5% were AI users and 84.5% were TAM users. The mean age was 54.1 (SD±12.1) years and 19.6% had history of taxane exposure prior to AI/TAM initiation. There were significant differences ( $p < 0.0001$ ) in the crude rates of pain reliever use (68.7% vs. 65.0%), diagnosed arthritis (16.8% vs. 11.7%) and CTS/TF (2.6% vs. 1.1%) within a year after AIs or TAM initiation. After matching, AI users had higher odds of receiving pain relievers (OR: 1.13, 95%CI: 1.02-1.24), having a diagnosis of arthritis (OR: 1.09, 95%CI: 1.00-1.18) and a diagnosis of CTS/TF (OR: 2.19, 95%CI: 1.76-2.74) compared to TAM users (**Table 1**). Similar findings were seen using cause-specific Cox regression and competing risk regression (**Table 1**).

**Conclusion:** We found that AI users have a higher risk of A/MSK within the first year of treatment compared with TAM users among Taiwanese BC women. Timely pain management and close follow-up for AI-induced A/MSK is suggested to prevent poor adherence or discontinuation of AI therapy.

## Can Vs. Do: Using Walking Speed and Moderate-to-Vigorous Physical Activity to Predict Incident Low Health-Related Quality of Life and Disability

**Louise Thoma**<sup>1</sup>, Hiral Master<sup>1</sup>, Meredith Christiansen<sup>1</sup>, Dana Mathews<sup>2</sup> and Daniel White<sup>3</sup>, <sup>1</sup>Physical Therapy and Biomechanics and Movement Science, University of Delaware, Newark, DE, <sup>2</sup>Physical Therapy, Biomechanics and Movement Science, University of Delaware, Newark, DE, <sup>3</sup>Department of Physical Therapy, University of Delaware, Newark, DE

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ACR/ARHP Combined: Epidemiology and Public Health: Prevention, Recognition, and Treatment

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:**

Walking speed is a measure of performance, i.e., what people “can” do, and is a known predictor of future health, disability, and mortality in older adults. Time in moderate-to-vigorous physical activity (MVPA), is a complementary measure of the frequency of behavior at given intensity, i.e., what people actually “do”, and is also associated with future health and mortality. However, it is unclear how both walking speed and MVPA are jointly associated with future health. The purpose of this study was to examine the associations of combined walking speed (what people “can” do) and MVPA (what people “do”) categories with health-related quality of life (HR-QoL) and disability in adults with or at risk of knee osteoarthritis (OA).

## Methods:

We used data from the Osteoarthritis Initiative, a large cohort study of people with or at risk for knee OA. Walking speed and MVPA were collected at the 48-month visit. Walking speed was calculated from a 20-m walk test. MVPA was measured with an accelerometer (Actigraph GT1M) worn at the hip for  $\geq 10$  hrs/day for  $\geq 4$  days, and defined as  $\geq 2020$  counts/min. We classified people as Fast-Active ( $>1.2$  m/s and MVPA  $>11$  min/day, median value of the sample), Fast-Inactive ( $>1.2$  m/s and MVPA  $<11$  min/day), Slow-Active ( $<1.2$  m/s and MVPA  $>11$  min/day), and Slow-Inactive ( $>1.2$  m/s and MVPA  $<11$  min/day). Study outcomes were incident low HR-QoL measured with the Short-Form 12 Physical Component Score (SF-12 PCS, Score  $<40$  indicating low HR-QoL) and incident disability measured with the Late Life Disability Instrument (Limitation Score [LLDI-L]  $<50$  and Frequency Score [LLDI-F]  $<70$  indicating disability) measured 4 years later. We calculated risk ratios and 95% confidence intervals adjusting for potential confounders at baseline.

## Results:

Of 1876 people with baseline walking speed and MVPA data (55% women, age  $65.1 \pm 9.1$  years, BMI  $28.4 \pm 4.8$  kg/m<sup>2</sup>), 1419, 1250, and 1413 people were free of the outcome at baseline and had 4-year follow-up data for the PCS, LLDI-L, and LLDI-F, respectively. At the 4-year follow up, 11-15% of the analytic sample developed low HR-QoL and disability (Table 1). The Fast-Inactive and Slow-Inactive groups had greater risk of incident low HR-QoL compared to the Fast-Active group; the Slow-Active group had similar risk. The Slow-Inactive group had greater risk for incident disability (LLDI-F) compared to the Fast-Active group; otherwise the groups had similar risk.

## Conclusion:

Compared to people who were fast and active, those who were slow and active were at similar risk, those who were fast and inactive had greater risk of HR-QoL, and those who were slow and inactive had greater risk of developing low HR-QoL and disability. Advising patients to “do”, i.e. spend more time in MVPA (e.g. a brisk walk), may be as or more important than ensuring that they “can” do, i.e. walk fast enough for community ambulation, to prevent the development of future low HR-QoL.

**Table 1. Descriptive statistics and risk ratios (95% Confidence Interval) for the incident outcomes by exposure group**

\*adjusted for baseline age, sex, body mass index, education, race, comorbidity, presence of radiographic OA, and presence of knee symptoms

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Several lines of evidence suggest that brain-derived neurotrophic factor (BDNF) is involved in the pathophysiology of fibromyalgia (FM) and studies have found that FM patients have altered serum and plasma BDNF levels. However, it is not known whether polymorphisms of the *BDNF* gene are associated with FM. In this study, we explored the association between polymorphisms of the *BDNF* gene with FM susceptibility and the severity of symptoms.

**Methods:** The study enrolled 409 patients with FM and 423 controls from 10 medical centers that participated in the Korean nationwide FM survey study. Alleles at 10 positions in the *BDNF* gene were genotyped: rs2883187 (C>T), rs7103873 (G>C), rs7103411 (C>T), rs10835210 (C>A), rs11030104 (A>G), rs12273539 (C>T), rs11030102 (C>G), rs11030101 (A>T), rs6265 (G>A), and rs7124442 (C>T).

**Results:** The allele and genotype frequencies of *BDNF* rs11030104 differed significantly between the FM patients and controls ( $P=0.031$ ). The GG genotype of rs11030104 had a protective role against FM ( $P=0.016$ ) and the G allele of rs11030104 was negatively associated with the presence of FM compared with the A allele ( $P=0.013$ ). In comparison, although the allele and genotype frequencies of *BDNF* rs12273539 did not differ between the FM patients and controls, the TT genotype of *BDNF* rs12273539 was associated with susceptibility to FM ( $P=0.038$ ). Haplotype analyses suggested that some *BDNF* haplotypes have a protective role against FM. Finally, we found that that some genotypes and haplotypes of the *BDNF* gene contribute to the specific symptoms of FM.

**Conclusion:** This study is the first to evaluate the associations of *BDNF* gene polymorphisms with FM. Our results suggest that some *BDNF* single-nucleotide polymorphisms and haplotypes are associated with susceptibility to, and contribute to the symptoms of, FM.

# Effects of Add-on Transcranial Direct Current Stimulation on Pain in Korean Patients with Fibromyalgia

**Ji-Hyoun Kang**<sup>1</sup>, Kyung-Eun Lee<sup>2</sup>, Dong-Jin Park<sup>1</sup> and Shin-Seok Lee<sup>1</sup>, <sup>1</sup>Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South), <sup>2</sup>Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South)

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Despite promising preliminary results of transcranial direct current stimulation (tDCS) treatment in patients with fibromyalgia (FM), several issues need to be addressed, including its limited efficacy, low response rate, and poor tolerability. We investigated the efficacy and safety of tDCS as an add-on treatment for chronic widespread pain in Korean patients with FM.

**Methods:** This study enrolled 38 patients, who were refractory to pain medications, seen at Chonnam National University Hospital from May 2016 to December 2016. A conventional tDCS device was used to supply 2 mA of current for 20 minutes on 5 consecutive days. The anode was placed over the primary motor cortex (M1) and the cathode was located contralateral supraorbital area. The primary end point was a change in visual analogue scale (VAS) pain score at the end of treatment and secondary end points included changes in Fibromyalgia Impact Questionnaire (FIQ), Brief Pain Inventory (BPI), Brief Fatigue Inventory (BFI), Beck Depression Inventory (BDI), State-Trait Anxiety Inventory (STAI), and Medical Outcomes Study Sleep Scale scores.

**Results:** After tDCS, 38 patients showed clinical improvements in the VAS pain score on days 6, 13 and 36 compared with day 0 ( $p = < 0.001$ ). However, improvement of FIQ scores was only seen at day 36. The BPI and BDI were significantly decreased on days 6 and 13, while BFI and STAI-I were significantly improved only at day 6. The most of improved indices were not maintained until day 36. There were no significant improvements in Sleep Scale scores after tDCS at days 6, 13, and 36. No serious adverse event was observed.

**Conclusion:** Our results suggest that tDCS has the potential to produce significant pain relief in FM patients, and may constitute an effective add-on treatment for these patients.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:**

We previously validated the Michigan Body Map (MBM) to accurately assess widespread body pain and as a means of administering the Widespread Pain Index for the 2011 Fibromyalgia Survey Criteria. Given the increased use of electronic platforms for patient reported outcomes, this study aimed to validate an electronic version of the MBM, including a version allowing for the rating of pain in different body zones.

Methods:

Patients (n = 68; M<sub>age</sub> = 51.7, SD = 15.1; 57.4% female; 85.3% White) were recruited from a pain clinic. For Aim 1, participants completed the MBM in paper (MBM-P) and electronic (MBM-E) forms in randomized order, as well as completed a structured interview to assess their experience and to verbally affirm pain locations. For Aim 2, participants also completed the Brief Pain Inventory (BPI) and a modified version of the MBM assessing pain zone severity. Data were analyzed using StataIC 13.

Results:

There were no differences between MBM-E or MBM-P in preference, ease of completion, ability to show painful areas, or ability to distinguish right and left sides of the body (Figure 1). Of the 2,380 possible regions (35 body areas/participant), 46 (1.9%) body areas on the MBM-P and 38 (1.6%) body areas on the MBM-E were discrepant when compared to verbal report as the gold standard (McNemar’s  $\chi^2 = 0.76, p = 0.38$ ). There were no differences in accuracy between the MBM-E and MBM-P in each of the body zones with the exception of a small improvement in accuracy of the back region for the MBM-E (McNemar’s  $\chi^2 = 7.36, p = .01$ ). There were no associations between age or comfort using electronic screens and discrepancies on the MBM-P or the MBM-E. Participants did not believe the MBM-E looked different from the MBM-P or have difficulty marking areas of pain on the MBM-E (Table 1). Participants did report some issues with reading or sizing on the MBM-E. For Aim 2, participants indicated they preferred the MBM-E and the MBM-E with pain zones more than the BPI as a way to best describe their pain (Figure 2).

Conclusion:

The present study demonstrates the utility, reliability and construct validity of an electronic version of the MBM. Moreover, the new MBM-E with pain zones allows patients to rate pain intensity and was preferred to the classic 0-10 scales from the BPI to describe their pain.

1. Brummett CM, et al. Pain 2016,157(6)

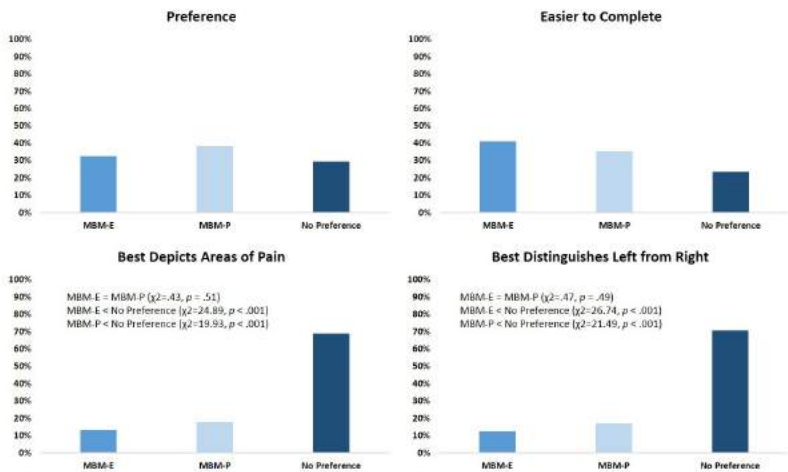

Figure 1. Comparison between the electronic (MBM-E) and paper (MBM-P) Michigan Body Map. There were no significant differences in preference or perceptions of ease to complete between the MBM-E and the MBM-P. Participants indicated "No Preference" more than MBM-E or MBM-P for which MBM best depicts areas of pain and best distinguishes left from right. \*Signifies statistically significant difference.

Table 1

## Problems with Electronic MBM

	No	Yes	$\chi^2$	<i>p</i>
Did they look different?	55 (83.33%)	11 (16.67%)	1.83	.18
Did you have any issues with reading or sizing of the body map or labels?	53 (77.94%)	15 (22.06%)	3.31	.07
Did you have any trouble or difficulty marking areas of pain?	58 (85.29%)	10 (14.71%)	1.47	.23

## Preferred Method for Describing Pain

Figure 2. Most preferred method for describing pain. Participants preferred the MBM-E (Original) and the MBM-E (Zones) more than the BPI. There was no significant difference in preference between MBM-E (Original) and MBM-E (Zones).

## Identifying Pain Sites Highly Associated with the Fibromyalgia (FM) Phenotype

Louis Lu<sup>1</sup>, Stephanie Moser<sup>2</sup>, Chad M. Brummett<sup>2</sup> and Daniel J. Clauw<sup>3</sup>, <sup>1</sup>Anesthesiology & Perioperative Care, UC Irvine, Orange, CA, <sup>2</sup>Anesthesiology, University of Michigan, Ann Arbor, MI, <sup>3</sup>Chronic Pain & Fatigue Research Center, University of Michigan, Ann Arbor, MI

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Fibromyalgia is challenging to diagnose given its overlapping symptoms with other chronic pain conditions. The most characteristic feature of FM is widespread pain, operationalized by the 2016 FM Survey Criteria as involving at least 4 out of 5 body regions (axial region and limbs). We hypothesized that certain pain locations may be virtually pathognomonic of FM, because these pain sites occur commonly in FM patients but are very uncommon in individuals without FM.

**Methods:** This is a single center retrospective observational study of patients recruited prior to elective surgery to be in an institutional biorepository. Patients completed the Michigan Body Map to assess the presence or absence of pain in 35 body sites, as well as the 2011 FM Survey Criteria. FM symptom (FS) scores were calculated by adding the widespread pain index (WPI) and symptom severity (SS) scale. Based on the 2016 Modified FM Criteria, patients were diagnosed with FM if they reported pain in 4+ body regions and their FS scores were 12+. Controls were patients that did not meet the criteria. Univariate differences were assessed via t-tests and chi-square tests. Multivariate linear regression accounted for age and gender.

**Results:** 891 patients (5.5%) out of 16,273 patients were diagnosed with FM. Median age for FM patients was 53 vs 54 ( $p = 0.62$ ) and 72% female vs 52% ( $p < 0.0001$ ). Pain sites with the highest odds ratios between FM patients and controls were the left upper arm (23.9), left lower arm (23.4), right upper arm (22.6), right lower arm (21.8), left shoulder (21.6), and right shoulder (18.7). Upon multivariate analysis, statistically significant sites were the head ( $p = 0.006$ ), face ( $p = 0.04$ ), left upper arm ( $p = 0.004$ ), left lower arm ( $p = 0.0001$ ), left wrist/hand ( $p = 0.02$ ), left knee ( $p < 0.0001$ ), left lower leg ( $p = 0.002$ ), left ankle/foot ( $p = 0.007$ ), right jaw ( $p = 0.01$ ), right upper arm ( $p = 0.006$ ), right elbow ( $p < 0.0001$ ), right lower arm ( $p < 0.0001$ ), right wrist/hand ( $p < 0.0001$ ), right knee ( $p < 0.0001$ ), and right lower leg ( $p = 0.001$ ). See **Table 1** for the results of all queried body sites.

**Conclusion:** Pain in non-joint regions of all four limbs, in addition to the head, face and jaw, were all statistically more significantly seen in individuals with FM and unusual in non-FM patients. Though other regions of pain were also commonly seen in FM, because they were also seen in non-FM patients, they would not be helpful in differentiating a chronic pain patient with FM vs. one with a different underlying cause.

**Table 1:**

Site	FM Patients	Controls	Odds Ratio	Multivariate Analysis p-value
Head	41.6%	8.7%	7.5 (6.5 - 8.7)	<b>0.006</b>
Face	10.2%	2.5%	4.4 (3.4 - 5.6)	<b>0.04</b>
Neck	66.4%	13.8%	12.4 (10.7 - 14.4)	0.08

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Fibromyalgia syndrome (FMS) is a condition characterized by widespread pain, sleep disturbance and chronic fatigue, and mood disorder .FMS was suggested to represent a prototype of central nervous system hypersensitivity (central sensitivity-CS). While the mechanisms underlying CS remain incompletely understood, a role for limbic and sleep related dysregulation has been argued. The aim of the current study was to examine the feasibility of fMRI-inspired *Electrical Finger Print (EFP)* of the amygdala as a probe for NeuroFeedback (amyg-EFP NF) training for FM patients. We expected to find improved sleep quality among trainees successful in downregulating amygdala activity.

### Methods:

Thirty four FMS patients (3M:31F, average age 35.6 SD=11.82) underwent 10 sessions of amyEFP-NF, targeting down-regulation of the amygdala. Nine patients received rewarding sham NF and served as a control group. The 24 patients that received real feedback were divided into successful (succ+) (N=13) and unsuccessful (succ-) (N=12) feedback learners. Two interfaces were used to give the feedback: Auditory feedback and multi-modal virtual reality feedback. An objective outcome measure of sleep quality was taken using the WatchPAT device before and after NF training

**Results:** Repeated measures ANOVA for feedback learning provided significant results ( $F=3.23$   $p=0.05$ ), indicating that succ+ subjects displayed improved ability to regulate their amyEFP signal following treatment, in comparison to succ- and sham participants. The three groups also differed in REM latency improvement: repeated measures ANOVA for REM latency was significant ( $F=3.557$   $p=0.04$ ),

indicating that only succ+ subjects displayed longer REM latency following amyEFP-NF. Furthermore, the change in REM latency was correlated with feedback learning only in the succ+ group ( $R=0.497$   $p=0.05$ )

#### **Conclusion:**

In order to improve the sleep quality of patients suffering from central sensitivity disorder we targeted the amygdala, a limbic hub that is known to be affected by sleep impairment. We show feedback-specific effect of improved REM latency, a well-known marker for mood disorder. This study provides novel evidence of neurofeedback specific effect on objective sleep measures in FMS patients.

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

#### **Background/Purpose:**

Both the fibromyalgia impact questionnaire (FIQ) and the polysymptomatic distress scale (PSD) have been proposed as measures of FM impact and severity. It is not known how they related to each other and to what extent they relate to FM process items such as pain, depression, anxiety, and catastrophizing.

We set to compare the correlation between FIQ and PSD, and their correlates with depression, anxiety, and catastrophizing, and to determine the individual impact of FIQ and PSD on pain disability index as a measure of the extent to which fibromyalgia pain interferes with a patient's ability to engage in essential life activities. In this study we considered pain disability index as a surrogate for FM severity.

#### **Methods:**

The PSD is the sum of two variables used in the 2010 preliminary American College of Rheumatology fibromyalgia criteria, the widespread pain index (WPI) and symptom severity scale (SS). The FIQ, captures the total spectrum of problems related to FM and has been used as a measure of fibromyalgia severity.

The pain disability index measures the impact of chronic pain on seven essential life activities, family, recreational, social, occupational, sexual, self care, and life support. and is the sum of the scores (0 - 10) of all life activities divided by the number of activities rated. We measured the patient health questionnaire (PHQ-9) for depression, the general anxiety disorder scale (GAD-7), and the pain catastrophizing scale.

#### **Results:**

Patients diagnosed clinically with FM were included: n 555, 85.5% female, 79.5% white, age 44.3 (12), 87.2% met ACR 2010 FM criteria, PHQ-9 13.7 (6.5), GAD-7 8.6 (6.6), pain catastrophizing scale 22.6 (13.4), PSD 21 (10.6), FIQ 57.9 (20.4), pain disability index 5.3 (2.3).

FIQ correlated with PSD  $r$  0.465, GAD-7  $r$  0.368, PHQ-9  $r$  0.476, pain catastrophizing scale  $r$  0.416, pain disability index  $r$  0.602; PSD score correlated with GAD-7  $r$  0.233, PHQ-9  $r$  0.371, pain catastrophizing scale  $r$  0.262, pain disability index  $r$  0.377. All correlations were significant at  $p < 0.001$ .

Linear regression was calculated to predict FIQ based on GAD-7, PHQ-9 and pain catastrophizing scale. A significant regression equation was found  $F(1, 120) = 42.064$ ,  $P < 0.001$ ,  $R^2$  0.513 of FIQ. Depression and catastrophizing scores remaining independent predictors of FIQ. A similar model significantly predicts the PSD score,  $F(1, 130) = 26.849$ ,  $P < 0.001$ ,  $R^2$  0.383 of PSD; only depression measured by PHQ-9 remained an independent predictor of PSD. To measure the individual contribution of FIQ and PSD score on pain disability index we performed a linear regression model. A significant regression equation was found  $F(2, 165) = 154.619$ ,  $R^2$  0.652 of PDI. In this model, FIQ but not PSD remained independent predictor of pain disability index.

### Conclusion:

Our data suggests that the FIQ and the PSD show only a moderate degree of correlation. Also, the FIQ has stronger associations with FM process measures including depression, anxiety, pain catastrophizing and pain disability index, compared to the PSD. This may explain why the FIQ, but not the PSD remains an independent predictor of pain disability score.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Imaging of Rheumatic Diseases I: Novel Imaging and Scoring Systems

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Enthesitis affects approximately a third of patients with psoriatic arthritis (PsA) and is often considered the earliest site of inflammation. The accuracy of clinical examination of enthesitis is limited. Ultrasound could improve detection of enthesitis, however, there is no accepted score for assessment of sonographic enthesitis in PsA. The objective of this study is to assess the performance of various sonographic elemental enthesal lesions in distinguishing between PsA and healthy controls which will inform the development of a novel sonographic enthesitis score for PsA.

**Methods:** A total of 100 age- and sex-matched individuals (50 PsA and 50 controls) were recruited for this cross-sectional study. Patients with PsA were recruited during their clinic visits. Healthy controls with no personal or family history of inflammatory arthritis were recruited from hospital personnel and advertisements. Eleven enthesal sites were scanned bilaterally according to a standardized protocol by two sonographers. The selection of enthesal sites for this study was based on systematic literature review and expert opinion of rheumatologists experienced in musculoskeletal ultrasound in PsA. Based on OMERACT definition of sonographic enthesitis, the following lesions were assessed: structural changes, thickness, erosion, enthesophytes, calcification, power Doppler (PD) signal, bursitis, and bone irregularities. The images were read by two readers blinded to the clinical information. The intra- and inter-rater reliability for scoring the lesions was excellent (ICC 0.92 to 0.96). Chi square tests were used to compare the frequency of the various lesions between PsA and controls. The sensitivity, specificity and positive predictive value (PPV) of enthesal lesions were computed.

**Results:** Mean age was  $55 \pm 10$  years, 59% were males, average BMI was 29, and average disease duration was 14.6 years. The frequencies of the various enthesal lesions and their ability to distinguish between PsA and controls are presented in Table 1. The

lesions that had the highest PPV were: PD at the enthesis (PD grade greater than 2 (100%) and PD grade greater than 1 (97%)), erosions (89%) and bone proliferation (87%). In general, the sensitivity of was much lower ranging from 0.1% to 27%. No significant differences were found in the frequencies of calcifications or bursitis between PsA patients and controls.

**Conclusion:** We identified elemental ultrasonographic abnormalities that could distinguish PsA and controls. This information will contribute to the development of a new sonographic score for assessment of enthesitis in patients with PsA that could be used for diagnostic purposes and contribute to new understanding and clinical application of ultrasonographic enthesitis at the bedside.

**Table 1: The Frequencies, Sensitivities, Specificities and Positive Predictive Values of Enteseal Lesions**

	PsA (%)	Control (%)	Sensitivity (%)	Specificity (%)	PPV (%)	p value

## Assessment of Structural Damage of the Thumb Base in Patients with Hand Osteoarthritis: Comparing the Newly Developed Omeract Magnetic Resonance Imaging Scoring System with Standard Radiography

S. van Beest<sup>1</sup>, F.P.B. Kroon<sup>1</sup>, W. Damman<sup>1</sup>, R. Liu<sup>1</sup>, H.M. Kroon<sup>2</sup> and M. Kloppenburg<sup>3</sup>, <sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Radiology, Leiden University Medical Center, Leiden, Netherlands, <sup>3</sup>Rheumatology and Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Imaging of Rheumatic Diseases I: Novel Imaging and Scoring Systems

**Session Type:** ACR Concurrent Abstract Session

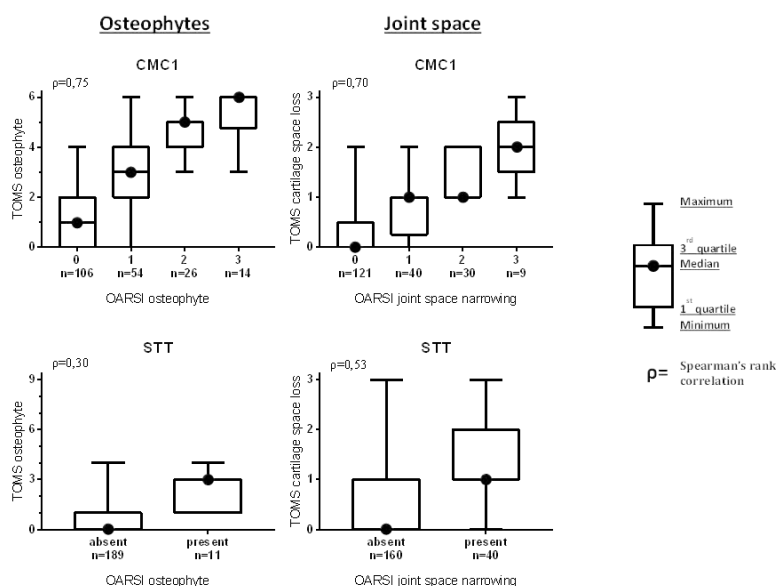

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Thumb base osteoarthritis (OA) is characterized by structural damage, most commonly evaluated by radiography. However radiography is insensitive. Magnetic resonance (MR) imaging could be a valuable alternative, however a standardized scoring method for thumb base MR images did not exist until recently OMERACT developed the thumb base OA MRI scoring system (TOMS). Our aim was to investigate the validity of the new TOMS by comparing TOMS scores with radiographic scores.

**Methods:** Two hundred patients (83.5% women, median age 60.5 years) with primary hand OA (90.5% fulfilling ACR classification criteria) from the rheumatology outpatient clinic, who had dorsopalmar radiographs and MR scans of the right thumb base, were studied. T1- and fat suppressed T2-turbo spin weighted sequences were obtained on a 1.5 Tesla scanner. Radiographs of the first carpometacarpal (CMC1) and scaphotrapezotrapezoid (STT) joints were scored using the OARSI atlas (osteophytes and joint space narrowing [JSN] in CMC1: 0-3 and STT: absent/present) in consensus by two readers with good intra-reader reliability. MR images were scored using TOMS (osteophytes in CMC1: 0-6 and STT: 0-9; cartilage space loss [CSL] for both joints: 0-3) by two readers, with good intra- and inter-reader reliability. For analysis we used the average of both readers. Readers were blinded for clinical and other imaging data. To study validity, the distribution of the TOMS scores for osteophytes and CSL were described stratified for the different radiographic stages for osteophytes and JSN, respectively.

**Results:** On MR images osteophytes were detected in the vast majority of thumb bases (CMC1 n=172; STT n=102). The score of TOMS increased with more severe radiographic stages (see figures). However, the number of patients without any osteophytes in both CMC1 and STT was considerably lower for TOMS (n=19) than for the OARSI (n=105) scoring. A similar difference was apparent for absence of CSL (n=82) versus JSN (n=107) in both CMC1 and STT. Patients with isolated STT osteophytes were quite rare for both TOMS (n=9) and the OARSI (n=1) scoring. The most prominent discrepancy between TOMS and OARSI sensitivity was found for osteophytes: an additional 170 joints (CMC1 n=79; STT n=91) were found positive with TOMS, while only 1 OARSI-positive CMC1 scored negative with TOMS.

**Conclusion:** Scores of OA features assessed on MR images by TOMS were correlated with radiographic scores, indicating good validity of the TOMS. Furthermore, the frequencies of positive features assessed on MR images were higher compared to those on radiographs, suggesting high sensitivity for the TOMS.

## **A Non-Invasive Ultrasound Surface Wave Elastography Technique for Assessing Interstitial Lung Disease**

**Thomas Osborn**<sup>1</sup>, Xiaoming Zhang<sup>2</sup>, Sanjay Kalra<sup>3</sup>, Boran Zhou<sup>4</sup> and Brian Bartholmai<sup>5</sup>, <sup>1</sup>Rheumatology, Mayo Clinic, Rochester, MN, <sup>2</sup>Mayo Clinic college of Medicine, Rochester, MN, <sup>3</sup>Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN, <sup>4</sup>Radiology, Mayo Clinic, Rochester, MN, <sup>5</sup>Thoracic Radiology, Mayo Clinic, Rochester, MN

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Imaging of Rheumatic Diseases I: Novel Imaging and Scoring Systems

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Surface wave elastography is an ultrasound based noninvasive technique to measure tissue viscoelasticity (“stiffness”). Preliminary studies in assessing scleroderma associated skin thickening have been promising. Ultrasonography is not widely used in clinic for lung assessment. Lung tissue is normally filled with air, and the difference in acoustic impedance between air and tissue is large. Most of the energy of an ultrasound wave is reflected from the lung surface and ultrasound cannot image deep lung tissue. In this abstract, we present a novel technique, lung ultrasound surface wave elastography, for measuring the elastic properties of superficial lung tissue. The lung changes in many interstitial lung diseases (ILD), including scleroderma associated ILD, are peripheral/superficial and have fibrosis-related “stiffening.”

**Methods:** A handheld vibrator was used to generate a small, local, and 0.1 second harmonic vibration on the chest of a subject. A Versonics ultrasound probe (L11-4/central frequency of 6.4 MHz) was used to measure the resulting surface wave speed on the lung. In a large clinical study of ILD patients, we measure both lungs through six intercostal spaces for patients and controls. Patients were selected from the Adult Pulmonary and Rheumatology outpatient clinics. Clinical and CT diagnosis of interstitial lung disease, either idiopathic or associated with a connective tissue disease/autoimmune inflammatory arthritis. Controls were never-smoking, asymptomatic adults with no history of cardiorespiratory disease. We compared 91 ILD patients to 30 normal controls. The 91 ILD patients’ diagnoses included: Scleroderma (39), rheumatoid arthritis (12), overlap CTD (10), idiopathic ILD (10), antisynthetase (7), myositis (7), Sjögren’s (5), and SLE (1).

**Results:** The surface wave speed was measured at 100 Hz, 150 Hz, and 200 Hz. The surface wave speeds at 100 Hz, were  $2.26 \pm 0.4$  m/s and  $2.87 \pm 0.53$  m/s, respectively, for 30 healthy subjects and 91 patients with ILD at the lower right lungs. The surface wave speeds were significantly higher in ILD patients than that in healthy subjects ( $p < 0.001$ ) at each intercostal space and at each frequency.

**Conclusion:** Lung ultrasound surface wave elastography may prove to be a useful noninvasive and nonionizing technique to measure the elastic properties of superficial lung tissue. Significant differences of wave speed between healthy subjects and patients with peripherally distributed interstitial fibrosis were found. Lung ultrasound surface wave elastography has potential utility in assessing ILDs.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Imaging of Rheumatic Diseases I: Novel Imaging and Scoring Systems

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Magnetic resonance imaging (MRI) is the gold standard for detection of inflammation in the sacroiliac joints (SIJ) of patients (pts) with axial spondyloarthritis (axSpA), while for chronic, structural changes (erosions, sclerosis and ankylosis) conventional radiographs (CR) and computed tomography (CT) are often preferred. The 3D volumetric interpolated breath-hold sequence (VIBE) is an MRI technique, easy to acquire in daily practice, that can visualize cartilage especially well because of its good contrast to synovial tissue. Here we compare the ability of the VIBE technique to detect structural changes in comparison to CR and CT in SIJs of axSpA patients in relation to symptom duration and age.

**Methods:** Complete sets of MRI (T1 and VIBE techniques), CT and CR of SIJs of 109 AS patients were available. Two readers evaluated all images independently, blinded to demographic data and in separate sessions for each technique. The assessment of lesions was performed based on SIJ-quadrants (SQ) to score erosions, sclerosis and ankylosis (SIJ-halves). Lesions were counted as positive if both readers were in agreement. Comparisons between MRI techniques were performed by Wilcoxon-test. Linear regression analysis was used to evaluate the influence of age and disease duration on the occurrence of different structural lesions by modeling the differences in the number of lesions in different imaging techniques as dependent variable.

## Results:

The mean age  $\pm$  standard deviation was  $45.3 \pm 13.9$  years (y), 55 pts (50.5%) were aged  $\leq 45$ y, 67.9% male, 82.3% HLA-B27+, 58 pts (53.2%) had a disease duration  $\leq 3$ y. Agreement for positive and negative findings between MRI and CT was generally high ( $>80\%$  of SQs in all subgroups) and agreement between readers for all techniques and lesion types was excellent (ICC=0.979-0.997).

Overall, MRI detected significantly more SQ with erosions in pts  $\leq 45$ y (n=134) and in pts with disease duration  $\leq 3$ y (n=125) as compared to CT (n=91, p=0.002 and n=90, p=0.003, respectively) and in pts with age  $\leq 45$ y (n=61, p<0.001) as compared to CR, while there were no differences between MRI and CT in pts.  $>45$ y or disease duration  $>3$ y. Linear regression analysis showed that MRI was superior in the detection of erosions in younger ages as compared to CT (B=0.032, p=0.001).

However, CT detected significantly more SIJ halves with ankylosis in all subgroups and more SQ with sclerosis in pts with disease duration  $\leq 3$ y (n=64 vs. n=37, respectively, p=0.006), and it also detected more SQ with sclerosis in pts  $>45$ y (n=67 vs. n=38, p=0.001) and disease duration  $>3$ y (n=64 vs. n=40, p=0.003) as compared to MRI, while no differences were found in the assessment of ankylosis.

**Conclusion:** MRI in the T1 and VIBE technique is more sensitive in the detection of erosions as compared to CT and CR in axSpA pts with short disease duration and younger age. This is due to its ability to identify structural damage in the SIJ cartilage that has not yet extended to the underlying bone. These differences are not found in pts with longer disease duration or older age. This data suggests a more prominent role for MRI also for the early detection of structural changes in the SIJ of axSpA pts..

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Imaging of Rheumatic Diseases I: Novel Imaging and Scoring Systems

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose :** Tenosynovitis is very common in patients with RA and is associated with lower physical function. Several studies have confirmed the limitations of clinical examination for detection of tenosynovitis in comparison with ultrasound (US) and a highly validated and reliable US scoring system is therefore needed if implementing US-tenosynovitis as an outcome measure in clinical trials. The OMERACT US group's tenosynovitis scoring system has a good single and multicenter intra- and inter-observer agreement, whereas the sensitivity to change in a multicenter design has never been tested.

Furthermore, it is unknown whether low grade synovial hypertrophy without Doppler Signal represents true inflammation, i.e. can be eliminated by anti-inflammatory therapy and is sensitive to change.

The aim of this study was to test the sensitivity to change of the OMERACT US scoring system for tenosynovitis, including minimal signs of tenosynovitis, in a multicenter design in order to validate it as an outcome measure in RA multicenter clinical trials. Furthermore, to assess the association between US and HAQ and DAS28.

**Methods:** Forty-nine patients with established RA (duration  $\geq 1$  year) and 18 early RA patients ( $< 1$  year) with US-verified tenosynovitis were recruited from six rheumatology outpatient clinics in four different countries, if they were scheduled for treatment intensification with synthetic and/or biological DMARD. Tenosynovitis was assessed at baseline, and at three and six months' follow-up, by GS and Doppler, using the semi-quantitative OMERACT scoring system. Furthermore, HAQ and DAS28 were assessed.

**Results:** At baseline tenosynovitis was most frequently found at the extensor carpi ulnaris and tibialis posterior tendons (70.7% and 44.4%, respectively). The overall GS score showed a statistically significant decrease from baseline median 5 (25<sup>th</sup>;75<sup>th</sup> percentile: 2;7) to 6 months 0 (0;3) and the overall Doppler score decreased statistically significant from baseline 3 (2;6) to 6 months 0 (0;1), both with a  $p < 0.01$ . Both GS and Doppler showed high responsiveness (SRM  $> 0.9$ ), as did HAQ and DAS28 (table 1). Among tendons with grey scale (GS)=1/Doppler=0, 36 of 39 (92.3%) showed therapy-induced improvements. Changes in US-scores were statistically significantly associated with DAS28 ( $p=0.02$ ), but not with HAQ.

**Conclusion:** In conclusion, this RA multicenter study documented a high sensitivity to change of both GS and Doppler US tenosynovitis scores, indicating utility of the OMERACT US scoring system for diagnosing and monitoring tenosynovitis in multicenter trials. Secondly, synovial hypertrophy without Doppler signal, do respond to therapy, suggesting it reflects true inflammation. Finally, changes in US tenosynovitis scores are associated with changes in DAS28.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Imaging of Rheumatic Diseases I: Novel Imaging and Scoring Systems

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Remission in rheumatoid arthritis (RA) is often assessed using the following indices: disease activity scores (DAS-28), clinical disease activity index (CDAI), Simplified Disease Activity Index (SDAI) and Routine Assessment of Patient Index Data (RAPID-3). There is increasing literature supporting the benefits of using imaging modalities to better define remission in RA. Musculoskeletal ultrasound (MUS) allows for direct visualization of diverse pathologic features such as cortical bone erosions, synovial thickening, and synovial vascularity in the joints affected by RA with high sensitivity, specificity, and accuracy. The purpose of this study was to investigate the association between clinical outcome measures and ultrasound score of the dominant hand in RA patients.

**Methods:** This was a single center study of patients from the RA clinic at the University of Rochester seen between July 2015 and April 2017. The DAS-28, CDAI, SDAI are collected as standard of care in the RA clinic. Patients are also offered the option of doing the RAPID-3 and getting MUS evaluations as part of their assessment. All clinical measures were collected by AA and AC. MUS exams were done by RT, who was blinded to the clinical scores, using a GE Logiq E9 (2014 model). MSK evaluations were done, using frequencies of 15-18 MHz for gray scale (GS). The following joints were assessed: dorsal wrist, 2nd, 3rd, 4th and 5th MCPs and the 2nd, 3rd, 4th and 5th PIP. MCP joints 2-5 were scanned from a dorsal aspect, and PIP joints 2-5 were scanned from a volar aspect. The scans were retrospectively scored for presence of synovitis on GS and Power Doppler (PD) (0=none; 1=mild; 2=moderate and 3=severe) for each joint. A total score was calculated by adding GS and PD scores and compared to clinical measures.

**Results:** A total of 113 patients volunteered for MUS but complete data were available in only 67. The median age of the group was 61 years and comprised 41 females and 26 males, with 62 being sero-positive and 38 with erosive disease. A total of 26 patients were in remission by DAS-28(CRP), 12 by CDAI, 14 by SDAI and 9 by RAPID-3, criteria. Low disease activity was seen in 11 by DAS-28, 17 by CDAI, 22 by SDAI and 9 by RAPID-3 criteria while 25, 24, 19 and 18 patients were with moderate disease activity and 5, 14, 12 and 31 had high disease activity, respectively. The median scores on MUS GS and PD for each category of disease activity are shown in Table 1. Interestingly, the median score on PD was 0 for remission by all outcome measures. MUS scores were associated with disease activity scores and a positive correlation was detected between MUS (GS and PD) scores and DAS-28 scores.

**Conclusion:** Most patients in clinical remission as assessed by DAS-28, CDAI, SDAI and RAPID-3 had no activity on PD and low scores on GS MUS evaluations. MUS of the dominant hand, using a simple scoring system, can be as effective in defining remission.

	DAS-28 (CRP)		CDAI		SDAI		RAPID-3	
	GS	PD	GS	PD	GS	PD	GS	PD
Remission	1	0	1	0	1	0	1	0
Low-disease activity	2	2	2	0	3	2	1	0
Moderate disease activity	5	4	4	2	4	2	3.5	3
High disease activity	7	4	10	4.5	8.5	3.5	5	2

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Immune checkpoint inhibitors have revolutionized the treatment of advanced malignancies. By blocking T-cell inhibition these drugs result in immune targeting of tumor cells and normal tissue. As such, their main toxicity is inducing immune-mediated tissue damage. Patients with preexisting rheumatologic diseases were excluded from the clinical trials for these agents, and little is known about the safety, efficacy, or risk for disease flares in these patients.

**Methods:** A retrospective medical record review was performed to identify all patients who received checkpoint inhibitor therapy at Mayo Clinic, Rochester between 2011 and 2016. Those with preexisting rheumatologic disease were identified using specific diagnostic codes.

**Results:** There were 16 patients identified (81% female, mean age 68.3). The most common rheumatologic diseases were rheumatoid arthritis (5), polymyalgia rheumatica (5), Sjogren's syndrome (2), and systemic lupus erythematosus (2). Seven patients were receiving treatment with immunosuppressive therapy upon starting a checkpoint inhibitor. The primary malignancies were melanoma (10), pulmonary (4), or hematologic (2). In most cases checkpoint inhibitors were offered only after failure of several other therapies.

Immune-related adverse events (IRAE) occurred in 6 patients and all were treated successfully with corticosteroids and discontinuation of therapy. Survival was significantly prolonged in patients with an IRAE (17 months vs. 1.4 months [p=0.003]). There were no significant differences in time from cancer diagnosis to immunotherapy, duration of immunotherapy, age, or sex between these groups.

**Conclusion:** To our knowledge, this represents the largest single-center cohort of patients with rheumatologic diseases who were exposed to cancer immunotherapy. Only a minority of these patients experienced a flare of their preexisting rheumatologic disease or any other IRAE. The presence of an IRAE was associated with significantly prolonged survival.

Table 1. Baseline Characteristics

First publication: September 18, 2017

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

### Background/Purpose:

Inflammatory eye diseases such as scleritis and uveitis are associated with systemic autoimmune disease (SAD) and can be the initial manifestation of a concurrent or subsequent SAD. Despite this association, there remains no consensus on the initial diagnostic workup for patients without evidence of systemic involvement.

### Methods:

We performed a retrospective review of patients seen at Cleveland Clinic between 2013 and 2014 by the ophthalmology department with a diagnosis of uveitis or scleritis based on ICD 9 and 10 codes. Subjects were included if they had recurrent or chronic uveitis or scleritis based on 2005 SUN working group nomenclature and no diagnosis of SAD prior to the inflammatory eye disease. Charts were further reviewed for any subsequent development of SAD. Sensitivity and specificity analysis was performed based on the following tests ANA, ACE, RF, CCP and ANCA and the associated SAD.

### Results:

2351 patients were identified with uveitis or scleritis, of which 545 patients were recurrent or chronic and were included in the analysis. Eighty-five patients (15.6%) were subsequently diagnosed with a systemic autoimmune disease: sarcoidosis (54%), spondyloarthritis (22%), rheumatoid arthritis (13%), systemic lupus erythematosus (7%), and anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (3.5%). Sensitivities of the screening tests are shown below.

<i>screening test</i>	<i>Number of unique patients with screening test ordered at least once</i> <i>(n=545)</i>	<i>Number of patients diagnosed with SAD</i>	<i>Sensitivity of serologies for diagnosis of SAD in patients with scleritis or uveitis (95% CI)</i>
ANA	232	6 SLE	*
ACE	262	46 Sarcoidosis	0.59 (0.41-0.77)
RF	165	11 Rheumatoid Arthritis	0.5 (0.19-0.81)
CCP	118	11 Rheumatoid Arthritis	0.5 (0.19-0.81)
HLA-B27	175	19 Spondyloarthritis	0.55 (0.25-0.84)
C-ANCA	120	3 ANCA Vasculitis	*
P-ANCA	120	3 ANCA Vasculitis	*

\*Due to small sample size, sensitivity was not calculated.

### Conclusion:

15% of patients diagnosed with chronic or recurrent autoimmune uveitis or scleritis subsequently developed a systemic autoimmune disease. Laboratory testing such as ANA for SLE, HLA-B27 for spondyloarthritis, RF and CCP for rheumatoid arthritis, C-ANCA and P-ANCA for ANCA associated vasculitis and ACE level for sarcoidosis were not sensitive for screening tests. Therefore, it is inadequate to use laboratory testing alone to guide referral for evaluation of systemic autoimmune disease in patients with chronic or recurrent uveitis or scleritis. Other aspects, such as characteristics of the eye findings and patient symptoms should be evaluated to improve sensitivity.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** TARC, also known as chemokine ligand 17 (CCR17), is expressed in the thymus and is produced by dendritic cells, endothelial cells, keratinocytes and fibroblasts. TARC has affinity as a ligand for CCR4 and CCR8, which are predominantly expressed by Th2 cells. High serum concentration of TARC is determined in allergic diseases such as atopic dermatitis and bronchial asthma. Several studies have reported frequent atopic symptoms among patients with IgG4-related disease (IgG4-RD). We investigated the role of TARC as a biomarker in IgG4-RD, in which Th2 cytokines associate in disease states.

**Methods:** We evaluated the serum concentration of TARC from 26 IgG4-RD patients, 22 healthy controls (HC) by ELISA. We also analyzed the correlations between TARC concentration and clinical parameters. To investigate the biological effect of TARC toward pathogenesis in IgG4-RD, in vitro induction of plasmablasts from peripheral blood mononuclear cells (PBMCs) in patients with IgG4-RD by TARC was evaluated.

**Results:** We found that the serum concentration of TARC in the IgG4-RD was significantly higher than HC (IgG4-RD mean 493.9 ng/mlHC mean 262.0 ng/mlCp<0.001). ROC curve for TARC distinguish IgG4-RD from HC, the cutoff value 296.5 ng/ml (sensitivity 80.8%, specificity 72.7%). Serum concentration of TARC from IgG4-RD positively correlated with number of organ involvement (Fig. 1) whereas showed the correlation neither with serum IgG4 nor eosinophil number in peripheral blood. In addition, no difference in TARC concentration was found among IgG4-RD patients with or without atopic symptoms. TARC in vitro clearly induced the formation of plasmablasts from patients with IgG4-RD (Fig. 2).

**Conclusion:** Collectively, our data suggest that TARC is an essential Th2 cytokine in patients with IgG4-RD. TARC may be involved in the development of IgG4-RD through an aberrant induction of plasmablasts.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The aim was to explore patterns of osteoarticular involvement in SAPHO syndrome using cluster analysis of lesions revealed by whole body bone scintigraphy.

**Methods:** Data on whole body bone scintigraphy was collected in 157 patients enrolled in a single center cohort study<sup>1</sup> who fulfill the Kahn and Khan's criteria for SAPHO syndrome<sup>2</sup>. Twelve characteristic or most frequently involved osteoarticular sites in SAPHO syndrome revealed by whole body bone scintigraphy were analyzed by hierarchical cluster analysis with the Ward minimum-variance method.

**Results:** Three major subtypes with distinct patterns of osteoarticular involvement were identified: (A) the sternoclavicular type (52 patients), with predominant involvement of bilateral sternoclavicular joints, characterized by the classic "bull's head" sign; (B) the costal type (35 patients), with predominant lesions in the anterior ribs, particularly the first ribs; and (C) the spinal type (70 patients), with significantly higher frequency of lesions in the thoracic, lumbar and sacral spine. Interestingly, a significant increase in age at onset of skin lesions was observed in spinal type ( $40.1 \pm 11.2$  years) than sternoclavicular type ( $34.6 \pm 10.5$  years,  $p = 0.036$ ) and costal type ( $35.0 \pm 10.0$  years,  $p = 0.035$ ). On the other hand, the duration of disease was significantly higher in sternoclavicular type ( $93.2 \pm 120.4$  months) compared with costal type ( $27.6 \pm 32.2$  months,  $p = 0.001$ ) and spinal type ( $29.0 \pm 37.1$  months,  $p < 0.001$ ).

**Conclusion:** The osteoarticular involvement in SAPHO syndrome can be clustered into three distinct patterns with different clinical pictures. The costal involvement in SAPHO syndrome, which was less well recognized previously, may define a separate type of the disease.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

In a recent Phase III study (NCT02020889) in patients with Eosinophilic Granulomatosis with Polyangiitis (EGPA) the anti-interleukin-5 monoclonal antibody mepolizumab showed significant benefit when compared to placebo for both primary endpoints and all secondary endpoints. As not all subjects treated with mepolizumab were able to achieve remission, we investigated *post-hoc* the benefit in terms of not only remission, but also oral corticosteroid reduction, and/or relapses.

**Methods:** We conducted a Phase III, randomized, placebo-controlled, double-blind, parallel-group, multi-center study in patients with EGPA and a history of relapsing or refractory disease on stable therapy with prednisolone/prednisone  $\geq 7.5$ – $\leq 50$ mg/day with or without additional immunosuppressive therapy for  $\geq 4$  weeks. Patients were randomized 1:1 to receive mepolizumab 300mg or placebo subcutaneously, in addition to standard of care, every 4 weeks for 52 weeks. Remission was defined with both the stringent definition utilized in the primary endpoint (Birmingham Vasculitis Activity Score [BVAS]=0, corticosteroid dose  $\leq 4$ mg/day) as well as the European League Against Rheumatism (EULAR) definition (BVAS=0, corticosteroid dose  $\leq 7.5$ mg/day). Oral corticosteroid reduction was defined *post-hoc* as  $\geq 50\%$  reduction from baseline in average prednisolone/prednisone dose during Weeks 48-52. Benefit in relapse was defined *post-hoc* if a subject was relapse free throughout the 52 week treatment period. We also summarized specific sub-populations of clinical interest: baseline blood eosinophil count  $< 150$  cells/ $\mu$ L, oral corticosteroid dose  $> 20$  mg/day, and weight  $> 85$  kg.

**Results:** 136 patients received at least one dose of study medication (mepolizumab n=68, placebo n=68). With the primary endpoint definition of remission the results showed that 53 (78%) subjects in the mepolizumab group received clinical benefit in terms of remission and/or a 50% reduction in oral corticosteroid dose and/or having no relapses during the study treatment period, compared with 22 (32%) subjects in the placebo group. For the EULAR definition of remission 59 (87%) subjects in the mepolizumab group received clinical benefit compared with 36 (53%) subjects in the placebo group. In all of the sub-populations described, clinical benefit was seen in greater percentages of subjects treated with mepolizumab compared to placebo.

**Conclusion:** Using a broader yet clinically relevant definition of response that includes remission, absence of relapse, and/or steroid reduction, a significantly greater proportion of mepolizumab treated patients experienced clinical benefit when compared to placebo. In addition, more subjects in sub-populations of interest experienced clinical benefit with mepolizumab treatment compared to placebo. ## **Epidemiology of Hospitalized Adult Onset Still's Disease in United States**

**Bella Y. Mehta**<sup>1</sup>, William Briggs<sup>2</sup> and Petros Efthimiou<sup>3</sup>, <sup>1</sup>Rheumatology, Hospital for Special Surgery/Weill Cornell Medicine/Mailman School of Public Health, New York, NY, <sup>2</sup>New York Presbyterian/ Brooklyn Methodist Hospital, New York, NY, <sup>3</sup>Medicine/Rheumatology, New York University School of Medicine/NYU Langone Health, New York, NY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** There is a dearth of epidemiological studies on Adult Onset Still's Disease (AOSD) and no consensus on its incidence and prevalence. Most studies report a majority of patients below the age of 35 [Sakata et al, Rheumatol Int 2016]. Our objective is to describe the demographics, complications and mortality of hospitalized patients with AOSD in USA.

**Methods:** Adult (>18 years) hospitalized patients between 2009 and 2013 from a nationwide inpatient sample (NIS) database were captured. AOSD patients were identified using the ICD-9 code 714.2 that was in use before 2015. Patients also coded for RA, SLE, Myositis, PMR, AS and Psoriatic Arthritis were excluded. This was done in order to capture patients with strictly AOSD. NIS is the largest all-payer inpatient care database in the United States with approximately 8 million hospitalizations each year. Discharge weights were used to enable nationwide estimates. Descriptive statistics were represented as means/medians for continuous and as frequencies (%) for categorical variables.

**Results:** Between 2009 and 2013, 5,820 AOSD patients were hospitalized (*Table 1*). AOSD patients had a mean age of 53.6 (SE – 0.6) years and 3817 (70.4%) were females. The racial/ethnic distribution showed that 56% white, 15% African American, 11.7% Hispanic and 3% Asian patients were affected. 37.6% of patients were hospitalized in urban teaching hospitals. The Mid-Atlantic census division had the highest number of patients (*Figure 1*). 100 (1.7%) developed Macrophage Activating Syndrome (MAS), 66 (1.1%) patients had disseminated intravascular coagulation (DIC) and 25(0.4%) had thrombotic thrombocytopenic purpura (TTP). The mean length of stay was 6.9 (SE- 0.3) days. There were 154 inpatient deaths in 5 years (mortality 2.6%) (*Table 2*). The patients who died during hospitalization were more likely to be older, mean age of 62.4 (SE- 3.1) years, women (69.2%) and/or Asian (13.9%).

**Conclusion:** In hospitalized US AOSD patients, the average age was higher than previously described in cross sectional studies. This may indicate an aging population with a higher number of comorbidities that prompt hospitalization. Mortality increased with age and was higher among women and Asians. To our knowledge, this is the largest epidemiological study of AOSD today in the USA.

# Continued Fracture Risk Reduction after 12 Months of Romosozumab Followed By Denosumab through 36 Months in the Extension of the Phase 3 Fracture Study in Postmenopausal Women with Osteoporosis

E Michael Lewiecki<sup>1</sup>, Rajani V Dinavahi<sup>2</sup>, Marise Lazaretti-Castro<sup>3</sup>, Peter R Ebeling<sup>4</sup>, J Adachi<sup>5</sup>, Akimitsu Miyauchi<sup>6</sup>, Evelien Gielen<sup>7</sup>, Cassandra E Milmont<sup>2</sup>, Cesar Libanati<sup>8</sup> and Andreas Grauer<sup>2</sup>, <sup>1</sup>New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, <sup>2</sup>Amgen Inc., Thousand Oaks, CA, <sup>3</sup>Federal University of São Paulo, São Paulo, Brazil, <sup>4</sup>Monash University, Melbourne, Australia, <sup>5</sup>McMaster University, Hamilton, ON, Canada, <sup>6</sup>Miyauchi Medical Center, Osaka, Japan, <sup>7</sup>University Hospitals Leuven, Leuven, Belgium, <sup>8</sup>UCB Pharma, Brussels, Belgium

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Romosozumab (Romo) is a monoclonal antibody that binds sclerostin with a dual effect, increasing bone formation and decreasing bone resorption. In the primary analysis of the multicenter, double-blind, FRActure study in postmenopausal women with osteoporosis (FRAME) (NCT01575834), women aged 55–90 (T-score  $\leq -2.5$  at total hip [TH] or femoral neck), Romo significantly reduced vertebral and clinical fracture risk vs placebo (Pbo) at 12 months (M).<sup>1</sup> A continued 75% new vertebral fracture and 33% clinical fracture relative risk reduction was observed at 24M in patients who initially received Romo, despite all patients receiving denosumab (DMAb) after 12M. BMD showed rapid and robust increases with Romo at the spine and hip, and these increases continued on transition to DMAb.<sup>1</sup>

**Methods:** In FRAME, patients received Pbo or Romo SC monthly for 12M, followed by open-label DMAb SC every 6M for 12M. Here, we report results through 36M after a further 12M of open-label DMAb. Key endpoints included patient incidence of new vertebral, clinical (nonvertebral plus symptomatic vertebral), and nonvertebral fracture, and BMD.

**Results:** Of the 7180 women enrolled, 5743 (80%) completed the 36M study (2892 Pbo followed by DMAb; 2851 Romo followed by DMAb). Through 36M, fracture risk reduction was observed for new vertebral, clinical, nonvertebral, and other predefined fracture endpoints in patients who received Romo followed by 24M of DMAb vs Pbo followed by 24M of DMAb (Table). At 36M, BMD continued to increase in the Romo followed by DMAb group to 18.1% (lumbar spine) and 9.4% (TH) (Figure). The mean differences in BMD in patients who received Romo in the first 12M compared with those initially on Pbo remained significant over the entire 36M ( $P < 0.001$ ). Adverse events were generally balanced between groups; no additional positively adjudicated cases of atypical femoral fracture or osteonecrosis of the jaw were reported since reporting the 24M data.<sup>1</sup>

**Conclusion:** In postmenopausal women with osteoporosis, Romo followed by DMAb was well tolerated and reduced new vertebral, clinical, and nonvertebral fracture risk vs Pbo followed by DMAb for 24M. BMD continued to increase in both groups. BMD in patients treated with Romo in the first 12M remained significantly higher than in those who initially received Pbo despite all patients receiving DMAb for 24M, underscoring the important foundational effect of Romo. The sequence of Romo followed by DMAb will be a promising treatment regimen for postmenopausal women with osteoporosis.

<sup>1</sup>Cosman *NEJM* 2016

**Table.** Summary of fracture endpoint results through month 36

Fracture Category	Incidence n/N1 (%)		RRR (%)	P Value
	Pbo/DMAb N = 3591	Romo/DMAb N = 3589		
New vertebral fracture	94/3327 (2.8)	32/3327 (1.0)	66	<0.001
Clinical fracture	196/3591 (5.5)	143/3589 (4.0)	27	0.004
Nonvertebral fracture	176/3591 (4.9)	139/3589 (3.9)	21	0.039
Major nonvertebral fracture	138/3591 (3.8)	100/3589 (2.8)	27	0.015
Major osteoporotic fracture	147/3591 (4.1)	103/3589 (2.9)	30	0.006
Multiple new or worsening vertebral fracture	20/3327 (0.6)	2/3327 (<0.1)	90	<0.001
New or worsening vertebral fracture	94/3327 (2.8)	33/3327 (1.0)	65	<0.001
Clinical new or worsening vertebral fracture	26/3591 (0.7)	5/3589 (0.1)	81	<0.001
Hip fracture	31/3591 (0.9)	18/3589 (0.5)	41	0.071

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Treatment with denosumab (DMAb) for 3 years significantly reduces the incidence of nonvertebral fractures (NVFx; Cummings *NEJM* 2009). While there are limited data describing the benefit/risk of long-term reduction in bone remodeling, recent findings show that subjects receiving DMAb for up to 7 years experience further decreases in NVFx risk (Ferrari *OI* 2015). To better characterize this observation, we evaluated the reproducibility of the 7-year findings in the FREEDOM Extension (EXT) cross-over (XO) group and assessed long-term fracture rates with 10 years of DMAb treatment in the EXT long-term (LT) group.

**Methods:** During FREEDOM, subjects were randomized to placebo or DMAb 60 mg every 6 months (Q6M) for 3 years. Subjects who missed  $\leq 1$  dose could enroll in the 7-year EXT, when all subjects were to receive open-label DMAb 60 mg Q6M; LT subjects could receive up to 10 years of DMAb and XO subjects could receive up to 7 years of DMAb. The NVFx rate in the first 3 years of DMAb was compared with 1) years 4-7 in LT and XO groups separately and combined, and 2) years 4-10 in the LT group. Adjusted rate ratios (RR, 95% confidence intervals [CIs]) between observational periods were computed by generalized estimating equation Poisson regression.

**Results:** Of 5,928 subjects eligible for the EXT, 4,550 (77%) enrolled (N = 2,343 LT; N = 2,207 XO). Baseline characteristics at FREEDOM and EXT and percent of subjects who completed the EXT were balanced between groups. The NVFx rate (95% CI) in the LT group was 1.98 (1.67-2.34) per 100 subject-years during the first 3 years of DMAb treatment and 1.54 (1.29-1.83) during years 4-7 (RR 0.79,  $p = 0.046$ ; Table). To confirm this observation, the NVFx rate in the XO group was 2.37 (1.97-2.84) during the first 3 years of DMAb treatment and 1.52 (1.24-1.87) during years 4-7 (RR 0.65,  $p = 0.002$ ). The NVFx rate in the combined LT + XO group was 2.15

(1.90-2.43) during the first 3 years and 1.53 (1.34-1.75) during years 4-7 (RR 0.72,  $p < 0.001$ ). The LT group showed a NVFx rate of 1.44 (1.24-1.66) during years 4-10 (RR 0.74,  $p = 0.008$ ). For 6,089 subjects exposed to DMAb in FREEDOM or the EXT, the rate of bone safety events (ONJ or AFF) was 4.2 per 10,000 subject-years.

**Conclusion:** Compared with the first 3 years of DMAb treatment, a longer duration of DMAb therapy was associated with a further decrease in NVFx rate through 10 years. Long-term reduction in bone remodeling is not only associated with continued increases in BMD (Bone ASBMR 2016), but also with a favorable benefit/risk profile for bone.

**Table. Comparison of Nonvertebral Fracture Rates up to 10 Years of Denosumab Treatment**

	First 3 Years of DMAb Treatment	Years 4-7 of DMAb Treatment	Years 4-10 of DMAb Treatment
<b>Long-term Subjects</b> (N = 2343)	140 Fractures	126 Fractures	184 Fractures
Fracture Rate (95% CI)	1.98 (1.67-2.34)	1.54 (1.29-1.83)	1.44 (1.24-1.66)
Rate Ratio (95% CI)	[Referent]	0.79 (0.62-1.00)	0.74 (0.60-0.93)
<i>p</i> -value		$p = 0.046$	$p = 0.008$
<b>Cross-over Subjects</b> (N = 1731)	123 Fractures	91 Fractures	--
Fracture Rate (95% CI)	2.37 (1.97-2.84)	1.52 (1.24-1.87)	--
Rate Ratio (95% CI)	[Referent]	0.65 (0.50-0.86)	--
<i>p</i> -value		$p = 0.002$	
<b>Long-term and Cross-over Subjects Combined</b> (N = 4074)	263 Fractures	217 Fractures	--
Fracture Rate (95% CI)	2.15 (1.90-2.43)	1.53 (1.34-1.75)	--
Rate Ratio (95% CI)	[Referent]	0.72 (0.61-0.86)	--
<i>p</i> -value		$p < 0.001$	

N = number of subjects who completed FREEDOM (ie, completed their 3-year visit and did not discontinue IP), did not miss >1 dose of IP in FREEDOM, and who enrolled in the Extension. In addition, cross-over subjects completed 3 years of the extension and did not miss >1 dose of DMAb during the first 3 years of the Extension. Fracture rates and rate ratios were obtained using generalized estimating equation Poisson models; fracture rates are per 100 subject-years. Rate ratios relative to the first 3 years of DMAb treatment were adjusted for age, total hip BMD T-score, weight, and history of nonvertebral fracture. In addition, the treatment group variable was included in the model for the combined analysis only.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Glucocorticoid (GC)-induced osteoporosis (GIOP) remains the most common secondary cause of osteoporosis. We previously demonstrated that denosumab (DMAb) significantly increased lumbar spine (LS) BMD more than risedronate (RIS) at 12 mos in GC-treated individuals. Here, we explored the effects of DMAb and RIS on LS BMD in predefined subgroups to determine whether these factors affected the treatment effect.

**Methods:** This was a phase 3, randomized, double-blind, double-dummy, active-controlled study to evaluate DMAb vs. RIS in GC-treated individuals for 24 mos. Eligible subjects were women and men  $\geq 18$  yrs receiving GC therapy at a dose  $\geq 7.5$  mg prednisone daily or its equivalent for  $\geq 3$  mos or  $< 3$  mos prior to screening (GC-continuing [GC-C] and GC-initiating [GC-I], respectively). All subjects  $< 50$  yrs were required to have a history of osteoporotic fracture. GC-C subjects  $\geq 50$  yrs were required to have a LS, total hip, or femoral neck T-score  $\leq -2.0$ ; or a T-score  $\leq -1.0$  with a history of osteoporotic fracture. Subjects were randomized 1:1 to SC DMAb 60 mg every 6 mos or oral RIS 5 mg daily for 24 mos. Subjects were to receive daily calcium ( $\geq 1000$  mg) and vitamin D ( $\geq 800$  IU). Effect of DMAb vs. RIS with respect to percentage change from baseline in LS BMD at 12 mos was determined in the GC-C and GC-I subpopulations and in 7 predefined subgroups that may influence treatment effect (gender, race, age group, baseline BMD T-score, geographic region, menopausal status, and baseline GC daily dose).

**Results:** A total of 795 subjects (505 GC-C and 290 GC-I) enrolled in the study. Baseline characteristics were balanced between treatment groups. As previously shown (Saag, ACR 2016), DMAb resulted in greater gains in LS BMD at 12 mos compared with RIS for both the GC-C and GC-I subpopulations (Table). Results from all of the subgroups consistently demonstrated a greater increase in LS BMD at mo 12 with DMAb compared with RIS. A significant quantitative interaction was observed only in the gender analysis in the GC-I subpopulation. However, non-significant qualitative interaction testing indicated that there was no evidence that the direction of the DMAb effect differed by gender in this subpopulation.

**Conclusion:** DMAb consistently increased BMD more than RIS at the LS at 12 mos across 7 different subgroups of GC-treated individuals. DMAb has the potential to become a better treatment option for patients newly initiating or continuing GC who are at increased risk for fracture.

**Table. Difference in Lumbar Spine BMD Percentage Change From Baseline at Month 12 (GC-C and GC-I Subpopulations)**

	GC-C Subpopulation		GC-I Subpopulation

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** As renal function may decline with age, it is important to understand the safety and efficacy of therapeutic agents for postmenopausal osteoporosis (PMO) and the effect these agents may have on intrinsic renal function in patients with age-related renal insufficiency. We assessed the safety and efficacy of denosumab among subjects with mild-to-moderate renal insufficiency who participated in the “Fracture REduction Evaluation of Denosumab in Osteoporosis every 6 Months” (FREEDOM) extension study.

**Methods:** Subjects were grouped based on baseline estimated glomerular filtration rate (eGFR) normalized to body surface area and calculated using the MDRD study equation. Change in eGFR from baseline to last on-study visit for each subject was assessed and summarized. The annualized rates of new vertebral fractures (VFX), non-VFX, and adverse events (AEs) were assessed for the subgroups of subjects with normal renal function (eGFR  $\geq 90$  mL/min), mild renal insufficiency (eGFR = 60-89 mL/min; CKD stage 2), or moderate renal insufficiency (eGFR = 30-59 mL/min; CKD stage 3). These outcomes were evaluated for the long-term arm (up to 10 years of denosumab treatment) and the crossover arm (up to 7 years of denosumab treatment).

**Results:** The majority of subjects in the long-term arm (1969/2343; 84%) and crossover arm (1781/2206; 81%) had mild or moderate renal insufficiency (CKD stage 2 or 3) prior to receiving denosumab. Few subjects ( $n = 4$  long-term arm;  $n = 5$  crossover arm) had an eGFR = 15-29 mL/min (CKD stage 4) at baseline, and none had CKD stage 5. Most subjects (1325/1969 [67%] long-term arm; 1216/1781 [68%] crossover arm) with baseline CKD stage 2 or 3 had relatively stable renal function, remaining within the same CKD subgroup at the last on-study visit. Less than 1% of subjects progressed from CKD stage 2 or 3 to CKD stage 4, and no subjects initiated renal replacement therapy. The incidence of new VFX was similar among subjects with normal eGFR or CKD stage 2 or 3 in both the long-term arm (Figure) and crossover arm (data not shown). The percentage of subjects reporting serious AEs was similar among the renal subgroups for both the long-term arm (54% normal GFR; 52% CKD stage 2; 57% CKD stage 3) and crossover arm (43% normal GFR; 42% CKD stage 2; 45% CKD stage 3).

**Conclusion:** The safety and efficacy of denosumab did not substantially differ among subjects with mild-to-moderate renal insufficiency. Furthermore, long-term exposure to denosumab does not appear to have a meaningful effect on renal function in women with PMO.

Figure. Annualized Incidence Rate of New VFX for the Long-Term Treatment Arm

VFX were diagnosed by protocol-specified spine x-rays. For the long-term treatment arm, spine x-rays were not performed yearly during the FREEDOM Extension Study. Thus, time is duplicated and rates of VFX are annualized to account for different spine x-ray schedules.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** In the ACTIVE phase III trial, postmenopausal women with osteoporosis were randomized 1:1:1 to abaloparatide (ABL; n=824), blinded placebo (PBO; n=821), or open-label teriparatide (n=818). During ACTIVE, ABL increased BMD and reduced vertebral, nonvertebral, clinical, and major osteoporotic fractures compared to PBO. Women who completed ABL or PBO treatment in ACTIVE were eligible to enroll in an extension study (ACTIVEExtend) to receive up to 24 months of open-label alendronate (ALN). The objectives of ACTIVEExtend were to provide additional safety information and to evaluate vertebral and nonvertebral fracture endpoints.

**Methods:** The ACTIVEExtend study enrolled 558 women from the original ABL group and 581 from the PBO group of the ACTIVE study (92% of women who completed ABL or PBO treatment in ACTIVE). Pre-specified endpoints, including vertebral, nonvertebral, clinical, and major osteoporotic fractures, were assessed over the 43-month period from ACTIVE baseline to the end of ACTIVEExtend (18 months of ABL or PBO treatment, 1 month for re-consent, and 24 months of ALN treatment). Nonvertebral fracture endpoints were assessed using the Kaplan-Meier (KM) method, proportional hazard model, and logrank test for patients enrolled in ACTIVEExtend and for the full ITT population randomized to ABL or PBO treatment in ACTIVE.

**Results:** During the 43-month period, 5.6% (n=32) of evaluable women sustained a new morphometric vertebral fracture in the PBO followed by ALN (PBO/ALN) group compared to 0.9% (n=5) in the ABL/ALN group, an 84% relative risk reduction (p<0.0001).

The **Table** shows the KM rates of nonvertebral fracture endpoints over 43 months from ACTIVE baseline through the end of ACTIVEExtend for both the ACTIVEExtend cohorts as well as the full ACTIVE ITT population.

The incidence of adverse events (AEs) including severe and serious AEs during ALN treatment period was similar for both study groups. The most common AEs were arthralgia, URI, and back pain. No cases of atypical femoral fracture or osteonecrosis of the jaw were reported.

**Conclusion:** In the ACTIVEExtend study, administration of ABL for 18 months followed by ALN for 24 months resulted in sustained vertebral and nonvertebral fracture reduction compared to PBO followed by ALN. In the full randomized ACTIVE ITT population, over 43 months, in the ABL + ABL/ALN groups, there was a significant reduction in the incidence of vertebral and non-vertebral fractures as well as hip fractures compared to the PBO + PBO/ALN groups.

**Table.** Kaplan-Meier rates of nonvertebral fracture endpoints during the 43-month analysis period (from ACTIVE baseline through the end of ACTIVEExtend).

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Hypophosphatasia (HPP) is a rare inherited disorder caused by mutations in *ALPL* (alkaline phosphatase liver type *ALPL* gene). Clinical presentation is variable and adult forms of the disease are usually milder than those affecting infants and children. It can be easily overlooked or misdiagnosed as chondrocalcinosis or osteoporosis, which can lead to erroneous therapeutic decisions. The primary objectives were to estimate the prevalence of patients with adult forms of HPP, to analyze their clinical and functional characteristics and to compare these findings between the patients with or without mutations. **Methods:** In this cross-sectional study, 1.536.711 ALP measurements from 386.356 patients were evaluated between 2009 and 2015. Those having at least two values below 35 IU/l and none above 45 IU/l constituted the study population, a total of 427 patients were included. Among them, 31 were excluded because of secondary hypophosphatasemia and 13 were lost on follow-up. 108 patients were contacted by phone to fulfill a questionnaire about clinical manifestations and health assessment. Patients were divided into two groups according to whether or not they presented a positive (HPP GT+) or negative (HPP GT-) genetic test. **Results:** Demographic and clinical characteristics are shown in Table 1. Of the 108 patients evaluated, genetic results were available for 85: 47% (40/85) were found to have pathogenic mutations, five previously unreported with the remaining having variants of unknown significance. We identified compound heterozygous mutations in an adult patient diagnosed with infantile HPP and the rest were in heterozygosity and associated with a less severe phenotype. Nine patients carried mutations associated with odontohypophosphatasia. A significantly higher proportion of patients in the HPP GT+ group presented bone pain (80 v 46.7%, p=0.001), dental abnormalities (35 v 13.3%, p=0.01), premature dental loss (17.5 v 2.2%, p=0.02), and stress fractures (10.2 v 0%, p=0.047). Furthermore, there was a non-significant trend to present orthopedic surgery, chondrocalcinosis and peripheral fractures in this group. No significant differences were found in muscle weakness, vertebral fractures,

calcific peri-arthritis, renal disease or necessity of analgesic medication. In terms of biochemical tests, an elevation of serum phosphate was found in the HPP GT+ group ( $4.1 \pm 0.8$  v  $3.6 \pm 0.6$ ,  $p=0.01$ ). No differences were observed in pain assessment (Visual Analogue Scale-VAS) and the health assessment questionnaire (HAQ-DI). **Conclusion:** The diagnosis of HPP can be difficult and is often missed or delayed, particularly in adults. The prevalence of HPP in patients with low ALP values is high and although clinical presentation is milder in adults, it often presents with bone pain, dental abnormalities, premature loss and fractures. These data should promote a proactive attitude towards detection of adult HPP.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Autoinflammatory Diseases

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Haploinsufficiency of A20 (HA20) is a newly discovered autoinflammatory disease caused by mutations in *TNFAIP3*. A20 is a protein with a crucial role in the negative regulation of inflammation and immunity. This study aimed at describing the clinical phenotypes and disease course of patients with HA20.

**Methods:** All cases from the initial publication were reviewed (1), additional cases were identified through the group who described the disease. Standardized data collection forms were used to collect demographic, clinical, laboratory, imaging and histologic features, disease course and treatment regimens.

**Results:** A total of 17 patients (82% female) from 7 families with a genetic diagnosis of HA20 were included. Behçet disease, followed by SLE and JIA were the most frequent diagnoses prior to confirmation of HA20. Clinical phenotypes were heterogeneous between and within families. First symptoms commonly occurred in early childhood, disease onset ranged from the 1<sup>st</sup> week of life to 29 years of age. Most common presenting symptoms were recurrent oral and/or genital ulcers in 59% of patients. During disease course, symptoms and disease severity varied highly. Recurrent painful oral, genital and/or gastrointestinal ulcers were the hallmark feature in all patients. Ulcers recurred frequently (monthly to every few months), isolated or in combination with other symptoms such as fever. Singular or multiple ulcers lasted 7-10 days and some healed with scarring. Other symptoms commonly observed during disease course are shown in Table 1. Most patients had a relapsing-remitting disease course, one patient died. Laboratory features included elevated acute phase reactants, especially during relapses, and the fluctuating presence of various autoantibodies such as antinuclear antibodies (4/10 patients tested) and anti-dsDNA (2/5 patients). Lupus anticoagulant was positive in 6/7, anticardiolipin antibodies in 2/5 patients tested. Tissue biopsy of different sites was performed in 9/17 patients (53%) and revealed non-specific chronic inflammation in 6, findings consistent with class V lupus nephritis in 1 and normal results in 2 patients. There was no standardized treatment: 15/17 (88%) patients received various immunosuppressive therapies, seven of them also biologic agents. More recently, therapeutic approaches were based on functional cytokine studies.

**Conclusion:** Early-onset recurrent oral, genital and/or gastrointestinal ulcers are the hallmark feature of HA20. Other signs and symptoms and disease course varied considerably with an overall high morbidity and mortality. Treatment regimens should be based on disease severity, cytokine inhibitors are often required to control relapses.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Autoinflammatory Diseases

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** JAK inhibitors reduce IFN-signaling ex vivo. We evaluated the PK and PD of the oral JAK1 and JAK2 inhibitor, baricitinib, from data collected in a compassionate use program in patients with Chronic Atypical Neutrophilic Dermatitis with Lipodystrophy and Elevated temperature (CANDLE) (1), STING Associated Vasculopathy with onset during Infancy (SAVI) (2), and other presumed IFN-driven AIDs with the goal to support a clinically derived dosing regimen for pediatric and young adult patients with CANDLE, SAVI, and other rare IFN-mediated diseases.

**Methods:** Baricitinib dosing was titrated based on clinical response and safety measures, with PK assessments following dose escalations in a compassionate use program (NCT01724580). Population pharmacokinetic (PopPK) modeling was applied to assess the PK profile of baricitinib. The effect of baricitinib treatment on STAT-1 phosphorylation, IFN-response gene expression (25-gene IFN score), and serum IP-10 levels, was assessed.

**Results:** A total of 18 patients received between 0.1 to 17 mg of baricitinib daily for up to 53 months. Weight and renal function significantly influenced PK parameters volume of distribution and clearance, respectively. The half-life of baricitinib, particularly in patients less than or equal to 40 kg, was considerably shorter than in adult patients with rheumatoid arthritis (RA), resulting in the need for dosing up to 4 times daily. On effective therapeutic doses (ranging from 6 to 13 mg/day), the daily drug exposure or mean area-under-the-concentration-versus-time curve over a 24-hour period (AUC<sub>24,SS</sub>) at the final PK assessment was 2388 nM\*hr, which is 1.83-fold higher than the mean exposures obtained in adult RA patients receiving baricitinib 4 mg once-daily in phase 3 studies (Table 1). IFN-alpha stimulated STAT-1 phosphorylation (pSTAT-1) in immune cells from CANDLE and SAVI patients negatively correlated with plasma baricitinib levels. A 25-gene IFN score and serum IP-10 levels, both markers of IFN signaling, significantly decrease with increased drug exposure. A subset of CANDLE patients normalized the 25-gene IFN score at AUC<sub>24,SS</sub> values between ~1500-2000 nM\*hr, but higher exposures were required in patients with more severe disease.

**Conclusion:** Baricitinib blocks IFN signaling in patients with CANDLE, SAVI, and other interferonopathies. PK/PD data suggest that pediatric patients with rare interferonopathies require treatment with higher daily doses and more frequent dosing versus adult RA patients. PopPK and PD data support an empirically derived dosing regimen based on body weight and estimated glomerular filtration rate (eGFR) to guide initial dosing of baricitinib in patients with rare interferonopathies.

**Funding:** The Intramural Research Program of NIH, NIAID, NIAMS, CC and Eli Lilly and Company.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Autoinflammatory Diseases

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Familial Mediterranean fever (FMF), Hyper IgD Syndrome (HIDS)/mevalonate kinase deficiency (MKD) and TNF-receptor associated periodic syndrome (TRAPS) are monogenic auto-inflammatory diseases caused by mutations in the *MEFV*, *MVK* and *TNFRSF1A* genes, respectively.<sup>1</sup> We analyzed responses to canakinumab (CAN), a fully human anti-IL-1 $\beta$  monoclonal antibody, in the pivotal, controlled CLUSTER trial in patients with colchicine-resistant FMF (crFMF), HIDS/MKD and TRAPS, according to *MEFV*, *MVK* and *TNFRSF1A* genes.

**Methods:** Inclusion criteria were: age  $\geq 2$  years with a baseline flare, fulfillment of Tel Hashomer criteria, at least one known *MEFV* exon 10 gene mutation,  $\geq 1$  documented flare/month on colchicine (crFMF); genetic or enzymatic diagnosis of HIDS/MKD and  $\geq 3$  documented flares in 6 months (HIDS/MKD); *TNFRSF1A* gene mutation and chronic or recurrent ( $>6$  flares/year) disease (TRAPS). The study design has been reported previously.<sup>2</sup> Overall, 63 crFMF, 72 HIDS/MKD, and 46 TRAPS patients were randomized 1:1, to receive CAN 150 mg or placebo q4w. Patients (pts) were eligible for blinded escape until Day 29 if the baseline flare did not resolve and received 1 add-on injection of CAN 150 mg. We analyzed the proportion of patients showing complete response (resolution of the baseline flare and no new flare until Week 16) from those pts initially randomized to CAN (31 crFMF, 37 HIDS/MKD, 22 TRAPS).

**Results:** The primary outcome of complete response was achieved by more pts randomized to CAN than to placebo ( $p < 0.001$  for each disease cohort).<sup>2</sup> Among the crFMF pts randomized to CAN, no significant difference in complete response were observed between 25 pts homozygous for M694V and six pts heterozygous for exon 10 mutations (Table). In HIDS/MKD pts, the proportion of CAN responders was higher in pts carrying at least one V377I mutation, compared to those carrying other mutations. Most of the TRAPS pts with classic pathogenic mutations achieved complete response.

**Table.** Proportion of patients randomized to canakinumab attaining the primary outcome at week 16 according to the genotypes

	Responders
	including 150 mg q4w to 300 mg q4w before Day 29
	n/M (%)
<b>crFMF</b>	
Patients with M694V/M694V	17/25 (68.0)
Patients heterozygous for M694V or M694I or M680I	5/6 (83.3)
<b>HIDS/MKD</b>	
Patients with atleast one V377I mutation	18/25 (72.0) <sup>1</sup>
Patients with mutations other than V377I and/or mutations classically associated to mevalonic aciduria	3/12 (25.0)
<b>TRAPS</b>	
Patients with classic pathogenic mutations ( N65I, H105P or T50M) including cysteine mutation	14/14 (100.0) <sup>2</sup>
Patients with P46L or R92Q or mutation	2/8 (25.0)

<sup>1</sup> p<0.05 versus patients with Non V377I/non V377I and patients with 1 mutation associated with mevalonic aciduria

<sup>2</sup> p<0.001 versus patients with R92Q or P46L

**Conclusion:** Homozygous and heterozygous patients with crFMF showed no difference in CAN responses. Among HIDS/MKD pts, the proportion of CAN responders was higher among those carrying at least one V377I mutation. Among TRAPS pts, all pts carrying mutations associated with classical TRAPS responded to CAN; the poor response rate of pts carrying R92Q or P46L variants shows that the disease associated with these variants differs from classic TRAPS, not only in clinical features, but also in the role that IL-1 $\beta$  production plays in the pathogenesis.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Autoinflammatory Diseases

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Systemic juvenile idiopathic arthritis is an autoinflammatory childhood arthritis with prominent innate immune activity. Macrophage activation syndrome is a severe and potentially fatal complication of sJIA. IL-18 is felt to play a key role in pathogenesis of sJIA and in particular MAS; possibly through IFN- $\gamma$  activation. IL-18 binding protein (IL-18BP) is an endogenous inhibitor that binds IL-18 tightly. However, clinical effects of blocking IL-18 in sJIA are still unknown.

**Objective:** To examine serum IL-18 levels in sJIA patients with regards to disease activity, MAS features, and other novel MAS biomarkers. Additionally, we report the use of recombinant IL-18 BP (rIL-18BP) in a patient with severe, refractory sJIA and MAS.

**Methods:** Serum samples obtained from 20 established sJIA patients. Total IL-18, CXCL9 and S100 protein were measured. In addition, in one patient serial free IL-18 levels were determined. We compared IL-18 levels in patients with active vs inactive disease as well as with history of MAS vs no MAS.

#### **Results:**

Serum IL-18 levels were higher in patients with active sJIA (mean  $52537 \text{ pg/ml} \pm 24442$ ,  $N=10$ ), but were still persistently elevated ( $2733 \pm 889$ ,  $N=10$ , upper limit of normal 540) in majority of patients with inactive disease ( $p=0.07$ ). Patients with history of MAS had significantly higher IL-18 levels ( $63170 \pm 29586$ ,  $N=8$ ) as compared to those without MAS history ( $3945 \pm 1708$ ,  $N=12$ ,  $p=0.03$ ). Only patients with fever had significantly higher IL-18 levels compared to their counter parts ( $P=0.03$ ), while arthritis and elevated ESR or CRP showed no difference ( $p=0.1$  and  $0.08$  respectively). We observed a weak but significant correlation between total IL-18 and CXCL9 (correlation coefficient of 0.4 ( $p=0.03$ )) but not for S100A8/A9. Given these findings by us and others, we utilized Tadekinig alfa (rhIL-18BP) in a 5 year old male with sJIA and persistently elevated free IL-18 levels. His course was complicated by recurrent MAS, failure of all prior biologic treatments, chronic high dose steroids with flare of sJIA and MAS upon attempts to wean steroids. He was started on rhIL-18BP 2mg/kg/dose subcutaneous every 48h in addition to continuous IL-1 inhibition attempting to control disease and prevent MAS. His initial total and free serum IL-18 levels were high at 117356 pg/ml and 46.8 pg/ml respectively. Although his total IL-18 remained elevated after start of rhIL-18BP, free IL-18 was undetectable. In addition, since initiation of Tadekinig alfa, steroid dose was decreased by more than 50% with increase in linear growth. While on Tadekinig alfa, he developed two MAS episodes (triggered by parainfluenza and acute gastroenteritis), but both were mild and easily controlled.

#### **Conclusion:**

Total serum IL-18 levels were elevated in the majority of sJIA patients regardless of disease activity, with higher levels in patients with active disease and those with history of MAS. This indicates that IL-18 might be an important driver of sJIA and MAS. Use of rIL-18 BP improved patient disease course with less frequent and easily controlled MAS episodes. This response raises optimism about use of rIL-18 BP in patients with IL-18 driven disease preventing life-threatening MAS.

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Autoinflammatory Diseases

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Systemic onset Juvenile Idiopathic Arthritis (sJIA) is a disease characterized by systemic inflammation in addition to arthritis and it's diagnosis currently still depends on the clinical ILAR classification criteria of 2003, with arthritis as a required criterium. A significant portion of patients however exhibit inflammatory symptoms weeks, sometimes even months before showing signs of any joint involvement, making the diagnosis of sJIA challenging for the treating clinician due to the broad differential diagnosis of systemic inflammation. Recent insights in the underlying auto-inflammatory disease mechanisms in sJIA have proposed several candidate biomarkers aiding in the diagnostic process, including interleukin-18 (IL-18), a member of the IL-1 family. Here, we compare peripheral blood serum levels of IL-18 in sJIA at disease onset with several important differential diagnoses.

Here, we tested the value of IL-18 as a diagnostic biomarker aiding in diagnosing sJIA and differentiating sJIA from children with systemic infection (INF), acute lymphatic leukaemia (ALL) and auto-immune conditions like vasculitis.

**Methods:** A cohort was assembled retrospectively consisting of patients with sJIA at disease onset (n=39, presenting initially with and without arthritis, ultimately diagnosed according to ILAR criteria), oligo- and polyarticular JIA (n=28), ALL (n=18), various auto-immune diseases including vasculitis (n=14) and healthy controls (HC, n=30). Clinical and laboratory data were extracted from patient files. Peripheral blood serum IL-18 measurements were performed using a multiplex immunoassay based on Luminex technology.

**Results:** Of all sJIA patients (n=39), 97.1% experienced fever on the day of sampling. A cutaneous rash was seen in 82.9% of patients and 40% of patients suffered from lymphadenopathy at disease onset. 68.6% of patients showed overt arthritis (median joint count 1.5, IQR 0-3) and 77.1% suffered from arthralgia (median joint count 2, IQR 1-4). At time of sampling, 57.1% of patients were being treated with NSAID.

IL-18 values (pg/ml, median, IQR) were evidently elevated in sJIA (5465, 1962-13428) and differed significantly from the levels measured in the other disease groups (oligo JIA (274, 172-378), poly JIA (177, 121-342), ALL (542, 315-869), other auto-immune diseases including vasculitis (64, 36-131)) and healthy controls (228, 175-327). The IL-18 levels in the serum of children with systemic infections are currently being measured.

We evaluated different cut-off values for IL-18 using an ROC curve. A value of 1500pg/ml performed best, with a specificity of 0.976 and a sensitivity of 0.800.

**Conclusion:** Here we show the potential value of IL-18 as a diagnostic biomarker for sJIA in the process of differential diagnosis. When sJIA is suspected in a patient with symptoms of systemic inflammation with or without arthritis, an IL-18 level of 1500 or higher seems clearly suggestive of sJIA. In patients with suspected sJIA but IL-18 levels below 1500, we recommend additional diagnostic modalities, including for example PET scan or bone marrow biopsy where indicated, to rule out other diagnoses like childhood malignancy.

## the Ferritin to ESR Ratio: A Simple Measure to Distinguish Macrophage Activation Syndrome from Systemic Arthritis Flare

Esraa M. A. Elouseily<sup>1,2</sup>, Francesca Minoia<sup>3</sup>, Timothy Beukelman<sup>2</sup>, Angelo Ravelli<sup>4</sup> and Randy Q. Cron<sup>2</sup>, <sup>1</sup>Pediatrics, Assiut University, Assiut, Egypt, <sup>2</sup>Pediatric Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>3</sup>Istituto Giannina Gaslini, Genoa, Italy, <sup>4</sup>University of Genova, Genova, Italy

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Autoinflammatory Diseases

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Macrophage activation syndrome (MAS) is a life threatening complication of systemic juvenile idiopathic arthritis (sJIA). As MAS often shares clinical and laboratory features with sJIA disease flare, it can be difficult to distinguish. For new sJIA diagnoses, MAS associated with sJIA (sJIA-MAS) also has to be discerned from infection. A previous study suggested a serum ferritin to erythrocyte sedimentation rate (ESR) ratio of  $>80$  could identify MAS among a small cohort of children with new-onset sJIA (J Rheumatol. 2013;40:1191). As a simple and quick tool, the ferritin to ESR ratio was explored to differentiate sJIA-MAS from active sJIA without MAS (flare), and from hospitalized febrile patients with systemic infections (SI).

### Methods:

Data was reviewed from a multinational study of patients with sJIA-MAS (n=362), sJIA flare (n=404), and SI (n=345) (Arthritis Rheumatol. 2014;66:3160). Patients without documented ESR or ferritin were excluded, leaving 262 sJIA-MAS, 262 sJIA flare, and 93 SI. Receiver operating characteristic curves for ferritin/ESR were constructed, and areas under the curves (AUC) were calculated with 95% confidence intervals. The Youden index was used to determine the optimal ferritin/ESR cut-point.

### Results:

For the ferritin/ESR ratio, comparing sJIA-MAS vs. sJIA flare, a cut off value of 21.5 had a sensitivity of 0.82 and specificity of 0.78 (AUC: 0.87 [0.84-0.90]). Comparing the ratio in sJIA-MAS cases vs. SI, a cut off value of 11.3 had a sensitivity of 0.91 and specificity of 0.93 (AUC: 0.95 [0.92-0.97]). Comparing sJIA-MAS cases vs. all others (sJIA flare & SI combined), a cut off value of 21.5 had a sensitivity of 0.82 and specificity of 0.83. (AUC: 0.89 [0.87-0.92]).

### Conclusion:

The ferritin/ESR ratio with a cut off value of 21.5 accurately distinguishes sJIA-MAS from sJIA flare. This discriminatory ratio performs comparably to and is less complicated than the recent MAS in sJIA classification criteria (Ann Rheum Dis. 2016;75:481). In distinguishing sJIA-MAS from hospitalized infection, a ferritin/ESR ratio of 11.3 was a powerful tool with high sensitivity and specificity. The ferritin/ESR ratio is a quick and simple measure for distinguishing sJIA-MAS from sJIA flare and infection. Future studies should explore the measure in different MAS cohorts.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects III: Obesity and Other Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Despite animal models, little is known about synovial tissue (ST) composition of overweight/obese Rheumatoid Arthritis patients. The aim of the study was to investigate the impact of high Body Mass Index (BMI) on ST inflammation of RA patients from disease onset to stable remission achievement.

**Methods:** One-hundred twenty five RA patients [(57 DMARDs naïve, 43 Methotrexate inadequate responder (MTX-IR) and 25 in stable clinical (DAS<1.6) and ultrasound remission under MTX+TNF-i respectively] were enrolled and underwent ST biopsy. At study entry RA patients were divided based on BMI (kg/m<sup>2</sup>) in normal weight (BMI<25), overweight (BMI>25) and obese (BMI>30) respectively. Immunohistochemistry for CD68<sup>+</sup>, CD21<sup>+</sup>, CD20<sup>+</sup> and CD3<sup>+</sup> cells was performed. Each naïve RA patient was treated according to the treat to target (T2T) strategy and followed for 12 months.

**Results:** Among the whole RA cohort, naïve RA were younger ( $53.5 \pm 15.4$  years) than MTX-IR RA ( $59.5 \pm 13.8$  years) and RA patients in stable remission ( $57.2 \pm 15.0$ ;  $p=0.02$  using ANOVA test), whereas there were no significant differences in terms of other demographic, immunological and clinical characteristics comparing naïve to treatment and MTX-IR RA patients. The overweight/obesity rate was comparable between the 3 subgroups [34(59.6%) naïve RA vs 25(58.2%) MTX-IR RA vs 14(56.0%) RA in stable remission were overweight/obese,  $p>0.05$ ]. However, naïve RA patients with BMI>30 kg/m<sup>2</sup> showed more likely follicular synovitis (78.6%) than normal weight naïve RA (39.1%;  $p=0.02$ ). Particularly, naïve RA with BMI>35kg/m<sup>2</sup> showed higher histological

scores for CD68<sup>+</sup> (p=0.03 and p=0.01 for lining and sublining), sublining CD20<sup>+</sup> (p=0.005), CD21<sup>+</sup> (p<0.001 and p=0.003 for lining and sublining) and sublining CD3<sup>+</sup> cells (p=0.003) than normal weight naïve RA. Moreover, BMI directly correlated with synovial aggregate grade (R=0.311; p=0.02) and histological scores of CD21<sup>+</sup> (R=0.344; p=0.01), CD20<sup>+</sup> (R=0.295; p=0.03) and CD3<sup>+</sup> cells (R=0.256; p=0.05) in naïve RA. Conversely, MTX-IR RA patients showed similar synovial inflammation degree based on different BMI categories. Regardless of the synovial inflammatory pattern (follicular vs diffuse), naïve overweight/obese RA patients showed a worse clinical response to T2T strategy compared to normal weight naïve RA at 6 and 12 months follow-up respectively (p<0.05 for both). Finally, despite RA in stable remission showed lower disease activity index (DAS) and inflammatory markers (ESR and CRP) than naïve RA (p<0.001 for each comparison), overweight/obese RA in stable remission showed higher degree of residual synovial inflammation in terms of sublining CD68<sup>+</sup> cells (p=0.001), lining CD20<sup>+</sup> cells (p=0.04), and lining and sublining CD3<sup>+</sup> cells (p=0.04 and p=0.05 respectively) compared to normal weight RA patients in stable remission.

**Conclusion:** Overweight and obesity are associated with higher degree of histologically proven synovitis in RA patients from the time of disease onset to the achievement of stable remission influencing the response rate to T2T regimen. These findings suggest that BMI control should be a key target during the whole disease course in RA patients.

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** We sought to identify biomarkers associated with erosive disease and bone loss in an inception rheumatoid arthritis (RA) cohort receiving treat-to-target combination DMARD therapy without oral corticosteroids. Markers of osteoclast activation (RANKL) and inhibition [osteoprotegerin (OPG)], osteoblast inhibition [Dickkopf-1 (Dkk-1), sclerostin (SOST), osteopontin (OPN)], were serially tested. The degree of inflammation (TNFα, IL6, IL1b, ACTH); adipose tissue activity (leptin, insulin) and markers of bone turnover/damage [osteocalcin (OC), parathyroid hormone (PTH), fibroblast growth factor-23 (FGF23)], were also tested.

**Methods:** Patients with early RA (< 1 year; fulfilling ACR 1987 and/or 2010 classification criteria) received triple therapy (methotrexate, sulfasalazine, hydroxychloroquine) escalated to achieve DAS28 remission. Serum biomarkers were analysed using human bone panel Luminex kits in patients (n=112) at 0, 6, 12 months, and controls (n=33). Responses to treatment were analysed by mixed model regression. Principal component analysis (PCA) was performed on the within-individual correlations between treatment responses. Erosion and femoral neck bone density (BMD) data were available at 0, 1, 2, 3 years, and were analysed using the biomarker

log(mean) as a predictor, adjusted for baseline covariates. Erosion progression was analysed using a zero inflated Poisson regression model.

**Results:** 53% of the cohort were anti-CCP (cyclic-citrullinated peptide) positive; mean (SD) age was 58(14) years, DAS28 5.5(1.3), 73% females, 60% current/past smokers and 20% had erosive disease. Table 1 summarises results. Nine biomarkers changed following therapy: IL6, TNFa, IL1b, RANKL levels were decreased, whereas leptin, SOST, PTH, OC, OPG were increased. IL6 and TNFa represented two different axes of the treatment response (PCA analysis, Figure 1). Anti-CCP positivity (p = 0.009), higher disease activity (p<0.001), OPN (p<0.001), and lower leptin levels (p=0.002) were associated with higher erosion counts, and older age (p=0.001) and higher TNFa (p = 0.022) were associated with a lower probability of remaining erosion-free. Higher TNFa (p=0.003) and lower leptin (p = 0.029) levels were associated with lower BMD.

**Conclusion:** Biomarkers from both treatment response axes (Figure 1) are associated with erosive disease and bone loss in RA. Low leptin (Component 1) may be a new biomarker for erosive disease and bone loss in RA, and its improvement with treatment was correlated with suppression of IL-6. OPN, which was invariant to treatment, may be a novel biomarker for active erosive disease.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects III: Obesity and Other Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** We evaluated the associations between MBDA score and age and between MBDA score and BMI in patients with rheumatoid arthritis (RA). These relationships may be important to patient management and clinical decision-making.

**Methods:** Data in this retrospective study are from CORRONA, a longitudinal RA registry comprising >625 US rheumatologists in 40 states. Patients included must have had an MBDA test performed between 1 month before to 7 days after a CORRONA visit, which was the source of patient characteristics and clinical data. MBDA scores were categorized as low (<30), moderate (30-44), and high (>44). Age was categorized by decade (<40, 40-49, 50-59, 60-69, 70-79, and >80 years). BMI was categorized as  $\leq 25$ , >25-30, >30-<35,  $\geq 35$  kg/m<sup>2</sup>. Associations between age or BMI and MBDA score were evaluated using the Chi-square and trend tests.

**Results:** 878 patients were included: 77.9% were female with mean age 60.9 years, mean weight of 177.6 lbs, and mean RA disease duration of 10.7 years. Approximately half of patients (54%) were using methotrexate or other conventional DMARDs (21%), and nearly half (45%) were using a biologic (Table 1). Mean MBDA score was 42.6, with 18% in the low, 38% moderate and 44% high MBDA categories. The distribution of patients across the low, moderate and high MBDA categories was significantly associated with age by decade (Figure 1) both by chi-square test ( $p=0.001$ ) and trend test ( $p<0.0001$ ). MBDA category was also significantly associated with BMI (chi-square  $p=0.001$ ; trend test  $p<0.0001$ ) (Table 1). Low MBDA scores were observed in 135 of 545 (24.8%) patients with BMI  $\leq 30$  and 6 of 142 (4.2%) with MBDA scores  $\geq 35$  (Table 1). Conversely, high MBDA scores were observed in 196 of 545 (36.0%) of patients with BMI  $\leq 30$  and in 91 of 142 (64.1%) with BMI  $\geq 35$  (Table 1).

**Conclusion:** Age and BMI were each found to have a significant association with the MBDA score. These data suggest inflammatory biomarkers in RA may be affected by non-RA related factors. The magnitude of these effects deserves further evaluation in order to provide guidance on the interpretation of MBDA scores in older patients and those with very high BMI ( $\geq 35$ ).

Table 1. Patient Characteristics Overall and According to MBDA Category

Characteristic at Time of Testing	Overall Population	Low MBDA	Moderate MBDA	High MBDA

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects III: Obesity and Other Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

An unfavorable body composition is often present in chronic arthritis patients. This unfavorable composition is a loss of muscle mass (sarcopenia), with a stable or increased (abdominal) fat mass (sarcopenic obesity). Since it is unknown when this unfavorable composition develops, we compared body composition in disease-modifying antirheumatic drugs (DMARD)-naïve early arthritis patients with non-arthritis controls and explored the association, in early arthritis patients, with disease activity and traditional cardiovascular risk factors.

### **Methods:**

317 consecutive early arthritis patients (84% rheumatoid arthritis according to 2010 ACR/EULAR criteria) and 1268 age-/gender-/ethnicity-matched non-arthritis controls underwent a Dual-energy X-ray absorptiometry scan to assess fat percentage, fat mass index, fat mass distribution and lean (muscle) mass index. Additionally, disease activity, acute phase proteins, lipid profile and blood pressure were evaluated.

### **Results:**

Sarcopenia and sarcopenic obesity was 4-5 times more common in early arthritis patients, with a significantly lower mean lean mass index (females 6% and males 7% lower,  $p<0.01$ ). Patients had more fat distributed to the trunk (females  $p<0.01$ , males  $p=0.07$ ) and females had a 4% higher mean fat mass index ( $p<0.01$ ). An unfavorable body composition was associated with a higher blood pressure and an atherogenic lipid profile. There was no relationship with disease activity, physical function or acute phase proteins.

### **Conclusion:**

Sarcopenia and sarcopenic obesity is 4-5 times more common in early arthritis patients, and is in early arthritis patients associated with a higher blood pressure and an atherogenic lipid profile. Therefore, cardiovascular risk is already increased at the clinical onset of arthritis making cardiovascular risk management necessary in early arthritis patients.

Figure. Prevalence of sarcopenia and sarcopenic obesity in early arthritis patients compared with non-arthritis controls.

Table. Body composition of early arthritis patients and non- arthritis controls stratified for gender.

	Mean values for control females (n=880)	Differences for female arthritis patients (n=220), B or OR and (CI) p-value	Mean values for control males (n=388)	Differences for male arthritis patients (n=97), B or OR and (CI) p-value

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects III: Obesity and Other Comorbidities

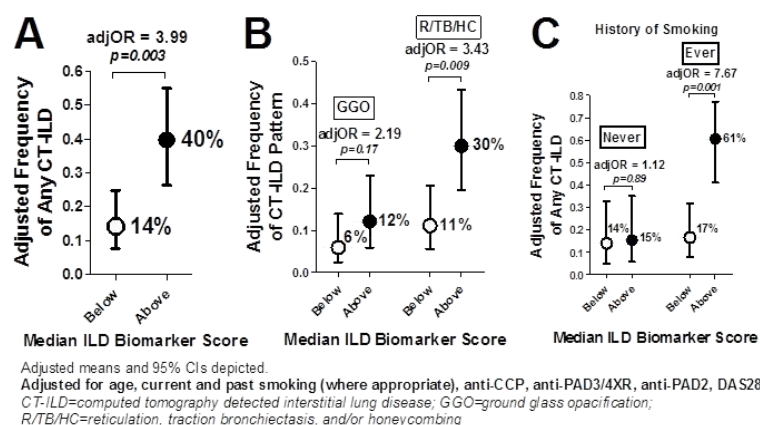

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The pathogenesis and prediction of RA-associated interstitial lung disease (ILD), an extra-articular manifestation with high morbidity and mortality, is poorly understood. We explored the associations of serum levels of inflammatory mediators with radiographic ILD in RA.

**Methods:** RA patients participating in a study of subclinical cardiovascular disease underwent computed tomography (CT) of the chest with interpretation by a pulmonary radiologist for CT-ILD features. A panel of 28 cytokines, chemokines, proteases, and other immune mediators was measured from serum using various optimized methods at the time of CT scanning. Generalized linear models were constructed to model the serum biomarkers associated with CT-ILD. A weighted biomarker score was constructed for each patient based on the biomarker level and its MV regression coefficient and modeled on CT-ILD, adjusting for pertinent confounders.

**Results:** A total of 156 RA patients [60% female, mean age 59 years, median RA duration=8 years, 76% seropositive for RF or anti-CCP, median DAS28=3.6] had both CT scanning and serum biomarkers measured. Any CT-ILD was found in 47 (30%) with a pattern of ground glass opacification (GGO) in 18 (44% of those with ILD) and reticulation, traction bronchiectasis, or honeycombing (R/TB/HC) in 23 (56% of those with ILD). In multivariable (MV) modeling, serum IL-10 and MMP-3 were significantly positively associated with any CT-ILD, while IL-6R was significantly inversely associated, even after adjusting for relevant confounders (listed in Fig). The association of the weighted biomarker score based on these 3 factors with ILD was not linear, as there was a markedly stronger association among patients with a score above the median (adjOR=3.99;  $p=0.003$ ), translating to an adjusted prevalence of ILD of 40% for those with a higher biomarker score vs. only 14% among those with a lower score (Fig A). The association of the biomarker score was stronger for predicting R/TB/HC than GGO (Fig B), and was only significant among those with a history of smoking (Fig C). The area under the receiver operator curve (AUC-ROC) for predicting any CT-ILD with the biomarker score alone was 0.654 (95%CI 0.573-0.734) which increased to 0.834 with the additional covariates added to the model. The AUC-ROC for the biomarker score alone for predicting CT-ILD among ever smokers was 0.726 (95%CI 0.632-0.819). Interestingly, those with a higher biomarker score did not differ from those with a lower score on demographics or RA disease activity, severity, or treatment characteristics.

**Conclusion:** Both IL-10 and MMP-3 have been implicated in lung fibrosis in non-RA diseases. These findings suggest further evaluation of IL-10, MMP-3, and IL-6R levels are merited to determine if these biomarkers have utility in predicting ILD in some patients with RA, particularly among those with a history of smoking.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects III: Obesity and Other Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Patients with rheumatoid arthritis (RA) have a higher incidence of cardiovascular disease (CVD) and prevalence of arterial stiffness (AS) due to chronic inflammation. AS in RA correlates not only with traditional CV risk factors, but also with current inflammation. Increased number and duration of flares over time and cumulative RA disease activity contribute to risk of CVD. While achieving Disease Activity Score in 28 joints (DAS) remission was associated with significant benefits in articular disease, its effect on co-morbidities such as CVD risk is uncertain. A more rigorous and sustained control of inflammation might be associated with a more favourable CV outcome in RA patients. The objective of this study was to investigate the effect of achieving sustained remission (DAS28 <2.6) on progression of arterial stiffness in early RA patients.

**Methods:** This is a post-hoc analysis of a prospective, randomized, controlled trial. 110 early RA patients received 1-year treatment based on a treat-to-target, tight-control protocol. Pulse wave velocity (PWV) and augmentation index (AIx) were measured at baseline and 12 months. Changes in AIx and PWV over 1-year was compared between patients who achieved sustained DAS remission (at 6, 9 and 12 months) (SDR group) and those who did not (non-SDR group).

**Results:** Sustained DAS remission was achieved in 37 (34%) patients. Baseline clinical characteristics and cardiovascular risk factors between the two groups were similar, except the symptom duration in the SDR group was significantly shorter. After 12 months, the change in PWV was significantly different between the two groups (SDR group: -67.0 [-153.0 to -43.5] cm/s vs non-SDR group: 14.0 [-68.0 to 14.5] cm/s,  $p=0.007$ ). The change in AIx was similar between the two groups. Using multivariate regression analysis, independent predictors for PWV reduction included achieving sustained DAS remission ( $\beta=-73$ , 95% CI: -150.1 to -9.1,  $p=0.027$ ) and a shorter symptom duration ( $\beta=6.3$ , 95% CI: 0.6 to 12.0,  $p=0.032$ ).

**Conclusion:** A significantly greater improvement in PWV was observed in patients who achieved sustained DAS remission compared to those who did not, indirectly supporting the notion that remission in RA confers diminished cardiovascular morbidity.

*We would like to acknowledge the Health and Medical Research Fund (HMRF) for funding support (HMRF Project No.10110071)*

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Upadacitinib (UPA) is an oral, selective JAK-1 inhibitor in development for the treatment of patients (pts) with moderate to severe rheumatoid arthritis (RA) and other immune-mediated diseases.

**Methods:** This Phase 3 study in pts with inadequate response (IR) to csDMARDs included a double-blind placebo (PBO)-controlled period (Period 1, reported here), during which pts were randomized 1:1:1 to receive once-daily (QD) extended-release formulation of UPA at 15 mg or 30 mg, or PBO for 12 weeks (wks). The primary efficacy endpoints were the proportion of pts who achieved an ACR20 response and the proportion who achieved DAS28-CRP low disease activity (LDA,  $\leq 3.2$ ) at Wk 12, using non-responder imputation (NRI).

## Results:

Of 661 pts who were randomized, all received study drug, and 618 (93.5%) completed Period 1. At baseline, demographics and disease characteristics were similar across arms. The study met all primary and key secondary endpoints with p values < 0.001 for both doses. At Wk 12, significantly more pts receiving UPA 15 mg and 30 mg QD vs PBO achieved an ACR20 response (63.8% and 66.2% vs 35.7%, p<.001), and DAS28-CRP LDA (48.4% and 47.9% vs 17.2%, p<.001) (**Table 1**). Onset of action was rapid with significantly more pts in both UPA arms achieving ACR20 at Wk 1 vs PBO. At Wk 12, significantly more pts met ACR50 and ACR70 in the UPA 15 mg (38% and 20.8%) and 30 mg QD arms (43.4% and 26.5%) vs PBO (14.9% and 5.9%). Significantly more patients receiving UPA 15 mg and 30 mg QD vs PBO achieved DAS28-CRP <2.6 (30.8% and 28.3% vs 10%, p<.001)] and CDAI-LDA (40.3% and 42% vs 19%, p<.001), and pts receiving UPA at both doses experienced significantly greater improvements in DAS28-CRP, HAQ-DI, morning stiffness and FACIT-F vs PBO (p<.001).

Adverse events (AEs) and serious AEs were numerically higher with UPA than PBO (**Table 2**). The overall incidence of infection was higher for UPA 15 mg and 30 mg QD vs PBO, but few were serious infections. There were 4 cases of herpes zoster/Varicella Zoster Virus infection (1 on PBO). Asymptomatic CPK elevations were only reported for patients on UPA. Two malignancies and 3 adjudicated cardiovascular events were reported. There were no deaths, cases of TB or GI perforations. Types and frequency of laboratory abnormalities were similar to findings in Phase 2 studies with UPA.

**Conclusion:** The efficacy of UPA at 15 mg and 30 mg QD vs PBO was demonstrated in this csDMARD-IR study population. The most notable responses were observed in the more stringent endpoints of LDA (by either DAS28-CRP or CDAI) and ACR70. The safety and tolerability profile was consistent with observations in the Phase 2 studies with UPA.

**Table 1. Efficacy Endpoints at Week 12<sup>#</sup>**

Endpoint	Placebo N=221	Upadacitinib 15 mg QD N=221	Upadacitinib 30 mg QD N=219
<b>Primary Endpoints</b>			
ACR20 (%)	35.7	63.8 ***	66.2 ***
DAS28-CRP LDA (%)	17.2	48.4 ***	47.9 ***
<b>Key Secondary Endpoints</b>			
ACR20 at Week 1 (%)	8.6	22.2 ***	28.3 ***
ACR50 (%)	14.9	38.0 ***	43.4 ***
ACR70 (%)	5.9	20.8 ***	26.5 ***
DAS28-CRP <2.6 (%)	10.0	30.8 ***	28.3 ***
CDAI LDA (%)	19.0	40.3 ***	42.0 ***
Δ DAS28-CRP	-1.02	-2.20 ***	-2.34 ***
Δ HAQ-DI	-0.25	-0.59 ***	-0.54 ***
Δ SF-36 PCS	3.03	7.58 ***	8.01 ***
Δ Morning Stiffness Duration (min.)	-34.27	-85.28 ***	-85.13 ***
Δ FACIT-F	2.96	7.91 ***	7.74 ***

Values are LS mean unless otherwise specified. Δ, Change from baseline; QD, once daily; ACR20/50/70, 20/50 or 70% improvement in ACR criteria; DAS28-CRP, 28-joint disease activity score using C-reactive protein; HAQ-DI, health assessment questionnaire disability index; SF-36 PCS, short form 36- physical component score; LDA, low disease activity; FACIT-F, functional assessment of chronic illness therapy-fatigue (FACIT-F)

<sup>#</sup>Results for binary endpoints are based on NRI analysis. Results for DAS28-CRP and HAQ-DI are based on Multiple Imputation analysis. Results for other continuous endpoints are based on MMRM (Mixed Effect Model Repeat Measurement) analysis.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Trials Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Although methotrexate (MTX) is often administered in combination with biologics for the treatment of rheumatoid arthritis (RA), it may be discontinued due to intolerance or to reduce medication burden. This study evaluated whether tocilizumab-monotherapy (TCZ-MONO) is non-inferior to TCZ + MTX in maintaining clinical response in patients who achieve low disease activity with TCZ + MTX in the COMP-ACT trial.

**Methods:** US patients with RA who were inadequate responders to MTX initially received MTX ( $\geq 15$  mg/week orally) plus TCZ 162 mg subcutaneous (SC) either weekly (patients  $\geq 100$  kg) or every 2 weeks (patients  $< 100$  kg). Patients who had not achieved low disease activity (DAS28  $\leq 3.2$ ) at week 12 could escalate from q2w to qw dosing. Patients who achieved DAS28-ESR  $\leq 3.2$  at week 24 were randomized 1:1 to receive TCZ-MONO or TCZ + MTX until week 52 (double-blind). The primary outcome measured was the comparison of mean change in DAS28-ESR score from weeks 24 to 40 between the TCZ-MONO and TCZ + MTX arms (non-inferiority margin of 0.6). Secondary outcomes included the proportion of patients achieving DAS28  $< 2.6$ , DAS28  $\leq 3.2$  and American College of Rheumatology 20%/50%/70% (ACR20/50/70) responses at weeks 40 and 52, and safety. Trial registration number: NCT01855789.

**Results:** Of 718 patients enrolled, 296 were randomized at week 24 (TCZ-MONO, n = 148; TCZ + MTX, n = 148). Early discontinuation in the randomized cohort occurred in 12.2% of patients in the TCZ-MONO group and 10.2% in the TCZ + MTX group. Baseline characteristics were balanced between treatment groups (mean age, 55.5 years; 74.8% female; mean RA duration, 6.8 years; mean DAS28-ESR, 6.3). At week 24, DAS28 scores were similar in both groups, but ACR responses were  $\approx 8\%$  to 11% lower in the TCZ-MONO group prior to MTX withdrawal (randomization). The mean change in DAS28 was similar between the randomized treatment groups (**Table 1**). For the primary efficacy analysis, the mean changes in DAS28 from weeks 24 to 40 were 0.46 and 0.14 in the TCZ-MONO and TCZ + MTX groups, respectively (95% CI, 0.045-0.592). This study met the primary endpoint by demonstrating that discontinuing MTX in TCZ responders was noninferior to continuing MTX. The safety of TCZ-SC in this study was consistent with the known safety profile, with no new safety signals observed (**Table 2**). The most common SAE was infection, occurring in 4.1% of patients. TCZ + MTX had greater frequency of AEs, SAEs and serious infections than TCZ-MONO.

**Conclusion:** These results demonstrate that patients receiving TCZ + MTX who achieve low disease activity can discontinue MTX and maintain disease control.

**Table 1. Efficacy of TCZ as Monotherapy and in Combination With MTX**

	<b>TCZ-MONO (n = 147)</b>	<b>TCZ + MTX (n = 147)</b>	<b>Difference (95% CI) (TCZ-MONO minus TCZ + MTX)</b>
<b>ADAS28-ESR, mean (SEM)*</b>

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Trials Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). We compared patient-reported outcomes (PROs) among patients receiving tofacitinib monotherapy, tofacitinib + methotrexate (MTX), and adalimumab (ADA) + MTX, in a head-to-head trial of patients with RA and inadequate responses to MTX (MTX-IR).

**Methods:** ORAL Strategy (NCT02187055) was a Phase 3b/4, 1-year, triple dummy, active randomized controlled trial (RCT). Patients were randomized 1:1:1 to receive tofacitinib 5 mg twice daily (BID; tofa mono), tofacitinib 5 mg BID + MTX (tofa+MTX) or subcutaneous ADA 40 mg every other week + MTX (ADA+MTX); MTX doses were 15–25 mg/wk. PROs (secondary endpoints in this RCT) assessed at Months (Mos) 6 and 12 included mean changes from baseline in: patient global assessment of disease activity (visual analog scale [VAS]); arthritis pain (VAS); Health Assessment Questionnaire-Disability Index (HAQ-DI); Short Form-36 Health Survey; EuroQol 5-dimensions Questionnaire; Work Productivity and Activity Impairment Questionnaire; Functional Assessment of Chronic Illness Therapy-Fatigue; and the proportion of patients reporting improvements in HAQ-DI  $\geq$  minimum clinically important difference (MCID; -0.22). Nominal p values were calculated with no adjustment for multiple comparisons.

**Results:** Among 1146 patients treated (tofa mono: n=384; tofa+MTX: n=376; ADA+MTX: n=386), baseline demographics and disease characteristics were comparable. At Mos 6 and 12, improvements in all PROs were similar for tofa+MTX and ADA+MTX (there were essentially no differences based on nominal p values) and numerically greater than with tofacitinib monotherapy (Table). Mean changes from baseline in HAQ-DI scores were similar in each treatment group at Mos 6 and 12; similar proportions reported improvements  $\geq$  MCID.

**Conclusion:** MTX-IR patients with RA reported PRO improvements with all 3 treatment regimens that were clinically meaningful, comparable for tofacitinib + MTX and adalimumab + MTX, and numerically higher with combination therapy than with tofacitinib monotherapy. Nominal p values should be interpreted with caution as they were not controlled for Type 1 error.

Table. LSM changes from baseline in patient-reported outcomes and proportion reporting improvements in HAQ-DI ≥MCID at Month 6 and Month 12 in ORAL Strategy.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Trials Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Fractalkine (CX3CL1/FKN) is a chemokine that regulates chemotaxis and adhesion of CX3C chemokine receptor 1 (CX3CR1)-expressing inflammatory cells. We previously presented the interim results of a 12-week treatment phase during phase 1/2, open-label, multiple ascending dose clinical trial of E6011, a novel humanized anti-FKN monoclonal antibody, in Japanese

active rheumatoid arthritis (RA) patients<sup>1</sup>. This is the first report of the 52-week safety, pharmacokinetics and efficacy of this clinical trial (NCT02196558).

**Methods:** Japanese patients with active RA who have shown inadequate responses or intolerance to methotrexate (MTX) or TNF inhibitor received E6011 at week 0, 1, 2, and then every 2 weeks for up to week 10 during the Treatment Phase. If no safety concerns were raised, subjects who showed a  $\geq 20\%$  improvement in both tender and swollen joint counts were given the option to receive 20 additional biweekly administrations at the same dose in the Extension Phase; 52 weeks in total.

**Results:** Twelve, 15, and 10 subjects were enrolled in the 100, 200, and 400 mg cohorts, respectively. Of these subjects, a total of 28 subjects were entered in the Extension Phase with 11, 11 and 6 subjects in the 100, 200, and 400 mg cohorts, respectively. As a result, repeated dose of E6011 was found safe and well tolerated during the Extension Phase. The incidence of AE, treatment-related AE and SAE was 83.8%, 48.6% and 13.5%, respectively. There were no severe AE or deaths, and no significant differences were observed in the incidence or severity of AE across the cohorts. After starting multiple dose administration of E6011, the steady state was achieved at week 2, and was held up to week 52. ACR 20 response rates at Week 12 and 52 (LOCF) were 75.0% and 58.3%, 80.0% and 73.3%, and 70.0% and 60.0% in the 100, 200, and 400 mg cohort respectively.

**Conclusion:** E6011 was safe and well tolerated, and demonstrated durable efficacy for 52-week in active RA with an inadequate response or intolerance to MTX or TNF inhibitor therapies. These results support the continuation of E6011 clinical study in phase 2 trials during which an optimal clinical dose and further safety and efficacy thresholds should be confirmed in a placebo controlled double-blinded manner.

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Trials Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** In patients (pts) with active rheumatoid arthritis (RA) despite DMARD treatment, sirukumab, a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, significantly reduced signs and symptoms and inhibited radiographic progression vs placebo at 52 wks in SIRROUND-D. Long-term efficacy (Wk 104) and safety (Wk 120) results are presented.

**Methods:** In this Phase 3 study, 1670 pts with moderate to severe active RA refractory to DMARDs ( $\geq 6/66$  swollen and  $\geq 6/68$  tender joints and minimum CRP  $\geq 8.0$  mg/L) were randomized (1:1:1) to SC sirukumab 50mg q4w, sirukumab 100mg q2w, or placebo q2w. Pts in the placebo group with  $<20\%$  improvement in swollen/tender joints at Wks 18 or 40 or still taking placebo at Wk 52 were re-randomized to sirukumab. Pts received blinded sirukumab in an active-controlled period from Wk 52 to 104, followed by a 16-wk safety phase to Wk 120. Efficacy endpoints, ACR20/50/70/90 responses, DAS28(CRP) remission, Short Form-36 (SF-36) Health Survey mental and physical component summary (MCS, PCS) scores, and HAQ-DI, were analyzed for pts on study treatment at Wk 52. Pts with data missing or who terminated study treatment were considered ACR20/50/70/90 non-responders and not achieving DAS28(CRP) remission. Missing MCS, PCS, and HAQ-DI scores were imputed using the non-missing score at Wk 52 or 76, whichever was the last prior visit. Treatment-emergent adverse events (AEs) and serious AEs were assessed for all pts who received  $\geq 1$  dose of study drug.

**Results:** Of 1114 pts originally randomized to sirukumab and 556 to placebo, 944 and 458 were receiving sirukumab at Wk 52 for a total of 1402 pts in efficacy analyses from Wk 52 to 104. Of pts originally randomized to sirukumab, the proportions of pts achieving ACR20/50/70/90 responses and DAS28(CRP) remission were consistent at Wks 52 and 104 (**Table**); among those who achieved ACR20 and ACR50 responses at Wk 52, 90% and 79%, respectively, in each sirukumab dose group maintained them at Wk 104. Improvements from baseline in MCS and PCS scores and HAQ-DI were comparable for each outcome at Wks 52 and 104. Among pts originally randomized to placebo who crossed over to sirukumab, Wk 104 responses were similar to those for pts originally randomized to sirukumab. Through Wk 120 for all pts in the study, incidences of AEs and serious AEs, respectively, were similar with sirukumab 50mg q4w (84.0% and 17.7%) and 100mg q2w (86.7% and 16.5%). The most common AEs with sirukumab ( $\geq 10\%$  in either group) were elevated liver enzymes, upper respiratory tract infection, nasopharyngitis, and injection site erythema. Serious AEs with the highest incidence were infections and infestations.

**Conclusion:** In this 2-year Phase 3 study of sirukumab in pts with active RA despite DMARDs, improvements in signs and symptoms of RA and health-related physical and emotional well-being were maintained. No new safety signals were reported through Wk 120.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Trials Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Filgotinib is an orally administered, selective inhibitor of Janus Kinase 1 (JAK1) currently in Phase 3 development for the treatment of rheumatoid arthritis (RA).

**Methods:** Previously, two 24-week Phase 2b studies were conducted in subjects with moderately to severely active RA (DARWIN 1, DARWIN 2; Ref 1, 2). Upon completing one of these studies, subjects could receive open-label filgotinib in the DARWIN 3 long-term follow-up study, given as 200 mg QD (100 mg QD for males in the US) or 100 mg BID. This report summarizes safety data from the first dose of filgotinib in DARWIN 1, 2 or 3 until the time that the last subject completed 84 weeks of filgotinib dosing. Efficacy is summarized for all subjects through Week 84 of DARWIN 3.

**Results:** Ninety percent of subjects (790 of 877) completed the Phase 2b studies, and 739 (84%) enrolled in DARWIN 3; 603 (82%) were female and the mean age was 53 years; 560 completed 84 weeks of filgotinib dosing. When the last subject completed 84 weeks in DARWIN 3, 520 (70.4%) subjects remained on study and 219 (29.6%) had discontinued. Most frequent reasons for discontinuation were positive/indeterminate QuantiFERON (10.3%; no active tuberculosis), protocol specified adverse event (AE) stopping rules (6.8%) and withdrawal of consent (5.8%). Cumulative patient years of exposure (PYE) were 1708 with a median time on study drug of 917 days (range 64 to 1329 days). A summary of safety events and laboratory abnormalities are summarized below. Based on ‘observed

case' analysis, 86%, 69%, and 47% of 560 subjects achieved ACR20/50/70, respectively, and 71% (386/543) achieved DAS28-CRP  $\leq 3.2$ .

**Conclusion:** Filgotinib long-term follow-up data demonstrate a favorable safety and durable efficacy profile in subjects with RA, consistent with prior reports.

**Table 1: Summary of Exposure and Safety Outcomes Per 100 PYE**

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Common endoplasmic reticulum (ER) aminopeptidase 1 (*ERAP1*) haplotypes influence the risk of developing axial spondyloarthritis (SpA) in HLA-B27-positive individuals, with loss-of-function and reduced expression conferring protection.

ERAP1 increases the pool of short peptides, which are thought to be optimal for binding to most HLA class I molecules. The role of B27 in this model is not clearly defined, although misfolding and expression of cell surface dimers have both been implicated, while CD8+ T cells appear to be dispensable. Thus, the role of peptides in axial SpA remains unclear. We investigated the interaction between ERAP1 and HLA-B27 in the rat model of SpA.

**Methods:** ERAP1-deficient rats generated by genome editing were crossed with disease prone HLA-B27 transgenic (B27 Tg) rats (33-3 Tg locus), and B7 Tg rats as controls. The phenotype was monitored for up to 6 months. Colitis was assessed by stool and histology scores. Bone marrow-derived macrophages (BMM) were used to examine HLA class I by FACS and immunoprecipitation with conformation-specific antibodies. ER stress was assessed by quantitative PCR.

**Results:** ERAP1 deficiency reduced the prevalence of arthritis and orchitis by 64% and 58%, respectively ( $p < 0.05$ ), in male B27 Tg rats. Clinical colitis was unaffected, while histology scores were slightly increased in rats lacking ERAP1 ( $p < 0.05$ ). Wild type and B7 Tg rats with and without ERAP1 remained healthy. BMM from B27 Tg ERAP1<sup>-/-</sup> rats exhibited a 12-fold increase in cell surface B27 displaying long peptides (MARB4), a 40% and 50% increase in free heavy chains (FHC) and FHC dimers of B27, respectively ( $p < 0.05$ ), while folded complexes (ME1) were increased 25% (NS). Immunoprecipitation of total cellular folded and FHC revealed that ERAP1 deficiency reduced the pool of B27 FHC by 30%, including a 50% reduction in misfolded disulfide-linked and BiP-bound dimers, and increased the ratio of folded/free HC by 56% ( $p < 0.05$  for each). In contrast, for B7, total cellular FHC were increased 3-fold ( $p < 0.05$ ) by ERAP1 deficiency, and the ratio of folded/free HC was reduced by 60% ( $p < 0.05$ ). B27 upregulation results in the accumulation of misfolded, disulfide-linked dimers. ERAP1-deficiency resulted in a significant reduction in the accumulation of misfolded and BiP-bound B27 during upregulation. This was associated with attenuated activation of the unfolded protein response, with upregulation of *Hsp5a* and *Ddit3* reduced by up to 50%, and attenuated *Xbp1* splicing ( $p < 0.05$ ).

**Conclusion:** ERAP1-deficiency protects B27 Tg line 33-3 rats from arthritis and orchitis, without reducing the severity of gut inflammation. We demonstrate that ERAP1 deficiency promotes B27 folding and reduces misfolding and its consequences, while increasing the expression of cell surface dimers and aberrant long peptide complexes. Interestingly, ERAP1 deficiency impairs the formation of folded B7 complexes, consistent with the importance of short peptides for most other HLA alleles. Together, these results suggest that the preservation of long peptides in the absence of ERAP1 may rescue B27 from misfolding, and identify ERAP1 as a potential target for therapeutic intervention in SpA.

## Impaired Control of Autoreactive T Cell Expansion Is Coupled with Type-1 Regulatory T Cell Deficiency in BALB/c ZAP70<sup>W163C</sup> Mutant Mice

M. Arifur Rahman<sup>1</sup>, Daphne Montizaan<sup>2</sup>, Zaied Ahmed Bhuyan<sup>3</sup>, Linda Rehaume<sup>3</sup> and Ranjeny Thomas<sup>4</sup>, <sup>1</sup>The University of Queensland Diamantina Institute, The University of Queensland, Brisbane, Australia, <sup>2</sup>The University of Groningen, Groningen, Netherlands, <sup>3</sup>The University of Queensland Diamantina Institute, Translational Research Institute, Brisbane, Australia, <sup>4</sup>Dendright Pty Ltd, Brisbane, Australia

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** In the context of reduced TCR signaling in the BALB/c ZAP70<sup>W163C</sup> mutant (SKG) mouse, development of arthritis, psoriasis-like skin inflammation and ileitis after intra-peritoneal injection of microbial  $\beta$ -glucan (curdlan), is characterized by an overwhelming increase of autoreactive CD4+ T cells in the peripheral organs. Inflammatory disease in SKG mice is observed within 7 days in the intervertebral joint of the upper tail, sacroiliac joints and Achilles tendon. However, curdlan-triggered arthritis in BALB/c mice is mild to absent. The mechanism by which systemic microbial-derived adjuvant promotes T-cell-mediated tissue inflammation in SKG mice but not in BALB/c mice is poorly understood. Here, we studied the role of peripheral Type-1 regulatory T (Tr1) cells in regulating activation and proliferation of autoreactive T cells in the genetically predisposed mice model of Spondyloarthritis (SpA).

**Methods:** To elucidate the dynamics of post-curdan CD4<sup>+</sup> T cell expansion and regulation, syngeneic luciferase-expressing CD4<sup>+</sup> T cells were magnetically sorted from SKG.luc<sup>+</sup> mice, adoptively transferred, and tracked *in vivo* post-curdan in SKG and BALB/c mice using *in vivo* bioluminescence imaging. Development of arthritis was monitored in these mice by measuring width of the ankles, wrists and footpads using calipers. Flow cytometry was used to phenotypically characterize effector and regulatory T cell populations. Tr1 cells were generated from naïve CD4<sup>+</sup> T cells *in vitro* using anti-CD3/anti-CD28 and IL-27.

**Results:** After transfer of SKG.luc<sup>+</sup> CD4<sup>+</sup> T cells to SKG hosts, bioluminescent images showed CD4<sup>+</sup> T cell accumulation in spleen and inguinal lymph nodes 3 days after curdalan, and traffic to joints, tail, and ears at day 7. Subsequently the signal continued to expand as arthritis increased in severity. After transfer of SKG.luc<sup>+</sup> CD4<sup>+</sup> T cells to BALB/c hosts, signals increased in spleen and inguinal lymph nodes 7 days after curdalan, but subsequently disappeared within 1 week. Furthermore, T cells expanding in SKG mice were significantly more likely to produce IL-17 than in BALB/c mice. In addition, the frequency of CD4<sup>+</sup>Foxp3<sup>+</sup> regulatory T (Treg) cells were significantly higher in SKG mice, both in naïve and after curdalan, compared to BALB/c mice. In contrast, the frequency of CD4<sup>+</sup>Foxp3-IL-10+IFN- $\gamma$  Tr1 regulatory T cells was significantly lower in SKG than BALB/c mice. Differentiation of naïve SKG or BALB/c CD4<sup>+</sup> T cells to Tr1 cells *in vitro* in the presence of IL-27 was comparable.

**Conclusion:** These data indicate that autoreactive Th17 cells first expand as a result of autoantigen presented in inguinal lymph nodes in SKG and BALB/c mice. While they are tightly regulated in BALB/c hosts, they expand and rapidly infiltrate joints and skin in SKG hosts, despite increased frequencies of Foxp3<sup>+</sup> Treg cells. In contrast, Tr1 cell differentiation is deficient in SKG mice *in vivo* but can be restored *in vitro* with addition of IL-27. The data suggest that while IL-27 signaling is intact in ZAP70<sup>W163C</sup> mutant T cells, IL-27 production is reduced and contributes to the lack of peripheral tolerance in SKG hosts.

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology

**Session Type:** ACR Concurrent Abstract Session

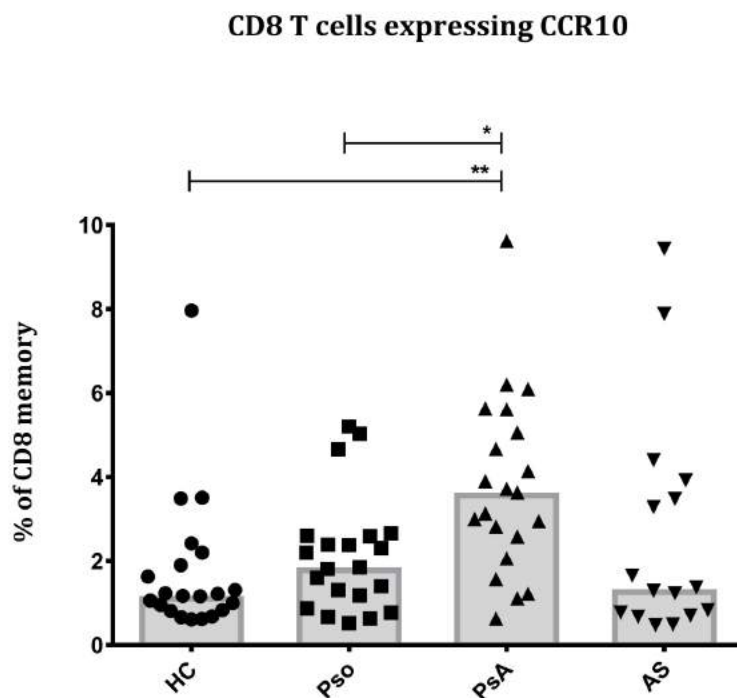

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Studies that compare the immune cell phenotype or function from patients with psoriatic arthritis (PsA) to patients with psoriasis limited to cutaneous involvement (Pso) are exceedingly scarce, particularly in patients without immune-modulatory medications that confound results. A head-to-head comparison of the immune cell composition in PsA and Pso is an essential step to understand the development of rheumatic manifestations in patients with psoriasis.

**Methods:** Blood samples and clinical parameters were collected from 23 healthy controls (HC), 21 patients with psoriasis in whom psoriatic arthritis was excluded by a rheumatologist (Pso), 21 patients with psoriatic arthritis meeting CASPAR criteria (PsA) and 16 patients with ankylosing spondylitis meeting ASAS criteria but without psoriasis (AS). The Pso and PsA cohorts were matched for age, gender, CRP, ESR, psoriasis duration and psoriasis skin severity. All patients were free from biological or conventional DMARD therapy. Using a highly standardized flow-cytometric protocol the peripheral blood mononuclear cells (PBMCs) from patients and controls underwent extensive extracellular and intracellular immunophenotyping capable of detecting over 110 different myeloid and lymphoid cell subsets / populations. In synovial fluid (SF) samples from patients with psoriatic arthritis the level of CCL27 was determined using Luminex Technology and the presence of CCR10<sup>+</sup> CD8 T cells was evaluated by flow-cytometry.

**Results:** The overall phenotype and immune cell composition showed remarkable overlap in PsA and Pso, with both cohorts characterized by an increase in the frequency of regulatory T cells, an increase in IL-17A & IL-22 co-producing CD4 and CD8 T cells, a decrease in plasmacytoid dendritic cells, and a decrease in mucosal-associated invariant T (MAIT)-like cells. Only one specific cell population differentiated the PsA from Pso cohort: CCR10+ CD8 T cells, being enriched in PsA as compared to Pso (Figure 1). These CCR10+ CD8 T cells had an effector memory status, were CXCR3-CCR6- and predominantly co-expressed CCR4. While the CCR4+ CD8 T cell frequencies were positively correlated to psoriasis skin severity, the CCR10+ CD8 T cell frequencies were not related to skin severity. Analysis of SF samples from psoriatic arthritis patients confirmed the presence of CCL27, the ligand for CCR10 receptor, and the expression of CCR10 on SF CD8 T cells.

**Conclusion:** A broad immunophenotyping strategy has revealed a potentially novel role for CD8 T cells expressing CCR10 to mediate the progression from cutaneous disease to joint disease in psoriatic arthritis. Further functional studies are needed to investigate the role these cells play in the different compartments affected by the disease.

**Figure 1:**  
The frequency of memory CD8 T cells that expressed CCR10 was elevated in PsA as compared to Pso ( $p<0.01$ ) and HC ( $p<0.001$ ), with a trend towards higher levels in PsA as compared to AS ( $p=0.05$ ). The frequency of memory CD8 T cells expressing CCR10 was also significantly higher in PsA compared to Pso and HC when calculated as % of total CD8 T cells (data not shown).

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** HLA-B27 has been hypothesized to alter gut microbiota and host-microbe interactions to promote spondyloarthritis (SpA). In HLA-B27 transgenic (HLA-B27 Tg) rats with experimental SpA, we have reported that HLA-B27 effects on gut microbiota diverge on different genetic backgrounds despite common patterns of immune dysregulation. Using an integrative analysis of gut microbiome and host transcriptome (inter-omics), we asked which microbes correlate with immune dysregulation on different genetic backgrounds, and whether they have similar functional implications.

**Methods:** We correlated the relative frequency of gut microbes determined by 16S rRNA gene sequencing, with host gene expression determined by RNAseq, for cecum and colon samples derived from 193 HLA-B27 Tg and wild type (WT) rats from Dark Agouti (DA), Lewis (LEW) and Fischer (F344) backgrounds. Microbes with a relative abundance of >0.1% in at least one sample, and genes with expression values (reads per kilobase million; RPKM) >1 in at least one sample and a coefficient of variation >0.8 across the dataset were included. Significant correlation coefficients (r) between the microbial relative frequency and transcript RPKM value (p<0.05) were used to identify relevant relationships. PICRUSt was used to predict microbial functions based on metagenomic profiles, which were then correlated with disease severity (histology scores), and significant metabolic perturbations associated with inflammation were identified (q<0.05 based on FDR-corrected p-values was used).

**Results:** Inter-omic analysis revealed several microbes associated with dysregulated cytokines driving inflammatory response pathways (e.g. IL-23, IL-17, IL-12, IFN- $\gamma$ , TNF) in both cecum and colon. While some microbes were differentially abundant on both LEW and F344 backgrounds (*Clostridium*, *Ruminococcus*), other differences were unique to either LEW (*Prevotella*, *Dehalobacterium*, *Sutterella*) or F344 (*Akkermansia*, *rc4-4*, *Coprococcus*, *Blautia*). Interestingly, many microbes that were strongly correlated with immune dysregulation (e.g. *Granulicatella*, *Staphylococcus* and members of family *Lachnospiraceae*) were not identified by analyzing effects of HLA-B27 alone. Metabolic functions of microbes determined by PICRUSt revealed involvement of similar pathways (e.g. fatty acid and glycan biosynthesis, steroid biosynthesis) in both HLA-B27 Tg LEW and HLA-B27 Tg F344 rats, despite dramatic differences in microbial dysbiosis.

**Conclusion:** Inter-omic analysis of gut microbiota and the host immune response in experimental SpA provides an unprecedented view of the complexity of microbial dysbiosis associated with HLA-B27 and gut inflammation. Perturbation of common metabolic pathways by divergent gut microbiota on different genetic backgrounds during inflammation suggests important functional overlaps that may be key to evoking similar host immune dysregulation. These results suggest that effects of HLA-B27 in the human population will depend on other genetic factors, and that microbial communities and their function may be more important than individual microbes.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Ankylosing spondylitis (AS) has a strong connection with gut inflammation: 10% of AS patients have inflammatory bowel disease (IBD) and 60% have subclinical ileal inflammation. Further, there is strong overlap between genetic susceptibility to IBD and to AS. This suggests that immune events in the gut may impact on joint inflammation but what directs cells in the gut-joint axis is undefined. For this reason, we are examining trafficking molecule expression on immune cells. Identification of trafficking molecules at a single-cell level has been possible through flow cytometry, but spectral overlap limits the number of parameters that can be tested simultaneously. Advances in single-cell mass cytometry have led to platforms such as Cytometry by Time-of-flight (CyTOF) that utilize stable lanthanide metal-conjugated antibodies bound to cells. This eliminates spectral overlap, thereby allowing for analysis of >30 parameters/cell. Our objectives are 1) to assess differential expression patterns of trafficking molecules between AS patients and controls, and 2) to generate tissue-specific cellular signatures.

**Methods:** Male subjects under 40 years of age fulfilling the mNY criteria were recruited from a longitudinal AS cohort. The following cells were surface stained using a 36-marker antibody panel: (i) Peripheral blood mononuclear cells (PBMC) from 30 AS patients, 20 healthy controls and 18 rheumatoid arthritis (RA) patients; (ii) Synovial fluid mononuclear cells (SFMC) from 10 AS patients and 4 RA patients. After acquiring on CyTOF2, data were subjected to SPADE and viSNE analysis for data visualization and Citrus and FlowJo for statistical analysis.

**Results:** Few differences were detected in PBMC trafficking marker expression between patients and controls. In AS SFMC mature CD4<sup>+</sup> T cells, CXCR4 was reduced but CCR2, CCR5 and CD49a median expression was elevated (FDR<0.05). Furthermore, CCR2, CCR5 and CD49a were co-expressed in CD4<sup>+</sup>CD45RO<sup>+</sup> cells. Mature CD8<sup>+</sup> T cells were increased in frequency in AS SFMC, with significant changes in their phenotype:  $\beta$ 7<sup>+</sup>, CD103<sup>+</sup>, CD18<sup>+</sup>, CD29<sup>+</sup> and CD49a<sup>+</sup> integrin expression was increased in CD8<sup>+</sup>CD45RO<sup>+</sup> cells in AS SFMC vs paired AS PBMC (mean 9.05% vs 0.97%, p=0.0061), whereas similar comparison of RA SFMC vs RA PBMC showed less significant differences (mean 4.5% vs 0.63%, p=0.0578).

**Conclusion:** Analysis using mass cytometry revealed disease- and tissue-specific alterations in trafficking marker expression on AS patient T cells. We identified a novel integrin manifesting CD8<sup>+</sup> mature T cell subset (CD49a<sup>+</sup>CD103<sup>+</sup> $\beta$ 7<sup>+</sup>CD29<sup>+</sup>CD18<sup>+</sup>) with some specificity for AS. Further experiments to determine similar expression profile on gut tissue biopsies from AS patients, as well as murine gut and joint tissues from experimental AS, are in progress to examine the arthritogenic potential of these cells. CyTOF represents an innovative new technology which can provide new insights into the immune mechanisms linking inflammation in the AS gut and the joint. These insights could lay the groundwork for innovative immunotherapy for AS in the future.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

An intriguing link exists between gut and joint inflammation in spondyloarthritis (SpA). About 50% of patients has subclinical (eg. microscopic) gut inflammation, which represents a risk factor for development of Crohn's disease, sacroiliac inflammation and evolution in to Ankylosing Spondylitis. However, the underlying mechanisms are still relatively poorly understood. Our goal was to examine the relationship between TNF, microscopic gut inflammation and axial inflammation using human samples and a novel mouse model. We speculated that TNF in the gut represents an important risk factor for disease severity and progression in SpA.

### **Methods:**

We examined in situ expression of TNF, TNFR1 and TNFR2 using triple in situ hybridisation in gut biopsies of human SpA patients. Furthermore, we generated intestinal specific human TNF transgenic mice, in which hTNF is under control of a rat iFABP (fatty acid binding protein) promoter, generating a mouse-model over-expressing human TNF in the ileum. These mice, together with wild type littermates, were evaluated for the development of arthritis up until the age of 13 weeks after which they were euthanized and ankle and sacroiliac joints as well as ileum were processed for histology.

### **Results:**

There was a marked upregulation of TNF in inflamed versus non- inflamed gut biopsies of human SpA patients. We also noted a predominant upregulation of TNFR1 on intestinal epithelium and TNFR2 in lamina propria respectively. Of interest, IL-17 and IL-23 were also markedly increased while IL-22 was most abundant in chronically inflamed samples. In line with this, we found that patients with gut inflammation had a higher need for anti-TNF therapy and their degree of clinical response after anti-TNF was also markedly higher. Our transgenic mice exhibited a runt phenotype and hallmarks of inflammatory bowel disease, including increased intestinal permeability and inflammation compared to their wild-type littermates. While in peripheral joints no clear signs of arthritis were observed, the sacroiliac joints in transgenic mice, by contrast, showed marked signs of inflammation as well as bone erosion and destruction.

### **Conclusion:**

These data propose a new paradigm that gut-derived TNF is sufficient to trigger sacroiliitis and provide an alternate explanation on the relationship between gut inflammation, evolution to inflammatory bowel disease and axial inflammation in SpA.

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Biomarkers

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Interferon gamma (IFN-G) is critical cytokine for defense against intracellular pathogens; it is also involved in the pathogenesis of systemic lupus erythematosus (SLE). The IFN-G release assay (IGRA) estimates probability of latent tuberculosis (TB) infection (LTBI) based on whole-blood IFN-G release upon exposure to TB antigen, mitogen (IGRA-MT) or no stimulation (IGRA-NL). We previously observed that elevated IGRA-NL values (representing spontaneous IFN-G release, SIR) are associated with a limited set of diagnoses, including LTBI and SLE. Here, we examine the clinical and immunologic correlates of SIR in a cohort of SLE patients undergoing IGRA testing. We hypothesize that SIR is associated with active SLE and select disease manifestations.

**Methods:** We queried a clinical data repository (2010–2016) from a U.S. academic medical center for subjects with a diagnosis of SLE, a positive ANA and at least one IGRA result (n=167). SLE classification by SLICC criteria was confirmed by chart review (n=99). Of these 99, 53 had sufficient data to calculate a complete SELENA-SLEDAI (SLEDAI) score at the time of IGRA testing. We then assessed relationships between IGRA-NL, IGRA-NL/MT ratios, SLEDAI and related clinical/immunologic variables using univariate (Fisher's Exact, Kruskal-Wallis, Mann Whitney tests) and multivariate (linear regression) analyses.

**Results:** The cohort of 99 patients was 85% female, 71% non-white, with a median (range) age of 36 years (18–84) and disease duration of 3.9 years (0–39). Median (range) for SLEDAI (n = 53) was 12 (0–33). Compared to subjects without SLEDAI scores, subjects with SLEDAI scores had significantly shorter disease duration and higher IGRA-NL/MT ratios. Linear regression analysis revealed a significant positive association between IGRA-NL/MT ratios and SLEDAI ( $r = 0.53$ ,  $p < 0.0001$ ) that was stronger than that of IGRA-NL ( $r = 0.21$ ,  $p = 0.0616$ ) or anti-dsDNA ( $r = 0.32$ ,  $p = 0.0107$ ). The linear association between IGRA-NL/MT and SLEDAI remained significant ( $p = 0.031$ ) after controlling for all non-SLEDAI variables significantly associated with upper-half IGRA-NL/MT ratios (history of APLA/lupus inhibitor, low complement, Coombs' positivity, current prednisone 5-20 mg/d, current/past hydroxychloroquine use). SLEDAI features positively associated with upper-half IGRA-NL/MT were proteinuria ( $p = 0.0028$ ), rash ( $p = 0.0024$ ), low complement ( $p = 0.0394$ ) and fever ( $p = 0.0030$ ). Using a 50<sup>th</sup> percentile cutoff, IGRA-NL/MT could predict active disease (SLEDAI > 6) with a sensitivity of 77.5% and a specificity of 61.5% ( $p = 0.0128$ ), which was superior to either anti-dsDNA or IGRA-NL (neither statistically significant).

**Conclusion:** In our cohort of SLE patients undergoing IGRA testing, IGRA-NL/MT ratios correlated with and predicted active disease better than either anti-dsDNA or IGRA-NL. Correlation between IGRA-NL/MT and select disease features supports a pathogenic role for IFN-G activation in renal, dermatologic and systemic manifestations of SLE. Thus, the IGRA test may represent a readily available assay with unique biomarker potential in SLE.

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Biomarkers

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:**

SLE is an IFN-I-mediated disease with dysregulated handling of self-nuclear antigens triggering anti-viral immune mechanisms. The level of IFN-I activity appears to stratify for disease severity and therapy response but existing studies using IFN-stimulated gene (ISG) expression signatures weakly correlates with clinical features. ISG expression influenced by cellular composition of sample and individual cell responses. CD317/Tetherin is a cell surface protein encoded by the interferon-stimulated gene *BST2*. So we aimed to develop a fast, convenient assay to measure cell-specific IFN-I suitable for analysis of large cohorts of patients using flow cytometry correlates with disease activity and predicts clinical flare.

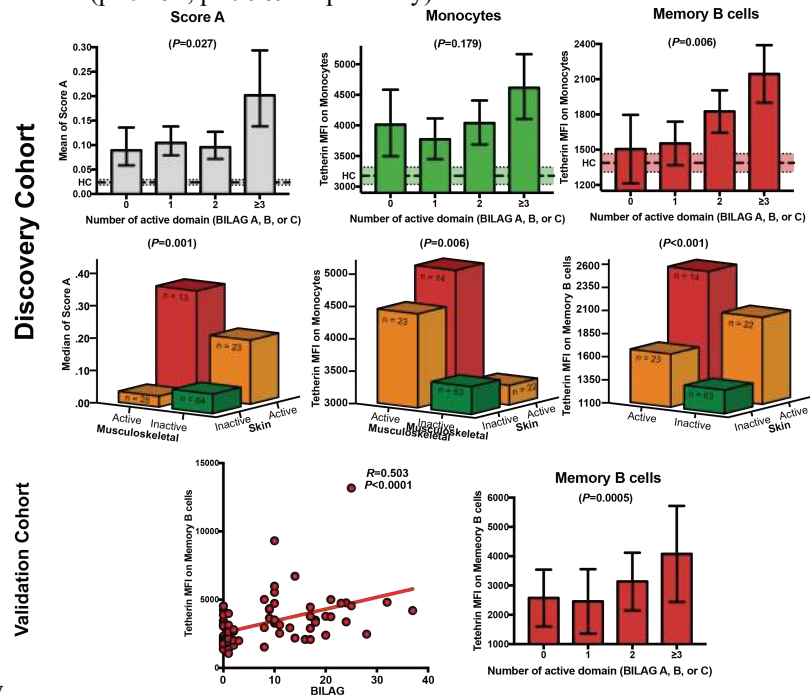

**Methods:**

We developed a flow cytometric assay for cell-specific IFN-I response using tetherin, as well as ISG gene expression score derived from 18 well known. FACS sorting was used to evaluate cell-specific interferon response by both assays. IFN-I biomarkers were then evaluated against diagnosis, disease activity in a discovery cohort of 156 SLE patients with 30 ACPA+ANA- RA (DAS28>3.2) and 22 healthy controls. A longitudinal validation cohort of 80 patients with monitoring of tetherin in an independent routine diagnostic laboratory was recruited to confirm findings and test prediction of flares.

**Results:**

*In vitro*, ISG expression score predominantly reflected monocyte signal and many ISGs responded to both IFN-a and IFN-g. Flow cytometric analysis of tetherin (BST2) accurately determined cell-specific response to IFN-I in a dose-responsive manner and was more selective for IFN-I.

In the discovery cohort, B cell tetherin was associated with diagnosis and clinical disease activity equally or more closely than gene expression score or monocyte tetherin. Memory B cell tetherin was increased with renal (p=0.005) or haematological (p=0.005) activity with no differences in ISG score for these domains (p=0.152, p=0.989 respectively). The validation cohort confirmed the relationship

between B cell tetherin and disease activity

and also, showed that higher B cell tetherin predicted increased risk of future clinical flares. (Fig 2)

#### Conclusion:

The B cell response to IFN-I predicts clinical features of SLE, and tetherin provides a convenient, validated method to analyse this pathway in routine clinical practice. Tetherin is also a tool for future research in cell-specific IFN-I response in a broad spectrum of other diseases.

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Biomarkers

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** A major unmet need in SLE is the identification of a biomarker that consistently tracks with disease activity. One current approach is measuring complement activation by evaluating consumption of serum C3 and C4. However, since they are acute phase reactants, interpretation of these levels is challenging as serum levels may not decrease until late in a disease flare. iC3b is a proteolytically derived molecule of C3b, and increases with complement activation. iC3b/C3 ratio measures complement consumption relative to production, which may provide for a more accurate assessment of complement activation. We hypothesize that blood iC3b and iC3b/C3 levels will provide a more specific and reliable marker of complement activation and disease activity in SLE.

**Methods:** 159 adult SLE patients were enrolled in this prospective, longitudinal, observational study. 83 patients with 3-7 study visits were used for this longitudinal analysis. C3 and C4 were measured by nephelometry; iC3b by a lateral flow assay using an investigational medical device. SLE disease activity was measured using the SLEDAI 2K Responder Index-50 instrument. Statistical analyses were performed using SAS v9.4. Multilevel regression models examined associations for SLE disease activity. Ordinal logistic

regression models with generalized estimating equation modeling (GEE) examined associations for clinically meaningful changes since the outcome variable is ordinal. Odds ratios and 95% confidence intervals were estimated using Proc GLIMMIX and Proc GENMOD. Receiver operator curves and areas under the curve were performed using iC3b/C3 ratios, C3, C4, and dsDNA levels.

**Results:** Blood levels of iC3b, C3, iC3b/C3 ratio, C4, dsDNA, and prednisone use each correlated with SLE disease activity (Figure 1A). Multilevel multiple logistic regression analysis revealed only iC3b/C3 ratio, dsDNA levels, and prednisone use were significant predictors of disease activity (Figure 1B). To determine whether iC3b/C3 ratio can predict clinically meaningful changes in SLE disease activity, we evaluated the interpatient longitudinal associations between clinical deterioration, stability, and improvement and iC3b/C3 ratios. Only iC3b/C3 ratio significantly predicted clinically meaningful changes in disease activity in multivariate regression analysis. iC3b/C3 ratio also discriminated for active versus inactive disease (AUC=0.657, 95% CI=0.604-0.710).

**Conclusion:** In this prospective, longitudinal study, blood iC3b/C3 ratios are more strongly associated with active SLE disease compared to other traditional biomarkers of disease activity. Likewise, iC3b/C3 ratio is predictive of clinical meaningful changes in SLE disease activity. Finally, iC3b/C3 ratio discriminated for active SLE. These data suggest iC3b/C3 ratio may provide clinical utility as a biomarker for SLE disease activity.

**Figure 1: iC3b/C3 ratio correlated with active SLE disease**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Biomarkers

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** We have developed the iCHIP<sup>1,2</sup> to profile repertoires of serum autoantibodies. The first iCHIP application was the SLE-key RuleOut test<sup>3,4</sup>, to rule out a diagnosis of SLE with 94% sensitivity, 75% specificity, and 93% negative predictive value (NPV). In current study we asked whether the SLE-key test results are stable over time, and whether the test results can be used as a serologic signature of lupus which is independent of treatment and/or disease activity.

**Methods:** We determined the SLE-key scores for 197 paired serum samples submitted by 4 independent academic lupus centers. SLEDAI scores at the time of blood draw ranged from 0 to 22. The mean absolute SLEDAI difference between the paired samples was  $6.2 \pm 3.4$ ; 60% of pairs manifested a decrease in SLEDAI score at time point 2 (T2) relative to time point 1 (T1), and 40% showed an increase. T2-T1 time interval ranged from several weeks to 12 years (mean  $1.5 \pm 2.3$  years). The sensitivity of the SLE-key score between T1 and T2 to technical variability was determined independently. Subjects exhibiting score changes of more than 2SD were defined as “changers”, and within 2SD were classified as “stable” (Figure 1).

**Results:** The SLE-Key test identifies an SLE-specific serologic signature based on a profile of IgG and IgM autoantibodies to a combination of two nucleic acids (complex ssDNA and a defined oligonucleotide) and three nuclear antigens (u1snRNP, Smith, and histone). This signature was found to be stable (within 95% confidence) in 71.6% (141/197) of subjects. Moreover, 84% (47/56) of the “changers” had no resultant change in their SLE-key RuleOut status (i.e. “Ruled Out” or “Not Ruled Out”). Of the remaining 9 patients, 7 changed from Not Ruled Out at T1 to Ruled Out at T2, and 2 subjects changed from SLE Ruled Out at T1 to Not Ruled Out at T2. The stability of the signature was independent of age, race, and time post diagnosis or between sampling. Furthermore, the signature was also independent of SLEDAI score.

**Conclusion:** The SLE-key RuleOut test detects a serologic signature which remains stable, irrespective of time or SLEDAI in >70% of subjects. This signature may therefore be helpful clinically to confirm a historical diagnosis of SLE in patients that currently have low disease activity. Even among the “changers”, the large majority had no change in their SLE-key RuleOut status. The stability of this signature over time indicates that it functions as a biomarker of SLE, but may not reflect disease activity. We are currently studying the possible reasons for a changing score in the remaining 30% of subjects, and the differences between the “changers” and the “stable” subjects.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Biomarkers

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

About 15-30% of Lupus Nephritis (LN) patients do not respond to first-line immunosuppressive therapy. P-glycoprotein (P-gp) mediated efflux of corticosteroids (CS) may contribute to the treatment unresponsiveness. Tacrolimus is a P-gp inhibitor and hence, may overcome this resistance. We, therefore, aimed to study the response to Tacrolimus, along with the expression and function of P-gp on peripheral blood lymphocytes (PBL) in patients with refractory and relapsing proliferative (ISN/RPS Class III/IV) Lupus Nephritis.

### **Methods:**

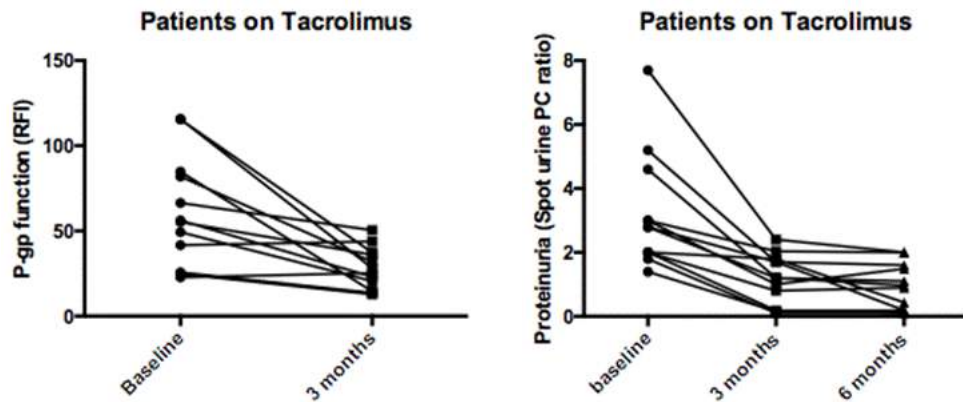

We enrolled 12 refractory/relapsing LN patients (6 patients refractory to CYC based regimens and 6 patients with renal relapse) and treated them with CS + Tacrolimus (2-3 mg/day) for 6 months. Expression and function of P-gp on PBL was measured by flow cytometry (as relative fluorescence index, RFI) before and 3 months after Tacrolimus therapy. P-gp expression and function, before Tacrolimus therapy, was also compared with that in 16 LN patients who were naive to immunosuppressive drugs and CS (treatment-naive LN patients). Renal response was assessed according to ACR response criteria after 3 and 6 months of Tacrolimus therapy. Renal disease activity was measured by renal SLEDAI (rSLEDAI). The data (median and IQR) was analysed using non-parametric tests.

### **Results:**

P-gp expression and function on PBL of refractory/relapsing LN patients before Tacrolimus therapy was significantly increased as compared to the treatment-naive LN patients ( $p < 0.01$  and  $p < 0.001$  respectively). 8 out of 12 refractory/relapsing LN patients achieved renal response (5 partial response, PR and 3 complete response, CR) as early as 3 months after start of Tacrolimus therapy, and 11 patients achieved renal response (7 PR and 4 CR) at 6 months from start of Tacrolimus therapy. Proteinuria decreased from median urine protein creatinine ratio (UPCR) of 2.80 (2.00-3.40) at baseline to 1.20 (0.66-1.73) at 3 months ( $p < 0.001$ ) and to 0.80 (0.19-1.30) at 6 months ( $p < 0.01$ ). Median rSLEDAI decreased from 8 (8-12) at baseline to 4 (3-5) at 3 months ( $p < 0.01$ ) and to 4 (0-4) at 6 months ( $p < 0.01$ ). There was significant decrease both in P-gp expression [RFI, 3.33 (2.87-4.97) vs 2.03 (1.25-3.86),  $p < 0.05$ ] and P-gp function (RFI, 55.7 (29.7-84.1) vs 26.8 (16.1-37.0),  $p < 0.01$ ) after 3 months of Tacrolimus therapy. None of the patients developed any adverse effects except one who developed rise in serum creatinine after 4 months of therapy.

### **Conclusion:**

Tacrolimus achieves renal response in refractory/relapsing proliferative LN patients by overcoming P-glycoprotein mediated treatment unresponsiveness.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Biomarkers

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The goal of this study is to investigate how urinary angiostatin, VCAM-1 and established measures of renal function relate to specific histologic findings in paired kidney biopsy samples from patients with lupus nephritis (LN).

**Methods:** Patients fulfilling the ACR classification for SLE were recruited into the study. Urine samples were collected from 54 lupus nephritis patients together with concurrent kidney biopsy samples and examined for urinary angiostatin and vascular cell adhesion molecule 1 (VCAM-1) protein levels. SLE disease activity was assessed using the SLEDAI, renal disease activity was assessed by the renal SLEDAI (range 0-16; 0= inactive LN,  $\geq 8$ = active renal). The ISN/RPS criteria were used to assess the histologic features of LN. Our patients were categorized into two groups; active proliferative (ISN/RPS classes III/IV) and non-proliferative (classes I/II/V). Biopsy activity and chronicity indices (BAI, BCI respectively) were used for biopsy assessment according to the standards of NIH for LN, the BAI score (range 0-24; 0= inactive LN) and BCI score (range 0-12; 0= no LN chronicity), with BAI and BCI scores of  $\geq 7$  and  $\geq 4$  respectively considered as risk factors for poor LN outcomes. Nonparametric tests were used to examine the association of both urinary biomarkers and established traditional laboratory markers of renal function with nine specific renal histologic features seen in LN using concurrent renal biopsies.

**Results:** 54 active LN patients (94.4% women, age  $33.3 \pm 9.7$  years) and 20 healthy controls were studied. Unlike conventional laboratory measures, urinary angiostatin and VCAM-1 levels normalized to Cr were significantly higher in patients with active proliferative LN than non-proliferative LN (angiostatin  $21900 \pm 3.43$  vs  $2200 \pm 0.79$  pg/ng;  $P < 0.0001$ ; VCAM-1  $1249 \pm 3.93$  vs  $166 \pm 42.5$  pg/ng;  $P < 0.0001$ ). A significant correlation was found between urine VCAM-1 and SLEDAI ( $r = 0.324$ ,  $P < 0.05$ ), as well as renal SLEDAI ( $r = 0.319$ ,  $P < 0.05$ ). Urinary angiostatin correlated significantly with renal SLEDAI ( $r = 0.327$ ,  $P < 0.05$ ). Urinary angiostatin and VCAM-1 strongly correlated with the renal biopsy activity index in concurrent biopsies ( $r = 0.929$ ,  $P < 0.001$  and  $r = 0.97$ ,  $P < 0.001$  respectively), but not with the chronicity index. Both angiostatin and VCAM-1 showed an outstanding ability (AUC 0.97, 0.98

respectively) to predict concurrent renal biopsy activity index score  $\geq 7$ , compared to conventional measures such as sCr, eGFR and uPCR. Whereas urine VCAM-1 was most significantly associated with fibrous crescents, urine angiostatin was most significantly associated with endocapillary proliferation, cellular crescents, fibrinoid necrosis and fibrous crescents in concurrent renal biopsies.

**Conclusion:** Urinary angiostatin and VCAM-1 are associated with specific histologic features of LN activity and chronicity in concurrent renal biopsies. Further longitudinal studies are necessary to delineate the utility of these two urinary proteins in tracking renal pathology changes in SLE patients, and predicting long-term patient and renal mortality in LN.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

To examine the global gene expression profile in patients with very early diffuse systemic sclerosis (SSc).

### **Methods:**

Skin biopsies were obtained from patients enrolled in the Prospective Registry for Early Systemic Sclerosis (PRESS). All patients had diffuse cutaneous involvement and disease duration < 2 years. Fifty-seven patients and 33 age-, gender-matched controls were examined by nextGen RNA Sequencing (Depth: 50 million reads, 75 bp length) on Illumina HiSeq 3000 platform. Cell type-specific signature scores were calculated for each patient sample compared to the average score in controls as previously described (Assassi et al. Arthritis Rheum 2015). Gene signatures for 15 cell types present in skin were calculated including: Fibroblasts, keratinocytes, CD4+ and DC8+ T-cells, NK cells, dendritic cells, M1 and M2 macrophages, and B-cells.

### **Results:**

The median disease duration was only 1.1 years while median mRSS score was 22. In comparison to controls, 2537 transcripts were differentially expressed (FDR <5%).

An Ingenuity Pathway Analysis revealed that the following top over-represented pathways: Hepatic fibrosis ( $p=3.85 \times 10^{-39}$ ), granulocyte adhesion and diapedesis ( $p=3.11 \times 10^{-19}$ ), leukocyte extravasation signaling ( $p=2.79 \times 10^{-16}$ ), Th1 and Th2 activation pathway

( $p=1.44 \times 10^{-15}$ ), agranulocyte adhesion and diapedesis ( $p=6.56 \times 10^{-14}$ ). The cell-type specific signature score analysis revealed a prominent up-regulation of innate and adaptive immune cell types. The three most frequent activated cell-type signatures were M2 Macrophage (present in 96% of patient samples), fibroblast (93%), and microvascular endothelial cells (91%). Interestingly, the proportion of patient samples with an adaptive immune system signature was much higher than the frequencies observed in our previously published data set (61 SSc patients with mean disease duration of 7.7 years and 36 matched controls). Specifically, CD8+ T cell, CD4+ T cell, and B-cell signatures were present in 67%, 61%, and 67% of samples in the present study whereas those signatures were present in less than 25% of SSc samples with established disease in the previous data set. Figure shows the distribution of signature scores for adaptive immune cell types in the present data set (early diffuse SSc) and previously published study (established SSc).

## Conclusion:

Skin samples of patients with early diffuse involvement have a prominent adaptive immune signature which is not present in established disease. This finding can have important implications for clinical trials targeting adaptive immune system.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Vascular injury is a hallmark event in the pathogenesis of Systemic Sclerosis (SSc). Endothelial dysfunction happens early in the course of the disease and drives some of the most prominent clinical manifestations of scleroderma, including Raynaud's phenomenon, telangiectasias and gastric antral vascular ectasias, pulmonary arterial hypertension and scleroderma renal crisis. The exact mechanisms that lead to endothelial cell injury and propagate the vasculopathy in scleroderma are not well understood. Single cell RNA sequencing provides a robust platform for cellular identification, allows gene expression analysis at the single cell level and accounts for cellular heterogeneity.

## Methods:

The study was completed in the Scleroderma Center of UPMC in collaboration with the Scleroderma Research Center of Boston University and the Broad Institute of Boston. We implemented single cell sorting and subsequent RNA sequencing of cells isolated from scleroderma and healthy control skin. The analysis was performed using R software. We used t-distributed stochastic neighbor embedding (t-SNE) with k-means clustering to identify the various cell types. We performed pathway analysis using Gene Set Enrichment Analysis (GSEA) and Ingenuity Pathway Analysis (IPA). Finally, we independently verified distinct markers using immunohistochemistry on skin biopsies and qPCR in primary endothelial cells isolated from skin of scleroderma patients and healthy controls.

## Results:

In order to visualize and ultimately define the various cell subsets in the single cell RNA sequencing dataset, we used t-SNE analysis, a method of unsupervised learning for dimensionality reduction. 2D projection of the t-SNE coupled with k-means clustering effectively reduced the dimensionality of the data. By combining the t-SNE analysis with the expression of known endothelial cell markers, including VWF, PECAM1 and CDH5, we were able to positively identify the endothelial cells among the sorted single cells from healthy and scleroderma skin. Subsequently, we analyzed the differential expression profile between the endothelial cells from healthy and scleroderma skin. Using GSEA and IPA analysis, we were able to demonstrate that the SSc endothelial cell expression profile is enriched in processes associated with extracellular matrix generation, negative regulation of angiogenesis and epithelial-to-mesenchymal transition. Finally, two of the top differentially expressed genes, HSPG2 and APLNR, were independently verified. Primary endothelial cells isolated from scleroderma skin expressed higher levels of *APLNR* mRNA compared to endothelial cells isolated from healthy skin. Immunohistochemistry studies of skin biopsies revealed that HSPG2 showed increased expression in the perivascular area of scleroderma skin compared to healthy skin.

## Conclusion:

Using single cell RNA sequencing we were able to identify an endothelial cell gene signature in scleroderma skin. Differential gene expression and pathway analysis revealed that endothelial cells from scleroderma patients exhibit a pattern of endothelial injury and activation as well as increased extracellular matrix generation and negative regulation of angiogenesis.

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The Retinoic-acid related Orphan Receptor-alpha (ROR $\alpha$ ) is a member of the nuclear receptor superfamily and a ligand-dependent transcription factor implicated in a wide range of physiological and pathological processes. The key objective for this study is to evaluate the role of ROR $\alpha$  in tissue repair and to elucidate antifibrotic effects of targeting ROR $\alpha$  in preclinical models of fibrosis.

**Methods:** The expression was analysed by qPCR, Western blot and immunofluorescence staining. The expression of ROR $\alpha$  was modulated via genetic abrogation or adenoviral overexpression. ROR $\alpha$  was also targeted pharmaceutically using the small molecule inhibitor SR3335. The role of ROR $\alpha$  in fibrosis was evaluated in TGF- $\beta$  receptor I (TBRI) and bleomycin-induced murine models.

**Results:** The expression of ROR $\alpha$  was increased in fibroblasts in both human and murine fibrotic lung and liver. Activation of canonical Wnt/  $\beta$ -catenin signalling mimicked the upregulation of ROR $\alpha$  in fibrosis and potently induced ROR $\alpha$  expression. Consistently, reporter-assays showed that canonical Wnt ligands induced the promoter activity of ROR $\alpha$  target gene BM1a1. Overexpression of ROR $\alpha$  in fibroblasts induced fibroblast-to-myofibroblast transition and collagen release. Inactivation of ROR $\alpha$  signalling, either by knockout of ROR $\alpha$  or by treatment with SR3335 inhibited WNT- and TGF- $\beta$ -dependent fibroblast activation and blocked extracellular matrix secretion. Inhibition of ROR $\alpha$  also demonstrated potent antifibrotic effects in the mouse models of bleomycin- and TBRI-induced fibrosis. Mice treated with SR3335 demonstrated reduced dermal thickening, decreased hydroxyproline content and impaired myofibroblast differentiation as compared to vehicle-treated mice.

**Conclusion:** Our study identifies ROR $\alpha$  as a key checkpoint of TGF- $\beta$ - and WNT- induced fibroblast activation. ROR $\alpha$  is induced in fibrotic diseases in a WNT-dependent manner to promote TGF- $\beta$ - and WNT-induced fibroblast activation and tissue fibrosis. Targeting of ROR $\alpha$  simultaneously interferes with TGF- $\beta$ - and WNT-signalling as two core profibrotic pathways, which translates into potent antifibrotic effects.

## Background/Purpose:

Autophagy (Atg) is catabolic process allowing cells to degrade unnecessary or dysfunctional cellular organelles. Aberrant activation of Atg has been implicated into the pathogenesis of various diseases.

## Methods:

We generated *Atg7<sup>fl/fl</sup> × Col1a2;CreER* mice with selective inactivation of Atg in fibroblasts. The role of the Atg was investigated in the model of bleomycin- and TβRIact-induced dermal and pulmonary fibrosis. Overexpression of *Myst1* and *Beclin1* was achieved by adenoviral overexpression. ChIP and reporter assays were performed to study physical and functional interactions between MYST1 and SMAD3.

## Results:

Atg is strongly activated in fibroblasts from SSc skin and also in experimental dermal and pulmonary fibrosis as compared to respective non-fibrotic control tissue with overexpression of ATG7 and of BECLIN, downregulation of the autophagy substrate p62 and activation of autophagy-dependent reporter activity. The aberrant activation of Atg has profound stimulatory effects on fibroblasts. Activation of Atg by forced expression of BECLIN1 promoted fibroblast-to-myofibroblast transition and stimulates the collagen release *in vitro* and *in vivo*. Moreover, inactivation of autophagy by fibroblast-specific knockout of *Atg7* prevented myofibroblast differentiation and ameliorated fibrosis, demonstrating that activation of Atg is both, sufficient and required, for fibroblast activation and tissue fibrosis. We also provide evidence that TGFβ activates Atg by an epigenetic mechanism to amplify its profibrotic effects. TGFβ induces Atg in fibrotic diseases by SMAD3-dependent downregulation of the H4K16-histoneacetyltransferase MYST1, which controls the expression of core components of the Atg machinery such as ATG7 and BECLIN1. Forced expression of MYST1 abrogates the stimulatory effects of TGFβ on Atg and re-establishes the epigenetic control of autophagy in fibrotic conditions. Overexpression of MYST1 prevents the aberrant activation of Atg, inhibits TGFβ-induced fibroblast activation and ameliorates experimental dermal and pulmonary fibrosis.

## Conclusion:

We demonstrate that the epigenetic control of Atg is disturbed by a TGFβ-dependent downregulation of MYST1 in SSc. The resulting uncontrolled activation of Atg promotes fibroblast-to-myofibroblast transition and tissue fibrosis. Restoration of the epigenetic control of autophagy limits the profibrotic effects of TGFβ and ameliorates experimental fibrosis. These findings link uncontrolled TGFβ signaling to aberrant autophagy and altered epigenetics in fibrotic diseases.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

SSc patients frequently suffer from primary cardiac involvement. The main histological feature is fibrosis, but the mechanisms responsible for the heart failure remain unclear. It is known that cellular progenitors, including stromal cells, differentiate into myofibroblasts and autophagy may favor fibrosis through enhanced differentiation of cardiac stromal cells. Here we describe the role of Fos-related antigen 2 (fra-2)/autophagy crosstalk in TGF $\beta$ -dependent myocardial fibrosis in SSc.

### **Methods:**

Immunohistochemistry (IHC) and immunofluorescence (IF) were performed on endomyocardial biopsies (EMBs) from SSc patients and hearts from fra-2<sup>tg</sup> SSc mouse model and WT mice. Myocardial stromal Ter119<sup>+</sup>CD45<sup>+</sup>CD31<sup>-</sup> (Lin<sup>-</sup>) gp38<sup>+</sup> stromal cells were sorted for in vitro culture. The cellular phenotype was assessed by qPCR, IF, stress fiber staining, SIRCOL and contraction assay on sorted cells. The antisense oligonucleotide GapmeR was used to knock-down fra-2.

### **Results:**

Fibrosis, collagen deposition and  $\alpha$ SMA<sup>+</sup> myofibroblasts were increased in the myocardium of SSc patients (n=10). Fra-2 and autophagy markers such as LC3B, Beclin-1 and Atg5 were expressed in fibrotic cardiac tissues. In parallel, the myocardium of fra-2<sup>tg</sup> mice showed higher expression of the profibrotic markers  $\alpha$ SMA, vimentin and collagen I compared to WT mice (n=5), as well the expression of LC3B and Beclin-1 in fibrotic regions. Among cardiac stromal cells (Lin<sup>-</sup>), the frequency of gp38<sup>+</sup> cells was significantly higher in fra-2<sup>tg</sup> myocardium compared to WT mice (n=8, p=0.02). Lin<sup>-</sup>/gp38<sup>+</sup> cells co-expressed  $\alpha$ SMA, vimentin and collagen I together with LC3B and Beclin-1 (n=3). Following TGF $\beta$  stimulation, WT Lin<sup>-</sup>/gp38<sup>+</sup> cells entered fibroblast-to-myofibroblast transition characterized by increased mRNA and protein levels of  $\alpha$ SMA, collagen I, fibronectin (n=3-6), formation of  $\alpha$ SMA<sup>+</sup> fibers and stress fibers (n=3), increased cell proliferation (n=5; p=0.04), contraction capability (n=5; p<0.05) and collagen secretion (n=5; p=0.04). TGF $\beta$  stimulation of WT Lin<sup>-</sup>/gp38<sup>+</sup> cells induced the expression of LC3B, Beclin-1 and Atg5 at mRNA and protein level (n=3-5). Accordingly, TGF $\beta$  inhibition caused the downregulation of these markers (n=3). In contrast to WT cells, fra-2<sup>tg</sup> Lin<sup>-</sup>/gp38<sup>+</sup> cells showed the presence of  $\alpha$ SMA<sup>+</sup> fibers, stress fibers and an increased contraction capability even without TGF $\beta$  stimulation. Finally, fra-2 silencing resulted in decreased Lin<sup>-</sup>/gp38<sup>+</sup> cell differentiation and autophagy activity as following: levels of  $\alpha$ SMA and collagen I (n=5; p=0.007), secreted collagens (n=5; p<0.05) and  $\alpha$ SMA fibers (n=3) were significantly downregulated in addition to a significant decrease of mRNA and protein expression of LC3B, Beclin-1 and Atg5 (n=3).

### **Conclusion:**

The TGF $\beta$ /fra-2 axis regulates the autophagy process, leading in turn to stromal-to-myofibroblast transition. Therefore, targeting autophagy might ameliorate the fibrotic process during heart remodeling in SSc.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

## Background/Purpose:

Fibrotic disorders such as systemic sclerosis (SSc) result in end-stage organ failure and loss of function, consequently causing high morbidity and mortality. We recently demonstrated that the C-terminal domain of endostatin, known as E4, prevented and reversed both dermal and pulmonary fibrosis. In this study, we investigated the mechanism by which E4 exerts anti-fibrotic effects using pre-clinical models of SSc.

## Methods:

To assess the effects of E4, lung fibroblasts were treated with TGF- $\beta$  with vehicle or E4. The expression levels and activity of matrix metalloproteases (MMP)-1 and MMP-3 were evaluated by using real-time PCR, immunoblotting (IB), and collagen and casein zymography, respectively. Furthermore, the mRNA and protein levels of the pro-fibrotic proteins, connective tissue growth factor (CTGF) and insulin-like growth factor binding protein (IGFBP)-3, were measured using real-time PCR and IB, respectively. *In vivo*, bleomycin with vehicle or E4 was administered intratracheally to 6 to 8-week-old C57BL/6J male mice to induce lung fibrosis. Lung and bronchoalveolar lavage fluid (BALF) were collected 7 days post-treatment, and the levels and activity of hepatocyte growth factor (HGF) were measured using real-time PCR and immunoblotting.

## Results:

The mRNA levels of MMP-1 and MMP-3 were increased by E4. Similarly, secreted MMP-1 and MMP-3 protein levels were upregulated in culture supernatants. Furthermore, MMP-1 and MMP-3 activity was increased as assessed by zymography. TGF- $\beta$  increased the expression levels of CTGF and IGFBP-3 in primary human fibroblasts, and E4 abrogated these effects. *In vivo*, bleomycin reduced HGF levels in BALF and lung tissues. E4 peptide partially blocked these effects.

## Conclusion:

Our results demonstrate that E4 increased MMP-1 and MMP-3 levels and activity. The ability of E4 to reverse fibrosis can thus be explained, in part, by its increase of MMP, thus promoting extracellular matrix (ECM) degradation. In addition, E4 reduced levels of the pro-fibrotic mediators CTGF and IGFBP-3 while increasing levels of the anti-fibrotic and anti-inflammatory factor HGF. Our findings suggest that the anti-fibrotic effects of E4 peptide are multi-pronged and include decreasing levels of essential pro-fibrotic mediators, increasing levels of an anti-fibrotic mediator, and promoting ECM degradation.

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The pathophysiology of osteoarthritis (OA) involves wear and tear, and a state of low-grade inflammation. Wear and tear leads to tissue degradation followed by tissue repair responses including TGF $\beta$ -induced myofibroblast production of extracellular matrix (ECM). Fibronectins are an essential part of the ECM, and injection of fibronectin fragments into rabbit joints is an established animal model of OA. Recently, alternatively spliced fibronectin containing the ED-A domain (ED-A FN) has been shown to activate Toll-like receptor 4. In this study, we hypothesize that FN fragments containing the ED-A domain could be one mechanism transducing mechanical events into inflammatory signals in OA.

### Methods:

Samples of synovial membrane and cartilage were obtained from patients with knee OA undergoing joint replacement surgery. Immunostaining was performed on synovial membranes. Fibroblast-like synovial cells (FLS) isolated by enzymatic digestion of remnant synovial membrane were stimulated with TGF $\beta$ , TNF $\alpha$ , lipopolysaccharide, IL-6, OA synovial fluid from two different donors, or chondrocyte lysate, and culture supernatants were analyzed for ED-A FN by immunofluorescence staining. ED-A FN fragments were obtained by plasmin digestion of cellular FN. Synovial cells isolated by enzymatic digestion and human monocyte-derived macrophages (MDM) were incubated with recombinant ED-A FN, plasmin, cellular FN, or cellular FN digested with plasmin; and culture supernatants were analyzed for MCP-1 and TNF $\alpha$ .

### Results:

We hypothesized that ED-A FN is produced by OA FLS in response to products reflecting tear and wear in OA. Indeed, the production of ED-A FN by OA FLS was increased by TGF $\beta$ , OA synovial fluid, and lysed chondrocytes in all experiments (n=3, see figure). ED-A FN co-localized with the myofibroblast marker  $\alpha$ SMA in both the OA FLS (n=3) and in the OA synovial membranes (n=8). We further hypothesized that ED-A FN expression is associated with inflammation in OA. ED-A FN staining was associated with both number of lining layer cells ( $\rho=0.85$  and  $p=0.011$ ) and infiltrating sublining cells ( $\rho=0.88$  and  $p=0.007$ ) in the OA synovium (n=8), and co-localized with both MCP-1 and TNF $\alpha$  (n=5). Recombinant ED-A FN increased the production of both MCP-1 and TNF $\alpha$  by MDM (n=3) and OA FLS (n=3). Finally, we demonstrated that the FN fragments containing the ED-A domain generated the same production of both MCP-1 and TNF $\alpha$  as recombinant ED-A FN.

### Conclusion:

The disease process in OA shares features with the chronic wound healing response including myofibroblast differentiation and that humeral mediators found in the joint can promote myofibroblast production of ED-A FN. We additionally show that recombinant and plasmin-derived ED-A fragments can induce generation of pro-inflammatory mediators from FLS and MDM. This study supports targeting the formation of ED-A FN or the enzymatic fragmentation of FN to reduce pro-inflammatory responses in OA.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

No therapy for osteoarthritis (OA) has yet to deliver both structural and symptomatic benefits. Symic is approaching this unmet clinical need with a novel matrix regulator, SB-061, inspired by aggrecan. Aggrecan is a critical component for cartilage structure and plays a key role as part of the protective molecules shielding collagen from degradation. Native aggrecan is lost early in the progression of OA and restoring the function of aggrecan in the joint is hypothesized to reduce OA progression. SB-061 was designed as a novel functional mimic of aggrecan, and was evaluated in a standard rodent model of OA.

### **Methods:**

SB-061 was synthesized by linking the glycosaminoglycan chondroitin sulfate (CS) with peptides known to bind to hyaluronic acid (HA). An ELISA assay was developed by immobilizing HA on a plate and using an antibody to the SB-061 molecule to confirm the concentration dependent binding of SB-061 to HA. *In vivo* experiments were performed to assess the pain reducing effect of SB-061. Rats received a medial meniscal tear in their right hind-limbs, and SB-061 was injected into the injured joint beginning 1 week after surgery and weekly throughout the study. Incapacitance testing was performed to detect differences in pain related responses (load bearing on the injured joint) throughout the duration of the 6-week study.

### **Results:**

SB-061 demonstrates high affinity binding to HA ( $EC_{50} = 10nM$ ) and produces a robust, dose related reduction in pain responses following intra-articular injection in a rat model of OA. The timecourse and magnitude of SB-061 mediated analgesic effects in the rat OA model were comparable across 4 independent studies with a maximum pain reduction of approximately 30% at week 4 of treatment. Continued weekly dosing of SB-061 resulted in a sustained reduction of pain throughout the course of the study, whereas termination of SB-061 dosing resulted in a diminishment of the pain relief effect over a two week period. These results are superior to historical data with a clinically relevant dose of an NSAID administered at similar times following the meniscal tear surgery. We hypothesize that SB-061 acts as a matrix regulator via its aggrecan-like properties to produce a sustained pain relieving effect in this model.

### **Conclusion:**

We have demonstrated that SB-061 functionally mimics aggrecan with respect to binding to HA, and significantly reduces pain related responses in a sustained manner in an industry standard animal model of OA. These data suggest that SB-061 may exhibit clinical efficacy in human OA via a similar mechanism. Additional studies are underway to elucidate the mechanism of action of SB-061 within the joint and its potential for disease modification.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is controversy about the effect of catabolic cytokines in regenerative medicine. The purpose of this study was to evaluate the effect of interleukin 1 $\beta$  (IL1 $\beta$ ) in the repair capacity of bone marrow mesenchymal stromal cells (BMSCs) seeded on collagen (Col)/proteoglycan (PG) scaffolds, in an *in vitro* cartilage lesion model.

**Methods:** Samples were obtained from hips (BMSCs and cartilage) and knees (only cartilage) of patients who underwent total joint replacement. 3 mm-diameter lesions were made in cartilage biopsies using a dental drill. Injured biopsies were pre-treated with 10 ng/ml of IL1 $\beta$  for 24 hours.  $2 \times 10^5$  BMSCs were seeded on type I and II Col with heparan sulfate (C1C2HS), and C1C2 with chondroitin sulfate (C1C2CHS) scaffolds. Resulting constructs were introduced inside the lesion and cultured for 60 days in chondrogenic medium. Controls without IL1 $\beta$  pre-treatment were performed. Histological analyses were made and repaired tissue was evaluated using the International Cartilage Research Society scale II (ICRSII) [1].

**Results:** In the IL1 $\beta$  pre-treated model, Hematoxylin-Eosin staining (HE, Figure) showed neotissue formation within the lesion with fewer rounded cells than in the non pre-treated model. Staining with Masson's Trichrome (MT, Figure) showed the presence of Col in the extracellular matrix (ECM) of all the constructs. The presence of PGs detected by Safranin O (SO, Figure) staining was more metachromatic in non pre-treated C1C2HS ( $52.426 \pm 4.877$ ) and C1C2CHS ( $32.722 \pm 8.781$ ) constructs than in IL1 $\beta$  pre-treated C1C2HS ( $20.973 \pm 6.849$ ) and C1C2CHS ( $23.228 \pm 1.704$ ) ones.

By ICRS II assessment of the non-pretreated model, the repair score for C1C2CHS was 46% (fibrocartilage neotissue), and 73% (mixed fibrocartilage and hyaline cartilage) for C1C2HS constructs. In the IL1 $\beta$  pre-treated model, morphological changes with the loss of ECM components observed by SO and MT staining resulted in lowering of the ICRSII scores.

**Conclusion:** In absence of IL1 $\beta$ , BMSCs seeded on Col and PG scaffolds showed higher *in vitro* cartilage repair capacity than in the IL1 $\beta$  pre-treated model. *References:* [1]. **Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

**Background:** Effective treatments for Osteoarthritis (OA) are not available. In aging-related diseases, including OA, failure of cellular homeostasis mechanisms, such as autophagy can cause extracellular matrix destruction and cell death. Chondrocytes are essential for the maintenance of cartilage integrity. With aging, chondrocyte function is diminished, contributing to a cellular senescence phenotype often observed in OA chondrocytes. In addition, a defect in autophagy is observed in both aging and cartilage degeneration. *The objective of this study was to identify anti-senescence and pro-autophagy molecules by a cell-based high-throughput screening (HTS) in human chondrocytes.*

### Methods:

**Methods:** To induce cellular senescence or reduced autophagy, immortalized human chondrocytes, TC28a2 were seeded in 384 well plates, and treated with IL-6 (20ng/ml) for 72 or 18 hours, respectively. Then, chondrocytes were incubated with Prestwick Chemical Library (1120 approved drugs) at 10 $\mu$ M for 72 hours. To identify anti-senescence hits, nuclei was stained with Hoechst 33342 (2,5 $\mu$ g/ml), while  $\beta$ -galactosidase subcellular structures was stained by using ImaGene Green C<sub>12</sub>FDG substrate (30 $\mu$ M). To evaluate autophagic flux, a reporter cell line was generated by lentiviral transfection of pBABE-mCherry-EGFP-LC3 plasmid in TC28a2 chondrocytes. Plates were imaged by using Operetta® High Content Screening (HCS) System. Relative intensity of C<sub>12</sub>FDG in cytoplasm and relative spot intensity of cytoplasm were determined to quantitate  $\beta$ -galactosidase activity and autophagic flux respectively. For compound validation, senescence markers, autophagic flux, inflammation and apoptosis were evaluated in human chondrocytes. Moreover, cartilage degradation and autophagy were evaluated by safranin O staining and immunohistochemistry in human cartilage explants.

### Results:

**Results:** A primary screening was performed to identify anti-senescence compounds by measurement of senescence-associated  $\beta$ -galactosidase activity. 252 compounds with anti-senescence effects were identified. The anti-senescence hits were analyzed by

monitoring autophagic flux. 26 compounds with both anti-senescence and pro-autophagy effects were selected. Then, one compound was selected for further validation. The compound reduced senescence ( $p < 0.001$ ) and increased autophagic flux ( $p < 0.0001$ ) in response to IL-6. Western Blot analysis showed protective effect against defective autophagy, senescence and inflammation. Interestingly, this protective effect was partially mediated by mTOR inhibition, a proposed mechanism to prevent cartilage aging. Moreover, the selected compound conferred protection against cell death by apoptosis and reduced nitric oxide (NO) production into supernatants ( $p < 0.05$ ) and cartilage degradation in response to IL-1 $\beta$ .

#### Conclusion:

**Conclusions:** These observations provide a unique opportunity to study cartilage aging with the objective to explore the therapeutic potential of pharmacological prevention of chondrocyte senescence and autophagy as a strategy to slow or reverse aging-associated changes, prevent the onset of OA and provide benefits for its clinical management.

## A2A Adenosine Receptor (A2AR) Stimulation Modulates NR4A2 Orphan Receptor Expression during Osteoclast Differentiation

**Carmen Corciulo**<sup>1</sup>, Tuere Wilder<sup>1</sup> and Bruce Cronstein<sup>2</sup>, <sup>1</sup>Department of Medicine, Division of Rheumatology, NYU School of Medicine, New York, NY, <sup>2</sup>Rheumatology, New York University School of Medicine, Division of Rheumatology, New York, NY  
**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Orphan receptors comprise a large number of evolutionarily conserved molecules that have unknown ligands but may have potent biologic effects. Among these receptors are the nuclear receptors (NR) which are important regulators of gene expression; subgroup A of NR (NR4A) includes 3 members, Nurr77 (NR4A1), Nurr-1 (NR4A2) and Nor 1 (NR4A3), important regulators of many physiological and pathological conditions. NR4A2 is involved in the regulation of bone homeostasis by transactivation of the osteoprotegerin promoter in an osteoblast cell line and is also thought to reduce NF $\kappa$ B signaling. Because stimulation of A2AR, which markedly reduces bone resorption by osteoclasts, increases expression of NR4A2 in cells of myeloid origin (monocytes/macrophages) we determined whether NR4A2 might also play a role in regulating bone resorption as well.

**Methods:** Immunohistochemistry of articular bone was used to determine NR4A2 expression in bone. Osteoclast precursors were isolated from primary bone marrow cells and, along with the murine macrophage cell line RAW 264.7 cells, were induced to differentiate into osteoclasts following treatment with M-CSF and RANKL (30ng/ml). NR4A2 expression was measured *in vitro* by RT-PCR and Western Blot.

**Results:** NR4A2 is expressed in articular bone (osteoclasts, osteoblasts and osteocytes) but not articular chondrocytes. During osteoclast differentiation induced by RANKL treatment of primary osteoclast precursors there is a marked reduction of NR4A2 mRNA expression (75% of control,  $p < 0.01$ ). Similarly, RANKL induction of osteoclast differentiation by RAW 264.7 cells is also associated with diminished NR4A2 mRNA expression (Day 3, 99.8% reduction,  $p < 0.01$ ). Moreover immunofluorescence and western blotting data show cytosolic and nuclear NR4A2 negatively correlates with expression of cathepsin-K, consistent with reduced NR4A2 expression during osteoclast differentiation (nuclear NR4A2 is decreased by 27% and 49% at days 3 and 6 of osteoclast differentiation, respectively). Interestingly treatment of osteoclast precursors with CGS21680 (1  $\mu$ M), a selective A2AR agonist, reverses this expression pattern, significantly increasing NR4A2 mRNA expression in both primary macrophages (2 fold increase *vs* control;  $p < 0.05$ ) and RAW 264.7 cells (51 fold increase *vs* control;  $p < 0.01$ ).

**Conclusion:** Reduced expression of NR4A2 is characteristic of osteoclast differentiation and stimulation of A2AR receptors on osteoclast precursors reverses both the reduction in NR4A2 expression and osteoclast differentiation.

## **Mitochondrial ROS Activate the p38-MAPK/AP1 Pathway to Induce the Expression of Matrix Metalloproteases and IL-6 in Human Chondrocytes**

**Mohammad Y. Ansari**<sup>1</sup> and Tariq M Haqqi<sup>2</sup>, <sup>1</sup>Anatomy & Neurobiology, Northeast Ohio Medical University, Rootstown, OH, <sup>2</sup>Anatomy & Neurobiology, Northeast Ohio Medical University, Rootstown, OH

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Mitochondria not only ‘power’ the cell, but are also essential for maintaining physiological levels of prooxidants (ROS) which is critical for homeostasis. Damaged and dysfunctional mitochondria are hallmarks of aging-related diseases including osteoarthritis (OA) but how they contribute to the pathogenesis of OA is not clear. Here we investigated the mechanism of mitochondrial dysfunction-induced expression of IL-6 and MMP-3, -9 and -13 in human normal and OA chondrocytes.

### **Methods:**

OA cartilage samples were obtained from donors who underwent total joint replacement surgery at Crystal Clinic, Akron, OH. Normal knee cartilage samples were from post mortem donors via NDRI. Mitochondrial dysfunction in chondrocytes was induced by treatment with IL-1 $\beta$  or CCCP (Carbonyl cyanide *m*-chlorophenyl hydrazone). JC-1 staining of chondrocytes was used to measure the loss of mitochondrial membrane potential. Mitochondrial ROS levels were analyzed by MitoSOX probe. Chondrocytes treated to induce mitochondrial damage were harvested and (1) RNA was prepared for measuring gene expression by TaqMan assays; and (2) total lysate was prepared for protein expression analysis by immunoblotting for OA signature genes. Culture supernatants were used to determine the levels of secreted IL-6 and MMP-13 protein by ELISA. ATP levels in normal and OA chondrocytes treated with CCCP or IL-1 $\beta$  were measured by Mitochondrial ToxGlo Assay. Activation of p38-MAPK and cFos was determined by Western immunoblotting using antibodies validated for the total and phosphorylated proteins. Activation of the NF- $\kappa$ B and AP1 signaling pathways was analyzed by reporter assays, immunoblotting for I $\kappa$ B $\alpha$  degradation and nuclear translocation of cFos using immunofluorescence staining. Nucleofection was used to transfect chondrocytes.

### **Results:**

IL-1 $\beta$  or CCCP treatment caused a significant loss of mitochondrial membrane potential and production of mitochondrial ROS in chondrocytes as measured by JC-1 and MitoSOX staining respectively. OA chondrocytes compared to normal chondrocytes had significantly low ATP levels and treatment with IL-1 $\beta$  or CCCP resulted in reduced production of ATP in normal chondrocytes. Both normal and OA chondrocytes with damaged mitochondria showed increased mRNA expression of IL-6 and MMP-3, -9 and -13 and the phosphorylation of p38MAPK, cFos and nuclear translocation of cFos. In normal or OA chondrocytes treated with CCCP or H<sub>2</sub>O<sub>2</sub>, activation of NF $\kappa$ B as determined by immunoblotting for I $\kappa$ B $\alpha$  degradation, was not observed. Also, in normal or OA chondrocytes transfected with either AP1 or NF $\kappa$ B activity reporter vectors and then treated with CCCP, activation of AP1 but not of NF- $\kappa$ B was observed. Treatment of chondrocytes with damaged/dysfunctional mitochondria with mitochondrial ROS inhibitor Mito-TEMPO, inhibited the AP1 activation and suppressed the expression of IL-6, MMP-3 -9 and -13 mRNA and protein.

**Conclusion:** Here we show for the first time that mitochondrial damage/dysfunction contributes to the pathogenesis of OA via p38 MAPK/AP1 activation and not through the activation of NF- $\kappa$ B pathway. This knowledge may help in designing novel therapies for the management of OA.

### SESSION INFORMATION

Session Date: Tuesday, November 7, 2017

Session Title: Biology and Pathology of Bone and Joint Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Osteoarthritis (OA) is an age-related musculoskeletal disease and the most common form of arthritis characterized by low grade synovial inflammation and articular cartilage degeneration. Many different cell types have been implicated in the pathogenesis of OA and interplay between these cells contribute to the dynamic events associated with disease. Recently, extracellular vesicles (EVs) have emerged as mediators of intercellular communication. Being carriers of proteins, genetic information and metalloproteinases, their involvement in many diseases has now been established. There is however very little known about the pathophysiological role of EVs in musculoskeletal diseases. In this study, we investigated the effect of plasma EVs from OA patients during chondrogenic differentiation of mesenchymal stem cells (MSCs).

**Methods:** Plasma-derived extracellular vesicles (pEVs) were isolated from plasma of OA patients and age-matched healthy controls using size-exclusion chromatography. EV containing fractions were characterized according to ISEV guidelines [1]. Pelleted MSCs were stimulated with TGF- $\beta$  and BMP-2 to induce chondrogenic differentiation, either in the presence of pEVs isolated from OA patients or healthy controls. After 8 days, RNA was isolated and RT-qPCR was performed to determine the gene expression profiles.

**Results:** No significant difference was observed in particle concentration, size or protein concentration between OA patients and age-matched controls. In the presence of pEVs from OA patients MSC-derived chondrocytes showed a significant increase in the expression of *MMP13* (6.1-fold), *RUNX2* (1.9-fold) and *RANKL* (2.3-fold), compared to pEVs from healthy controls. A trend towards higher *ADAMTS5* expression (2.5-fold,  $p=0.0685$ ) with OA pEVs was also observed. Additionally, we found significantly higher expression of *WISP1* (24-fold), suggesting activation of Wnt signaling. All other proinflammatory genes tested were not significantly different between the two groups.

**Conclusion:** A previous study [2] has shown that EVs released from IL-1 $\beta$  stimulated synovial fibroblasts can induce osteoarthritic changes in articular chondrocytes. Here, we show direct evidence that circulating pEVs from OA patients can enhance OA-related genes, like *MMP13*, in MSC-derived chondrocytes. The expression profile found suggest the presence of Wnt-proteins on pEVs from OA patients, which are known to be involved in cartilage development and we previously have shown that WISP-1 expression is a feature of experimental and human OA [3].

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Osteoporosis predominantly affects elderly people and is characterized by bone loss, increased fracture risk and reduced regeneration ability. An inverse relationship between bone marrow adipose tissue and bone mineral density in osteoporosis and during aging is well documented, but the role of fat–bone interactions in the pathogenesis of osteoporosis is poorly understood. Adipose tissue is metabolically highly active. Adipokines (e.g. visfatin, resistin and leptin) are adipocyte-derived factors with immunomodulatory properties and they might influence the differentiation of bone marrow-derived mesenchymal stem cells (MSC) into osteoblasts and adipocytes. Thus, the presence of adipokines in bone tissue of femoral heads and their effects on MSC differentiation were analyzed.

**Methods:** RNA and MSC were isolated from spongiosa of femoral heads derived from hip replacement surgery of osteoarthritis patients or after osteoporotic femoral neck fracture. Adipogenic as well as osteogenic MSC differentiation was performed with and without adipokines. For the transfer and differentiation of MSC on cancellous bone, bone fragments were purified and sterilized. Gene expression was evaluated by Realtime PCR. Matrix mineralization was assayed using Alizarin red S staining and proinflammatory factors were measured by ELISA.

### Results:

Higher levels of visfatin (FF mean  $7.77 \pm 1.86$ ,  $n=11$ ; OA  $2.25 \pm 0.36$ ,  $n=13$ ) and leptin (FF mean  $21.98 \pm 5.41$ ,  $n=11$ ; OA  $15.86 \pm 3.93$ ,  $n=12$ ) could be detected in osteoporotic (FF) bone compared to non-osteoporotic (OA) bone, however resistin was reduced in FF (FF mean  $7.73 \pm 2.95$ ,  $n=9$ ; OA  $34.28 \pm 9.27$ ,  $n=12$ ). Visfatin induced the secretion of proinflammatory factors (IL-6, IL-8, MCP-1 and GRO- $\alpha$ ) during both, osteogenic and adipogenic differentiation. Significantly increased matrix mineralization (visfatin:  $82\% \pm 28\%$ , control:  $3.9\% \pm 1.8\%$ ;  $n=3$ ) and downregulated collagen type 1 expression (e.g. d21: -4.6-fold,  $n=7$ ) were detected in osteogenically differentiated cells after visfatin stimulation. In contrast to leptin and resistin, visfatin reduced the expression of MMP2, MMP13, TIMP1 and TIMP2 (e.g. d21: -2.4-fold / -3.18-fold / -3.2-fold / -4.3 fold, respectively) during osteogenic differentiation. The expression of MMP13 (e.g. d21: 104-fold,  $n=9$ ) and MMP2 (e.g. d21: 5.1-fold,  $n=9$ ) was significantly enhanced after stimulation with visfatin during adipogenic differentiation under standard cell culture conditions, however visfatin-mediated MMP13 expression (e.g. d21: 13.8-fold,  $n=7$ ) as well as induction of IL-6 and IL-8 release was markedly reduced during differentiation on purified autologous cancellous bone.

**Conclusion:** The results support the hypothesis that adipokines, especially the visfatin-mediated increase of matrix mineralization and reduction of collagen type 1 expression might lead to enhanced bone fragility and contribute to the pathogenesis of osteoporosis. Moreover visfatin-induced release of proinflammatory cytokines and dysregulated expression of MMPs and TIMPs during MSC-differentiation might influence bone turnover at the adipose tissue/bone interface

## Bimekizumab Blocks T Cell-Mediated Osteogenic Differentiation of Periosteal Stem Cells: Coupling Pathological Bone Formation to IL-17A and IL-17F Signaling

Mittal Shah<sup>1,2</sup>, Ash Maroof<sup>1</sup>, Rawiya Al-Hosni<sup>2</sup>, Panagiotis Gikas<sup>3</sup>, Neil Gozzard<sup>1</sup>, Stevan Shaw<sup>1</sup> and **Scott Roberts**<sup>1,2</sup>, <sup>1</sup>UCB Pharma, Slough, United Kingdom, <sup>2</sup>University College London, London, United Kingdom, <sup>3</sup>The Royal National Orthopaedic Hospital, London, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Structural tissue damage, as a result of pathological bone formation, is a major cause of disability in spondyloarthritis (SpA). A paucity of *in vitro* models that faithfully replicate human skeletal biology has impeded research into the cellular and molecular triggers for this osteoimmunologic phenomenon. Nevertheless, clinical and animal studies have defined IL-17 signaling as a key regulator of SpA disease; however, the role of IL-17 in bone pathology is poorly understood. IL-17-producing  $\gamma\delta$ -T cells have a critical function in periosteal bone formation for fracture repair,<sup>1</sup> the periosteum has also been implicated in pathological bone formation in SpA disease progression.<sup>2</sup> This study aimed to investigate IL-17 signaling in the context of pathological bone formation using a biomimetic human periosteum derived stem cell (hPDSC) model of osteogenic differentiation.

**Methods:** hPDSCs were obtained through enzymatic digestion of periosteal biopsies from patients undergoing orthopedic surgery. Expanded cultures were treated with recombinant human IL-17A, IL-17F, or both over 96h and expression of gene markers evaluated. hPDSCs were also stimulated using a biomimetic protocol in combination with IL-17A and IL-17F, or human Th17 and  $\gamma\delta$ -T-cell supernatants (SNs) (as a surrogate disease-like inflammatory milieu). Antibodies with strong-affinity to IL-17A, IL-17F, or bimekizumab (a humanized monoclonal IgG1 antibody with strong affinity for both IL-17A and IL-17F) were used to define the role of these cytokines in the SNs. Expression of osteogenic markers and matrix mineralization was assessed to define *in vitro* bone formation.

**Results:** Under basal conditions IL-17A and IL-17F significantly up-regulated *IL-6* expression and transiently enhanced the expression of the osteogenic transcription factor *RUNX-2*. When IL-17 cytokines were combined in a biomimetic protocol, both IL-17A and IL-17F promoted osteogenic differentiation. Following 9 days' exposure, IL-17F enhanced the expression of most osteogenic markers to a greater extent than IL-17A alone. Conversely, IL-17A treatment resulted in elevated *in vitro* mineralization vs IL-17F. The SNs potentially enhanced hPDSC osteogenic differentiation and mineralization. While *IL-6* expression and *in vitro* bone formation were blocked by neutralization of IL-17A or IL-17F individually, dual neutralization with bimekizumab exhibited the greatest effect on most of the tested parameters.

**Conclusion:** These data show that both IL-17A and IL-17F enhance *in vitro* osteogenic differentiation and bone formation from hPDSCs. The source of these cytokines has not been established but may, for example, involve enthesal resident  $\gamma\delta$ -T cells. We propose that IL-17A and IL-17F drive pathological bone formation resulting in enthesophytes at the enthesis/periosteum interface. Current therapeutics display limited efficacy in blocking enthesophyte formation, hence inhibition of both IL-17A and IL-17F with bimekizumab offers an attractive therapeutic strategy to prevent this debilitating feature of SpA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Estrogen deficiency and glucocorticoid (GC) therapy are the main causes of postmenopausal and secondary osteoporosis, respectively. Bone loss in both states relate to a negative bone balance (bone resorption exceeding formation), driven primarily by increased bone resorption in the case of estrogen deficiency, and by decreased bone formation with GC therapy.<sup>1</sup> Both conditions increase in the risk of fragility fractures, including vertebral fractures.<sup>1</sup> Abaloparatide (ABL), an anabolic PTHrP analog, increased bone formation and reduced the risk of new vertebral and nonvertebral fracture in women with postmenopausal osteoporosis at high risk of fracture.<sup>2</sup> In estrogen-deficient ovariectomized (OVX) rats, ABL increased bone formation, bone mineral density (BMD) and bone strength without increasing bone resorption.<sup>3, 4</sup> The current study assessed effect of ABL on BMD in a rabbit bone loss model that combines increased bone resorption via OVX<sup>5</sup> plus impaired bone formation via GC therapy.<sup>6</sup>

**Methods:** 32 6-month-old female New Zealand White rabbits underwent OVX, 24 of which received the GC methylprednisolone (OVX + GC; daily, SC) starting 1 day after OVX. Another 8 rabbits had sham surgery and did not receive GC (Sham). After a 6-week bone depletion period, OVX + GC rabbits continued to receive GC and treatment began with daily SC vehicle (VEH) or ABL at 5 µg/kg (ABL5) or 25 µg/kg (ABL25) (all n = 8). The remaining OVX and Sham controls received VEH. Lumbar vertebra areal BMD (LV BMD) was assessed before surgery and at treatment week 0, 4, 8 and 12 by dual X-ray absorptiometry (DXA). Animals were sacrificed after 12 weeks of treatment.

**Results:** The OVX + GC VEH group showed an absolute reduction in LV BMD of 30.4% between the start and end of the bone depletion, indicating osteopenia prior to treatment initiation. LV BMD in the OVX + GC VEH group was significantly lower vs OVX controls at the end of the bone depletion period, demonstrating a significant independent contribution of GC to osteopenia. Progressive bone loss continued in the OVX + GC VEH group throughout the treatment period; by treatment week 12 their LV BMD was 49.8% lower than before the bone depletion period, 47.2% lower than Sham controls, and 36.6% lower than OVX VEH controls. ABL dose-dependently increased LV BMD, and by treatment week 8 the effect of ABL25 on LV BMD was significant compared with OVX + GC VEH controls ( $P < 0.05$ ). By treatment week 12, LV BMD in the ABL25 group was increased by 15.7% vs treatment week 0, whereas LV BMD in the OVX + GC VEH controls decreased by 27.8% over that time ( $P = 0.0001$ ).

**Conclusion:** These data indicate that ABL robustly increased BMD in rabbits rendered severely osteopenic by the combined effects of OVX plus GC therapy. These findings also provide preclinical support for investigating the potential of ABL for increasing BMD in patients with bone loss caused by GC therapy.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ankylosing spondylitis (AS) is characterized by inflammation, high osteoblastic activity, leading to ankyloses. Transforming growth factor beta 1 (TGFB1) has been known to be a proinflammatory cytokine in inflammatory disorder and is expressed in AS. This study was undertaken to investigate the role of TGFB1 on osteoblast differentiation, to determine where TGFB1 can stimulate the osteoblast-induced bone formation that is a hallmark of AS.

**Methods:** All experimental and clinical samples were male. Serum from 26 patients with AS, 23 patients with rheumatoid arthritis (RA), and 28 healthy controls (HC) were collected. Bone tissues were obtained at surgery from facet joints of 10 patients with AS and 26 patients with noninflammatory spinal disease from traffic trauma or spinal compression disease, who served as controls. Expression of TGFB1 in patient serum and bone tissues with AS was confirmed by ELISA and immunohistochemistry, respectively. Primary osteoprogenitor cells were cultured to assess osteoblastic activity, using intracellular alkaline phosphatase (ALP) activity and staining, calcium deposit, and hydroxyapatite staining. Additionally, we observed the effect of TGFB1 on the expression of BMP2 which was evaluated by qPCR, promoter assay, immunostaining, immunoblotting, and Chromatin Immunoprecipitation (ChIP) assay.

**Results:** Serum and bone tissues of AS patients exhibited higher level of TGFB1 than those of RA and controls. Moreover, treatment of TGFB1 with primary osteoprogenitor cells showed an increase in phos-smad2 and phos-smad3 proteins, intercellular ALP activity, and BMP2 transcript under non-osteoblastic stimuli. TGFB1 also activated phos-smad2 protein directly binds to proximal region at Smad protein binding element (SBE) in BMP2 promoter. Interestingly, a slight stimulation of TGFB1 in immature stage promises more rapid differentiation toward mature stage under osteogenic stimuli.

**Conclusion:** TGFB1 was highly expressed in AS patients, which were considered to promote osteoblastic activity and osteoblast differentiation by a direct activation of BMP2 signaling pathway. These findings suggest that activation of TGFB1 contribute to the pathogenesis of new bone formation and TGFB1 appears to be a novel therapeutic target in preventing progression of AS.

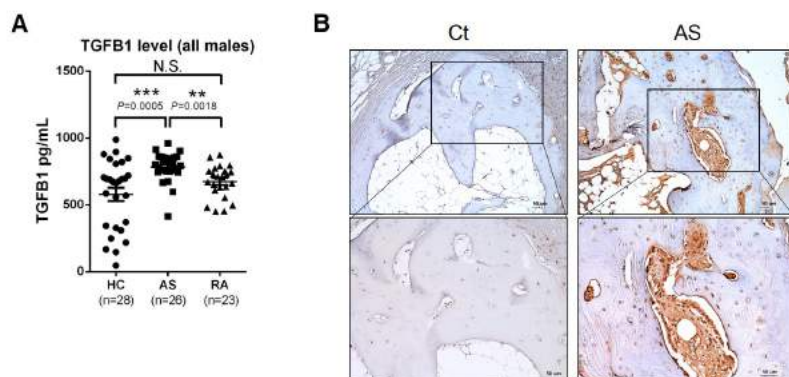

Figure: TGFB1 is highly activated in AS. A, serum level of TGFB1 in AS and RA patients and healthy control as determined by ELISA assay. B, Immunohistochemical staining for TGFB1 in AS and normal bone.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adenosine, generated from the catabolism of adenine nucleotides, modulates cell function by interacting with specific cell-surface receptors (A<sub>1</sub>R, A<sub>2A</sub>R, A<sub>2B</sub>R, A<sub>3</sub>R). Inhibition of osteoclast formation *via* adenosine A<sub>2A</sub> receptor stimulation or increasing local adenosine concentration stimulates new bone formation as well as rhBMP-2. Bone alterations have been observed in HIV (Human Immunodeficiency Virus) disease for nearly two decades, in particular a higher risk of low bone mineral density (BMD) and fragility fractures. Treatment with Tenofovir leads to changes in bone catabolism markers and significant reductions in BMD in children and young adults. Tenofovir is taken up by cells and phosphorylated and inhibits HIV-reverse transcriptase by mimicking AMP. We have recently found that Tenofovir inhibits Pannexin-1/Connexin-43-mediated ATP release from cells and decreases extracellular adenosine levels and fibrosis in murine models. Here we determined if Tenofovir directly affects bone and if Dipyridamole, may be a useful treatment to counteract the effects.

**Methods:** M-CSF/RANKL-induced osteoclast (OC) were studied in primary murine bone marrow culture as the number of TRAP-positive cells after challenge with Tenofovir (1nM-100µM) alone or in combination with Dipyridamole (1nM-100µM). OC differentiation markers were study by RT-PCR. Male C57Bl/6 mice were divided into four groups: saline 0.9% (control), Tenofovir 75mg/Kg/day, Dipyridamole 25mg/Kg/day, combination Tenofovir/Dipyridamole for 4 weeks (n=10 each). Double labelling of bone with calcein /Alizarin Red was performed to analized bone formation and long bones prepared for microCT and histology.

**Results:** Tenofovir produced a dose-dependent increase in OC differentiation (EC<sub>50</sub>=44.5nM) that was reversed by Dipyridamole (IC<sub>50</sub>=0.3µM). Tenofovir increases Cathepsin K and NFATc1 mRNA levels during OC differentiation, and the effect was reverted by Dipyridamole. *In vivo*, mice treated with Tenofovir lost nearly 10% of body weight (p<0.001) and DXA analysis revealed a decrease in % fat (p<0.05), effect reverted by Dipyridamole. Tenofovir reduced bone formation *in vivo* (19±2µm bone apposition vs 35±4µm in control, p<0.05) and this effect was reverted by Dipyridamole (30±3µm, p<0.05 vs Tenofovir alone). microCT analysis revealed decrease BMD and altered trabecular bone in Tenofovir-treated mice, been reverted in the presence of Dipyridamole. TRAP-staining showed increased OC *in vivo* in Tenofovir-treated mice (88±31 vs 27±1 OC/hpf in control, p<0.005) that was reverted inn the pressence of Dipyridamole (30±2OC/hpf, p<0.05 vs Tenofovir alone). Similar results were obtained for Cathepsin K and CD68. RANKL positive cells were increased in the presence of Tenofovir meanwhile OPG positive cells decreases, and both effets were reverted in the presence of Dipyridamole.

**Conclusion:** These results indicate that Tenofovir enhances osteoclast differentiation and inhibits osteoblast differentiation by an adenosine-ATP-dependent mechanism and suggests that treatment with agents that increase local adenosine concentrations, like Dipyridamole, might prevent bone loss following Tenofovir treatment.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

General Synovitis score (GSS) has been developed by Krenn et al in order to discriminate inflammatory arthritis (IA) and non-inflammatory arthritis (NIA) (1). This score allow to quantify inflammation by scoring 3 major components of synovitis: lining layer hyperplasia, activation of resident cells (stroma) and inflammatory infiltrate. All components are graded semi-quantitatively from 0 to 3 and the total score is on 9. High-grade synovitis is highly associated with IA and is defined by a score above 5 with a sensitivity of 61.7% and a specificity of 96.1%. As immunohistochemistry (IHC) is frequently used to better characterize synovitis, we propose to create a new IMMunologic SYnovitis SCore (IMSYC) adding 5 components to the GSS: CD68, CD3, CD20, CD31 and Ki67 immunostaining.

Our work aimed to evaluate the diagnostic performance of this new score including IHC, to define the best cut off for inflammatory arthritis recognition, and to compare its diagnostic performance with the GSS.

## Methods:

Synovial samples from patients were obtained during surgical procedure (arthroplasty or synovectomy). All patients gave written consent prior surgery. Samples were cut and Hematoxylin and eosin stained. CD68, CD3, CD20, CD31 and Ki67 IHC were performed. GSS was assessed for each slide and semi-quantitative 4 scale scores (0-3) were given for each immunostaining, in a blind manner. The score is calculated on 24 (GSS 0-9 points, and 0-3 score for each of the 5 immunostaining).

The 2 readers met and scored a representative amount of slides with a spearman correlation coefficient of 0.95 ( $p < 0.0005$ ). They then defined a consensual and reproducible scoring atlas.

## Results:

53 patients were included. 25 were females (47,2%), mean age was 62.1 years (standard deviation (SD) 13.2 years). 36 had IA reparsed as follows: 28 Rheumatoid arthritis (RA), 5 had Psoriatic arthritis (Psa), 3 had Undifferentiated arthritis (UA). "Non inflammatory" arthritis group included 10 patients with Osteoarthritis (OA) and 7 with ligaments or meniscus injuries (post traumatic arthritis (PtA).

Mean Synovitis Score was significantly superior in the IA group 5.70 [SD 0.321] vs. 3.51 [SD 0.351] ;  $p < 0.001$ ). Mean IMSYC was significantly superior in the IA group 14.94 [SD 0.747] vs. 8.50 [SD 0.639];  $p < 0.001$ ). In univariate analysis by logistic regression, GSS (Odd Ratio (OR) 2.27;  $p < 0.001$ ), CD3 (OR 4.3;  $p = 0.002$ ), CD68 (OR 4.5;  $p = 0.002$ ), Ki67 (OR 11.8;  $p < 0.001$ ), CD31 scores (OR 6.5;  $p = 0.001$ ) and were significantly associated with IA, however CD20 score was not (OR 0.9;  $p = 0.34$ ).

ROC curve analysis of diagnostic performances determined the score of 10.5 out of 24 as the best cut off for discrimination between IA and non-IA with a sensitivity of 74.3% and specificity of 100%. The area under ROC curves (AUC) were nearly statistically different between GSS (0.81) and IMSYC (0.93) ( $p = 0.05$ ).

**Conclusion:** We hereby propose a new synovitis score including IHC. This score has a better sensitivity and specificity than the Synovitis score for discrimination between inflammatory and non-inflammatory arthritis. Moreover, IMSYC accurately describes synovial membrane immunophenotype and could therefore give a basis for tissue driven therapies in rheumatic diseases, especially in RA.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Osteoarthritis is the most common joint disease and involves whole joint, including degeneration of articular cartilage and surrounding tissues. Although widely prevalent, the exact mechanisms involved in pathogenesis of OA are not well understood. Increasing body of data suggest role of low-grade, subclinical, in pathogenesis of OA. However the role of immune cell subsets in OA is poorly investigated. In present study we have applied a combination of single cell mass cytometry for analysis of the peripheral immunome and next generation RNA-sequencing on cell pellet from knee joint fluid to characterise immune cells and pathways.

### Methods:

Patients samples were taken from a randomized controlled trial on treatment of symptomatic knee OA using colchicine for 16 weeks (1) (2). Patients were grouped as having  $\geq 30\%$  improvement in WOMAC (improvement group) and improvement of WOMAC not reaching 30% (Worsening group) at study end regardless of treatment arms. For RNA sequencing analysis 16 paired patient samples, from baseline and study end, were used. For mass cytometry analysis, 37 marker panel was designed to aid in identification of major peripheral blood mononuclear cell (PBMCs) subsets. Unsupervised clustering of mass cytometry data was performed using in-house developed analysis software MARVIS. This software combines dimension reduction and clustering steps to identify all possible cellular subsets from high dimension data. Further, custom R scripts helped in identifying nodes that were differentially expressed between the study groups and also phenotype of these nodes.

### Results:

Differential gene expression analysis comparing baseline vs week 16 from worsening group revealed changes in 696 genes and in improvement group 89 genes were identified. Estimation of cell type abundances, using Cibersort algorithm, showed increased frequency of M2 macrophages, follicular helper T cells and activated NK cells in worsening group and increased memory CD4 T cells in improvement group. Mass cytometry analysis of PBMCs showed increase in inflammatory Tbet<sup>+</sup> ILC subsets in worsening group (n=6) and an increase in Th2 like GATA3<sup>+</sup> CD4 T cells in improvement group (n=6) at baseline.

### Conclusion:

Our systematic multi dimensional approach reveals differences in the alteration of immune cells in knee OA patients with/ without symptoms improvement, both at synovial fluid level and systemic blood level. Further analysis may provide insights into mechanistic pathways involved in pathogenesis of OA, the interaction between tissue and systemic circulation and for advent of novel OA therapies.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CTLA-4 is a surface protein on T lymphocytes, which negatively regulates the co-stimulation process between antigen-presenting cells and T cells. CTLA-4 binds to monocytes via CD80/CD86, which are precursor of osteoclast. In addition, CTLA-4 has been shown to directly inhibit osteoclast formation. However, little is known about the effect of CTLA-4 on osteoclast generation from human monocytes and monocytes exposed to inflammatory cytokines. The aim of this study was to evaluate the effect of a CTLA4-Ig (Abatacept) on osteoclastogenesis in human peripheral monocytes and TNF $\alpha$ -treated inflammatory monocytes.

**Methods:** Peripheral blood mononuclear cells are separated by Ficoll-Paque gradient centrifugation. Highly purified monocytes are prepared from prepared mononuclear cells using MACS microbeads (Pan Monocyte Isolation kit). In this study, more than 92 % of obtained cells are CD14-positive, as determined by flow cytometric analysis. Cultures were maintained in  $\alpha$ -minimal essential medium for 7-14 days with both or either of M-CSF, RANKL and/or TNF $\alpha$  in the presence or absence of CTLA4-Ig. Osteoclasts were identified by TRAP staining and bone resorptive activity using the osteo assay surface multiwell plate. The expressions of CD80/CD86 on resting and TNF $\alpha$ -pretreated monocyte were determined by flow cytometric analysis.

**Results:** Peripheral monocytes from healthy donors were incubated with M-CSF (50 ng/ml) and RANKL (100 ng/ml) in the presence of increasing doses of CTLA4-Ig for 5~7 days. After the culture, generated osteoclasts were determined by TRAP staining and bone resorptive activity. CTLA-4 inhibited the osteoclast generation in a dose-dependent manner (in the range of 0 to 500  $\mu$ g/ml). To examine the effect of CTLA4-Ig on monocytes exposed to inflammatory cytokines, peripheral monocytes were preincubated with TNF $\alpha$  for 48 hours, and then cultured with RANKL. When the expression of CD80/CD86 antigens on peripheral monocytes was analysed, CD86 was only expressed on resting monocytes. Interestingly, TNF $\alpha$  pretreatment potently induced the expression of CD80, suggesting modification of action of CTLA-4. CTLA4-Ig more potently inhibited osteoclast generation from TNF $\alpha$ -treated monocytes than those from resting monocytes.

**Conclusion:** CTLA4-Ig directly inhibits osteoclast generation from human peripheral monocytes. In addition, the inhibitory effect of CTLA4-Ig is more potent in TNF $\alpha$ -treated inflammatory monocytes than resting monocytes, suggesting that CTLA4-Ig could inhibit osteoclast generation in inflammatory monocytes at inflamed joints of RA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

In the Western society adiposity and metabolic syndrome are an increasing field of medical research. Both entities influence the expression of adipokines such as adiponectin, visfatin or leptin, which also modulate the progress of osteoarthritis (OA).

To evaluate these comorbidities together, we combined a high-fat diet (HFD) with the DMM mouse model (destabilization of the medial meniscus). The serologic and local effects of HFD at different states of OA development were correlated to local/systemic adipokine expression.

### Methods:

HFD and ND (normal diet) as control were fed to male C57Bl/6 mice for 3 months followed by surgical DMM (time point 0). Joints, organs and sera were collected 4, 6, and 8 weeks after surgery. Concentrations of the adipocytokines leptin, visfatin, adiponectin and IL-6 in the sera were measured by ELISA. Liver fat was scored to show metabolic changes. Arthritis progression was scored and quantified using histologic stainings of the joints (H/E, safranin O, Pappenheim and Masson-Goldner's trichrome). Immunohistochemical stainings of the mouse joints were performed to evaluate the local distribution of adipokines. Adipokine levels were correlated to arthritis scores, fatty liver score and bodyweight.

### Results:

At all time points, OA was significantly induced, especially by HFD compared to ND (e.g.: OA score at 6 weeks HFD 3.7 vs. ND 1.4). Systemically, leptin levels were significantly higher in HFD compared to ND, but DMM decreased leptin levels at all time points independent from diet (e.g. 4 weeks: HFD healthy 18.4 ng/ml vs. HFD DMM 3.7ng/ml). Systemic leptin levels correlate with liver fat content. Interestingly, the systemic changes of adiponectin by DMM were only present at week 8 (HFD healthy 5176ng/ml vs. HFD DMM 6149ng/ml). The combination of HFD and DMM did not show significant effects on serum levels of adiponectin, visfatin or IL-6 in this experimental setting. Local adipokine expression in the joints was independent from systemic adipokine levels.

### Conclusion:

The data show that similar to the human setting, OA in the DMM model is deteriorated by HFD. This is serologically reflected by reduced protective leptin levels but not increased proinflammatory visfatin or adiponectin supporting the idea of a prominent local rather than systemic pathophysiology.

## A Dual Role for IL-23 Receptor Signaling in Normal Bone Remodeling Versus Inflammation-Mediated Bone Damage during Arthritis

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The interleukin (IL)-23/IL-17A immune pathway is critical for the development of autoimmune arthritis. Systemic exposure of IL-23 induced chronic arthritis, increased osteoclast differentiation and systemic bone loss in mice. However, the role of IL-23 on normal and pathologic bone remodeling is not fully elucidated. Here we examined the role of IL-23R signaling on bone remodeling in steady state and on bone damage during a T cell-mediated inflammatory arthritis using wild type (WT) and IL-23RKO mice.

### **Methods:**

Femurs of naïve WT and IL-23RKO mice were used for MicroCT analysis of the bone and a three-point bending test for bone strength. Bone marrow cells (BM) were cultured towards osteoclasts with MCSF, RANKL and +/- IL-17 and assessed for osteoclast-like cells using tartrate-resistant acid phosphatase (TRAP) staining and bone resorption assay.

For antigen-induced arthritis (AIA), WT and IL-23R<sup>GFP+ /GFP+</sup> (IL-23RKO) mice were immunized with methylated bovine serum albumin (mBSA) supplemented in Complete Freund's Adjuvant. After 7 days mice were injected in the knee joints with mBSA. Mice were macroscopically scored at given time points and knees were used for histological analysis of joint inflammation and bone erosion.

### **Results:**

MicroCT data revealed a low bone mass phenotype in naïve IL-23RKO mice compared to WT mice, with lower trabecular bone volume fraction, thickness and number as well as lower cortical volume and thickness. Three-point bending data show significantly reduced maximum force in IL-23RKO femurs. However, IL-17 stimulation of both WT and IL-23RKO BM cells increased osteoclast bone resorption activity *in vitro*.

In contrast, histological analysis revealed significantly less inflammation-mediated bone damage in knees of IL-23RKO versus WT mice during AIA. This was accompanied with significantly less severe joint inflammation, although the onset of arthritis was not prevented in IL-23RKO mice.

### **Conclusion:**

IL-23R signaling is important for the maintenance of bone mass under steady state conditions. However, although the effect of IL-17A on bone resorption is independent of IL-23R signaling, T cell driven inflammatory bone erosion during arthritis is IL-23R signaling dependent.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Drug repositioning is a recent pharmaceutical strategy to discover new uses for market-approved drugs with known safety profiles that can provide quick transition from the laboratory bench to bedside. Suramin is a poly-sulfonated molecule, used for the treatment of African sleeping sickness. Suramin has been used *in vitro* to isolate MMPs and tissue inhibitor of

metalloproteinase 3 (TIMP3) from the rat uterus. Here, we investigated therapeutic repositioning of suramin to protect the joint against the development of osteoarthritis, hypothesizing that suramin interacts with cartilage extracellular matrix (ECM) proteins.

**Methods:** *In vitro* ECM deposition in the presence or absence of suramin was studied in murine chondrogenic ATDC5 cells or in human articular chondrocytes from osteoarthritis and control patients, by gene expression and protein analysis, colorimetric staining and immunohistochemistry. To study the effect of suramin *in vivo*, the drug was injected intra-articularly in the papain-model of osteoarthritis in wild-type C57/Bl6 mice. Disease severity was analyzed by histology, immunohistochemistry and contrast-enhanced nanofocus computed tomography.

**Results:** In ATDC5 micromass cultures, suramin treatment increased tissue inhibitor of metalloproteinase-3 (TIMP3) levels and decreased the activity of matrix metalloproteinases (MMPs) and aggrecanases. Suramin treatment thus resulted in increased glycosaminoglycan content. This effect on the cartilage ECM was prevented by co-culture with anti-TIMP3 antibody. Mice treated intra-articularly with repetitive suramin injections in the disease model of osteoarthritis, showed reduced cartilage damage compared to controls, with increased TIMP3, and decreased MMP and aggrecanase activity. Translational validation in human chondrocytes confirmed increased TIMP3 function and reduced cartilage breakdown after suramin treatment.

**Conclusion:** Suramin prevented the development of osteoarthritis in a mouse model of direct cartilage damage. Mechanistically, the effects of suramin appear to be mediated by a functional increase of TIMP3, and a subsequent decrease in the activity of catabolic enzymes.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Our goal is to develop an *in vitro* 3D joint model to simulate the immune mediated pathogenesis of arthritides in order to present an alternative experimental setup for traditional animal models. There are currently no appropriate *in vitro* models capable of simulating an arthritic joint in such a comprehensive way that all relevant humoral and cellular factors as well as the different tissue types are involved. Therefore, we work to establish an *in vitro* 3D healthy joint model, followed by the simulation of an arthritic joint. The *in vitro* 3D joint model is planned to consist of an (1) osteogenic part and (2) a chondrogenic part, (3) the joint space with synovial fluid, and (4) the synovial membrane.

Development of the first two components of our *in vitro* 3D joint model, namely (1) the osteogenic and (2) the chondrogenic part.

### Methods:

We used  $\beta$ -tricalcium phosphate (TCP) with 60% porosity as the mineral part of our osteogenic model. This substrate was populated with human bone marrow derived mesenchymal stromal cells (hMSC) predifferentiated towards the osteoblastic lineage and then cultured for up to 21 days under normoxic conditions (37 °C, 18% O<sub>2</sub>). The adhesion of the cells and their structural integrity were evaluated by Scanning Electron Microscopy and Laser Scanning Microscopy. To confirm cell attachment and biocompatibility of  $\beta$ -TCP particles, cellular release of LDH (after 1 d) was assessed, and LIVE/DEAD staining was applied (1, 7, 14, 21 d). Osteogenic

differentiation was verified on gene expression level using qRT-PCR. The chondrogenic model, a scaffold-free 3D cartilage construct (fzmb GmbH), was generated using native hMSC. Chondrogenic differentiation was performed under hypoxia (37 °C, 1% O<sub>2</sub>) with intermittent mechanical stimulation and analyzed by histology (HE staining) and immunohistology (Col1a1, Col2a1, Alcian Blue).

## Results:

We have been able to successfully develop an *in vitro* 3D bone model by seeding predifferentiated hMSC (after 24-hour preincubation with osteogenic medium) on a  $\beta$ -TCP scaffold. The analysis of cell viability via LDH detection did not show any toxic effects during cultivation of the cells seeded. Histological and immunofluorescence analyses demonstrated good cell attachment, cell integrity and metabolic activity of the  $\beta$ -TCP scaffold until day 21, demonstrating the good suitability of both the scaffold and the cultivation method. mRNA expression of bone-related genes such as *RUNX2*, *SPP1* and *COL1A1* confirmed phenotypic changes as induced during osteogenic differentiation. The development of a cartilage phenotype from the accordingly differentiated hMSC was confirmed by HE and Alcian Blue staining as well as by Col1a1 and Col2a1 expression. Histological analyses performed after 21 d of co-cultivation showed successful colonization, connectivity and initial calcification implying a functional transitional bridging area.

**Conclusion:** These initial results from our *in vitro* 3D models confirm good cell vitality indicating successful progression of developing our model. This 3D multi-component joint model should enable us to simulate arthritis and to study the efficacy of drug treatment *in vitro*.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Thy1 (CD90) is a glycosylated, glycosylphosphatidylinositol (GPI)-anchored membrane protein originally identified as a marker for mouse T cells but subsequent reports noted expression on stem cells, osteoblasts and fibroblasts. Thy1 is abundantly expressed by mesenchymal stem cells and inhibits adipogenesis. We examined the contribution of Thy1 to osteoblastogenesis and bone homeostasis.

**Methods:** A pre-osteoblastic MC3T3 cell line, and primary bone marrow derived mesenchymal stem cells from wild type (WT) C57BL/6 mice were cultured in osteogenic conditions for up to 21 days. Messenger RNA (mRNA) and protein expression of Thy1 and the OB differentiation markers RUNX2, BGLAP, COL1A1, were analyzed by real-time PCR and western blot. Similarly, mouse embryonic fibroblasts (MEFs) isolated from WT and Thy1 knockout (KO) mice were cultured in osteogenic media. Mineralized matrix and calcium deposition were examined with alizarin red staining. To study the impact of Thy1 depletion on bone quality in the normal and obese mice, 2 month old C57BL/6 WT and Thy1 KO mice were fed a normal or high fat diet for 2 months and long bones were analyzed with micro-CT to compare changes in bone architecture and overall bone quality.

**Results:** *In vitro* assays revealed that osteogenic conditions transiently increased Thy1 expression during OB differentiation. *In vitro* experiments with WT and Thy1 KO mesenchymal cells and MEFs further revealed that in the absence of Thy1, osteoblastogenesis was delayed as noted by alizarin red staining. Micro CT analysis of long bones in WT and Thy1 KO mice revealed that when Thy1 KO and WT mice were fed a high fat diet, bone quality at 4 months differed significantly between WT and KO mice. In particular, a significant reduction in trabecular bone quality was noted in Thy1 KO mice. The most significant differences were seen in tibial trabecular bone volume/total volume (BV/TV):  $0.12 \pm 0.02$  in WT vs  $0.09 \pm 0.01$  in Thy1 KO, ( $p < 0.03$ ), femoral BV/TV:  $0.37 \pm 0.15$  in WT vs  $0.19 \pm 0.03$  in Thy1 KO femur, ( $p < 0.03$ ) and tibial trabecular bone connectivity density:  $50.01 \pm 10.85$  in WT vs  $28.29 \pm 6.72$  in Thy1 KO, ( $p < 0.01$ ), and femoral trabecular bone connectivity density:  $42.03 \pm 14.42$  in WT vs  $22.17 \pm 7.79$  in Thy1 KO femur, ( $p < 0.019$ ); overall more than a 40% decrease. Interestingly, significant differences were not detected in WT and Thy1 KO mice fed a normal diet.

**Conclusion:** We find that Thy1 is required for differentiation of OB based on our *in vitro* experiments. Absence or decreased expression of Thy1 was associated with reduced bone quality. Of note, higher levels of Thy1 mRNA and protein levels were reported in osteoarthritis patients, a disease characterized by osteophyte formation with higher prevalence in obese individuals. Thus, Thy1 may serve as an important mechanistic link between bone formation and obesity.

## **TNF- $\alpha$ Overrides the Ability of RANK Ligand to Induce Osteoclast Differentiation of Classical Circulating Precursors**

Cecilia Ansalone<sup>1</sup>, Flavia Sunzini<sup>1</sup>, Caitlin Duncan<sup>1</sup>, Sabarinadh Chilaka<sup>1</sup>, Iain B. McInnes<sup>2</sup> and Carl S. Goodyear<sup>3</sup>, <sup>1</sup>Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom, <sup>2</sup>University of Glasgow, Glasgow, United Kingdom, <sup>3</sup>Institute of Infection, Immunity and Inflammation, College of Medicine, Veterinary Medicine and Life Sciences, University of Glasgow, Glasgow, United Kingdom

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

TNF- $\alpha$  is well known to be involved in inflammatory-induced bone destruction. This is widely supported by clinical studies showing reduced bone pathology after anti-TNF- $\alpha$  therapies. Numerous *in vivo* and *in vitro* studies in rodents have demonstrated that TNF $\alpha$  directly contributes to osteoclast(OC)-mediated joint destruction. Moreover, specific murine OC precursors are expand during inflammatory arthritis. Despite this, it is still unclear which population within the human myeloid compartment primarily contributes to OC-mediated bone erosion, and whether or not TNF- $\alpha$  has a direct impact on all pre-cursors equally. Here we have investigated the direct effect of TNF- $\alpha$  on different circulating myeloid populations and their subsequent differentiation into osteoclasts.

**Methods:** Total CD14<sup>+</sup> monocytes, monocyte subsets (CD14<sup>+</sup>CD16<sup>-</sup>, CD14<sup>+</sup>CD16<sup>+</sup>, CD14<sup>dim</sup>CD16<sup>+</sup>), and myeloid dendritic cell precursors (pre-DCs; CD16<sup>-</sup>CD14<sup>-</sup>CD11c<sup>+</sup>) were isolated from peripheral blood of healthy donors using either magnetic separation or FACS. Selected populations were differentiated into OC with M-CSF and RANK-L in the presence or absence of TNF- $\alpha$ . Mature OCs were stained with tartrate-resistant acid phosphatase and quantified by light microscopy. Mineral-coated surfaces were used to assess the resorption activity of mature OCs. Flow cytometry analysis was used to assess surface protein expression during OC differentiation. Antibody blocking studies and selective inhibition of IKK- $\beta$  were performed to determine the role of TNFR1 and TNFR2 in OC development. Gene expression was assessed by RT-qPCR.

**Results:** Simultaneous stimulation of CD14<sup>+</sup> monocytes with RANK-L and TNF- $\alpha$  resulted in complete abolishment of OC differentiation and resorption. Notably, these cells acquired a macrophage phenotype. In contrast, delayed addition of TNF- $\alpha$  (72h pre-stimulation with RANKL) enhanced osteoclast numbers. Importantly, CD14<sup>+</sup> monocytes expressed both TNFR1 and TNFR2 but only

the level of TNFR1 decreased during OC differentiation. Blockade of TNFR1 negated the inhibitory capacity of simultaneous TNF- $\alpha$  whilst blockade of TNFR2 reverted the enhancing capacity of TNF- $\alpha$ . Inhibition of IKK- $\beta$  revealed that the TNFR1-driven inhibitory signal was dependent on the canonical NF- $\kappa$ B pathway. At a molecular level, TNF- $\alpha$  signalling in CD14<sup>+</sup> monocytes blocked the M-CSF-driven up-regulation of RANK transcript.

In comparison to CD14<sup>+</sup> monocytes, pre-DCs differentiated quicker and more efficiently into OCs under M-CSF and RANK-L stimulation. Interestingly, pre-DCs were found to express less TNFR1 than CD14<sup>+</sup> monocytes and TNF- $\alpha$  failed to inhibit RANK expression and thus their differentiation into functional OCs.

**Conclusion:** We have shown that the hierarchy between TNF- $\alpha$  and RANK-L is crucial for driving the differentiation of CD14<sup>+</sup> monocytes into either macrophage or osteoclasts. In comparison, this axis does not influence the ability of pre-DCs to differentiate down the OC lineage. This study provides new insight in the contribution of different circulating myeloid precursors to bone destruction in a TNF- $\alpha$  rich environment.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is a need to standardize platelet-rich plasma (PRP)-derived products and their dosage to evaluate efficacy for each intended indication. Our purpose here was to test the anti-inflammatory effects of PRP releasates (PRP-rs) from PRP with standardized (absolute) platelet concentrations in OA knee and hip chondrocytes stimulated with IL-1B.

**Methods:** Blood was obtained from healthy volunteers after informed consent. PRPs with different platelet concentrations (0, 0.25, 0.5, 0.75, 1.5, 3, 6 and 15x10<sup>5</sup>platelets/uL) were prepared by first, separating platelets and platelet poor plasma (PPP), and then re-suspending platelets in known absolute numbers. PRPs were then clotted with CaCl<sub>2</sub> to obtain their PRP-rs. Human chondrocytes (hCH) were isolated from OA hip and knee joints after informed consent. Co-stimulation of hCH with IL-1B and the different PRP-rs (10% in DMEM) was used to test their anti-inflammatory effect. We assessed the expression of relevant inflammatory markers with qRT-PCR, ELISA and immunocytochemistry. GraphPad Prism software was used for data analysis with both parametric (ANOVA + Bonferroni's post hoc test) and non-parametric (Kruskal-Wallis + Dunn's test) approaches.

**Results:** Inflammatory stimulation with IL-1B sharply increased the expression of iNOS, COX-2, PTGES, MMP-13 and IL-6. All PRP-rs showed a significant anti-inflammatory effect in knee OA hCH for all markers, ranging from 80% for COX-2 to 99% for iNOS (Fig.1a-c). Remarkably, this reduction was not dependent on platelet dose; even PPP showed maximum anti-inflammatory effect. As for hip OA hCH, only the lower platelet doses of 0 - 0.75x10<sup>5</sup>/uL reduced the expression of COX-2 (~90%), PTGES and MMP-13 (~90%) significantly (Fig.1f-g). Increasing platelet doses (except for iNOS, Fig.1e) resulted in a progressive loss of this anti-inflammatory effect in hip OA hCH. ELISA quantitation of MMP-13 protein corroborated these trends on knee and hip hCH: all PRP-rs (except 6 and 15x10<sup>5</sup>/uL) reduced MMP-13 to approximately basal levels (Fig 1d, h). Immunocytochemistry of iNOS and COX-2 in knee hCH were concordant with qRT-PCR results as well (Fig 2).

**Conclusion :** PRP-r can exert anti-inflammatory effects in OA hCH but platelet enrichment is not needed for knee OA hCH, and it is detrimental in hip OA. In this case, only doses below peripheral blood platelet concentration ( $< 1.5 \times 10^5$  platelet/uL) were effective. Therefore, platelet dosages in PRP need to be standardized to evaluate efficacy and might need to be adjusted for different indications.

Figure 3. Gene expression of the pro-inflammatory markers iNOS, COX-2 and MMP-13 (a-c, e-g), and MMP-13 protein quantification (d, h), in knee (a-d) and hip (e-h) OA chondrocytes. Platelet concentrations on the X axis are  $\times 10^5$  platelets/ $\mu$ L. Data are expressed as mean  $\pm$  SD. \* p-value < 0.05 with respect to Basal, # p-value < 0.05 with respect to  $0.1 \times 10^5$ , \$ p-value < 0.05 with respect to  $0.5 \times 10^5$ , and > p-value < 0.05 with respect to  $1.5 \times 10^5$ . n = 3 for knee, n = 3 for hip.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The rising number of adults with arthritis and associated activity limitations present a serious public health problem. Although studies have explored lower limb osteoarthritis (OA) at the knee and hip, few have focused on the foot. Therefore, the purpose of this study is to determine the frequency of foot OA and identify potential associated risk factors.

**Methods:** Participants were from the Johnston County OA Project, a community-based study of individuals in rural North Carolina with and without OA. Weight-bearing anteroposterior and lateral radiographic images of the foot were obtained. Based on the La Trobe radiographic atlas, foot radiographic OA (rOA) was defined as a score of 2 or more for osteophytes or joint space narrowing in at least one of the following 5 joint sites: 1<sup>st</sup> metatarsophalangeal joint, 1<sup>st</sup> & 2<sup>nd</sup> cuneo-metatarsal joints, navicular-1<sup>st</sup> cuneiform joint, and talo-navicular joint. Foot symptoms were assessed via questionnaire by answering the question: “On most days of any one month in the last 12 months did you have pain, aching or stiffness in your [left/right] foot?” Symptomatic OA (sxOA) was defined as symptoms in the presence of foot rOA. At the joint level, separate logistic regression models with generalized estimating equations (GEE) to account for intra-person correlations were performed to examine discrete associations (odds ratios [OR]) of foot rOA or sxOA with age, body mass index (BMI), sex (women/men), race (African-American/Caucasian), history of foot injury (yes/no), and foot symptoms ([yes/no], rOA models only). Next, multiple logistic regression models with GEE were performed for foot rOA or sxOA outcomes adjusting for all factors (foot symptoms: rOA models only).

**Results:** Of the 864 participants with available data (mean age 71 yrs, mean BMI 30.8 kg/m<sup>2</sup>, 68.2% women, 33.4% African American), 22.1% had rOA, 20.4% had foot symptoms, 5.3% had sxOA, and 3.8% reported prior foot injury. In adjusted models, symptoms vs. no symptoms were associated with 1.48 times the odds of rOA (Table 1). Compared to non-obese (BMI<30) participants, obese (BMI≥30) individuals had 1.74 times the odds of rOA (Table 1) and 3.30 times the odds of sxOA (Table 2). African Americans vs. Caucasians had 1.49 times the odds of rOA; the association was not statistically significant in the adjusted model (Table 1).

**Conclusion:** In this community-based cohort, 1 out of 5 older adults had foot rOA and 1 out of 20 had foot sxOA. Obesity was linked with foot OA, even when considering other factors, suggesting that weight reduction may be an important strategy, especially for individuals with sxOA.

## Effect of Initiating Metformin Vs. Sulfonylureas on the Risk of Total Knee Arthroplasty

Yuqing Zhang<sup>1</sup>, Christine Peloquin<sup>2</sup>, Na Lu<sup>3</sup>, Tuhina Neogi<sup>3</sup> and David T. Felson<sup>3</sup>, <sup>1</sup>School Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>2</sup>Boston University School of Medicine, Boston, MA, <sup>3</sup>Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Metformin is the most widely used first-line therapy for type 2 diabetes. Studies have suggested that metformin reduces inflammation and lowers levels of PGE2, IL-1 $\beta$ , IL-6 and TNF $\alpha$  in macrophages through its effects on AMPK and the NF- $\kappa$ B pathway. Further, by activating AMPK, metformin may suppress chondrocyte matrix catabolic responses to inflammatory cytokines. However, few studies have assessed the effect of metformin on the risk of end-stage knee OA.

**Methods:** We carried out 2 studies to examine the effect of metformin on the risk of total knee arthroplasty (TKA). Subjects, drawn from The Health Improvement Network (THIN) in the United Kingdom, were between 40-90 years old (year 2000-2014) and had clinical OA with no history of renal disease or TKA. In the first cohort study, each metformin initiator was propensity-score matched to a sulfonylurea initiator within 12-month accrual block. Subjects were followed to the date of TKA, disenrollment from THIN, or 12/31/2014. We plotted cumulative risk of TKA for each cohort accounting for competing risk and examined the relation of metformin to the risk of TKA using Cox proportional hazards model. In the second case-control study conducted among metformin initiators only, we randomly selected up-to four controls from a risk set matched to each TKA case by age, sex, and year of metformin initiation. We estimated the odds ratio (OR) of TKA according to recency of use (i.e., remote: stopped metformin prescription  $\geq 12$  months prior to TKA; recent: stopped metformin prescription between  $>15$  days - $<12$  months prior to TKA; and current use: metformin use within 15 days prior to TKA) and duration of use among the current users (i.e.,  $<1$  year, 1- $<2$  years, 2- $<4$  years, and 4+ years) using conditional logistic regression model adjusting for BMI, NSAIDs use, OA duration, GP visits prior to metformin use, Townsend deprivation score, comorbidities and other oral antidiabetics.

**Results:** The baseline characteristics were well balanced in the two comparison cohorts (n=1,387 in each cohort) in the first study. Over 15,871 person-years of follow-up, 75 TKA cases (incidence rate: 9.04/1000 person-years) in the metformin cohort and 63 (incidence rate: 8.31/1000 person-years) in the sulfonylureas cohort had TKA. No difference in the risk of TKA was observed between the cohorts ( $p > 0.65$ , Figure 1). Compared with sulfonylurea initiators the hazard ratio of TKA for metformin initiators was 1.08 (95% CI: 0.77-1.51). The ORs of TKA for recent and current use of metformin were 0.88 (95% CI: 0.61-1.27) and 1.12 (95% CI: 0.84-1.49), respectively, compared with remote use. There was no dose-response relationship between duration of metformin: ORs of TKA were 1.04, 1.14, 1.22 and 1.05 for use  $<1$  year, 1- $<2$  years, 2-4 years and 4+ years, respectively, compared with remote use.

**Conclusion:** Our findings suggest that in persons with OA, metformin use does not lower the risk for TKA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Arthrocentesis (AC) is a common and simple yet invasive procedure with potential of serious complications. There are no studies evaluating how often this procedure is utilized among hospitalized patients and if the outcomes are different when the procedure occurs. We explored the same using a large inpatient US database.

## Methods:

Using the largest inpatient National Inpatient Sample (NIS) data from 2004-2013, we identified adults with AC related discharges based on ICD-9 procedure codes. We calculated the proportion/rate of AC by sex, racial groups and arthritis categories; and outcomes (mean LOS and mortality). Analysis was done using STATA and Joinpoint Regression software. SVY commands were used to derive national estimation. Annual Percentage Changes (APC) were calculated to check the significance of changing trend ( $p < 0.05$ ) unless specified.

## Results:

Our study included 686,538 discharges with AC as a procedure during hospitalization from 2004-2013. There was an overall increasing trend in total number ( $APC=2.26$ ) and rate of arthrocentesis ( $APC=2.73$ ) (Fig-1). However, the use of AC showed decreasing trends for crystal disease, OA, RA, infective and hemarthrotic/traumatic arthropathy (Fig-2). Interestingly, LOS among discharges with AC had decreasing trend compared to those without, while mortality rate remained same throughout (Fig-3). All sex and race categories showed increasing trend of AC utilization during inpatient stays.

## Conclusion:

There was an increasing trend of utilizing arthrocentesis among hospitalized patients from 2004-2013 with a concurrent decreasing trend of LOS and stable mortality rate among those patients. This highlights the improvement in quality of this procedure performed in the hospitals of US. The reducing trends among etiologic categories such as crystal disease, RA, OA and infective arthritis might indicate better outpatient management of these patients with improved disease control and thus requiring less invasive procedures like AC.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Prior studies suggest that high intake of antioxidants, fish, olive oil, and nuts may decrease risk of chronic inflammatory diseases and reduce inflammatory biomarkers. Current knowledge remains scarce regarding a potential association of dietary factors and incident SLE. We aimed to prospectively evaluate the association between the Alternate Healthy Eating Index 2010 (AHEI-2010), a dietary quality index that measures how well Americans' diets conform to the Dietary Guidelines for Americans, and risk of incident SLE and its subtypes of dsDNA positive (+) versus negative (-) SLE.

**Methods:** We included 79,939 female nurses in NHS (1984-2012) and 93,554 in NHSII (1991-2013). Lifestyle, environmental, and medical data were collected through biennial questionnaires. Dietary data were obtained from validated food frequency questionnaires at baseline and approximately every 4 years during follow-up. Incident SLE was confirmed by medical record review. Time-varying Cox regression models estimated pooled hazard ratios (HRs [95% confidence intervals]) of SLE risk, overall and by dsDNA subtype, in association with cumulative average AHEI-2010 (in quartiles, with higher AHEI-2010 quartiles corresponding to a 'healthier' diet) through the 2-year cycle prior to diagnosis, controlling for potential confounders. Individual AHEI-2010 components and SLE risk were assessed separately.

**Results:** We identified 183 SLE cases (88 dsDNA+ and 95 dsDNA-) during nearly 20 years of follow-up from 1984 to 2013 in NHS/NHSII. In multivariable-adjusted models, we found that greater adherence to the highest, or 'healthiest' quartile of AHEI-2010 (vs. lowest quartile, reference) was not associated with SLE risk overall (HR 0.93 [95% CI 0.59-1.44]) or after stratification by dsDNA+ (HR 0.85 [95% CI 0.44-1.60]) or dsDNA- (HR 0.99 [95% CI 0.54-1.83]) subtypes (**Table**). However, women in the highest quartile of nut/legume intake had a decreased risk of developing SLE (HR 0.77 [95% CI 0.62-0.97], p-trend 0.02) compared to women in the lowest quartile. No association was demonstrated with other individual AHEI-2010 components and SLE risk.

**Conclusion:** Healthy diet as quantified by the AHEI-2010 was not associated with SLE risk overall or by dsDNA subtype among women. We did however observe a potential 23% reduction in overall SLE risk with high nut/legume intake, known to be a rich source of anti-inflammatory polyunsaturated fats. This finding suggesting a link between a dietary component and SLE risk is hypothesis generating and warrants further investigation.

**Table. Hazard ratios (95% CI) for incident SLE, overall and stratified by double stranded DNA (dsDNA) subtype, according to cumulative Alternate Healthy Eating Index (AHEI-2010) in Nurses' Health Study and Nurses' Health Study II<sup>1</sup>**

dsDNA positive SLE					
Case/person-years	22/972,075	26/975,040	21/975,617	19/976,222	
Age adjusted model	1.0 (ref)	1.20 (0.68-2.11)	0.96 (0.52-1.74)	0.91 (0.49-1.69)	0.32
Multivariable-model <sup>d</sup>	1.0 (ref)	1.14 (0.64-2.03)	0.91 (0.49-1.67)	0.85 (0.44-1.60)	0.24
dsDNA negative SLE					
Case/person-years	23/975,008	31/978,009	18/978,581	21/979,256	
Age adjusted model	1.0 (ref)	1.37 (0.81-2.33)	0.78 (0.42-1.45)	0.95 (0.52-1.71)	0.73
Multivariable-model <sup>d</sup>	1.0 (ref)	1.37 (0.80-2.35)	0.79 (0.42-1.48)	0.99 (0.54-1.83)	0.83

<sup>1</sup>Hazard ratios were calculated by using time-varying Cox proportional hazards models.

<sup>2</sup>AHEI-2010 is a dietary quality index that measures how well Americans' diets conform to the Dietary Guidelines for Americans and is derived from 11 foods/nutrients consistently associated with lower risk of chronic diseases: vegetables, fruits, whole grains, nuts/legumes, sugar-sweetened beverages, red/processed meat, trans-fat % of energy, long-chain omega-3 fats, polyunsaturated fat, sodium and alcohol (each scored from 1 to 10). AHEI-2010 ranges from 0 to 110. Higher AHEI-2010 quartiles correspond to a 'healthier' diet.

<sup>3</sup>p-trend was derived from tests of linear trend across quartiles of AHEI scores by treating the median value of each category as a continuous variable.

<sup>4</sup>Adjusted for age (continuous), smoking (never/past/current), early menarche (≤10 years, >10 years), oral contraceptive use (ever/never), postmenopausal status and postmenopausal hormone use (premenopausal, postmenopausal with no hormone use, postmenopausal with hormone use [ever]), census tract median family income (<\$60,000, ≥\$60,000) and total calorie intake (continuous) and BMI (kg/m<sup>2</sup>; <25, 25-29.9, or ≥30).

## Association of CRP with BMI in Males and Females

**Taik Kim**<sup>1</sup>, Stephen J. Ganocy<sup>2</sup>, Maria Antonelli<sup>3</sup>, Douglas Einstadter<sup>4</sup> and Stanley Ballou<sup>1</sup>, <sup>1</sup>Rheumatology, Case Western Reserve University/MetroHealth Medical Center, Cleveland, OH, <sup>2</sup>Case Western Reserve University, Cleveland, OH, <sup>3</sup>Department of Medicine/Division of Rheumatology, Case Western Reserve University School of Medicine, MetroHealth Medical Center, Cleveland, OH, <sup>4</sup>Case Western Reserve University at MetroHealth Medical Center, Cleveland, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

C-reactive Protein (CRP) is an inflammatory marker commonly used to help aid in diagnosis, assess disease activity or monitor response to therapy. It is well established that many factors alter the serum CRP level, excluding infectious, malignancy, or rheumatologic causes. Obesity has been demonstrated to be a risk factor that contributes to elevated CRP levels. There is evidence that adiposity influences CRP levels and not vice versa (1). The proposed mechanism is that human adipose tissue expresses and releases the pro-inflammatory cytokine interleukin-6, inducing low-grade systemic inflammation in individuals with excess body fat (2).

The widely accepted reference range of CRP in healthy individuals is <1.0 mg/dL. The objective of our study was to quantify the association between obesity and CRP in order to establish an upper reference limit CRP for a given body mass index (BMI) in a healthy adult population.

### Methods:

The NHANES (National Health and Nutrition Examination Survey) data from 2000 to 2010 was analyzed. Age was limited to 21 years and above to represent the adult population. BMI was limited to  $\leq 50$  kg/m<sup>2</sup> and CRP limited to  $\leq 5$  mg/dL to exclude extreme values. The total number of analyzed subjects was 37303.

Quantile regression analysis was used to determine the median (CRP50) and 95<sup>th</sup> percentile CRP (CRP95) at various BMI levels. CRP95 was accepted as the upper reference limit of CRP.

Subgroup analysis was done comparing a younger population (21 to 45 years old) and older population (50 years old and above) and all analyses were based on gender.

### Results:

Both CRP50 and CRP95 increase with increase in BMI.

The slope estimate of CRP95 was higher in females compared to males (0.0761 vs 0.0455 (P<0.001), respectively).

From these results we derived a simple calculation to approximate the CRP95, or reference upper limit of CRP, for a given BMI:

Males:  $CRP \leq 1.0 + (BMI - 25)/25$

Females:  $CRP \leq 1.0 + (BMI - 25)/12.5$

Subgroup analyses showed that the younger female subgroup had the highest increase in CRP95 (slope estimate=0.089) and the older male group showed almost no increase in CRP95 with increase in BMI (slope estimate=0.002).

### Conclusion:

Serum CRP levels increase with BMI increase in adults, and are higher in females than males at all elevated levels of BMI. BMI seems to influence the 95<sup>th</sup> percentile CRP of younger females most and older males least.

We propose a practical calculation that can predict the upper reference limit of CRP for a given BMI.

## Health Care Provider Advice for Weight Loss Among US Adults with Arthritis, National Health Interview Survey, 2014

Jennifer M. Hootman<sup>1</sup>, Miriam G. Cisternas<sup>2</sup>, Louise Murphy<sup>3</sup> and Teresa J. Brady<sup>4</sup>, <sup>1</sup>Centers for Disease Control and Prevention, Kennesaw, GA, <sup>2</sup>MGC Data Services, Carlsbad, CA, <sup>3</sup>Division of Population Health, Centers for Disease Control and Prevention, Atlanta, GA, <sup>4</sup>Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Most clinical practice guidelines for the management of osteoarthritis recommend weight loss for adults with arthritis who are overweight or obese. A health care provider's (HCP) advice for weight loss is strongly associated with weight loss attempts. The purpose of this study is to estimate the prevalence and characteristics of adults with arthritis reporting a HCP's advice to lose weight among overweight and obese adults with arthritis.

### Methods:

The National Health Interview Survey, conducted annually, targets the civilian, non-institutionalized population and gathers data on a variety of health topics. We used data from 2014 (sample size 36,697). Doctor-diagnosed arthritis was defined as a 'yes' to: "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus or fibromyalgia?" HCP advice for weight loss was defined as a 'yes' response to "Has a doctor or other health professional EVER suggested losing weight to help your arthritis or joint symptoms?" Age-standardized prevalence (%) and 95% confidence intervals (CI) of HCP advice for weight loss was calculated using statistical weights to account for the complex survey design. Prevalence was calculated by sociodemographic characteristics (age, sex, race/ethnicity, and education) and health-related characteristics (arthritis-related activity limitation (AAAL), self-rated health (excellent/very good, good, fair/poor), body mass index (BMI; 25.0-<30 overweight and 30.0+ obese), smoking status (current, former, never), physical activity level (inactive, insufficient, meets recommendations) and having a primary care provider (yes, no). Low rates of HCP advice for weight loss was defined as < 45%.

### Results:

Age-standardized prevalence of HCP advice for weight loss among overweight/obese adults with arthritis was 45.8% (CI 43.3-48.2%). Subgroups with low rates of HCP advice for weight loss included males (41.2%), Non-Hispanic Others (25.6%), < high school education (41.9%), university degree (44.7%), work status 'other' (42.4%), none to mild joint pain (41.0%), excellent/very good health (37.9%), current smokers (40.4%) and those meeting physical activity recommendations (42.9%). Prevalence rates of HCP advice for weight loss increased as overweight/obesity increased (Figure). Subgroups with the highest rates (>55.0%) were extreme obesity (80.3%), Obese Class II (65.3%), Non-Hispanic Asian (57.6%), unable to work/disabled (55.6%), and those with fair/poor health (55.0%).

### Conclusion:

Less than half of overweight/obese adults with arthritis report having been advised by a health care provider to lose weight. Additional health care professional education/training and system improvements like electronic reminders may help increase rates of recommended provider advice and weight loss attempts.

# An Approach to Linkage of Registry Data to Medicare Claims Using Multiple Non-Unique Identifiers

**Fenglong Xie**<sup>1</sup>, **Lang Chen**<sup>1</sup>, **Huifeng Yun**<sup>2</sup>, **Jeffrey D Greenberg**<sup>3</sup> and **Jeffrey R. Curtis**<sup>4</sup>, <sup>1</sup>Division of Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>University of Alabama at Birmingham, Birmingham, AL, <sup>3</sup>NYU School of Medicine, New York, NY, <sup>4</sup>Rheumatology & Immunology, University of Alabama at Birmingham, Birmingham, AL  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Registries and claims data can complement each other to facilitate observational studies. However, methods to link on multiple non-unique identifiers (MNUI) are limited and therefore, there is a need to develop and test an approach to link registry data to Medicare claims using multiple non-unique identifiers.

**Methods:** Social security numbers (SSN) from participants in the Corrona registry with at least one registry visit in 2014 or prior were linked by CMS to Medicare fee-for-service (FFS) data. Using CMS created crosswalk file between Corrona ID (CID) and Medicare ID (MID), birth date (DOB) and sex, we established the SSN linkage as a gold standard. Using full DOB, sex, visit dates in registry and CMS data, and Corrona physician NPI, we developed an approach for linkage using MNUI based on 1) sex; 2) DOB elements (day, month and year, with year at most +1 year), 3) number of visit dates matching exactly between Corrona and Medicare data, where the Medicare provider NPI matched the Corrona physician. These features were each included in a logistic regression model to evaluate the likelihood of a successful match using SSN+sex+DOB as the gold standard.

**Results:** The SSN linkage with sex and DOB confirmation resulted in 2,527 linked patients with any type of Medicare coverage. Among these, 1,854 had at least one month of Medicare FFS coverage in which a Corrona visit occurred. The initial match result in 565,856 potential pairings of CID and MID. The C-index for the model was 0.996. Choosing 0.06 as cut-points of predicted probability to achieve a PPV greater than 0.90, the algorithm predicted 1,858 matches; among then 1,732 were consistent with the SSN linkage. Keeping only the pairs with highest predicted probability result in 1,846 matches; among these, 1,731 were correct matches. Sensitivity of the approach was 0.93 (1,731/1,854), 95% CI: 0.92-0.95. The Positive predicted value (PPV) was 0.94 (1,731/1846), 95%CI: 0.93-0.95.

**Conclusion:** Linkage of an outpatient registry with administrative claims data using multiple non-unique identifiers is both technically feasible and accurate and yields high sensitivity and PPV

## Impact of Maternal Systemic Autoimmune Rheumatic Diseases on Neonatal Outcomes: A Population-Level Analysis

**Stephanie Keeling**<sup>1</sup>, **Anamaria Savu**<sup>2</sup> and **Padmaja Kaul**<sup>3</sup>, <sup>1</sup>Department of Medicine, University of Alberta, Division of Rheumatology, Edmonton, AB, Canada, <sup>2</sup>Canadian Vigour Center, Edmonton, AB, Canada, <sup>3</sup>Cardiology, University of Alberta, Edmonton, AB, Canada  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Background/Purpose:** The impact of systemic autoimmune rheumatic diseases (SARDs) on peripartum outcomes is not well described at a population level despite the potential for active disease in this period.

**Methods:** The patient population consisted of women giving birth between January 1, 2005 to December 31, 2014 (n=312,081). For women with multiple gestations during the period, one birth event was randomly selected. Women with SARDs included any of the following: systemic lupus erythematosus, systemic sclerosis, myositis and sjogren's syndrome, diagnoses based on the presence of International Classification of Disease version 9/10 codes in outpatient or inpatient records. Baseline characteristics, comorbidities, medication use (available for all births after January 1, 2009), and neonatal outcomes among women with and without SARDs were compared

**Results:** Compared to women with no SARDs (n=311,755), women with SARDs (n=326, 0.1%) were slightly older (SARDs 31.3 vs No SARDs 29.3 years (p<0.01)) but did not differ in terms of rural residence, ethnicity, median household income or nulliparity. However, rates of pre-term delivery, emergent cesarean section, induction, hypertensive disorders/eclampsia and mortality were higher among women with SARDs than those with no SARDs (Table 1). Offspring of women with SARDs had lower birth weights, were more likely small for gestational age (SGA), and had longer stays in neonatal ICU (Table 1). Among women with SARDs, prescription rates in the 270 days prior to delivery were highest for anti-malarials (Table 2). After multivariable adjustment, both NSAIDS use (OR(95% CI): 5.24 (1.57, 17.52), p<0.01) and steroid use (OR(95% CI): 3.15 (1.31, 7.59), p<0.01) were significantly associated with a higher risk of preterm delivery.

**Conclusion:** Women with SARDs are at an increased risk of adverse outcomes during pregnancy. The association between corticosteroid and NSAID use and preterm delivery requires further investigation. Our findings suggest the need for closer monitoring and coordinated care with obstetrics and perinatology in these high risk women.

**Table 1. Maternal and Neonatal Outcomes in SARDs vs No SARDs**

OUTCOME	Mothers *		
	No SARDs # (%)	SARDs # (%)	P-Value
Pre-term Delivery	22205 (7.1)	58 (17.8)	< 0.01
C-section (Emergent)	51132 (16.4)	82 (25.2)	< 0.01
Hypertensive Disorders	20029 (6.4)	47 (14.4)	< 0.01
Small for Gestational Age	35047 (11.2)	68 (20.9)	< 0.01
Congenital Anomaly	5810 (1.9)	11 (3.4)	0.05
Mean days in Neonatal ICU	0.8 (5.0)	2.3 (9.6)	< 0.01

\*Sensitivity analysis utilizing primiparous SARDs vs NonSARDs women confirmed similar results

**Table 2. Unadjusted Effect of Medication Use During Pregnancy on Maternal and Neonatal Outcomes (\*\* p<0.05)**

Outcome	Steroids	Nonsteroidal Anti-Inflammatories	Antimalarials
# (%) SARDs patients on medication	33 (16.3)	13 (6.4)	51 (25.1)
SGA [OR (95% CI)]	2.06 (0.91, 4.67)	1.08 (0.29, 4.12)	1.54 (0.74, 3.20)
Gestational Diabetes [OR (95% CI)]	1.67 (0.51, 5.47)	N/A	0.91 (0.28, 2.93)
Preterm Delivery [OR (95% CI)]	<b>3.84 (1.66, 8.89)**</b>	<b>4.96 (1.55, 15.85)**</b>	1.82 (0.83, 4.00)
C-section [OR (95% CI)]	0.88 (0.41, 1.90)	0.98 (0.31, 3.11)	0.57 (0.29, 1.13)
Hypertensive Disorders of Pregnancy [OR (95% CI)]	<b>3.67 (1.51, 8.93)**</b>	0.50 (0.06, 4.03)	1.23 (0.51, 2.99)

## **Burden of Rheumatic Disease Among Korean Women in Childbearing Years Based on the National Health Insurance Service-National Sample Cohort**

**Min Kyung Chung**<sup>1</sup>, Jisoo Lee<sup>1</sup>, Eun-Hee Ha<sup>2</sup> and Ji-Young Shin<sup>2</sup>, <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Republic of (South), <sup>2</sup>Department of Occupational and Environmental Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many rheumatic diseases predominantly affect women in their reproductive years, and have a significant impact on childbearing, but its burden remains incompletely understood. The study aimed to identify the prevalence and incidence of rheumatic diseases among Korean women in childbearing years, and the effect of the diseases on prevalence of comorbidities, and pregnancy rate.

**Methods:** From National Health Insurance Service-National Sample Cohort (NHIS-NSC) data during 2010-2013, we identified 210,328 women aged between 20-44 years. Among these women, we estimated the prevalence and incidence of rheumatic diseases including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and ankylosing spondylitis (AS). Prevalence of chronic diseases such as cancer (Ca), hypertension (HT), hyperlipidemia (HLD), and diabetes mellitus (DM) was compared in women with or without rheumatic diseases. We also investigated pregnancy rate in women with rheumatic or chronic diseases, and control subjects without rheumatic or chronic diseases.

**Results:** Total prevalence of rheumatic diseases in childbearing years during 2010-2013 was 0.43%. Total incidence during 2010-2013 was 9.37 cases per 10,000 person-years. Women with rheumatic diseases had significantly higher association with chronic diseases compared with those without (28.38% vs 10.19%,  $p < 0.001$ ), and had increased risk for HT (OR 3.24,  $p < 0.001$ ) and HLD (OR 3.25,  $p < 0.001$ ). Pregnancy rate was significantly lower in women with rheumatic diseases compared with the control (12.60% vs 18.69%,  $p < 0.001$ ). Among women with rheumatic diseases, women with RA (OR 0.44,  $p < 0.001$ ) were less likely to become pregnant, whereas women with SLE and AS had comparable rate of pregnancy compared with the normal control. Likelihood of becoming pregnant in women with RA is comparable with women with Ca (OR 0.49,  $p < 0.001$ ), HT (OR 0.76,  $p < 0.001$ ), and HLD (OR 0.48,  $p < 0.001$ ).

**Conclusion:** Rheumatic diseases are a significant burden for women in childbearing years causing increased co-morbidities and reduced pregnancy rate.

### Multimorbidity in Patients with Sarcoidosis: A Population-Based Cohort Study

**Background/Purpose:** Recent studies have suggested an increased risk of comorbidity in patients with sarcoidosis. However, whether sarcoidosis is associated with increased incidence of multimorbidity is not known.

**Methods:** 345 patients (50% female; 90% Caucasian, 5% African-American; mean age 45.6 years) with incident sarcoidosis in 1976-2013 in a geographically well-defined population were identified from a comprehensive medical record linkage system. Diagnosis of sarcoidosis was confirmed by individual medical record review which required diagnosis of sarcoidosis by physician supported by histopathology, compatible clinical presentation, and exclusion of other granulomatous diseases. A total of 345 sex and age-matched comparators (50% female; 95% Caucasian, 1% African-American; mean age 45.4 years) were also identified from the same underlying population. Cases and comparators were then reviewed for 18 common chronic comorbidities at index date and after index date. Aalen-Johansen methods were used to estimate the cumulative incidence of multimorbidity (defined as presence or at least 2 chronic comorbidities) adjusted for the competing risk of death. Cox proportional hazards models with adjustment for age, sex, and calendar year were used to compare the rate of development of multimorbidity between cases and comparators.

**Results:** At index date, 111 patients with sarcoidosis and 110 comparators without sarcoidosis had multimorbidity (p value 1.0). The mean number of comorbidities was 1.2 in both groups. During a median follow-up of 12.9 years among patients with sarcoidosis and 15.6 years among comparators, 156 patients with sarcoidosis developed multimorbidity compared to 142 comparators, corresponding to an adjusted hazard ratio of 1.60 (95% confidence interval, 1.07 – 1.69). The percentage of patients developing multimorbidity by years since sarcoidosis incidence/index date is shown in the figure. Analysis by specific comorbidity revealed significantly increased incidence of congestive heart failure, coronary artery disease, arrhythmia, cerebrovascular accident, arthritis, asthma, depression, diabetes and osteoporotic fracture after the index date among patients with sarcoidosis. The most common combination of comorbidities was hypertension and hyperlipidemia, although these were not significantly increased in sarcoidosis relative to comparators.

**Conclusion:** This first ever population-based evaluation of multimorbidity in sarcoidosis revealed that patients have a significantly increased incidence of multimorbidity after the diagnosis of sarcoidosis.

Figure. Probability of developing 2,3,4, 5+ comorbidities according to years since sarcoidosis incidence/ index date for patients with sarcoidosis (S) and comparators (C).

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We did not grasp how many and where pediatric rheumatic patients exist in Japan quite exactly until now. About juvenile idiopathic arthritis (JIA), child-onset systemic lupus erythematosus (SLE), juvenile dermatomyositis (JDM), child-onset Sjögren's syndrome (SS), we would like to know the actual situation of follow-up in clinical pediatric facilities in Japan.

**Methods:** For 519 clinical pediatric training institutes in Japan Pediatric Society, we performed the questionnaire survey for grasping the number of patients < 16 and ≥16 years about the above diseases with letter form. The answer period was from May 1 to December 31, 2016.

**Results:** As for the answer from 474 institutes (91.3%), the number of patients < 16 and ≥16 years were as follows; JIA: 1,704 vs 750, SLE: 404 vs 525, JDM: 268 vs 113, SS: 148 vs 126, individually. As results of statistical analysis, we could recognize that the number of JIA was approximately 2,700, that of SLE 1,000, that of JDM 400 and that of SS 300 in the whole Japan. Because the population of 2016 of Japan < 16 years was 16,954,000, the prevalence of each disease < 16 years was 11.0, 2.6, 1.7, 1.0 per 100,000 persons. We also reported the detail of the medical actual situation such as the enforcement systems of the transition medicine in the childhood-onset rheumatic diseases, based on 1) number of patients at 47 prefectures in Japan (Table), 2) distribution of pediatric rheumatic specialists, 3) cooperation with the core institutions for pediatric rheumatology in each medical area.

**Conclusion:** This is the first accurate report about of national survey of childhood-onset rheumatic diseases followed up in the clinical pediatric facilities in Japan. We are convinced that these results build the foundation to plan the cooperation with patient and family society, the choice of the clinical trial facilities of the new medicine, and the construction of both domestic and international pediatric rheumatic disease-registry in future.

Table. Number of patients at 47 prefectures in Japan

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sarcopenia is a syndrome characterized by progressive loss of skeletal muscle mass, which results in decreased muscle strength and impairment of functional capacity. Moreover, sarcopenia is an important clinical problem in older people with some adverse outcomes including an increased risk of death. Despite the increasing frequency of this clinical condition, prospective data

about risk factors for low muscle mass are scarce and few studies have performed a comprehensive evaluation of clinical data, laboratory bone parameters and bone mineral density (BMD) to determine more accurately the contribution of each of these variables to risk of low muscle mass in elderly persons. Moreover, the influence of the visceral fat assessed by DXA on low muscle mass is poorly studied. Thus, this study aimed to identify the main risk factors (clinical, laboratory parameters, BMD, body composition by DXA including visceral fat) for low muscle mass, in a longitudinal, prospective, population-based cohort of Brazilian older women.

**Methods:** A total of 408 women aged 65 years and older from the São Paulo Ageing & Health study (SPAH) was evaluated with clinical data, laboratory bone tests, BMD and body composition by DXA. All risk factors were performed at baseline (2005-2007). Along with the Foundation for the National Institutes of Health (FNIH) criteria, low muscle mass was defined when appendicular lean mass divided by body mass index (ALM/BMI) is less than 0.512 (value for female). After a mean follow-up of  $4.3 \pm 0.8$  years, subjects were classified according to the appendicular muscle mass obtained by DXA. Logistic regression models were used to identify independent risk factors for low muscle mass.

**Results:** 116 women (28.4%; 95% CI: 24.0-32.7) had low muscle mass at the end of follow-up. Age averages were  $73.3 \pm 4.9$  years and  $72.5 \pm 4.5$  years, in the low muscle mass group and in the normal muscle mass group, respectively ( $p=0.11$ ). Mean BMI was  $30.6 \pm 5.2$  kg/m<sup>2</sup> in low muscle mass group and  $28.1 \pm 4.7$  kg/m<sup>2</sup> in normal group ( $p<0.001$ ). In multivariate analyses, predictors of low muscle mass were: number of falls (OR = 1.14, 95% CI 1.02-1.27,  $p=0.016$ ), TSH levels (OR = 1.08, 95% CI 1.01-1.15,  $p=0.018$ , per each 1  $\mu$ UI/L-increase), serum creatinine (OR = 11.11, 95% CI 2.78-33.33,  $p<0.001$ , per each 1 mg/dL-decrease) and visceral adipose tissue (VAT) mass (OR = 1.17, 95% CI 1.07-1.27,  $p<0.001$ , per each 100g-increase).

#### **Conclusion:**

Falls, higher TSH, lower creatinine and higher VAT were risk factors for low muscle mass in community-dwelling older women. These results reinforced that visceral fat, which is associated with metabolic syndrome and chronic inflammation, is related to muscle mass consumption and fragility in elderly. Taken together, these findings support the notion that more attention should be paid to these factors in clinical practice, since they are potentially reversible with adequate therapeutic intervention.

#### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Biologic disease-modifying anti-rheumatic drugs (DMARDs) have been widely used for treatment of rheumatoid arthritis (RA) in United States. However, it is not clear whether biologics are associated with elevated cancer risk. We estimated cancer incidence rates (IRs) among anti-TNF users and evaluated biologic use after cancer diagnosis among RA patients, using validated cancer outcomes from the U.S. SEER program.

**Methods:** Using 2006-2013 SEER-Medicare linked data and a 5% non-cancer sample, we identified new anti-TNF users (etanercept, adalimumab, certolizumab, golimumab, infliximab) among RA patients, identified using algorithms that required  $\geq 1$  rheumatologist diagnosis code for RA at any time before specific drug use. New users were defined specific to each drug as no use of that therapy in the 'baseline' period. Eligible subjects were continuously enrolled in Medicare Parts A, B and D in baseline and throughout follow up. Patients with history of cancer were excluded. We identified all cancers reported to SEER nationally, as confirmed nationally by trained

tumor registrars. Follow up started from the drug initiation date and ended at the earliest date of: malignancy, a 90-day gap in current exposure, death, switch to another biologic, or loss of Medicare coverage. We calculated the number of cancer events in both SEER and 5% non-cancer sample, and then calculated the weighted national IRs of cancer for each drug, along with 95% confidence interval, by multiplying the observed person years for non-cancer patients with 20. Subgroup analyses based on the concurrent use of methotrexate (MTX) were conducted. We also evaluated patients' subsequent biologic use after their cancer diagnosis.

**Results:** We identified 1,374 new anti-TNF users in SEER-Medicare linked cancer registry and 5% non-cancer sample. Of these, 36.5% used infliximab, 25.9% adalimumab, 20.3% etanercept, 11.0% certolizumab, and 6.1% golimumab. During follow-up, we identified 231 cancers yielding a weighted IR from a low of 0.8 (golimumab) to a high of 1.9 (certolizumab) per 1000 person years across different anti-TNFs. IRs with concurrent MTX use were greater than those without MTX (table). After cancer diagnosis, 60-70% of patients resumed the same anti-TNF, 15-25% discontinued all biologic use, and the remainder switched to non-biologic DMARDs or other biologics. This pattern was consistent across different anti-TNFs.

**Conclusion:** Crude incidence rates of cancer among RA patients were comparable between users of different anti-TNF users. Concurrent MTX use was associated with higher cancer risk, although ongoing work is evaluating potential confounding.

<b>Table: Incident rates of cancer in 2006-2013 SEER- Medicare data among anti-TNF users with RA, with and without concurrent methotrexate use</b>				
<b>Anti-TNFs</b>	<b>MTX</b>	<b>Validated Cancer Events, n</b>	<b>Weighted Average Follow-up time<sup>†</sup></b>	<b>Weighted cancer incidence rate (95% CI) per 1000 person years</b>

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Noninfectious uveitis (NIU) is a collection of intraocular inflammatory disorders associated with significant visual impairment. Corticosteroids (CS) are typically the first-line drug therapy for NIU. Despite a general awareness that patients with long-term CS exposure can suffer from serious ocular and systemic adverse events (AEs), a clear understanding of the relationship between CS exposure and the occurrence of AEs, especially in a real-world setting, is lacking. This study estimates the associations between CS exposure and the risks of developing certain ophthalmologic-related complications and systemic AEs using a large, retrospective, administrative claims database.

**Methods:** This analysis used data from the Truven Health MarketScan Commercial Claims Encounters database from Q1 2011 – Q1 2016, which collects data from approximately 100 different insurance companies representing about 93 million covered lives. NIU patients were included if they were older than 18 years, had two or more CS prescription fills after an NIU diagnosis, and continuous enrollment for at least 8 months (6 months prior to first CS fill and at least 2 months after). CS exposure was captured via time-dependent cumulative treatment duration (in months), cumulative daily dose of systemic CS fills, and cumulative number of topical CS fills (including eye drops and CS injections). The outcomes of interest were time to ophthalmologic-related complications (glaucoma, blindness and cataract) and time to systemic AEs (osteoporosis, cardiac failure and infections). Multivariate Cox regression models were developed to assess the relationship of CS exposure with the risk of each outcome, controlling for baseline covariates, i.e., age, gender, various comorbidities, use of immunosuppressants and biologic therapies.

**Results:** Among the 56,782 patients with NIU eligible for the study, 60% were female and the average age was 56 years. The cumulative number of topical CS fills was associated with a significant increase in the risk of developing all ophthalmologic-related complications (hazard ratios [HR] of 1.10, 1.06, 1.04 for glaucoma, blindness and cataract, respectively), all p-values <0.001. The cumulative systemic CS duration was associated with a significant increase in the risk of all systemic AEs (HR of 1.03, 1.02 and 1.01 for osteoporosis, cardiac failure and infections, respectively), all p-values <0.001, while the cumulative systemic CS daily dose had no substantial impact on any outcome. Immunosuppressant therapies were associated with a significant increase in the risk of blindness (HR=1.40), cataract (HR=1.20) and osteoporosis (HR=1.47), all p-values <0.05. Biologic therapies were not associated with a significant increased risk of developing any of the outcomes.

**Conclusion:** Increased exposure to topical CS was associated with a significant increase in the risk of developing ophthalmologic-related complications, and longer duration of systemic CS was associated with a significant increase in the risk of CS-related AEs. These findings suggest that therapies alternative to corticosteroids could be beneficial in minimizing ophthalmologic complications and AEs among patients with NIU.

## **The Risk of Hydroxychloroquine Toxic Retinopathy and Its Risk Factors in the Treatment of Rheumatic Diseases: A Systematic Review**

**April Jorge**<sup>1</sup>, Sharan K. Rai<sup>2</sup> and Hyon K. Choi<sup>2</sup>, <sup>1</sup>Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>2</sup>Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Hydroxychloroquine (HCQ) is widely used in the treatment of systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and other rheumatic diseases. While generally well-tolerated and regarded as one of the safest treatment options for these conditions, the major long-term risk is vision-threatening retinopathy. The risk of retinopathy has been shown to vary by amount of HCQ exposure. However, the true risk of HCQ retinopathy remains unclear, and clinical consensus may be lacking between US and European rheumatology and ophthalmology societies regarding the safe dosing of HCQ. Our objective was to systematically review and appraise current evidence of the risk of HCQ retinopathy and its purported risk factors.

#### **Methods:**

We conducted a systematic search of MEDLINE and EMBASE databases through June 2017. Inclusion criteria were: 1) study sample including individuals treated with HCQ; 2) study design of either retrospective or prospective study with a comparator group; and 3) retinopathy outcomes reported. The primary outcome was HCQ retinopathy incidence and/or prevalence, and other data of interest included measures of HCQ exposure (e.g., mean daily dose, mean cumulative dose, and mean duration of HCQ use), method of HCQ retinopathy ascertainment, risk factors for HCQ retinopathy, and rheumatologic diagnosis.

#### **Results:**

We identified 3,236 unique citations. Of these, 28 studies were ultimately included in the systematic review. Ten studies (all published in 2014 or later) reported current standard-of-care screening modalities (e.g., Humphreys visual fields (VF) and spectral domain-optical coherence tomography (SD-OCT)). Eleven studies reported the use of only older screening modalities (e.g., funduscopy, visual acuity, and color vision assessments), 5 studies used ophthalmologist reports of toxicity, and 2 studies did not describe a method of retinopathy ascertainment. Of the 10 recent studies, HCQ retinopathy risk estimates ranged from 2.9-30.5%, with 2 studies reporting a risk of 10% or higher. Of the 18 older studies, HCQ retinopathy risk estimates ranged from 0.5%-21%, with 2 studies reporting a risk over 5%. Twelve studies examined predictors of retinopathy. Of these, 3 found age and 1 found CKD to be predictors of retinopathy. Duration of HCQ use, cumulative dose of HCQ, and daily dose of HCQ were associated with HCQ retinopathy risk in 5, 4, and 2 studies, respectively. Underlying rheumatologic disease (e.g., SLE versus RA) did not impact retinopathy risk. The mean daily HCQ doses varied from 3.1mg/kg/day to 8.4mg/kg/day for the overall cohorts exposed to HCQ, with some studies reporting dose per ideal body weight and others reporting actual body weight.

#### **Conclusion:**

This is the first systematic review on the risk of toxic retinopathy secondary to HCQ. The risk estimate of HCQ retinopathy varies considerably in the published literature, with increased risk estimates reported in recent studies. More recent ophthalmologic screening methods including SD-OCT have increased sensitivity to detect earlier stages of retinopathy. Prospective studies are urgently needed to accurately characterize the risk and risk factors of HCQ retinopathy.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

Chikungunya (CKV) is a disease caused by an alphavirus, transmitted by mosquitoes of the genus *Aedes*. Is characterized by arthralgia, myalgia, arthritis and tenosynovitis.<sup>1</sup> Anticyclic citrullinated peptide antibodies (ACPA) are considered specific markers of rheumatoid arthritis (RA). However ACPA have also been detected in patients with other types of chronic inflammatory rheumatism.<sup>2</sup> The objective of this study is to investigate the positivity of ACPA in post-chikungunya arthritis.

#### Methods:

This was a ambispective study, cross-sectional, with patients who were taken from the group comprised a total of 514 patients from the register of patients with musculoskeletal post-chikungunya infections in the rheumatology department of the Hospital Docente Padre Billini, from December 2013 to June 2017,<sup>3</sup> patients who met the classification criteria for reactive arthritis.<sup>4</sup> at the Hospital Docente Padre Bilini, in the period December 2013 - June 2017. Inclusion criteria: Meet the criteria for reactive arthritis. Exclusion criteria: Patients under the age of 18, who have had prior joints symptoms or another diseases that explains the symptoms. ACPA was performed to the patients in the period May - June 2017 and clinical records were reviewed. The program SPSS V23.

#### Results:

Of a total of 514 patients, 41 patients met the criteria. 90.2% (37) was female, 46-64 years was the most frequent age range. 70.7% (29) had synovitis, of these 29 patients, 75.8% (22) had chronic stage synovitis. At the start of the study 9.7% (4) had positive ACPA and in time seroconversion to 34.1% (14). 24.3% (10) had positive rheumatoid factor (RF). 19.5% (8) had RA according to the 2012 American College of Rheumatology classification criteria for RA, of these 8 patients, the 87.5% (7) had ACPA positive. 2.4% (1) developed an undifferentiated polyarthropathy y 2.4% (1) met criteria for spondyloarthritis with axial and peripheral HLAB27 positive. 14.6% (6) increase C reactive protein and 46.3% (19) increase erythrocyte sedimentation rate. 12.1% (5) were smokers.

#### Conclusion:

34.1% (14) of 41 patients had ACPA positive over time, of these 14 patients, 57.1% (8) developed ACPA positive RA and 42.8% (6) had positive RF. This demonstrates a relationship between CKV infection arthritis clinics for the first time with musculoskeletal manifestation secondary arthritis and ACPA positivity over time, together with a high risk of developing RA.

## Risk of Tuberculosis in Biologic Users for Rheumatic Diseases: Results from the South African Biologics Registry

**Clive Pettipher**<sup>1</sup> and Romela Benitha<sup>2</sup>, <sup>1</sup>Rheumatology, Private Practice, Stellenbosch, South Africa, <sup>2</sup>Rheumatology, Private Practice, Johannesburg, South Africa

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

To evaluate the rate of tuberculosis (TB) in biologic users for rheumatic diseases in South Africa, a TB endemic country, the effectiveness of our latent TB (LTB) screening program, risk factors and clinical outcome.

## Methods:

Documented cases of TB were collected from the South African biologics registry (SABIO), practicing rheumatologists and pharmaceutical companies. Data on demographics, LTB screening tests and prophylaxis, biologic and DMARD therapies, TB diagnosis and treatment outcomes were recorded. A matched control arm evaluated the risk of TB in non-biologics users.

## Results:

96 TB cases were collected from June 1999 to June 2017 (RA=55 (57%), AS=27 (28%), PsA=4 (4%), JIA=10 (10%)). The rate of TB was 1,240/100,000 person-years for all biologic users (n=96) compared to the control arm of 0/100,000 years (n=0) with an incidence rate difference of 0.0124 (95% CI 0.007 to 0.018,  $p<0.0001$ ). Of these, 60/96 (62.5%) had pulmonary and 36/96 (37.5%) had extra-pulmonary disease. Reactivation TB occurred in 45/96 (51%) cases, despite a vigilant LTB screening program; new TB in 49/96 (47%) cases and 2 were undetermined. TB occurred in all 7 biologics licenced for use in SA (adalimumab 48, infliximab 15, golimumab 3, etanercept 19, tocilizumab 2, abatacept 5 and rituximab 4) with the majority from monoclonal TNF inhibitors (1,683/100 000 person-years) compared to etanercept (861/100,000 years) and non-TNF inhibitors (681/100,000 years). The incidence rate ratio (IRR) for monoclonal inhibitors compared to etanercept was 1.96 (95% CI 1.16 to 3.45,  $p=0.005$ ) and 2.47 (95% CI 1.29 to 5.19,  $p=0.002$ ) compared to non-TNF inhibitors. There was no significant difference between non-TNF inhibitors and etanercept (IRR 0.79; 95% CI 0.34 to 1.75,  $p=0.336$ ). From registry data, it was extrapolated that 625 from 4830 patients (12.9%) screened LTB positive and were treated, yet 14 still developed TB (9 reactivation and 5 new onset TB). The majority (77) of TB cases, screened negative and screening was not done in 5. Steroid use, methotrexate use and male gender were significantly associated with acquiring TB (OR = 6.12;  $p<0.001$ , OR=7.5;  $p<0.001$  and OR = 1.82;  $p=0.005$  respectively), while the underlying rheumatic condition, race and geographic region were not. Two drug resistant TB cases and 6 deaths were recorded.

## Conclusion:

TB poses a significant risk to all biologics users, including non-anti TNF's in SA, a TB endemic country, despite our screening program. Concomitant methotrexate and steroid use further increase this risk.

## Comparison of TB rates in biologic users across registries

	SABIO		BADBADASER		US National
	(RSA)	BSRBR (British)	(Spanish)	RATIO (French)	bank
Total number of patients	4 830	10 712	5 198	Not reported	6 460
Number of TB cases	96	40	15	69	4
TB rate using anti TNF per 100 000 person-years	1 387	106	172	116	52
TB rate using non-anti TNF per 100 000 person-years	681	Not reported	Not reported	Not reported	Not reported

## TB rates of individual biologic agents (SABIO)

	Sum of biologic exposure (years)	TB cases per drug (n=96)	TB rate per 100 000 person-years
Adalimumab	2,954	48	1,625

# Strongyloides Screening in Immunocompromised Immigrant Rheumatology Patients

Sahitya Mallipeddi<sup>1</sup>, Christina Coyle<sup>2</sup> and **Beverly Johnson**<sup>1</sup>, <sup>1</sup>Rheumatology, Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Infectious Diseases, Albert Einstein College of Medicine, Bronx, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Strongyloides Stercoralis is a helminthic infection that is usually chronic and asymptomatic and may persist undiagnosed for decades. Patients from strongyloides endemic areas (tropics and subtropics) on immunosuppression are at risk for disseminated disease that carries a high morbidity and mortality. Our aim is to prospectively evaluate the prevalence of Strongyloides infection in immunocompromised immigrant patients with rheumatic diseases.

**Methods:** A single center, prospective, pilot study was conducted at an urban safety net hospital caring for a large immigrant population from September 2016 to June 2017. Inclusion criteria included subjects with rheumatologic diagnosis who are from strongyloides endemic areas on immunosuppressant drugs. A strongyloides screening questionnaire was developed in collaboration with the infectious disease division. Patients were interviewed to obtain medical history, demographic, and social variables. Strongyloides serology was performed with ELISA at the medical center. If there was a positive or indeterminate test, treatment protocol was initiated in parasitology clinic. Statistical analysis was performed using SPSS. Institutional IRB approval was obtained.

**Results:** A total of 101 patients were screened. The most frequent diagnosis was lupus (39%) followed by rheumatoid arthritis (32%). Most of the patients immigrated from South America (62.6%) and rest of the population was from Asia and Africa. The majority of the patients were female (83.8%). A total of 88 patients completed strongyloides screening and out of which four (4.5%) had positive tests and three (3.4%) had an indeterminate tests. In terms of the socioeconomic conditions, 90.7 % had a bathroom in the house in their home country, 86.6% had running water in the house, 36.1% responded that they swam in fresh water and 43.3% had their home situated in the country side. Over half (56.3%) of the patients were on steroids, (9% on prednisone 15 mg and above), 15.4% of the patients were on biologic DMARDs and 72.5% were on non-biologic DMARDs.

**Conclusion:** We found 7.95% of patients were strongyloides positive or indeterminate. This is likely an underestimate of the true prevalence of strongyloides infection in this population as our population may be representing a higher socioeconomic status (SES) than the general immigrant population as over 90.7% of patients had bathrooms in their home country and 86.6% had running water which is a surrogate marker of higher SES. Further investigation into larger cohorts may be required to quantify the true incidence and prevalence of strongyloides in this population. Given the magnitude of the morbidity and mortality that strongyloides can cause in immunocompromised patients, health care providers should consider strongyloides screening in their immunocompromised patients. As the exposure may be remote and patients are asymptomatic, increased awareness among physicians is critical in identifying and treating high risk populations to prevent the occurrence of severe strongyloides infection. To our knowledge, this is one of the few studies to evaluate prospectively for strongyloides infection in high risk individuals and the only one in patients with rheumatic disease.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Progressive multifocal leukoencephalopathy (PML), a rare, usually fatal, central nervous system demyelinating disorder that occurs in immunocompromised hosts, results from reactivation of the JC virus. We undertook this study to determine the frequency of rheumatic and other diseases associated with an immunocompromised state in a national cohort of PML hospitalizations derived from the Nationwide Inpatient Sample (NIS).

**Methods:** The NIS, established as part of the Healthcare Cost and Utilization Project, is a 20% sample of all US hospital discharges weighted to represent the entire US population. Data collected and analyzed from January 1<sup>st</sup> 1998 until December 31<sup>st</sup> 2011. A NIS sampling design change in 2012 precluded reliably including the data from 2012 to 2014. International Classification of the Diseases, Ninth Revision, Clinical Modification codes were used to identify the total number of hospitalizations for PML and diseases of interest (rheumatic diseases, multiple sclerosis (MS), human immunodeficiency virus (HIV) infection, hematologic and solid organ malignancies, and bone marrow and solid organ transplants). Information on demographics and hospital characteristics (region and type of hospital) was also collected. All analyses were performed using SAS enterprise guide, version 7.13 (SAS Institute, Cary, NC).

**Results:** A total of 17,268 hospitalizations for PML was identified over the 14 year period. The frequency of hospitalizations for PML among the diseases of interest is presented in Table 1. Details of demographics and hospital characteristics are presented in Table 2. Among the rheumatic diseases, there were 145 (0.84%) PML hospitalizations with SLE, 103 (0.60%) PML hospitalizations with RA, 11 (0.06%) PML hospitalizations with granulomatosis with polyangiitis, and no PML hospitalizations with microscopic polyangiitis. Hospitalization rates for PML per 100,000 hospitalizations among patients with rheumatic diseases are presented in Table 3.

**Conclusion:** PML is a rare complication even among diseases at high risk for JC virus reactivation. The frequency of PML hospitalizations among rheumatic diseases was reassuringly low. Only among rheumatic disease patients with HIV, MS, or a hematologic malignancy did the rate of PML hospitalizations increase substantially.

Table 1: Frequency of hospitalizations for PML among diseases of interest 1998 through 2011

Diseases	Hospitalization for PML, N (Percent)

### SESSION INFORMATION

Session Date: Tuesday, November 7, 2017

Session Title: Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

**Background/Purpose:** The prevalence of Rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) antibodies in the general population may vary widely, as RF is present in 0-5% and anti-CCP in 0-9% of healthy controls, but the clinical significance in the general population remains unclear. We determined the prevalence of RF and anti-CCP antibodies in a large sample of the general population and their predictive value over developing rheumatoid arthritis (RA) over 16 years.

**Methods:** We took advantage of a randomly selected sample of a general population study initiated in 1998 (Isola I, originally including 2,828 subjects; 53% women, age 43±13 years) from a well-defined Northern Italian area. Serum RF and anti-CCP were tested in recent years by ELISA on 2,690 samples and data collected in 2017 (Isola II: 50% women, age 58±13 years). Administrative databases were searched for RA diagnoses occurring between enrollment and May 31<sup>st</sup> 2017. The risk ratio (RR) was calculated for incident RA cases between subjects exposed and not exposed to RF and anti-CCP antibodies.

**Results:** RF was positive in 276 (10.2%), while anti-CCP were found in 127 (4.7%) subjects, with the latter at medium-high titer (>30 U/mL) in 25 (0.9%) subjects. Twelve (0.4%) cases of RA were found over 16 years, of which 3 (25%) positive for RF and 5 (41.7%) positive for anti-CCP antibodies, mostly at medium-high titer (4/5, 80%). Only one (8.3%) case of RA was positive both for RF and anti-CCP antibodies. We observed two cases of Sjögren's syndrome, both positive for RF, while one was positive also for anti-CCP. The risk ratio (RR) of developing RA over 16 years is 3.08 (95% confidence interval – CI – 0.82-11.56, p=0.07) for RF positive subjects and 20.13 (95% CI 5.09-79.52, p<0.001), for anti-CCP antibodies positive subjects, and it increases up to 67.46 (95%CI 16.36-253.98; p<0.001) for medium-high titer anti-CCP antibodies.

**Conclusion:** We report a high prevalence of RF and anti-CCP in the general population of a Northern Italian region, but only anti-CCP are associated with a significantly increased risk of RA over 16 years.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Allergy and autoimmune disease are related to the immune system. It was not clear in the previous studies whether allergic disease (e.g., asthma, allergic rhinitis, and atopic dermatitis) are associated with rheumatoid arthritis (RA).

## Methods:

We analyzed RA, allergic disease (asthma, allergic rhinitis, and atopic dermatitis) and the serum immunoglobulin E (IgE) against inhalant antigen (total IgE, IgE *Dermatophagoides farina* (*df*), IgE *cockroach* and IgE *dog*) from the data of KNHANES (N=8958, estimated population size=47933924). We analyzed the prevalence of RA and allergic diseases using general linear model and logistic regression with complex sample design method adjusted by age and sex and evaluated the association between RA and allergic diseases including serum IgE levels.

## Results:

The prevalence of RA was 2.22 % [95% CI: 1.46-3.38]. The prevalence of allergic diseases was 22.89% [95% CI: 20.61-25.35]. The prevalence of RA with allergic disease (2.63 % [95% CI: 1.68-4.10]) were significantly increased compared with that of RA without allergic diseases (1.91 % [95% CI: 0.99-3.67]) (p =0.02). Asthma (adjusted odds ratio (OR): 2.60 [1.89-3.58], p<0.001) and atopic dermatitis (adjusted OR: 2.22 [1.81-2.73], p<0.001) were positively associated with RA.

Total IgE levels were increased in RA patients (RA vs. control: 561.99 ± 286.98 kU/L vs. 269.17 ± 16.37 kU/L, p=0.04). But serum IgE *df* were decreased in RA patients (RA vs. control: 1.39 ± 0.63 kU/L vs. 5.09 ± 0.43 kU/L, p<0.01). Serum IgE *cockroach* level (RA vs. control: 1.39 ± 0.87 kU/L vs. 0.52 ± 0.05 kU/L, p=0.06) and serum IgE *dog* levels (RA vs. control: 0.10 ± 0.04 kU/L vs. 0.34 ± 0.12 kU/L, p=0.15) were not different.

## Conclusion:

We showed increased prevalence of RA patients in the individuals with the allergic diseases than those without allergic diseases. Serum total IgE levels was increased in RA patients of the KNHANES data of Korean populations.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is an autoimmune disease characterized by the presence of RA-related autoantibodies prior to the development of clinical disease. While HLA-shared epitope (SE) is the strongest genetic factor for RA, genome-wide association scans (GWAS) have identified additional single nucleotide polymorphisms (SNPs) associated with RA. We investigated whether these SNPs were associated with the presence of anti-cyclic citrullinated peptide autoantibodies (CCP) in RA-free At-Risk individuals, and/or with progression to classified RA in CCP positive (CCP+) individuals.

**Methods:** We tested 1066 RA-free first degree relatives (FDRs) of RA patients for CCP2 and CCP3.1 as part of the Studies of the Etiology of RA (SERA); 124 ever tested CCP+ at baseline or during follow-up. We examined associations between 41 GWAS-identified SNPs and ever CCP+ using logistic regression in additive models. We also assessed SE, age, and sex as effect modifiers. When a significant interaction was found, results were stratified. Of the CCP+ FDRs, 84 were followed over time and 10 developed classified RA. We examined whether the SNPs were associated with development of RA in CCP+ FDRs using Cox proportional hazards; effect modification was not tested due to small numbers. As each SNP was of interest due to the known association with RA, we did not adjust for multiple comparisons in this exploratory analysis.

**Results:** FDRs who were ever CCP+ were less likely to be  $\geq 50$  years old than CCP- FDRs (Table 1). Significant SNP and CCP+ associations and their interactions are presented in table 2. For some SNPs, associations differed by SE, age, and sex. In longitudinal analyses, CCP+ FDRs who developed RA were less likely to be non-Hispanic White (NHW) and more likely to be SE+ than CCP+ FDRs that did not develop RA (Table 1). In CCP+ FDRs, progression to RA was associated with different SNPs than those associated with CCP+ (Table 2).

**Conclusion:** These findings indicate that some RA-associated SNPs may play a role in the early development of serum CCP+ in absence of RA, and others may play a role in the progression from CCP+ without RA to classifiable disease. Moreover, associations between SNPs and autoimmunity differ by SE, age, and sex, suggesting disease heterogeneity. The effect modification by SE that we observed may suggest that GWAS SNPs may have a more influential effect when the individual does not have SE to promote disease. These findings need further exploration to inform disease mechanisms, prediction and therapeutic/prevention studies.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Epidemiology and Public Health Poster III: Rheumatic Disease Risk and Outcomes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The major SARD have an increased mortality compared to the general population. It is well known that the main causes of death in Systemic Lupus Erythematosus (SLE) are infections (INF), cardiovascular events (CV), neoplasia (NEO) and disease activity. However, the compared mortality of Mixed Connective Tissue Disease (MCTD), Systemic Sclerosis (SSc), Poly/Dermatomyositis (PM/DM), overlap syndromes (OS), Sjögren's syndrome (SS), Antiphospholipid syndrome (APS), systemic vasculitis (SV), and undifferentiated or incomplete Connective Tissue Disease (UCTD) is poorly described. To analyze the causes of death and the autoantibodies (AAB) profile among the SARD.

**Methods:** This was a single center, prospective and observational study. Mortality by all causes and relationship with AAB profile were analyzed in patients diagnosed of SLE, MCTD, SSc, PM/DM, OS (simultaneous or sequential criteria of 2 or more SARD), SS, APS, SV and UCTD or incomplete SARD (at least one clinical criterion of the classification criteria and a related antibody of any of the SARD). Data were obtained from the "Systemic Autoimmune Rheumatic Diseases Registry" of a tertiary referral hospital from 1986 to 2016. Patients with rheumatoid arthritis were excluded. The SARD registry counts with the institutional review board approval.

**Results:** 1750 patients were included, of whom 1453 (83%) were women. Five hundred fifty six SLE, 125 SSc, 111 PM/DM, 91 OS, 90 MCTD, 250 SS, 71 APS, 211 SV, 117 UCTD and 128 losses to follow-up, the global follow up rate was 92.7%. A global mortality of 350 (20%) cases was observed: 101 INF (28,8%), 89 CV (25,4%), 51 NEO (14,5%), 45 due to disease activity (12,8%), 41 other causes (11,7%) and 23 from unknown causes (6,5%). Table 1 shows detailed mortality causes compared by diseases. A higher mortality was associated ( $p<0,05$ ) with older patients (71 years, 20-96), SV (OR 3,65), male patients (OR 1,95), SSC/PM/DM (OR 1,76), MCTD (OR 1,6) and OS (OR 1,43). AAB to pANCA (OR 4,43), anti-topoisomerase I (OR 3,64), myositis-specific AAB (OR 3,0), cANCA (OR 2,19) and anticardiolipin (OR 1,89) were associated with poorer survival. A higher survival rate was observed in patients with SLE (OR 1,7), SS (OR 1,69) and UCTD (OR 15,57) ( $p<0,05$ ).

**Conclusion:** The main causes of death among SARD patients are CV (MCTD, SLE, and SSc), severe infections (OS, SV, and PM/DM), disease activity (APS) and neoplasia (SS). A higher mortality is observed among ANCA positive SV, anti-topoisomerase I positive SSC, MCTD, OS, anticardiolipin and myositis-specific positive patients.

CAUSES	SLE %	SSC %	MCTD %	SV %	PM/DM %	OS %	SS %	APS %
CV	30,86	27,02	42,3	25,55	18,18	16,12	17,64	21,4

## Fibromyalgia in Real Life a National French Web-Based Survey in 4516 Patients

**Francoise Laroche**<sup>1</sup>, julien Guerin<sup>2</sup>, deborah Azoulay<sup>3</sup>, joel Coste<sup>4</sup> and serge Perrot<sup>3</sup>, <sup>1</sup>Pain and Palliative care, APHP Hospital, Paris, France, <sup>2</sup>CETD, APHP Hospital, Paris, France, <sup>3</sup>CETD, Paris, France, <sup>4</sup>Biostatistics in university Hospital, Paris, France

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Fibromyalgia (FM) is the most frequent widespread chronic pain disorder (1,6% of the French population) (1). The medical and socioeconomic burden is high and severity depends on medical status and symptoms as defined by the OMERACT criteria (2). Most of the studies are performed in specialized centers, recruiting the most severe patients, but very few data exist on its real impact on daily life.

### Methods:

A large internet-based national survey of people suffering from FM was developed by a national patient association (Fibromyalgie-SOS Association) on their website, in France in 2014. The survey included 103 qualitative and quantitative questions that were developed by 3 medical experts (including rheumatologists) and patients.

### Results:

The questionnaire was completed by 4516 people. Respondents were predominantly middleaged (48 yrs) females (93%), most of whom had FM symptoms duration for 12 years and a diagnosis for 5 years. Diagnosis was made by a rheumatologist in 54% of the cases. The symptoms were concordant with the OMERACT domains (chronic pain, fatigue stiffness and other FM-associated symptoms) as previously published by Bennett in 2007 (3). The mean FIQ (Fibromyalgia Impact Questionnaire) score was 51 (0-100). 55% were currently working but 65% of them have been on sick leave in the 12 previous months. FIQ was mostly impacted by injustice feeling (+4.5), part time job (+2.4) and low income - less than 1000 euros monthly (+2.3) (linear regression).

Somatic comorbidities were mostly osteoarthritis (49%). Psychological comorbidities were injustice feeling (77%), cognitive symptoms (62%), anxiety (52%) and depression (48%). Initiating factors were reported by 73% of them: physical (50%) and/or psychological (76%). Aggravating factors included excess of activities, conflicts, traumatism and displacement. Treatments were provided by general practitioner (85%), physiotherapist (63%), rheumatologist (54%) and osteopathic manual practitioner (41%). Treatment was prescribed in 76.6% of the patients, including paracetamol alone (51.4%), paracetamol and weak opioids (64%), strong opioids (20.1%), antidepressants (81.5%), antiepileptic agents (54.5%), nonsteroidals NSAIDs (53.8%), anxiolytics (52.4%) and steroids (12.8%).

### Conclusion:

This unique descriptive survey in a large population provides data on symptoms, emotional distress, prescribing habits and impact of FM on daily life and work. Results show that FM is altered by emotional (including injustice feeling) and socio-economic factors.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Global trial data demonstrate the efficacy of pregabalin for the treatment of pain associated with fibromyalgia (FM), but there are currently no approved medical treatments for FM-related pain in China.

**Methods:** A phase 3, 14-week, multicenter, randomized, double-blind, flexible-dose, parallel-group, placebo-controlled trial was conducted in China (Feb 2012–Oct 2016) to assess the efficacy and safety of pregabalin in Chinese patients with FM. Eligible patients were aged ≥18 years, met the American College of Rheumatology 1990 criteria for FM, and had a mean numeric daily pain rating scale score of ≥4 (0=‘no pain’ to 10=‘worst possible pain’; 24-hr recall period) over a 7 day baseline period. Patients were randomized (1:1) to receive pregabalin (dosed twice daily) or matching placebo as follows: 1-week screening/placebo run-in, 2-week dose titration (150 mg/day titrated to 300–450 mg/day, based on efficacy and tolerability), 12-week fixed dose, and 1-week taper. Treatment allocation used a computer-generated pseudorandom code and the random permuted blocks method. The primary endpoint was change from baseline to endpoint (Week 14) in mean pain score analyzed using a mixed-model repeated measures (MMRM) approach; weekly mean pain scores were also evaluated using MMRM. Secondary endpoints included the percentage of patients with ≥30% and ≥50% reduction in endpoint mean pain score, Patient Global Impression of Change (PGIC), Fibromyalgia Impact Questionnaire (FIQ) total score, and measures of sleep. Adverse events (AEs) were also reported.

**Results:** In total, 343 patients were randomized and 334 (86% female; average age 44 years) were treated (170 pregabalin, 164 placebo). Reduction in mean pain score was significantly greater with pregabalin than placebo at endpoint (least square mean difference [95% confidence interval],  $-0.73 [-1.10, -0.36]$ ;  $P=0.0001$ ) and at every week during the study ( $P<0.05$ ) (Fig 1). Pregabalin treatment improved the percentage of patients achieving  $\geq 30\%$  ( $P=0.0044$ ) and  $\geq 50\%$  ( $P=0.0189$ ) reduction in pain score over placebo at endpoint. Pregabalin, compared with placebo, also significantly improved sleep interference score ( $P<0.0001$ ). There was no statistically significant improvement in PGIC, FIQ total score and the Medical Outcomes Study–Sleep Scale sleep disturbance score at endpoint with pregabalin versus placebo. The most commonly reported AEs in the pregabalin vs placebo groups were dizziness (41.8% vs 18.3%), somnolence (17.6% vs 7.9%), headache (5.9% vs 6.1%) and upper respiratory tract infection (5.9% vs 4.3%), consistent with the safety profile of pregabalin.

## Conclusion:

Pregabalin was effective in reducing pain compared with placebo and is well tolerated in Chinese patients with FM.

This study was sponsored by Pfizer.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

- **Background/Purpose:** More than 20% of the general population suffer from functional syndromes. It has been reported that the mitochondrial polymorphism at position 16519 is associated with functional syndromes, such as migraine, cycling vomiting syndrome, irritable bowel syndrome, non-specific abdominal pain, chronic fatigue syndrome and complex regional pain syndrome. The aim of this study was to evaluate the association of polymorphism 16519 in patients with fibromyalgia (FM).
- **Methods:** Patients with fibromyalgia according to the 1990 or 2010 ACR criteria and be able to provide informed consent and healthy controls were recruited for this study. Inclusion criteria were: age  $\geq 18$  years old, diagnosis of FM, and as exclusion criteria: patients with another rheumatic comorbidity. The protocol was approved by the Ethics Committee of the Hospital Central Dr. Ignacio Morones Prieto, San Luis Potosí, México. Statistical analysis was performed with  $\chi^2$  test.
- **Results:** We included 40 FM patients and 36 controls, all patients were women. Mean age were 49.1 years (SD 11 years) in the group of FM and 43.2 years (SD 11.9 years) in the control group. The demographic characteristics of both groups are in table 1. In the FM group the average number of positive tender points was 10 (SD 5), with average Widespread Pain Index (WPI) of 10 (SD 5), average symptom Severity Score 7 (SD 2.7) and the Fibromyalgia Impact Questionnaire (FIQ) 52.8 (SD 19.3). The presence of the polymorphism 16519 in the group of FM was observed in 21/40 (53%) vs 29/36 (80.6%) of control group, with a p value of 0.010, OR 0.27 (IC 95% 0.080 – 0.82). We did not find association between the polymorphism and the severity score.
- **Conclusion:** The polymorphism at position 16519 has been reported previously as a genetic factor predisposing individuals to develop functional syndrome; our results showed a negative association between this polymorphism and patients with fibromyalgia.

Table 1. Demographic characteristics of patient with Fibromyalgia and control group

Variable	Fibromyalgia (n=40)	Control (n=36)
16519 polymorphism	21 (52.5%)	29 (80.6%)
Females	40 (100%)	36 (100%)
Age	49.1 (SD 11)	43.2 (SD 11.9)
Weight	66.1 (SD 10.2)	65 (SD 8.5)
Height (cm)	156.2 (SD 5.8)	157.2 (SD 6.1)
Body Mass Index (kg/m <sup>2</sup> )	26.9 (SD 5.8)	26.3 (SD 3.5)
Years with Fibromyalgia disease	3.1 (SD 2.4)	NA
Number of tender points	10 (SD 5)	NA
Widespread Pain Index (WPI)	10 (SD 5)	NA
Symptom Severity Score (SS)	7 (SD 2.7)	NA
Fibromyalgia Impact Questionnaire (FIQ)	52.8 (SD 19.3)	NA
Fatigue	31 (77.5%)	NA
Sleep disorder	33 (82.5%)	NA
Cognitive disorder	22 (55%)	NA
Somatic disorder	27 (67.5%)	NA
Arthralgia	11 (27.5%)	NA
Depression	22 (55%)	NA
Anxiety	16 (40%)	NA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Background/Purpose:**

The ACR 2010 preliminary criteria for fibromyalgia (FM) classifies patients in high WPI group, widespread pain index (WPI)  $\geq 7$ , symptom severity scale (SS)  $\geq 5$ , and low WPI group, WPI 3-6, SS  $\geq 9$ .

It is not clear why some FM patients have less pain. Low WPI FM have lower disability scores, lower pain and global severity than high WPI group. Are there differences in the characteristics of low WPI and high WPI FM patients with regards to depressive, anxiety symptoms, pain and global FM severity and catastrophizing scores?

**Methods:**

Consecutive clinically diagnosed FM patients were classified in low WPI or high WPI groups, demographic and clinical data was compared. Questionnaires used: patient health questionnaire (PHQ-9), general anxiety disorder questionnaire (GAD-7), health assessment questionnaire disability index (HAQ-DI), fibromyalgia impact questionnaire (FIQ), pain disability index, pain catastrophizing scale, polysymptomatic distress scale (PSD), as the sum of WPI and SS.

**Results:**

Of 552 patients diagnosed clinically with FM, age 44.3 (12), 79.5% white, 85.5% female, 4% met the low WPI and 82.1% met the high WPI criteria.

Only SS, WPI and PSD, were each significantly different between low and high WPI groups (Table 1). To understand why, we looked at the individual correlations of WPI and SS (Table 2). In linear regression model, PHQ-9, GAD-7, Pain disability index, Pain catastrophizing, HAQ-DI and FIQ significantly predict WPI,  $F(6,98)=4.904$ ,  $P<0.0001$ ,  $R^2$  0.184; FIQ remains an independent predictor of WPI. The same model predicts SS,  $F(6, 98)=17.932$ ,  $P<0.0001$ ,  $R^2$  0.523; FIQ, pain catastrophizing score, PHQ-9 remain independent predictors of SS.

Table 1. Fibromyalgia and severity measures according to criteria categories. Values are mean (SD) unless specified. Low WPI and high WPI group are statistically significant different from each other at $p<0.05$ if flagged with asterisks; * $p<0.05$ ; ** $P<0.001$			
	All	WPI 3-6 and SS $\geq 9$	WPI $\geq 7$ and SS $\geq 5$
N	475	22	453
Age, yrs	43.9 (11.7)	40.9 (12.9)	44.1 (11.6)
Female, %	86.7%	90.9%	86.5%
Race white %	79.8%	81.8%	79.7%
Employed full time %	36.4%	36.4%	36.4%
WPI	12.6 (3.7)	4.6 (1.0)	12.9 (3.4)**
SS	9.3 (1.9)	10.4 (1.1)	9.2 (1.9)*
PSD	21.9 (4.5)	15 (1.4)	22.2 (4.3)**
FIQ	60.6 (19.4)	47.5 (13.7)	60.9 (7.2)
PHQ-9	13.3 (6.0)	12.4 (5.3)	13.3 (6.1)
GAD-7	9.5 (7.1)	8.8 (6.2)	9.5 (7.2)
HAQ-DI	1.2 (1.6)	1.2 (1.9)	1.2 (1.5)
Pain catastrophizing	23.9 (13.2)	20.3 (14)	24 (13.3)
Pain disability index	5.6 (2.1)	4.9 (2.4)	5.7 (2.1)

Table 2. WPI and SS correlations with pain disability index, FIQ, HAQ-DI, PHQ-9, GAD7 and PSD. Unless specified by \* all correlations were significant at  $p < 0.0001$ , \*  $P < 0.05$

	WPI	SS
PSD	0.911	0.541
SS	0.175	
Pain disability index	0.301	0.421
FIQ	0.352	0.569
HAQ-DI	0.293	0.316
PHQ-9	0.271	0.516
GAD-7	0.170	0.344
Pain catastrophizing	0.205*	0.338

### Conclusion:

No differences were found between high and low WPI groups, except for significantly higher PSD scores, despite many variables trending higher in the high WPI group, possibly due to the low number of patients in the low WPI group. We found that WPI and SS differ in their strength of association with core FM domains, which suggests they contribute differently to FM diagnosis.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fibromyalgia is a widespread chronic pain syndrome (FMS) the pathogenesis of which remains incompletely understood. FMS patients demonstrate an altered profile of chemokines relative to healthy controls (HC). (1) An interplay between glial and neuro-glial cells involving an extensive cytokines/chemokines network has been suggested as a potential key mechanism underlying chronic pain. (2,3) Eotaxin-2 is a potent chemoattractant for eosinophils, basophils and lymphocytes, distributed in a variety of tissues, including human brain. (4)

The aim of the current study was to compare serum levels of eotaxin-2 between FMS patients and HC and to examine a potential correlation between eotaxin-2 levels and clinical parameters of FMS.

**Methods:** 50 patients fulfilling ACR 2010 diagnostic criteria for FMS and 15 HC were recruited. Patients filled out questionnaires to assess and document severity of symptoms of FMS and depression, including the widespread pain index (WPI), the symptom severity scale (SSS), the fibromyalgia impact questionnaire (FIQ), and the Beck depression inventory (BDI). Serum levels of Eotaxin-2 (ELISA) were determined in all participants. High sensitive CRP (hs-CRP) was measured in the FMS group. Data were statistically analyzed with SPSS (version 20) and the significance level was set to P value of 0.05.

**Results:** The FMS cohort included predominantly females (84%), mean age 49 yo, mean disease duration of 6 years, with the following characteristics (means): WPI 12.5 ( $\pm 4.2$ ), SSS 9.1 ( $\pm 1.9$ ), FIQ 63.9 ( $\pm 16.9$ ), BDI 20 ( $\pm 11$ ). FMS patients exhibited significantly higher eotaxin-2 serum levels (pg/ml) vs HC: 833 ( $\pm 384$ ) vs 622 ( $\pm 149$ ), *p*-value 0.04, respectively. (Figure 1)

Mean hsCRP levels among FMS patients were 4.8 $\pm$ 6 mg/dl, a value not indicative of acute inflammation, and no correlation was found between the eotaxin-2 and hs-CRP levels. Further, no correlation was found between Eotaxin-2 /hs-CRP levels and severity measures of FMS or depression.

**Conclusion:** Significantly increased levels of Eotaxin-2 were demonstrated in FMS compared with HC, with no correlation observed between Eotaxin-2 and hsCRP levels. Further, no correlation was found between FMS activity and Eotaxin-2 levels. Thus, Eotaxin-2 does not appear to be a candidate for a disease activity biomarker. Further research is warranted into the role of this chemokine in the pathophysiology of the FMS.

Figure 1. Serum concentration of eotaxin-2 in patients with FMS vs controls

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Disabled status in fibromyalgia (FM) was found to be associated with lower education, higher FM symptom burden, and lower functional status. Less is known about the characteristics of unemployed FM patients who are not receiving any form of disability benefits.

### **Methods:**

Patients diagnosed clinically with fibromyalgia were enrolled and classified according to employment status and compared. Questionnaires used: patient health questionnaire (PHQ-9), general anxiety disorder -7 questionnaire (GAD-7), health assessment questionnaire disability index (HAQ-DI), fibromyalgia impact questionnaire (FIQ), pain disability index, pain catastrophizing scale, polysymptomatic distress scale (PSD) as the sum of widespread pain index (WPI), and the symptom severity scale (SS).

### **Results:**

Of 555 FM patients, 87.2% met the ACR 2010 preliminary FM criteria, 38.4% working full time, 13.3% part time, 11.7% receiving disability, 27.9% unemployed 2.7% students and 5.9% retired. We compared patients who were employed either full or part time and/or student, with unemployed FM patients (Table 1).

Binomial logistic regression was performed to ascertain the effects of BMI, education level, PHQ-9, GAD-7, HAQ-DI, pain related disability, FIQ, pain catastrophizing score, and PSD on the likelihood that FM patients were unemployed. The model explained 49.2% (Nagelkerke R<sup>2</sup>) of the variance in unemployed status, and correctly classified 82.8% of the cases, sensitivity 77.1%, specificity 86.5%, positive predictive value 79.4%, negative predictive value 84.9%. Of the nine predictor variables only three were statistically significant: FIQ, pain catastrophizing score and the pain disability index. Increasing FIQ, pain disability index, and pain catastrophizing were each significantly associated with increasing likelihood of being unemployed.

We also compared unemployed to disabled FM patients, and the only significant difference observed was that more disabled FM were recipients of Medicare 25.5% vs 4%  $p=0.001$ .

### **Conclusion:**

Compared to employed fibromyalgia patients, those who are unemployed have higher BMI, are more depressed and experience higher physical and pain related disability. They also have higher FM severity and distress, measured by FIQ and PSD.

Increasing fibromyalgia severity, pain related disability, and catastrophizing predict unemployment status in patients with FM. This information suggests that in order to prevent unemployment, we need to identify early the subset of FM patients with severe FM, who catastrophize and have high pain related disability scores. This subset of FM patients, may need intensive multidisciplinary interventions that include physical and occupational therapy and psychological interventions that can modify patients' maladaptive responses to pain.

Table 1: Characteristics of employed and unemployed patients with fibromyalgia. Values are the mean (standard deviation) or percentages.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Similar to other chronic disorders, Fibromyalgia syndrome (FMS) poses a major challenge for patients coping capacities and extracts a far-reaching cost on functioning and quality of life. Various aspects of resilience are utilized by individuals coping with chronic health disorders and previous research points to the positive effects of faith, religiosity and spirituality as tools for coping with illness. However, the role played by these factors in coping with chronic pain such as FMS has not previously been studied. The purpose of the current study was to evaluate the link between religiosity and spirituality and the outcomes of FMS.

## **Methods:**

Fifty five FMS patients (ACR criteria) attending a tertiary rheumatology clinic were recruited. Demographic data was registered. Level of spirituality/religiosity was estimated by the validated Hebrew version of the Spiritual and Religious Attitudes in Dealing with Illness (SpREUK) Questionnaire for Religiosity, Spirituality and Health, which contains 5 domains. Locus of control (LOC) was evaluated by the Locus of control questionnaire. FMS related outcome measures included the Fibromyalgia Impact Questionnaire (FIQ) (Validated Hebrew version), the SF-36, and the Beck Depression Index (BDI), assessing depression and anxiety.

## **Results:**

A significant negative correlation was found between two domains of the SpREUK ("search for meaningful support" and "trust in higher guidance") and domains of the SF-36: "Role limitation due to physical health" and "Role limitation due to emotional health" ( $p < 0.05$ ). When comparing patients on basis of religious sector (secular, conservative, religious) secular patients showed significantly higher scores on SF-36 domains of "Role limitation due to emotional health" and "General health" compared with other sectors ( $p < 0.05$ ).

No significant correlation was found between LOC (internal versus external) and FMS outcome measures. No significant correlation was found between SpREUK domains and the BDI.

## **Conclusion:**

In the current study, higher levels of religiosity/spirituality appeared to be inversely correlated with specific outcome measures of FMS. Unlike other chronic medical conditions, FMS patients do not appear to gain benefit from high levels of religiosity or spirituality; conversely, more severe FMS patients may be more prone to turn to religiosity/spirituality for support, so it is not possible to determine the direction of a casual relation. Chronic pain may pose a unique challenge for the faith of religious individuals who are obliged to cope with their suffering in context of a religious frame of beliefs. Physicians treating FMS patients should be aware of the impact of religious belief and spirituality on the physical and mental health in these patients.

# **Impact of Whole-Body Cryotherapy on Gene Expression of Peripheral Blood Cells in Patients with Fibromyalgia and Association with Patient-Reported Outcomes**

Susanne Drynda<sup>1</sup>, Oliver Mika<sup>2</sup> and Joern Kekow<sup>3</sup>, <sup>1</sup>University of Magdeburg, Clinic of Rheumatology, Vogelsang-Gommern, Germany, <sup>2</sup>University of Magdeburg, Clinic of Rheumatology, Gommern, Germany, <sup>3</sup>University of Magdeburg, Clinic of Rheumatology, Magdeburg, Germany

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Whole-body cryotherapy (WBCT) has been demonstrated in several studies as being effective in the reduction of inflammatory symptoms and in providing pain relief. It is recommended for the treatment of arthritis, fibromyalgia (FMS) and ankylosing spondylitis. The mode of action of this therapy, which consists of a brief exposure to temperatures between -110 and -160°C in special cryochambers, has not been fully elucidated.

The aim of this study was to investigate the changes in the gene expression of selected genes (CCL4, TGFBR3, CD69, MAP2K3, and IL-8) going through a series of three exposures to WBCT within three days and to analyse the association with patient reported outcomes.

## Methods:

Twenty six patients with fibromyalgia (24 female/2 male, age 51.8±8.9 years (mean±SD) were included in the study and underwent 3 exposures to WBCT in a cryochamber system (Zimmer MedizinSysteme GmbH, Germany) with 3 chambers (10 seconds at -10°C, 10 seconds at -60°C and for a maximum of 3 minutes at -110°C) on 3 consecutive days. During the study patients did not change their medication. Patients were asked to complete a questionnaire of 11 questions (including pain, restlessness, physical function, and headache). Blood was collected immediately prior to (baseline) and directly after the first exposure to WBCT and after the third exposure using PAXgene RNA tubes. Total RNA was extracted with the PAXgene Blood RNA kit. Gene expression levels of MAP2K3, CCL4, TGFBR3, CD69, and IL-8 were analysed by real-time PCR.

## Results:

All 26 patients tolerated the application of the WBCT well. The VAS pain reduced significantly from 6.0±0.3 at baseline to 4.1±0.3 after the third cold exposure ( $p<0.001$ ). In 15 patients an improvement by at least 20% of the patient reported outcomes was found.

The gene expression levels of CCL4, CD69 and TGFBR3 decreased significantly ( $p<0.001$ ,  $p<0.01$ , and  $p<0.05$ , resp.) In contrast, the expression of MAP2K3 was found to be significantly up-regulated ( $p<0.05$ ). No significant change was observed regarding the IL-8 expression.

Changes of the expression levels were not found to be associated with improvements of VAS pain, headache, restlessness, or physical function.

## Conclusion:

The results of our study indicate that the whole-body cryotherapy may cause subtle but significant changes in gene expression levels of CCL4, CD69, MAP2K3, and TGFBR3 in immune cells of peripheral blood. The MAP2K3 expression is known to be regulated by environmental stress, which is in accordance with the observed up-regulation of MAP2K3 expression. The down-regulation of the CD69, a marker for T-cell activation and the chemokine CCL4 that is produced by T-cells, indicate that the exposure to WBCT has an effect on peripheral T-cells. This effect seems to be independent from the patients' response.

Further studies are necessary to elucidate the molecular mechanisms associated with the therapeutic effect of the WBCT.

# The Etiology of Fibromyalgia May be Related to Increased Muscle Pressure

**Robert S. Katz**<sup>1</sup>, Jessica L. Polyak<sup>2</sup>, Alexandra Katz Small<sup>3</sup>, Ben J Small<sup>4</sup> and Frank Leavitt<sup>1</sup>, <sup>1</sup>Rush University Medical Center, Chicago, IL, <sup>2</sup>Rheumatology Associates S.C., Chicago, IL, <sup>3</sup>University of Illinois College of Medicine, Chicago, IL, <sup>4</sup>Rheumatology, University of Illinois at Chicago Medical School, Chicago, IL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## The Etiology of Fibromyalgia May be Related to Increased Muscle Pressure

**Background/Purpose:** The muscles are tender in fibromyalgia syndrome (FMS) patients, and the location of pain is generally over the muscles, as seen in body diagrams shaded in by patients with fibromyalgia. Previous research also showed a reduced lordotic curve of the cervical spine on lateral-view radiographs, suggesting a muscular etiology and possible increased muscle tension. We measured muscle pressure directly in patients with FMS and controls.

**Methods:** Fibromyalgia patients meeting the 2010 ACR criteria for the diagnosis were evaluated using a pressure gauge attached to a No. 22 needle, and 0.3 cc of saline was injected into the mid portion of the trapezius muscle of patients with fibromyalgia, and also into normal controls. The pressure in mm Hg was determined using this device. In addition, patients and controls had dolorimetry testing and manual compression of the trapezius muscles to determine the amount of tenderness.

**Results:** 103 FMS patients were evaluated, 88 females and 15 males. The mean age was 52 y o for females and 47.5 y o for males. The mean dolorimetry score in the FMS patients was 8.1mmHg (0-30). The muscle pressure in fibromyalgia patients averaged 33mmHg (22-43). The mean pain scale on a 1-10 visual analog scale, with 10 being the worst, was 7 in these FMS patients. In 16 fibromyalgia patients with mild muscle tenderness, the mean dolorimetry reading was 11.8, mean muscle pressure reading was 28.7 mmHg, and the mean pain scale rating was 5. In the 52 FMS patients with moderate tenderness over the trapezius muscle, the mean dolorimetry reading was 7.9, the mean muscle pressure score was 33.9 mmHg, and the mean pain score was 6. In the FMS group with extreme muscle tenderness (30 patients with fibromyalgia), the mean dolorimetry score was 6.6, the mean muscle pressure reading was 35.5 mmHg, and the mean pain scale rating was 8. In the controls, 7 males and 18 females, the diagnoses included 15 with RA, 6 with SLE, and 4 healthy office personnel. The mean dolorimetry score in this group was 21.2 (0-30). The mean muscle pressure was 12.2 mmHg (8.0-18.0). The mean pain VAS scale score was 2. Mild muscle tenderness was noted in 1 patient.

Table 1. Performance means for Pain, Tenderness and Muscle Pressure in the Fibromyalgia and Control groups.

			95% CI	p
Pain*	6.71 ± 1.88*	1.68 ± 1.86	4.2, 5.9	0.001
Tenderness				
Digital	2.10 ± 0.73	0.56 ± 0.82	1.2, 1.9	0.001
Dolorimeter	8.09 ± 4.09	21.21 ± 8.65	-16.8, -9.5	0.001
Intramuscular Pressure	33.46 ± 6.00	12.20 ± 3.97	18.7, 23.7	0.001

\*Values are mean ± SD

\* Pain in trapezius was an inclusion criterion for the fibromyalgia sample.

95% CI = 95% confidence interval.

**Conclusion:** Patients with fibromyalgia, compared to controls, have significantly increased intramuscular pressure. Muscles were also tender and dolorimetry scores were low indicating decreased tolerance for manually applied pressure. The amount of muscle tenderness correlated with the muscle pressure. The pain in fibromyalgia may be related to increased muscle pressure and tension. Fibromyalgia patients may be unconsciously tightening their muscles. Though pain centers in the brain light up quickly (central sensitization) in fibromyalgia patients when pressure is applied to the muscles, this finding may be due to increased muscle tenderness and elevated muscle pressure in fibromyalgia patients.

## **Leptin, a Hypothalamic Signaling Hormone, Is Elevated in Fibromyalgia Patients**

**Robert S. Katz**, Rush University Medical Center, Chicago, IL

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Leptin, a 16 kDa protein, acts on receptors in brain neurons, especially in the hypothalamus. It could affect the hypothalamic-pituitary axis and be involved in the stress response. We analyzed leptin levels in the serum of patients with fibromyalgia and rheumatoid arthritis.

**Methods:** Leptin levels were assessed in 27 fibromyalgia syndrome patients and six rheumatoid arthritis patients followed in a rheumatology office practice. Leptin was measured by the University of Miami Immunology Laboratory.

**Results:** Leptin levels varied between 1.7 and 70.7 ng/ml (mean 28.0) in FMS patients and 0.6 to 33.0 ng/ml (mean 10.1) in rheumatoid arthritis patients. The mean leptin/BMI ratio for 20 FMS pts was 1.0. The mean leptin/BMI for RA was 0.50.

**Conclusion:** Leptin levels appear to be elevated in fibromyalgia patients and could provide a link between chronic stress, the hypothalamic-pituitary axis, and fibromyalgia. Leptin might be a potential therapeutic target in fibromyalgia.

## **The Types of Stress That Appear to Aggravate the Symptoms of Fibromyalgia**

**Robert S. Katz**, Rush University Medical Center, Chicago, IL

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The types of stresses evaluated include financial stress (i.e., decreased income, unexpected expenses or outgoings); employment stress (i.e. job promotion, relocation, increased workload or travel, etc.); family/spouse stress (i.e. medical illness or addiction, unemployment); psychological/emotional stress (i.e. death of a loved one, divorce); physical stress (i.e. motor vehicle accident, pregnancy/childbirth, personal medical illness), and patients were asked if they had no obvious stress at the time of flare-ups or at the onset of their symptoms.

**Methods:** Patients with fibromyalgia and rheumatic disease controls filled out a questionnaire, including questions regarding the type of stress they experienced and its effect on their pain. Financial stress, employment stress, Family/spouse stress, psychological/emotional stress, physical stress was all listed as possible stresses that have an effect on the patient's pain.

**Results:** Fibromyalgia patients meeting the 2011 ACR criteria for the diagnosis and non-FMS rheumatic disease controls filled out a questionnaire on the types of stresses affecting their pain. The questionnaire used a 1-10 visual analog scale (VAS- 0-10; 10= an extreme effect on pain).

Family Stress- 98 FMS patients, the mean VAS score was 5.1; In 161 controls, the mean VAS was 4.3 (P>.03)

Financial Stress- 100 FMS patients, the mean VAS score was 4.3; In 161 controls, the mean VAS was 3.7. (n/s)

Job Stress- 88 FMS patients, the mean VAS score 5.5; In 149 control patients the mean VAS was 4.2. (P>.002)

Health Stress- 97 FMS patients, the mean VAS score was 6.9; In 162 controls, the mean VAS score was 5.0. (P>.001)

Marital Stress- 88 FMS patients, the mean VAS score was 3.0; In 145 controls, the mean VAS score was 2.7. (n/s)

**Conclusion:** Reduction of stress should be an important goal especially for fibromyalgia patients. These patients appear to have a more

significant effect on their illness due to stress. It seems that all types of stress – financial, job, emotional, health issues, physical, and family/marital stress – have a greater effect on the pain in fibromyalgia than in rheumatic disease controls. Participation by psychologists and psychiatrists in the treatment of the patient's stress may be important. And the rheumatologist, primary care physician, and office nurse may also help with stress reduction techniques and medications. Interdisciplinary programs may be helpful for some patients and these may include cognitive behavioral therapy, biofeedback, individual therapy, massage, meditation and other relaxation therapies, and yoga.

## The Cervical Spine in Fibromyalgia Patients: Loss of Lordotic Curve Is Characteristic of Fibromyalgia and Can Assist in the Diagnosis

**Robert S. Katz**<sup>1</sup>, Alexandra Katz Small<sup>2</sup>, Ben J Small<sup>3</sup> and Anthony Farkasch<sup>4</sup>, <sup>1</sup>Rush University Medical Center, Chicago, IL, <sup>2</sup>University of Illinois College of Medicine, Chicago, IL, <sup>3</sup>Rheumatology, University of Illinois at Chicago Medical School, Chicago, IL, <sup>4</sup>Rheumatology Associates S.C., Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with fibromyalgia have widespread pain. We have found that a lateral view of a cervical spine radiograph frequently identifies a loss of the lordotic curve but otherwise normal architecture. We asked rheumatology nurse professionals to evaluate visually whether the cervical spine was straight on the lateral view in fibromyalgia and non-fibromyalgia rheumatic disease patients.

**Methods:** 121 cervical spine radiographs were reviewed by a rheumatology nurse without knowledge of the patient's diagnosis. Only the lateral view of the cervical spine was visualized to determine whether it was straight. A straight cervical spine is seen in fibromyalgia patients and may assist in the diagnosis. Other abnormalities of the cervical spine including disc space narrowing, osteophytes, spondylolisthesis, and reactive bony changes were also noted if present.

**Results:** Of the 121 cervical spine radiographs reviewed the rheumatology nurse, there were 84 patients with fibromyalgia, and 37 non-fibromyalgia rheumatic disease controls. Without being told the patients diagnosis, the nurse was able to correctly diagnosis 66 (75.5%) of the 84 fibromyalgia patients, and was able to accurately say that

29) of the control patients did not in fact have fibromyalgia.

Normal Cobb  
Angle (normal  
cervical lordosis)

Fibromyalgia  
(Straight Spine)

Fibromyalgia  
(Straight Spine)

**Conclusion:** A straight cervical spine can be used to assist in the diagnosis of fibromyalgia. The loss of lordotic curve without other radiographic abnormalities (disc space narrowing, reactive bony changes, etc.) is present in the majority of fibromyalgia patients and not in the non-fibromyalgia rheumatic disease patients. A straight cervical spine is further evidence of increased muscle tension in fibromyalgia.

**Disclosure:** R. S. Katz, None; A. Katz Small, None; B. J. Small, None; A. Farkasch, None.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fibromyalgia patients are reported to have a straight neck on lateral x-ray views of the cervical spine. We measured the Cobb angle in fibromyalgia and non-fibromyalgia rheumatic disease patients in a rheumatology office practice.

**Methods:** The Cobb angle between the bottom of C2 and the top of C7 was measured in rheumatic disease patients without knowledge of the diagnosis..

**Results:** 121 patients, (84 fibromyalgia with a mean age of 45.3 and 37 non-fibromyalgia rheumatic disease controls with a mean age of 52.7), had radiographs of their cervical spine, which the Cobb angle was measured. We found that the cervical spine becomes noted as a "straight neck" at the 7° mark and below. There were 50 FMS and 13 controls with a cervical Cobb of 7° or below. Between 8° and 10° is where the cervical spine "straightness" becomes more prominent; there were 10 FMS and 1 control with a Cobb between 8° and 10°. There were 24 FMS and 23 control patients with a cervical Cobb angle of 11° or higher.

**Conclusion:** The Cobb angle between C2 and C7 was less than 10 degrees in fibromyalgia patients and greater than 10 degrees in rheumatic disease patients without fibromyalgia. The straight neck is present in fibromyalgia and may assist in the diagnosis. The cut-off point of 10 degrees may help to determine the presence of a significant loss of lordotic curve in future studies of fibromyalgia.

## Using the BILAG to Assess the Activity of Lupus in Patients with Fibromyalgia

**Robert S. Katz**<sup>1</sup>, Jessica L. Polyak<sup>2</sup> and Frank Leavitt<sup>1</sup>, <sup>1</sup>Rush University Medical Center, Chicago, IL, <sup>2</sup>Rheumatology Associates S.C., Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The BILAG is often used to assess the efficacy of lupus treatments, and is a commonly used tool in lupus drug trials. But the BILAG contains many symptoms, which are also present in fibromyalgia, and the presence of concomitant fibromyalgia in lupus patients may nullify the results of clinical drug trials. Fibromyalgia patients may not respond well to the treatment and also have more drug side effects.

**Methods:** Fibromyalgia patients, meeting the 2011 ACR criteria for the diagnosis, took an in-office survey listing some of the British Isles Lupus Activity Group (BILAG) lupus symptoms. The symptoms asked of fibromyalgia and non-fibromyalgia patients included anemia; mouth or nasal sores; numbness and tingling; persistent headache; chest pain; skin rash; hair loss; cognitive changes; arthritis; and colitis. They were asked to score the above symptoms using the following scale: 1, improving; 2, same; 3, worse; and 4, new.

**Results:** The following symptoms frequently represented by fibromyalgia patients and are among those that are part of BILAG Lupus Activity Index: Anemia, Headache, Rash, "Arthritis", Oral Ulcers, Chest Pain, Hair Loss, Colitis, Numbness, and Cognitive

**Conclusion:** Many fibromyalgia patients reported that certain symptoms that are listed in the BILAG were present including mouth and oral ulcers; hair loss; numbness and tingling; cognitive changes; headaches; arthritis; and chest pain.

Concomitant lupus and fibromyalgia can nullify the results of lupus clinical drug trials and interfere with the accurate assessment of lupus. Many fibromyalgia patients report some of the symptoms listed in the BILAG, which is considered a reliable instrument for assessing lupus disease activity, but if the presence of concomitant fibromyalgia is not assessed, the results of the BILAG may be invalid. Using the 2010 ACR criteria guidelines and a simple one-page form for assessing the presence of fibromyalgia, concomitant fibromyalgia can be determined in lupus patients. This would make the BILAG a more accurate assessment tool if used for pure lupus.

**Disclosure:** R. S. Katz, None; J. L. Polyak, None; F. Leavitt, None.

## Exercise in Fibromyalgia Patients

**Robert S. Katz**<sup>1</sup>, Jessica L. Polyak<sup>2</sup> and Frank Leavitt<sup>1</sup>, <sup>1</sup>Rush University Medical Center, Chicago, IL, <sup>2</sup>Rheumatology Associates S.C., Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** It has been reported that aerobic exercise may be beneficial for fibromyalgia patients. Stamina and energy, sense of well-being, and increased mental relaxation can be achieved with an exercise program. We asked fibromyalgia patients whether exercise had a beneficial effect on their illness.

**Methods:** An office questionnaire was given to rheumatic disease patients in a rheumatology office practice. The patients were asked about the effect of aerobic exercise, muscle strengthening exercise, stretching, and yoga and whether they made their symptoms better or worse and whether it affected their level of pain.

The patients were divided into Fibromyalgia Syndrome (FMS) patients and non-FMS rheumatic disease controls.

**Results:** 78 FMS patients and 167 non-FMS rheumatic disease pts were compared. The mean number of days which 78 Fibromyalgia Syndrome patients reported exercising was 3.4, compared to 3.6 days for non-FMS rheumatic disease controls (n/s). The time devoted by FMS patients per exercise session was 32.6 min, compared to 44.7 min for controls (P <.001)

Using a 0-10 visual analogue scale with 10 being the worst score (makes pain much worse), fibromyalgia patients reported a mean of 7.0 for aerobic exercise, where controls reported a mean of 4.3 (P <.001). The mean for muscle strengthening for FMS was 5.4, and

controls 4.2 (P<.001). Stretching exercises, mean for FMS patients was 4.1, compared to 3.1 for non-FMS patients (P<.001). Yoga exercises seemed to be preferred among fibromyalgia patients, the mean was 4.0, controls 3.5 (n/s).

Fibromyalgia patients exercise approximately the same number of days as non-FMS rheumatic disease patients. Aerobic and also muscle strengthening and stretching exercises were found to make FMS patients' symptoms worse. There was no significant difference between groups for yoga.

	Diagnosis	Patients	Mean	Std. Deviation	Sig
Days/Exercise	Fibromyalgia	78	3.372	1.9145	NS
	Controls	167	3.641	1.757	
Time/ Exercise	Fibromyalgia	79	32.633	19.3339	0.001
	Controls	162	44.722	21.105	
Aerobic	Fibromyalgia	71	6.986	5.2222	0.001
	Controls	149	4.302	2.3787	
Muscle	Fibromyalgia	73	5.411	2.3795	0.001
	Controls	143	4.203	2.174	
Streatching	Fibromyalgia	84	4.131	2.3531	0.001
	Controls	154	3.097	1.7555	
Yoga	Fibromyalgia	36	4.000	2.2552	NS
	Controls	51	3.471	2.0528	

VAS Visual Analog Scale (1=Makes it much better 10=Makes it much worse)

**Conclusion:** Assuming one objective is to get FMS patients to do aerobic exercise on a regular basis, the exercises would need to be modified in a way that patients are able to perform them without a significant increase in symptoms.

We initiated a program in which patients are asked to do 10 minutes of aerobic exercise (huffing and puffing) daily on a stationary bike. Preliminary anecdotal observations suggest that patients exercising daily on the stationary bike, appear to be doing better.

If the studies are correct that regular aerobic exercise may benefit fibromyalgia, the fact that these patients tend to feel worse is an obstacle. It is interesting that yoga, a relaxation technique, was more helpful than other forms of exercise evaluated.

Whether achievable aerobic exercise, such as 10 minutes on a stationary bike daily, or a focus on relaxing activities such as yoga will have a greater positive effect on the symptoms of fibromyalgia, is unclear, but more research needs to be done to help fibromyalgia patients overcome the levels of fatigue and pain and poor general function in order to try regular, brief exercise.

## Most Fibromyalgia Patients in a Rheumatology Office Practice Accept the Diagnosis of Fibromyalgia

**Robert S. Katz**<sup>1</sup>, Jessica L. Polyak<sup>2</sup> and Frank Leavitt<sup>1</sup>, <sup>1</sup>Rush University Medical Center, Chicago, IL, <sup>2</sup>Rheumatology Associates S.C., Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In the community, many comments are made about fibromyalgia that are not accurate, such as, it is a made-up illness; a 'garbage' diagnosis; everything else needs to be excluded to diagnose someone with fibromyalgia; it is an unscientific term; or it is a name used for autoimmune conditions, such as lupus, when the doctor is uncertain. We asked patients with fibromyalgia in a rheumatology office practice what they thought when they were given the diagnosis of fibromyalgia by a rheumatologist.

**Methods:** 37 patients with clinically diagnosed fibromyalgia were given an in-office questionnaire. The questions included whether fibromyalgia was a diagnosis that made them feel good and that the doctor understood that was the cause of their symptoms; whether they felt that the diagnosis was not accurate; whether they felt that fibromyalgia is a made-up, unscientific term; whether they felt that they really had lupus or some other disorder; and whether they felt that fibromyalgia was not a real diagnosis.

**Results:** Patients generally accept the diagnosis of fibromyalgia but are concerned that physicians and non-physicians may think that it is “all in their heads”. See table.

Questions	Male	Female
What do you think when you received it?		
A. Felt good about diagnosis was made.	3	25
B. Felt that this is not my true diagnosis.	0	3
C. Felt that fibromyalgia is a made-up diag.	0	0
D. Felt that I really have Lupus or some other disorder	1	5
E. Felt that fibromyalgia is not a real diag.	0	0
I don't like the diagnosis of fibromyalgia		
A. Doctors and other think it's all "in your head"	2	16
B. It's not a real diagnosis	0	3
C. It's a diagnosis used when everything else is ruled out	1	3
D. Other	1	11
I do like and accept the diagnosis of fibromyalgia		
A. It could have been a life threatening condition	2	8
B. I am glad to have gotten a diagnosis	2	16
C. I know that it is not a progressive or crippling	0	3
D. Other	0	6

**Conclusion:** The great majority of fibromyalgia patients in a rheumatology office practice felt good that a diagnosis was made to explain their symptoms. Only a minority thought that the diagnosis was either inaccurate or that the term “fibromyalgia” was an unscientific one and not a real diagnosis.

The biggest problem accepting the diagnosis is that many patients think that doctors and others feel that the symptoms are ‘all in your head’.

The word is spreading about fibromyalgia, such that many patients now accept the diagnosis and feel more comfortable that something more serious and progressive is not present. Though fibromyalgia can be challenging to treat, at least in a rheumatology office practice patients do feel more comfortable given that diagnosis.

A few patients will push back, and these can be a source of stress for the patient and for medical practitioners. The ACR 2010 guidelines for the diagnosis, which can be summarized in a one-page sheet that the patient and practitioner fill out, can assist in verifying the diagnosis. Through scientific research, and also advertising FDA approved drugs to patients, the diagnosis of fibromyalgia appears to be generally accepted.

## Improving Sleep in Fibromyalgia Patients Ameliorates Their Pain

**Robert S. Katz,** Rush University Medical Center, Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fibromyalgia patients complain of poor sleep. We assessed whether patients with fibromyalgia who were able to significantly improve their sleep, including sleeping uninterrupted through the night, had less pain. It is possible that solid rest at night can lead to muscle relaxation and central nervous system rest and result in improvement in fibromyalgia symptoms.

**Methods:** 37 patients were given the opportunity to participate in this rheumatology office trial. Patients with diagnosed fibromyalgia according to the 2010 ACR criteria who had poor sleep were given amitriptyline, doxepin, or trazodone in gradually increasing dosages, enough for them to sleep through the night. Those who completed at least two weeks of medication therapy in doses enough to make them sleep well were further evaluated for a response in terms of pain level and fatigue.

**Results:** See graph below

Average Pain Scale Prior to Medication	7.8	(0-10 scale; 0=no pain, 10=severe pain)
Average Pain Scale After Medication	3.4	
Average Energy Level Prior to Medication	4.3	(0-10 scale; 0=no energy, 10=high energy)
Average Energy Level After Medication	7.1	
<b>Medication</b>	<b># of patients taking</b>	
Amitriptyline	22 (59.4%)	
Doxepin	9 (24.3%)	
Trazodone	6 (16.3%)	

**Conclusion :** In this open label, uncontrolled study, we found that many patients who are able to sleep through the night by using amitriptyline, doxepin, or trazodone had an improvement in pain and global scores for Fibromyalgia. Starting with low dosage given early in the evening, generally 7 PM, and titrating upward until uninterrupted sleep was achieved. Good sustained sleep maybe therapeutic in this illness, but to achieve that may require a significant step-wise increase in these medications until uninterrupted sleep is achieved.

## Effectiveness and Durability of a Brief Multidisciplinary Treatment Program for Patients with Fibromyalgia

Jessica Gehin<sup>1</sup>, Andy Abril<sup>2</sup>, Fernando Rivera<sup>3</sup>, Benjamin Wang<sup>4</sup>, Ronald Butendieck<sup>2</sup>, Florentina Berianu<sup>2</sup>, Kenneth Calamia<sup>2</sup>, Madeleine Allman<sup>1</sup>, Isabel Abril<sup>1</sup> and Barbara Bruce<sup>1</sup>, <sup>1</sup>Department of Psychiatry and Psychology, Mayo Clinic Florida, Jacksonville, FL, <sup>2</sup>Division of Rheumatology, Mayo Clinic Florida, Jacksonville, FL, <sup>3</sup>Division of Consultative and Diagnostic Medicine, Mayo Clinic Florida, Jacksonville, FL, <sup>4</sup>Rheumatology, Mayo Clinic Florida, Jacksonville, FL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fibromyalgia (FM) effects upwards of 60 million adults in the US alone. The disability and psychological distress often observed in these patients has been documented. Despite a recent update of diagnostic criteria for FM by the American College of Rheumatology (ACR) and the availability of demonstrated effective interventions for the treatment of FM, patients continue to be misunderstood, misdiagnosed and often left untreated. The purpose of this study is to examine the effectiveness and durability of a brief multidisciplinary intervention for patients with FM provided in a tertiary care setting in improving functioning and psychological distress.

**Methods:** Four hundred and twenty two (422) patients who participated in the Fibromyalgia Treatment Program between August 2015 and August 2016 were subjects in this study. The patients in the study were referred to a tertiary medical center for evaluation of fibromyalgia symptoms and were subsequently diagnosed with FM by meeting the 2010 ACR criteria. The patients were then enrolled

in a 2-day multidisciplinary treatment program. Patients completed the Fibromyalgia Impact Questionnaire – Revised (FIQR), the Center for Epidemiological Studies of Depression Scale (CES-D), and the Pain Catastrophizing Scale (PCS) at the time of admission to the program and at 3-month and 6-month follow-up. The treatment program targeted Cognitive Behavioral Therapy (CBT) skills of evidence-based education regarding FM, chronic fatigue and central sensitization in addition to activity pacing, exercise, relaxation strategies, sleep hygiene, and moderation.

**Results:** The average age of patients was 48 years with a range of 19-79. The majority was female (90%). Duration of fibromyalgia symptoms on average was 10 years at the time of referral. At the time of admission to the program, patients were functionally impaired and psychologically distressed. The FIQR results on admission showed an average score of 60.0 which is in the severe level of impairment range. The average CES-D score on admission was 25.4 suggesting significant depression. The PCS scores on admission were on average 25 suggesting elevated levels of pain catastrophizing. At 3-month follow-up, the scores on all three measures were significantly decreased and the improvement observed across all scores were maintained or further improved at 6 month follow-up.

**Conclusion:** A brief multidisciplinary treatment program for patients with Fibromyalgia appears to be effective at decreasing functional impairment and psychological distress and the improvements are maintained or further improved at 3 and 6 month follow-up.

## **Fibromyalgia in Russian Refugees: Translation and Validation of the Revised Symptom Impact Questionnaire**

**Kim Jones**<sup>1</sup>, Robert M. Bennett<sup>1</sup>, Ronald Friend<sup>2</sup> and Neema Mohammad Nader<sup>2</sup>, <sup>1</sup>Schools of Nursing and Medicine, Oregon Health & Science University, Portland, OR, <sup>2</sup>School of Nursing, Oregon Health & Science University, Portland, OR

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The Revised Symptom Impact Questionnaire (SIQR) is an updated version of the Revised Fibromyalgia Impact Questionnaire (FIQR) that can be used in both fibromyalgia and non-fibromyalgia patients (FM). The SIQR has been translated into 8 other languages but no Russian version is currently available, even though Russian asylum seekers are the fast-growing segment of North America. Unrelenting stress endured by refugees and immigrants put them at increased risk for multiple health related problems, including FM. However, no tool currently exists to monitor FM in Russian speakers of the former Soviet bloc. This project describes the process of creating a culturally appropriate scale to assess FM severity in Russian speaking people.

### **Methods:**

We used the Mapi Research Trust process to translate a validated questionnaire to Russian. The SIQR is a 21-item scale consisting of 3 subscales which assess physical functioning, common symptoms experienced in fibromyalgia, and global impact. The process of translation and validation of the SIQR involved: conceptual analysis of source questionnaire, forward/backward translation, committee review, pretesting, and revision.

### **Results:**

The author (NMN) and 2 Russian interpreters translated the English version of the SIQR. A certified translator with formal education in the Russia Federation evaluated the translation. These 3 bilingual individuals back-translated the questionnaire. Committee review of the back translation was done by the original developers (RMB, RF & KDJ). 12 Russian speakers completed the pretest questionnaire. As expected, there were some challenges creating equivalent questionnaire items, mostly involving the physical function items. For example, some subjects endorsed the words “ходить в магазин” (go to a store), while others preferred “ходить за покупками” (go

shopping). For the final version the translators used “ходить за продовольственными продуктами” (go shopping for groceries). Additionally, masculine, feminine and gender neutral noun and verb tenses were used to ensure semantic equivalence. Thus, some words separated gender by slash punctuation. One example of gender was, “Я был/была полностью подавлен/подавлена моим симптомами” (I felt completely overwhelmed by my symptoms).

**Conclusion:** We developed a semantically equivalent translation of the SIQR in the Russian language. We are now testing it in a larger sample of Russian speaking patients living in the United States to establish its psychometric properties, including its reliability and validity.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

RA patients are managed using treat-to target (T2T) regimens often utilizing the DAS28CRP as an outcome measure. In this study we compared clinical changes in RA disease activity with changes in MRI inflammation on T2T escalation.

### **Methods:**

80 seropositive rheumatoid arthritis (RA) patients on conventional disease-modifying anti-rheumatic drugs (cDMARDs) were enrolled if they had DAS28CRP > 3.2: Group A escalated to another cDMARD combination, Group B to anti-TNF therapy/cDMARDs. Contrast-enhanced 3T-MRI wrist scans were obtained before (V1) and 4 months after (V2) regimen change. Scan pairs were scored by one experienced radiologist reader for synovitis, osteitis and tenosynovitis, summed as MRI inflammation (MRI(i)) score, plus erosions. Associations between DAS28CRP and MRIi were investigated.

### **Results:**

58 patients were enrolled in Group A (42 female, 16 male) and 22 in Group B (18, 4). 66 scan pairs were available for analysis including 8 pairs from 4 patients who were sequentially enrolled into Group A then Group B. Intra-reader reliability was high: ICC(av) 0.89 (0.56 - 0.97). DAS28CRP and disease duration (months) were lower in Group A than B; 4.22 vs 5.16 (p = 0.001) and 30 vs 77 (p = 0.01). Change in DAS28CRP (median (range) Group A: -0.92 (-3.30, 1.61), Group B: -1.38 (-3.59, 0.26) (p = 0.31). Change in MRI(i) Group A, 0 (-25, 7) and Group B, 0 (-7, 28) (p = 0.37). Combining groups, change in MRI(i) correlated with change in DAS28CRP (Spearman's  $\rho$  0.36, P = 0.003). Using multiple linear regression analysis adjusting for age, gender, duration, anti-CCP titer and MRI erosion score (V1), change in DAS28CRP was associated with change in MRI(i) so that for every unit increase in change in DAS28CRP there was a 1.83U increase in change in MRI(i), p = 0.052. The components of MRI(i) were analyzed and only MRI tendonitis correlated with change in DAS28CRP (Spearman's  $\rho$  0.33, P = 0.007). There was no significant difference between groups for change in MRI(i) although the fall in score was numerically greater for Group A (-3.61) than Group B (-0.73), p = 0.18. Change in MRI(i) was associated with the MRI erosion score (V1) (p = 0.0054).

## Conclusion:

We report the first study investigating the link between clinical and imaging inflammation on T2T escalation in a real world RA cohort. The association was surprisingly weak, especially in those escalating to anti-TNFs where chronic inflammation associated with longer disease duration may have been less amenable to intervention. Given the efficacy of T2T regimens using clinical targets, the use of MRI targets cannot be advocated as yet. Further studies are needed to investigate the long-term implications of persisting MRI inflammation in clinically normal joints.

## Are MRI-Detected Erosions Specific for RA? a Large Explorative Cross-Sectional Study

**Debbie M. Boeters**<sup>1</sup>, Wouter P. Nieuwenhuis<sup>1</sup>, Hanna W van Steenbergen<sup>1</sup>, M. Reijnders<sup>2</sup>, Robert B.M. Landewé<sup>3</sup> and Annette H.M. van der Helm-van Mil<sup>1</sup>, <sup>1</sup>Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Department of Radiology, Leiden University Medical Center, Leiden, Netherlands, <sup>3</sup>University of Amsterdam and Atrium Medical Center, Amsterdam, Netherlands

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Magnetic resonance imaging (MRI) is recommended in the diagnostic process of rheumatoid arthritis (RA), as it can detect joint damage early. However MRI-detected erosions are also present in symptom-free controls, especially at older age. It is unclear how RA-specific erosions on MRI can be distinguished from physiological erosions in symptom-free individuals. Therefore this study compared MRI-detected erosions between RA-patients and healthy controls, including evaluation of the effect of age.

**Methods:** 589 newly-presenting early arthritis patients (284 RA, 305 other arthritides) and 193 symptom-free controls underwent contrast-enhanced MRI of unilateral metacarpophalangeal(MCP)- and metatarsophalangeal(MTP)-joints. Total erosion score according to the RAMRIS method, number, severity, location of erosions and simultaneous presence of MRI-detected inflammation (synovitis and/or bone marrow edema) were compared between groups; participants were categorized in three age-groups (<40, 40-59, ≥60).

**Results:** RA-patients had higher total erosion scores than controls but there was large overlap of MRI-erosion scores between RA-patients and controls, as visually no separate clustering of groups was observed (Figure). Severe erosions (grade≥2) and MTP5-erosions were specific for RA (specificity 98-100% and 90-98% for different age-groups). MTP1-erosions were only specific if aged<40

(specificity 98%) and erosions with inflammation if aged<60 (specificity 91-100%).  $\geq 1$  of the mentioned erosions characteristics were present in 28% of RA-patients. Comparing RA-patients with other arthritides revealed that severe erosions and MTP5-erosions remained specific for RA (specificity  $\geq 90\%$ ) as well as MTP1-erosions if aged<40 (specificity 92%), in contrast to erosions combined with inflammation (specificity 49-86%).

**Conclusion:** Whilst RA-patients at disease presentation had significantly higher erosion-scores than controls, scores of individuals were largely overlapping. Erosion characteristics specific for RA were identified, but were present in a minority of RA-patients.

Figure: Predicted probabilities of having RA (probability of 0 indicates 0% chance of having RA and probability of 1 indicates 100% chance of having RA), obtained from logistic regression. The total MRI-detected erosion score was used to predict whether a patient had RA.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

To ascertain the predictors of erosion progression in patients with early RA using high-resolution peripheral quantitative computed tomography (HR-pQCT).

#### **Methods:**

In this prospective study, 80 ERA patients were treated with a tight-control protocol aiming at remission using csDMARDs. HR-pQCT examinations were performed at baseline and after one year post-baseline. Erosion number and volume and the bone density of the surrounding bone were quantified. Erosion progression was defined as an erosion showing both (a) an increase in erosion volume exceeding the smallest detectable change (SDC) and (b) a decrease in bone density surrounding the erosion exceeding the SDC.

#### **Results:**

45% ERA patients showed erosion progression. Logistic regression analysis showed that greater erosion depth ( $p=0.043$ ) and higher damage joint count ( $p=0.035$ ) at baseline were independent predictors of erosion progression at 12 months. Erosion depth discriminated ERA patients with erosion progression from those without progression with an area under receiver operating characteristic curve of 0.798 (95% CI: [0.650, 0.946];  $p=0.002$ ). An erosion depth at baseline of  $\geq 1.225$  mm predicted erosion progression with a sensitivity of 81.3%, specificity of 71.4% and a Youden index of 0.527.

#### **Conclusion:**

Erosion depth at baseline is an indicator of erosion progression in ERA patients treated with csDMARDs. Deeper erosions are more likely to progress than shallower erosions.

#### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

HR-pQCT is a high resolution CT dedicated to human extremities. It has been used mainly for osteoporosis, while in more recent years it has been applied to research in rheumatoid arthritis (RA).

The purpose of this study is to develop a method to quantify the erosion volume of distal radius in patients with RA semiautomatically using second generation HR-pQCT.

#### **Methods:**

Ten patients with RA (ave. 66 years, 7 female, 3 male) participated in this study. The wrist joint was scanned using HR-pQCT (XtremeCT II, Scanco Medical, Switzerland) at the voxel size of 61  $\mu$ m.

The erosion volume was measured semiautomatically using the dedicated software (TRI/3D-BON, Ratoc System Engineering, Tokyo).

All concave regions on the bone surface around the distal radius were extracted automatically by subtracting the bone region from the smoothed bone model. Erosions were selected manually by a medical doctor based on certain criteria. The volume of the erosions were measured by voxel counting.

### Results:

16 erosions were detected by HR-pQCT, mainly located on the palmar side of the distal radius (palmar: 12, dorsal: 3, radial: 1). The average volume of the erosions was  $5.5 \text{ mm}^3$ , minimum  $0.3 \text{ mm}^3$ , and maximum  $20.0 \text{ mm}^3$ .

### Conclusion:

The semiautomatic method to quantify the erosion volume of distal radius in RA patients by HR-pQCT was developed. The opinion as to whether concave regions are pathological erosion or physiological concave, vascular channel or recess of osteophyte is difficult and should be performed by an experienced tester.
